But can psycho-analysis do more here? Yes, it actually can. I hope to be able to show you that, even in a case so hard of access as this, it can discover something which makes a first understanding possible. And to begin with I would draw your attention to the inconspicuous detail that the patient herself positively provoked the anonymous letter, which now gave support to her delusion, by informing the scheming housemaid on the previous day that it would cause her the greatest unhappiness if her husband had a love affair with a young girl. In this way she first put the notion of sending the anonymous Letter into the housemaid's head. Thus the delusion acquires a certain independence of the letter; it had been present already in the patient as a fear - or was it as a wish? Let us now add to this the small further indications yielded by only two analytic sessions. The patient, indeed, behaved in a very unco-operative way when, after telling me her story, she was asked for her further thoughts, ideas and memories. She said that nothing occurred to her, that she had told me everything already, and after two sessions the experiment with me had in fact to be broken off because she announced that she already felt well and that she was sure the pathological idea would not come back. She only said this, of course, from resistance and from dread of the continuation of the analysis. Nevertheless, during these two sessions she let fall a few remarks which allowed of, and indeed necessitated, a particular interpretation; and this interpretation threw a clear light on the genesis of her delusion of jealousy. She herself was intensely in love with a young man, with the same son-in-law who had persuaded her to come to me as a patient. She herself knew nothing, or perhaps only a very little, of this love; in the family relationship that existed between them it was easy for this passionate liking to disguise itself as innocent affection. After all our experiences elsewhere, it is not hard for us to feel our way into the mental life of this upright wife and worthy mother, of the age of fifty-three. Being in love like this, a monstrous and impossible thing, could not become conscious; but it remained in existence and, even though it was unconscious, it exercised a severe pressure. Something had to become of it, some relief had to be looked for; and the easiest mitigation was offered, no doubt, by the mechanism of displacement which plays a part so regularly in the generating of delusional jealousy. If not only were she, the old woman, in love with a young man, but if also her old husband were having a love affair with a young girl, then her conscience would be relieved of the weight of her unfaithfulness. The phantasy of her husband's unfaithfulness thus acted as a cooling compress on her burning wound. Her own love had not become conscious to her, but its mirror-reflection, which brought her such an advantage, now became conscious as an obsession and delusion. No arguments against it could, of course, have any effect, for they were only directed against the mirror-image and not against the original which gave the other its strength and which lay hidden, inviolable, in the unconscious.
Many attempts at treatment miscarried during the early period of analysis because they were undertaken in cases which were altogether unsuited to the procedure and which we should exclude to-day on the basis of our present view of the indications for treatment. But these indications, too, could only be arrived at by experiment. In those days we did not know a priori that paranoia and dementia praecox in strongly marked forms are inaccessible, and we had a right to make trial of the method on all kinds of disorders. But most of the failures of those early years were due not to the doctor's fault or an unsuitable choice of patients but to unfavourable external conditions. Here we have only dealt with internal resistances, those of the patient, which are inevitable and can be overcome. The external resistances which arise from the patient's circumstances, from his environment, are of small theoretical interest but of the greatest practical importance. Psycho-analytic treatment may be compared with a surgical operation and may similarly claim to be carried out under arrangements that will be the most favourable for its success. You know the precautionary measures adopted by a surgeon: a suitable room, good lighting, assistants, exclusion of the patient's relatives, and so on. Ask yourselves now how many of these operations would turn out successfully if they had to take place in the presence of all the members of the patient's family, who would stick their noses into the field of the operation and exclaim aloud at every incision. In psycho-analytic treatments the intervention of relatives is a positive danger and a danger one does not know how to meet. One is armed against the patient's internal resistances which one knows are inevitable, but how can one ward off these external resistances? No kind of explanations make any impression on the patient's relatives; they cannot be induced to keep at a distance from the whole business, and one cannot make common cause with them because of the risk of losing the confidence of the patient, who - quite rightly moreover - expects the person in whom he has put his trust to take his side. No one who has any experience of the rifts which so often divide a family will, if he is an analyst, be surprised to find that the patient's closest relatives sometimes betray less interest in his recovering than in his remaining as he is. When, as so often, the neurosis is related to conflicts between members of a family, the healthy party will not hesitate long in choosing between his own interest and the sick party's recovery. It is not to be wondered at, indeed, if a husband looks with disfavour on a treatment in which, as he may rightly suspect, the whole catalogue of his sins will be brought to light. Nor do we wonder at it; but we cannot in that case blame ourselves if our efforts remain unsuccessful and the treatment is broken off prematurely because the husband's resistance is added to that of his sick wife. We had in fact undertaken something which in the prevailing circumstances was unrealizable.

[1916-1917, 3498]

We know how important doubt is to the physician who is analysing an obsessional neurosis. It is the patient's strongest weapon, the favourite expedient of his resistance. This same doubt enabled our patient to lie entrenched behind a respectful indifference and to allow the efforts of the treatment to slip past him for years together. Nothing changed, and there was no way of convincing him. At last I recognized the importance of the intestinal trouble for my purposes; it represented the small trait of hysteria which is regularly to be found at the root of an obsessional neurosis. I promised the patient a complete recovery of his intestinal activity, and by means of this promise made his incredulity manifest. I then had the satisfaction of seeing his doubt dwindle away, as in the course of the work his bowel began, like a hysterically affected organ, to 'join in the conversation', and in a few week's time recovered its normal functions after their long impairment.

[1918b, 3557]
The manifestations of a compulsion to repeat (which we have described as occurring in the early activities of infantile mental life as well as among the events of psycho-analytic treatment) exhibit to a high degree an instinctual character and, when they act in opposition to the pleasure principle, give the appearance of some 'daemonic' force at work. In the case of children's play we seemed to see that children repeat unpleasurable experiences for the additional reason that they can master a powerful impression far more thoroughly by being active than they could by merely experiencing it passively. Each fresh repetition seems to strengthen the mastery they are in search of. Nor can children have their pleasurable experiences repeated often enough, and they are inexorable in their insistence that the repetition shall be an identical one. This character trait disappears later on. If a joke is heard for a second time it produces almost no effect; a theatrical production never creates so great an impression the second time as the first; indeed, it is hardly possible to persuade an adult who has very much enjoyed reading a book to re-read it immediately. Novelty is always the condition of enjoyment. But children will never tire of asking an adult to repeat a game that he has shown them or played with them, till he is too exhausted to go on. And if a child has been told a nice story, he will insist on hearing it over and over again rather than a new one; and he will remorselessly stipulate that the repetition shall be an identical one and will correct any alterations of which the narrator may be guilty - though they may actually have been made in the hope of gaining fresh approval. None of this contradicts the pleasure principle; repetition, the re-experiencing of something identical, is clearly in itself a source of pleasure. In the case of a person in analysis, on the contrary, the compulsion to repeat the events of his childhood in the transference evidently disregards the pleasure principle in every way. The patient behaves in a purely infantile fashion and thus shows us that the repressed memory-traces of his primaeval experiences are not present in him in a bound state and are indeed in a sense incapable of obeying the secondary process. It is to this fact of not being bound, moreover, that they owe their capacity for forming, in conjunction with the residues of the previous day, a wishful phantasy that emerges in a dream. This same compulsion to repeat frequently meets us as an obstacle to our treatment when at the end of an analysis we try to induce the patient to detach himself completely from his physician. It may be presumed, too, that when people unfamiliar with analysis feel an obscure fear - a dread of rousing something that, so they feel, is better left sleeping - what they are afraid of at bottom is the emergence of this compulsion with its hint of possession by some 'daemonic' power.

[1920g, 3738]
In the girl’s account of her conscious motives the father did not figure at all; there was not
even any mention of fear of his anger. In the motives laid bare by the analysis, on the other
hand, he played the principal part. Her relation to her father had the same decisive importance
for the course and outcome of the analytic treatment, or rather, analytic exploration. Behind her
pretended consideration for her parents, for whose sake she had been willing to make the
attempt to be transformed, lay concealed her attitude of defiance and revenge against her father
which held her fast to her homosexuality. Secure under this cover, the resistance set a
considerable region free to analytic investigation. The analysis went forward almost without any
signs of resistance, the patient participating actively with her intellect, though absolutely tranquil
emotionally. Once when I expounded to her a specially important part of the theory, one
touching her nearly, she replied in an inimitable tone, 'How very interesting', as though she were
a *grande dame* being taken over a museum and glancing through her lorgnon at objects to
which she was completely indifferent. The impression one had of her analysis was not unlike
that of a hypnotic treatment, where the resistance has in the same way withdrawn to a certain
boundary line, beyond which it proves to be unconquerable. The resistance very often pursues
similar tactics - Russian tactics, as they might be called - in cases of obsessional neurosis. For
a time, consequently, these cases yield the clearest results and permit a deep insight into the
causation of the symptoms. But presently one begins to wonder how it is that such marked
progress in analytic understanding can be unaccompanied by even the slightest change in the
patient's compulsions and inhibitions, until at last one perceives that everything that has been
accomplished is subject to a mental reservation of doubt, and that behind this protective barrier
the neurosis can feel secure. 'It would be all very fine', thinks the patient, often quite
consciously, 'if I were obliged to believe what the man says, but there is no question of that, and
so long as this is so I need change nothing.' Then, when one comes to close quarters with the
motives for this doubt, the fight with the resistances breaks out in earnest.

[1920a, 3852]

We showed on an earlier occasion that the resistance that has to be overcome in analysis
proceeds from the ego, which clings to its anticathexes. It is hard for the ego to direct its
attention to perceptions and ideas which it has up till now made a rule of avoiding, or to
acknowledge as belonging to itself impulses that are the complete opposite of those which it
knows as its own. Our fight against resistance in analysis is based upon this view of the facts. If
the resistance is itself unconscious, as so often happens owing to its connection with the
repressed material, we make it conscious. If it is conscious, or when it has become conscious,
we bring forward logical arguments against it; we promise the ego rewards and advantages if it
will give up its resistance. There can be no doubt or mistake about the existence of this
resistance on the part of the ego. But we have to ask ourselves whether it covers the whole
state of affairs in analysis. For we find that even after the ego has decided to relinquish its
resistances it still has difficulty in undoing the repressions; and we have called the period of
strenuous effort which follows after its praiseworthy decision, the phase of 'working-through'.
The dynamic factor which makes a working-through of this kind necessary and comprehensible
is not far to seek. It must be that after the ego's resistance has been removed the power of the
compulsion to repeat - the attraction exerted by the unconscious prototype upon the repressed
instinctual process - has still to be overcome. There is nothing to be said against describing this
factor as the *resistance of the unconscious*. There is no need to be discouraged by these
emendations. They are to be welcomed if they add something to our knowledge, and they are
no disgrace to us so long as they enrich rather than invalidate our earlier views - by limiting
some statement, perhaps, that was too general or by enlarging some idea that was too narrowly
formulated.

[1926d, 4312]
It must not be supposed that these emendations provide us with a complete survey of all the kinds of resistance that are met with in analysis. Further investigation of the subject shows that the analyst has to combat no less than five kinds of resistance, emanating from three directions - the ego, the id and the super-ego. The ego is the source of three of these, each differing in its dynamic nature. The first of these three ego-resistances is the repression resistance, which we have already discussed above and about which there is least new to be added. Next there is the transference resistance, which is of the same nature but which has different and much clearer effects in analysis, since it succeeds in establishing a relation to the analytic situation or the analyst himself and thus re-animating a repression which should only have been recollected. The third resistance, though also an ego-resistance, is of quite a different nature. It proceeds from the gain from illness and is based upon an assimilation of the symptom into the ego. It represents an unwillingness to renounce any satisfaction or relief that has been obtained. The fourth variety, arising from the id, is the resistance which, as we have just seen, necessitates 'working-through'. The fifth, coming from the super-ego and the last to be discovered, is also the most obscure though not always the least powerful one. It seems to originate from the sense of guilt or the need for punishment; and it opposes every move towards success, including, therefore, the patient's own recovery through analysis.

Yes, we are only beginning to appreciate the significance of all these important circumstances. That is why my description was bound to turn out so obscure. But now I can proceed. We describe all the forces that oppose the work of recovery as the patient's 'resistances'. The gain from illness is one such resistance. The 'unconscious sense of guilt' represents the super-ego's resistance; it is the most powerful factor, and the one most dreaded by us. We meet with still other resistances during the treatment. If the ego during the early period has set up a repression out of fear, then the fear still persists and manifests itself as a resistance if the ego approaches the repressed material. And finally, as you can imagine, there are likely to be difficulties if an instinctual process which has been going along a particular path for whole decades is suddenly expected to take a new path that has just been made open for it. That might be called the id's resistance. The struggle against all these resistances is our main work during an analytic treatment; the task of making interpretations is nothing compared to it. But as a result of this struggle and of the overcoming of the resistances, the patient's ego is so much altered and strengthened that we can look forward calmly to his future behaviour when the treatment is over. On the other hand, you can understand now why we need such long treatments. The length of the path of development and the wealth of the material are not the decisive factors. It is more a question of whether the path is clear. An army can be held up for weeks on a stretch of country which in peace time an express train crosses in a couple of hours - if the army has to overcome the enemy's resistance there. Such battles call for time in mental life too. I am unfortunately obliged to tell you that every effort to hasten analytic treatment appreciably has hitherto failed. The best way of shortening it seems to be to carry it out according to the rules.
The further our work proceeds and the more deeply our insight penetrates into the mental life of neurotics, the more clearly two new factors force themselves on our notice, which demand the closest attention as sources of resistance. Both of them are completely unknown to the patient, neither of them could be taken into account when our pact was made; nor do they arise from the patient's ego. They may both be embraced under the single name of ‘need to be ill or to suffer’, but they have different origins though in other respects they are of a kindred nature. The first of these two factors is the sense of guilt or consciousness of guilt, as it is called, though the patient does not feel it and is not aware of it. It is evidently the portion of the resistance contributed by a super-ego that has become particularly severe and cruel. The patient must not become well but must remain ill, for he deserves no better. This resistance does not actually interfere with our intellectual work, but it makes it inoperative; indeed, it often allows us to remove one form of neurotic suffering, but is ready at once to replace it by another, or perhaps by some somatic illness. The sense of guilt also explains the cure or improvement of severe neuroses which we occasionally observe after real misfortunes: all that matters is that the patient should be miserable - in what way is of no consequence. The uncomplaining resignation with which such people often put up with their hard fate is most remarkable, but also revealing. In warding off this resistance we are obliged to restrict ourselves to making it conscious and attempting to bring about the slow demolition of the hostile super-ego. [1940a [1938], 4989]

With the recognition that the properties of the ego which we meet with in the form of resistances can equally well be determined by heredity as acquired in defensive struggles, the topographical distinction between what is ego and what is id loses much of its value for our investigation. If we advance a step further in our analytic experience, we come upon resistances of another kind, which we can no longer localize and which seem to depend on fundamental conditions in the mental apparatus. I can only give a few examples of this type of resistance; the whole field of enquiry is still bewilderingly strange and insufficiently explored. We come across people, for instance, to whom we should be inclined to attribute a special 'adhesiveness of the libido'. The processes which the treatment sets in motion in them are so much slower than in other people because, apparently, they cannot make up their minds to detach libidinal cathexes from one object and displace them on to another, although we can discover no special reason for this cathetic loyalty. One meets with the opposite type of person, too, in whom the libido seems particularly mobile; it enters readily upon the new cathexes suggested by analysis, abandoning its former ones in exchange for them. The difference between the two types is comparable to the one felt by a sculptor, according to whether he works in hard stone or soft clay. Unfortunately, in this second type the results of analysis often turn out to be very impermanent: the new cathexes are soon given up once more, and we have an impression, not of having worked in clay, but of having written on water. In the words of the proverb: "Soon got, soon gone." [1937c, 5036]
How do we remove the resistance? In the same way: by discovering it and showing it to the patient. Indeed, the resistance too is derived from a repression - from the same one that we are endeavouring to resolve, or from one that took place earlier. It was set up by the anticathexis which arose in order to repress the objectionable impulse. Thus we now do the same thing that we tried to do to begin with: interpret, discover and communicate; but now we are doing it at the right place. The anticathexis or the resistance does not form part of the unconscious but of the ego, which is our collaborator, and is so even if it is not conscious. As we know, the word 'unconscious' is being used here in two senses: on the one hand as a phenomenon and on the other as a system. This sounds very difficult and obscure; but is it not only repeating what we have already said in earlier passages? We have long been prepared for it. We expect that this resistance will be given up and the anticathexis withdrawn when our interpretation has made it possible for the ego to recognize it. What are the motive forces that we work with in such a case? First with the patient's desire for recovery, which has induced him to take part with us in our joint work, and secondly with the help of his intelligence, to which we give support by our interpretation. There is no doubt that it is easier for the patient's intelligence to recognize the resistance and to find the translation corresponding to what is repressed if we have previously given him the appropriate anticipatory ideas. If I say to you: 'Look up at the sky! There's a balloon there!' you will discover it much more easily than if I simply tell you to look up and see if you can see anything. In the same way, a student who is looking through a microscope for the first time is instructed by his teacher as to what he will see; otherwise he does not see it at all, though it is there and visible.

[1916-1917, 3479]

All the libido, as well as everything opposing it, is made to converge solely on the relation with the doctor. In this process the symptoms are inevitably divested of libido. In place of his patient's true illness there appears the artificially constructed transference illness, in place of the various unreal objects of the libido there appears a single, and once more imaginary, object in the person of the doctor. But, by the help of the doctor's suggestion, the new struggle around this object is lifted to the highest psychical level: it takes place as a normal mental conflict. Since a fresh repression is avoided, the alienation between ego and libido is brought to an end and the subject's mental unity is restored. When the libido is released once more from its temporary object in the person of the doctor, it cannot return to its earlier objects, but is at the disposal of the ego. The forces against which we have been struggling during our work of therapy are, on the one hand, the ego's antipathy to certain trends of the libido - an antipathy expressed in a tendency to repression - and, on the other hand, the tenacity or adhesiveness of the libido, which dislikes leaving objects that it has once cathected.

[1916-1917, 3494]
In order to make it easier to understand this 'compulsion to repeat', which emerges during the psycho-analytic treatment of neurotics, we must above all get rid of the mistaken notion that what we are dealing with in our struggle against resistances is resistance on the part of the unconscious. The unconscious - that is to say, the 'repressed' - offers no resistance whatever to the efforts of the treatment. Indeed, it itself has no other endeavour than to break through the pressure weighing down on it and force its way either to consciousness or to a discharge through some real action. Resistance during treatment arises from the same higher strata and systems of the mind which originally carried out repression. But the fact that, as we know from experience, the motives of the resistances, and indeed the resistances themselves, are unconscious at first during the treatment, is a hint to us that we should correct a shortcoming in our terminology. We shall avoid a lack of clarity if we make our contrast not between the conscious and the unconscious but between the coherent ego and the repressed. It is certain that much of the ego is itself unconscious, and notably what we may describe as its nucleus; only a small part of it is covered by the term 'preconscious'. Having replaced a purely descriptive terminology by one which is systematic or dynamic, we can say that the patient's resistance arises from his ego, and we then at once perceive that the compulsion to repeat must be ascribed to the unconscious repressed. It seems probable that the compulsion can only express itself after the work of treatment has gone half-way to meet it and has loosened the repression.

There is no doubt that the resistance of the conscious and unconscious ego operates under the sway of the pleasure principle: it seeks to avoid the unpleasure which would be produced by the liberation of the repressed. Our efforts, on the other hand, are directed towards procuring the toleration of that unpleasure by an appeal to the reality principle. But how is the compulsion to repeat - the manifestation of the power of the repressed - related to the pleasure principle? It is clear that the greater part of what is re-experienced under the compulsion to repeat must cause the ego unpleasure, since it brings to light activities of repressed instinctual impulses. That, however, is unpleasure of a kind we have already considered and does not contradict the pleasure principle: unpleasure for one system and simultaneously satisfaction for the other. But we come now to a new and remarkable fact, namely that the compulsion to repeat also recalls from the past experiences which include no possibility of pleasure, and which can never, even long ago, have brought satisfaction even to instinctual impulses which have since been repressed.

But it is to be noted that only in rare instances can we observe the pure effects of the compulsion to repeat, unsupported by other motives. In the case of children’s play we have already laid stress on the other ways in which the emergence of the compulsion may be interpreted; the compulsion to repeat and instinctual satisfaction which is immediately pleasurable seem to converge here into an intimate partnership. The phenomena of transference are obviously exploited by the resistance which the ego maintains in its pertinacious insistence upon repression; the compulsion to repeat, which the treatment tries to bring into its service is, as it were, drawn over by the ego to its side (clinging as the ego does to the pleasure principle). A great deal of what might be described as the compulsion of destiny seems intelligible on a rational basis; so that we are under no necessity to call in a new and mysterious motive force to explain it.
Trotter gives as the list of instincts which he considers as primary those of self-preservation, of nutrition, of sex, and of the herd. The last often comes into opposition with the others. The feelings of guilt and of duty are the peculiar possessions of a gregarious animal. Trotter also derives from the herd instinct the repressive forces which psycho-analysis has shown to exist in the ego, and from the same source accordingly the resistances which the physician comes up against in psycho-analytic treatment. Speech owes its importance to its aptitude for mutual understanding in the herd, and upon it the identification of the individuals with one another largely rests.

[1921c, 3810]

In the further course of psycho-analytic work, however, even these distinctions have proved to be inadequate and, for practical purposes, insufficient. This has become clear in more ways than one; but the decisive instance is as follows. We have formed the idea that in each individual there is a coherent organization of mental processes; and we call this his ego. It is to this ego that consciousness is attached; the ego controls the approaches to motility - that is, to the discharge of excitations into the external world; it is the mental agency which supervises all its own constituent processes, and which goes to sleep at night, though even then it exercises the censorship on dreams. From this ego proceed the repressions, too, by means of which it is sought to exclude certain trends in the mind not merely from consciousness but also from other forms of effectiveness and activity. In analysis these trends which have been shut out stand in opposition to the ego, and the analysis is faced with the task of removing the resistances which the ego displays against concerning itself with the repressed. Now we find during analysis that, when we put certain tasks before the patient, he gets into difficulties; his associations fail when they should be coming near the repressed. We then tell him that he is dominated by a resistance; but he is quite unaware of the fact, and, even if he guesses from his unpleasant feelings that a resistance is now at work in him, he does not know what it is or how to describe it. Since, however, there can be no question but that this resistance emanates from his ego and belongs to it, we find ourselves in an unforeseen situation. We have come upon something in the ego itself which is also unconscious, which behaves exactly like the repressed - that is, which produces powerful effects without itself being conscious and which requires special work before it can be made conscious. From the point of view of analytic practice, the consequence of this discovery is that we land in endless obscurities and difficulties if we keep to our habitual forms of expression and try, for instance, to derive neuroses from a conflict between the conscious and the unconscious. We shall have to substitute for this antithesis another, taken from our insight into the structural conditions of the mind - the antithesis between the coherent ego and the repressed which is split off from it.¹

[1923b, 3951]
We showed on an earlier occasion that the resistance that has to be overcome in analysis proceeds from the ego, which clings to its anticathexes. It is hard for the ego to direct its attention to perceptions and ideas which it has up till now made a rule of avoiding, or to acknowledge as belonging to itself impulses that are the complete opposite of those which it knows as its own. Our fight against resistance in analysis is based upon this view of the facts. If the resistance is itself unconscious, as so often happens owing to its connection with the repressed material, we make it conscious. If it is conscious, or when it has become conscious, we bring forward logical arguments against it; we promise the ego rewards and advantages if it will give up its resistance. There can be no doubt or mistake about the existence of this resistance on the part of the ego. But we have to ask ourselves whether it covers the whole state of affairs in analysis. For we find that even after the ego has decided to relinquish its resistances it still has difficulty in undoing the repressions; and we have called the period of strenuous effort which follows after its praiseworthy decision, the phase of ‘working-through’. The dynamic factor which makes a working-through of this kind necessary and comprehensible is not far to seek. It must be that after the ego's resistance has been removed the power of the compulsion to repeat - the attraction exerted by the unconscious prototype upon the repressed instinctual process - has still to be overcome. There is nothing to be said against describing this factor as the resistance of the unconscious. There is no need to be discouraged by these emendations. They are to be welcomed if they add something to our knowledge, and they are no disgrace to us so long as they enrich rather than invalidate our earlier views - by limiting some statement, perhaps, that was too general or by enlarging some idea that was too narrowly formulated.

It must not be supposed that these emendations provide us with a complete survey of all the kinds of resistance that are met with in analysis. Further investigation of the subject shows that the analyst has to combat no less than five kinds of resistance, emanating from three directions - the ego, the id and the super-ego. The ego is the source of three of these, each differing in its dynamic nature. The first of these three ego-resistances is the repression resistance, which we have already discussed above and about which there is least new to be added. Next there is the transference resistance, which is of the same nature but which has different and much clearer effects in analysis, since it succeeds in establishing a relation to the analytic situation or the analyst himself and thus re-animating a repression which should only have been recollected. The third resistance, though also an ego-resistance, is of quite a different nature. It proceeds from the gain from illness and is based upon an assimilation of the symptom into the ego. It represents an unwillingness to renounce any satisfaction or relief that has been obtained. The fourth variety, arising from the id, is the resistance which, as we have just seen, necessitates 'working-through'. The fifth, coming from the super-ego and the last to be discovered, is also the most obscure though not always the least powerful one. It seems to originate from the sense of guilt or the need for punishment; and it opposes every move towards success, including, therefore, the patient's own recovery through analysis.
Yes, we are only beginning to appreciate the significance of all these important circumstances. That is why my description was bound to turn out so obscure. But now I can proceed. We describe all the forces that oppose the work of recovery as the patient's 'resistances'. The gain from illness is one such resistance. The 'unconscious sense of guilt' represents the super-ego's resistance; it is the most powerful factor, and the one most dreaded by us. We meet with still other resistances during the treatment. If the ego during the early period has set up a repression out of fear, then the fear still persists and manifests itself as a resistance if the ego approaches the repressed material. And finally, as you can imagine, there are likely to be difficulties if an instinctual process which has been going along a particular path for whole decades is suddenly expected to take a new path that has just been made open for it. That might be called the id's resistance. The struggle against all these resistances is our main work during an analytic treatment; the task of making interpretations is nothing compared to it. But as a result of this struggle and of the overcoming of the resistances, the patient's ego is so much altered and strengthened that we can look forward calmly to his future behaviour when the treatment is over. On the other hand, you can understand now why we need such long treatments. The length of the path of development and the wealth of the material are not the decisive factors. It is more a question of whether the path is clear. An army can be held up for weeks on a stretch of country which in peace time an express train crosses in a couple of hours - if the army has to overcome the enemy's resistance there. Such battles call for time in mental life too. I am unfortunately obliged to tell you that every effort to hasten analytic treatment appreciably has hitherto failed. The best way of shortening it seems to be to carry it out according to the rules.

[1926e, 4366]

Now, however, another problem awaits us - at the opposite end of the ego, as we might put it. It is presented to us by an observation during the work of analysis, an observation which is actually a very old one. As not infrequently happens, it has taken a long time to come to the point of appreciating its importance. The whole theory of psycho-analysis is, as you know, in fact built up on the perception of the resistance offered to us by the patient when we attempt to make his unconscious conscious to him. The objective sign of this resistance is that his associations fail or depart widely from the topic that is being dealt with. He may also recognize the resistance subjectively by the fact that he has distressing feelings when he approaches the topic. But this last sign may also be absent. We then say to the patient that we infer from his behaviour that he is now in a state of resistance; and he replies that he knows nothing of that, and is only aware that his associations have become more difficult. It turns out that we were right; but in that case his resistance was unconscious too, just as unconscious as the repressed, at the lifting of which we were working. We should long ago have asked the question: from what part of his mind does an unconscious resistance like this arise? The beginner in psycho-analysis will be ready at once with the answer: it is, of course, the resistance of the unconscious. An ambiguous and unserviceable answer! If it means that the resistance arises from the repressed, we must rejoin: certainly not! We must rather attribute to the repressed a strong upward drive, an impulsion to break through into consciousness. The resistance can only be a manifestation of the ego, which originally put the repression into force and now wishes to maintain it. That, moreover, is the view we always took. Since we have come to assume a special agency in the ego, the super-ego, which represents demands of a restrictive and rejecting character, we may say that repression is the work of this super-ego and that it is carried out either by itself or by the ego in obedience to its orders. If then we are met by the case of the resistance in analysis not being conscious to the patient, this means either that in quite important situations the super-ego and the ego can operate unconsciously, or - and this would be still more important - that portions of both of them, the ego and the super-ego themselves, are unconscious. In both cases we have to reckon with the disagreeable discovery that on the one hand (super-) ego and conscious and on the other hand repressed and unconscious are far from coinciding.

[1933a, 4677]
With the mention of resistance we have reached the second and more important part of our task. We have already learnt that the ego protects itself against the invasion of undesired elements from the unconscious and repressed id by means of anticathexes, which must remain intact if it is to function normally. The more hard-pressed the ego feels, the more convulsively it clings (as though in a fright) to these anticathexes, in order to protect what remains of itself from further irruptions. But this defensive purpose does not by any means accord with the aims of our treatment. What we desire, on the contrary, is that the ego, emboldened by the certainty of our help, shall dare to take the offensive in order to reconquer what has been lost. And it is here that we become aware of the strength of these anticathexes in the form of resistances to our work. The ego draws back in alarm from such undertakings, which seem dangerous and threaten unpleasure; it must be constantly encouraged and soothed if it is not to fail us. This resistance, which persists throughout the whole treatment and is renewed at every fresh piece of work, is known, not quite correctly, as the resistance due to repression. We shall find that it is not the only one that faces us. It is interesting to notice that in this situation the party-divisions are to some extent reversed: for the ego struggles against our instigation, while the unconscious, which is ordinarily our opponent, comes to our help, since it has a natural 'upward drive' and desires nothing better than to press forward across its settled frontiers into the ego and so to consciousness. The struggle which develops, if we gain our end and can induce the ego to overcome its resistances, is carried through under our direction and with our assistance. Its outcome is a matter of indifference: whether it results in the ego accepting, after a fresh examination, an instinctual demand which it has hitherto rejected, or whether it dismisses it once more, this time for good and all. In either case a permanent danger has been disposed of, the compass of the ego has been extended and a wasteful expenditure of energy has been made unnecessary.
[1940a [1938], 4988]
Let us once more glance over the situation which we have reached in our attempt at bringing help to the patient's neurotic ego. That ego is no longer able to fulfil the task set it by the external world (including human society). Not all of its experiences are at its disposal, a large proportion of its store of memories have escaped it. Its activity is inhibited by strict prohibitions from the super-ego, its energy is consumed in vain attempts at fending off the demands of the id. Beyond this, as a result of continuous irruptions by the id, its organization is impaired, it is no longer capable of any proper synthesis, it is torn by mutually opposed urges, by unsettled conflicts and by unsolved doubts. To start with, we get the patient's thus weakened ego to take part in the purely intellectual work of interpretation, which aims at provisionally filling the gaps in his mental assets, and to transfer to us the authority of his super-ego; we encourage it to take up the struggle over each individual demand made by the id and to conquer the resistances which arise in connection with it. At the same time we restore order in the ego by detecting the material and urges which have forced their way in from the unconscious, and expose them to criticism by tracing them back to their origin. We serve the patient in various functions, as an authority and a substitute for his parents, as a teacher and educator; and we have done the best for him if, as analysts, we raise the mental processes in his ego to a normal level, transform what has become unconscious and repressed into preconscious material and thus return it once more to the possession of his ego. On the patient's side a few rational factors work in our favour, such as the need for recovery which has its motive in his sufferings, and the intellectual interest that we may awaken in him in the theories and revelations of psycho-analysis; but of far greater force is the positive transference with which he meets us. Fighting against us, on the other hand, are the negative transference, the ego's resistance due to repression (that is, its unpleasure at having to lay itself open to the hard work imposed on it), the sense of guilt arising from its relation to the super-ego and the need to be ill due to deep-going changes in the economics of his instincts. The share taken by the last two factors decides whether the case is to be regarded as slight or severe. Apart from these, a few other factors may be discerned as having a favourable or unfavourable bearing. A certain psychical inertia, a sluggishness of the libido, which is unwilling to abandon its fixations cannot be welcome to us; the patient's capacity for sublimating his instincts plays a large part and so does his capacity for rising above the crude life of the instincts; so, too, does the relative power of his intellectual functions.

[1940a [1938], 4990]
The therapeutic effect depends on making conscious what is repressed, in the widest sense of the word, in the id. We prepare the way for this making conscious by interpretations and constructions, but we have interpreted only for ourselves not for the patient so long as the ego holds on to its earlier defences and does not give up its resistances. Now these resistances, although they belong to the ego, are nevertheless unconscious and in some sense separated off within the ego. The analyst recognizes them more easily than he does the hidden material in the id. One might suppose that it would be sufficient to treat them like portions of the id and, by making them conscious, bring them into connection with the rest of the ego. In this way, we should suppose, one half of the task of analysis would be accomplished; we should not reckon on meeting with a resistance against the uncovering of resistances. But what happens is this. During the work on the resistances the ego withdraws - with a greater or less degree of seriousness - from the agreement on which the analytic situation is founded. The ego ceases to support our efforts at uncovering the id; it opposes them, disobeys the fundamental rule of analysis, and allows no further derivatives of the repressed to emerge. We cannot expect the patient to have a strong conviction of the curative power of analysis. He may have brought along with him a certain amount of confidence in his analyst, which will be strengthened to an effective point by the factors of the positive transference which will be aroused in him. Under the influence of the unpleasurable impulses which he feels as a result of the fresh activation of his defensive conflicts, negative transferences may now gain the upper hand and completely annul the analytic situation. The patient now regards the analyst as no more than a stranger who is making disagreeable demands on him, and he behaves towards him exactly like a child who does not like the stranger and does not believe anything he says. If the analyst tries to explain to the patient one of the distortions made by him for the purposes of defence, and to correct it, he finds him uncomprehending and inaccessible to sound arguments. Thus we see that there is a resistance against the uncovering of resistances, and the defensive mechanisms really do deserve the name which we gave them originally, before they had been more closely examined. They are resistances not only to the making conscious of contents of the id, but also to the analysis as a whole, and thus to recovery.
[1937c, 5034]
The other members of this class of wish-fulfilments - hysterical symptoms, for instance - possess one essential characteristic, however, which I cannot discover in dreams. I have learnt from the researches which I have mentioned so often in the course of this work that in order to bring about the formation of a hysterical symptom both currents of our mind must converge. A symptom is not merely the expression of a realized unconscious wish; a wish from the preconscious which is fulfilled by the same symptom must also be present. So that the symptom will have of at least two determinants, one arising from each of the systems involved in the conflict. As in the case of dreams, there are no limits to the further determinants that may be present - to the 'overdetermination' of the symptoms. The determinant which does not arise from the Ucs. is invariably, so far as I know, a train of thought reacting against the unconscious wish - a self-punishment, for instance. I can therefore make the quite general assertion that a hysterical symptom develops only where the fulfilments of two opposing wishes, arising each from a different psychical system, are able to converge in a single expression. (Compare in this connection my most recent formulations on the origin of hysterical symptoms in my paper on hysterical phantasies and their relation to bisexuality.) Examples would serve very little purpose here, since nothing but an exhaustive elucidation of the complications involved could carry conviction. I will therefore leave my assertion to stand for itself and only quote an example in order to make the point clear, and not to carry conviction. In one of my women patients, then, hysterical vomiting turned out to be on the one hand the fulfilment of an unconscious phantasy dating from her puberty - of a wish, that is, that she might be continuously pregnant and have innumerable children, with a further wish, added later, that she might have them by as many men as possible. A powerful defensive impulse had sprung up against this unbridled wish. And, since the patient might lose her figure and her good looks as a result of her vomiting, and so might cease to be attractive to anyone, the symptom was acceptable to the punitive train of thought as well; and since it was permitted by both sides it could become a reality. This was the same method of treating a wish-fulfilment as was adopted by the Parthian queen towards the Roman triumvir Crassus. Believing that he had embarked on his expedition out of love of gold, she ordered molten gold to be poured down his throat when he was dead: 'Now', she said, 'you have what you wanted.' But all that we so far know about dreams is that they express the fulfilment of a wish from the unconscious; it seems as though the dominant, preconscious system acquiesces in this after insisting upon a certain number of distortions. Nor is it possible as a general rule to find a train of thought opposed to the dream-wish and, like its counterpart, realized in the dream. Only here and there in dream-analyses do we come upon signs of reactive creations, like, for instance, my affectionate feelings for my friend R. in the dream of my uncle (cf. p. 637 ff.). But we can find the missing ingredient from the preconscious elsewhere. Whereas the wish from the Ucs. is able to find expression in the dream after undergoing distortions of every kind, the dominant system withdraws into a wish to sleep, realizes that wish by bringing about the modifications which it is able to produce in the cathexes within the psychical apparatus, and persists in that wish throughout the whole duration of sleep.¹

Motives that support the patient in being ill are probably to be found in all fully developed cases. But there are some in which the motives are purely internal - such as desire for self-punishment, that is, penitence and remorse. It will be found much easier to solve the therapeutic problem in such cases than in those in which the illness is related to the attainment of some external aim. In Dora's case that aim was clearly to touch her father's heart and to detach him from Frau K.

¹[1900a, 999]

[1905e, 1383]
At the next session, which was the seventh, he took up the same subject once more. He could not believe, he said, that he had ever entertained such a wish against his father. He remembered a story of Sudermann’s, he went on, that had made a deep impression upon him. In this story there was a woman who, as she sat by her sister’s sick-bed, felt a wish that her sister should die so that she herself might marry her husband. The woman thereupon committed suicide, thinking she was not fit to live after being guilty of such baseness. He could understand this, he said, and it would be only right if his thoughts were the death of him, for he deserved nothing less.¹ - I remarked that it was well known to us that patients derived a certain satisfaction from their sufferings, so that in reality they all resisted their own recovery to some extent. He must never lose sight of the fact that a treatment like ours proceeded to the accompaniment of a constant resistance; I should be repeatedly reminding him of this fact. [1909d, 2146]

There is another phenomenon, however, which is far stranger. In our analyses we discover that there are people in whom the faculties of self-criticism and conscience - mental activities, that is, that rank as extremely high ones - are unconscious and unconsciously produce effects of the greatest importance; the example of resistance remaining unconscious during analysis is therefore by no means unique. But this new discovery, which compels us, in spite of our better critical judgement, to speak of an ‘unconscious sense of guilt’, bewilders us far more than the other and sets us fresh problems, especially when we gradually come to see that in a great number of neuroses an unconscious sense of guilt of this kind plays a decisive economic part and puts the most powerful obstacles in the way of recovery. If we come back once more to our scale of values, we shall have to say that not only what is lowest but also what is highest in the ego can be unconscious. It is as if we were thus supplied with a proof of what we have just asserted of the conscious ego: that it is first and foremost a body-ego. [1923b, 3961]

There are certain people who behave in a quite peculiar fashion during the work of analysis. When one speaks hopefully to them or expresses satisfaction with the progress of the treatment, they show signs of discontent and their condition invariably becomes worse. One begins by regarding this as defiance and as an attempt to prove their superiority to the physician, but later one comes to take a deeper and juster view. One becomes convinced, not only that such people cannot endure any praise or appreciation, but that they react inversely to the progress of the treatment. Every partial solution that ought to result, and in other people does result, in an improvement or a temporary suspension of symptoms produces in them for the time being an exacerbation of their illness; they get worse during the treatment instead of getting better. They exhibit what is known as a ‘negative therapeutic reaction’. [1923b, 3983]

There is no doubt that there is something in these people that sets itself against their recovery, and its approach is dreaded as though it were a danger. We are accustomed to say that the need for illness has got the upper hand in them over the desire for recovery. If we analyse this resistance in the usual way then, even after allowance has been made for an attitude of defiance towards the physician and for fixation to the various forms of gain from illness, the greater part of it is still left over; and this reveals itself as the most powerful of all obstacles to recovery, more powerful than the familiar ones of narcissistic inaccessibility, a negative attitude towards the physician and clinging to the gain from illness. [1923b, 3983]
In the end we come to see that we are dealing with what may be called a 'moral' factor, a sense of guilt, which is finding its satisfaction in the illness and refuses to give up the punishment of suffering. We shall be right in regarding this disheartening explanation as final. But as far as the patient is concerned this sense of guilt is dumb; it does not tell him he is guilty; he does not feel guilty, he feels ill. This sense of guilt expresses itself only as a resistance to recovery which it is extremely difficult to overcome. It is also particularly difficult to convince the patient that this motive lies behind his continuing to be ill; he holds fast to the more obvious explanation that treatment by analysis is not the right remedy for his case.¹

The description we have given applies to the most extreme instances of this state of affairs, but in a lesser measure this factor has to be reckoned with in very many cases, perhaps in all comparatively severe cases of neurosis. In fact it may be precisely this element in the situation, the attitude of the ego ideal, that determines the severity of a neurotic illness. We shall not hesitate, therefore, to discuss rather more fully the way in which the sense of guilt expresses itself under different conditions.

¹ The battle with the obstacle of an unconscious sense of guilt is not made easy for the analyst. Nothing can be done against it directly, and nothing indirectly but the slow procedure of unmasking its unconscious repressed roots, and of thus gradually changing it into a conscious sense of guilt. One has a special opportunity for influencing it when this Ucs. sense of guilt is a 'borrowed' one - when it is the product of an identification with some other person who was once the object of an erotic cathexis. A sense of guilt that has been adopted in this way is often the sole remaining trace of the abandoned love-relation and not at all easy to recognize as such. (The likeness between this process and what happens in melancholia is unmistakable.) If one can unmask this former object-cathexis behind the Ucs. sense of guilt, the therapeutic success is often brilliant, but otherwise the outcome of one's efforts is by no means certain. It depends principally on the intensity of the sense of guilt; there is often no counteracting force of a similar order of strength which the treatment can oppose to it. Perhaps it may depend, too, on whether the personality of the analyst allows of the patient's putting him in the place of his ego ideal, and this involves a temptation for the analyst to play the part of prophet, saviour and redeemer to the patient. Since the rules of analysis are diametrically opposed to the physician's making use of his personality in any such manner, it must be honestly confessed that here we have another limitation to the effectiveness of analysis; after all, analysis does not set out to make pathological reactions impossible, but to give the patient's ego freedom to decide one way or the other.

Let us keep to a habit of our technique and consider first the extreme and unmistakably pathological form of this masochism. I have described elsewhere¹ how in analytic treatment we come across patients to whom, owing to their behaviour towards its therapeutic influence, we are obliged to ascribe an 'unconscious' sense of guilt. I pointed out the sign by which such people can be recognized (a 'negative therapeutic reaction') and I did not conceal the fact that the strength of such an impulse constitutes one of the most serious resistances and the greatest danger to the success of our medical or educative aims. The satisfaction of this unconscious sense of guilt is perhaps the most powerful bastion in the subject's (usually composite) gain from illness - in the sum of forces which struggle against his recovery and refuse to surrender his state of illness. The suffering entailed by neuroses is precisely the factor that makes them valuable to the masochistic trend. It is instructive, too, to find, contrary to all theory and expectation, that a neurosis which has defied every therapeutic effort may vanish if the subject becomes involved in the misery of an unhappy marriage, or loses all his money, or develops a dangerous organic disease. In such instances one form of suffering has been replaced by another; and we see that all that mattered was that it should be possible to maintain a certain amount of suffering.

Patients do not easily believe us when we tell them about the unconscious sense of guilt. They know only too well by what torments - the pangs of conscience - a conscious sense of guilt, a consciousness of guilt, expresses itself, and they therefore cannot admit that they could harbour exactly analogous impulses in themselves without being in the least aware of them. We may, I think, to some extent meet their objection if we give up the term 'unconscious sense of guilt', which is in any case psychologically incorrect, and speak instead of a 'need for punishment', which covers the observed state of affairs just as aptly. We cannot, however, restrain ourselves from judging and localizing this unconscious sense of guilt in the same way as we do the conscious kind.

After these preliminaries we can return to our consideration of moral masochism. We have said that, by their behaviour during treatment and in life, the individuals in question give an impression of being morally inhibited to an excessive degree, of being under the domination of an especially sensitive conscience, although they are not conscious of any of this ultra-morality. On closer inspection, we can see the difference there is between an unconscious extension of morality of this kind and moral masochism. In the former, the accent falls on the heightened sadism of the super-ego to which the ego submits; in the latter, it falls on the ego's own masochism which seeks punishment, whether from the super-ego or from the parental powers outside. We may be forgiven for having confused the two to begin with; for in both cases it is a question of a relationship between the ego and the super-ego (or powers that are equivalent to it), and in both cases what is involved is a need which is satisfied by punishment and suffering. It can hardly be an insignificant detail, then, that the sadism of the super-ego becomes for the most part glaringly conscious, whereas the masochistic trend of the ego remains as a rule concealed from the subject and has to be inferred from his behaviour.

It must not be supposed that these emendations provide us with a complete survey of all the kinds of resistance that are met with in analysis. Further investigation of the subject shows that the analyst has to combat no less than five kinds of resistance, emanating from three directions - the ego, the id and the super-ego. The ego is the source of three of these, each differing in its dynamic nature. The first of these three ego-resistances is the repression resistance, which we have already discussed above and about which there is least new to be added. Next there is the transference resistance, which is of the same nature but which has different and much clearer effects in analysis, since it succeeds in establishing a relation to the analytic situation or the analyst himself and thus re-animating a repression which should only have been recollected. The third resistance, though also an ego-resistance, is of quite a different nature. It proceeds from the gain from illness and is based upon an assimilation of the symptom into the ego. It represents an unwillingness to renounce any satisfaction or relief that has been obtained. The fourth variety, arising from the id, is the resistance which, as we have just seen, necessitates 'working-through'. The fifth, coming from the super-ego and the last to be discovered, is also the most obscure though not always the least powerful one. It seems to originate from the sense of guilt or the need for punishment; and it opposes every move towards success, including, therefore, the patient's own recovery through analysis.
Yes, we are only beginning to appreciate the significance of all these important circumstances. That is why my description was bound to turn out so obscure. But now I can proceed. We describe all the forces that oppose the work of recovery as the patient's 'resistances'. The gain from illness is one such resistance. The 'unconscious sense of guilt' represents the super-ego's resistance; it is the most powerful factor, and the one most dreaded by us. We meet with still other resistances during the treatment. If the ego during the early period has set up a repression out of fear, then the fear still persists and manifests itself as a resistance if the ego approaches the repressed material. And finally, as you can imagine, there are likely to be difficulties if an instinctual process which has been going along a particular path for whole decades is suddenly expected to take a new path that has just been made open for it. That might be called the id's resistance. The struggle against all these resistances is our main work during an analytic treatment; the task of making interpretations is nothing compared to it. But as a result of this struggle and of the overcoming of the resistances, the patient's ego is so much altered and strengthened that we can look forward calmly to his future behaviour when the treatment is over. On the other hand, you can understand now why we need such long treatments. The length of the path of development and the wealth of the material are not the decisive factors. It is more a question of whether the path is clear. An army can be held up for weeks on a stretch of country which in peace time an express train crosses in a couple of hours - if the army has to overcome the enemy's resistance there. Such battles call for time in mental life too. I am unfortunately obliged to tell you that every effort to hasten analytic treatment appreciably has hitherto failed. The best way of shortening it seems to be to carry it out according to the rules.
[1926e, 4366]
In the first place, I suspect that the reader has the impression that our discussions on the sense of guilt disrupt the framework of this essay: that they take up too much space, so that the rest of its subject-matter, with which they are not always closely connected, is pushed to one side. This may have spoiled the structure of my paper; but it corresponds faithfully to my intention to represent the sense of guilt as the most important problem in the development of civilization and to show that the price we pay for our advance in civilization is a loss of happiness through the heightening of the sense of guilt.¹ Anything that still sounds strange about this statement, which is the final conclusion of our investigation, can probably be traced to the quite peculiar relationship - as yet completely unexplained - which the sense of guilt has to our consciousness. In the common case of remorse, which we regard as normal, this feeling makes itself clearly enough perceptible to consciousness. Indeed, we are accustomed to speak of a 'consciousness of guilt' instead of a 'sense of guilt'. Our study of the neuroses, to which, after all we owe the most valuable pointers to an understanding of normal conditions, brings us up against some contradictions. In one of those affections, obsessional neurosis, the sense of guilt makes itself noisily heard in consciousness; it dominates the clinical picture and the patient's life as well, and it hardly allows anything else to appear alongside of it. But in most other cases and forms of neurosis it remains completely unconscious, without on that account producing any less important effects. Our patients do not believe us when we attribute an 'unconscious sense of guilt' to them. In order to make ourselves at all intelligible to them, we tell them of an unconscious need for punishment, in which the sense of guilt finds expression. But its connection with a particular form of neurosis must not be over-estimated. Even in obsessional neurosis there are types of patients who are not aware of their sense of guilt, or who only feel it as a tormenting uneasiness, a kind of anxiety, if they are prevented from carrying out certain actions. It ought to be possible eventually to understand these things; but as yet we cannot. Here perhaps we may be glad to have it pointed out that the sense of guilt is at bottom nothing else but a topographical variety of anxiety; in its later phases it coincides completely with fear of the super-ego. And the relations of anxiety to consciousness exhibit the same extraordinary variations. Anxiety is always present somewhere or other behind every symptom; but at one time it takes noisy possession of the whole of consciousness, while at another it conceals itself so completely that we are obliged to speak of unconscious anxiety or, if we want to have a clearer psychological conscience, since anxiety is in the first instance simply a feeling, of possibilities of anxiety. Consequently it is very conceivable that the sense of guilt produced by civilization is not perceived as such either, and remains to a large extent unconscious, or appears as a sort of malaise, a dissatisfaction, for which people seek other motivations. Religions, at any rate, have never overlooked the part played in civilization by a sense of guilt. Furthermore - a point which I failed to appreciate elsewhere² - they claim to redeem mankind from this sense of guilt, which they call sin. From the manner in which, in Christianity, this redemption is achieved - by the sacrificial death of a single person, who in this manner takes upon himself a guilt that is common to everyone - we have been able to infer what the first occasion may have been on which this primal guilt, which was also the beginning of civilization, was acquired.³

[1930a, 4523]
There is, as we think, no doubt about the origin of this unconscious need for punishment. It behaves like a piece of conscience, like a prolongation of our conscience into the unconscious; and it must have the same origin as conscience and correspond, therefore, to a piece of aggressiveness that has been internalized and taken over by the super-ego. If only the words went together better, we should be justified for all practical purposes in calling it an 'unconscious sense of guilt'. Theoretically we are in fact in doubt whether we should suppose that all the aggressiveness that has returned from the external world is bound by the super-ego and accordingly turned against the ego, or that a part of it is carrying on its mute and uncanny activity as a free destructive instinct in the ego and the id. A distribution of the latter kind is the more probable; but we know nothing more about it. There is no doubt that, when the super-ego was first instituted, in equipping that agency use was made of the piece of the child's aggressiveness towards his parents for which he was unable to effect a discharge outwards on account of his erotic fixation as well as of external difficulties; and for that reason the severity of the super-ego need not simply correspond to the strictness of the upbringing. It is very possible that, when there are later occasions for suppressing aggressiveness, the instinct may take the same path that was opened to it at that decisive point of time.

People in whom this unconscious sense of guilt is excessively strong betray themselves in analytic treatment by the negative therapeutic reaction which is so disagreeable from the prognostic point of view. When one has given them the solution of a symptom, which should normally be followed by at least its temporary disappearance, what they produce instead is a momentary exacerbation of the symptom and of the illness. It is often enough to praise them for their behaviour in the treatment or to say a few hopeful words about the progress of the analysis in order to bring about an unmistakable worsening of their condition. A non-analyst would say that the 'will to recovery' was absent. If you follow the analytic way of thinking, you will see in this behaviour a manifestation of the unconscious sense of guilt, for which being ill, with its sufferings and impediments, is just what is wanted. The problems which the unconscious sense of guilt has opened up, its connections with morality, education, crime and delinquency, are at present the preferred field of work for psycho-analysts.

The further our work proceeds and the more deeply our insight penetrates into the mental life of neurotics, the more clearly two new factors force themselves on our notice, which demand the closest attention as sources of resistance. Both of them are completely unknown to the patient, neither of them could be taken into account when our pact was made; nor do they arise from the patient's ego. They may both be embraced under the single name of 'need to be ill or to suffer', but they have different origins though in other respects they are of a kindred nature. The first of these two factors is the sense of guilt or consciousness of guilt, as it is called, though the patient does not feel it and is not aware of it. It is evidently the portion of the resistance contributed by a super-ego that has become particularly severe and cruel. The patient must not become well but must remain ill, for he deserves no better. This resistance does not actually interfere with our intellectual work, but it makes it inoperative; indeed, it often allows us to remove one form of neurotic suffering, but is ready at once to replace it by another, or perhaps by some somatic illness. The sense of guilt also explains the cure or improvement of severe neuroses which we occasionally observe after real misfortunes: all that matters is that the patient should be miserable - in what way is of no consequence. The uncomplaining resignation with which such people often put up with their hard fate is most remarkable, but also revealing. In warding off this resistance we are obliged to restrict ourselves to making it conscious and attempting to bring about the slow demolition of the hostile super-ego.
Let us once more glance over the situation which we have reached in our attempt at bringing help to the patient's neurotic ego. That ego is no longer able to fulfil the task set it by the external world (including human society). Not all of its experiences are at its disposal, a large proportion of its store of memories have escaped it. Its activity is inhibited by strict prohibitions from the super-ego, its energy is consumed in vain attempts at fending off the demands of the id. Beyond this, as a result of continuous irruptions by the id, its organization is impaired, it is no longer capable of any proper synthesis, it is torn by mutually opposed urges, by unsettled conflicts and by unsolved doubts. To start with, we get the patient's thus weakened ego to take part in the purely intellectual work of interpretation, which aims at provisionally filling the gaps in his mental assets, and to transfer to us the authority of his super-ego; we encourage it to take up the struggle over each individual demand made by the id and to conquer the resistances which arise in connection with it. At the same time we restore order in the ego by detecting the material and urges which have forced their way in from the unconscious, and expose them to criticism by tracing them back to their origin. We serve the patient in various functions, as an authority and a substitute for his parents, as a teacher and educator; and we have done the best for him if, as analysts, we raise the mental processes in his ego to a normal level, transform what has become unconscious and repressed into preconscious material and thus return it once more to the possession of his ego. On the patient's side a few rational factors work in our favour, such as the need for recovery which has its motive in his sufferings, and the intellectual interest that we may awaken in him in the theories and revelations of psycho-analysis; but of far greater force is the positive transference with which he meets us. Fighting against us, on the other hand, are the negative transference, the ego's resistance due to repression (that is, its unpleasure at having to lay itself open to the hard work imposed on it), the sense of guilt arising from its relation to the super-ego and the need to be ill due to deep-going changes in the economics of his instincts. The share taken by the last two factors decides whether the case is to be regarded as slight or severe. Apart from these, a few other factors may be discerned as having a favourable or unfavourable bearing. A certain psychical inertia, a sluggishness of the libido, which is unwilling to abandon its fixations cannot be welcome to us; the patient's capacity for sublimating his instincts plays a large part and so does his capacity for rising above the crude life of the instincts; so, too, does the relative power of his intellectual functions.

[1940a [1938], 4990]
In yet another group of cases the distinguishing characteristics of the ego, which are to be held responsible as sources of resistance against analytic treatment and as impediments to therapeutic success, may spring from different and deeper roots. Here we are dealing with the ultimate things which psychological research can learn about: the behaviour of the two primal instincts, their distribution, mingling and defusion - things which we cannot think of as being confined to a single province of the mental apparatus, the id, the ego or the super-ego. No stronger impression arises from the resistances during the work of analysis than of there being a force which is defending itself by every possible means against recovery and which is absolutely resolved to hold on to illness and suffering. One portion of this force has been recognized by us, undoubtedly with justice, as the sense of guilt and need for punishment, and has been localized by us in the ego's relation to the super-ego. But this is only the portion of it which is, as it were, psychically bound by the super-ego and thus becomes recognizable; other quotas of the same force, whether bound or free, may be at work in other, unspecified places. If we take into consideration the total picture made up of the phenomena of masochism immanent in so many people, the negative therapeutic reaction and the sense of guilt found in so many neurotics, we shall no longer be able to adhere to the belief that mental events are exclusively governed by the desire for pleasure. These phenomena are unmistakable indications of the presence of a power in mental life which we call the instinct of aggression or of destruction according to its aims, and which we trace back to the original death instinct of living matter. It is not a question of an antithesis between an optimistic and a pessimistic theory of life. Only by the concurrent or mutually opposing action of the two primal instincts - Eros and the death instinct -, never by one or the other alone, can we explain the rich multiplicity of the phenomena of life.

[1937c, 5037]

If an analysis is dominated by powerful factors that impose a negative therapeutic reaction, such as a sense of guilt, a masochistic need for suffering or repugnance to receiving help from the analyst, the patient's behaviour after he has been offered a construction often makes it very easy for us to arrive at the decision that we are in search of. If the construction is wrong, there is no change in the patient; but if it is right or gives an approximation to the truth, he reacts to it with an unmistakable aggravation of his symptoms and of his general condition.
[1937d, 5056]
At the next session, which was the seventh, he took up the same subject once more. He could not believe, he said, that he had ever entertained such a wish against his father. He remembered a story of Sudermann's, he went on, that had made a deep impression upon him. In this story there was a woman who, as she sat by her sister's sick-bed, felt a wish that her sister should die so that she herself might marry her husband. The woman thereupon committed suicide, thinking she was not fit to live after being guilty of such baseness. He could understand this, he said, and it would be only right if his thoughts were the death of him, for he deserved nothing less.¹ - I remarked that it was well known to us that patients derived a certain satisfaction from their sufferings, so that in reality they all resisted their own recovery to some extent. He must never lose sight of the fact that a treatment like ours proceeded to the accompaniment of a constant resistance; I should be repeatedly reminding him of this fact.[1909d, 2146]

If you further consider that the patient makes all the chance events that occur during his analysis into interferences with it, that he uses as reasons for slackening his efforts every diversion outside the analysis, every comment by a person of authority in his environment who is hostile to analysis, any chance organic illness or any that complicates his neurosis and, even, indeed, every improvement in his condition - if you consider all this, you will have obtained an approximate, though still incomplete, picture of the forms and methods of the resistance, the struggle against which accompanies every analysis.[1916-1917, 3366]

As far as I can see, the danger threatens from two directions in especial. On the one hand, when the illness has been broken down by the analysis, the patient makes the most assiduous efforts to create for himself in place of his symptoms new substitutive satisfactions, which now lack the feature of suffering. He makes use of the enormous capacity for displacement possessed by the now partly liberated libido, in order to cathect with libido and promote to the position of substitutive satisfactions the most diverse kinds of activities, preferences and habits, not excluding some that have been his already. He continually finds new distractions of this kind, into which the energy necessary to carrying on the treatment escapes, and he knows how to keep them secret for a time. It is the analyst's task to detect these divergent paths and to require him every time to abandon them, however harmless the activity which leads to satisfaction may be in itself. The half-recovered patient may also enter on less harmless paths - as when, for instance, if he is a man, he seeks prematurely to attach himself to a woman. It may be observed, incidentally, that unhappy marriage and physical infirmity are the two things that most often supersede a neurosis. They satisfy in particular the sense of guilt (need for punishment) which makes many patients cling so fast to their neuroses. By a foolish choice in marriage they punish themselves; they regard a long organic illness as a punishment by fate and thereafter often cease to keep up their neurosis.[1919a, 3632]

There are certain people who behave in a quite peculiar fashion during the work of analysis. When one speaks hopefully to them or expresses satisfaction with the progress of the treatment, they show signs of discontent and their condition invariably becomes worse. One begins by regarding this as defiance and as an attempt to prove their superiority to the physician, but later one comes to take a deeper and juster view. One becomes convinced, not only that such people cannot endure any praise or appreciation, but that they react inversely to the progress of the treatment. Every partial solution that ought to result, and in other people does result, in an improvement or a temporary suspension of symptoms produces in them for the time being an exacerbation of their illness; they get worse during the treatment instead of getting better. They exhibit what is known as a 'negative therapeutic reaction'.[1923b, 3983]
There is no doubt that there is something in these people that sets itself against their recovery, and its approach is dreaded as though it were a danger. We are accustomed to say that the need for illness has got the upper hand in them over the desire for recovery. If we analyse this resistance in the usual way then, even after allowance has been made for an attitude of defiance towards the physician and for fixation to the various forms of gain from illness, the greater part of it is still left over; and this reveals itself as the most powerful of all obstacles to recovery, more powerful than the familiar ones of narcissistic inaccessibility, a negative attitude towards the physician and clinging to the gain from illness.

In the end we come to see that we are dealing with what may be called a 'moral' factor, a sense of guilt, which is finding its satisfaction in the illness and refuses to give up the punishment of suffering. We shall be right in regarding this disheartening explanation as final. But as far as the patient is concerned this sense of guilt is dumb; it does not tell him he is guilty; he does not feel guilty, he feels ill. This sense of guilt expresses itself only as a resistance to recovery which it is extremely difficult to overcome. It is also particularly difficult to convince the patient that this motive lies behind his continuing to be ill; he holds fast to the more obvious explanation that treatment by analysis is not the right remedy for his case.

The description we have given applies to the most extreme instances of this state of affairs, but in a lesser measure this factor has to be reckoned with in very many cases, perhaps in all comparatively severe cases of neurosis. In fact it may be precisely this element in the situation, the attitude of the ego ideal, that determines the severity of a neurotic illness. We shall not hesitate, therefore, to discuss rather more fully the way in which the sense of guilt expresses itself under different conditions.

The battle with the obstacle of an unconscious sense of guilt is not made easy for the analyst. Nothing can be done against it directly, and nothing indirectly but the slow procedure of unmasking its unconscious repressed roots, and of thus gradually changing it into a *conscious* sense of guilt. One has a special opportunity for influencing it when this *Ucs.* sense of guilt is a "borrowed" one - when it is the product of an identification with some other person who was once the object of an erotic cathexis. A sense of guilt that has been adopted in this way is often the sole remaining trace of the abandoned love-relation and not at all easy to recognize as such. (The likeness between this process and what happens in melancholia is unmistakable.) If one can unmask this former object-cathexis behind the *Ucs.* sense of guilt, the therapeutic success is often brilliant, but otherwise the outcome of one's efforts is by no means certain. It depends principally on the intensity of the sense of guilt; there is often no counteracting force of a similar order of strength which the treatment can oppose to it. Perhaps it may depend, too, on whether the personality of the analyst allows of the patient's putting him in the place of his ego ideal, and this involves a temptation for the analyst to play the part of prophet, saviour and redeemer to the patient. Since the rules of analysis are diametrically opposed to the physician's making use of his personality in any such manner, it must be honestly confessed that here we have another limitation to the effectiveness of analysis; after all, analysis does not set out to make pathological reactions impossible, but to give the patient's ego *freedom* to decide one way or the other.
Let us keep to a habit of our technique and consider first the extreme and unmistakably pathological form of this masochism. I have described elsewhere¹ how in analytic treatment we come across patients to whom, owing to their behaviour towards its therapeutic influence, we are obliged to ascribe an 'unconscious' sense of guilt. I pointed out the sign by which such people can be recognized (a 'negative therapeutic reaction') and I did not conceal the fact that the strength of such an impulse constitutes one of the most serious resistances and the greatest danger to the success of our medical or educative aims. The satisfaction of this unconscious sense of guilt is perhaps the most powerful bastion in the subject's (usually composite) gain from illness - in the sum of forces which struggle against his recovery and refuse to surrender his state of illness. The suffering entailed by neuroses is precisely the factor that makes them valuable to the masochistic trend. It is instructive, too, to find, contrary to all theory and expectation, that a neurosis which has defied every therapeutic effort may vanish if the subject becomes involved in the misery of an unhappy marriage, or loses all his money, or develops a dangerous organic disease. In such instances one form of suffering has been replaced by another; and we see that all that mattered was that it should be possible to maintain a certain amount of suffering.

[1924c, 4078]

Patients do not easily believe us when we tell them about the unconscious sense of guilt. They know only too well by what torments - the pangs of conscience - a conscious sense of guilt, a consciousness of guilt, expresses itself, and they therefore cannot admit that they could harbour exactly analogous impulses in themselves without being in the least aware of them. We may, I think, to some extent meet their objection if we give up the term 'unconscious sense of guilt', which is in any case psychologically incorrect, and speak instead of a 'need for punishment', which covers the observed state of affairs just as aptly. We cannot, however, restrain ourselves from judging and localizing this unconscious sense of guilt in the same way as we do the conscious kind.

[1924c, 4078]

It must not be supposed that these emendations provide us with a complete survey of all the kinds of resistance that are met with in analysis. Further investigation of the subject shows that the analyst has to combat no less than five kinds of resistance, emanating from three directions - the ego, the id and the super-ego. The ego is the source of three of these, each differing in its dynamic nature. The first of these three ego-resistances is the repression resistance, which we have already discussed above and about which there is least new to be added. Next there is the transference resistance, which is of the same nature but which has different and much clearer effects in analysis, since it succeeds in establishing a relation to the analytic situation or the analyst himself and thus re-animating a repression which should only have been recollected. The third resistance, though also an ego-resistance, is of quite a different nature. It proceeds from the gain from illness and is based upon an assimilation of the symptom into the ego. It represents an unwillingness to renounce any satisfaction or relief that has been obtained. The fourth variety, arising from the id, is the resistance which, as we have just seen, necessitates 'working-through'. The fifth, coming from the super-ego and the last to be discovered, is also the most obscure though not always the least powerful one. It seems to originate from the sense of guilt or the need for punishment; and it opposes every move towards success, including, therefore, the patient's own recovery through analysis.

[1926d, 4313]
Oh, that is not so hard to understand. Think of the war neurotics, who do not have to serve, precisely because they are ill. In civil life illness can be used as a screen to gloss over incompetence in one's profession or in competition with other people; while in the family it can serve as a means for sacrificing the other members and extorting proofs of their love or for imposing one's will upon them. All of this lies fairly near the surface; we sum it up in the term 'gain from illness'. It is curious, however, that the patient - that is, his ego - nevertheless knows nothing of the whole concatenation of these motives and the actions which they involve. One combats the influence of these trends by compelling the ego to take cognizance of them. But there are other motives, that lie still deeper, for holding on to being ill, which are not so easily dealt with. But these cannot be understood without a fresh journey into psychological theory. [1926e, 4364]

We have travelled somewhat far from our basis. I will tell you in retrospect the starting-point of these reflections on the theory of the instincts. It was the same as that which led us to revise the relation between the ego and the unconscious - the impression derived from the work of analysis that the patient who puts up a resistance is so often unaware of that resistance. Not only the fact of the resistance is unconscious to him, however, but its motives as well. We were obliged to search out these motives or motive, and to our surprise we found them in a powerful need for punishment which we could only class with masochistic wishes. The practical significance of this discovery is not less than its theoretical one, for the need for punishment is the worst enemy of our therapeutic efforts. It is satisfied by the suffering which is linked to the neurosis, and for that reason holds fast to being ill. It seems that this factor, an unconscious need for punishment, has a share in every neurotic illness. And here those cases in which the neurotic suffering can be replaced by suffering of another kind are wholly convincing. I will report an experience of this kind. [1933a, 4712]

People in whom this unconscious sense of guilt is excessively strong betray themselves in analytic treatment by the negative therapeutic reaction which is so disagreeable from the prognostic point of view. When one has given them the solution of a symptom, which should normally be followed by at least its temporary disappearance, what they produce instead is a momentary exacerbation of the symptom and of the illness. It is often enough to praise them for their behaviour in the treatment or to say a few hopeful words about the progress of the analysis in order to bring about an unmistakable worsening of their condition. A non-analyst would say that the 'will to recovery' was absent. If you follow the analytic way of thinking, you will see in this behaviour a manifestation of the unconscious sense of guilt, for which being ill, with its sufferings and impediments, is just what is wanted. The problems which the unconscious sense of guilt has opened up, its connections with morality, education, crime and delinquency, are at present the preferred field of work for psycho-analysts. [1933a, 4714]
The further our work proceeds and the more deeply our insight penetrates into the mental life of neurotics, the more clearly two new factors force themselves on our notice, which demand the closest attention as sources of resistance. Both of them are completely unknown to the patient, neither of them could be taken into account when our pact was made; nor do they arise from the patient's ego. They may both be embraced under the single name of 'need to be ill or to suffer', but they have different origins though in other respects they are of a kindred nature. The first of these two factors is the sense of guilt or consciousness of guilt, as it is called, though the patient does not feel it and is not aware of it. It is evidently the portion of the resistance contributed by a super-ego that has become particularly severe and cruel. The patient must not become well but must remain ill, for he deserves no better. This resistance does not actually interfere with our intellectual work, but it makes it inoperative; indeed, it often allows us to remove one form of neurotic suffering, but is ready at once to replace it by another, or perhaps by some somatic illness. The sense of guilt also explains the cure or improvement of severe neuroses which we occasionally observe after real misfortunes: all that matters is that the patient should be miserable - in what way is of no consequence. The uncomplaining resignation with which such people often put up with their hard fate is most remarkable, but also revealing. In warding off this resistance we are obliged to restrict ourselves to making it conscious and attempting to bring about the slow demolition of the hostile super-ego.

Let us once more glance over the situation which we have reached in our attempt at bringing help to the patient's neurotic ego. That ego is no longer able to fulfil the task set it by the external world (including human society). Not all of its experiences are at its disposal, a large proportion of its store of memories have escaped it. Its activity is inhibited by strict prohibitions from the super-ego, its energy is consumed in vain attempts at fending off the demands of the id. Beyond this, as a result of continuous irruptions by the id, its organization is impaired, it is no longer capable of any proper synthesis, it is torn by mutually opposed urges, by unsettled conflicts and by unsolved doubts. To start with, we get the patient's thus weakened ego to take part in the purely intellectual work of interpretation, which aims at provisionally filling the gaps in his mental assets, and to transfer to us the authority of his super-ego; we encourage it to take up the struggle over each individual demand made by the id and to conquer the resistances which arise in connection with it. At the same time we restore order in the ego by detecting the material and urges which have forced their way in from the unconscious, and expose them to criticism by tracing them back to their origin. We serve the patient in various functions, as an authority and a substitute for his parents, as a teacher and educator; and we have done the best for him if, as analysts, we raise the mental processes in his ego to a normal level, transform what has become unconscious and repressed into preconscious material and thus return it once more to the possession of his ego. On the patient's side a few rational factors work in our favour, such as the need for recovery which has its motive in his sufferings, and the intellectual interest that we may awaken in him in the theories and revelations of psychoanalysis; but of far greater force is the positive transference with which he meets us. Fighting against us, on the other hand, are the negative transference, the ego's resistance due to repression (that is, its unpleasure at having to lay itself open to the hard work imposed on it), the sense of guilt arising from its relation to the super-ego and the need to be ill due to deep-going changes in the economics of his instincts. The share taken by the last two factors decides whether the case is to be regarded as slight or severe. Apart from these, a few other factors may be discerned as having a favourable or unfavourable bearing. A certain psychical inertia, a sluggishness of the libido, which is unwilling to abandon its fixations cannot be welcome to us; the patient's capacity for sublimating his instincts plays a large part and so does his capacity for rising above the crude life of the instincts; so, too, does the relative power of his intellectual functions.

[1940a [1938], 4989]

[1940a [1938], 4990]
In yet another group of cases the distinguishing characteristics of the ego, which are to be held responsible as sources of resistance against analytic treatment and as impediments to therapeutic success, may spring from different and deeper roots. Here we are dealing with the ultimate things which psychological research can learn about: the behaviour of the two primal instincts, their distribution, mingling and defusion - things which we cannot think of as being confined to a single province of the mental apparatus, the id, the ego or the super-ego. No stronger impression arises from the resistances during the work of analysis than of there being a force which is defending itself by every possible means against recovery and which is absolutely resolved to hold on to illness and suffering. One portion of this force has been recognized by us, undoubtedly with justice, as the sense of guilt and need for punishment, and has been localized by us in the ego's relation to the super-ego. But this is only the portion of it which is, as it were, psychically bound by the super-ego and thus becomes recognizable; other quotas of the same force, whether bound or free, may be at work in other, unspecified places. If we take into consideration the total picture made up of the phenomena of masochism immanent in so many people, the negative therapeutic reaction and the sense of guilt found in so many neurotics, we shall no longer be able to adhere to the belief that mental events are exclusively governed by the desire for pleasure. These phenomena are unmistakable indications of the presence of a power in mental life which we call the instinct of aggression or of destruction according to its aims, and which we trace back to the original death instinct of living matter. It is not a question of an antithesis between an optimistic and a pessimistic theory of life. Only by the concurrent or mutually opposing action of the two primal instincts - Eros and the death instinct -, never by one or the other alone, can we explain the rich multiplicity of the phenomena of life.

If an analysis is dominated by powerful factors that impose a negative therapeutic reaction, such as a sense of guilt, a masochistic need for suffering or repugnance to receiving help from the analyst, the patient's behaviour after he has been offered a construction often makes it very easy for us to arrive at the decision that we are in search of. If the construction is wrong, there is no change in the patient; but if it is right or gives an approximation to the truth, he reacts to it with an unmistakable aggravation of his symptoms and of his general condition.
It is less easy to demonstrate the existence of another resistance, our means of combating which are specially inadequate. There are some neurotics in whom, to judge by all their reactions, the instinct of self-preservation has actually been reversed. They seem to aim at nothing other than self-injury and self-destruction. It is possible too that the people who in fact do in the end commit suicide belong to this group. It is to be assumed that in such people far-reaching defusions of instinct have taken place, as a result of which there has been a liberation of excessive quantities of the destructive instinct directed inwards. Patients of this kind are not able to tolerate recovery through our treatment and fight against it with all their strength. But we must confess that this is a case which we have not yet succeeded in completely explaining. [1940a [1938], 4989]

Let us once more glance over the situation which we have reached in our attempt at bringing help to the patient's neurotic ego. That ego is no longer able to fulfil the task set it by the external world (including human society). Not all of its experiences are at its disposal, a large proportion of its store of memories have escaped it. Its activity is inhibited by strict prohibitions from the super-ego, its energy is consumed in vain attempts at fending off the demands of the id. Beyond this, as a result of continuous irruptions by the id, its organization is impaired, it is no longer capable of any proper synthesis, it is torn by mutually opposed urges, by unsettled conflicts and by unsolved doubts. To start with, we get the patient's thus weakened ego to take part in the purely intellectual work of interpretation, which aims at provisionally filling the gaps in his mental assets, and to transfer to us the authority of his super-ego; we encourage it to take up the struggle over each individual demand made by the id and to conquer the resistances which arise in connection with it. At the same time we restore order in the ego by detecting the material and urges which have forced their way in from the unconscious, and expose them to criticism by tracing them back to their origin. We serve the patient in various functions, as an authority and a substitute for his parents, as a teacher and educator; and we have done the best for him if, as analysts, we raise the mental processes in his ego to a normal level, transform what has become unconscious and repressed into preconscious material and thus return it once more to the possession of his ego. On the patient's side a few rational factors work in our favour, such as the need for recovery which has its motive in his sufferings, and the intellectual interest that we may awaken in him in the theories and revelations of psycho-analysis; but of far greater force is the positive transference with which he meets us. Fighting against us, on the other hand, are the negative transference, the ego's resistance due to repression (that is, its unpleasure at having to lay itself open to the hard work imposed on it), the sense of guilt arising from its relation to the super-ego and the need to be ill due to deep-going changes in the economics of his instincts. The share taken by the last two factors decides whether the case is to be regarded as slight or severe. Apart from these, a few other factors may be discerned as having a favourable or unfavourable bearing. A certain psychical inertia, a sluggishness of the libido, which is unwilling to abandon its fixations cannot be welcome to us; the patient's capacity for sublimating his instincts plays a large part and so does his capacity for rising above the crude life of the instincts; so, too, does the relative power of his intellectual functions. [1940a [1938], 4990]
In yet another group of cases the distinguishing characteristics of the ego, which are to be held responsible as sources of resistance against analytic treatment and as impediments to therapeutic success, may spring from different and deeper roots. Here we are dealing with the ultimate things which psychological research can learn about: the behaviour of the two primal instincts, their distribution, mingling and defusion - things which we cannot think of as being confined to a single province of the mental apparatus, the id, the ego or the super-ego. No stronger impression arises from the resistances during the work of analysis than of there being a force which is defending itself by every possible means against recovery and which is absolutely resolved to hold on to illness and suffering. Only by the concurrent or mutually opposing action of the two primal instincts - Eros and the death instinct -, never by one or the other alone, can we explain the rich multiplicity of the phenomena of life.

[1937c, 5037]
The second motive for counter-wish dreams is so obvious that it is easy to overlook it, as I did myself for some considerable time. There is a masochistic component in the sexual constitution of many people, which arises from the reversal of an aggressive, sadistic component into its opposite. Those who find their pleasure, not in having physical pain inflicted on them, but in humiliation and mental torture, may be described as ‘mental masochists’. It will at once be seen that people of this kind can have counter-wish dreams and unpleasurable dreams, which are none the less wish-fulfilments since they satisfy their masochistic inclinations. I will quote one such dream, produced by a young man who in his earlier years had greatly tormented his elder brother, to whom he had a homosexual attachment. His character having undergone a fundamental change, he had the following dream, which was in three pieces: I. *His elder brother was chaffing him.* II. *Two grown men were caressing each other with a homosexual purpose.* III. *His brother had sold the business of which he himself had looked forward to becoming the director.* He awoke from the last dream with the most distressing feelings. Nevertheless it was a masochistic wishful dream, and might be translated thus: ‘It would serve me right if my brother were to confront me with this sale as a punishment for all the torments he had to put up with from me.

[1900a, 653]
In this series of dreams dreamt by an author who had been a journeyman tailor in his youth, it is hard to recognize the dominance of wish-fulfilment. All the dreamer's enjoyment lay in his day-time existence, whereas in his dreams he was still haunted by the shadow of an unhappy life from which he had at last escaped. Some dreams of my own of a similar kind have enabled me to throw a little light on the subject. As a young doctor I worked for a long time at the Chemical Institute without ever becoming proficient in the skills which that science demands; and for that reason in my waking life I have never liked thinking of this barren and indeed humiliating episode in my apprenticeship. On the other hand I have a regularly recurring dream of working in the laboratory, of carrying out analyses and of having various experiences there. These dreams are disagreeable in the same way as examination dreams and they are never very distinct. While I was interpreting one of them, my attention was eventually attracted by the word 'analysis', which gave me a key to their understanding. Since those days I have become an 'analyst', and I now carry out analyses which are very highly spoken of, though it is true that they are 'psycho-analyses'. It was now clear to me: if I have grown proud of carrying out analyses of that kind in my daytime life and feel inclined to boast to myself of how successful I have become, my dreams remind me during the night of those other, unsuccessful analyses of which I have no reason to feel proud. They are the punishment dreams of a parvenu, like the dreams of the journeyman tailor who had grown into a famous author. But how does it become possible for a dream, in the conflict between a parvenu's pride and his self-criticism, to side with the latter, and choose as its content a sensible warning instead of an unlawful wish-fulfilment? As I have already said, the answer to this question raises difficulties. We may conclude that the foundation of the dream was formed in the first instance by an exaggeratedly ambitious phantasy, but that humiliating thoughts that poured cold water on the phantasy found their way into the dream instead. It may be remembered that there are masochistic impulses in the mind, which may be responsible for a reversal such as this. I should have no objection to this class of dreams being distinguished from 'wish-fulfilment dreams' under the name of 'punishment dreams'. I should not regard this as implying any qualification of the theory of dreams which I have hitherto put forward; it would be no more than a linguistic expedient for meeting the difficulties of those who find it strange that opposites should converge. But a closer examination of some of these dreams brings something more to light. In an indistinct part of the background of one of my laboratory dreams I was of an age which placed me precisely in the gloomiest and most unsuccessful year of my medical career. I was still without a post and had no idea how I could earn my living; but at the same time I suddenly discovered that I had a choice open to me between several women whom I might marry! So I was once more young, and, more than everything, she was once more young - the woman who had shared all these difficult years with me. The unconscious instigator of the dream was thus revealed as one of the constantly gnawing wishes of a man who is growing older. The conflict raging in other levels of the mind between vanity and self-criticism had, it is true, determined the content of the dream; but it was only the more deeply-rooted wish for youth that had made it possible for that conflict to appear as a dream. Even when we are awake we sometimes say to ourselves: "Things are going very well to-day and times were hard in the old days; all the same, it was lovely then - I was still young."

[1900a, 918]
Several other forms of creative writing, however, are equally subject to these same preconditions for enjoyment. Lyric poetry serves the purpose, more than anything, of giving vent to intense feelings of many sorts - just as was at one time the case with dancing. Epic poetry aims chiefly at making it possible to feel the enjoyment of a great heroic character in his hour of triumph. But drama seeks to explore emotional possibilities more deeply and to give an enjoyable shape even to forebodings of misfortune; for this reason it depicts the hero in his struggles, or rather (with masochistic satisfaction) in defeat. This relation to suffering and misfortune might be taken as characteristic of drama, whether, as happens in serious plays, it is only concern that is aroused, and afterwards allayed, or whether, as happens in tragedies, the suffering is actually realized. The fact that drama originated out of sacrificial rites (cf. the goat and the scapegoat) in the cult of the gods cannot be unrelated to this meaning of drama. It appeases, as it were, a rising rebellion against the divine regulation of the universe, which is responsible for the existence of suffering. Heroes are first and foremost rebels against God or against something divine; and pleasure is derived, as it seems, from the affliction of a weaker being in the face of divine might - a pleasure due to masochistic satisfaction as well as to direct enjoyment of a character whose greatness is insisted upon in spite of everything. Here we have a mood like that of Prometheus, but alloyed with a paltry readiness to let oneself be soothed for the moment by a temporary satisfaction.

[S1942a [1905], 1608]

Suffering of every kind is thus the subject-matter of drama, and from this suffering it promises to give the audience pleasure. Thus we arrive at a first precondition of this form of art: that it should not cause suffering to the audience, that it should know how to compensate, by means of the possible satisfactions involved, for the sympathetic suffering which is aroused. (Modern writers have particularly often failed to obey this rule.) But the suffering represented is soon restricted to mental suffering; for no one wants physical suffering who knows how quickly all mental enjoyment is brought to an end by the changes in somatic feeling that physical suffering brings about. If we are sick we have one wish only: to be well again and to be quit of our present state. We call for the doctor and medicine, and for the removal of the inhibition on the play of phantasy which has pampered us into deriving enjoyment even from our own sufferings. If a spectator puts himself in the place of someone who is physically ill he finds himself without any capacity for enjoyment or psychical activity. Consequently a person who is physically ill can only figure on the stage as a piece of stage property and not as a hero, unless, indeed, some peculiar physical aspects of his illness make psychical activity possible - such, for instance, as the sick man’s forlorn state in the Philoctetes or the hopelessness of the sufferers in the class of plays that centre round consumptives.

[S1942a [1905], 1609]
People are acquainted with mental suffering principally in connection with the circumstances in which it is acquired; accordingly, dramas dealing with it require some event out of which the illness shall arise and they open with an exposition of this event. It is only an apparent exception that some plays, such as the *Ajax* and the *Philoctetes*, introduce the mental illness as already fully established; for in Greek tragedies, owing to the familiarity of the material, the curtain rises, as one might say, in the middle of the play. It is easy to give an exhaustive account of the preconditions governing an event of the kind that is here in question. It must be an event involving conflict and it must include an effort of will together with resistance. This precondition found its first and grandest fulfilment in a struggle against divinity. I have already said that a tragedy of this kind is one of rebellion, in which the dramatist and the audience take the side of the rebel. The less belief there comes to be in divinity, the more important becomes the human regulation of affairs; and it is this which, with increasing insight, comes to be held responsible for suffering. Thus the hero’s next struggle is against human society, and here we have the class of *social* tragedies. Yet another fulfilment of the necessary precondition is to be found in a struggle between individual men. Such are tragedies of *character*, which exhibit all the excitement of an ‘*agon*’, and which are best played out between outstanding characters who have freed themselves from the bond of human institutions - which, in fact, must have two heroes. Fusions between these two last classes, with a hero struggling against institutions embodied in powerful characters, are of course admissible without question. Pure tragedies of character lack the rebellious source of enjoyment, but this emerges once again no less forcibly in social dramas (in Ibsen for instance) than it did in the historical plays of the Greek classical tragedians.

Let us keep to a habit of our technique and consider first the extreme and unmistakably pathological form of this masochism. I have described elsewhere¹ how in analytic treatment we come across patients to whom, owing to their behaviour towards its therapeutic influence, we are obliged to ascribe an ‘unconscious’ sense of guilt. I pointed out the sign by which such people can be recognized (a ‘negative therapeutic reaction’) and I did not conceal the fact that the strength of such an impulse constitutes one of the most serious resistances and the greatest danger to the success of our medical or educative aims. The satisfaction of this unconscious sense of guilt is perhaps the most powerful bastion in the subject’s (usually composite) gain from illness - in the sum of forces which struggle against his recovery and refuse to surrender his state of illness. The suffering entailed by neuroses is precisely the factor that makes them valuable to the masochistic trend. It is instructive, too, to find, contrary to all theory and expectation, that a neurosis which has defied every therapeutic effort may vanish if the subject becomes involved in the misery of an unhappy marriage, or loses all his money, or develops a dangerous organic disease. In such instances one form of suffering has been replaced by another; and we see that all that mattered was that it should be possible to maintain a certain amount of suffering.

¹[1942a [1905], 1609]

¹[1924c, 4078]
We have travelled somewhat far from our basis. I will tell you in retrospect the starting-point of these reflections on the theory of the instincts. It was the same as that which led us to revise the relation between the ego and the unconscious - the impression derived from the work of analysis that the patient who puts up a resistance is so often unaware of that resistance. Not only the fact of the resistance is unconscious to him, however, but its motives as well. We were obliged to search out these motives or motive, and to our surprise we found them in a powerful need for punishment which we could only class with masochistic wishes. The practical significance of this discovery is not less than its theoretical one, for the need for punishment is the worst enemy of our therapeutic efforts. It is satisfied by the suffering which is linked to the neurosis, and for that reason holds fast to being ill. It seems that this factor, an unconscious need for punishment, has a share in every neurotic illness. And here those cases in which the neurotic suffering can be replaced by suffering of another kind are wholly convincing. I will report an experience of this kind.

[1933a, 4712]

It is less easy to demonstrate the existence of another resistance, our means of combating which are specially inadequate. There are some neurotics in whom, to judge by all their reactions, the instinct of self-preservation has actually been reversed. They seem to aim at nothing other than self-injury and self-destruction. It is possible too that the people who in fact do in the end commit suicide belong to this group. It is to be assumed that in such people far-reaching defusions of instinct have taken place, as a result of which there has been a liberation of excessive quantities of the destructive instinct directed inwards. Patients of this kind are not able to tolerate recovery through our treatment and fight against it with all their strength. But we must confess that this is a case which we have not yet succeeded in completely explaining.

[1940a [1938], 4989]
Let us once more glance over the situation which we have reached in our attempt at bringing help to the patient's neurotic ego. That ego is no longer able to fulfil the task set by the external world (including human society). Not all of its experiences are at its disposal, a large proportion of its store of memories have escaped it. Its activity is inhibited by strict prohibitions from the super-ego, its energy is consumed in vain attempts at fending off the demands of the id. Beyond this, as a result of continuous irruptions by the id, its organization is impaired, it is no longer capable of any proper synthesis, it is torn by mutually opposed urges, by unsettled conflicts and by unsolved doubts. To start with, we get the patient's thus weakened ego to take part in the purely intellectual work of interpretation, which aims at provisionally filling the gaps in his mental assets, and to transfer to us the authority of his super-ego; we encourage it to take up the struggle over each individual demand made by the id and to conquer the resistances which arise in connection with it. At the same time we restore order in the ego by detecting the material and urges which have forced their way in from the unconscious, and expose them to criticism by tracing them back to their origin. We serve the patient in various functions, as an authority and a substitute for his parents, as a teacher and educator; and we have done the best for him if, as analysts, we raise the mental processes in his ego to a normal level, transform what has become unconscious and repressed into preconscious material and thus return it once more to the possession of his ego. On the patient's side a few rational factors work in our favour, such as the need for recovery which has its motive in his sufferings, and the intellectual interest that we may awaken in him in the theories and revelations of psycho-analysis; but of far greater force is the positive transference with which he meets us. Fighting against us, on the other hand, are the negative transference, the ego's resistance due to repression (that is, its unpleasure at having to lay itself open to the hard work imposed on it), the sense of guilt arising from its relation to the super-ego and the need to be ill due to deep-going changes in the economics of his instincts. The share taken by the last two factors decides whether the case is to be regarded as slight or severe. Apart from these, a few other factors may be discerned as having a favourable or unfavourable bearing. A certain psychical inertia, a sluggishness of the libido, which is unwilling to abandon its fixations cannot be welcome to us; the patient's capacity for sublimating his instincts plays a large part and so does his capacity for rising above the crude life of the instincts; so, too, does the relative power of his intellectual functions.

[1940a [1938], 4990]
In yet another group of cases the distinguishing characteristics of the ego, which are to be held responsible as sources of resistance against analytic treatment and as impediments to therapeutic success, may spring from different and deeper roots. Here we are dealing with the ultimate things which psychological research can learn about: the behaviour of the two primal instincts, their distribution, mingling and defusion - things which we cannot think of as being confined to a single province of the mental apparatus, the id, the ego or the super-ego. No stronger impression arises from the resistances during the work of analysis than of there being a force which is defending itself by every possible means against recovery and which is absolutely resolved to hold on to illness and suffering. One portion of this force has been recognized by us, undoubtedly with justice, as the sense of guilt and need for punishment, and has been localized by us in the ego's relation to the super-ego. But this is only the portion of it which is, as it were, psychically bound by the super-ego and thus becomes recognizable; other quotas of the same force, whether bound or free, may be at work in other, unspecified places. If we take into consideration the total picture made up of the phenomena of masochism immanent in so many people, the negative therapeutic reaction and the sense of guilt found in so many neurotics, we shall no longer be able to adhere to the belief that mental events are exclusively governed by the desire for pleasure. These phenomena are unmistakable indications of the presence of a power in mental life which we call the instinct of aggression or of destruction according to its aims, and which we trace back to the original death instinct of living matter. It is not a question of an antithesis between an optimistic and a pessimistic theory of life. Only by the concurrent or mutually opposing action of the two primal instincts - Eros and the death instinct -, never by one or the other alone, can we explain the rich multiplicity of the phenomena of life. [1937c, 5037]

How parts of these two classes of instincts combine to fulfil the various vital functions, under what conditions such combinations grow looser or break up, to what disturbances these changes correspond and with what feelings the perceptual scale of the pleasure principle replies to them - these are problems whose elucidation would be the most rewarding achievement of psychological research. For the moment we must bow to the superiority of the forces against which we see our efforts come to nothing. Even to exert a psychical influence on simple masochism is a severe tax upon our powers. [1937c, 5038]

If an analysis is dominated by powerful factors that impose a negative therapeutic reaction, such as a sense of guilt, a masochistic need for suffering or repugnance to receiving help from the analyst, the patient's behaviour after he has been offered a construction often makes it very easy for us to arrive at the decision that we are in search of. If the construction is wrong, there is no change in the patient; but if it is right or gives an approximation to the truth, he reacts to it with an unmistakable aggravation of his symptoms and of his general condition. [1937d, 5056]
There would be nothing more to discuss or worry about in this behaviour of transference, if it were not that two points remain unexplained about it which are of particular interest to psycho-analysis. Firstly, we do not understand why transference is so much more intense with neurotic subjects in analysis than it is with other such people who are not being analysed; and secondly, it remains a puzzle why in analysis transference emerges as the most powerful resistance to the treatment, whereas outside analysis it must be regarded as the vehicle of cure and the condition of success. For our experience has shown us - and the fact can be confirmed as often as we please - that if a patient's free associations fail¹ the stoppage can invariably be removed by an assurance that he is being dominated at the moment by an association which is concerned with the doctor himself or with something connected with him. As soon as this explanation is given, the stoppage is removed, or the situation is changed from one in which the associations fail into one in which they are being kept back. At first sight it appears to be an immense disadvantage in psycho-analysis as a method that what is elsewhere the strongest factor towards success is changed in it into the most powerful medium of resistance. If, however, we examine the situation more closely, we can at least clear away the first of our two problems. It is not a fact that transference emerges with greater intensity and lack of restraint during psycho-analysis than outside it. In institutions in which nerve patients are treated non-analytically, we can observe transference occurring with the greatest intensity and in the most unworthy forms, extending to nothing less than mental bondage, and moreover showing the plainest erotic colouring. Gabriele Reuter, with her sharp powers of observation, described this at a time when there was no such thing as psycho-analysis, in a remarkable book which betrays in every respect the clearest insight into the nature and genesis of neuroses.² These characteristics of transference are therefore to be attributed not to psycho-analysis but to neurosis itself.

[1912b, 2458]
Our second problem - the problem of why transference appears in psycho-analysis as
resistance - has been left for the moment untouched; and we must now approach it more
closely. Let us picture the psychological situation during the treatment. An invariable and
indispensable precondition of every onset of a psychoneurosis is the process to which Jung has
given the appropriate name of 'introversion'.¹ That is to say: the portion of libido which is
capable of becoming conscious and is directed towards reality is diminished, and the portion
which is directed away from reality and is unconscious, and which, though it may still feed the
subject's phantasies, nevertheless belongs to the unconscious, is proportionately increased.
The libido (whether wholly or in part) has entered on a regressive course and has revived the
subject's infantile imagos.² The analytic treatment now proceeds to follow it; it seeks to track
down the libido, to make it accessible to consciousness and, in the end, serviceable for reality.
Where the investigations of analysis come upon the libido withdrawn into its hiding-place, a
struggle is bound to break out; all the forces which have caused the libido to regress will rise up
as 'resistances' against the work of analysis, in order to conserve the new state of things. For if
the libido's introversion or regression had not been justified by a particular relation between the
subject and the external world - stated in the most general terms, by the frustration of
satisfaction - and if it had not for the moment even become expedient, it could never have taken
place at all. But the resistances from this source are not the only ones or indeed the most
powerful. The libido at the disposal of the subject's personality had always been under the
influence of the attraction of his unconscious complexes (or more correctly, of the portions of
those complexes belonging to the unconscious), and it entered on a regressive course because
the attraction of reality had diminished. In order to liberate it, this attraction of the unconscious
has to be overcome; that is, the repression of the unconscious instincts and of their productions,
which has meanwhile been set up in the subject, must be removed. This is responsible for by
far the largest part of the resistance, which so often causes the illness to persist even after the
turning away from reality has lost its temporary justification. The analysis has to struggle against
the resistances from both these sources. The resistance accompanies the treatment step by
step. Every single association, every act of the person under treatment must reckon with the
resistance and represents a compromise between the forces that are striving towards recovery
and the opposing ones which I have described.

[1912b, 2459]

If now we follow a pathogenic complex from its representation in the conscious (whether this
is an obvious one in the form of a symptom or something quite inconspicuous) to its root in the
unconscious, we shall soon enter a region in which the resistance makes itself felt so clearly
that the next association must take account of it and appear as a compromise between its
demands and those of the work of investigation. It is at this point, on the evidence of our
experience, that transference enters on the scene. When anything in the complexive material (in
the subject-matter of the complex) is suitable for being transferred on to the figure of the doctor,
that transference is carried out; it produces the next association, and announces itself by
indications of a resistance - by a stoppage, for instance. We infer from this experience that the
transference-idea has penetrated into consciousness in front of any other possible associations
because it satisfies the resistance. An event of this sort is repeated on countless occasions in
the course of an analysis. Over and over again, when we come near to a pathogenic complex,
the portion of that complex which is capable of transference is first pushed forward into
consciousness and defended with the greatest obstinacy.¹

[1912b, 2460]

¹ This, however, should not lead us to conclude in general that the element selected for transference-
resistance is of peculiar pathogenic importance. If in the course of a battle there is a particularly embittered
struggle over the possession of some little church or some individual farm, there is no need to suppose
that the church is a national shrine perhaps, or that the house shelters the army's pay-chest. The value to
the object may be a purely tactical one and may perhaps emerge only in this one battle.

[1912b, 2460]
Thus transference in the analytic treatment invariably appears to us in the first instance as the strongest weapon of the resistance, and we may conclude that the intensity and persistence of the transference are an effect and an expression of the resistance. The mechanism of transference is, it is true, dealt with when we have traced it back to the state of readiness of the libido, which has remained in possession of infantile imagos; but the part transference plays in the treatment can only be explained if we enter into its relations with resistance. [1912b, 2461]

How does it come about that transference is so admirably suited to be a means of resistance? It might be thought that the answer can be given without difficulty. For it is evident that it becomes particularly hard to admit to any proscribed wishful impulse if it has to be revealed in front of the very person to whom the impulse relates. Such a necessity gives rise to situations which in the real world seem scarcely possible. But it is precisely this that the patient is aiming at when he makes the object of his emotional impulses coincide with the doctor. Further consideration, however, shows that this apparent gain cannot provide the solution of the problem. Indeed, a relation of affectionate and devoted dependence can, on the contrary help a person over all the difficulties of making an admission In analogous real situations people will usually say: 'I feel no shame in front of you: I can say anything to you.' Thus the transference to the doctor might just as easily serve to facilitate admissions, and it is not clear why it should make things more difficult. [1912b, 2461]

The further question may be raised of why it is that the resistance phenomena of transference only appear in psycho-analysis and not in indifferent forms of treatment (e.g. in institutions) as well. The reply is that they do show themselves in these other situations too, but they have to be recognized as such. The breaking out of a negative transference is actually quite a common event in institutions. As soon as a patient comes under the dominance of the negative transference he leaves the institution in an unchanged or relapsed condition. The erotic transference does not have such an inhibiting effect in institutions, since in them, just as in ordinary life, it is glossed over instead of being uncovered. But it is manifested quite clearly as a resistance to recovery, not, it is true, by driving the patient out of the institution - on the contrary, it holds him back in it - but by keeping him at a distance from life. For, from the point of view of recovery, it is a matter of complete indifference whether the patient overcomes this or that anxiety or inhibition in the institution; what matters is that he shall be free of it in his real life as well. [1912b, 2463]

The negative transference deserves a detailed examination, which it cannot be given within the limits of the present paper. In the curable forms of psychoneurosis it is found side by side with the affectionate transference, often directed simultaneously towards the same person. Bleuler has coined the excellent term 'ambivalence' to describe this phenomenon.¹ Up to a point, ambivalence of feeling of this sort seems to be normal; but a high degree of it is certainly a special peculiarity of neurotic people. In obsessional neurotics an early separation of the 'pairs of opposites' seems to be characteristic of their instinctual life and to be one of their constitutional preconditions. Ambivalence in the emotional trends of neurotics is the best explanation of their ability to enlist their transferences in the service of resistance. Where the capacity for transference has become essentially limited to a negative one, as is the case with paranoics, there ceases to be any possibility of influence or cure. [1912b, 2463]
In all these reflections, however, we have hitherto dealt only with one side of the phenomenon of transference; we must turn our attention to another aspect of the same subject. Anyone who forms a correct appreciation of the way in which a person in analysis, as soon as he comes under the dominance of any considerable transference-resistance, is flung out of his real relation to the doctor, how he feels at liberty then to disregard the fundamental rule of psycho-analysis which lays it down that whatever comes into one's head must be reported without criticizing it, how he forgets the intentions with which he started the treatment, and how he regards with indifference logical arguments and conclusions which only a short time before had made a great impression on him — anyone who has observed all this will feel it necessary to look for an explanation of his impression in other factors besides those that have already been adduced. Nor are such factors far to seek: they arise once again from the psychological situation in which the treatment places the patient.

[1912b, 2464]

The question then arises whether the advantage gained by the patient would not to some extent counterbalance the sacrifice made by the physician. I may venture to form a judgement about this, since for ten years or so I set aside one hour a day, and sometimes two, for gratuitous treatments, because I wanted, in order to find my way about in the neuroses, to work in the face of as little resistance as possible. The advantages I sought by this means were not forthcoming. Free treatment enormously increases some of a neurotic’s resistances - in young women, for instance, the temptation which is inherent in their transference-relation, and in young men, their opposition to an obligation to feel grateful, an opposition which arises from their father-complex and which presents one of the most troublesome hindrances to the acceptance of medical help. The absence of the regulating effect offered by the payment of a fee to the doctor makes itself very painfully felt; the whole relationship is removed from the real world, and the patient is deprived of a strong motive for endeavouring to bring the treatment to an end.

[1913c, 2485]

Before I wind up these remarks on beginning analytic treatment, I must say a word about a certain ceremonial which concerns the position in which the treatment is carried out. I hold to the plan of getting the patient to lie on a sofa while I sit behind him out of his sight. This arrangement has a historical basis; it is the remnant of the hypnotic method out of which psycho-analysis was evolved. But it deserves to be maintained for many reasons. The first is a personal motive, but one which others may share with me. I cannot put up with being stared at by other people for eight hours a day (or more). Since, while I am listening to the patient, I, too, give myself over to the current of my unconscious thoughts, I do not wish my expressions of face to give the patient material for interpretations or to influence him in what he tells me. The patient usually regards being made to adopt this position as a hardship and rebels against it, especially if the instinct for looking (scopophilia) plays an important part in his neurosis. I insist on this procedure, however, for its purpose and result are to prevent the transference from mingling with the patient's associations imperceptibly, to isolate the transference and to allow it to come forward in due course sharply defined as a resistance. I know that many analysts work in a different way, but I do not know whether this deviation is due more to a craving for doing things differently or to some advantage which they find they gain by it.

[1913c, 2487]
If one looks into the situation more closely one recognizes the influence of motives which further complicate things - of which some are connected with being in love and others are particular expressions of resistance. Of the first kind are the patient's endeavour to assure herself of her irresistibility, to destroy the doctor's authority by bringing him down to the level of a lover and to gain all the other promised advantages incidental to the satisfaction of love. As regards the resistance, we may suspect that on occasion it makes use of a declaration of love on the patient's part as a means of putting her analyst's severity to the test, so that, if he should show signs of compliance, he may expect to be taken to task for it. But above all one gets an impression that the resistance is acting as an agent provocateur; it heightens the patient's state of being in love and exaggerates her readiness for sexual surrender in order to justify the workings of repression all the more emphatically, by pointing to the dangers of such licentiousness. All these accessory motives, which in simpler cases may not be present, have, as we know, been regarded by Adler as the essential part of the whole process. [1915a, 2513]

Many analysts will no doubt be agreed on the method by which other women, who are less violent in their love, can be gradually made to adopt the analytic attitude. What we do, above all, is to stress to the patient the unmistakable element of resistance in this 'love'. Genuine love, we say, would make her docile and intensify her readiness to solve the problems of her case, simply because the man she was in love with expected it of her. In such a case she would gladly choose the road to completion of the treatment, in order to acquire value in the doctor's eyes and to prepare herself for real life, where this feeling of love could find a proper place. Instead of this, we point out, she is showing a stubborn and rebellious spirit, she has thrown up all interest in her treatment, and clearly feels no respect for the doctor's well-founded convictions. She is thus bringing out a resistance under the guise of being in love with him; and in addition to this she has no compunction in placing him in a cleft stick. For if he refuses her love, as his duty and his understanding compel him to do, she can play the part of a woman scorned, and then withdraw from his therapeutic efforts out of revenge and resentment, exactly as she is now doing out of her ostensible love. [1915a, 2517]

I think we have told the patient the truth, but not the whole truth regardless of the consequences. Of our two arguments the first is the stronger. The part played by resistance in transference-love is unquestionable and very considerable. Nevertheless the resistance did not, after all, create this love; it finds it ready to hand, makes use of it and aggravates its manifestations. Nor is the genuineness of the phenomenon disproved by the resistance. The second argument is far weaker. It is true that the love consists of new editions of old traits and that it repeats infantile reactions. But this is the essential character of every state of being in love. There is no such state which does not reproduce infantile prototypes. It is precisely from this infantile determination that it receives its compulsive character, verging as it does on the pathological. Transference-love has perhaps a degree less of freedom than the love which appears in ordinary life and is called normal; it displays its dependence on the infantile pattern more clearly and is less adaptable and capable of modification; but that is all, and not what is essential. [1915a, 2518]
Intellectual resistances are not the worst; one always remains superior to them. But the patient also knows how to put up resistances, without going outside the framework of the analysis, the overcoming of which is among the most difficult of technical problems. Instead of remembering, he repeats attitudes and emotional impulses from his early life which can be used as a resistance against the doctor and the treatment by means of what is known as ‘transference’. If the patient is a man, he usually extracts this material from his relation to his father, into whose place he fits the doctor, and in that way he makes resistances out of his efforts to become independent in himself and in his judgements, out of his ambition, the first aim of which was to do things as well as his father or to get the better of him, or out of his unwillingness to burden himself for the second time in his life with a load of gratitude. Thus at times one has an impression that the patient has entirely replaced his better intention of making an end to his illness by the alternative one of putting the doctor in the wrong, of making him realize his impotence and of triumphing over him. Women have a masterly gift for exploiting an affectionate, erotically tinged transference to the doctor for the purposes of resistance. If this attachment reaches a certain height, all their interest in the immediate situation in the treatment and all the obligations they undertook at its commencement vanish; their jealousy, which is never absent, and their exasperation at their inevitable rejection, however considerately expressed, are bound to have a damaging effect on their personal understanding with the doctor and so to put out of operation one of the most powerful motive forces of the analysis.

Resistances of this kind should not be one-sidedly condemned. They include so much of the most important material from the patient's past and bring it back in so convincing a fashion that they become some of the best supports of the analysis if a skilful technique knows how to give them the right turn. Nevertheless, it remains a remarkable fact that this material is always in the service of the resistance to begin with and brings to the fore a façade that is hostile to the treatment. It may also be said that what is being mobilized for fighting against the alterations we are striving for are character-traits, attitudes of the ego. In this connection we discover that these character-traits were formed in relation to the determinants of the neurosis and in reaction against its demands, and we come upon traits which cannot normally emerge, or not to the same extent, and which may be described as latent. Nor must you get an impression that we regard the appearance of these resistances as an unforeseen risk to analytic influence. No, we are aware that these resistances are bound to come to light; in fact we are dissatisfied if we cannot provoke them clearly enough and are unable to demonstrate them to the patient. Indeed we come finally to understand that the overcoming of these resistances is the essential function of analysis and is the only part of our work which gives us an assurance that we have achieved something with the patient.

Transference. - If further proof were needed of the truth that the motive forces behind the formation of neurotic symptoms are of a sexual nature, it would be found in the fact that in the course of analytic treatment a special emotional relation is regularly formed between the patient and the physician. This goes far beyond rational limits. It varies between the most affectionate devotion and the most obstinate enmity and derives all of its characteristics from earlier erotic attitudes of the patient's which have become unconscious. This transference alike in its positive and in its negative form is used as a weapon by the resistance; but in the hands of the physician it becomes the most powerful therapeutic instrument and it plays a part scarcely to be overestimated in the dynamics of the process of cure.
Another advantage of the method is that it need never break down. It must theoretically always be possible to have an association, provided that no conditions are made as to its character. Yet there is one case in which in fact a breakdown occurs with absolute regularity; from its very uniqueness, however, this case too can be interpreted.

I now come to the description of a factor which adds an essential feature to my picture of analysis and which can claim, alike technically and theoretically, to be regarded as of the first importance. In every analytic treatment there arises, without the physician's agency, an intense emotional relationship between the patient and the analyst which is not to be accounted for by the actual situation. It can be of a positive or of a negative character and can vary between the extremes of a passionate, completely sensual love and the unbridled expression of an embittered defiance and hatred. This transference - to give it its short name - soon replaces in the patient's mind the desire to be cured, and, so long as it is affectionate and moderate, becomes the agent of the physician's influence and neither more nor less than the mainspring of the joint work of analysis. Later on, when it has become passionate or has been converted into hostility, it becomes the principal tool of the resistance. It may then happen that it will paralyse the patient's powers of associating and endanger the success of the treatment. Yet it would be senseless to try to evade it; for an analysis without transference is an impossibility. It must not be supposed, however, that transference is created by analysis and does not occur apart from it. Transference is merely uncovered and isolated by analysis. It is a universal phenomenon of the human mind, it decides the success of all medical influence, and in fact dominates the whole of each person's relations to his human environment. We can easily recognize it as the same dynamic factor which the hypnotists have named 'suggestibility', which is the agent of hypnotic rapport and whose incalculable behaviour led to difficulties with the cathartic method as well. When there is no inclination to a transference of emotion such as this, or when it has become entirely negative, as happens in dementia praecox or paranoia, then there is also no possibility of influencing the patient by psychological means.

It is perfectly true that psycho-analysis, like other psychotherapeutic methods, employs the instrument of suggestion (or transference). But the difference is this: that in analysis it is not allowed to play the decisive part in determining the therapeutic results. It is used instead to induce the patient to perform a piece of psychical work - the overcoming of his transference resistances - which involves a permanent alteration in his mental economy. The transference is made conscious to the patient by the analyst, and it is resolved by convincing him that in his transference-attitude he is re-experiencing emotional relations which had their origin in his earliest object-attachments during the repressed period of his childhood. In this way the transference is changed from the strongest weapon of the resistance into the best instrument of the analytic treatment. Nevertheless its handling remains the most difficult as well as the most important part of the technique of analysis.

[1925d, 4217]
We showed on an earlier occasion that the resistance that has to be overcome in analysis proceeds from the ego, which clings to its anticathexes. It is hard for the ego to direct its attention to perceptions and ideas which it has up till now made a rule of avoiding, or to acknowledge as belonging to itself impulses that are the complete opposite of those which it knows as its own. Our fight against resistance in analysis is based upon this view of the facts. If the resistance is itself unconscious, as so often happens owing to its connection with the repressed material, we make it conscious. If it is conscious, or when it has become conscious, we bring forward logical arguments against it; we promise the ego rewards and advantages if it will give up its resistance. There can be no doubt or mistake about the existence of this resistance on the part of the ego. But we have to ask ourselves whether it covers the whole state of affairs in analysis. For we find that even after the ego has decided to relinquish its resistances it still has difficulty in undoing the repressions; and we have called the period of strenuous effort which follows after its praiseworthy decision, the phase of 'working-through'.

The dynamic factor which makes a working-through of this kind necessary and comprehensible is not far to seek. It must be that after the ego's resistance has been removed the power of the compulsion to repeat - the attraction exerted by the unconscious prototype upon the repressed instinctual process - has still to be overcome. There is nothing to be said against describing this factor as the resistance of the unconscious. There is no need to be discouraged by these emendations. They are to be welcomed if they add something to our knowledge, and they are no disgrace to us so long as they enrich rather than invalidate our earlier views - by limiting some statement, perhaps, that was too general or by enlarging some idea that was too narrowly formulated.

[1926d, 4312]

It must not be supposed that these emendations provide us with a complete survey of all the kinds of resistance that are met with in analysis. Further investigation of the subject shows that the analyst has to combat no less than five kinds of resistance, emanating from three directions - the ego, the id and the super-ego. The ego is the source of three of these, each differing in its dynamic nature. The first of these three ego-resistances is the repression resistance, which we have already discussed above and about which there is least new to be added. Next there is the transference resistance, which is of the same nature but which has different and much clearer effects in analysis, since it succeeds in establishing a relation to the analytic situation or the analyst himself and thus re-animating a repression which should only have been recollected. The third resistance, though also an ego-resistance, is of quite a different nature. It proceeds from the gain from illness and is based upon an assimilation of the symptom into the ego. It represents an unwillingness to renounce any satisfaction or relief that has been obtained. The fourth variety, arising from the id, is the resistance which, as we have just seen, necessitates 'working-through'. The fifth, coming from the super-ego and the last to be discovered, is also the most obscure though not always the least powerful one. It seems to originate from the sense of guilt or the need for punishment; and it opposes every move towards success, including, therefore, the patient's own recovery through analysis.

[1926d, 4313]

Yes. It is favourable to start with. But when this falling in love has grown deeper, its whole nature comes to light, much of which is incompatible with the task of analysis. The patient's love is not satisfied with being obedient; it grows exacting, calls for affectionate and sensual satisfactions, it demands exclusiveness, it develops jealousy, and it shows more and more clearly its reverse side, its readiness to become hostile and revengeful if it cannot obtain its ends. At the same time, like all falling in love, it drives away all other mental material; it extinguishes interest in the treatment and in recovery - in short, there can be no doubt that it has taken the place of the neurosis and that our work has had the result of driving out one form of illness with another.

[1926e, 4367]
But it is far from being the case that his ego is content to play the part of passively and
obediently bringing us the material we require and of believing and accepting our translation of
it. A number of other things happen, a few of which we might have foreseen but others of which
are bound to surprise us. The most remarkable thing is this. The patient is not satisfied with
regarding the analyst in the light of reality as a helper and adviser who, moreover, is
remunerated for the trouble he takes and who would himself be content with some such role as
that of a guide on a difficult mountain climb. On the contrary, the patient sees in him the return,
the reincarnation, of some important figure out of his childhood or past, and consequently
transfers on to him feelings and reactions which undoubtedly applied to this prototype. This fact
of transference soon proves to be a factor of undreamt-of importance, on the one hand an
instrument of irreplaceable value and on the other hand a source of serious dangers. This
transference is ambivalent: it comprises positive (affectionate) as well as negative (hostile)
attitudes towards the analyst, who as a rule is put in the place of one or other of the patient's
parents, his father or mother. So long as it is positive it serves us admirably. It alters the whole
analytic situation; it pushes to one side the patient's rational aim of becoming healthy and free
from his ailments. Instead of it there emerges the aim of pleasing the analyst and of winning his
applause and love. It becomes the true motive force of the patient's collaboration; his weak ego
becomes strong; under its influence he achieves things that would ordinarily be beyond his
power; he leaves off his symptoms and seems apparently to have recovered - merely for the
sake of the analyst. The analyst may shamefacedly admit to himself that he set out on a difficult
undertaking without any suspicion of the extraordinary powers that would be at his command.
[1940a [1938], 4984]

The therapeutic successes that occurred under the sway of the positive transference are open
to the suspicion of being of a suggestive nature. If the negative transference gains the upper
hand, they are blown away like chaff before the wind. We observe with horror that all our trouble
and labour hitherto have been in vain. Indeed, what we might have regarded as a permanent
intellectual gain by the patient, his understanding of psycho-analysis and his reliance on its
efficacy, suddenly vanish. He behaves like a child who has no power of judgement of his own
but blindly believes anyone whom he loves and no one who is a stranger to him. The danger of
these states of transference evidently lies in the patient's misunderstanding their nature and
taking them for fresh real experiences instead of reflections of the past. If he (or she) becomes
aware of the strong erotic desire that lies concealed behind the positive transference, he
believes that he has fallen passionately in love; if the transference changes over, then he feels
insulted and neglected, he hates the analyst as his enemy and is ready to abandon the
analysis. In both these extreme cases he has forgotten the pact that he made at the beginning
of the treatment and has become useless for continuing the common work. It is the analyst's
task constantly to tear the patient out of his menacing illusion and to show him again and again
that what he takes to be new real life is a reflection of the past. And lest he should fall into a
state in which he is inaccessible to all evidence, the analyst takes care that neither the love nor
the hostility reach an extreme height. This is effected by preparing him in good time for these
possibilities and by not overlooking the first signs of them. Careful handling of the transference
on these lines is as a rule richly rewarded. If we succeed, as we usually can, in enlightening the
patient on the true nature of the phenomena of transference, we shall have struck a powerful
weapon out of the hand of his resistance and shall have converted dangers into gains. For a
patient never forgets again what he has experienced in the form of transference; it carries a
greater force of conviction than anything he can acquire in other ways.
[1940a [1938], 4986]
To begin with I was greatly annoyed at this increase in my psychological work, till I came to see that the whole process followed a law; and I then noticed, too, that transference of this kind brought about no great addition to what I had to do. For the patient the work remained the same: she had to overcome the distressing affect aroused by having been able to entertain such a wish even for a moment; and it seemed to make no difference to the success of the treatment whether she made this psychical repudiation the theme of her work in the historical instance or in the recent one connected with me. The patients, too, gradually learnt to realize that in these transferences on to the figure of the physician it was a question of a compulsion and an illusion which melted away with the conclusion of the analysis. I believe, however, that if I had neglected to make the nature of the ‘obstacle’ clear to them I should simply have given them a new hysterical symptom - though, it is true, a milder one - in exchange for another which had been generated spontaneously.

[1895d, 268]

A little reflection enables one to find one's bearings. First and foremost, one keeps in mind the suspicion that anything that interferes with the continuation of the treatment may be an expression of resistance. There can be no doubt that the outbreak of a passionate demand for love is largely the work of resistance. One will have long since noticed in the patient the signs of an affectionate transference, and one will have been able to feel certain that her docility, her acceptance of the analytic explanations, her remarkable comprehension and the high degree of intelligence she showed were to be attributed to this attitude towards her doctor. Now all this is swept away. She has become quite without insight and seems to be swallowed up in her love. Moreover, this change quite regularly occurs precisely at a point of time when one is having to try to bring her to admit or remember some particularly distressing and heavily repressed piece of her life-history. She has been in love, therefore, for a long time; but now the resistance is beginning to make use of her love in order to hinder the continuation of the treatment, to deflect all her interest from the work and to put the analyst in an awkward position.

[1915a, 2512]
If we are able once more to clarify the position, we find that the cause of the disturbance is that the patient has transferred on to the doctor intense feelings of affection which are justified neither by the doctor's behaviour nor by the situation that has developed during the treatment. The form in which this affection is expressed and what its aims are depend of course on the personal relation between the two people involved. If those concerned are a young girl and a youngish man, we shall get the impression of a normal case of falling in love; we shall find it understandable that a girl should fall in love with a man with whom she can be much alone and talk of intimate things and who has the advantage of having met her as a helpful superior; and we shall probably overlook the fact that what we should expect from a neurotic girl would rather be an impediment in her capacity for love. The further the personal relations between doctor and patient diverge from this supposed case, the more we shall be surprised to find nevertheless the same emotional relationship constantly recurring. It may still pass muster if a woman who is unhappy in her marriage appears to be seized with a serious passion for a doctor who is still unattached, if she is ready to seek a divorce in order to be his or if, where there are social obstacles, she even expresses no hesitation about entering into a secret liaison with him. Such things come about even outside psycho-analysis. But in these circumstances we are astonished to hear declarations by married women and girls which bear witness to a quite particular attitude to the therapeutic problem: they had always known, they say, that they could only be cured by love, and before the treatment began they had expected that through this relation they would at last be granted what life had hitherto withheld from them; it had only been in this hope that they had taken so much trouble over the treatment and overcome all the difficulties in communicating their thoughts - and we on our part can add: and had so easily understood what is otherwise so hard to believe. But an admission of this sort surprises us: it throws all our calculations to the winds. Can it be that we have left the most important item out of our account?

[1916-1917, 3483]

And indeed, the greater our experience the less we are able to resist making this correction, though having to do so puts our scientific pretensions to shame. On the first few occasions one might perhaps think that the analytic treatment had come up against a disturbance due to a chance event - an event, that is, not intended and not provoked by it. But when a similar affectionate attachment by the patient to the doctor is repeated regularly in every new case, when it comes to light again and again, under the most unfavourable conditions and where there are positively grotesque incongruities, even in elderly women and in relation to grey-bearded men, even where, in our judgement, there is nothing of any kind to entice - then we must abandon the idea of a chance disturbance and recognize that we are dealing with a phenomenon which is intimately bound up with the nature of the illness itself.

[1916-1917, 3484]
I must begin by making it clear that a transference is present in the patient from the beginning of the treatment and for a while is the most powerful motive in its advance. We see no trace of it and need not bother about it so long as it operates in favour of the joint work of analysis. If it then changes into a resistance, we must turn our attention to it and we recognize that it alters its relation to the treatment under two different and contrary conditions: firstly, if as an affectionate trend it has become so powerful, and betrays signs of its origin in a sexual need so clearly, that it inevitably provokes an internal opposition to itself, and, secondly, if it consists of hostile instead of affectionate impulses. The hostile feelings make their appearance as a rule later than the affectionate ones and behind them; their simultaneous presence gives a good picture of the emotional ambivalence which is dominant in the majority of our intimate relations with other people. The hostile feelings are as much an indication of an emotional tie as the affectionate ones, in the same way as defiance signifies dependence as much as obedience does, though with a 'minus' instead of a 'plus' sign before it. We can be in no doubt that the hostile feelings towards the doctor deserve to be called a 'transference', since the situation in the treatment quite certainly offers no adequate grounds for their origin; this necessary view of the negative transference assures us, therefore, that we have not gone wrong in our judgement of the positive or affectionate one.

Transference. - If further proof were needed of the truth that the motive forces behind the formation of neurotic symptoms are of a sexual nature, it would be found in the fact that in the course of analytic treatment a special emotional relation is regularly formed between the patient and the physician. This goes far beyond rational limits. It varies between the most affectionate devotion and the most obstinate enmity and derives all of its characteristics from earlier erotic attitudes of the patient's which have become unconscious. This transference alike in its positive and in its negative form is used as a weapon by the resistance; but in the hands of the physician it becomes the most powerful therapeutic instrument and it plays a part scarcely to be overestimated in the dynamics of the process of cure.

I now come to the description of a factor which adds an essential feature to my picture of analysis and which can claim, alike technically and theoretically, to be regarded as of the first importance. In every analytic treatment there arises, without the physician's agency, an intense emotional relationship between the patient and the analyst which is not to be accounted for by the actual situation. It can be of a positive or of a negative character and can vary between the extremes of a passionate, completely sensual love and the unbridled expression of an embittered defiance and hatred. This transference - to give it its short name - soon replaces in the patient's mind the desire to be cured, and, so long as it is affectionate and moderate, becomes the agent of the physician's influence and neither more nor less than the mainspring of the joint work of analysis. Later on, when it has become passionate or has been converted into hostility, it becomes the principal tool of the resistance. It may then happen that it will paralyse the patient's powers of associating and endanger the success of the treatment. Yet it would be senseless to try to evade it; for an analysis without transference is an impossibility. It must not be supposed, however, that transference is created by analysis and does not occur apart from it. Transference is merely uncovered and isolated by analysis. It is a universal phenomenon of the human mind, it decides the success of all medical influence, and in fact dominates the whole of each person's relations to his human environment. We can easily recognize it as the same dynamic factor which the hypnotists have named 'suggestibility', which is the agent of hypnotic rapport and whose incalculable behaviour led to difficulties with the cathartic method as well. When there is no inclination to a transference of emotion such as this, or when it has become entirely negative, as happens in dementia praecox or paranoia, then there is also no possibility of influencing the patient by psychological means.

[1916-1917, 3485]

[1923a, 3924]

[1925d, 4217]
But it is far from being the case that his ego is content to play the part of passively and obediently bringing us the material we require and of believing and accepting our translation of it. A number of other things happen, a few of which we might have foreseen but others of which are bound to surprise us. The most remarkable thing is this. For a patient never forgets again what he has experienced in the form of transference; it carries a greater force of conviction than anything he can acquire in other ways. [1940a [1938], 4986]
It was not I but Dr. Breuer who received news of her about seven months later. Her health had continued good for several months but had then broken down again as a result of a fresh psychical shock. Her elder daughter, during their first stay in Vienna, had already followed her mother in developing neck-cramps and mild hysterical states; but in particular, she had suffered from pains in walking owing to a retroverted uterus. On my advice she had gone for treatment to Dr. N., one of our most distinguished gynaecologists, who had put her uterus right by massage, and she had remained free from trouble for several months. Her trouble recurled, however, while they were at home, and her mother called in a gynaecologist from the neighbouring University town. He prescribed a combined local and general treatment for the girl, which, however, brought on a severe nervous illness (she was seventeen at the time). It is probable that this was already an indication of her pathological disposition which was to manifest itself a year later in a character-change. Her mother, who had handed the girl over to the doctors with her usual mixture of docility and mistrust, was overcome by the most violent self-reproaches after the unfortunate outcome of the treatment. A train of thought which I have not investigated brought her to the conclusion that Dr. N. and I were together responsible for the girl's illness because we had made light of her serious condition. By an act of will as it were, she undid the effects of my treatment and promptly, relapsed into the states from which I had freed her. A distinguished physician in her neighbourhood, to whom she went for advice, and Dr. Breuer, who was in correspondence with her, succeeded in convincing her of the innocence of the two targets of her accusations; but even after this was cleared up, the aversion to me which she formed at the time was left over as a hysterical residue, and she declared that it was impossible for her to take up her treatment with me again. On the advice of the same medical authority she turned for help to a Sanatorium in North Germany. At Breuer's desire I explained to the physician in charge the modifications of hypnotic therapy which I had found effective in her case.

I have finally to discuss yet another topic, which plays an undesirably large part in the carrying out of cathartic analyses such as these. I have already admitted the possibility of the pressure technique failing, of its not eliciting any reminiscence in spite of every assurance and insistence. If this happens, I said, there are two possibilities: either, at the point at which we are investigating, there is really nothing more to be found - and this we can recognize from the complete calmness of the patient's facial expression; or we have come up against a resistance which can only be overcome later, we are faced by a new stratum into which we cannot yet penetrate - and this, once more, we can infer from the patient's facial expression, which is tense and gives evidence of mental effort. But there is yet a third possibility which bears witness equally to an obstacle, but an external obstacle, and not one inherent in the material. This happens when the patient's relation to the physician is disturbed, and it is the worst obstacle that we can come across. We can, however, reckon on meeting it in every comparatively serious analysis.

I have already indicated the important part played by the figure of the physician in creating motives to defeat the psychical force of resistance. In not a few cases, especially with women and where it is a question of elucidating erotic trains of thought, the patient's co-operation becomes a personal sacrifice, which must be compensated by some substitute for love. The trouble taken by the physician and his friendliness have to suffice for such a substitute. If, now, this relation of the patient to the physician is disturbed, her co-operativeness fails, too; when the physician tries to investigate the next pathological idea, the patient is held up by an intervening consciousness of the complaints against the physician that have been accumulating in her. In my experience this obstacle arises in three principal cases.
(1) If there is a personal estrangement - if, for instance, the patient feels she has been neglected, has been too little appreciated or has been insulted, or if she has heard unfavourable comments on the physician or the method of treatment. This is the least serious case. The obstacle can easily be overcome by discussion and explanation, even though the sensitiveness and suspiciousness of hysterical patients may occasionally attain surprising dimensions.

[1895d, 266]

If the theory of analytic technique is gone into, it become, evident that transference is an inevitable necessity. Practical experience, at all events, shows conclusively that there is no means of avoiding it, and that this latest creation of the disease must be combated like all the earlier ones. This happens, however, to be by far the hardest part of the whole task. It is easy to learn how to interpret dreams, to extract from the patient's associations his unconscious thoughts and memories, and to practise similar explanatory arts: for these the patient himself will always provide the text. Transference is the one thing the presence of which has to be detected almost without assistance and with only the slightest clues to go upon, while at the same time the risk of making arbitrary inferences has to be avoided. Nevertheless, transference cannot be evaded, since use is made of it in setting up all the obstacles that make the material inaccessible to treatment, and since it is only after the transference has been resolved that a patient arrives at a sense of conviction of the validity of the connections which have been constructed during the analysis.

[1905e, 1450]
I have been obliged to speak of transference, for it is only by means of this factor that I can elucidate the peculiarities of Dora's analysis. Its great merit, namely, the unusual clarity which makes it seem so suitable as a first introductory publication, is closely bound up with its great defect, which led to its being broken off prematurely. I did not succeed in mastering the transference in good time. Owing to the readiness with which Dora put one part of the pathogenic material at my disposal during the treatment, I neglected the precaution of looking out for the first signs of transference, which was being prepared in connection with another part of the same material a part of which I was in ignorance. At the beginning it was clear that I was replacing her father in her imagination, which was not unlikely, in view of the difference between our ages. She was even constantly comparing me with him consciously, and kept anxiously trying to make sure whether I was being quite straightforward with her, for her father 'always preferred secrecy and roundabout ways'. But when the first dream came, in which she gave herself the warning that she had better leave my treatment just as she had formerly left Herr K.'s house, I ought to have listened to the warning myself. 'Now,' I ought to have said to her, 'it is from Herr K. that you have made a transference on to me. Have you noticed anything that leads you to suspect me of evil intentions similar (whether openly or in some sublimated form) to Herr K.'s? Or have you been struck by anything about me or got to know anything about me which has caught your fancy, as happened previously with Herr K.' Her attention would then have been turned to some detail in our relations, or in my person or circumstances, behind which there lay concealed something analogous but immeasurably more important concerning Herr K. And when this transference had been cleared up, the analysis would have obtained access to new memories, dealing, probably, with actual events. But I was deaf to this first note of warning, thinking I had ample time before me, since no further stages of transference developed and the material for the analysis had not yet run dry. In this way the transference took me unawares, and, because of the unknown quantity in me which reminded Dora of Herr K., she took her revenge on me as she wanted to take her revenge on him, and deserted me as she believed herself to have been deceived and deserted by him. Thus she acted out an essential part of her recollections and phantasies instead of reproducing it in the treatment. What this unknown quantity was I naturally cannot tell. I suspect that it had to do with money, or with jealousy of another patient who had kept up relations with my family after her recovery. When it is possible to work transferences into the analysis at an early stage, the course of the analysis is retarded and obscured, but its existence is better guaranteed against sudden and overwhelming resistances. [1905e, 1452]

If cruel impulses and revengeful motives, which have already been used in the patient's ordinary life for maintaining her symptoms, become transferred on to the physician during treatment, before he has had time to detach them from himself by tracing them back to their sources, then it is not to be wondered at if the patient's condition is unaffected by his therapeutic efforts. For how could the patient take a more effective revenge than by demonstrating upon her own person the helplessness and incapacity of the physician? Nevertheless, I am not inclined to put too low a value on the therapeutic results even of such a fragmentary treatment as Dora's. [1905e, 1454]

Her alleged facial neuralgia was thus a self-punishment - remorse at having once given Herr K. a box on the ear, and at having transferred her feelings of revenge on to me. I do not know what kind of help she wanted from me, but I promised to forgive her for having deprived me of the satisfaction of affording her a far more radical cure for her troubles. [1905e, 1456]
The further question may be raised of why it is that the resistance phenomena of transference only appear in psycho-analysis and not in indifferent forms of treatment (e.g. in institutions) as well. The reply is that they do show themselves in these other situations too, but they have to be recognized as such. The breaking out of a negative transference is actually quite a common event in institutions. As soon as a patient comes under the dominance of the negative transference he leaves the institution in an unchanged or relapsed condition. The erotic transference does not have such an inhibiting effect in institutions, since in them, just as in ordinary life, it is glossed over instead of being uncovered. But it is manifested quite clearly as a resistance to recovery, not, it is true, by driving the patient out of the institution - on the contrary, it holds him back in it - but by keeping him at a distance from life. For, from the point of view of recovery, it is a matter of complete indifference whether the patient overcomes this or that anxiety or inhibition in the institution; what matters is that he shall be free of it in his real life as well.

[1912b, 2463]

The negative transference deserves a detailed examination, which it cannot be given within the limits of the present paper. In the curable forms of psychoneurosis it is found side by side with the affectionate transference, often directed simultaneously towards the same person. Bleuler has coined the excellent term 'ambivalence' to describe this phenomenon.¹ Up to a point, ambivalence of feeling of this sort seems to be normal; but a high degree of it is certainly a special peculiarity of neurotic people. In obsessional neurotics an early separation of the 'pairs of opposites' seems to be characteristic of their instinctual life and to be one of their constitutional preconditions. Ambivalence in the emotional trends of neurotics is the best explanation of their ability to enlist their transferences in the service of resistance. Where the capacity for transference has become essentially limited to a negative one, as is the case with paranoids, there ceases to be any possibility of influence or cure.

[1912b, 2463]

What interests us most of all is naturally the relation of this compulsion to repeat to the transference and to resistance. We soon perceive that the transference is itself only a piece of repetition, and that the repetition is a transference of the forgotten past not only on to the doctor but also on to all the other aspects of the current situation. We must be prepared to find, therefore, that the patient yields to the compulsion to repeat, which now replaces the impulse to remember, not only in his personal attitude to his doctor but also in every other activity and relationship which may occupy his life at the time - if, for instance, he falls in love or undertakes a task or starts an enterprise during the treatment. The part played by resistance, too, is easily recognized. The greater the resistance, the more extensively will acting out (repetition) replace remembering. For the ideal remembering of what has been forgotten which occurs in hypnosis corresponds to a state in which resistance has been put completely on one side. If the patient starts his treatment under the auspices of a mild and unpronounced positive transference it makes it possible at first for him to unearth his memories just as he would under hypnosis, and during this time his pathological symptoms themselves are quiescent. But if, as the analysis proceeds, the transference becomes hostile or unduly intense and therefore in need of repression, remembering at once gives way to acting out. From then onwards the resistances determine the sequence of the material which is to be repeated. The patient brings out of the armoury of the past the weapons with which he defends himself against the progress of the treatment - weapons which we must wrest from him one by one.

[1914g, 2502]

¹ We know that the transference can manifest itself in other, less tender feelings, but I do not propose to go into that side of the matter here.

[1915a, 2510]
But such fine weather cannot last for ever. One day it clouds over. Difficulties arise in the treatment; the patient declares that nothing more occurs to him. He gives the clearest impression of his interest being no longer in the work and of his cheerfully disregarding the instructions given him to say everything that comes into his head and not to give way to any critical obstacle to doing so. He behaves as though he were outside the treatment and as though he had not made this agreement with the doctor. He is evidently occupied with something, but intends to keep it to himself. This is a situation that is dangerous for the treatment. We are unmistakably confronted by a formidable resistance. But what has happened to account for it?

[1916-1917, 3482]

I must begin by making it clear that a transference is present in the patient from the beginning of the treatment and for a while is the most powerful motive in its advance. We see no trace of it and need not bother about it so long as it operates in favour of the joint work of analysis. If it then changes into a resistance, we must turn our attention to it and we recognize that it alters its relation to the treatment under two different and contrary conditions: firstly, if as an affectionate trend it has become so powerful, and betrays signs of its origin in a sexual need so clearly, that it inevitably provokes an internal opposition to itself, and, secondly, if it consists of hostile instead of affectionate impulses. The hostile feelings make their appearance as a rule later than the affectionate ones and behind them; their simultaneous presence gives a good picture of the emotional ambivalence which is dominant in the majority of our intimate relations with other people. The hostile feelings are as much an indication of an emotional tie as the affectionate ones, in the same way as defiance signifies dependence as much as obedience does, though with a 'minus' instead of a 'plus' sign before it. We can be in no doubt that the hostile feelings towards the doctor deserve to be called a 'transference', since the situation in the treatment quite certainly offers no adequate grounds for their origin; this necessary view of the negative transference assures us, therefore, that we have not gone wrong in our judgement of the positive or affectionate one.

[1916-1917, 3485]

There is every reason now for us to improve our earlier dynamic account of the therapeutic process and to bring it into harmony with our new realization. If the patient is to fight his way through the normal conflict with the resistances which we have uncovered for him in the analysis, he is in need of a powerful stimulus which will influence the decision in the sense which we desire, leading to recovery. Otherwise it might happen that he would choose in favour of repeating the earlier outcome and would allow what had been brought up into consciousness to slip back again into repression. At this point what turns the scale in his struggle is not his intellectual insight which is neither strong enough nor free enough for such an achievement - but simply and solely his relation to the doctor. In so far as his transference bears a 'plus' sign, it clothes the doctor with authority and is transformed into belief in his communications and explanations. In the absence of such a transference, or if it is a negative one, the patient would never even give a hearing to the doctor and his arguments. In this his belief is repeating the story of its own development; it is a derivative of love and, to start with, needed no arguments. Only later did he allow them enough room to submit them to examination, provided they were brought forward by someone he loved. Without such supports arguments carried no weight, and in most people's lives they never do. Thus in general a man is only accessible from the intellectual side too, in so far as he is capable of a libidinal cathexis of objects; and we have good reason to recognize and to dread in the amount of his narcissism a barrier against the possibility of being influenced by even the best analytic technique.

[1916-1917, 3487]
The acceptance of suggestions on individual points is no doubt discouraged by the fact that during the treatment we are struggling unceasingly against resistances which are able to transform themselves into negative (hostile) transferences. Nor must we fail to point out that a large number of the individual findings of analysis, which might otherwise be suspected to being products of suggestion, are confirmed from another and irreproachable source. Our guarantors in this case are the sufferers from dementia praecox and paranoia, who are of course far above any suspicion of being influenced by suggestion. The translations of symbols and the phantasies, which these patients produce for us and which in them have forced their way through into consciousness, coincide faithfully with the results of our investigations into the unconscious of transference neurotics and thus confirm the objective correctness of our interpretations, on which doubt is so often thrown. You will not, I think, be going astray if you trust analysis on these points.

In the case of our patient, it was not doubt but the affective factor of revenge against her father that made her cool reserve possible, that divided the analysis into two distinct phases, and rendered the results of the first phase so complete and perspicuous. It seemed, further, as though nothing resembling a transference to the physician had been effected. That, however, is of course absurd, or, at least, is a loose way of expressing things. For some kind of relation to the analyst must come into being, and this relation is almost always transferred from an infantile one. In reality she transferred to me the sweeping repudiation of men which had dominated her ever since the disappointment she had suffered from her father. Bitterness against men is as a rule easy to gratify upon the physician; it need not evoke any violent emotional manifestations, it simply expresses itself by rendering futile all his endeavours and - by clinging to the illness. I know from experience how difficult it is to make a patient understand just precisely this mute kind of symptomatic behaviour and to make him aware of this latent, and often exceedingly strong, hostility without endangering the treatment. As soon, therefore, as I recognized the girl's attitude to her father, I broke off the treatment and advised her parents that if they set store by the therapeutic procedure it should be continued by a woman doctor. The girl had in the meanwhile promised her father that at any rate she would give up seeing the 'lady', and I do not know whether my advice, the reasons for which are obvious, will be followed.

Transference. - If further proof were needed of the truth that the motive forces behind the formation of neurotic symptoms are of a sexual nature, it would be found in the fact that in the course of analytic treatment a special emotional relation is regularly formed between the patient and the physician. This goes far beyond rational limits. It varies between the most affectionate devotion and the most obstinate enmity and derives all of its characteristics from earlier erotic attitudes of the patient's which have become unconscious. This transference alike in its positive and in its negative form is used as a weapon by the resistance; but in the hands of the physician it becomes the most powerful therapeutic instrument and it plays a part scarcely to be over-estimated in the dynamics of the process of cure.

There is no doubt that there is something in these people that sets itself against their recovery, and its approach is dreaded as though it were a danger. We are accustomed to say that the need for illness has got the upper hand in them over the desire for recovery. If we analyse this resistance in the usual way then, even after allowance has been made for an attitude of defiance towards the physician and for fixation to the various forms of gain from illness, the greater part of it is still left over; and this reveals itself as the most powerful of all obstacles to recovery, more powerful than the familiar ones of narcissistic inaccessibility, a negative attitude towards the physician and clinging to the gain from illness.
I now come to the description of a factor which adds an essential feature to my picture of analysis and which can claim, alike technically and theoretically, to be regarded as of the first importance. In every analytic treatment there arises, without the physician's agency, an intense emotional relationship between the patient and the analyst which is not to be accounted for by the actual situation. It can be of a positive or of a negative character and can vary between the extremes of a passionate, completely sensual love and the unbridled expression of an embittered defiance and hatred. This *transference* - to give it its short name - soon replaces in the patient's mind the desire to be cured, and, so long as it is affectionate and moderate, becomes the agent of the physician's influence and neither more nor less than the mainspring of the joint work of analysis. Later on, when it has become passionate or has been converted into hostility, it becomes the principal tool of the resistance. It may then happen that it will paralyse the patient's powers of associating and endanger the success of the treatment. Yet it would be senseless to try to evade it; for an analysis without transference is an impossibility. It must not be supposed, however, that transference is created by analysis and does not occur apart from it. Transference is merely uncovered and isolated by analysis. It is a universal phenomenon of the human mind, it decides the success of all medical influence, and in fact dominates the whole of each person's relations to his human environment. We can easily recognize it as the same dynamic factor which the hypnotists have named 'suggestibility', which is the agent of hypnotic *rapport* and whose incalculable behaviour led to difficulties with the cathartic method as well. When there is no inclination to a transference of emotion such as this, or when it has become entirely negative, as happens in dementia praecox or paranoia, then there is also no possibility of influencing the patient by psychological means.

[1925d, 4217]

The therapeutic successes that occurred under the sway of the positive transference are open to the suspicion of being of a *suggestive* nature. If the negative transference gains the upper hand, they are blown away like chaff before the wind. We observe with horror that all our trouble and labour hitherto have been in vain. Indeed, what we might have regarded as a permanent intellectual gain by the patient, his understanding of psycho-analysis and his reliance on its efficacy, suddenly vanish. He behaves like a child who has no power of judgement of his own but blindly believes anyone whom he loves and no one who is a stranger to him. The danger of these states of transference evidently lies in the patient's misunderstanding their nature and taking them for fresh real experiences instead of reflections of the past. If he (or she) becomes aware of the strong erotic desire that lies concealed behind the positive transference, he believes that he has fallen passionately in love; if the transference changes over, then he feels insulted and neglected, he hates the analyst as his enemy and is ready to abandon the analysis. In both these extreme cases he has forgotten the pact that he made at the beginning of the treatment and has become useless for continuing the common work. It is the analyst's task constantly to tear the patient out of his menacing illusion and to show him again and again that what he takes to be new real life is a reflection of the past. And lest he should fall into a state in which he is inaccessible to all evidence, the analyst takes care that neither the love nor the hostility reach an extreme height. This is effected by preparing him in good time for these possibilities and by not overlooking the first signs of them. Careful handling of the transference on these lines is as a rule richly rewarded. If we succeed, as we usually can, in enlightening the patient on the true nature of the phenomena of transference, we shall have struck a powerful weapon out of the hand of his resistance and shall have converted dangers into gains. For a patient never forgets again what he has experienced in the form of transference; it carries a greater force of conviction than anything he can acquire in other ways.

[1940a [1938], 4986]
Let us once more glance over the situation which we have reached in our attempt at bringing help to the patient's neurotic ego. That ego is no longer able to fulfil the task set it by the external world (including human society). Not all of its experiences are at its disposal, a large proportion of its store of memories have escaped it. Its activity is inhibited by strict prohibitions from the super-ego, its energy is consumed in vain attempts at fending off the demands of the id. Beyond this, as a result of continuous irruptions by the id, its organization is impaired, it is no longer capable of any proper synthesis, it is torn by mutually opposed urges, by unsettled conflicts and by unsolved doubts. To start with, we get the patient's thus weakened ego to take part in the purely intellectual work of interpretation, which aims at provisionally filling the gaps in his mental assets, and to transfer to us the authority of his super-ego; we encourage it to take up the struggle over each individual demand made by the id and to conquer the resistances which arise in connection with it. At the same time we restore order in the ego by detecting the material and urges which have forced their way in from the unconscious, and expose them to criticism by tracing them back to their origin. We serve the patient in various functions, as an authority and a substitute for his parents, as a teacher and educator; and we have done the best for him if, as analysts, we raise the mental processes in his ego to a normal level, transform what has become unconscious and repressed into preconscious material and thus return it once more to the possession of his ego. On the patient's side a few rational factors work in our favour, such as the need for recovery which has its motive in his sufferings, and the intellectual interest that we may awaken in him in the theories and revelations of psycho-analysis; but of far greater force is the positive transference with which he meets us. Fighting against us, on the other hand, are the negative transference, the ego's resistance due to repression (that is, its unpleasure at having to lay itself open to the hard work imposed on it), the sense of guilt arising from its relation to the super-ego and the need to be ill due to deep-going changes in the economics of his instincts. The share taken by the last two factors decides whether the case is to be regarded as slight or severe. Apart from these, a few other factors may be discerned as having a favourable or unfavourable bearing. A certain psychical inertia, a sluggishness of the libido, which is unwilling to abandon its fixations cannot be welcome to us; the patient's capacity for sublimating his instincts plays a large part and so does his capacity for rising above the crude life of the instincts; so, too, does the relative power of his intellectual functions.

[1940a [1938], 4990]
The therapeutic effect depends on making conscious what is repressed, in the widest sense of the word, in the id. We prepare the way for this making conscious by interpretations and constructions, but we have interpreted only for ourselves not for the patient so long as the ego holds on to its earlier defences and does not give up its resistances. Now these resistances, although they belong to the ego, are nevertheless unconscious and in some sense separated off within the ego. The analyst recognizes them more easily than he does the hidden material in the id. One might suppose that it would be sufficient to treat them like portions of the id and, by making them conscious, bring them into connection with the rest of the ego. In this way, we should suppose, one half of the task of analysis would be accomplished; we should not reckon on meeting with a resistance against the uncovering of resistances. But what happens is this. During the work on the resistances the ego withdraws - with a greater or less degree of seriousness - from the agreement on which the analytic situation is founded. The ego ceases to support our efforts at uncovering the id; it opposes them, disobeys the fundamental rule of analysis, and allows no further derivatives of the repressed to emerge. We cannot expect the patient to have a strong conviction of the curative power of analysis. He may have brought along with him a certain amount of confidence in his analyst, which will be strengthened to an effective point by the factors of the positive transference which will be aroused in him. Under the influence of the unpleasurable impulses which he feels as a result of the fresh activation of his defensive conflicts, negative transferences may now gain the upper hand and completely annul the analytic situation. The patient now regards the analyst as no more than a stranger who is making disagreeable demands on him, and he behaves towards him exactly like a child who does not like the stranger and does not believe anything he says. If the analyst tries to explain to the patient one of the distortions made by him for the purposes of defence, and to correct it, he finds him uncomprehending and inaccessible to sound arguments. Thus we see that there is a resistance against the uncovering of resistances, and the defensive mechanisms really do deserve the name which we gave them originally, before they had been more closely examined. They are resistances not only to the making conscious of contents of the id, but also to the analysis as a whole, and thus to recovery.

[1937c, 5034]
Other innovations in technique relate to the physician himself. We have become aware of the 'counter-transference', which arises in him as a result of the patient's influence on his unconscious feelings, and we are almost inclined to insist that he shall recognize this counter-transference in himself and overcome it. Now that a considerable number of people are practising psycho-analysis and exchanging their observations with one another, we have noticed that no psycho-analyst goes further than his own complexes and internal resistances permit; and we consequently require that he shall begin his activity with a self-analysis and continually carry it deeper while he is making his observations on his patients. Anyone who fails to produce results in a self-analysis of this kind may at once give up any idea of being able to treat patients by analysis.
[1910d, 2309]
By enlightening Hans on this subject I had cleared away his most powerful resistance against allowing his unconscious thoughts to be made conscious; for his father was himself acting as his physician. The worst of the attack was now over; there was a plentiful flow of material; the little patient summoned up courage to describe the details of his phobia, and soon began to take an active share in the conduct of the analysis.¹

¹ Even in analyses in which the physician and the patient are strangers, fear of the father plays one of the most important parts as a resistance against the reproduction of the unconscious pathogenic material. Resistances are sometimes in the nature of ‘motifs’. But sometimes, as in the present instance, one piece of the unconscious material is capable from its actual content of operating as an inhibition against the reproduction of another piece.

(b) I will hasten on to the innovations in the field of technique, where indeed nearly everything still awaits final settlement, and much is only now beginning to become clear. There are now two aims in psycho-analytic technique: to save the physician effort and to give the patient the most unrestricted access to his unconscious. As you know, our technique has undergone a fundamental transformation. At the time of the cathartic treatment what we aimed at was the elucidation of the symptoms; we then turned away from the symptoms and devoted ourselves instead to uncovering the ‘complexes’, to use a word which Jung has made indispensable; now, however, our work is aimed directly at finding out and overcoming the ‘resistances’, and we can justifiably rely on the complexes coming to light without difficulty as soon as the resistances have been recognized and removed. Some of you have since felt a need to be able to make a survey of these resistances and classify them. I will ask you to examine your material and see whether you can confirm the generalized statement that in male patients the most important resistances in the treatment seem to be derived from the father-complex and to express themselves in fear of the father, in defiance of the father and in disbelief of the father.

The question then arises whether the advantage gained by the patient would not to some extent counterbalance the sacrifice made by the physician. I may venture to form a judgement about this, since for ten years or so I set aside one hour a day, and sometimes two, for gratuitous treatments, because I wanted, in order to find my way about in the neuroses, to work in the face of as little resistance as possible. The advantages I sought by this means were not forthcoming. Free treatment enormously increases some of a neurotic’s resistances - in young women, for instance, the temptation which is inherent in their transference-relation, and in young men, their opposition to an obligation to feel grateful, an opposition which arises from their father-complex and which presents one of the most troublesome hindrances to the acceptance of medical help. The absence of the regulating effect offered by the payment of a fee to the doctor makes itself very painfully felt; the whole relationship is removed from the real world, and the patient is deprived of a strong motive for endeavouring to bring the treatment to an end.

¹ [1909b, 2105]

[1910d, 2309]

[1913c, 2485]
Fear of castration plays an extremely large part, in the case of the youthful neurotics whom we come across, as an interference in their relations with their father. The illuminating instance reported by Ferenczi (1913a) has shown us how a little boy took as his totem the beast that had pecked at his little penis. When our children come to hear of ritual circumcision, they equate it with castration. The parallel in social psychology to this reaction by children has not yet been worked out, so far as I am aware. In primaeval times and in primitive races, where circumcision is so frequent, it is performed at the age of initiation into manhood and it is at that age that its significance is to be found; it was only as a secondary development that it was shifted back to the early years of life. It is of very great interest to find that among primitive peoples circumcision is combined with cutting the hair and knocking out teeth or is replaced by them, and that our children, who cannot possibly have any knowledge of this, in fact treat these two operations, in the anxiety with which they react to them, as equivalents of castration.

The disturbances to which a child's original narcissism is exposed, the reactions with which he seeks to protect himself from them and the paths into which he is forced in doing so - these are themes which I propose to leave on one side, as an important field of work which still awaits exploration. The most significant portion of it, however, can be singled out in the shape of the 'castration complex' (in boys, anxiety about the penis - in girls, envy for the penis) and treated in connection with the effect of early deterrence from sexual activity. Psycho-analytic research ordinarily enables us to trace the vicissitudes undergone by the libidinal instincts when these, isolated from the ego-instincts, are placed in opposition to them; but in the particular field of the castration complex, it allows us to infer the existence of an epoch and a psychical situation in which the two groups of instincts, still operating in unison and inseparably mingled, make their appearance as narcissistic interests. It is from this context that Adler has derived his concept of the 'masculine protest', which he has elevated almost to the position of the sole motive force in the formation of character and neurosis alike and which he bases not on a narcissistic, and therefore still a libidinal, trend, but on a social valuation. Psycho-analytic research has from the very beginning recognized the existence and importance of the 'masculine protest', but it has regarded it, in opposition to Adler, as narcissistic in nature and derived from the castration complex. The 'masculine protest' is concerned in the formation of character, into the genesis of which it enters along with many other factors, but it is completely unsuited for explaining the problems of the neuroses, with regard to which Adler takes account of nothing but the manner in which they serve the ego-instincts. I find it quite impossible to place the genesis of neurosis upon the narrow basis of the castration complex, however powerfully it may come to the fore in men among their resistances to the cure of a neurosis. Incidentally, I know of cases of neurosis in which the 'masculine protest', or, as we regard it, the castration complex, plays no pathogenic part, and even fails to appear at all.

[1914c, 2946]
Though I am anxious to cut short this discussion still further, I must nevertheless tell you a little about the sexual researches of children: they are too characteristic of infantile sexuality and of too great significance for the symptomatology of the neuroses to be passed over. Infantile sexual researches begin very early, sometimes before the third year of life. They do not relate to the distinction between the sexes, for this means nothing to children, since they (or at any rate boys) attribute the same male genital to both sexes. If, afterwards, a boy makes the discovery of the vagina from seeing his little sister or a girl playmate, he tries, to begin with, to disavow the evidence of his senses, for he cannot imagine a human creature like himself who is without such a precious portion. Later on, he takes fright at the possibility thus presented to him; and any threats that may have been made to him earlier, because he took too intense an interest in his little organ, now produce a deferred effect. He comes under the sway of the castration complex, the form taken by which plays a great part in the construction of his character if he remains normal, in his neurosis if he falls ill, and in his resistances if he comes into analytic treatment. As regards little girls, we can say of them that they feel greatly at a disadvantage owing to their lack of a big, visible penis, that they envy boys for possessing one and that, in the main for this reason, they develop a wish to be a man - a wish that re-emerges later on, in any neurosis that may arise if they meet with a mishap in playing a feminine part. In her childhood, moreover, a girl's clitoris takes on the role of a penis entirely: it is characterized by special excitability and is the area in which auto-erotic satisfaction is obtained. The process of a girl's becoming a woman depends very much on the clitoris passing on this sensitivity to the vaginal orifice in good time and completely. In cases of what is known as sexual anaesthesia in women the clitoris has obstinately retained its sensitivity.

This revolt against castration or a feminine attitude has been torn out of its organic context by Alfred Adler. He has linked it superficially or falsely with the longing for power, and has postulated it as an independent 'masculine protest'. Since a neurosis can only arise from a conflict between two trends, it is as justifiable to see the cause of 'every' neurosis in the masculine protest as it is to see it in the feminine attitude against which the protest is being made. It is quite true that this masculine protest plays a regular part in the formation of character - in some types of people a very large part - and that we meet it in the analysis of neurotic men as a vigorous resistance. Psycho-analysis has attached due importance to the masculine protest in connection with the castration complex, without being able to accept its omnipotence or its omnipresence in neuroses. The most marked case of a masculine protest with all its manifest reactions and character-traits that I have met with in analysis was that of a patient who came to me for treatment on account of an obsessional neurosis in whose symptoms the unresolved conflict between a masculine and a feminine attitude (fear of castration and desire for castration) found clear expression. In addition, the patient had developed masochistic phantasies which were wholly derived from a wish to accept castration; and he had even gone beyond these phantasies to real satisfaction in perverse situations. The whole of his state rested - like Adler's theory itself - on the repression and denial of early infantile fixations of love.

If we ask an analyst what his experience has shown to be the mental structures least accessible to influence in his patients, the answer will be: in a woman her wish for a penis, in a man his feminine attitude towards his own sex, a precondition of which would, of course, be the loss of his penis.
The two corresponding themes are in the female, *an envy for the penis* - a positive striving to possess a male genital - and, in the male, a struggle against his passive or feminine attitude to another male. What is common to the two themes was singled out at an early date by psychoanalytic nomenclature as an attitude towards the castration complex. Subsequently Alfred Adler brought the term 'masculine protest' into current use. It fits the case of males perfectly; but I think that, from the start, 'repudiation of femininity' would have been the correct description of this remarkable feature in the psychical life of human beings.

In trying to introduce this factor into the structure of our theory, we must not overlook the fact that it cannot, by its very nature, occupy the same position in both sexes. In males the striving to be masculine is completely ego-syntonic from the first; the passive attitude, since it presupposes an acceptance of castration, is energetically repressed, and often its presence is only indicated by excessive overcompensations. In females, too, the striving to be masculine is ego-syntonic at a certain period - namely in the phallic phase, before the development to femininity has set in. But it then succumbs to the momentous process of repression whose outcome, as has so often been shown, determines the fortunes of a woman's femininity. A great deal depends on whether a sufficient amount of her masculinity complex escapes repression and exercises a permanent influence on her character. Normally, large portions of the complex are transformed and contribute to the construction of her femininity: the appeased wish for a penis is destined to be converted into a wish for a baby and for a husband, who possesses a penis. It is strange, however, how often we find that the wish for masculinity has been retained in the unconscious and, from out of its state of repression, exercises a disturbing influence.

The paramount importance of these two themes - in females the wish for a penis and in males the struggle against passivity - did not escape Ferenczi's notice. In the paper read by him in 1927 he made it a requirement that in every successful analysis those two complexes must have been mastered.¹ I should like to add that, speaking from my own experience, I think that in this Ferenczi was asking a very great deal. At no other point in one's analytic work does one suffer more from an oppressive feeling that all one's repeated efforts have been in vain, and from a suspicion that one has been 'preaching to the winds', than when one is trying to persuade a woman to abandon her wish for a penis on the ground of its being unrealizable or when one is seeking to convince a man that a passive attitude to men does not always signify castration and that it is indispensable in many relationships in life. The rebellious overcompensation of the male produces one of the strongest transference-resistances. He refuses to subject himself to a father-substitute, or to feel indebted to him for anything, and consequently he refuses to accept his recovery from the doctor. No analogous transference can arise from the female's wish for a penis, but it is the source of outbreaks of severe depression in her, owing to an internal conviction that the analysis will be of no use and that nothing can be done to help her. And we can only agree that she is right, when we learn that her strongest motive in coming for treatment was the hope that, after all, she might still obtain a male organ, the lack of which was so painful to her.

¹[1937c, 5044]
²[1937c, 5045]
But we also learn from this that it is not important in what form the resistance appears, whether as a transference or not. The decisive thing remains that the resistance prevents any change from taking place - that everything stays as it was. We often have the impression that with the wish for a penis and the masculine protest we have penetrated through all the psychological strata and have reached bedrock, and that thus our activities are at an end. This is probably true, since, for the psychical field, the biological field does in fact play the part of the underlying bedrock. The repudiation of femininity can be nothing else than a biological fact, a part of the great riddle of sex.¹ It would be hard to say whether and when we have succeeded in mastering this factor in an analytic treatment. We can only console ourselves with the certainty that we have given the person analysed every possible encouragement to re-examine and alter his attitude to it.

[1937c, 5046]

If an analysis is dominated by powerful factors that impose a negative therapeutic reaction, such as a sense of guilt, a masochistic need for suffering or repugnance to receiving help from the analyst, the patient's behaviour after he has been offered a construction often makes it very easy for us to arrive at the decision that we are in search of. If the construction is wrong, there is no change in the patient; but if it is right or gives an approximation to the truth, he reacts to it with an unmistakable aggravation of his symptoms and of his general condition.

[1937d, 5056]
If we ask an analyst what his experience has shown to be the mental structures least accessible to influence in his patients, the answer will be: in a woman her wish for a penis, in a man his feminine attitude towards his own sex, a precondition of which would, of course, be the loss of his penis.

[1940a [1938], 5001]

The two corresponding themes are in the female, *an envy for the penis* - a positive striving to possess a male genital - and, in the male, a struggle against his passive or feminine attitude to another male. What is common to the two themes was singled out at an early date by psychoanalytic nomenclature as an attitude towards the castration complex. Subsequently Alfred Adler brought the term 'masculine protest' into current use. It fits the case of males perfectly; but I think that, from the start, 'repudiation of femininity' would have been the correct description of this remarkable feature in the psychical life of human beings.

[1937c, 5044]

In trying to introduce this factor into the structure of our theory, we must not overlook the fact that it cannot, by its very nature, occupy the same position in both sexes. In males the striving to be masculine is completely ego-syntonic from the first; the passive attitude, since it presupposes an acceptance of castration, is energetically repressed, and often its presence is only indicated by excessive overcompensations. In females, too, the striving to be masculine is ego-syntonic at a certain period — namely in the phallic phase, before the development to femininity has set in. But it then succumbs to the momentous process of repression whose outcome, as has so often been shown, determines the fortunes of a woman's femininity. A great deal depends on whether a sufficient amount of her masculinity complex escapes repression and exercises a permanent influence on her character. Normally, large portions of the complex are transformed and contribute to the construction of her femininity: the appeased wish for a penis is destined to be converted into a wish for a baby and for a husband, who possesses a penis. It is strange, however, how often we find that the wish for masculinity has been retained in the unconscious and, from out of its state of repression, exercises a disturbing influence.

[1937c, 5044]

The paramount importance of these two themes — in females the wish for a penis and in males the struggle against passivity — did not escape Ferenczi's notice. In the paper read by him in 1927 he made it a requirement that in every successful analysis those two complexes must have been mastered.¹ I should like to add that, speaking from my own experience, I think that in this Ferenczi was asking a very great deal. At no other point in one's analytic work does one suffer more from an oppressive feeling that all one's repeated efforts have been in vain, and from a suspicion that one has been 'preaching to the winds', than when one is trying to persuade a woman to abandon her wish for a penis on the ground of its being unrealizable or when one is seeking to convince a man that a passive attitude to men does not always signify castration and that it is indispensable in many relationships in life. The rebellious overcompensation of the male produces one of the strongest transference-resistances. He refuses to subject himself to a father-substitute, or to feel indebted to him for anything, and consequently he refuses to accept his recovery from the doctor. No analogous transference can arise from the female's wish for a penis, but it is the source of outbreaks of severe depression in her, owing to an internal conviction that the analysis will be of no use and that nothing can be done to help her. And we can only agree that she is right, when we learn that her strongest motive in coming for treatment was the hope that, after all, she might still obtain a male organ, the lack of which was so painful to her.

[1937c, 5045]
But we also learn from this that it is not important in what form the resistance appears, whether as a transference or not. The decisive thing remains that the resistance prevents any change from taking place - that everything stays as it was. We often have the impression that with the wish for a penis and the masculine protest we have penetrated through all the psychological strata and have reached bedrock, and that thus our activities are at an end. This is probably true, since, for the psychical field, the biological field does in fact play the part of the underlying bedrock. The repudiation of femininity can be nothing else than a biological fact, a part of the great riddle of sex.⁴ It would be hard to say whether and when we have succeeded in mastering this factor in an analytic treatment. We can only console ourselves with the certainty that we have given the person analysed every possible encouragement to re-examine and alter his attitude to it.

[1937c, 5046]
The most obvious and striking point of agreement between the obsessional prohibitions of neurotics and taboos is that these prohibitions are equally lacking in motive and equally puzzling in their origin. Having made their appearance at some unspecified moment, they are forcibly maintained by an irresistible fear. No external threat of punishment is required, for there is an internal certainty, a moral conviction, that any violation will lead to intolerable disaster. The most that an obsessional patient can say on this point is that he has an undefined feeling that some particular person in his environment will be injured as result of the violation. Nothing is known of the nature of the injury; and indeed even this wretchedly small amount of information is more often obtained in connection with the expiatory and defensive actions which we shall have to discuss later than with the prohibitions themselves.

Obsessional prohibitions involve just as extensive renunciations and restrictions in the lives of those who are subject to them as do taboo prohibitions; but some of them can be lifted if certain actions are performed. Thereafter, these actions must be performed: they become compulsive or obsessive acts, and there can be no doubt that they are in the nature of expiation, penance, defensive measures and purification. The commonest of these obsessive acts is washing in water ('washing mania'). Some taboo prohibitions can be replaced in just the same way; or rather their violation can be made good by a similar 'ceremonial'; and here again lustration with water is the preferred method.

In our clinical history of a case we have insisted that the imposition of the prohibition in very early childhood is the determining point; a similar importance attaches in the subsequent developments to the mechanism of repression at the same early age. As a result of the repression which has been enforced and which involves a loss of memory - an amnesia - the motives for the prohibition (which is conscious) remain unknown; and all attempts at disposing of it by intellectual processes must fail, since they cannot find any base of attack. The prohibition owes its strength and its obsessive character precisely to its unconscious opponent, the concealed and undiminished desire - that is to say, to an internal necessity inaccessible to conscious inspection. The ease with which the prohibition can be transferred and extended reflects a process which falls in with the unconscious desire and is greatly facilitated by the psychological conditions that prevail in the unconscious. The instinctual desire is constantly shifting in order to escape from the impasse and endeavours to find substitutes - substitute objects and substitute acts - in place of the prohibited ones. In consequence of this, the prohibition itself shifts about as well, and extends to any new aims which the forbidden impulse may adopt. Any fresh advance made by the repressed libido is answered by a fresh sharpening of the prohibition. The mutual inhibition of the two conflicting forces produces a need for discharge, for reducing the prevailing tension; and to this may be attributed the reason for the performance of obsessive acts. In the case of a neurosis these are clearly compromise actions: from one point of view they are evidences of remorse, efforts at expiation, and so on, while on the other hand they are at the same time substitutive acts to compensate the instinct for what has been prohibited. It is a law of neurotic illness that these obsessive acts fall more and more under the sway of the instinct and approach nearer and nearer to the activity which was originally prohibited.

If the violation of a taboo can be made good by atonement or expiation, which involve the renunciation of some possession or some freedom, this proves that obedience to the taboo injunction meant in itself the renunciation of something desirable. Emancipation from one renunciation is made up for by the imposition of another one elsewhere. This leads us to conclude that atonement is a more fundamental factor than purification in the ceremonials of taboo.
I shall not attempt to give a complete catalogue of the instances quoted by Frazer of restrictions imposed upon victorious manslayers. I will only remark upon a few more such cases in which their taboo character is particularly marked or in which the restrictions are accompanied by expiation, purification and other ceremonials.

However much the details and variations of the ceremonies of expiation and purification after the slaying of enemies might be of interest for deeper research into the subject, I shall break off at this point, since for our present purpose they have nothing more to tell us. I may perhaps suggest that the temporary or permanent isolation of professional executioners, which has persisted to the present day, may belong in this connection. The position of the public hangman in mediaeval society offers a good picture of the workings of taboo among savages.¹

In the accepted explanation of all these observances of appeasement, restriction, expiation and purification, two principles are combined: the extension of the taboo from the slain man on to everything that has come in contact with him, and the fear of the slain man's ghost. How these two factors are to be combined with each other to explain the ceremonials, whether they are to be regarded as of equal weight, whether one is primary and the other secondary, and if so which - none of these questions receives an answer, and indeed it would be hard to find one. We, on the other hand, can lay stress on the unity of our view, which derives all of these observances from emotional ambivalence towards the enemy.

Intellectual resistances are not the worst; one always remains superior to them. But the patient also knows how to put up resistances, without going outside the framework of the analysis, the overcoming of which is among the most difficult of technical problems. Instead of remembering, he repeats attitudes and emotional impulses from his early life which can be used as a resistance against the doctor and the treatment by means of what is known as 'transference'. If the patient is a man, he usually extracts this material from his relation to his father, into whose place he fits the doctor, and in that way he makes resistances out of his efforts to become independent in himself and in his judgements, out of his ambition, the first aim of which was to do things as well as his father or to get the better of him, or out of his unwillingness to burden himself for the second time in his life with a load of gratitude. Thus at times one has an impression that the patient has entirely replaced his better intention of making an end to his illness by the alternative one of putting the doctor in the wrong, of making him realize his impotence and of triumphing over him. Women have a masterly gift for exploiting an affectionate, erotically tinged transference to the doctor for the purposes of resistance. If this attachment reaches a certain height, all their interest in the immediate situation in the treatment and all the obligations they undertook at its commencement vanish; their jealousy, which is never absent, and their exasperation at their inevitable rejection, however considerately expressed, are bound to have a damaging effect on their personal understanding with the doctor and so to put out of operation one of the most powerful motive forces of the analysis.
Where the transference arises, what difficulties it raises for us, how we overcome them and what advantages we eventually derive from it - these are questions to be dealt with in a technical guide to analysis, and I shall only touch on them lightly to-day. It is out of the question for us to yield to the patient's demands deriving from the transference; it would be absurd for us to reject them in an unfriendly, still more in an indignant, manner. We overcome the transference by pointing out to the patient that his feelings do not arise from the present situation and do not apply to the person of the doctor, but that they are repeating something that happened to him earlier. In this way we oblige him to transform his repetition into a memory. By that means the transference, which, whether affectionate or hostile, seemed in every case to constitute the greatest threat to the treatment, becomes its best tool, by whose help the most secret compartments of mental life can be opened.

[1916-1917, 3485]

But it became ever clearer that the aim which had been set up - the aim that what was unconscious should become conscious - is not completely attainable by that method. The patient cannot remember the whole of what is repressed in him, and what he cannot remember may be precisely the essential part of it. Thus he acquires no sense of conviction of the correctness of the construction that has been communicated to him. He is obliged to repeat the repressed material as a contemporary experience instead of, as the physician would prefer to see, remembering it as something belonging to the past.¹ These reproductions, which emerge with such unwished-for exactitude, always have as their subject some portion of infantile sexual life - of the Oedipus complex, that is, and its derivatives; and they are invariably acted out in the sphere of the transference, of the patient's relation to the physician. When things have reached this stage, it may be said that the earlier neurosis has now been replaced by a fresh, 'transference neurosis'. It has been the physician's endeavour to keep this transference neurosis within the narrowest limits: to force as much as possible into the channel of memory and to allow as little as possible to emerge as repetition. The ratio between what is remembered and what is reproduced varies from case to case. The physician cannot as a rule spare his patient this phase of the treatment. He must get him to re-experience some portion of his forgotten life, but must see to it, on the other hand, that the patient retains some degree of aloofness, which will enable him, in spite of everything, to recognize that what appears to be reality is in fact only a reflection of a forgotten past. If this can be successfully achieved, the patient's sense of conviction is won, together with the therapeutic success that is dependent on it.

[1920g, 3723]

Patients repeat all of these unwanted situations and painful emotions in the transference and revive them with the greatest ingenuity. They seek to bring about the interruption of the treatment while it is still incomplete; they contrive once more to feel themselves scorned, to oblige the physician to speak severely to them and treat them coldly; they discover appropriate objects for their jealousy; instead of the passionately desired baby of their childhood, they produce a plan or a promise of some grand present - which turns out as a rule to be no less unreal. None of these things can have produced pleasure in the past, and it might be supposed that they would cause less unpleasure to-day if they emerged as memories or dreams instead of taking the form of fresh experiences. They are of course the activities of instincts intended to lead to satisfaction; but no lesson has been learnt from the old experience of these activities having led instead only to unpleasure. In spite of that, they are repeated, under pressure of a compulsion.

[1920g, 3725]
The manifestations of a compulsion to repeat (which we have described as occurring in the early activities of infantile mental life as well as among the events of psycho-analytic treatment) exhibit to a high degree an instinctual character and, when they act in opposition to the pleasure principle, give the appearance of some 'daemonic' force at work. In the case of children's play we seemed to see that children repeat unpleasurable experiences for the additional reason that they can master a powerful impression far more thoroughly by being active than they could by merely experiencing it passively. Each fresh repetition seems to strengthen the mastery they are in search of. Nor can children have their pleasurable experiences repeated often enough, and they are inexorable in their insistence that the repetition shall be an identical one. This character trait disappears later on. If a joke is heard for a second time it produces almost no effect; a theatrical production never creates so great an impression the second time as the first; indeed, it is hardly possible to persuade an adult who has very much enjoyed reading a book to re-read it immediately. Novelty is always the condition of enjoyment. But children will never tire of asking an adult to repeat a game that he has shown them or played with them, till he is too exhausted to go on. And if a child has been told a nice story, he will insist on hearing it over and over again rather than a new one; and he will remorselessly stipulate that the repetition shall be an identical one and will correct any alterations of which the narrator may be guilty - though they may actually have been made in the hope of gaining fresh approval. None of this contradicts the pleasure principle; repetition, the re-experiencing of something identical, is clearly in itself a source of pleasure. In the case of a person in analysis, on the contrary, the compulsion to repeat the events of his childhood in the transference evidently disregards the pleasure principle in every way. The patient behaves in a purely infantile fashion and thus shows us that the repressed memory-traces of his primaeval experiences are not present in him in a bound state and are indeed in a sense incapable of obeying the secondary process. It is to this fact of not being bound, moreover, that they owe their capacity for forming, in conjunction with the residues of the previous day, a wishful phantasy that emerges in a dream. This same compulsion to repeat frequently meets us as an obstacle to our treatment when at the end of an analysis we try to induce the patient to detach himself completely from his physician. It may be presumed, too, that when people unfamiliar with analysis feel an obscure fear - a dread of rousing something that, so they feel, is better left sleeping - what they are afraid of at bottom is the emergence of this compulsion with its hint of possession by some 'daemonic' power.

[1920g, 3738]
For these reasons I refrained altogether from holding out to the parents any prospect of their wish being fulfilled. I merely said I was prepared to study the girl carefully for a few weeks or months, so as then to be able to pronounce how far a continuation of the analysis would be likely to influence her. In quite a number of cases, indeed, an analysis falls into two clearly distinguishable phases. In the first, the physician procures from the patient the necessary information, makes him familiar with the premises and postulates of psycho-analysis, and unfolds to him the reconstruction of the genesis of his disorder as deduced from the material brought up in the analysis. In the second phase the patient himself gets hold of the material put before him; he works on it, recollects what he can of the apparently repressed memories, and tries to repeat the rest as if he were in some way living it over again. In this way he can confirm, supplement, and correct the inferences made by the physician. It is only during this work that he experiences, through overcoming resistances, the inner change aimed at, and acquires for himself the convictions that make him independent of the physician's authority. These two phases in the course of the analytic treatment are not always sharply divided from each other; this can only happen when the resistance obeys certain conditions. But when this is so, one may bring up as an analogy the two stages of a journey. The first comprises all the necessary preparations, to-day so complicated and hard to effect, before, ticket in hand, one can at last go on to the platform and secure a seat in the train. One then has the right, and the possibility, of travelling into a distant country; but after all these preliminary exertions one is not yet there - indeed, one is not a single mile nearer to one's goal. For this to happen one has to make the journey itself from one station to the other, and this part of the performance may well be compared with the second phase of the analysis.

[1920a, 3842]

In Beyond the Pleasure Principle (1920g) I have dealt with the economic problem of how what are in every respect distressing experiences of the early infantile sexual period can succeed in forcing their way through to some kind of reproduction. I was obliged to ascribe to them an extraordinarily strong upward drive in the shape of the 'compulsion to repeat' - a force able to overcome the repression which, in obedience to the pleasure principle, weighs down upon them - though not until 'the work of treatment has gone half-way to meet it and has loosened the repression'. Here we may add that it is the positive transference that gives this assistance to the compulsion to repeat. Thus an alliance has been made between the treatment and the compulsion to repeat, an alliance which is directed in the first instance against the pleasure principle but of which the ultimate purpose is the establishment of the dominion of the reality principle. As I have shown in the passage to which I am referring, it happens only too often that the compulsion to repeat throws over its obligations under this alliance and is not content with the return of the repressed merely in the form of dream-pictures.

[1923c, 4038]
We showed on an earlier occasion that the resistance that has to be overcome in analysis proceeds from the ego, which clings to its anticathexes. It is hard for the ego to direct its attention to perceptions and ideas which it has up till now made a rule of avoiding, or to acknowledge as belonging to itself impulses that are the complete opposite of those which it knows as its own. Our fight against resistance in analysis is based upon this view of the facts. If the resistance is itself unconscious, as so often happens owing to its connection with the repressed material, we make it conscious. If it is conscious, or when it has become conscious, we bring forward logical arguments against it; we promise the ego rewards and advantages if it will give up its resistance. There can be no doubt or mistake about the existence of this resistance on the part of the ego. But we have to ask ourselves whether it covers the whole state of affairs in analysis. For we find that even after the ego has decided to relinquish its resistances it still has difficulty in undoing the repressions; and we have called the period of strenuous effort which follows after its praiseworthy decision, the phase of 'working-through'.

The dynamic factor which makes a working-through of this kind necessary and comprehensible is not far to seek. It must be that after the ego's resistance has been removed the power of the compulsion to repeat - the attraction exerted by the unconscious prototype upon the repressed instinctual process - has still to be overcome. There is nothing to be said against describing this factor as the resistance of the unconscious. There is no need to be discouraged by these emendations. They are to be welcomed if they add something to our knowledge, and they are no disgrace to us so long as they enrich rather than invalidate our earlier views - by limiting some statement, perhaps, that was too general or by enlarging some idea that was too narrowly formulated.

It must not be supposed that these emendations provide us with a complete survey of all the kinds of resistance that are met with in analysis. Further investigation of the subject shows that the analyst has to combat no less than five kinds of resistance, emanating from three directions - the ego, the id and the super-ego. The ego is the source of three of these, each differing in its dynamic nature. The first of these three ego-resistances is the repression resistance, which we have already discussed above and about which there is least new to be added. Next there is the transference resistance, which is of the same nature but which has different and much clearer effects in analysis, since it succeeds in establishing a relation to the analytic situation or the analyst himself and thus re-animating a repression which should only have been recollected. The third resistance, though also an ego-resistance, is of quite a different nature. It proceeds from the gain from illness and is based upon an assimilation of the symptom into the ego. It represents an unwillingness to renounce any satisfaction or relief that has been obtained. The fourth variety, arising from the id, is the resistance which, as we have just seen, necessitates 'working-through'. The fifth, coming from the super-ego and the last to be discovered, is also the most obscure though not always the least powerful one. It seems to originate from the sense of guilt or the need for punishment; and it opposes every move towards success, including, therefore, the patient's own recovery through analysis.
Our conviction that a portion of erotic life that has been abnormally employed lies at the basis of neuroses must be unshakeably strengthened by this experience. With this discovery we are once more on a firm footing and can venture to make this love itself the object of analysis. And we can make another observation. Analytic love is not manifested in every case as clearly and blatantly as I have tried to depict it. Why not? We can soon see. In proportion as the purely sensual and the hostile sides of his love try to show themselves, the patient's opposition to them is aroused. He struggles against them and tries to repress them before our very eyes. And now we understand what is happening. The patient is repeating in the form of falling in love with the analyst mental experiences which he has already been through once before; he has transferred on to the analyst mental attitudes that were lying ready in him and were intimately connected with his neurosis. He is also repeating before our eyes his old defensive actions; he would like best to repeat in his relation to the analyst all the history of that forgotten period of his life. So what he is showing us is the kernel of his intimate life history: he is reproducing it tangibly, as though it were actually happening, instead of remembering it. In this way the riddle of the transference-love is solved and the analysis can proceed on its way - with the help of the new situation which had seemed such a menace to it. [1926e, 4368]

'That is very cunning. And is the patient so easy to convince that he is not in love but only obliged to stage a revival of an old piece!' [1926e, 4369]

Everything now depends on that. And the whole skill in handling the 'transference' is devoted to bringing it about. As you see, the requirements of analytic technique reach their maximum at this point. Here the gravest mistakes can be made or the greatest successes be registered. It would be folly to attempt to evade the difficulties by suppressing or neglecting the transference; whatever else had been done in the treatment, it would not deserve the name of an analysis. To send the patient away as soon as the inconveniences of his transference neurosis make their appearance would be no more sensible, and would moreover be cowardly. It would be as though one had conjured up spirits and run away from them as soon as they appeared. Sometimes, it is true, nothing else is possible. There are cases in which one cannot master the unleashed transference and the analysis has to be broken of; but one must at least have struggled with the evil spirits to the best of one's strength. To yield to the demands of the transference, to fulfil the patient's wishes for affectionate and sensual satisfaction, is not only justly forbidden by moral considerations but is also completely ineffective as a technical method for attaining the purpose of the analysis. A neurotic cannot be cured by being enabled to reproduce uncorrected an unconscious stereotype plate that is ready to hand in him. If one engages in compromises with him by offering him partial satisfactions in exchange for his further collaboration in the analysis, one must beware of falling into the ridiculous situation of the cleric who was supposed to convert a sick insurance agent. The sick man remained unconverted but the cleric took his leave insured. The only possible way out of the transference situation is to trace it back to the patient's past, as he really experienced it or as he pictured it through the wish-fulfilling activity of his imagination. And this demands from the analyst much skill, patience, calm and self-abnegation. [1926e, 4369]
But the moralist will console himself for a long time to come with the improbability of our speculations. A queer instinct indeed, directed to the destruction of its own organic home! Poets, it is true, talk of such things; but poets are irresponsible people and enjoy the privilege of poetic licence. Incidentally, such ideas are not foreign even to physiology: consider the notion, for instance, of the mucous membrane of the stomach digesting itself. It must be admitted, however, that our self-destructive instinct calls for support on a wider basis. One cannot, after all, venture on a hypothesis of such a wide range merely because a few poor fools have linked their sexual satisfaction to a peculiar condition. A more profound study of the instincts will, I believe, give us what we need. The instincts rule not only mental but also vegetative life, and these organic instincts exhibit a characteristic which deserves our deepest interest. (We shall not be able to judge until later whether it is a general characteristic of instincts.) For they reveal an effort to restore an earlier state of things. We may suppose that from the moment at which a state of things that has once been attained is upset, an instinct arises to create it afresh and brings about phenomena which we can describe as a 'compulsion to repeat'. Thus the whole of embryology is an example of the compulsion to repeat. A power of regenerating lost organs extends far up into the animal kingdom, and the instinct for recovery to which, alongside of therapeutic assistance, our cures are due must be the residue of this capacity which is so enormously developed in the lower animals. The spawning migrations of fishes, the migratory flights of birds, and possibly all that we describe as manifestations of instinct in animals, take place under the orders of the compulsion to repeat, which expresses the conservative nature of the instincts. Nor have we far to look in the mental field for its manifestations. We have been struck by the fact that the forgotten and repressed experiences of childhood are reproduced during the work of analysis in dreams and reactions, particularly in those occurring in the transference, although their revival runs counter to the interest of the pleasure principle; and we have explained this by supposing that in these cases a compulsion to repeat is overcoming even the pleasure principle. Outside analysis, too, something similar can be observed. There are people in whose lives the same reactions are perpetually being repeated uncorrected, to their own detriment, or others who seem to be pursued by a relentless fate, though closer investigation teaches us that they are unwittingly bringing this fate on themselves. In such cases we attribute a 'daemonic' character to the compulsion to repeat.

[1933a, 4710]

(2) Two points must be stressed in regard to the common characteristics or peculiarities of neurotic phenomena: (a) The effects of traumas are of two kinds, positive and negative. The former are attempts to bring the trauma into operation once again - that is, to remember the forgotten experience or, better still, to make it real, to experience a repetition of it anew, or, even if it was only an early emotional relationship, to revive it in an analogous relationship with someone else. We summarize these efforts under the name of 'fixations' to the trauma and as a 'compulsion to repeat'. They may be taken up into what passes as a normal ego and, as permanent trends in it, may lend it unalterable character-traits, although, or rather precisely because, their true basis and historical origin are forgotten. Thus a man who has spent his childhood in an excessive and to-day forgotten attachment to his mother, may spend his whole life looking for a wife on whom he can make himself dependent and by whom he can arrange to be nourished and supported. A girl who was made the object of a sexual seduction in her early childhood may direct her later sexual life so as constantly to provoke similar attacks. It may easily be guessed that from such discoveries about the problem of neurosis we can penetrate to an understanding of the formation of character in general.

[1939a, 4901]
It would be worth while to understand how it was that the monotheist idea made such a deep impression precisely on the Jewish people and that they were able to maintain it so tenaciously. It is possible, I think, to find an answer. Fate had brought the great deed and misdeed of primaeval days, the killing of the father, closer to the Jewish people by causing them to repeat it on the person of Moses, an outstanding father-figure. It was a case of 'acting out' instead of remembering, as happens so often with neurotics during the work of analysis. To the suggestion that they should remember, which was made to them by the doctrine of Moses, they reacted, however, by disavowing their action; they remained halted at the recognition of the great father and thus blocked their access to the point from which Paul was later to start his continuation of the primal history. It is scarcely a matter of indifference or of chance that the violent killing of another great man became the starting-point of Paul's new religious creation as well. This was a man whom a small number of adherents in Judaea regarded as the Son of God and as the Messiah who had been announced, and to whom, too, a part of the childhood story invented for Moses was later carried over, but of whom in fact we know scarcely more with certainty than of Moses - whether he was really the great teacher portrayed by the Gospels or whether, rather, it was not the fact and circumstances of his death which were decisive for the importance which his figure acquired. Paul, who became his apostle, had not known him himself.
[1939a, 4912]

And now for the other side of the situation. Since the transference reproduces the patient's relation with his parents, it takes over the ambivalence of that relation as well. It almost inevitably happens that one day his positive attitude towards the analyst changes over into the negative, hostile one. This too is as a rule a repetition of the past. His obedience to his father (if it is his father that is in question), his courting of his father's favour, had its roots in an erotic wish directed towards him. Some time or other that demand will press its way forward in the transference as well and insist on being satisfied. In the analytic situation it can only meet with frustration. Real sexual relations between patients and analysts are out of the question, and even the subtler methods of satisfaction, such as the giving of preference, intimacy and so on, are only sparingly granted by the analyst. A rejection of this kind is taken as the occasion for the change-over; probably things happened in the same way in the patient's childhood.
[1940a [1938], 4986]
The therapeutic successes that occurred under the sway of the positive transference are open to the suspicion of being of a suggestive nature. If the negative transference gains the upper hand, they are blown away like chaff before the wind. We observe with horror that all our trouble and labour hitherto have been in vain. Indeed, what we might have regarded as a permanent intellectual gain by the patient, his understanding of psycho-analysis and his reliance on its efficacy, suddenly vanish. He behaves like a child who has no power of judgement of his own but blindly believes anyone whom he loves and no one who is a stranger to him. The danger of these states of transference evidently lies in the patient's misunderstanding their nature and taking them for fresh real experiences instead of reflections of the past. If he (or she) becomes aware of the strong erotic desire that lies concealed behind the positive transference, he believes that he has fallen passionately in love; if the transference changes over, then he feels insulted and neglected, he hates the analyst as his enemy and is ready to abandon the analysis. In both these extreme cases he has forgotten the pact that he made at the beginning of the treatment and has become useless for continuing the common work. It is the analyst's task constantly to tear the patient out of his menacing illusion and to show him again and again that what he takes to be new real life is a reflection of the past. And lest he should fall into a state in which he is inaccessible to all evidence, the analyst takes care that neither the love nor the hostility reach an extreme height. This is effected by preparing him in good time for these possibilities and by not overlooking the first signs of them. Careful handling of the transference on these lines is as a rule richly rewarded. If we succeed, as we usually can, in enlightening the patient on the true nature of the phenomena of transference, we shall have struck a powerful weapon out of the hand of his resistance and shall have converted dangers into gains. For a patient never forgets again what he has experienced in the form of transference; it carries a greater force of conviction than anything he can acquire in other ways.

At the moment, however, we are not concerned with the pathogenic role of the defensive mechanisms. What we are trying to discover is what influence the alteration of the ego which corresponds to them has upon our therapeutic efforts. The material for an answer to this question is given in the volume by Anna Freud to which I have already referred. The essential point is that the patient repeats these modes of reaction during the work of analysis as well, that he produces them before our eyes, as it were. In fact, it is only in this way that we get to know them. This does not mean that they make analysis impossible. On the contrary, they constitute half of our analytic task. The other half, the one which was first tackled by analysis in its early days, is the uncovering of what is hidden in the id. During the treatment our therapeutic work is constantly swinging backwards and forwards like a pendulum between a piece of id-analysis and a piece of ego-analysis. In the one case we want to make something from the id conscious, in the other we want to correct something in the ego. The crux of the matter is that the defensive mechanisms directed against former danger recur in the treatment as resistances against recovery. It follows from this that the ego treats recovery itself as a new danger.
ANALYSIS. - This dreamer belonged to a type whose therapeutic prospects are not favourable: up to a certain point they offer no resistance at all to analysis, but from then onwards turn out to be almost inaccessible. He interpreted this dream almost unaided. 'The Rotunda', he said, 'was my genitals and the captive balloon in front of it was my penis, whose limpness I have reason to complain of.' Going into greater detail, then, we may translate the Rotunda as the bottom (habitually regarded by children as part of the genitals) and the small annex in front of it as the scrotum. His father asked him in the dream what all this was, that is, what was the purpose and function of the genitals. It seemed plausible to reverse this situation and turn the dreamer into the questioner. Since he had in fact never questioned his father in this way, we had to look upon the dream-thought as a wish, or take it as a conditional clause, such as: 'If I had asked my father for sexual enlightenment...'. We shall presently find the continuation of this thought in another part of the dream.
[1900a, 826]

Let us now go back to the nurse's dream, in order to demonstrate the quality of depth in the wish-fulfilment contained in it. We already know that the lady's interpretation of the dream was by no means complete; there were portions of it to which she was unable to do justice. Moreover she suffered from an obsessional neurosis, a condition which, from what I have observed, makes it considerably harder to understand dream-symbols, just as dementia praecox makes it easier.
[1913a, 2591]
Before we draw any conclusion from impressions such as these, let us consider further the distinctions between the formation of substitutes in schizophrenia on the one hand, and in hysteria and obsessional neurosis on the other - subtle distinctions which nevertheless make a strange impression. A patient whom I have at present under observation has allowed himself to be withdrawn from all the interests of life on account of a bad condition of the skin of his face. He declares that he has black heads and deep holes in his face which everyone notices. Analysis shows that he is playing out his castration complex upon his skin. At first he worked at these blackheads remorselessly; and it gave him great satisfaction to squeeze them out, because, as he said, something spurted out when he did so. Then he began to think that a deep cavity appeared wherever he had got rid of a blackhead, and he reproached himself most vehemently with having ruined his skin for ever by 'constantly fiddling about with his hand'. Pressing out the content of the blackheads is clearly to him a substitute for masturbation. The cavity which then appears owing to his fault is the female genital, i.e. the fulfilment of the threat of castration (or the phantasy representing that threat) provoked by his masturbating. This substitutive formation has, in spite of its hypochondriacal character, considerable resemblance to a hysterical conversion; and yet we have a feeling that something different must be going on here, that a substitutive formation such as this cannot be attributed to hysteria, even before we can say in what the difference consists. A tiny little cavity such as a pore of the skin would hardly be used by a hysteric as a symbol for the vagina, which he is otherwise ready to compare with every imaginable object that encloses a hollow space. Besides, we should expect the multiplicity of these little cavities to prevent him from using them as a substitute for the female genital. The same applies to the case of a young patient reported by Tausk some years ago to the Vienna Psycho-Analytical Society. This patient behaved in other respects exactly as though he were suffering from an obsessional neurosis; he took hours to wash and dress, and so on. It was noticeable, however, that he was able to give the meaning of his inhibitions without any resistance. In putting on his stockings, for instance, he was disturbed by the idea that he must pull apart the stitches in the knitting, i.e. the holes, and to him every hole was a symbol of the female genital aperture. This again is a thing which we cannot attribute to an obsessional neurotic. Reitler observed a patient of the latter sort, who also suffered from having to take a long time over putting on his stockings; this man, after overcoming his resistances, found as the explanation that his foot symbolized a penis, that putting on the stocking stood for a masturbatory act, and that he had to keep on pulling the stocking on and off, partly in order to complete the picture of masturbation, and partly in order to undo that act.

[1915e, 3021]

But you must not take this warning of mine to mean that I propose to give you dogmatic lectures and to insist on your unqualified belief. Such a misunderstanding would do me a grave injustice. I do not wish to arouse conviction; I wish to stimulate thought and to upset prejudices. If as a result of lack of knowledge of the material you are not in a position to form a judgement, you should neither believe nor reject. You should listen and allow what I tell you to work on you. It is not so easy to arrive at convictions, or, if they are reached easily, they soon turn out to be worthless and incapable of resistance. The only person who has a right to a conviction is someone who, like me, has worked for many years at the same material and who, in doing so, has himself had the same new and surprising experiences. What is the good, then, in the sphere of the intellect, of these sudden convictions, these lightning-like conversions, these instantaneous rejections? Is it not clear that the 'coup de foudre', love at first sight, is derived from quite another sphere, from that of the emotions? We do not even require of our patients that they should bring a conviction of the truth of psycho-analysis into the treatment or be adherents of it. Such an attitude often raises our suspicions. The attitude that we find the most desirable in them is a benevolent scepticism. So you too should endeavour to allow the psycho-analytic view to grow up quietly in you alongside of the popular or psychiatric one, till opportunities arise for the two to influence each other, to compete with each other and to unite in leading to a conclusion.

[1916-1917, 3326]
The neuroses were the first subject of analysis, and for a long time they were the only one. No analyst could doubt that medical practice was wrong in separating those disorders from the psychoses and in attaching them to the organic nervous diseases. The theory of the neuroses belongs to psychiatry and is indispensable as an introduction to it. It would seem, however, that the analytic study of the psychoses is impracticable owing to its lack of therapeutic results. Mental patients are as a rule without the capacity for forming a positive transference, so that the principal instrument of analytic technique is inapplicable to them. There are nevertheless a number of methods of approach to be found. Transference is often not so completely absent but that it can be used to a certain extent; and analysis has achieved undoubted successes with cyclical depressions, light paranoic modifications, and partial schizophrenias. It has at least been a benefit to science that in many cases the diagnosis can oscillate for quite a long time between assuming the presence of a psychoneurosis or of a dementia praecox; for therapeutic attempts initiated in such cases have resulted in valuable discoveries before they have had to be broken off. But the chief consideration in this connection is that so many things that in the neuroses have to be laboriously fetched up from the depths are found in the psychoses on the surface, visible to every eye. For that reason the best subjects for the demonstration of many of the assertions of analysis are provided by the psychiatric clinic. It was thus bound to happen before long that analysis would find its way to the objects of psychiatric observation. I was able very early (1896) to establish in a case of paranoid dementia the presence of the same aetiological factors and the same emotional complexes as in the neuroses. Jung explained some most puzzling stereotypies in dements by bringing them into relation with the patients' life-histories; Bleuler demonstrated the existence in various psychoses of mechanisms like those which analysis had discovered in neurotics. Since then analysts have never relaxed their efforts to come to an understanding of the psychoses. Especially since it has been possible to work with the concept of narcissism, they have managed, now in this place and now in that, to get a glimpse beyond the wall. Most of all, no doubt, was achieved by Abraham in his elucidation of the melancholias. It is true that in this sphere all our knowledge is not yet converted into therapeutic power; but the mere theoretical gain is not to be despised, and we may be content to wait for its practical application. In the long run even the psychiatrists cannot resist the convincing force of their own clinical material. At the present time German psychiatry is undergoing a kind of 'peaceful penetration' by analytic views. While they continually declare that they will never be psycho-analysts, that they do not belong to the 'orthodox' school or agree with its exaggerations, and in particular that they do not believe in the predominance of the sexual factor, nevertheless the majority of the younger workers take over one piece or another of analytic theory and apply it in their own fashion to the material. All the signs point to the proximity of further developments in the same direction. [1925d, 4235]
Stated in terms of the conversion theory, this incontrovertible fact of the summation of traumas and of the preliminary latency of symptoms tells us that conversion can result equally from fresh symptoms and from recollected ones. This hypothesis completely explains the apparent contradiction that we observed between the events of Fräulein Elisabeth von R.'s illness and her analysis. There is no doubt that the continued existence in consciousness of ideas whose affect has not been dealt with can be tolerated by healthy individuals up to a great amount. The view which I have just been putting forward does no more than bring the behaviour of hysterical people nearer to that of healthy ones. What we are concerned with is clearly a quantitative factor - the question of how much affective tension of this kind an organism can tolerate. Even a hysteric can retain a certain amount of affect that has not been dealt with; if, owing to the occurrence of similar provoking causes, that amount is increased by summation to a point beyond the subject's tolerance, the impetus to conversion is given. Thus when we say that the construction of hysterical symptoms can proceed on the strength of recollected affects as well as fresh ones, we shall not be making any unfamiliar assertion, but stating something that is almost accepted as a postulate.

(1) Whether a neurotic illness occurs at all depends upon a quantitative factor - upon the total load on the nervous system as compared with the latter's capacity for resistance. Everything which can keep this quantitative factor below a certain threshold-value, or can bring it back to that level, has a therapeutic effect, since by so doing it keeps the aetiological equation unsatisfied.

What is to be understood by the 'total load' and by the 'capacity for resistance' of the nervous system, could no doubt be more clearly explained on the basis of certain hypotheses regarding the function of the nerves.

[1895d, 158]

[1895f, 365]
What can the other factors be which the ‘specific aetiology’ of hysteria still needs in order actually to produce the neurosis? That, Gentlemen, is a theme in itself, which I do not propose to enter upon. To-day I need only indicate the point of contact at which the two parts of the topic - the specific and the auxiliary aetiology - fit into one another. No doubt a considerable quantity of factors will have to be taken into account. There will be the subject's inherited and personal constitution, the inherent importance of the infantile sexual experiences, and, above all, their number: a brief relationship with a strange boy, who afterwards becomes indifferent, will leave a less powerful effect on a girl than intimate sexual relations of several years' standing with her own brother. In the aetiology of the neuroses quantitative preconditions are as important as qualitative ones: there are threshold-values which have to be crossed before the illness can become manifest. Moreover, I do not myself regard this aetiological series as complete; nor does it solve the riddle of why hysteria is not more common among the lower classes. (You will remember, by the way, what a surprisingly large incidence of hysteria was reported by Charcot among working-class men). I may also remind you that a few years ago I myself pointed out a factor, hitherto little considered, to which I attribute the leading role in provoking hysteria after puberty. I then put forward the view that the outbreak of hysteria may almost invariably be traced to a *psychical conflict* arising through an incompatible idea setting in action a *defence* on the part of the ego and calling up a demand for repression. What the circumstances are in which a defensive endeavour of this kind has the pathological effect of actually thrusting the memory which is distressing to the ego into the unconscious and of creating a hysterical symptom in its place I was not able to say at that time. But to-day I can repair the omission. The *defence achieves its purpose of thrusting the incompatible idea out of consciousness if there are infantile sexual scenes present in the (hitherto normal) subject in the form of unconscious memories, and if the idea that is to be repressed can be brought into logical or associative connection with an infantile experience of that kind.*

[Hitherto philosophers have had no occasion to concern themselves with a psychology of repression. We may therefore be permitted to make a first approach to this hitherto unknown topic by constructing a pictorial image of the course of events in dream-formation. It is true that the schematic picture we have arrived at - not only from the study of dreams - is a fairly complicated one; but we cannot manage with anything simpler. Our hypothesis is that in our mental apparatus there are two thought-constructing agencies, of which the second enjoys the privilege of having free access to consciousness for its products whereas the activity of the first is in itself unconscious and can only reach consciousness by way of the second. On the frontier between the two agencies, where the first passes over to the second, there is a censorship, which only allows what is agreeable to it to pass through and holds back everything else. According to our definition, then, what is rejected by the censorship is in a state of repression. Under certain conditions, of which the state of sleep is one, the relation between the strength of the two agencies is modified in such a way that what is repressed can no longer be held back. In the state of sleep this probably occurs owing to a relaxation of the censorship; when this happens it becomes possible for what has hitherto been repressed to make a path for itself to consciousness. Since, however, the censorship is never completely eliminated but merely reduced, the repressed material must submit to certain alterations which mitigate its offensive features. What becomes conscious in such cases is a compromise between the intentions of one agency and the demands of the other. *Repression - relaxation of the censorship - the formation of a compromise,* this is the fundamental pattern for the generation not only of dreams but of many other psychopathological structures; and in the latter cases too we may observe that the formation of compromises is accompanied by processes of condensation and displacement and by the employment of superficial associations, which we have become familiar with in the dream-work.]

[1896c, 424]

[1901a, 1089]
Footnote added 1924: At this point very interesting problems of an economic nature come in, questions taking into consideration the fact that the psychical processes aim at gaining pleasure and removing unpleasure. There is already an economic problem in how it becomes possible by way of substitutive associations to recapture a name that has been forgotten through motives of unpleasure. An excellent paper by Tausk (1913) gives good examples of how the forgotten name becomes accessible once more if one succeeds in connecting it with a pleasurably-toned association, which can counterbalance the unpleasure to be expected from the reproduction of the name.

[1901b, 1339]

The reproaches against her father for having made her ill, together with the self-reproach underlying them, the leucorrhoea, the playing with the reticule, the bed-wetting after her sixth year, the secret which she would not allow the doctors to tear from her - the circumstantial evidence of her having masturbated in childhood seems to me complete and without a flaw. In the present case I had begun to suspect the masturbation when she had told me of her cousin's gastric pains, and had then identified herself with her by complaining for days together of similar painful sensations. It is well known that gastric pains occur especially often in those who masturbate. According to a personal communication made to me by Wilhelm Fliess, it is precisely gastralgias of this character which can be interrupted by an application of cocaine to the 'gastric spot' discovered by him in the nose, and which can be cured by the cauterization of the same spot. In confirmation of my suspicion Dora gave me two facts from her conscious knowledge: she herself had frequently suffered from gastric pains, and she had good reasons for believing that her cousin was a masturbator. It is a very common thing for patients to recognize in other people a connection which, on account of their emotional resistances, they cannot perceive in themselves. And, indeed, Dora no longer denied my supposition, although she still remembered nothing. Even the date which she assigned to the bed-wetting, when she said that it lasted 'till a short time before the appearance of the nervous asthma', appears to me to be of clinical significance. Hysterical symptoms hardly ever appear so long as children are masturbating, but only afterwards, when a period of abstinence has set in;¹ they form a substitute for masturbatory satisfaction, the desire for which continues to persist in the unconscious until another and more normal kind of satisfaction appears - where that is still attainable. For upon whether it is still attainable or not depends the possibility of a hysteria being cured by marriage and normal sexual intercourse. But if the satisfaction afforded in marriage is again removed - as it may be owing to coitus interruptus, psychological estrangement, or other causes - then the libido flows back again into its old channel and manifests itself once more in hysterical symptoms.

[1905e, 1415]

I will gladly renounce all the methods of satisfaction proscribed by society, but am I certain that society will reward this renunciation by offering me one of the permitted methods - even after a certain amount of postponement? What these jokes whisper may be said aloud: that the wishes and desires of men have a right to make themselves acceptable alongside of exacting and ruthless morality. And in our days it has been said in forceful and stirring sentences that this morality is only a selfish regulation laid down by the few who are rich and powerful and who can satisfy their wishes at any time without any postponement. So long as the art of healing has not gone further in making our life safe and so long as social arrangements do no more to make it more enjoyable, so long will it be impossible to stifle the voice within us that rebels against the demands of morality. Every honest man will end by making this admission, at least to himself. The decision in this conflict can only be reached by the roundabout path of fresh insight. One must bind one’s own life to that of others so closely and be able to identify oneself with others so intimately that the brevity of one’s own life can be overcome; and one must not fulfil the demands of one’s own needs illegitimately, but must leave them unfulfilled, because only the continuance of so many unfulfilled demands can develop the power to change the order of society. But not every personal need can be postponed in this way and transferred to other people, and there is no general and final solution of the conflict.

[1905c, 1704]
The sexual instinct - or, more correctly, the sexual instincts, for analytic investigation teaches us that the sexual instinct is made up of many separate constituents or component instincts - is probably more strongly developed in man than in most of the higher animals; it is certainly more constant, since it has almost entirely overcome the periodicity to which it is tied in animals. It places extraordinarily large amounts of force at the disposal of civilized activity, and it does this in virtue of its especially marked characteristic of being able to displace its aim without materially diminishing in intensity. This capacity to exchange its originally sexual aim for another one, which is no longer sexual but which is psychically related to the first aim, is called the capacity for sublimation. In contrast to this displaceability, in which its value for civilization lies, the sexual instinct may also exhibit a particularly obstinate fixation which renders it unserviceable and which sometimes causes it to degenerate into what are described as abnormalities. The original strength of the sexual instinct probably varies in each individual; certainly the proportion of it which is suitable for sublimation varies. It seems to us that it is the innate constitution of each individual which decides in the first instance how large a part of his sexual instinct it will be possible to sublimate and make use of. In addition to this, the effects of experience and the intellectual influences upon his mental apparatus succeed in bringing about the sublimation of a further portion of it. To extend this process of displacement indefinitely is, however, certainly not possible, any more than is the case with the transformation of heat into mechanical energy in our machines. A certain amount of direct sexual satisfaction seems to be indispensable for most organizations, and a deficiency in this amount, which varies from individual to individual, is visited by phenomena which, on account of their detrimental effects on functioning and their subjective quality of unpleasure, must be regarded as an illness.

[1908d, 1952]

The retardation of sexual development and sexual activity at which our education and civilization aim is certainly not injurious to begin with. It is seen to be a necessity, when one considers the late age at which young people of the educated classes reach independence and are able to earn a living. (This reminds one, incidentally, of the intimate interconnection between all our cultural institutions and of the difficulty of altering any part of them without regard to the whole.) But abstinence continued long after the age of twenty is no longer unobjectionable for a young man; and it leads to other damage even when it does not lead to neurosis. People say, to be sure, that the struggle against such a powerful instinct, and the strengthening of all the ethical and aesthetic forces which are necessary for this struggle, 'steel' the character; and this is true for a few specially favourably organized natures. It must also be admitted that the differentiation of individual character, which is so marked in our day, has only become possible with the existence of sexual restriction. But in the vast majority of cases the struggle against sexuality eats up the energy available in a character and this at the very time when a young man is in need of all his forces in order to win his share and place in society. The relationship between the amount of sublimation possible and the amount of sexual activity necessary naturally varies very much from person to person and even from one calling to another. An abstinent artist is hardly conceivable; but an abstinent young savant is certainly no rarity. The latter can, by his self-restraint, liberate forces for his studies; while the former probably finds his artistic achievements powerfully stimulated by his sexual experience. In general I have not gained the impression that sexual abstinence helps to bring about energetic and self-reliant men of action or original thinkers or bold emancipators and reformers. Far more often it goes to produce well-behaved weaklings who later become lost in the great mass of people that tends to follow, unwillingly, the leads given by strong individuals.

[1908d, 1958]
Let me at this point state the principal finding to which we have been led by the psychoanalytic investigation of neurotics. The neuroses have no psychical content that is peculiar to them and that might not equally be found in healthy people. Or, as Jung has expressed it, neurotics fall ill of the same complexes against which we healthy people struggle as well. Whether that struggle ends in health, in neurosis, or in a countervailing superiority of achievement, depends on quantitative considerations, on the relative strength of the conflicting forces. [1910a, 2235]

But even if the historical material at our disposal were very abundant, and if the psychical mechanisms could be dealt with with the greatest assurance, there are two important points at which a psycho-analytic enquiry would not be able to make us understand how inevitable it was that the person concerned should have turned out in the way he did and in no other way. In Leonardo's case we have had to maintain the view that the accident of his illegitimate birth and the excessive tenderness of his mother had the most decisive influence on the formation of his character and on his later fortune, since the sexual repression which set in after this phase of childhood caused him to sublimate his libido into the urge to know, and established his sexual inactivity for the whole of his later life. But this repression after the first erotic satisfactions of childhood need not necessarily have taken place; in someone else it might perhaps not have taken place or might have assumed much less extensive proportions. We must recognize here a degree of freedom which cannot be resolved any further by psycho-analytic means. Equally, one has no right to claim that the consequence of this wave of repression was the only possible one. It is probable that another person would not have succeeded in withdrawing the major portion of his libido from repression by sublimating it into a craving for knowledge; under the same influences he would have sustained a permanent injury to his intellectual activity or have acquired an insurmountable disposition to obsessional neurosis. We are left, then, with these two characteristics of Leonardo which are inexplicable by the efforts of psycho-analysis: his quite special tendency towards instinctual repressions, and his extraordinary capacity for sublimating the primitive instincts. [1910c, 2303]

Psycho-analytic studies of psychical impotence have already been carried out and published by several writers.¹ Every analyst can confirm the explanations provided by them from his own clinical experience. It is in fact a question of the inhibitory influence of certain psychical complexes which are withdrawn from the subject's knowledge. An incestuous fixation on mother or sister, which has never been surmounted, plays a prominent part in this pathogenic material and is its most universal content. In addition there is the influence to be considered of accidental distressing impressions connected with infantile sexual activity, and also those factors which in a general way reduce the libido that is to be directed on to the female sexual object.² [1912d, 2338]

We have reduced psychical impotence to the failure of the affectionate and the sensual currents in love to combine, and this developmental inhibition has in turn been explained as being due to the influences of strong childhood fixations and of later frustration in reality through the intervention of the barrier against incest. There is one principal objection to the theory we advance; it does too much. It explains why certain people suffer from psychical impotence, but it leaves us with the apparent mystery of how others have been able to escape this disorder. Since we must recognize that all the relevant factors known to us - the strong childhood fixation, the incest-barrier and the frustration in the years of development after puberty - are to be found in practically all civilized human beings, we should be justified in expecting psychical impotence to be a universal affliction under civilization and not a disorder confined to some individuals. [1912d, 2341]
The fact that the curb put upon love by civilization involves a universal tendency to debase sexual objects will perhaps lead us to turn our attention from the object to the instincts themselves. The damage caused by the initial frustration of sexual pleasure is seen in the fact that the freedom later given to that pleasure in marriage does not bring full satisfaction. But at the same time, if sexual freedom is unrestricted from the outset the result is no better. It can easily be shown that the psychical value of erotic needs is reduced as soon as their satisfaction becomes easy. An obstacle is required in order to heighten libido; and where natural resistances to satisfaction have not been sufficient men have at all times erected conventional ones so as to be able to enjoy love. This is true both of individuals and of nations. In times in which there were no difficulties standing in the way of sexual satisfaction, such as perhaps during the decline of the ancient civilizations, love became worthless and life empty, and strong reaction-formations were required to restore indispensable affective values. In this connection it may be claimed that the ascetic current in Christianity created psychical values for love which pagan antiquity was never able to confer on it. This current assumed its greatest importance with the ascetic monks, whose lives were almost entirely occupied with the struggle against libidinal temptation.

One's first inclination is no doubt to trace back the difficulties revealed here to universal characteristics of our organic instincts. It is no doubt also true in general that the psychical importance of an instinct rises in proportion to its frustration. Suppose a number of totally different human beings were all equally exposed to hunger. As their imperative need for food mounted, all the individual differences would disappear and in their place one would see the uniform manifestations of the one unappeased instinct. But is it also true that with the satisfaction of an instinct its psychical value always falls just as sharply? Consider, for example, the relation of a drinker to wine. Is it not true that wine always provides the drinker with the same toxic satisfaction, which in poetry has so often been compared to erotic satisfaction - a comparison acceptable from the scientific point of view as well? Has one ever heard of the drinker being obliged constantly to change his drink because he soon grows tired of keeping to the same one? On the contrary, habit constantly tightens the bond between a man and the kind of wine he drinks. Does one ever hear of a drinker who needs to go to a country where wine is dearer or drinking is prohibited, so that by introducing obstacles he can reinforce the dwindling satisfaction that he obtains? Not at all. If we listen to what our great alcoholics, such as Böcklin,¹ say about their relation to wine, it sounds like the most perfect harmony, a model of a happy marriage. Why is the relation of the lover to his sexual object so very different?

Yet another line of thought extending into organic research branches off from psycho-analysis. We may ask ourselves whether the suppression of sexual component instincts which is brought about by environmental influences is sufficient in itself to call up functional disturbances in organs, or whether special constitutional conditions must be present in order that the organs may be led to an exaggeration of their erotogenic role and consequently provoke repression of the instincts. We should have to see in those conditions the constitutional part of the disposition to fall ill of psychogenic and neurotic disorders. This is the factor to which, as applied to hysteria, I gave the provisional name of 'somatic compliance'.

¹Böcklin
Perhaps I may be allowed to add a few words with a view to establishing the causes of this conflict that broke out in relation to the feminine wishful phantasy. As we know, when a wishful phantasy makes its appearance, our business is to bring it into connection with some frustration, some privation in real life. Now Schreber admits having suffered a privation of the kind. His marriage, which he describes as being in other respects a happy one, brought him no children; and in particular it brought him no son who might have consoled him for the loss of his father and brother and upon whom he might have drained off his unsatisfied homosexual affections.¹ His family line threatened to die out, and it seems that he felt no little pride in his birth and lineage. 'Both the Flechsigs and the Schrebers were members of "the highest nobility of Heaven", as the phrase went. The Schrebers in particular bore the title of "Margraves of Tuscany and Tasmania"; for souls, urged by some sort of personal vanity, have a custom of adorning themselves with somewhat high-sounding titles borrowed from this world.'² (24.) The great Napoleon obtained a divorce from Josephine (though only after severe internal struggles) because she could not propagate the dynasty.³ Dr. Schreber may have formed a phantasy that if he were a woman he would manage the business of having children more successfully; and he may thus have found his way back into the feminine attitude towards his father which he had exhibited in the earliest years of his childhood. If that were so, then his delusion that as a result of his emasculation the world was to be peopled with 'a new race of men, born from the spirit of Schreber' (288) - a delusion the realization of which he was continually postponing to a more and more remote future - would also be designed to offer him an escape from his childlessness. If the 'little men' whom Schreber himself finds so puzzling were children, then we should have no difficulty in understanding why they were collected in such great numbers on his head (158): they were in truth the 'children of his spirit'.⁴

In my Three Essays on the Theory of Sexuality I have expressed the opinion that each stage in the development of psychosexuality affords a possibility of 'fixation', and thus of a dispositional point. People who have not freed themselves completely from the stage of narcissism - who, that is to say, have at that point a fixation which may operate as a disposition to a later illness - are exposed to the danger that some unusually intense wave of libido, finding no other outlet, may lead to a sexualization of their social instincts and so undo the sublimations which they had achieved in the course of their development. This result may be produced by anything that causes the libido to flow backwards (i.e. that causes a 'regression'): whether, on the one hand, the libido becomes collaterally reinforced owing to some disappointment over a woman, or is directly dammed up owing to a mishap in social relations with other men - both of these being instances of 'frustration'; or whether, on the other hand, there is a general intensification of the libido, so that it becomes too powerful to find an outlet along the channels which are already open to it, and consequently bursts through its banks at the weakest spot. Since our analyses show that paranoics endeavours to protect themselves against any such sexualization of their social instinctual cathexes, we are driven to suppose that the weak spot in their development is to be looked for somewhere between the stages of auto-erotism, narcissism and homosexuality, and that their disposition to illness (which may perhaps be susceptible of more precise definition) must be located in that region. A similar disposition would have to be assigned to patients suffering from Kraepelin's dementia praecox or (as Bleuler has named it) schizophrenia; and we shall hope later on to find clues which will enable us to trace back the differences between the two disorders (as regards both the form they take and the course they run) to corresponding differences in the patients' dispositional fixations.

[1911c, 2431]
It is advisable to draw a sharp distinction between the two types of onset of illness - a sharper distinction than observation as a rule permits. In the first type what is prominent is a change in the external world; in the second type the accent falls on an internal change. In the first type the subject falls ill from an experience; in the second type it is from a developmental process. In the first case he is faced by the task of renouncing satisfaction, and he falls ill from his incapacity for resistance; in the second case his task is to exchange one kind of satisfaction for another, and he breaks down from his inflexibility. In the second case the conflict, which is between the subject's effort to remain as he is and the effort to change himself in order to meet fresh purposes and fresh demands from reality, is present from the first. In the former case the conflict only arises after the dammed-up libido has chosen other, and incompatible, possibilities of satisfaction. The part played by the conflict and the previous fixation of the libido is incomparably more obvious in the second type than in the first, in which such unserviceable fixations may perhaps only emerge as a result of the external frustration.

[1912c, 2561]

\( (d) \) Just as the third type has brought the dispositional determinant before us almost in isolation, so the fourth type, which now follows, draws our attention to another factor, which comes into consideration in every single case and might easily for that very reason be overlooked in a theoretical discussion. We see people fall ill who have hitherto been healthy, who have met with no fresh experience and whose relation to the external world has undergone no change, so that the onset of their illness inevitably gives an impression of spontaneity. A closer consideration of such cases, however, shows us that none the less a change has taken place in them whose importance we must rate very highly as a cause of illness. As a result of their having reached a particular period of life, and in conformity with regular biological processes, the quantity of libido in their mental economy has experienced an increase which is in itself enough to upset the equilibrium of their health and to set up the necessary conditions for a neurosis. It is well known that more or less sudden increases of libido of this kind are habitually associated with puberty and the menopause - with the attainment of a certain age in women; in some people they may in addition be manifested in periodicities that are still unknown. Here the damming-up of libido is the primary factor; it becomes pathogenic as a consequence of a relative frustration on the part of the external world, which would still have granted satisfaction to a smaller claim by the libido. The unsatisfied and dammed-up libido can once again open up paths to regression and kindle the same conflicts which we have demonstrated in the case of absolute external frustration. We are reminded in this way that the quantitative factor should not be left out of account in any consideration of the precipitating causes of illness. All the other factors - frustration, fixation, developmental inhibition - remain ineffective unless they affect a certain amount of libido and bring about a damming-up of libido of a certain height. It is true that we are unable to measure this amount of libido which seems to us indispensable for a pathogenic effect; we can only postulate it after the resulting illness has started. There is only one direction in which we can determine it more precisely. We may assume that it is not a question of an absolute quantity, but of the relation between the quota of libido in operation and the quantity of libido which the individual ego is able to deal with - that is, to hold under tension, to sublimate or to employ directly. For this reason a relative increase in the quantity of libido may have the same effects as an absolute one. An enfeeblement of the ego owing to organic illness or owing to some special demand upon its energy will be able to cause the emergence of neuroses which would otherwise have remained latent in spite of any disposition that might be present.

[1912c, 2563]
A certain practical importance may readily be allowed to these types of onset. They are to be met with in their pure form, indeed, in individual cases; we should not have noticed the third and fourth types if they had not in some subjects constituted the sole precipitating causes of the illness. The first type keeps before our eyes the extraordinarily powerful influence of the external world, and the second the no less important influence - which opposes the former one - of the subject's peculiar individuality. Pathology could not do justice to the problem of the precipitating factors in the neuroses so long as it was merely concerned with deciding whether those affections were of an 'endogenous' or 'exogenous' nature. It was bound to meet every observation which pointed to the importance of abstinence (in the widest sense of the word) as a precipitating cause with the objection that other people tolerate the same experiences without falling ill. If, however, it sought to lay stress on the peculiar individuality of the subject as being the essential factor decisive between illness and health, it was obliged to put up with the proviso that people possessing such a peculiarity can remain healthy indefinitely, just so long as they are able to retain that peculiarity. Psycho-analysis has warned us that we must give up the unfruitful contrast between external and internal factors, between experience and constitution, and has taught us that we shall invariably find the cause of the onset of neurotic illness in a particular psychical situation which can be brought about in a variety of ways.

[1912c, 2564]

In further pursuing the discussion of this thesis, are we to consider the nature of the frustration or the peculiar character of those who are affected by it? It is extremely seldom, after all, that frustration is universal and absolute. In order to operate pathogenically it must no doubt affect the mode of satisfaction which alone the subject desires, of which alone he is capable. There are in general very many ways of tolerating deprivation of libidinal satisfaction without falling ill as a result. In the first place, we know people who are able to put up with a deprivation of this kind without being injured: they are not happy, they suffer from longing, but they do not fall ill. Next, we must bear in mind that the sexual instinctual impulses in particular are extraordinarily plastic, if I may so express it. One of them can take the place of another, one of them can take over another's intensity; if the satisfaction of one of them is frustrated by reality, the satisfaction of another can afford complete compensation. They are related to one another like a network of intercommunicating channels filled with a liquid; and this is so in spite of their being subject to the primacy of the genitals - a state of affairs that is not at all easily combined in a single picture. Further, the component instincts of sexuality, as well as the sexual current which is compounded from them, exhibit a large capacity for changing their object, for taking another in its place - and one, therefore, that is more easily attainable. This displaceability and readiness to accept a substitute must operate powerfully against the pathogenic effect of a frustration. Among these protective processes against falling ill owing to deprivation there is one which has gained special cultural significance. It consists in the sexual trend abandoning its aim of obtaining a component or a reproductive pleasure and taking on another which is related genetically to the abandoned one but is itself no longer sexual and must be described as social. We call this process 'sublimation', in accordance with the general estimate that places social aims higher than the sexual ones, which are at bottom self-interested. Sublimation is, incidentally, only a special case of the way in which sexual trends are attached to other, non-sexual ones. We shall have to discuss it again in another connection.

[1916-1917, 3408]
You may now have an impression that deprivation has been reduced to insignificance owing to all these methods of tolerating it. But no, it retains its pathogenic power. The countermeasures are on the whole insufficient. There is a limit to the amount of unsatisfied libido that human beings on the average can put up with. The plasticity or free mobility of the libido is by no means fully preserved in everyone, and sublimation is never able to deal with more than a certain fraction of libido, quite apart from the fact that many people are gifted with only a small amount of capacity to sublimate. The most important of these limitations is evidently that upon the mobility of the libido, since it makes a person's satisfaction depend on the attainment of only a very small number of aims and objects. You have only to recall that an imperfect development of the libido leaves behind it very fertile and perhaps, too, very numerous libidinal fixations to early phases of the organization and of the finding of objects, which are for the most part incapable of real satisfaction, and you will recognize in libidinal fixation the second powerful factor which combines with frustration as the cause of illness. You can declare, as a schematic abbreviation, that libidinal fixation represents the predisposing, internal factor in the aetiology of the neuroses, while frustration represents the accidental, external one.

[1916-1917, 3408]

The importance of the part played by phantasy in the formation of symptoms will be made clear to you by what I have to tell you. I have explained how in the case of frustration the libido cathects regressively the positions which it has given up but to which some quotas of it have remained adhering. I shall not withdraw this or correct it, but I have to insert a connecting link. How does the libido find its way to these points of fixation? All the objects and trends which the libido has given up have not yet been given up in every sense. They or their derivatives are still retained with a certain intensity in phantasies. Thus the libido need only withdraw on to phantasies in order to find the path open to every repressed fixation. These phantasies have enjoyed a certain amount of toleration: they have not come into conflict with the ego, however sharp the contrasts between them may have been, so long as a particular condition is observed. This condition is of a quantitative nature and it is now upset by the backward flow of libido on to the phantasies. As a result of this surplus, the energetic cathexis of the phantasies is so much increased that they begin to raise claims, that they develop a pressure in the direction of becoming realized. But this makes a conflict between them and the ego inevitable. Whether they were previously preconscious or conscious, they are now subjected to repression from the direction of the ego and are at the mercy of attraction from the direction of the unconscious. From what are now unconscious phantasies the libido travels back to their origins in the unconscious - to its own points of fixation.

[1916-1917, 3428]
You will no doubt have observed that in these last discussions I have introduced a fresh factor into the structure of the aetiological chain - namely the quantity, the magnitude, of the energies concerned. We have still to take this factor into account everywhere. A purely qualitative analysis of the aetiological determinants is not enough. Or, to put it another way, a merely dynamic view of these mental processes is insufficient; an economic line of approach is also needed. We must tell ourselves that the conflict between two trends does not break out till certain intensities of cathexis have been reached, even though the determinants for it have long been present so far as their subject-matter is concerned. In the same way, the pathogenic significance of the constitutional factors must be weighed according to how much more of one component instinct than of another is present in the inherited disposition. It may even be supposed that the disposition of all human beings is qualitatively alike and that they differ only owing to these quantitative conditions. The quantitative factor is no less decisive as regards capacity to resist neurotic illness. It is a matter of what quota of unemployed libido a person is able to hold in suspension and of how large a fraction of his libido he is able to divert from sexual to sublimated aims. The ultimate aim of mental activity, which may be described qualitatively as an endeavour to obtain pleasure and avoid displeasure, emerges, looked at from the economic point of view, as the task of mastering the amounts of excitation (mass of stimuli) operating in the mental apparatus and of keeping down their accumulation which creates displeasure.

[1916-1917, 3429]

Even at that time I could not fail to notice that the causation of the illness did not always point to sexual life. One person, it was true, fell ill directly from a sexual noxa; but another did so because he had lost his fortune or had been through an exhausting organic illness. The explanation of these varieties came later, when we gained an insight into the suspected interrelations between the ego and the libido, and the explanation became the more satisfactory the deeper that insight extended. A person only falls ill of a neurosis if his ego has lost the capacity to allocate his libido in some way. The stronger is his ego, the easier will it be for it to carry out that task. Any weakening of his ego from whatever cause must have the same effect as an excessive increase in the claims of the libido and will thus make it possible for him to fall ill of a neurosis. There are other and more intimate relations between the ego and the libido; but these have not yet come within our scope, so I will not bring them up as part of my present explanation. What remains essential and makes things clear to us is that, in every case and no matter how the illness is set going, the symptoms of the neurosis are sustained by the libido and are consequently evidence that it is being employed abnormally.

[1916-1917, 3438]

Of course, the sexual abstinence now so warmly recommended by doctors only has the same importance in generating anxiety states when the libido which is prevented from finding a satisfying discharge is correspondingly strong and has not been dealt with for the greater part by sublimation. Indeed, the decision on whether the outcome is to be illness or not always lies with quantitative factors. Even where what is in question is not illness but the form assumed by a person's character, it is easy to recognize that sexual restriction goes hand in hand with some kind of anxiousness and hesitancy, while intrepidity and impudent daring bring along with them a free indulgence of sexual needs. However much these relations are altered and complicated by a variety of cultural influences, it nevertheless remains true of the average of mankind that anxiety has a close connection with sexual limitation.

[1916-1917, 3449]
If, then, there are children who come some way to meet this education in anxiety, and who go on to find dangers themselves that they have not been warned against, this is sufficiently explained by the fact that they have a greater amount of innate libidinal need in their constitution or have been prematurely spoiled by libidinal satisfaction. It is not to be wondered at if such children include, too, the later neurotics: as we know, what most facilitates the development of a neurosis is an incapacity to tolerate a considerable damming-up of libido over any great length of time. You will observe that here once more the constitutional factor comes into its rights - and these, indeed, we have never sought to dispute. We are only on our guard against those who in its favour neglect all other claims, and who introduce the constitutional factor at points at which the combined results of observation and analysis show that it does not belong or must take the last place. 
[1916-1917, 3454]

Think it over! You have learnt all that is essential about the determinants of falling ill as well as all the factors that come into effect after the patient has fallen ill. Where do these leave room for any therapeutic influence? In the first place there is hereditary disposition. We have not talked about it very often because it is emphatically stressed from other directions and we have nothing new to say about it. But do not suppose that we underestimate it; precisely as therapists we come to realize its power clearly enough. In any case we can do nothing to alter it; we too must take it as something given, which sets a limit to our efforts. Next there is the influence of early experiences in childhood, to which we are in the habit of giving prominence in analysis: they belong to the past and we cannot undo them. Then comes everything that we have summarized as 'real frustration' - the misfortunes of life from which arise deprivation of love, poverty, family quarrels, ill-judged choice of a partner in marriage, unfavourable social circumstances, and the strictness of the ethical standards to whose pressure the individual is subject. Here, to be sure, there would be handles enough for a very effective therapy, but it would have to be of the kind which Viennese folklore attributes to the Emperor Joseph - the benevolent interference of a powerful personage before whose will people bow and difficulties vanish. But who are we, that we should be able to adopt benevolence of this kind as an instrument of our therapy? Poor ourselves and socially powerless, and compelled to earn our livelihood from our medical activity, we are not even in a position to extend our efforts to people without means, as other doctors with other methods of treatment are after all able to do. Our therapy is too time-consuming and too laborious for that to be possible. Perhaps, however, you are clutching at one of the factors I have mentioned and believe that there you have found the point at which our influence can make its attack. If the ethical restrictions demanded by society play a part in the deprivation imposed on the patient, treatment can, after all, give him the courage, or perhaps a direct injunction, to disregard those barriers and achieve satisfaction and recovery while forgoing the fulfilment of an ideal that is exalted, but so often not adhered to, by society. The patient will thus become healthy by 'living a full life' sexually. This, it is true, casts a shadow on analytic treatment for not serving general morality. What it has given to the individual it will have taken from the community. 
[1916-1917, 3475]
With this as a starting-point we go on to make our first important discovery. We learn that, when we try to understand neurotic disorders, by far the greater significance attaches to the sexual instincts; that in fact neuroses are the specific disorders, so to speak, of the sexual function; that in general whether or not a person develops a neurosis depends on the quantity of his libido, and on the possibility of satisfying it and of discharging it through satisfaction; that the form taken by the disease is determined by the way in which the individual passes through the course of development of his sexual function, or, as we put it, by the fixations his libido has undergone in the course of its development; and, further, that by a special, not very simple technique for influencing the mind we are able to throw light on the nature of some groups of neuroses and at the same time to do away with them. Our therapeutic efforts have their greatest success with a certain class of neuroses which proceed from a conflict between the ego-instincts and the sexual instincts. For in human beings it may happen that the demands of the sexual instincts, whose reach of course extends far beyond the individual, seem to the ego to constitute a danger which threatens its self-preservation or its self-esteem. The ego then assumes the defensive, denies the sexual instincts the satisfaction they desire and forces them into those by-paths of substitutive satisfaction which become manifest as nervous symptoms. [1917a, 3609]

For a time psycho-analysis seemed fated to merge into psychology without being able to show why the psychology of the sick differed from that of the normal. In the course of its advance, however, it came up against the problem of dreams, which are abnormal products of the mind created by normal men under regularly recurrent physiological conditions. When psycho-analysis had solved the problem of dreams, it had discovered in unconscious psychical processes the common ground in which the highest and the lowest of mental impulses have their roots and from which spring the most normal as well as the most morbid and erratic of mental productions. The new picture of the workings of the mind began to grow ever clearer and more complete. It was a picture of obscure instinctual forces organic in origin, striving towards inborn aims, and, above them, of an agency comprising more highly organized mental structures - acquisitions of human evolution made under the impact of human history - an agency which has taken over portions of the instinctual impulses, has developed them further or has even directed them towards higher aims, but which in any case binds them firmly and manipulates their energy to suit its own purposes. This higher organization, however, which is known to us as the ego, has rejected another portion of these same elementary instinctual impulses as being unserviceable because they cannot be fitted into the organic unity of the individual or because they rebel against the individual's cultural aims. The ego is not in a position to exterminate these unsubdued mental powers, but it turns its back on them, lets them remain at the lowest psychological level, defends itself from their demands by the energetic erection of protective and antithetical barriers or seeks to come to terms with them by means of substitutive satisfactions. These instincts which have fallen victim to repression - untamed and indestructible, yet inhibited from any kind of activity - together with their primitive mental representatives, constitute the mental underworld, the nucleus of the true unconscious, and are at every moment ready to assert their demands and, by hook or by crook, to force their way forward to satisfaction. To this is due the instability of the proud superstructure of the mind, the emergence at night of the proscribed and repressed material in the form of dreams, and the tendency to fall ill with neuroses and psychoses as soon as the balance of power between the ego and the repressed shifts to the disadvantage of the ego. [1919g, 3703]
It seems to me that we have here an important discovery - namely, that the qualitative factor, the presence of certain neurotic formations, has less practical significance than the quantitative factor, the degree of attention or, more correctly, the amount of cathexis that these structures are able to attract to themselves. Our consideration of the first case, the jealous paranoia, led to a similar estimate of the importance of the quantitative factor, by showing that there also the abnormality essentially consisted in the hypercathexis of the interpretations of someone else's unconscious. We have long known of an analogous fact in the analysis of hysteria. The pathogenic phantasies, derivatives of repressed instinctual impulses, are for a long time tolerated alongside the normal life of the mind, and have no pathogenic effect until by a revolution in the libidinal economy they receive a hypercathexis; not till then does the conflict which leads to the formation of symptoms break out. Thus as our knowledge grows we are increasingly impelled to bring the economic point of view into the foreground. I should also like to throw out the question whether this quantitative factor that I am now dwelling on does not suffice to cover the phenomena which Bleuler and others have lately proposed to name 'switching'. One need only assume that an increase in resistance in the course taken by the psychical current in one direction results in a hypercathexis of another path and thus causes the flow to be switched into that path.

[1922b, 3905]

Psycho-analysis leads to less simple and satisfactory conclusions. What I have to say in this connection has long been familiar and I have nothing new to add. If the ego succeeds in protecting itself from a dangerous instinctual impulse, through, for instance, the process of repression, it has certainly inhibited and damaged the particular part of the id concerned; but it has at the same time given it some independence and has renounced some of its own sovereignty. This is inevitable from the nature of repression, which is, fundamentally, an attempt at flight. The repressed is now, as it were, an outlaw; it is excluded from the great organization of the ego and is subject only to the laws which govern the realm of the unconscious. If, now, the danger-situation changes so that the ego has no reason for fending off a new instinctual impulse analogous to the repressed one, the consequence of the restriction of the ego which has taken place will become manifest. The new impulse will run its course under an automatic influence - or, as I should prefer to say, under the influence of the compulsion to repeat. It will follow the same path as the earlier, repressed impulse, as though the danger-situation that had been overcome still existed. The fixating factor in repression, then, is the unconscious id's compulsion to repeat - a compulsion which in normal circumstances is only done away with by the freely mobile function of the ego. The ego may occasionally manage to break down the barriers of repression which it has itself put up and to recover its influence over the instinctual impulse and direct the course of the new impulse in accordance with the changed danger-situation. But in point of fact the ego very seldom succeeds in doing this: it cannot undo its repressions. It is possible that the way the struggle will go depends upon quantitative relations. In some cases one has the impression that the outcome is an enforced one: the regressive attraction exerted by the repressed impulse and the strength of the repression are so great that the new impulse has no choice but to obey the compulsion to repeat. In other cases we perceive a contribution from another play of forces: the attraction exerted by the repressed prototype is reinforced by a repulsion coming from the direction of difficulties in real life which stand in the way of any different course that might be taken by the new instinctual impulse.

[1926d, 4307]
We see from what has been said that quantitative relations - relations which are not directly observable but which can only be inferred - are what determine whether or not old situations of danger shall be preserved, repressions on the part of the ego maintained and childhood neuroses find a continuation. Among the factors that play a part in the causation of neuroses and that have created the conditions under which the forces of the mind are pitted against one another, three emerge into prominence: a biological, a phylogenetic and a purely psychological factor. [1926d, 4308]

Only let us hold fast to this: the nodal point and pivot of the whole situation is the relative strength of the ego organization. We shall then find it easy to complete our aetiological survey. As what may be called the normal causes of neurotic illness we already know the feebleness of the childhood ego, the task of dealing with the early sexual impulses and the effects of the more or less chance experiences of childhood. Is it not possible, however, that yet other factors play a part, derived from the time before the beginning of the child's life? For instance, an innate strength and unruliness of the instinctual life in the id, which from the outset sets the ego tasks too hard for it? Or a special developmental feebleness of the ego due to unknown reasons? Such factors must of course acquire an aetiological importance, in some cases a transcendent one. We have invariably to reckon with the instinctual strength of the id; if it has developed to excess, the prospects of our therapy are poor. We still know too little of the causes of a developmental inhibition of the ego. These then would be the cases of neurosis with an essentially constitutional basis. Without some such constitutional, congenital favouring factors a neurosis can, no doubt, scarcely come about. [1926e, 4383]

But if the relative feebleness of the ego is the decisive factor for the genesis of a neurosis, it must also be possible for a later physical illness to produce a neurosis, provided that it can bring about an enfeeblement of the ego. And that, once again, is very frequently found. A physical disorder of this kind can affect the instinctual life in the id and increase the strength of the instincts beyond the limit up to which the ego is capable of coping with them. The normal model of such processes is perhaps the alteration in women caused by the disturbances of menstruation and the menopause. Or again, a general somatic illness, indeed an organic disease of the nervous central organ, may attack the nutritional conditions of the mental apparatus and compel it to reduce its functioning and to bring to a halt its more delicate workings, one of which is the maintenance of the ego organization. In all these cases approximately the same picture of neurosis emerges; neurosis always has the same psychological mechanism, but, as we see, a most varied and often very complex aetiology. [1926e, 4383]
(2) For cultural reasons the most intense repression falls upon the sexual instincts; but it is precisely in connection with them that repression most easily miscarries, so that neurotic symptoms are found to be substitutive satisfactions of repressed sexuality. The belief that in man sexual life begins only at puberty is incorrect. On the contrary, signs of it can be detected from the beginning of extra-uterine existence; it reaches a first culminating point at or before the fifth year (‘early period’), after which it is inhibited or interrupted (‘latency period’) until the age of puberty, which is the second climax of its development. This diphasic onset of sexual development seems to be distinctive of the genus Homo. All experiences during the first period of childhood are of the greatest importance to the individual, and in combination with his inherited sexual constitution form the dispositions for the subsequent development of character and disease. It is wrong to make sexuality coincide with ‘genitality’. The sexual instincts pass through a complicated course of development, and it is only at the end of it that the ‘primacy of the genital zones’ is attained. Before this there are a number of ‘pregenital’ organizations of the libido - points at which it may become ‘fixated’ and to which, in the event of subsequent repression, it will return (‘regression’). The infantile fixations of the libido are what determine the form of any later neurosis. Thus the neuroses are to be regarded as inhibitions in the development of the libido. There are no specific causes of nervous disorders; the question whether a conflict finds a healthy solution or leads to a neurotic inhibition of function depends upon quantitative considerations.
[1926f, 4405]

Psycho-analytic work has shown us that it is precisely these frustrations of sexual life which people known as neurotics cannot tolerate. The neurotic creates substitutive satisfactions for himself in his symptoms, and these either cause him suffering in themselves or become sources of suffering for him by raising difficulties in his relations with his environment and the society he belongs to. The latter fact is easy to understand; the former presents us with a new problem. But civilization demands other sacrifices besides that of sexual satisfaction.
[1930a, 4500]
In order to remain faithful to our customary phraseology, we shall have to speak, not of transposing the psychical accent, but of displacing large amounts of cathexis. The question then is whether we are entitled to picture extensive displacements like this from one agency of the mental apparatus to another. It looks like a new hypothesis constructed ad hoc. Yet we may remind ourselves that we have repeatedly (even though not sufficiently often) taken a factor of this kind into account in our attempts at a metapsychological picture of mental events. Thus, for instance, we supposed that the difference between an ordinary erotic object-cathexis and the state of being in love is that in the latter incomparably more cathexis passes over to the object and that the ego empties itself as it were in favour of the object. In studying some cases of paranoia I was able to establish the fact that ideas of persecution are formed early and exist for a long time without any perceptible effect, until, as the result of some particular precipitating event, they receive sufficient amounts of cathexis to cause them to become dominant. The cure, too, of such paranoic attacks would lie not so much in a resolution and correction of the delusional ideas as in a withdrawal from them of the cathexis which has been lent to them. The alternations between melancholia and mania, between a cruel suppression of the ego by the super-ego and a liberation of the ego after that pressure, suggests a shift of cathexis of this kind; such a shift, moreover, would have to be brought in to explain a whole number of phenomena belonging to normal mental life. If this has been done hitherto only to a very limited extent, that is on account of our usual caution - something which deserves only praise. The region in which we feel secure is that of the pathology of mental life; it is here that we make our observations and acquire our convictions. For the present we venture to form a judgement on the normal mind only in so far as we can discern what is normal in the isolations and distortions of the pathological material. When once we have overcome this hesitancy we shall recognize what a large contribution is made to the understanding of mental processes by the static conditions as well as by the dynamic changes in the quantity of energetic cathexis.
[1927d, 4544]

The first of these factors is often unjustly overlooked. However great may be the plasticity of mental life and the possibility of reviving old conditions, not everything can be brought to life again. Some changes seem to be definitive and correspond to scars formed when a process has run its course. On other occasions one has an impression of a general stiffening of mental life; the psychical processes, to which one could very well indicate other paths, seem incapable of abandoning the old ones. But perhaps this is the same thing as what I mentioned just now, only looked at differently. All too often one seems to see that it is only the treatment's lack of the necessary motive force that prevents one from bringing the change about. One particular dependent relation, one special instinctual component, is too powerful in comparison with the opposing forces that we are able to mobilize. This is quite generally true with the psychoses. We understand them well enough to know the point at which the levers should be applied, but they would not be able to move the weight. It is here, indeed, that hope for the future lies: the possibility that our knowledge of the operation of the hormones (you know what they are) may give us the means of successfully combating the quantitative factors of the illnesses: but we are far from that to-day. I realize that the uncertainty in all these matters is a constant instigation towards perfecting analysis and in particular the transference. Beginners in analysis especially are left in doubt in case of a failure whether they should blame the peculiarities of the case or their own clumsy handling of the therapeutic procedure. But, as I have said already, I do not think much can be achieved by efforts in this direction.
[1933a, 4753]
During the study of the sexual functions we have been able to gain a first, preliminary conviction, or rather a suspicion, of two discoveries which will later be found to be important over the whole of our field. Firstly, the normal and abnormal manifestations observed by us (that is, the phenomenology of the subject) need to be described from the point of view of their dynamics and economics (in our case, from the point of view of the quantitative distribution of the libido). And secondly, the aetiology of the disorders which we study is to be looked for in the individual's developmental history - that is to say, in his early life.

[1940a [1938], 4966]

We shall not be disappointed, but, on the contrary, we shall find it entirely intelligible, if we reach the conclusion that the final outcome of the struggle we have engaged in depends on quantitative relations - on the quota of energy we are able to mobilize in the patient to our advantage as compared with the sum of energy of the powers working against us. Here once again God is on the side of the big battalions. It is true that we do not always succeed in winning, but at least we can usually recognize why we have not won. Those who have been following our discussion only out of therapeutic interest will perhaps turn away in contempt after this admission. But here we are concerned with therapy only in so far as it works by psychological means; and for the time being we have no other. The future may teach us to exercise a direct influence, by means of particular chemical substances, on the amounts of energy and their distribution in the mental apparatus. It may be that there are other still undreamt-of possibilities of therapy. But for the moment we have nothing better at our disposal than the technique of psycho-analysis, and for that reason, in spite of its limitations, it should not be despised.

[1940a [1938], 4991]

We need not be at a loss to find an answer to this question. Quantitative disharmonies are what must be held responsible for the inadequacy and sufferings of neurotics. The determining cause of all the forms taken by human mental life, is, indeed, to be sought in the reciprocal action between innate dispositions and accidental experiences. Now a particular instinct may be too strong or too weak innately, or a particular capacity may be stunted or insufficiently developed in life. On the other hand, external impressions and experiences may make demands of differing strength on different people; and what one person's constitution can deal with may prove an unmanageable task for another's. These quantitative differences will determine the variety of the results.

[1940a [1938], 4992]

The material on the other side is equally unambiguous. Twice in the course of individual development certain instincts are considerably reinforced: at puberty, and, in women, at the menopause. We are not in the least surprised if a person who was not neurotic before becomes so at these times. When his instincts were not so strong, he succeeded in taming them; but when they are reinforced he can no longer do so. The repressions behave like dams against the pressure of water. The same effects which are produced by these two physiological reinforcements of instinct, may be brought about in an irregular fashion by accidental causes at any other period of life. Such reinforcements may be set up by fresh traumas, enforced frustrations, or the collateral influence of instincts upon one another. The result is always the same, and it underlines the irresistible power of the quantitative factor in the causation of illness.

[1937c, 5024]

I feel as though I ought to be ashamed of so much ponderous exposition, seeing that everything I have said has long been familiar and self-evident. It is a fact that we have always behaved as if we knew all this; but, for the most part, our theoretical concepts have neglected to attach the same importance to the economic line of approach as they have to the dynamic and topographical ones. My excuse is therefore that I am drawing attention to this neglect.

[1937c, 5024]
Before we decide on an answer to this question, however, we must consider an objection whose force lies in the fact that we are probably predisposed in its favour. Our arguments, it will be said, are all deduced from the processes which take place spontaneously between the ego and the instincts, and they presuppose that analytic therapy can accomplish nothing which does not, under favourable and normal conditions, occur of itself. But is this really so? Is it not precisely the claim of our theory that analysis produces a state which never does arise spontaneously in the ego and that this newly created state constitutes the essential difference between a person who has been analysed and a person who has not? Let us bear in mind what this claim is based on. All repressions take place in early childhood; they are primitive defensive measures taken by the immature, feeble ego. In later years no fresh repressions are carried out; but the old ones persist, and their services continue to be made use of by the ego for mastering the instincts. New conflicts are disposed of by what we call 'after-repression'. We may apply to these infantile repressions our general statement that repressions depend absolutely and entirely on the relative strength of the forces involved and that they cannot hold out against an increase in the strength of the instincts. Analysis, however, enables the ego, which has attained greater maturity and strength, to undertake a revision of these old repressions; a few are demolished, while others are recognized but constructed afresh out of more solid material. These new dams are of quite a different degree of firmness from the earlier ones; we may be confident that they will not give way so easily before a rising flood of instinctual strength. Thus the real achievement of analytic therapy would be the subsequent correction of the original process of repression, a correction which puts an end to the dominance of the quantitative factor.

Applying these remarks to our present problem, I think that the answer to the question of how to explain the variable results of our analytic therapy might well be that we, too, in endeavouring to replace repressions that are insecure by reliable ego-syntonic controls, do not always achieve our aim to its full extent - that is, do not achieve it thoroughly enough. The transformation is achieved, but often only partially: portions of the old mechanisms remain untouched by the work of analysis. It is difficult to prove that this is really so; for we have no other way of judging what happens but by the outcome which we are trying to explain. Nevertheless, the impressions one receives during the work of analysis do not contradict this assumption; indeed, they seem rather to confirm it. But we must not take the clarity of our own insight as a measure of the conviction which we produce in the patient. His conviction may lack 'depth', as one might say; it is always a question of the quantitative factor, which is so easily overlooked. If this is the correct answer to our question, we may say that analysis, in claiming to cure neuroses by ensuring control over instinct, is always right in theory but not always right in practice. And this is because it does not always succeed in ensuring to a sufficient degree the foundations on which a control of instinct is based. The cause of such a partial failure is easily discovered. In the past, the quantitative factor of instinctual strength opposed the ego's defensive efforts; for that reason we called in the work of analysis to help; and now that same factor sets a limit to the efficacy of this new effort. If the strength of the instinct is excessive, the mature ego, supported by analysis, fails in its task, just as the helpless ego failed formerly. Its control over instinct is improved, but it remains imperfect because the transformation in the defensive mechanism is only incomplete. There is nothing surprising in this, since the power of the instruments with which analysis operates is not unlimited but restricted, and the final upshot always depends on the relative strength of the psychical agencies which are struggling with one another.

[1937c, 5024]

[1937c, 5026]
We started from the question of how we can shorten the inconveniently long duration of analytic treatment, and, still with this question of time in mind, we went on to consider whether it is possible to achieve a permanent cure or even to prevent future illness by prophylactic treatment. In doing so, we found that the factors which were decisive for the success of our therapeutic efforts were the influence of traumatic aetiology, the relative strength of the instincts which have to be controlled, and something which we have called an alteration of the ego. Only the second of these factors has been discussed by us in any detail, and in connection with it we have had occasion to recognize the paramount importance of the quantitative factor and to stress the claim of the metapsychological line of approach to be taken into account in any attempt at explanation.

[1937c, 5030]

The effect brought about in the ego by the defences can rightly be described as an ‘alteration of the ego’ if by that we understand a deviation from the fiction of a normal ego which would guarantee unshakable loyalty to the work of analysis. It is easy, then, to accept the fact, shown by daily experience, that the outcome of an analytic treatment depends essentially on the strength and on the depth of root of these resistances that bring about an alteration of the ego. Once again we are confronted with the importance of the quantitative factor, and once again we are reminded that analysis can only draw upon definite and limited amounts of energy which have to be measured against the hostile forces. And it seems as if victory is in fact as a rule on the side of the big battalions.

[1937c, 5034]

How parts of these two classes of instincts combine to fulfil the various vital functions, under what conditions such combinations grow looser or break up, to what disturbances these changes correspond and with what feelings the perceptual scale of the pleasure principle replies to them - these are problems whose elucidation would be the most rewarding achievement of psychological research. For the moment we must bow to the superiority of the forces against which we see our efforts come to nothing. Even to exert a psychical influence on simple masochism is a severe tax upon our powers.

[1937c, 5038]
To break the patient of the habit of masturbation is only one of the new therapeutic tasks which are imposed on the physician who takes the sexual aetiology of the neurosis into account; and it seems that precisely this task, like the cure of any other addiction, can only be carried out in an institution and under medical supervision. Left to himself, the masturbator is accustomed, whenever something happens that depresses him, to return to his convenient form of satisfaction. Medical treatment, in this instance, can have no other aim than to lead the neurasthenic, who has now recovered his strength, back to normal sexual intercourse. For sexual need, when once it has been aroused and has been satisfied for any length of time, can no longer be silenced; it can only be displaced along another path. Incidentally, the same thing applies to all treatments for breaking an addiction. Their success will only be an apparent one, so long as the physician contents himself with withdrawing the narcotic substance from his patients, without troubling about the source from which their imperative need for it springs. 'Habit' is a mere form of words, without any explanatory value. Not everyone who has occasion to take morphia, cocaine, chloral hydrate, and so on, for a period, acquires in this way an 'addiction' to them. Closer enquiry usually shows that these narcotics are meant to serve - directly or indirectly - as a substitute for a lack of sexual satisfaction; and whenever normal sexual life can no longer be re-established, we can count with certainty on the patient's relapse.

Nor, later on, does the University student cease these demonstrations against the compulsion of logic and reality, the dominance of which, however, he feels growing ever more intolerant and unrestricted. A large amount of student 'rags' are a part of this reaction. For man is a 'tireless pleasure-seeker' - I forget where I came across this happy expression - and any renunciation of a pleasure he has once enjoyed comes hard to him. With the cheerful nonsense of his Bierschwefel,¹ for instance, the student tries to rescue his pleasure in freedom of thinking, of which he is being more and more deprived by the schooling of academic instruction. Much later still, indeed, when as a grown man he meets others in scientific congresses and once more feels himself a learner, after the meeting is over there comes the Kneipzeitung,² which distorts the new discoveries into nonsense, and offers him a compensation for the fresh addition to his intellectual inhibition.

As people grow up, then, they cease to play, and they seem to give up the yield of pleasure which they gained from playing. But whoever understands the human mind knows that hardly anything is harder for a man than to give up a pleasure which he has once experienced. Actually, we can never give anything up; we only exchange one thing for another. What appears to be a renunciation is really the formation of a substitute or surrogate. In the same way, the growing child, when he stops playing, gives up nothing but the link with real objects; instead playing, he now phantasies. He builds castles in the air and creates what are called day-dreams. I believe that most people construct phantasies at times in their lives. This is a fact which has long been overlooked and whose importance has therefore not been sufficiently appreciated.

¹ Bierschwefel
² Kneipzeitung
LADIES AND GENTLEMEN, - With the discovery of infantile sexuality and the tracing back of neurotic symptoms to erotic instinctual components we have arrived at some unexpected formulas concerning the nature and purposes of neurotic illnesses. We see that human beings fall ill when, as a result of external obstacles or of an internal lack of adaptation, the satisfaction of their erotic needs in reality frustrated. We see that they then take flight into illness in order that by its help they may find a satisfaction to take the place of what has been frustrated. We recognize that the pathological symptoms constitute a portion of the subject's sexual activity or even the whole of his sexual life, and we find that the withdrawal from reality is the main purpose of the illness but also the main damage caused by it. We suspect that our patients' resistance to recovery is no simple one, but compounded of several motives. Not only does the patient's ego rebel against giving up the repressions by means of which it has risen above its original disposition, but the sexual instincts are unwilling to renounce their substitutive satisfaction so long as it is uncertain whether reality will offer them anything better.

[1910a, 2234]

(2) A general tendency of our mental apparatus, which can be traced back to the economic principle of saving expenditure, seems to find expression in the tenacity with which we hold on to the sources of pleasure at our disposal, and in the difficulty with which we renounce them. With the introduction of the reality principle one species of thought-activity was split off; it was kept free from reality-testing and remained subordinated to the pleasure principle alone.¹ This activity is phantasying, which begins already in children's play, and later, continued as day-dreaming, abandons dependence on real objects.

[1911b, 2555]

This ideal ego is now the target of the self-love which was enjoyed in childhood by the actual ego. The subject's narcissism makes its appearance displaced on to this new ideal ego, which, like the infantile ego, finds itself possessed of every perfection that is of value. As always where the libido is concerned, man has here again shown himself incapable of giving up a satisfaction he had once enjoyed. He is not willing to forgo the narcissistic perfection of his childhood; and when, as he grows up, he is disturbed by the admonitions of others and by the awakening of his own critical judgement, so that he can no longer retain that perfection, he seeks to recover it in the new form of an ego ideal. What he projects before him as his ideal is the substitute for the lost narcissism of his childhood in which he was his own ideal.

[1914c, 2948]

In what, now, does the work which mourning performs consist? I do not think there is anything far-fetched in presenting it in the following way. Reality-testing has shown that the loved object no longer exists, and it proceeds to demand that all libido shall be withdrawn from its attachments to that object. This demand arouses understandable opposition - it is a matter of general observation that people never willingly abandon a libidinal position, not even, indeed, when a substitute is already beckoning to them. This opposition can be so intense that a turning away from reality takes place and a clinging to the object through the medium of a hallucinatory wishful psychosis.¹ Normally, respect for reality gains the day. Nevertheless its orders cannot be obeyed at once. They are carried out bit by bit, at great expense of time and cathectic energy, and in the meantime the existence of the lost object is psychically prolonged. Each single one of the memories and expectations in which the libido is bound to the object is brought up and hypercathected, and detachment of the libido is accomplished in respect of it. Why this compromise by which the command of reality is carried out piecemeal should be so extraordinarily painful is not at all easy to explain in terms of economics. It is remarkable that this painful unpleasure is taken as a matter of course by us. The fact is, however, that when the work of mourning is completed the ego becomes free and uninhibited again.

[1917e, 3042]

Mourning over the loss of something that we have loved or admired seems so natural to the layman that he regards it as self-evident. But to psychologists mourning is a great riddle, one of those phenomena which cannot themselves be explained but to which other obscurities can be traced back. We possess, as it seems, a certain amount of capacity for love - what we call libido - which in the earliest stages of development is directed towards our own ego. Later, though still at a very early time, this libido is diverted from the ego on to objects, which are thus in a sense taken into our ego. If the objects are destroyed or if they are lost to us, our capacity for love (our libido) is once more liberated; and it can then either take other objects instead or can temporarily return to the ego. But why it is that this detachment of libido from its objects should be such a painful process is a mystery to us and we have not hitherto been able to frame any hypothesis to account for it. We only see that libido clings to its objects and will not renounce those that are lost even when a substitute lies ready to hand. Such then is mourning.

All the libido, as well as everything opposing it, is made to converge solely on the relation with the doctor. In this process the symptoms are inevitably divested of libido. In place of his patient's true illness there appears the artificially constructed transference illness, in place of the various unreal objects of the libido there appears a single, and once more imaginary, object in the person of the doctor. But, by the help of he doctor's suggestion, the new struggle around this object is lifted to the highest psychical level: it takes place as a normal mental conflict. Since a fresh repression is avoided, the alienation between ego and libido is brought to an end and the subject's mental unity is restored. When the libido is released once more from its temporary object in the person of the doctor, it cannot return to its earlier objects, but is at the disposal of the ego. The forces against which we have been struggling during our work of therapy are, on the one hand, the ego's antipathy to certain trends of the libido - an antipathy expressed in a tendency to repression - and, on the other hand, the tenacity or adhesiveness of the libido, which dislikes leaving objects that it has once cathexed.

We have treated the difficulty of cultural development as a general difficulty of development by tracing it to the inertia of the libido, to its disinclination to give up an old position for a new one. We are saying much the same thing when we derive the antithesis between civilization and sexuality from the circumstance that sexual love is a relationship between two individuals in which a third can only be superfluous or disturbing, whereas civilization depends on relationships between a considerable number of individuals. When a love-relationship is at its height there is no room left for any interest in the environment; a pair of lovers are sufficient to themselves, and do not even need the child they have in common to make them happy. In no other case does Eros so clearly betray the core of his being, his purpose of making one out of more than one; but when he has achieved this in the proverbial way through the love of two human beings, he refuses to go further.
I will now attempt to discover whether the aetiological conditions for anxiety neurosis which I set out above exhibit the common character that I have just attributed to them. The first aetiological factor I postulated for men was intentional abstinence. Abstinence consists in the withholding of the specific action which ordinarily follows upon libido. Such withholding may have two consequences. In the first place, the somatic excitation accumulates; it is then deflected into other paths, which hold out greater promise of discharge than does the path through the psyche. Thus the libido will in the end sink, and the excitation will manifest itself subcortically as anxiety. In the second place, if the libido is not diminished, or if the somatic excitation is expended, by a short cut, in emissions, or if, in consequence of being forced back, the excitation really ceases, then all kinds of things other than an anxiety neurosis will ensue. Abstinence, then, leads to anxiety neurosis in the manner described above. But it is also the operative agent in my second aetiological group, that of unconsummated excitation. My third group, that of coitus reservatus with consideration for the woman, operates by disturbing the man's psychical preparedness for the sexual process, in that it introduces alongside of the task of mastering the sexual affect another psychical task, one of a deflecting sort. In consequence of this psychical deflection, once more, libido gradually disappears, and the further course of things is then the same as in the case of abstinence. Anxiety in senescence (the male climacteric) requires another explanation. Here there is no diminution of libido; but, as in the female climacteric, so great an increase occurs in the production of somatic excitation that the psyche proves relatively insufficient to master it.

The two last aetiological conditions on our list seem to fall into place without difficulty. The tendency to anxiety in masturbators who have become neurasthenic is explained by the fact that it is very easy for them to pass into a state of 'abstinence' after they have been accustomed for so long to discharging even the smallest quantity of somatic excitation, faulty though that discharge is. Finally, the last case, - the generation of anxiety neurosis through severe illness, overwork, exhausting sick-nursing, etc., - finds an easy interpretation when brought into relation with the effects of coitus interruptus. Here the psyche, on account of its deflection, would seem to be no longer capable of mastering the somatic excitation, a task on which, as we know, it is continuously engaged. We are aware to what a low level libido can sink under these conditions; and we have here a good example of a neurosis which, although it exhibits no sexual aetiology, nevertheless exhibits a sexual mechanism.

For the rest, I might have been spared having to defend myself against these two objections of Löwenfeld's, if my respected opponent had paid greater attention to my paper itself. In it, both these objections are anticipated and answered. I have only been able to repeat here what I said there; and I have even purposely analysed the same cases over again. Moreover the aetiological formulas on which I have just laid weight are contained in the text of my paper. I will repeat them once more. I maintain that there exists a specific aetiological factor for anxiety neurosis which can be replaced in its operation by stock noxae in a QUANTITATIVE sense, but not in a QUALITATIVE one; I furthermore maintain that this specific factor determines above all the FORM of the neurosis; whether a neurotic illness occurs at all depends on the total load upon the nervous system (in proportion to its capacity to carry the load). As a rule the neuroses are overdetermined; that is to say, several factors operate together in their aetiology.
There is a great deal to be said about this. In the first place, Löwenfeld forces upon my theory an inference which it is not bound to accept. To suppose that in the storing-up of somatic sexual excitation the same thing must be happening as in the accumulation of the stimulus which leads to an epileptic convulsion, is to make a far too detailed hypothesis, and I have given no occasion for it; nor is it the only one that presents itself. I need only assume that the nervous system has the power to master a certain amount of somatic sexual excitation even where the latter is deflected from its aim, and that disturbances only occur when that quantum of excitation receives a sudden increment, and Löwenfeld's claim would be disposed of. I have not ventured to extend my theory in that direction, chiefly because I did not expect to find any solid points of support along that path. I should merely like to indicate that we ought not to think of the production of sexual tension independently of its distribution; that in normal sexual life this production, when it is stimulated by a sexual object, takes on a substantially different form from what it does in a state of psychical quiescence; and so on.

[1895f, 360]

If I consider this aetiological formula for anxiety neurosis in detail, I am able to add the following remarks. Whether a special personal constitution (which need not be produced by heredity) is absolutely necessary for the production of an anxiety neurosis, or whether any normal person can be made to have an anxiety neurosis by some given quantitative increase of the specific factor - this I am not able to decide with certainty; but I incline strongly to the latter view. -Hereditary disposition is the most important precondition for anxiety neurosis; but it is not an indispensable one, since it is absent in a class of borderline cases. -The presence of the specific sexual factor can, in the majority of cases, be demonstrated with certainty. In one series of cases (congenital ones) this factor is not separated from the precondition of heredity, but is fulfilled with the help of it. That is to say, in some patients this peculiarity of the vita sexualis - psychical inadequacy in mastering somatic sexual tension - is innate in the form of a stigma whereas ordinarily it is via that peculiarity that they acquire the neurosis. In another class of borderline cases the specific cause is contained in a contributory one. This is when the psychical inadequacy which I have just mentioned is brought about by exhaustion and such causes. All these cases fall into classes which melt into one another and do not form separate categories. In all of them, moreover, we find that the sexual tension undergoes the same vicissitudes; and for most of them the distinction between precondition, specific and auxiliary cause holds good, in conformity with the solution of the aetiological equation which I have given above.

[1895f, 364]

(1) Whether a neurotic illness occurs at all depends upon a quantitative factor - upon the total load on the nervous system as compared with the latter's capacity for resistance. Everything which can keep this quantitative factor below a certain threshold-value, or can bring it back to that level, has a therapeutic effect, since by so doing it keeps the aetiological equation unsatisfied.

[1895f, 365]
There is yet another thing to be noted in the relations between the hereditary precondition and the specific causes of neuroses. Experience shows - what one might have guessed in advance - that in these questions of aetiology one should not neglect the relative quantities, so to speak, of the aetiological influences. But one could not have guessed the following fact, which seems to arise from my observations: namely that heredity and the specific causes can replace each other as regards quantity, that the same pathological effect will be produced by the coincidence of a very serious specific aetiology with a moderate disposition or of a severely loaded nervous heredity with a slight specific influence. And we shall simply be meeting not unexpected extreme instances in this series if we come upon cases of neurosis in which we shall look in vain for an appreciable degree of hereditary disposition, provided that what is lacking is made up for by a powerful specific influence.

[1896a, 371]

The fact that the obsessional ideas and everything derived from them meet with no belief is no doubt because at their first repression the defensive symptom of conscientiousness has been formed and that that symptom, too, acquires an obsessional force. The subject's certainty of having lived a moral life throughout the whole period of his successful defence makes it impossible for him to believe the self-reproach which his obsessional idea involves. Only transitorily, too, on the appearance of a new obsessional idea and occasionally in melancholic states of exhaustion of the ego, do the pathological symptoms of the return of the repressed compel belief. The 'obsessional' character of the psychical formations which I have described here has quite generally nothing to do with attaching belief to them. Nor is it to be confused with the factor which is described as the 'strength' or 'intensity' of an idea. Its essence is rather indissolubility by psychical activity that is capable of being conscious; and this attribute undergoes no change, whether the idea to which the obsession attaches is stronger or weaker, or less or more intensely 'illuminated', or 'cathected with energy' and so on.

[1896b, 394]

The unconscious wishful impulses clearly try to make themselves effective in daytime as well, and the fact of transference, as well as the psychoses, show us that they endeavour to force their way by way of the preconscious system into consciousness and to obtain control of the power of movement. Thus the censorship between the Ucs. and the Pcs., the assumption of whose existence is positively forced upon us by dreams, deserves to be recognized and respected as the watchman of our mental health. Must we not regard it, however, as an act of carelessness on the part of that watchman that it relaxes its activities during the night, allows the suppressed impulses in the Ucs. to find expression, and makes it possible for hallucinatory regression to occur once more? I think not. For even though this critical watchman goes to rest - and we have proof that its slumbers are not deep - it also shuts the door upon the power of movement. No matter what impulses from the normally inhibited Ucs. may prance upon the stage, we need feel no concern; they remain harmless, since they are unable to set in motion the motor apparatus by which alone they might modify the external world. The state of sleep guarantees the security of the citadel that must be guarded. The position is less harmless when what brings about the displacement of forces is not the nightly relaxation in the critical censorship's output of force, but a pathological reduction in that force or a pathological intensification of the unconscious excitations while the preconscious is still cathected and the gateway to the power of movement stands open. When this is so, the watchman is overpowered, the unconscious excitations overwhelm the Pcs., and thence obtain control over our speech and actions; or they forcibly bring about hallucinatory regression and direct the course of the apparatus (which was not designed for their use) by virtue of the attraction exercised by perceptions on the distribution of our psychical energy. To this state of things we give the name of psychosis.

[1900a, 997]
I should have no hesitation in giving the same explanation of the attacks of night terrors accompanied by hallucinations (pavor nocturnus) which are so frequent in children. In this case too it can only be a question of sexual impulses which have not been understood and which have been repudiated. Investigation would probably show a periodicity in the occurrence of the attacks, since an increase in sexual libido can be brought about not only by accidental exciting impressions but also by successive waves of spontaneous developmental processes.

[1900a, 1013]

By analysing dreams we can take a step forward in our understanding of the composition of that most marvellous and most mysterious of all instruments. Only a small step, no doubt; but a beginning. And this beginning will enable us to proceed further with its analysis, on the basis of other structures which must be termed pathological. For illnesses - those, at least, which are rightly named 'functional' - do not presuppose the disintegration of the apparatus or the production of fresh splits in its interior. They are to be explained on a dynamic basis - by the strengthening and weakening of the various components in the interplay of forces, so many of whose effects are hidden from view while functions are normal. I hope to be able to show elsewhere how the compounding of the apparatus out of two agencies makes it possible for the normal mind too to function with greater delicacy than would be possible with only one of them.²

[1900a, 1035]

Various qualifications are required of anyone who is to be beneficially affected by psycho-analysis. To begin with, he must be capable of a psychically normal condition; during periods of confusion or melancholic depression nothing can be accomplished even in cases of hysteria. Furthermore, a certain measure of natural intelligence and ethical development are to be required of him; if the physician has to deal with a worthless character, he soon loses the interest which makes it possible for him to enter profoundly into the patient's mental life. Deep-rooted malformations of character, traits of an actually degenerate constitution, show themselves during treatment as sources of a resistance that can scarcely be overcome. In this respect the constitution of the patient sets a general limit to the curative effect of psychotherapy. If the patient's age is in the neighbourhood of the fifties the conditions for psycho-analysis become unfavourable. The mass of psychical material is then no longer manageable; the time required for recovery is too long; and the ability to undo psychical processes begins to grow weaker.

[1904a, 1560]
The fact that the sexual instinct behaves in general in a self-willed and inflexible fashion is also seen in the results produced by efforts at abstinence. Civilized education may only attempt to suppress the instinct temporarily, till marriage, intending to give it free rein afterwards with the idea of then making use of it. But extreme measures are more successful against it than attempts at moderating it; thus the suppression often goes too far, with the unwished-for result that when the instinct is set free it turns out to be permanently impaired. For this reason complete abstinence in youth is often not the best preparation for marriage for a young man. Women sense this, and prefer among their suitors those who have already proved their masculinity with other women. The harmful results which the strict demand for abstinence before marriage produces in women's natures are quite especially apparent. It is clear that education is far from underestimating the task of suppressing a girl's sensuality till her marriage, for it makes use of the most drastic measures. Not only does it forbid sexual intercourse and set a high premium on the preservation of female chastity, but it also protects the young woman from temptation as she grows up, by keeping her ignorant of all the facts of the part she is to play and by not tolerating any impulse of love in her which cannot lead to marriage. The result is that when the girl's parental authorities suddenly allow her to fall in love, she is unequal to this psychical achievement and enters marriage uncertain of her own feelings. In consequence of this artificial retardation in her function of love, she has nothing but disappointments to offer the man who has saved up all his desire for her. In her mental feelings she is still attached to her parents, whose authority has brought about the suppression of her sexuality; and in her physical behaviour she shows herself frigid, which deprives the man of any high degree of sexual enjoyment. I do not know whether the anaesthetic type of woman exists apart from civilized education, though I consider it probable. But in any case such education actually breeds it, and these women who conceive without pleasure show little willingness afterwards to face the pains of frequent childbirth. In this way, the preparation for marriage frustrates the aims of marriage itself. When later on the retardation in the wife's development has been overcome and her capacity to love is awakened at the climax of her life as a woman, her relations to her husband have long since been ruined; and, as a reward for her previous docility, she is left with the choice between unappeased desire, unfaithfulness or a neurosis.

[1908d, 1959]

I do not think much of the objection that neurotics are a special class of people, marked by an innate disposition that is 'degenerate', from whose childhood life we must not be allowed to infer anything about the childhood of other people. Neurotics are people much like others. They cannot be sharply differentiated from normal people, and in their childhood they are not always easily distinguishable from those who remain healthy in later life. It is one of the most valuable results of our psycho-analytic investigations to have discovered that the neuroses of such people have no special mental content that is peculiar to them, but that, as Jung has expressed it, they fall ill of the same complexes against which we healthy people struggle as well. The only difference is that healthy people know how to overcome those complexes without any gross damage demonstrable in practical life, whereas in nervous cases the suppression of the complexes succeeds only at the price of costly substitutive formations - that is to say, from a practical point of view it is a failure. In childhood neurotic and normal people naturally approximate to each other much more closely than they do in later life, so that I cannot regard it as a methodological error to make use of the communications of neurotics about their childhood for drawing conclusions by analogy about normal childhood life. But since those who later become neurotics very often have in their inborn constitution an especially strong sexual instinct and a tendency to precocity and to a premature expression of that instinct, they make it possible for us to recognize a great deal of infantile activity more sharply and clearly than our capacity for observation (which is in any case a blunted one) would enable us to do in other children. But we shall of course only be able to assess the true value of these communications made by neurotic adults when, following Havelock Ellis's example, we shall have thought it worth while to collect the childhood memories of healthy adults as well.

[1908c, 1967]
Let me at this point state the principal finding to which we have been led by the psycho-
analytic investigation of neurotics. The neuroses have no psychical content that is peculiar to
them and that might not equally be found in healthy people. Or, as Jung has expressed it,
neurotics fall ill of the same complexes against which we healthy people struggle as well.
Whether that struggle ends in health, in neurosis, or in a countervailing superiority of
achievement, depends on quantitative considerations, on the relative strength of the conflicting
forces.
[1910a, 2235]

At the summit of his life, when he was in his early fifties - a time when in women the sexual
characters have already under gone involution and when in men the libido not infrequently
makes a further energetic advance - a new transformation came over him. Still deeper layers of
the contents of his mind became active once more: but this further regression was to the benefit
of his art, which was in the process of becoming stunted. He met the woman who awakened his
memory of his mother's happy smile of sensual rapture; and, influenced by this revived memory,
he recovered the stimulus that guided him at the beginning of his artistic endeavours, at the
time when he modelled the smiling women. He painted the Mona Lisa, the 'St. Anne with Two
Others' and the series of mysterious pictures which are characterized by the enigmatic smile.
With the help of the oldest of all his erotic impulses he enjoyed the triumph of once more
conquering the inhibition in his art. This final development is obscured from our eyes in the
shadows of approaching age. Before this his intellect had soared upwards to the highest
realizations of a conception of the world that left his epoch far behind it.
[1910c, 2302]

The question of why this outburst of homosexual libido overtook the patient precisely at this
period (that is, between the dates of his appointment and of his move to Dresden) cannot be
answered in the absence of more precise knowledge of the story of his life. Generally speaking,
every human being oscillates all through his life between heterosexual and homosexual
feelings, and any frustration or disappointment in the one direction is apt to drive him over into
the other. We know nothing of these factors in Schreber's case, but we must not omit to draw
attention to a somatic factor which may very well have been relevant. At the time of this illness
Dr. Schreber was fifty-one years old, and he had therefore reached an age which is of critical
importance in sexual life. It is a period at which in women the sexual function, after a phase of
intensified activity, enters upon a process of far-reaching involution; nor do men appear to be
exempt from its influence, for men as well as women are subject to a 'climacteric' and to the
susceptibilities to disease which go along with it.¹
[1911c, 2418]
(d) Just as the third type has brought the dispositional determinant before us almost in isolation, so the fourth type, which now follows, draws our attention to another factor, which comes into consideration in every single case and might easily for that very reason be overlooked in a theoretical discussion. We see people fall ill who have hitherto been healthy, who have met with no fresh experience and whose relation to the external world has undergone no change, so that the onset of their illness inevitably gives an impression of spontaneity. A closer consideration of such cases, however, shows us that none the less a change has taken place in them whose importance we must rate very highly as a cause of illness. As a result of their having reached a particular period of life, and in conformity with regular biological processes, the quantity of libido in their mental economy has experienced an increase which is in itself enough to upset the equilibrium of their health and to set up the necessary conditions for a neurosis. It is well known that more or less sudden increases of libido of this kind are habitually associated with puberty and the menopause - with the attainment of a certain age in women; in some people they may in addition be manifested in periodicities that are still unknown. Here the damming-up of libido is the primary factor; it becomes pathogenic as a consequence of a relative frustration on the part of the external world, which would still have granted satisfaction to a smaller claim by the libido. The unsatisfied and dammed-up libido can once again open up paths to regression and kindle the same conflicts which we have demonstrated in the case of absolute external frustration. We are reminded in this way that the quantitative factor should not be left out of account in any consideration of the precipitating causes of illness. All the other factors - frustration, fixation, developmental inhibition - remain ineffective unless they affect a certain amount of libido and bring about a damming-up of libido of a certain height. It is true that we are unable to measure this amount of libido which seems to us indispensable for a pathogenic effect; we can only postulate it after the resulting illness has started. There is only one direction in which we can determine it more precisely. We may assume that it is not a question of an absolute quantity, but of the relation between the quota of libido in operation and the quantity of libido which the individual ego is able to deal with - that is, to hold under tension, to sublimate or to employ directly. For this reason a relative increase in the quantity of libido may have the same effects as an absolute one. An enfeeblement of the ego owing to organic illness or owing to some special demand upon its energy will be able to cause the emergence of neuroses which would otherwise have remained latent in spite of any disposition that might be present.

[1912c, 2563]

Stekel shares with many non-psycho-analytic writers an inclination to reject the morphological differentiations which we have made within the jumble of the neuroses and to lump them all together under one heading - under psychasthenia, perhaps. We have often contradicted him on this, and have held fast to our expectation that the morphologico-clinical differences will prove valuable as indications that have not yet been understood of essentially distinct processes. When he - justly - points out to us that he has regularly found the same complexes present in what are termed neurasthenics as in other neurotics, his argument fails to meet the point at issue. We have long known that the same complexes and conflicts are to be looked for, too, in all normal and healthy people. In fact, we have grown accustomed to attributing to every civilized human being a certain amount of repression of perverse impulses, a certain amount of anal erotism, of homosexuality and so on, as well as a piece of father-complex and mother-complex and of other complexes besides - just as in the chemical analysis of an organic substance we have every hope of finding certain elements: carbon, oxygen, hydrogen, nitrogen and a trace of sulphur. What distinguishes organic substances from one another is the relative amounts of these elements and the way in which the links between them are constituted. In the same way, in the case of normal and neurotic people what is in question is not whether these complexes and conflicts exist but whether they have become pathogenic and, if so, by means of what mechanisms they have become so.

[1912f, 2570]
Naturally this does not answer all the questions that we might ask in connection with this case. On the contrary, the case bristles with further problems-some that have in general not yet become soluble and others which could not be solved owing to the particular circumstances being unfavourable. For instance, why did this lady who was happily married fall in love with her son-in-law? and why did the relief, which might have been possible in other ways, take the form of this mirror-image this projection of her state on to her husband? You must no: think it is otiose or frivolous to raise such questions. We already have some material at our disposal which might possibly serve to answer them. The lady was at a critical age, at which sexual needs in women suffer a sudden and undesired increase; that alone might account for the event. Or it may further have been that her excellent and faithful husband had for some years no longer enjoyed the sexual capacity which the well-preserved woman required for her satisfaction. Experience has shown us that it is precisely men in this position, whose faithfulness can consequently be taken for granted, who are distinguished by treating their wives with unusual tenderness, and by showing particular forbearance for their nervous troubles. Or, again, it may not be without significance that the object of this pathogenic love was precisely the young husband of one of her daughters. A powerful erotic tie with a daughter, which goes back in the last resort to the mother's sexual constitution, often finds a way of persisting in a transformation of this sort. In this connection I may perhaps remind you that the relation between mother-in-law and son-in-law has been regarded from the earliest times of the human race as a particularly awkward one and that among primitive people it has given rise to very powerful taboo regulations and 'avoidances'. The relation is frequently excessive by civilized standards both in a positive and negative direction. Which of these three factors became operative in our case, or whether two of them or perhaps all three came together, I cannot, it is true, tell you; but that is only because I was not permitted to continue the analysis of the case for more than two sessions.

[1916-1917, 3335]

You will no doubt have observed that in these last discussions I have introduced a fresh factor into the structure of the aetiological chain - namely the quantity, the magnitude, of the energies concerned. We have still to take this factor into account everywhere. A purely qualitative analysis of the aetiological determinants is not enough. Or, to put it another way, a merely dynamic view of these mental processes is insufficient; an economic line of approach is also needed. We must tell ourselves that the conflict between two trends does not break out till certain intensities of cathectic have been reached, even though the determinants for it have long been present so far as their subject-matter is concerned. In the same way, the pathogenic significance of the constitutional factors must be weighed according to how much more of one component instinct than of another is present in the inherited disposition. It may even be supposed that the disposition of all human beings is qualitatively alike and that they differ only owing to these quantitative conditions. The quantitative factor is no less decisive as regards capacity to resist neurotic illness. It is a matter of what quota of unemployed libido a person is able to hold in suspension and of how large a fraction of his libido he is able to divert from sexual to sublimated aims. The ultimate aim of mental activity, which may be described qualitatively as an endeavour to obtain pleasure and avoid unpleasure, emerges, looked at from the economic point of view, as the task of mastering the amounts of excitation (mass of stimuli) operating in the mental apparatus and of keeping down their accumulation which creates unpleasure.

[1916-1917, 3429]
The fact of there being a connection between sexual restraint and anxiety states is, so far as I know, no longer disputed even by physicians who have no contact with psycho-analysis. But I can well believe that an attempt is made to reverse the relation and to put forward the view that the people concerned are such as are already inclined to apprehensiveness and for that reason practise restraint in sexual matters as well. This, however, is decisively contradicted by the behaviour of women, whose sexual activity is essentially of a passive nature - is determined, that is to say, by their treatment by the man. The more passionate a woman is - the more inclined, therefore, to sexual intercourse and the more capable of being satisfied - the more certain she is to react with manifestations of anxiety to a man's impotence or to coitus interruptus, whereas in the case of anaesthetic women or those without much libido such ill-treatment plays a far smaller part.

[1916-1917, 3449]

Of course, the sexual abstinence now so warmly recommended by doctors only has the same importance in generating anxiety states when the libido which is prevented from finding a satisfying discharge is correspondingly strong and has not been dealt with for the greater part by sublimation. Indeed, the decision on whether the outcome is to be illness or not always lies with quantitative factors. Even where what is in question is not illness but the form assumed by a person's character, it is easy to recognize that sexual restriction goes hand in hand with some kind of anxiousness and hesitancy, while intrepidity and impudent daring bring along with them a free indulgence of sexual needs. However much these relations are altered and complicated by a variety of cultural influences, it nevertheless remains true of the average of mankind that anxiety has a close connection with sexual limitation.

[1916-1917, 3449]

I am far from having told you of all the observations that speak in favour of the genetic relation I have asserted to exist between libido and anxiety. Among them, for instance, is the influence on anxiety disorders of certain phases of life to which, as in the case of puberty and the time of the menopause, a considerable increase in the production of libido may be attributed. In some states of excitement, too, it is possible to observe directly a mixture of libido and anxiety and the final replacement of libido by anxiety. The impression one gains from all these facts is twofold: first, that what is in question is an accumulation of libido which is kept away from its normal employment, and secondly, that here we are entirely in the sphere of somatic processes. How anxiety arises from libido is not at first discernible; we can only recognize that libido is absent and that anxiety is observed in its place.

[1916-1917, 3450]

If, then, there are children who come some way to meet this education in anxiety, and who go on to find dangers themselves that they have not been warned against, this is sufficiently explained by the fact that they have a greater amount of innate libidinal need in their constitution or have been prematurely spoiled by libidinal satisfaction. It is not to be wondered at if such children include, too, the later neurotics: as we know, what most facilitates the development of a neurosis is an incapacity to tolerate a considerable damming-up of libido over any great length of time. You will observe that here once more the constitutional factor comes into its rights - and these, indeed, we have never sought to dispute. We are only on our guard against those who in its favour neglect all other claims, and who introduce the constitutional factor at points at which the combined results of observation and analysis show that it does not belong or must take the last place.

[1916-1917, 3454]
I will digress for a moment to ask if you know what is meant by a causal therapy. That is how we describe procedure which does not take the symptoms of an illness as its point of attack but sets about removing its *causes*. Well, then, is our psycho-analytic method a causal therapy or not? The reply is not a simple one, but it may perhaps give us an opportunity of realizing the worthlessness of a question framed in this way. In so far as analytic therapy does not make it its first task to remove the symptoms, it is behaving like a causal therapy. In another respect, you may say, it is not. For we long ago traced the causal chain back through the repressions to the instinctual dispositions, their relative intensities in the constitution and the deviations in the course of their development. Supposing, now, that it was possible, by some chemical means, perhaps, to interfere in this mechanism, to increase or diminish the quantity of libido present at a given time or to strengthen one instinct at the cost of another - this then would be a causal therapy in the true sense of the word, for which our analysis would have carried out the indispensable preliminary work of reconnaissance. At present, as you know, there is no question of any such method of influencing libidinal processes; with our psychical therapy we attack at a different point in the combination - not exactly at what we know are the roots of the phenomena, but nevertheless far enough away from the symptoms, at a point which has been made accessible to us by some very remarkable circumstances.

With this as a starting-point we go on to make our first important discovery. We learn that, when we try to understand neurotic disorders, by far the greater significance attaches to the sexual instincts; that in fact neuroses are the specific disorders, so to speak, of the sexual function; that in general whether or not a person develops a neurosis depends on the quantity of his libido, and on the possibility of satisfying it and of discharging it through satisfaction; that the form taken by the disease is determined by the way in which the individual passes through the course of development of his sexual function, or, as we put it, by the fixations his libido has undergone in the course of its development; and, further, that by a special, not very simple technique for influencing the mind we are able to throw light on the nature of some groups of neuroses and at the same time to do away with them. Our therapeutic efforts have their greatest success with a certain class of neuroses which proceed from a conflict between the ego-instincts and the sexual instincts. For in human beings it may happen that the demands of the sexual instincts, whose reach of course extends far beyond the individual, seem to the ego to constitute a danger which threatens its self-preservation or its self-esteem. The ego then assumes the defensive, denies the sexual instincts the satisfaction they desire and forces them into those by-paths of substitutive satisfaction which become manifest as nervous symptoms.
For a time psycho-analysis seemed fated to merge into psychology without being able to show why the psychology of the sick differed from that of the normal. In the course of its advance, however, it came up against the problem of dreams, which are abnormal products of the mind created by normal men under regularly recurrent physiological conditions. When psycho-analysis had solved the problem of dreams, it had discovered in unconscious psychical processes the common ground in which the highest and the lowest of mental impulses have their roots and from which spring the most normal as well as the most morbid and erratic of mental productions. The new picture of the workings of the mind began to grow ever clearer and more complete. It was a picture of obscure instinctual forces organic in origin, striving towards inborn aims, and, above them, of an agency comprising more highly organized mental structures - acquisitions of human evolution made under the impact of human history -, an agency which has taken over portions of the instinctual impulses, has developed them further or has even directed them towards higher aims, but which in any case binds them firmly and manipulates their energy to suit its own purposes. This higher organization, however, which is known to us as the ego, has rejected another portion of these same elementary instinctual impulses as being unserviceable because they cannot be fitted into the organic unity of the individual or because they rebel against the individual's cultural aims. The ego is not in a position to exterminate these unsubdued mental powers, but it turns its back on them, lets them remain at the lowest psychological level, defends itself from their demands by the energetic erection of protective and antithetical barriers or seeks to come to terms with them by means of substitutive satisfactions. These instincts which have fallen victim to repression - untamed and indestructible, yet inhibited from any kind of activity - together with their primitive mental representatives, constitute the mental underworld, the nucleus of the true unconscious, and are at every moment ready to assert their demands and, by hook or by crook, to force their way forward to satisfaction. To this is due the instability of the proud superstructure of the mind, the emergence at night of the proscribed and repressed material in the form of dreams, and the tendency to fall ill with neuroses and psychoses as soon as the balance of power between the ego and the repressed shifts to the disadvantage of the ego.

Only let us hold fast to this: the nodal point and pivot of the whole situation is the relative strength of the ego organization. We shall then find it easy to complete our aetiological survey. As what may be called the normal causes of neurotic illness we already know the feebleness of the childhood ego, the task of dealing with the early sexual impulses and the effects of the more or less chance experiences of childhood. Is it not possible, however, that yet other factors play a part, derived from the time before the beginning of the child's life? For instance, an innate strength and unruliness of the instinctual life in the id, which from the outset sets the ego tasks too hard for it? Or a special developmental feebleness of the ego due to unknown reasons? Such factors must of course acquire an aetiological importance, in some cases a transcendent one. We have invariably to reckon with the instinctual strength of the id; if it has developed to excess, the prospects of our therapy are poor. We still know too little of the causes of a developmental inhibition of the ego. These then would be the cases of neurosis with an essentially constitutional basis. Without some such constitutional, congenital favouring factors a neurosis can, no doubt, scarcely come about.

[1919g, 3703]

[1926e, 4383]
But if the relative feebleness of the ego is the decisive factor for the genesis of a neurosis, it must also be possible for a later physical illness to produce a neurosis, provided that it can bring about an enfeeblement of the ego. And that, once again, is very frequently found. A physical disorder of this kind can affect the instinctual life in the id and increase the strength of the instincts beyond the limit up to which the ego is capable of coping with them. The normal model of such processes is perhaps the alteration in women caused by the disturbances of menstruation and the menopause. Or again, a general somatic illness, indeed an organic disease of the nervous central organ, may attack the nutritional conditions of the mental apparatus and compel it to reduce its functioning and to bring to a halt its more delicate workings, one of which is the maintenance of the ego organization. In all these cases approximately the same picture of neurosis emerges; neurosis always has the same psychological mechanism, but, as we see, a most varied and often very complex aetiology.

[1926e, 4383]

Compared with the other psychotherapeutic procedures psycho-analysis is beyond any doubt the most powerful. It is just and fair, too, that this should be so for it is also the most laborious and time-consuming; it would not be used on slight cases. In suitable cases it is possible by its means to get rid of disturbances and bring about changes for which in pre-analytic times one would not have ventured to hope. But it has its very appreciable limits. The therapeutic ambition of some of my adherents has made the greatest efforts to overcome these obstacles so that every sort of neurotic disorder might be curable by psycho-analysis. They have endeavoured to compress the work of analysis into a shorter duration, to intensify transference so that it may be able to overcome any resistance, to unite other forms of influence with it so as to compel a cure. These efforts are certainly praiseworthy, but, in my opinion, they are vain. They bring with them, too, a danger of being oneself forced away from analysis and drawn into a boundless course of experimentation. The expectation that every neurotic phenomenon can be cured may, I suspect, be derived from the layman's belief that the neuroses are something quite unnecessary which have no right whatever to exist. Whereas in fact they are severe, constitutionally fixed illnesses, which rarely restrict themselves to only a few attacks but persist as a rule over long periods or throughout life. Our analytic experience that they can be extensively influenced, if the historical precipitating causes and accidental auxiliary factors of the illness can be dealt with, has led us to neglect the constitutional factor in our therapeutic practice, and in any case we can do nothing about it; but in theory we ought always to bear it in mind. The radical inaccessibility of the psychoses to analytic treatment should, in view of their close relationship to the neuroses, restrict our pretensions in regard to these latter. The therapeutic effectiveness of psycho-analysis remains cramped by a number of weighty and scarcely assailable factors. In the case of children, where one might count on the greatest successes, the difficulties are the external ones connected with their relation to their parents, though these difficulties are after all a necessary part of being a child. In the case of adults the difficulties arise in the first instance from two factors: the amount of psychical rigidity present and the form of the illness with all that covers in the way of deeper determinants.

[1933a, 4752]
And now let us enquire about latency, which, in view of the analogy, is bound to interest us especially. A trauma in childhood may be followed immediately by a neurotic outbreak, an infantile neurosis, with an abundance of efforts at defence, and accompanied by the formation of symptoms. This neurosis may last a considerable time and cause marked disturbances, but it may also run a latent course and be overlooked. As a rule defence retains the upper hand in it; in any case alterations of the ego, comparable to scars, are left behind. It is only rarely that an infantile neurosis continues without interruption into an adult one. Far more often it is succeeded by a period of apparently undisturbed development - a course of things which is supported or made possible by the intervention of the physiological period of latency. Not until later does the change take place with which the definitive neurosis becomes manifest as a belated effect of the trauma. This occurs either at the irruption of puberty or some while later. In the former case it happens because the instincts, intensified by physical maturation, are able now to take up the struggle again in which they were at first defeated by the defence. In the latter case it happens because the reactions and alterations of the ego brought about by the defence now prove a hindrance in dealing with the new tasks of life, so that severe conflicts come about between the demands of the real external world and the ego, which seeks to maintain the organization which it has painstakingly achieved in its defensive struggle. The phenomenon of a latency of the neurosis between the first reactions to the trauma and the later outbreak of the illness must be regarded as typical. This latter illness may also be looked upon as an attempt at cure - as an effort once more to reconcile with the rest those portions of the ego that have been split off by the influence of the trauma and to unite them into a powerful whole vis-à-vis the external world. An attempt of this kind seldom succeeds, however, unless the work of analysis comes to its help, and even then not always; it ends often enough in a complete devastation or fragmentation of the ego or in its being overwhelmed by the portion which was early split off and which is dominated by the trauma. 

[1939a, 4902]

We need not be at a loss to find an answer to this question. Quantitative disharmonies are what must be held responsible for the inadequacy and sufferings of neurotics. The determining cause of all the forms taken by human mental life, is, indeed, to be sought in the reciprocal action between innate dispositions and accidental experiences. Now a particular instinct may be too strong or too weak innately, or a particular capacity may be stunted or insufficiently developed in life. On the other hand, external impressions and experiences may make demands of differing strength on different people; and what one person's constitution can deal with may prove an unmanageable task for another's. These quantitative differences will determine the variety of the results. 

[1940a [1938], 4992]
Every analyst will have treated a few cases which have had this gratifying outcome. He has succeeded in clearing up the patient's neurotic disturbance, and it has not returned and has not been replaced by any other such disturbance. Nor are we without some insight into the determinants of these successes. The patient's ego had not been noticeably altered and the aetiology of his disturbance had been essentially traumatic. The aetiology of every neurotic disturbance is, after all, a mixed one. It is a question either of the instincts being excessively strong - that is to say, recalcitrant to taming by the ego - or of the effects of early (i.e. premature) traumas which the immature ego was unable to master. As a rule there is a combination of both factors, the constitutional and the accidental. The stronger the constitutional factor, the more readily will a trauma lead to a fixation and leave behind a developmental disturbance; the stronger the trauma, the more certainly will its injurious effects become manifest even when the instinctual situation is normal. There is no doubt that an aetiology of the traumatic sort offers by far the more favourable field for analysis. Only when a case is a predominantly traumatic one will analysis succeed in doing what it is so superlatively able to do; only then will it, thanks to having strengthened the patient's ego, succeed in replacing by a correct solution the inadequate decision made in his early life. Only in such cases can one speak of an analysis having been definitively ended. In them, analysis has done all that it should and does not need to be continued. It is true that, if the patient who has been restored in this way never produces another disorder calling for analysis, we do not know how much his immunity may not be due to a kind fate which has spared him ordeals that are too severe.

A constitutional strength of instinct and an unfavourable alteration of the ego acquired in its defensive struggle in the sense of its being dislocated and restricted - these are the factors which are prejudicial to the effectiveness of analysis and which may make its duration interminable. One is tempted to make the first factor - strength of instinct - responsible as well for the emergence of the second - the alteration of the ego; but it seems that the latter too has an aetiology of its own. And, indeed, it must be admitted that our knowledge of these matters is as yet insufficient. They are only now becoming the subject of analytic study. In this field the interest of analysts seems to me to be quite wrongly directed. Instead of an enquiry into how a cure by analysis comes about (a matter which I think has been sufficiently elucidated) the question should be asked of what are the obstacles that stand in the way of such a cure.
Of the three factors which we have recognized as being decisive for the success or otherwise
of analytic treatment - the influence of traumas, the constitutional strength of the instincts and
alterations of the ego - what concerns us here is only the second, the strength of the instincts. A
moment's reflection raises a doubt whether the restrictive use of the adjective 'constitutional' (or
'congenital') is essential. However true it may be that the constitutional factor is of decisive
importance from the very beginning, it is nevertheless conceivable that a reinforcement of
instinct coming later in life might produce the same effects. If so, we should have to modify our
formula and say 'the strength of the instincts at the time' instead of 'the constitutional
strength of the instincts'. The first of our questions was: 'Is it possible by means of analytic therapy to
dispose of a conflict between an instinct and the ego, or of a pathogenic instinctual demand
upon the ego, permanently and definitively?' To avoid misunderstanding it is not unnecessary,
perhaps, to explain more exactly what is meant by 'permanently disposing of an instinctual
demand'. Certainly not 'causing the demand to disappear so that nothing more is ever heard
from it again'. This is in general impossible, nor is it at all to be desired. No, we mean something
else, something which may be roughly described as a 'taming' of the instinct. That is to say, the
instinct is brought completely into the harmony of the ego, becomes accessible to all the
influences of the other trends in the ego and no longer seeks to go its independent way to
satisfaction. If we are asked by what methods and means this result is achieved, it is not easy to
find an answer. We can only say: 'So muss denn doch die Hexe dran!' - the Witch
Metapsychology. Without metapsychological speculation and theorizing - I had almost said
'phantasying' - we shall not get another step forward. Unfortunately, here as elsewhere, what
our Witch reveals is neither very clear nor very detailed. We have only a single clue to start from
- though it is a clue of the highest value - namely, the antithesis between the primary and the
secondary processes; and to that antithesis I shall at this point turn.
[1937c, 5022]

If now we take up our first question once more, we find that our new line of approach
inevitably leads us to a particular conclusion. The question was whether it is possible to dispose
of an instinctual conflict permanently and definitively - i.e. to 'tame' an instinctual demand in that
fashion. Formulated in these terms, the question makes no mention at all of the strength of the
instinct; but it is precisely on this that the outcome depends. Let us start from the assumption
that what analysis achieves for neurotics is nothing other than what normal people bring about
for themselves without its help. Everyday experience, however, teaches us that in a normal
person any solution of an instinctual conflict only holds good for a particular strength of instinct,
or, more correctly, only for a particular relation between the strength of the instinct and the
strength of the ego.¹ If the strength of the ego diminishes, whether through illness or exhaustion,
or from some similar cause, all the instincts which have so far been successfully tamed may
renew their demands and strive to obtain substitutive satisfactions in abnormal ways.²
Irrefutable proof of this statement is supplied by our nightly dreams; they react to the sleeping
attitude assumed by the ego with an awakening of instinctual demands.
[1937c, 5023]

¹ Or, to be perfectly accurate, where that relation falls within certain limits.
[1937c, 5023]
The material on the other side is equally unambiguous. Twice in the course of individual development certain instincts are considerably reinforced: at puberty, and, in women, at the menopause. We are not in the least surprised if a person who was not neurotic before becomes so at these times. When his instincts were not so strong, he succeeded in taming them; but when they are reinforced he can no longer do so. The repressions behave like dams against the pressure of water. The same effects which are produced by these two physiological reinforcements of instinct, may be brought about in an irregular fashion by accidental causes at any other period of life. Such reinforcements may be set up by fresh traumas, enforced frustrations, or the collateral influence of instincts upon one another. The result is always the same, and it underlines the irresistible power of the quantitative factor in the causation of illness. [1937c, 5024]

We started from the question of how we can shorten the inconveniently long duration of analytic treatment, and, still with this question of time in mind, we went on to consider whether it is possible to achieve a permanent cure or even to prevent future illness by prophylactic treatment. In doing so, we found that the factors which were decisive for the success of our therapeutic efforts were the influence of traumatic aetiology, the relative strength of the instincts which have to be controlled, and something which we have called an alteration of the ego. Only the second of these factors has been discussed by us in any detail, and in connection with it we have had occasion to recognize the paramount importance of the quantitative factor and to stress the claim of the metapsychological line of approach to be taken into account in any attempt at explanation. [1937c, 5030]
The reproaches against her father for having made her ill, together with the self-reproach underlying them, the leucorrhoea, the playing with the reticule, the bed-wetting after her sixth year, the secret which she would not allow the doctors to tear from her - the circumstantial evidence of her having masturbated in childhood seems to me complete and without a flaw. In the present case I had begun to suspect the masturbation when she had told me of her cousin’s gastric pains, and had then identified herself with her by complaining for days together of similar painful sensations. It is well known that gastric pains occur especially often in those who masturbate. According to a personal communication made to me by Wilhelm Fliess, it is precisely gastralgias of this character which can be interrupted by an application of cocaine to the ‘gastric spot’ discovered by him in the nose, and which can be cured by the cauterization of the same spot. In confirmation of my suspicion Dora gave me two facts from her conscious knowledge: she herself had frequently suffered from gastric pains, and she had good reasons for believing that her cousin was a masturbator. It is a very common thing for patients to recognize in other people a connection which, on account of their emotional resistances, they cannot perceive in themselves. And, indeed, Dora no longer denied my supposition, although she still remembered nothing. Even the date which she assigned to the bed-wetting, when she said that it lasted ‘till a short time before the appearance of the nervous asthma’, appears to me to be of clinical significance. Hysterical symptoms hardly ever appear so long as children are masturbating, but only afterwards, when a period of abstinence has set in;¹ they form a substitute for masturbatory satisfaction, the desire for which continues to persist in the unconscious until another and more normal kind of satisfaction appears - where that is still attainable. For upon whether it is still attainable or not depends the possibility of a hysteria being cured by marriage and normal sexual intercourse. But if the satisfaction afforded in marriage is again removed - as it may be owing to coitus interruptus, psychological estrangement, or other causes - then the libido flows back again into its old channel and manifests itself once more in hysterical symptoms.

[1905e, 1415]

Nor do I know whether Herr K. would have done any better if it had been revealed to him that the slap Dora gave him by no means signified a final ‘No’ on her part, but that it expressed the jealousy which had lately been roused in her, while her strongest feelings were still on his side. If he had disregarded that first ‘No’, and had continued to press his suit with a passion which left room for no doubts, the result might very well have been a triumph of the girl’s affection for him over all her internal difficulties. But I think she might just as well have been merely provoked into satisfying her craving for revenge upon him all the more thoroughly. It is never possible to calculate towards which side the decision will incline in such a conflict of motives: whether towards the removal of the repression or towards its reinforcement. Incapacity for meeting a real erotic demand is one of the most essential features of a neurosis. Neurotics are dominated by the opposition between reality and phantasy. If what they long for the most intensely in their phantasies is presented to them in reality, they none the less flee from it; and they abandon themselves to their phantasies the most readily where they need no longer fear to see them realized. Nevertheless, the barrier erected by repression can fall before the onslaught of a violent emotional excitement produced by a real cause; it is possible for a neurosis to be overcome by reality. But we have no general means of calculating through what person or what event such a cure can be effected.¹

[1905e, 1445]
Think it over! You have learnt all that is essential about the determinants of falling ill as well as all the factors that come into effect after the patient has fallen ill. Where do these leave room for any therapeutic influence? In the first place there is hereditary disposition. We have not talked about it very often because it is emphatically stressed from other directions and we have nothing new to say about it. But do not suppose that we underestimate it; precisely as therapists we come to realize its power clearly enough. In any case we can do nothing to alter it; we too must take it as something given, which sets a limit to our efforts. Next there is the influence of early experiences in childhood, to which we are in the habit of giving prominence in analysis: they belong to the past and we cannot undo them. Then comes everything that we have summarized as 'real frustration' - the misfortunes of life from which arise deprivation of love, poverty, family quarrels, ill-judged choice of a partner in marriage, unfavourable social circumstances, and the strictness of the ethical standards to whose pressure the individual is subject. Here, to be sure, there would be handles enough for a very effective therapy, but it would have to be of the kind which Viennese folklore attributes to the Emperor Joseph - the benevolent interference of a powerful personage before whose will people bow and difficulties vanish. But who are we, that we should be able to adopt benevolence of this kind as an instrument of our therapy? Poor ourselves and socially powerless, and compelled to earn our livelihood from our medical activity, we are not even in a position to extend our efforts to people without means, as other doctors with other methods of treatment are after all able to do. Our therapy is too time-consuming and too laborious for that to be possible. Perhaps, however, you are clutching at one of the factors I have mentioned and believe that there you have found the point at which our influence can make its attack. If the ethical restrictions demanded by society play a part in the deprivation imposed on the patient, treatment can, after all, give him the courage, or perhaps a direct injunction, to disregard those barriers and achieve satisfaction and recovery while forgoing the fulfilment of an ideal that is exalted, but so often not adhered to, by society. The patient will thus become healthy by 'living a full life' sexually. This, it is true, casts a shadow on analytic treatment for not serving general morality. What it has given to the individual it will have taken from the community.

While he was at his secondary school the Fates provided him with a remarkable opportunity of reviving his wolf phobia, and of using the relation which lay behind it as an occasion for severe inhibitions. The master who taught his form Latin was called Wolf. From the very first he felt cowed by him, and he was once taken severely to task by him for having made a stupid mistake in a piece of Latin translation. From that time on he could not get free from a paralysing fear of this master, and it was soon extended to other masters besides. But the occasion on which he made his blunder in the translation was also to the purpose. He had to translate the Latin word 'filius', and he did it with the French word 'fils' instead of with the corresponding word from his own language. The wolf, in fact, was still his father.

[1916-1917, 3475]

[1918b, 3530]
Every analyst will have treated a few cases which have had this gratifying outcome. He has succeeded in clearing up the patient's neurotic disturbance, and it has not returned and has not been replaced by any other such disturbance. Nor are we without some insight into the determinants of these successes. The patient's ego had not been noticeably altered and the aetiology of his disturbance had been essentially traumatic. The aetiology of every neurotic disturbance is, after all, a mixed one. It is a question either of the instincts being excessively strong - that is to say, recalcitrant to taming by the ego - or of the effects of early (i.e. premature) traumas which the immature ego was unable to master. As a rule there is a combination of both factors, the constitutional and the accidental. The stronger the constitutional factor, the more readily will a trauma lead to a fixation and leave behind a developmental disturbance; the stronger the trauma, the more certainly will its injurious effects become manifest even when the instinctual situation is normal. There is no doubt that an aetiology of the traumatic sort offers by far the more favourable field for analysis. Only when a case is a predominantly traumatic one will analysis succeed in doing what it is so superlatively able to do; only then will it, thanks to having strengthened the patient's ego, succeed in replacing by a correct solution the inadequate decision made in his early life. Only in such cases can one speak of an analysis having been definitively ended. In them, analysis has done all that it should and does not need to be continued. It is true that, if the patient who has been restored in this way never produces another disorder calling for analysis, we do not know how much his immunity may not be due to a kind fate which has spared him ordeals that are too severe. [1937c, 5018]
I have now led you into the region in which the next advances in the work of analysis are to be expected. Since we have ventured to operate with the concept of ego-libido the narcissistic neuroses have become accessible to us: the task before us is to arrive at a dynamic elucidation of these disorders and at the same time to complete our knowledge of mental life by coming to understand the ego. The ego-psychology after which we are seeking must not be based on the data of our self-perceptions but (as in the case of the libido) on the analysis of disturbances and disruptions of the ego. It is likely that we shall have a low opinion of our present knowledge of the vicissitudes of the libido, which we have gained from a study of the transference neuroses, when we have achieved this greater task. But hitherto we have not made much progress with it. The narcissistic neuroses can scarcely be attacked with the technique that has served us with the transference neuroses. You will soon learn why. What always happens with them is that, after proceeding for a short distance, we come up against a wall which brings us to a stop. Even with the transference neuroses, as you know, we met with barriers of resistance, but we were able to demolish them bit by bit. In the narcissistic neuroses the resistance is unconquerable; at the most, we are able to cast an inquisitive glance over the top of the wall and spy out what is going on on the other side of it. Our technical methods must accordingly be replaced by others; and we do not know yet whether we shall succeed in finding substitute. Nevertheless, we have no lack of material with these patients either. They make a large number of remarks, even if they do not answer our questions, and for the time being it is our business to interpret these remarks with the help of the understanding we have gained from the symptoms of the transference neuroses. The agreement is great enough to guarantee us some initial advantage. It remains to be seen how far this technique will take us.

[1916-1917, 3467]

There are, however, other forms of illness in which, in spite of the conditions being the same, our therapeutic procedure is never successful. In them, too, it had been a question of an original conflict between the ego and the libido which led to repression - though this may call for a different topographical description; in them, too, it is possible to trace the points in the patient's life at which the repressions occurred; we make use of the same procedure, are ready to make the same promises and give the same help by the offer of anticipatory ideas; and once again the lapse of time between the repressions and the present day favours a different outcome to the conflict. And yet we do not succeed in lifting a single resistance or getting rid of a single repression. These patients, paranoids, melancholics, sufferers from dementia praecox, remain on the whole unaffected and proof against psycho-analytic therapy. What can be the reason for this? Not any lack of intelligence. A certain amount of intellectual capacity is naturally required in our patients; but there is certainly no lack of it in, for instance, the extremely shrewd combinatorial paranoids. Nor do any of the other motives seem to be absent. Thus the melancholics have a very high degree of consciousness, absent in paranoids, that they are ill and that that is why they suffer so much; but this does not make them more accessible. We are faced here by a fact which we do not understand and which therefore leads us to doubt whether we have really understood all the determinants of our possible success with the other neuroses.

[1916-1917, 3480]
Thus our therapeutic work falls into two phases. In the first, all the libido is forced from the symptoms into the transference and concentrated there; in the second, the struggle is waged around this new object and the libido is liberated from it. The change which is decisive for a favourable outcome is the elimination of repression in this renewed conflict so that the libido cannot withdraw once more from the ego by flight into the unconscious. This is made possible by the alteration of the ego which is accomplished under the influence of the doctor's suggestion. By means of the work of interpretation, which transforms what is unconscious into what is conscious, the ego is enlarged at the cost of this unconscious; by means of instruction, it is made conciliatory towards the libido and inclined to grant it some satisfaction, and its repugnance to the claims of the libido is diminished by the possibility of disposing of a portion of it by sublimation. The more closely events in the treatment coincide with this ideal description, the greater will be the success of the psycho-analytic therapy. It finds its limits in the lack of mobility of the libido, which may refuse to leave its objects, and the rigidity of narcissism, which will not allow transference on to objects to increase beyond certain bounds. Further light may perhaps be thrown on the dynamics of the process of cure if I say that we get hold of the whole of the libido which has been withdrawn from the dominance of the ego by attracting a portion of it on to ourselves by means of the transference.

[1916-1917, 3495]

With this as a starting-point we go on to make our first important discovery. We learn that, when we try to understand neurotic disorders, by far the greater significance attaches to the sexual instincts; that in fact neuroses are the specific disorders, so to speak, of the sexual function; that in general whether or not a person develops a neurosis depends on the quantity of his libido, and on the possibility of satisfying it and of discharging it through satisfaction; that the form taken by the disease is determined by the way in which the individual passes through the course of development of his sexual function, or, as we put it, by the fixations his libido has undergone in the course of its development; and, further, that by a special, not very simple technique for influencing the mind we are able to throw light on the nature of some groups of neuroses and at the same time to do away with them. Our therapeutic efforts have their greatest success with a certain class of neuroses which proceed from a conflict between the ego-instincts and the sexual instincts. For in human beings it may happen that the demands of the sexual instincts, whose reach of course extends far beyond the individual, seem to the ego to constitute a danger which threatens its self-preservation or its self-esteem. The ego then assumes the defensive, denies the sexual instincts the satisfaction they desire and forces them into those by-paths of substitutive satisfaction which become manifest as nervous symptoms.

[1917a, 3609]

Thus in our view the individual advances from narcissism to object-love. But we do not believe that the whole of the libido ever passes over from the ego to objects. A certain quantity of libido is always retained in the ego; even when object-love is highly developed, a certain amount of narcissism persists. The ego is a great reservoir from which the libido that is destined for objects flows out and into which it flows back from those objects. Object-libido was at first ego-libido and can be transformed back into ego-libido. For complete health it is essential that the libido should not lose this full mobility. As an illustration of this state of things we may think of an amoeba, whose viscous substance puts out pseudopodia, elongations into which the substance of the body extends but which can be retracted at any time so that the form of the protoplasmic mass is restored.

[1917a, 3610]
Various qualifications are required of anyone who is to be beneficially affected by psycho-analysis. To begin with, he must be capable of a psychically normal condition; during periods of confusion or melancholic depression nothing can be accomplished even in cases of hysteria. Furthermore, a certain measure of natural intelligence and ethical development are to be required of him; if the physician has to deal with a worthless character, he soon loses the interest which makes it possible for him to enter profoundly into the patient's mental life. Deep-rooted malformations of character, traits of an actually degenerate constitution, show themselves during treatment as sources of a resistance that can scarcely be overcome. In this respect the constitution of the patient sets a general limit to the curative effect of psychotherapy. If the patient's age is in the neighbourhood of the fifties the conditions for psycho-analysis become unfavourable. The mass of psychical material is then no longer manageable; the time required for recovery is too long; and the ability to undo psychical processes begins to grow weaker.

[1904a, 1560]

(3) The age of patients has this much importance in determining their fitness for psycho-analytic treatment, that, on the one hand, near or above the age of fifty the elasticity of the mental processes, on which the treatment depends, is as a rule lacking - old people are no longer educable - and, on the other hand, the mass of material to be dealt with would prolong the duration of the treatment indefinitely. In the other direction the age limit can be determined only individually; youthful persons under the age of adolescence are often exceedingly amenable to influence.

[1905a, 1569]
At the next session the patient showed great interest in what I had said, but ventured, so he
told me, to bring for ward a few doubts. - How, he asked, could the information that the self-
reproach, the sense of guilt, was justified have a therapeutic effect? - I explained that it was not
the information that had this effect, but the discovery of the unknown content to which the self-
reproach was really attached. - Yes, he said, that was the precise point to which his question
had been directed. - I then made some short observations upon the psychological differences
between the conscious and the unconscious, and upon the fact that everything conscious was
subject to a process of wearing-away, while what was unconscious was relatively
unchangeable; and I illustrated my remarks by pointing to the antiques standing about in my
room. They were, in fact, I said, only objects found in a tomb, and their burial had been their
preservation: the destruction of Pompeii was only beginning now that it had been dug up. - Was
there any guarantee, he next enquired, of what one’s attitude would be towards what was
discovered? One man, he thought, would no doubt behave in such a way as to get the better of
his self-reproach, but another would not. - No, I said, it followed from the nature of the
circumstances that in every case the affect would be overcome - for the most part during the
progress of the work itself. Every effort was made to preserve Pompeii, whereas people were
anxious to be rid of tormenting ideas like his. - He had said to himself, he went on, that a self-
reproach could only arise from a breach of a person's own inner moral principles and not from
that of any external ones. - I agreed, and said that the man who merely breaks an external law
often regards himself as a hero. - Such an occurrence, he continued, was thus only possible
where a disintegration of the personality was already present. Was there a possibility of his
effecting a reintegration of his personality? If this could be done, he thought he would be able to
make a success of his life, perhaps more of one than most people. - I replied that I was in
complete agreement with this notion of a splitting of his personality. He had only to assimilate
this new contrast, between a moral self and an evil one, with the contrast I had already
mentioned, between the conscious and the unconscious. The moral self was the conscious, the
evil self was the unconscious.¹ - He then said that, though he considered himself a moral
person, he could quite definitely remember having done things in his childhood which came
from his other self. - I remarked that here he had incidentally hit upon one of the chief
characteristics of the unconscious, namely, its relation to the infantile. The unconscious, I
explained, was the infantile; it was that part of the self which had become separated off from it
in infancy, which had not shared the later stages of its development, and which had in
consequence become repressed. It was the derivatives of this repressed unconscious that were
responsible for the involuntary thoughts which constituted his illness. He might now, I added,
discover yet another characteristic of the unconscious; it was a discovery which I should be glad
to let him make for himself. - He found nothing more to say in this immediate connection, but
instead he expressed a doubt whether it was possible to undo modifications of such long
standing. What, in particular, could be done against his idea about the next world, for it could
not be refuted by logic? - I told him I did not dispute the gravity of his case nor the significance
of his pathological constrictions; but at the same time his youth was very much in his favour as
well as the intactness of his personality. In this connection I said a word or two upon the good
opinion I had formed of him, and this gave him visible pleasure.
[1909d, 2143]
It is advisable to draw a sharp distinction between the two types of onset of illness - a sharper distinction than observation as a rule permits. In the first type what is prominent is a change in the external world; in the second type the accent falls on an internal change. In the first type the subject falls ill from an experience; in the second type it is from a developmental process. In the first case he is faced by the task of renouncing satisfaction, and he falls ill from his incapacity for resistance; in the second case his task is to exchange one kind of satisfaction for another, and he breaks down from his inflexibility. In the second case the conflict, which is between the subject's effort to remain as he is and the effort to change himself in order to meet fresh purposes and fresh demands from reality, is present from the first. In the former case the conflict only arises after the dammed-up libido has chosen other, and incompatible, possibilities of satisfaction. The part played by the conflict and the previous fixation of the libido is incomparably more obvious in the second type than in the first, in which such unserviceable fixations may perhaps only emerge as a result of the external frustration.

In one single respect an educator's responsibility may perhaps exceed that of a doctor. The doctor has as a rule to deal with psychical structures which have already become rigid and he will find in the patient's established individuality a limit to his own achievement but at the same time a guarantee of the patient's capacity to stand alone. The educator, however, works upon material which is plastic and open to every impression, and he must keep before himself an obligation not to mould the young mind in accordance with his own personal ideals but rather according to his subject's dispositions and possibilities.

These then are phenomena of an attempted advance from the new ground which has as a rule been regressively acquired; and we may set alongside them the efforts made in some neuroses to regain a position of the libido which was once held and subsequently lost. Indeed we can hardly draw any conceptual distinction between these two classes of phenomena. We are too apt to think that the conflict underlying a neurosis is brought to an end when the symptom has been formed. In reality the struggle can go on in many ways after this. Fresh instinctual components arise on both sides, and these prolong it. The symptom itself becomes an object of this struggle; certain trends anxious to preserve it conflict with others which strive to remove it and to re-establish the status quo ante. Methods are often sought of rendering the symptom nugatory by trying to regain along other lines of approach what has been lost and is now withheld by the symptom. These facts throw much light on a statement made by C. G. Jung to the effect that a peculiar 'psychical inertia', which opposes change and progress, is the fundamental precondition of neurosis. This inertia is indeed most peculiar; it is not a general one, but is highly specialized; it is not even all-powerful within its own field, but fights against tendencies towards progress and recovery which remain active even after the formation of neurotic symptoms. If we search for the starting-point of this special inertia, we discover that it is the manifestation of very early linkages - linkages which it is hard to resolve - between instincts and impressions and the objects involved in those impressions. These linkages have the effect of bringing the development of the instincts concerned to a standstill. Or in other words, this specialized 'psychical inertia' is only a different term, though hardly a better one, for what in psycho-analysis we are accustomed to call a 'fixation'.

[1912c, 2561]

[1913b, 2636]

[1915f, 3064]
The tenacity with which the libido adheres to particular trends and objects - what may be described as the 'adhesiveness' of the libido - makes its appearance as an independent factor, varying from individual to individual, whose determinants are quite unknown to us, but whose significance for the aetiology of the neuroses we shall certainly no longer underestimate. We should not, on the other hand, over-estimate the intimacy of this connection. For a similar 'adhesiveness' of the libido occurs (for unknown reasons) under numerous conditions in normal people, and it is found as a determining factor in people who are in one sense the contrary of neurotics - in perverts. It was known even before the days of psycho-analysis (cf. Binet) that in the anamnesis of perverts a very early impression of an abnormal instinctual trend or choice of object was quite often found, to which the subject's libido remained attached all through his life. It is often impossible to say what it is that enabled this impression to exercise such an intense attraction on the libido. I will describe a case of this sort which I myself observed.

[1916-1917, 3410]

All the libido, as well as everything opposing it, is made to converge solely on the relation with the doctor. In this process the symptoms are inevitably divested of libido. In place of his patient's true illness there appears the artificially constructed transference illness, in place of the various unreal objects of the libido there appears a single, and once more imaginary, object in the person of the doctor. But, by the help of he doctor's suggestion, the new struggle around this object is lifted to the highest psychical level: it takes place as a normal mental conflict. Since a fresh repression is avoided, the alienation between ego and libido is brought to an end and the subject's mental unity is restored. When the libido is released once more from its temporary object in the person of the doctor, it cannot return to its earlier objects, but is at the disposal of the ego. The forces against which we have been struggling during our work of therapy are, on the one hand, the ego's antipathy to certain trends of the libido - an antipathy expressed in a tendency to repression - and, on the other hand, the tenacity or adhesiveness of the libido, which dislikes leaving objects that it has once cathected.

[1916-1917, 3494]

Thus our therapeutic work falls into two phases. In the first, all the libido is forced from the symptoms into the transference and concentrated there; in the second, the struggle is waged around this new object and the libido is liberated from it. The change which is decisive for a favourable outcome is the elimination of repression in this renewed conflict so that the libido cannot withdraw once more from the ego by flight into the unconscious. This is made possible by the alteration of the ego which is accomplished under the influence of the doctor's suggestion. By means of the work of interpretation, which transforms what is unconscious into what is conscious, the ego is enlarged at the cost of this unconscious; by means of instruction, it is made conciliatory towards the libido and inclined to grant it some satisfaction, and its repugnance to the claims of the libido is diminished by the possibility of disposing of a portion of it by sublimation. The more closely events in the treatment coincide with this ideal description, the greater will be the success of the psycho-analytic therapy. It finds its limits in the lack of mobility of the libido, which may refuse to leave its objects, and the rigidity of narcissism, which will not allow transference on to objects to increase beyond certain bounds. Further light may perhaps be thrown on the dynamics of the process of cure if I say that we get hold of the whole of the libido which has been withdrawn from the dominance of the ego by attracting a portion of it on to ourselves by means of the transference.

[1916-1917, 3495]
The opposition which he at first offered to religion had three different points of origin. To begin with, there was, in general, his characteristic (which we have seen exemplified already) of fending off all novelties. Any position of the libido which he had once taken up was obstinately defended by him from fear of what he would lose by giving it up and from distrust of the probability of a complete substitute being afforded by the new position that was in view. This is an important and fundamental psychological peculiarity, which I described in my *Three Essays on the Theory of Sexuality* (1905d) as a susceptibility to 'fixation'. Under the name of psychical 'inertia' Jung has attempted to erect it into the principal cause of all the failures of neurotics. I think he is wrong in this; for this factor has a far more general application and plays an important part in the lives of the non-neurotic as well. Great mobility or sluggishness of libidinal cathexes (as well as of other kinds of energetic cathexes) are special characteristics which attach to many normal people and by no means to all neurotics, and which have hitherto not been brought into relation with other qualities. They are, as it were, like prime numbers, not further divisible. We only know one thing about them, and that is that mobility of the mental cathexes is a quality which shows striking diminution with the advance of age. This has given us one of the indications of the limits within which psycho-analytic treatment is effective. There are some people, however, who retain this mental plasticity far beyond the usual age-limit, and others who lose it very prematurely. If the latter are neurotics, we make the unwelcome discovery that it is impossible to undo developments in them which, in apparently similar circumstances, have been easily dealt with in other people. So that in considering the conversion of psychical energy no less than of physical, we must make use of the concept of an entropy, which opposes the undoing of what has already occurred.

[1918b, 3591]

Thus in our view the individual advances from narcissism to object-love. But we do not believe that the whole of the libido ever passes over from the ego to objects. A certain quantity of libido is always retained in the ego; even when object-love is highly developed, a certain amount of narcissism persists. The ego is a great reservoir from which the libido that is destined for objects flows out and into which it flows back from those objects. Object-libido was at first ego-libido and can be transformed back into ego-libido. For complete health it is essential that the libido should not lose this full mobility. As an illustration of this state of things we may think of an amoeba, whose viscous substance puts out pseudopodia, elongations into which the substance of the body extends but which can be retracted at any time so that the form of the protoplasmic mass is restored.

[1917a, 3610]
Psycho-Analysis as a Therapeutic Procedure. - Psycho-analysis has never set itself up as a panacea and has never claimed to perform miracles. In one of the most difficult spheres of medical activity it is the only possible method of treatment for certain illnesses and for others it is the method which yields the best or the most permanent results - though never without a corresponding expenditure of time and trouble. A physician who is not wholly absorbed in the work of giving help will find his labours amply repaid by obtaining an unhoped-for insight into the complications of mental life and the interrelations between the mental and the physical. Where at present it cannot offer help but only theoretical understanding, it may perhaps be preparing the way for some later, more direct means of influencing neurotic disorders. Its province is above all the two transference neuroses, hysteria and obsessional neurosis, in which it has contributed to the discovery of their internal structure and operative mechanisms; and, beyond them, all kinds of phobias, inhibitions, deformities of character, sexual perversions and difficulties in erotic life. Some analysts (Jelliffe, Groddeck, Felix Deutsch) have reported too that the analytic treatment of gross organic diseases is not unpromising, since a mental factor not infrequently contributes to the origin and continuance of such illnesses. Since psycho-analysis demands a certain amount of psychical plasticity from its patients, some kind of age-limit must be laid down in their selection; and since it necessitates the devotion of long and intense attention to the individual patient, it would be uneconomical to squander such expenditure upon completely worthless persons who happen to be neurotic. Experience upon material in clinics can alone show what modifications may be necessary in order to make psycho-analytic treatment accessible to wider strata of the population or to adapt it to weaker intelligences.

[1923a, 3926]

Yes, we are only beginning to appreciate the significance of all these important circumstances. That is why my description was bound to turn out so obscure. But now I can proceed. We describe all the forces that oppose the work of recovery as the patient's 'resistances'. The gain from illness is one such resistance. The 'unconscious sense of guilt' represents the super-ego's resistance; it is the most powerful factor, and the one most dreaded by us. We meet with still other resistances during the treatment. If the ego during the early period has set up a repression out of fear, then the fear still persists and manifests itself as a resistance if the ego approaches the repressed material. And finally, as you can imagine, there are likely to be difficulties if an instinctual process which has been going along a particular path for whole decades is suddenly expected to take a new path that has just been made open for it. That might be called the id's resistance. The struggle against all these resistances is our main work during an analytic treatment; the task of making interpretations is nothing compared to it. But as a result of this struggle and of the overcoming of the resistances, the patient's ego is so much altered and strengthened that we can look forward calmly to his future behaviour when the treatment is over. On the other hand, you can understand now why we need such long treatments. The length of the path of development and the wealth of the material are not the decisive factors. It is more a question of whether the path is clear. An army can be held up for weeks on a stretch of country which in peace time an express train crosses in a couple of hours - if the army has to overcome the enemy's resistance there. Such battles call for time in mental life too. I am unfortunately obliged to tell you that every effort to hasten analytic treatment appreciably has hitherto failed. The best way of shortening it seems to be to carry it out according to the rules.

[1926e, 4366]
The fact that women must be regarded as having little sense of justice is no doubt related to the predominance of envy in their mental life; for the demand for justice is a modification of envy and lays down the condition subject to which one can put envy aside. We also regard women as weaker in their social interests and as having less capacity for sublimating their instincts than men. The former is no doubt derived from the dissocial quality which unquestionably characterizes all sexual relations. Lovers find sufficiency in each other, and families too resist inclusion in more comprehensive associations. The aptitude for sublimation is subject to the greatest individual variations. On the other hand I cannot help mentioning an impression that we are constantly receiving during analytic practice. A man of about thirty strikes us as a youthful, somewhat unformed individual, whom we expect to make powerful use of the possibilities for development opened up to him by analysis. A woman of the same age, however, often frightens us by her psychical rigidity and unchangeability. Her libido has taken up final positions and seems incapable of exchanging them for others. There are no paths open to further development; it is as though the whole process had already run its course and remains thenceforward insusceptible to influence - as though, indeed, the difficult development to femininity had exhausted the possibilities of the person concerned. As therapists we lament this state of things, even if we succeed in putting an end to our patient's ailment by doing away with her neurotic conflict.

Compared with the other psychotherapeutic procedures psycho-analysis is beyond any doubt the most powerful. It is just and fair, too, that this should be so for it is also the most laborious and time-consuming; it would not be used on slight cases. In suitable cases it is possible by its means to get rid of disturbances and bring about changes for which in pre-analytic times one would not have ventured to hope. But it has its very appreciable limits. The therapeutic ambition of some of my adherents has made the greatest efforts to overcome these obstacles so that every sort of neurotic disorder might be curable by psycho-analysis. They have endeavoured to compress the work of analysis into a shorter duration, to intensify transference so that it may be able to overcome any resistance, to unite other forms of influence with it so as to compel a cure. These efforts are certainly praiseworthy, but, in my opinion, they are vain. They bring with them, too, a danger of being oneself forced away from analysis and drawn into a boundless course of experimentation. The expectation that every neurotic phenomenon can be cured may, I suspect, be derived from the layman's belief that the neuroses are something quite unnecessary which have no right whatever to exist. Whereas in fact they are severe, constitutionally fixed illnesses, which rarely restrict themselves to only a few attacks but persist as a rule over long periods or throughout life. Our analytic experience that they can be extensively influenced, if the historical precipitating causes and accidental auxiliary factors of the illness can be dealt with, has led us to neglect the constitutional factor in our therapeutic practice, and in any case we can do nothing about it; but in theory we ought always to bear it in mind. The radical inaccessibility of the psychoses to analytic treatment should, in view of their close relationship to the neuroses, restrict our pretensions in regard to these latter. The therapeutic effectiveness of psycho-analysis remains cramped by a number of weighty and scarcely assailable factors. In the case of children, where one might count on the greatest successes, the difficulties are the external ones connected with their relation to their parents, though these difficulties are after all a necessary part of being a child. In the case of adults the difficulties arise in the first instance from two factors: the amount of psychical rigidity present and the form of the illness with all that that covers in the way of deeper determinants.
The first of these factors is often unjustly overlooked. However great may be the plasticity of mental life and the possibility of reviving old conditions, not everything can be brought to life again. Some changes seem to be definitive and correspond to scars formed when a process has run its course. On other occasions one has an impression of a general stiffening of mental life; the psychical processes, to which one could very well indicate other paths, seem incapable of abandoning the old ones. But perhaps this is the same thing as what I mentioned just now, only looked at differently. All too often one seems to see that it is only the treatment's lack of the necessary motive force that prevents one from bringing the change about. One particular dependent relation, one special instinctual component, is too powerful in comparison with the opposing forces that we are able to mobilize. This is quite generally true with the psychoses. We understand them well enough to know the point at which the levers should be applied, but they would not be able to move the weight. It is here, indeed, that hope for the future lies: the possibility that our knowledge of the operation of the hormones (you know what they are) may give us the means of successfully combating the quantitative factors of the illnesses: but we are far from that to-day. I realize that the uncertainty in all these matters is a constant instigation towards perfecting analysis and in particular the transference. Beginners in analysis especially are left in doubt in case of a failure whether they should blame the peculiarities of the case or their own clumsy handling of the therapeutic procedure. But, as I have said already, I do not think much can be achieved by efforts in this direction.

[1933a, 4753]

Let us once more glance over the situation which we have reached in our attempt at bringing help to the patient's neurotic ego. That ego is no longer able to fulfil the task set it by the external world (including human society). Not all of its experiences are at its disposal, a large proportion of its store of memories have escaped it. Its activity is inhibited by strict prohibitions from the super-ego, its energy is consumed in vain attempts at fending off the demands of the id. Beyond this, as a result of continuous irruptions by the id, its organization is impaired, it is no longer capable of any proper synthesis, it is torn by mutually opposed urges, by unsettled conflicts and by unsolved doubts. To start with, we get the patient's thus weakened ego to take part in the purely intellectual work of interpretation, which aims at provisionally filling the gaps in his mental assets, and to transfer to us the authority of his super-ego; we encourage it to take up the struggle over each individual demand made by the id and to conquer the resistances which arise in connection with it. At the same time we restore order in the ego by detecting the material and urges which have forced their way in from the unconscious, and expose them to criticism by tracing them back to their origin. We serve the patient in various functions, as an authority and a substitute for his parents, as a teacher and educator; and we have done the best for him if, as analysts, we raise the mental processes in his ego to a normal level, transform what has become unconscious and repressed into preconscious material and thus return it once more to the possession of his ego. On the patient's side a few rational factors work in our favour, such as the need for recovery which has its motive in his sufferings, and the intellectual interest that we may awaken in him in the theories and revelations of psychoanalysis; but of far greater force is the positive transference with which he meets us. Fighting against us, on the other hand, are the negative transference, the ego's resistance due to repression (that is, its unpleasure at having to lay itself open to the hard work imposed on it), the sense of guilt arising from its relation to the super-ego and the need to be ill due to deep-going changes in the economics of his instincts. The share taken by the last two factors decides whether the case is to be regarded as slight or severe. Apart from these, a few other factors may be discerned as having a favourable or unfavourable bearing. A certain psychical inertia, a sluggishness of the libido, which is unwilling to abandon its fixations cannot be welcome to us; the patient's capacity for sublimating his instincts plays a large part and so does his capacity for rising above the crude life of the instincts; so, too, does the relative power of his intellectual functions.

[1940a [1938], 4990]
With the recognition that the properties of the ego which we meet with in the form of resistances can equally well be determined by heredity as acquired in defensive struggles, the topographical distinction between what is ego and what is id loses much of its value for our investigation. If we advance a step further in our analytic experience, we come upon resistances of another kind, which we can no longer localize and which seem to depend on fundamental conditions in the mental apparatus. I can only give a few examples of this type of resistance; the whole field of enquiry is still bewilderingly strange and insufficiently explored. We come across people, for instance, to whom we should be inclined to attribute a special 'adhesiveness of the libido'. The processes which the treatment sets in motion in them are so much slower than in other people because, apparently, they cannot make up their minds to detach libidinal cathexes from one object and displace them on to another, although we can discover no special reason for this cathetic loyalty. One meets with the opposite type of person, too, in whom the libido seems particularly mobile; it enters readily upon the new cathexes suggested by analysis, abandoning its former ones in exchange for them. The difference between the two types is comparable to the one felt by a sculptor, according to whether he works in hard stone or soft clay. Unfortunately, in this second type the results of analysis often turn out to be very impermanent: the new cathexes are soon given up once more, and we have an impression, not of having worked in clay, but of having written on water. In the words of the proverb: 'Soon got, soon gone.'¹

[1937c, 5036]

In another group of cases we are surprised by an attitude in our patients which can only be put down to a depletion of the plasticity, the capacity for change and further development, which we should ordinarily expect. We are, it is true, prepared to find in analysis a certain amount of psychical inertia. When the work of analysis has opened up new paths for an instinctual impulse, we almost invariably observe that the impulse does not enter upon them without marked hesitation. We have called this behaviour, perhaps not quite correctly, 'resistance from the id'. But with the patients I here have in mind, all the mental processes, relationships and distributions of force are unchangeable, fixed and rigid. One finds the same thing in very old people, in which case it is explained as being due to what is described as force of habit or an exhaustion of receptivity - a kind of psychical entropy. But we are dealing here with people who are still young. Our theoretical knowledge does not seem adequate to give a correct explanation of such types. Probably some temporal characteristics are concerned - some alterations of a rhythm of development in psychical life which we have not yet appreciated.

[1937c, 5037]
Even at that time I could not fail to notice that the causation of the illness did not always point
to sexual life. One person, it was true, fell ill directly from a sexual noxa; but another did so
because he had lost his fortune or had been through an exhausting organic illness. The
explanation of these varieties came later, when we gained an insight into the suspected
interrelations between the ego and the libido, and the explanation became the more satisfactory
the deeper that insight extended. A person only falls ill of a neurosis if his ego has lost the
capacity to allocate his libido in some way. The stronger is his ego, the easier will it be for it to
carry out that task. Any weakening of his ego from whatever cause must have the same effect
as an excessive increase in the claims of the libido and will thus make it possible for him to fall
ill of a neurosis. There are other and more intimate relations between the ego and the libido; but
these have not yet come within our scope, so I will not bring them up as part of my present
explanation. What remains essential and makes things clear to us is that, in every case and no
matter how the illness is set going, the symptoms of the neurosis are sustained by the libido and
are consequently evidence that it is being employed abnormally.

But if the relative feebleness of the ego is the decisive factor for the genesis of a neurosis, it
must also be possible for a later physical illness to produce a neurosis, provided that it can bring
about an enfeeblement of the ego. And that, once again, is very frequently found. A physical
disorder of this kind can affect the instinctual life in the id and increase the strength of the
instincts beyond the limit up to which the ego is capable of coping with them. The normal model
of such processes is perhaps the alteration in women caused by the disturbances of
menstruation and the menopause. Or again, a general somatic illness, indeed an organic
disease of the nervous central organ, may attack the nutritional conditions of the mental
apparatus and compel it to reduce its functioning and to bring to a halt its more delicate
workings, one of which is the maintenance of the ego organization. In all these cases
approximately the same picture of neurosis emerges; neurosis always has the same
psychological mechanism, but, as we see, a most varied and often very complex aetiology.

If now we take up our first question once more, we find that our new line of approach
inevitably leads us to a particular conclusion. The question was whether it is possible to dispose
of an instinctual conflict permanently and definitively - i.e. to 'tame' an instinctual demand in that
fashion. Formulated in these terms, the question makes no mention at all of the strength of the
instinct; but it is precisely on this that the outcome depends. Let us start from the assumption
that what analysis achieves for neurotics is nothing other than what normal people bring about
for themselves without its help. Everyday experience, however, teaches us that in a normal
person any solution of an instinctual conflict only holds good for a particular strength of instinct,
or, more correctly, only for a particular relation between the strength of the instinct and the
strength of the ego.¹ If the strength of the ego diminishes, whether through illness or exhaustion,
or from some similar cause, all the instincts which have so far been successfully tamed may
renew their demands and strive to obtain substitutive satisfactions in abnormal ways.²
Irrefutable proof of this statement is supplied by our nightly dreams; they react to the sleeping
attitude assumed by the ego with an awakening of instinctual demands.

² Here we have a justification of the claim to aetiological importance of such non-specific factors as
overwork, shock, etc. These factors have always been assured of general recognition, but have had to be
pushed into the background precisely by psycho-analysis. It is impossible to define health except in
metapsychological terms: i.e. by reference to the dynamic relations between the agencies of the mental
apparatus which have been recognized - or (if that is preferred) inferred or conjectured - by us.

¹ [1996-1917, 3438]

² [1926e, 4383]
In another neurotic disorder, dementia praecox (paraphrenia or schizophrenia), a condition which is in fact incurable, the patient is left, in the most severe cases, in a state of apparently complete apathy. Often his sole remaining actions are certain movements and gestures which are repeated monotonously and have been given the name of 'stereotypies'. An analytic investigation of residues of this kind, made by Jung, has shown that they are the remains of perfectly significant mimetic actions, which at one time gave expression to the subject's ruling wishes. The craziest speeches and the queerest poses and attitudes adopted by these patients become intelligible and can be given a place in the chain of their mental processes if they are approached on the basis of psycho-analytic hypotheses.

[1913], 2811

The ego takes a similar interest, however, in the development and maintenance of the neurosis in every other case. I have already shown that symptoms are supported by the ego, too, because they have a side with which they offer satisfaction to the repressing purpose of the ego. Moreover, settling the conflict by constructing a symptom is the most convenient way out and the one most agreeable to the pleasure principle: it unquestionably spares the ego a large amount of internal work which is felt as distressing. Indeed there are cases in which even the physician must admit that for a conflict to end in neurosis is the most harmless and socially tolerable solution. You must not be surprised to hear that even the physician may occasionally take the side of the illness he is combating. It is not his business to restrict himself in every situation in life to being a fanatic in favour of health. He knows that there is not only neurotic misery in the world but real, irremovable suffering as well, that necessity may even require a person to sacrifice his health; and he learns that a sacrifice of this kind made by a single person can prevent immeasurable unhappiness for many others. If we may say, then, that whenever a neurotic is faced by a conflict he takes flight into illness, yet we must allow that in some cases that flight is fully justified, and a physician who has recognized how the situation lies will silently and solicitously withdraw.

[1916-1917, 3435]
To a physician who was to undertake psycho-analytic treatment of the girl there were many grounds for misgiving. The situation he had to deal with was not the one that analysis demands, in which alone it can demonstrate its effectiveness. As is well known, the ideal situation for analysis is when someone who is otherwise his own master is suffering from an inner conflict which he is unable to resolve alone, so that he brings his trouble to the analyst and begs for his help. The physician then works hand in hand with one portion of the pathologically divided personality, against the other party in the conflict. Any situation which differs from this is to a greater or lesser degree unfavourable for psycho-analysis and adds fresh difficulties to the internal ones already present. Situations like that of a prospective house-owner who orders an architect to build him a villa to his own tastes and requirements, or of a pious donor who commissions an artist to paint a sacred picture in the corner of which is to be a portrait of himself in adoration, are at bottom incompatible with the conditions necessary for psycho-analysis. Thus, it constantly happens that a husband instructs the physician as follows: ‘My wife suffers from nerves, and for that reason gets on badly with me; please cure her, so that we may lead a happy married life again.’ But often enough it turns out that such a request is impossible to fulfil - that is to say, the physician cannot bring about the result for which the husband sought the treatment. As soon as the wife is freed from her neurotic inhibitions she sets about getting a separation, for her neurosis was the sole condition under which the marriage could be maintained. Or else parents expect one to cure their nervous and unruly child. By a healthy child they mean one who never causes his parents trouble, and gives them nothing but pleasure. The physician may succeed in curing the child, but after that it goes its own way all the more decidedly, and the parents are now far more dissatisfied than before. In short, it is not a matter of indifference whether someone comes to analysis of his own accord or because he is brought to it - whether it is he himself who desires to be changed, or only his relatives, who love him (or who might be expected to love him).

[1920a, 3840]
I have observed that this method is very often confused with hypnotic treatment by suggestion; I have noticed this because it happens comparatively often that colleagues who do not ordinarily confide their cases to me send me patients refractory patients, of course - with a request that I should hypnotize them. Now I have not used hypnosis for therapeutic purposes for some eight years (except for a few special experiments) so that I habitually send back these cases with the recommendation that anyone who relies upon hypnosis may employ it himself. There is, actually, the greatest possible antithesis between suggestive and analytic technique - the same antithesis which, in regard to the fine arts, the great Leonardo da Vinci summed up in the formulas: per via di porre and per via di levare. Painting, says Leonardo, works per via di porre, for it applies a substance - particles of colour - where there was no thing before, on the colourless canvas; sculpture, however, proceeds per via di levare, since it takes away from the block of stone all that hides the surface of the statue contained in it. In a similar way, the technique of suggestion aims at proceeding per via di porre; it is not concerned with the origin, strength and meaning of the morbid symptoms, but instead, it superimposes something - a suggestion - in the expectation that it will be strong enough to restrain the pathogenic idea from coming to expression. Analytic therapy, on the other hand, does not seek to add or to introduce anything new, but to take away something, to bring out something; and to this end concerns itself with the genesis of the morbid symptoms and the psychical context of the pathogenic idea which it seeks to remove. It is by the use of this mode of investigation that analytic therapy has increased our knowledge so notably. I gave up the suggestive technique, and with it hypnosis, so early in my practice because I despaired of making suggestion powerful and enduring enough to effect permanent cures. In every severe case I saw the suggestions which had been applied crumble away again; after which the disease or some substitute for it was back once more. Besides all this I have another reproach to make against this method, namely, that it conceals from us all insight into the play of mental forces; it does not permit us, for example, to recognize the resistance with which the patient clings to his disease and thus even fights against his own recovery; yet it is this phenomenon of resistance which alone makes it possible to understand his behaviour in daily life.

Finally, Gentlemen, I must confess that it is hardly fair to take up your attention for so long on the subject of psycho-analytic therapy without telling you in what this treatment consists and on what it is based. Still, as I am forced to be brief, I can only hint at this: This therapy, then, is based on the recognition that unconscious ideas - or better, the unconsciouslyness of certain mental processes - are the direct cause of the morbid symptoms. We share this opinion with the French school (Janet) who, by the way, owing to excessive schematization, refer the cause of hysterical symptoms to an unconscious idée fixe. Now please do not be afraid that this is going to land us in the depths of philosophical obscurities. Our unconscious is not quite the same thing as that of philosophers and, moreover, the majority of philosophers will hear nothing of 'unconscious mental processes'. If, however, you will look at the matter from our point of view, you will understand that the transformation of this unconscious material in the mind of the patient into conscious material must have the result of correcting his deviation from normality and of lifting the compulsion to which his mind has been subjected. For conscious will-power governs only conscious mental processes, and every mental compulsion is rooted in the unconscious. Nor need you ever fear that the patient will be harmed by the shock accompanying the introduction of the unconscious into consciousness, for you can convince yourselves theoretically that the somatic and emotional effect of an impulse that has become conscious can never be so powerful as that of an unconscious one. It is only by the application of our highest mental functions, which are bound up with consciousness, that we can control all our impulses.
There is, however, another angle from which you may seek to understand the psycho-analytic method. The uncovering and translating of the unconscious occurs in the face of a continuous resistance on the part of the patient. The process of bringing this unconscious material to light is associated with unpleasure, and because of this the patient rejects it again and again. It is for you then to interpose in this conflict in the patient's mental life. If you succeed in persuading him to accept, by virtue of a better understanding, something that up to now, in consequence of this automatic regulation by unpleasure, he has rejected (repressed), you will have accomplished something towards his education. For it is education even to induce someone who dislikes getting up early to do so all the same. Psycho-analytic treatment may in general be conceived of as such a re-education in overcoming internal resistances. Re-education of this kind is, however, in no respect more necessary to nervous patients than in regard to the mental element in their sexual life. For nowhere else have civilization and education done so much harm as in this field, and this is the point, as experience will show you, at which to look for those aetiologies of the neuroses that are amenable to influence; for the other aetiological factor, the constitutional component, consists of something fixed and unalterable. And from this it follows that one important qualification is required of the physician in this work: not only must his own character be irreproachable - 'As to morals, that goes without saying', as the hero of Vischer's novel Auch Einer was in the habit of declaring - but he must also have overcome in his own mind that mixture of prurience and prudery with which, unfortunately, so many people habitually consider sexual problems.
[1905a, 1571]

You must not suppose, Ladies and Gentlemen, that these discussions on sexual life and the psychosexual development of children have led us too far from psycho-analysis and the problem of curing nervous disorders. You can, if you like, regard psycho-analytic treatment as no more than a prolongation of education for the purpose of overcoming the residues of childhood.
[1910a, 2233]

Moreover, I can assure you that you are misinformed if you suppose that advice and guidance in the affairs of life play an integral part in analytic influence. On the contrary, so far as possible we avoid the role of a mentor such as this and there is nothing we would rather bring about than the patient should make his decisions for himself. With this purpose, too, we require him to postpone for the term of his treatment any vital decisions on choice of a profession, business undertakings, marriage or divorce, and only to put them in practice when the treatment is finished. You must admit that all this is different from what you pictured. Only in the case of some very youthful or quite helpless or unstable individuals are we unable to put the desired limitation of our role into effect. With them we have to combine the functions of a doctor and an educator; but when this is so we are quite conscious of our responsibility and behave with the necessary caution.
[1916-1917, 3476]
Comparison between Psycho-Analysis and Hypnotic and Suggestive Methods. - Psycho-analytic procedure differs from all methods making use of suggestion, persuasion, etc., in that it does not seek to suppress by means of authority any mental phenomenon that may occur in the patient. It endeavours to trace the causation of the phenomenon and to remove it by bringing about a permanent modification in the conditions that led to it. In psycho-analysis the suggestive influence which is inevitably exercised by the physician is diverted on to the task assigned to the patient of overcoming his resistances, that is, of carrying forward the curative process. Any danger of falsifying the products of a patient's memory by suggestion can be avoided by prudent handling of the technique; but in general the arousing of resistances is a guarantee against the misleading effects of suggestive influence. It may be laid down that the aim of the treatment is to remove the patient's resistances and to pass his repressions in review and thus to bring about the most far-reaching unification and strengthening of his ego, to enable him to save the mental energy which he is expending upon internal conflicts, to make the best of him that his inherited capacities will allow and so to make him as efficient and as capable of enjoyment as is possible. The removal of the symptoms of the illness is not specifically aimed at, but is achieved, as it were, as a by-product if the analysis is properly carried through. The analyst respects the patient's individuality and does not seek to remould him in accordance with his own - that is, according to the physician's - personal ideals; he is glad to avoid giving advice and instead to arouse the patient's power of initiative.

[1923a, 3927]
It might be thought that these psychical conditions which we have laid down for neuropaths as distinct from hystérichs - namely, ignorance or deliberate overlooking - would necessarily be more favourable for the production of a false connection than would be the presence of a split in consciousness, which, after all, withdraws material for causal connections from consciousness. The split, however, is rarely a clear cut one. As a rule, portions of the subconscious complex of ideas intrude into the subject's ordinary consciousness, and it is precisely they that provoke this kind of disturbance. What is usually perceived consciously, as in the instances I have quoted above, is the general feeling attached to the complex - a mood of anxiety, it may be, or of grief; and it is this feeling that, by a kind of 'compulsion to associate', must have a connection found for it with some complex of ideas which is present in consciousness. (Compare, too, the mechanism of obsessional ideas, described in two papers, 1894a and 1895c.)

It is a quite regular thing for the mood attaching to an experience and the subject-matter of that experience to come into different relations to the primary consciousness. This was shown in the case of another patient, Frau Cäcilie M., whom I got to know far more thoroughly than any of the other patients mentioned in these studies. I collected from her very numerous and convincing proofs of the existence of a psychical mechanism of hysterical phenomena such as I have put forward above. Personal considerations unfortunately make it impossible for me to give a detailed case history of this patient, though I shall have occasion to refer to it from time to time. Frau Cäcilie had latterly been in a peculiar hysterical state. This state was certainly not a unique one, though I do not know if it has hitherto been recognized. It might be called a 'hysterical psychosis for the payment of old debts'. The patient had experienced numerous psychical traumas and had spent many years in a chronic hysteria which was attended by a great variety of manifestations. The causes of all these states of hers were unknown to her and everyone else. Her remarkably well-stocked memory showed the most striking gaps. She herself complained that it was as though her life was chopped in pieces. One day an old memory suddenly broke in upon her clear and tangible and with all the freshness of a new sensation. For nearly three years after this she once again lived through all the traumas of her life - long-forgotten, as they seemed to her, and some, indeed, never remembered at all - accompanied by the acutest suffering and by the return of all the symptoms she had ever had. The 'old debts' which were thus paid covered a period of thirty-three years and made it possible to discover the origins, often very complicated, of all her abnormal states. The only way of relieving her was to give her an opportunity of talking off under hypnosis the particular reminiscence which was tormenting her at the moment, together with all its accompanying load of feelings and their physical expression. When I was prevented from doing so, so that she was obliged to say these things to a person in whose presence she felt embarrassed, it sometimes happened that she would tell him her story quite calmly and would subsequently, in hypnosis, produce for me all the tears, all the expressions of despair, with which she would have wished to accompany her recital. For a few hours after a purgation of this kind during hypnosis she used to be quite well and on the spot. After a short interval the next reminiscence of the series would break its way in. But this reminiscence would be preceded some hours earlier by the mood which was proper to it. She would become anxious or irritable or despairing without ever suspecting that this mood did not belong to the present moment but to the state to which she would next be subject. During this transition period she would habitually make a false connection to which she would obstinately cling until her next hypnosis. For instance, she once greeted me with the question: 'Am I not a worthless person? Is it not a sign of worthlessness that I said to you what I did yesterday?' What she had actually said to me the day before did not in fact seem to me to justify this damning verdict. After a short discussion, she clearly recognized this; but her next hypnosis brought to light a recollection of an occasion, twelve years earlier, which had aroused severe self-reproaches in her - though, incidentally, she no longer subscribed to them in the least.
This brings us to the technical errors which are to be seen in the doctor's procedure in this alleged case. It is a long superseded idea, and one derived from superficial appearances, that the patient suffers from a sort of ignorance, and that if one removes this ignorance by giving him information (about the causal connection of his illness with his life, about his experiences in childhood, and so on) he is bound to recover. The pathological factor is not his ignorance in itself, but the root of this ignorance in his inner resistances; it was they that first called this ignorance into being, and they still maintain it now. The task of the treatment lies in combating these resistances. Informing the patient of what he does not know because he has repressed it is only one of the necessary preliminaries to the treatment. If knowledge about the unconscious were as important for the patient as people inexperienced in psycho-analysis imagine, listening to lectures or reading books would be enough to cure him. Such measures, however, have as much influence on the symptoms of nervous illness as a distribution of menu-cards in a time of famine has upon hunger. The analogy goes even further than its immediate application; for informing the patient of his unconscious regularly results in an intensification of the conflict in him and an exacerbation of his troubles.

[1910k, 2378]
I next proceed to mention more particularly what is to be found in this paper and what is not to be found in it. The title of the work was originally 'Dreams and Hysteria', for it seemed to me peculiarly well-adapted for showing how dream-interpretation is woven into the history of a treatment and how it can become the means of filling in amnesias and elucidating symptoms. It was not without good reasons that in the year 1900 I gave precedence to a laborious and exhaustive study of dreams (*The Interpretation of Dreams*) over the publications upon the psychology of the neuroses which I had in view. And incidentally I was able to judge from its reception with what an inadequate degree of comprehension such efforts are met by other specialists at the present time. In this instance there was no validity in the objection that the material upon which had based my assertions had been withheld and that it was therefore impossible to become convinced of their truth by testing and checking them. For every one can submit his own dreams to analytic examination, and the technique of interpreting dreams may be easily learnt from the instructions and examples which I have given. I must once more insist, just as I did at that time, that a thorough investigation of the problems of dreams is an indispensable prerequisite for any comprehension of the mental processes in hysteria and the other psychoneuroses, and that no one who wishes to shirk that preparatory labour has the smallest prospect of advancing even a few steps into this region of knowledge. Since, therefore, this case history presupposes a knowledge of the interpretation of dreams, it will seem highly unsatisfactory to any reader to whom this presupposition does not apply. Such a reader will find only bewilderment in these pages instead of the enlightenment he is in search of, and he will certainly be inclined to project the cause of his bewilderment on to the author and to pronounce his views fantastic. But in reality this bewildering character attaches to the phenomena of the neurosis itself; its presence there is only concealed by the physician's familiarity with the facts, and it comes to light again with every attempt a explaining them. It could only be completely banished if we could succeed in tracing back every single element of a neurosis to factors with which we were already familiar. But everything tends to show that, on the contrary, we shall be driven by the study of neuroses to assume the existence of many new thing which will later on gradually become the subject of more certain knowledge. What is new has always aroused bewilderment and resistance.

[1905e, 1353]
There is, however, another angle from which you may seek to understand the psycho-analytic method. The uncovering and translating of the unconscious occurs in the face of a continuous resistance on the part of the patient. The process of bringing this unconscious material to light is associated with unpleasure, and because of this the patient rejects it again and again. It is for you then to interpose in this conflict in the patient's mental life. If you succeed in persuading him to accept, by virtue of a better understanding, something that up to now, in consequence of this automatic regulation by unpleasure, he has rejected (repressed), you will have accomplished something towards his education. For it is education even to induce someone who dislikes getting up early to do so all the same. Psycho-analytic treatment may in general be conceived of as such a re-education in overcoming internal resistances. Re-education of this kind is, however, in no respect more necessary to nervous patients than in regard to the mental element in their sexual life. For nowhere else have civilization and education done so much harm as in this field, and this is the point, as experience will show you, at which to look for those aetiologies of the neuroses that are amenable to influence; for the other aetiological factor, the constitutional component, consists of something fixed and unalterable. And from this it follows that one important qualification is required of the physician in this work: not only must his own character be irreproachable - 'As to morals, that goes without saying', as the hero of Vischer's novel Auch Einer was in the habit of declaring - but he must also have overcome in his own mind that mixture of prurience and prudery with which, unfortunately, so many people habitually consider sexual problems.

[1905a, 1571]

You must not suppose, Ladies and Gentlemen, that these discussions on sexual life and the psychosexual development of children have led us too far from psycho-analysis and the problem of curing nervous disorders. You can, if you like, regard psycho-analytic treatment as no more than a prolongation of education for the purpose of overcoming the residues of childhood.

[1910a, 2233]

Education and therapeutics stand in an assignable relation to each other. Education seeks to ensure that certain of a child's dispositions and inclinations shall not cause any damage either to the individual or to society. Therapeutics come into action if these same dispositions have already led to the unwished-for result of pathological symptoms. The alternative outcome - of the child's unserviceable dispositions leading, not to substitutes in the form of symptoms, but to direct perversions of character - is almost inaccessible to therapeutics and as a rule beyond the influence of an educator. Education is a prophylaxis, which is intended to obviate both outcomes - neurosis and perversion alike; psychotherapy seeks, to undo the less stable of the two outcomes and to institute a kind of after-education.

[1913b, 2635]
Psycho-analytic work is continually confronted with the task of inducing the patient to renounce an immediate and directly attainable yield of pleasure. He is not asked to renounce all pleasure; that could not, perhaps, be expected of any human being, and even religion is obliged to support its demand that earthly pleasure shall be set aside by promising that it will provide instead an incomparably greater amount of superior pleasure in another world. No, the patient is only asked to renounce such satisfactions as will inevitably have detrimental consequences. His privation is only to be temporary; he has only to learn to exchange an immediate yield of pleasure for a better assured, even though a postponed one. Or, in other words, under the doctor's guidance he is asked to make the advance from the pleasure principle to the reality principle by which the mature human being is distinguished from the child. In this educative process, the doctor's clearer insight can hardly be said to play a decisive part; as a rule, he can only tell his patient what the latter's own reason can tell him. But it is not the same to know a thing in one's own mind and to hear it from someone outside. The doctor plays the part of this effective outsider; he makes use of the influence which one human being exercises over another. Or - recalling that it is the habit of psycho-analysis to replace what is derivative and etiolated by what is original and basic - let us say that the doctor, in his educative work, makes use of one of the components of love. In this work of after-education, he is probably doing no more than repeat the process which made education of any kind possible in the first instance. Side by side with the exigencies of life, love is the great educator; and it is by the love of those nearest him that the incomplete human being is induced to respect the decrees of necessity and to spare himself the punishment that follows any infringement of them.

[1916d, 3100]

And now I must quickly make a short digression, to avoid the risk of your imagining that this therapeutic work is accomplished too easily. From what I have so far said a neurosis would seem to be the result of a kind of ignorance - a not knowing about mental events that one ought to know of. This would be a close approximation to some well-known Socratic doctrines, according to which even vices are based on ignorance. Now it would as a rule be very easy for a doctor experienced in analysis to guess what mental impulses had remained unconscious in a particular patient. So it ought not to be very difficult, either, for him to restore the patient by communicating his knowledge to him and so remedying his ignorance. One part at least of the symptom's unconscious sense could be easily dealt with in this way, though it is true that the doctor cannot guess much about the other part - the connection between the symptoms and the patient's experiences -, since he himself does not know those experiences but must wait till the patient remembers them and tells them to him. But even for this a substitute can in some instances be found. One can make enquiries about these experiences from the patient's relatives and they will often be able to recognize which of them had a traumatic effect, and they can even sometimes report experiences of which the patient himself knows nothing because they occurred at a very early period of his life. Thus, by combining these two methods, we should have a prospect of relieving the patient of his pathogenic ignorance with little expense of time or trouble.

[1916-1917, 3357]
If only that was how things happened! We came upon discoveries in this connection for which we were at first unprepared. Knowledge is not always the same as knowledge: there are different sorts of knowledge, which are far from equivalent psychologically. 'Il y a fagots et fagots', as Molière has said. The doctor's knowledge is not the same as the patient's and cannot produce the same effects. If the doctor transfers his knowledge to the patient as a piece of information, it has no result. No, it would be wrong to say that. It does not have the result of removing the symptoms, but it has another one - of setting the analysis in motion, of which the first signs are often expressions of denial. The patient knows after this what he did not know before - the sense of his symptom; yet he knows it just as little as he did. Thus we learn that there is more than one kind of ignorance. We shall need to have a somewhat deeper understanding of psychology to show us in what these differences consist. But our thesis that the symptoms vanish when their sense is known remains true in spite of this. All we have to add is that the knowledge must rest on an internal change in the patient such as can only be brought about by a piece of psychical work with a particular aim. We are faced here by problems which will presently be brought together into the dynamics of the construction of symptoms.

[1916-1917, 3358]

But you must not conclude from my eagerness in defending myself against the charge that neurotics are encouraged in analytic treatment to live a full life - you must not conclude from this that we influence them in favour of conventional virtue. That is at least as far from being the case. It is true that we are not reformers but merely observers; nevertheless, we cannot help observing with a critical eye and we have found it impossible to side with conventional sexual morality or to form a very high opinion of the manner in which society attempts the practical regulation of the problems of sexual life. We can present society with a blunt calculation that what is described as its morality calls for a bigger sacrifice than it is worth and that its proceedings are not based on honesty and do not display wisdom. We do not keep such criticisms from our patients' ears, we accustom them to giving unprejudiced consideration to sexual matters no less than to any others; and if, having grown independent after the completion of their treatment, they decide on their own judgement in favour of some midway position between living a full life and absolute asceticism, we feel our conscience clear whatever their choice. We tell ourselves that anyone who has succeeded in educating himself to truth about himself is permanently defended against the danger of immorality, even though his standard of morality may differ in some respect from that which is customary in society. Moreover, we must guard against over-estimating the importance of the part played by the question of abstinence in influencing neuroses. Only in a minority of cases can the pathogenic situation of frustration and the subsequent damming-up of libido be brought to an end by the sort of sexual intercourse that can be procured without much trouble.

[1916-1917, 3477]

Let us hope that the doctor is modest enough to attribute his patient's high opinion of him to the hopes he can rouse in him and to the widening of his intellectual horizon by the surprising and liberating enlightenment that the treatment brings with it. Under these conditions the analysis makes fine progress too. The patient understands what is interpreted to him and becomes engrossed in the tasks set him by the treatment; the material of memories and associations floods in upon him in plenty, the certainty and appositeness of his interpretations are a surprise to the doctor, and the latter can only take note with satisfaction that here is a patient who readily accepts all the psychological novelties which are apt to provoke the most bitter contradiction among healthy people in the outside world. Moreover the cordial relations that prevail during the work of analysis are accompanied by an objective improvement, which is recognized on all sides, in the patient's illness.

[1916-1917, 3482]
In the light of the knowledge we have gained from psycho-analysis we can describe the
difference between hypnotic and psycho-analytic suggestion as follows. Hypnotic treatment
seeks to cover up and gloss over something in mental life; analytic treatment seeks to expose
and get rid of something. The former acts like a cosmetic, the latter like surgery. The former
makes use of suggestion in order to forbid the symptoms; it strengthens the repressions, but,
 apart from that, leaves all the processes that have led to the formation of the symptoms
unaltered. Analytic treatment makes its impact further back towards the roots, where the
conflicts are which gave rise to the symptoms, and uses suggestion in order to alter the
outcome of those conflicts. Hypnotic treatment leaves the patient inert and unchanged, and for
that reason, too, equally unable to resist any fresh occasion for falling ill. An analytic treatment
demands from both doctor and patient the accomplishment of serious work, which is employed
in lifting internal resistances. Through the overcoming of these resistances the patient's mental
life is permanently changed, is raised to a high level of development and remains protected
against fresh possibilities of falling ill. This work of overcoming resistances is the essential
function of analytic treatment; the patient has to accomplish it and the doctor makes this
possible for him with the help of suggestion operating in an educative sense. For that reason
psycho-analytic treatment has justly been described as a kind of after-education.
[1916-1917, 3492]

We have formulated our task as physicians thus: to bring to the patient's knowledge the
unconscious, repressed impulses existing in him, and, for that purpose, to uncover the
resistances that oppose this extension of his knowledge about himself. Does the uncovering of
these resistances guarantee that they will also be overcome? Certainly not always; but our hope
is to achieve this by exploiting the patient's transference to the person of the physician, so as to
induce him to adopt our conviction of the inexpediency of the repressive process established in
childhood and of the impossibility of conducting life on the pleasure principle. I have set out
elsewhere the dynamic conditions prevailing in the fresh conflict through which we lead the
patient and which we substitute in him for his previous conflict - that of his illness. I have nothing
at the moment to alter in that account.
[1919a, 3628]

I do not think I have exhausted the range of desirable activity on the part of the physician in
saying that a condition of privation is to be kept up during the treatment. Activity in another
direction during analytic treatment has already, as you will remember, been a point at issue
between us and the Swiss school. We refused most emphatically to turn a patient who puts
himself into our hands in search of help into our private property, to decide his fate for him, to
force our own ideals upon him, and with the pride of a Creator to form him in our own image and
see that it is good. I still adhere to this refusal, and I think that this is the proper place for the
medical discretion which we have had to ignore in other connections. I have learnt by
experience, too, that such a far-reaching activity towards patients is not in the least necessary
for therapeutic purposes. For I have been able to help people with whom I had nothing in
common - neither race, education, social position nor outlook upon life in general - without
affecting their individuality. At the time of the controversy I have just spoken of, I had the
impression, to be sure, that the objections of our spokesmen - I think it was Ernest Jones who
took the chief part - were too harsh and uncompromising. We cannot avoid taking some patients
for treatment who are so helpless and incapable of ordinary life that for them one has to
combine analytic with educative influence; and even with the majority, occasions now and then
arise in which the physician is bound to take up the position of teacher and mentor. But it must
always be done with great caution, and the patient should be educated to liberate and fulfil his
own nature, not to resemble ourselves.
[1919a, 3633]
Let us keep to a habit of our technique and consider first the extreme and unmistakably pathological form of this masochism. I have described elsewhere² how in analytic treatment we come across patients to whom, owing to their behaviour towards its therapeutic influence, we are obliged to ascribe an 'unconscious' sense of guilt. I pointed out the sign by which such people can be recognized (a 'negative therapeutic reaction') and I did not conceal the fact that the strength of such an impulse constitutes one of the most serious resistances and the greatest danger to the success of our medical or educative aims. The satisfaction of this unconscious sense of guilt is perhaps the most powerful bastion in the subject's (usually composite) gain from illness - in the sum of forces which struggle against his recovery and refuse to surrender his state of illness. The suffering entailed by neuroses is precisely the factor that makes them valuable to the masochistic trend. It is instructive, too, to find, contrary to all theory and expectation, that a neurosis which has defied every therapeutic effort may vanish if the subject becomes involved in the misery of an unhappy marriage, or loses all his money, or develops a dangerous organic disease. In such instances one form of suffering has been replaced by another; and we see that all that mattered was that it should be possible to maintain a certain amount of suffering.

[1924c, 4078]

The second lesson has a somewhat conservative ring. It is to the effect that the work of education is something sui generis: it is not to be confused with psycho-analytic influence and cannot be replaced by it. Psycho-analysis can be called in by education as an auxiliary means of dealing with a child; but it is not a suitable substitute for education. Not only is such a substitution impossible on practical grounds but it is also to be disrecommended for theoretical reasons. The relation between education and psycho-analytic treatment will probably before long be the subject of a detailed investigation. Here I will only give a few hints. One should not be misled by the statement - incidentally a perfectly true one - that the psycho-analysis of an adult neurotic is equivalent to an after-education. A child, even a wayward and delinquent child, is still not a neurotic; and after-education is something quite different from the education of the immature. The possibility of analytic influence rests on quite definite preconditions which can be summed up under the term 'analytic situation'; it requires the development of certain psychical structures and a particular attitude to the analyst. Where these are lacking - as in the case of children, of juvenile delinquents, and, as a rule, of impulsive criminals - something other than analysis must be employed, though something which will be at one with analysis in its purpose. The theoretical chapters of the present volume will give the reader a preliminary grasp of the multiplicity of the decisions involved.

[1925f, 4168]

(3) By 'transference' is meant a striking peculiarity of neurotics. They develop towards their physician emotional relations, both of an affectionate and hostile character, which are not based upon the actual situation but are derived from their relations to their parents (the Oedipus complex). Transference is a proof of the fact that adults have not overcome their former childish dependence; it coincides with the force which has been named 'suggestion'; and it is only by learning to make use of it that the physician is enabled to induce the patient to overcome his internal resistances and do away with his repressions. Thus psycho-analytic treatment acts as a second education of the adult, as a corrective to his education as a child.

[1926f, 4406]
Our plan of cure is based on these discoveries. The ego is weakened by the internal conflict and we must go to its help. The position is like that in a civil war which has to be decided by the assistance of an ally from outside. The analytic physician and the patient's weakened ego, basing themselves on the real external world, have to band themselves together into a party against the enemies, the instinctual demands of the id and the conscientious demands of the super-ego. We form a pact with each other. The sick ego promises us the most complete candour - promises, that is, to put at our disposal all the material which its self-perception yields it; we assure the patient of the strictest discretion and place at his service our experience in interpreting material that has been influenced by the unconscious. Our knowledge is to make up for his ignorance and to give his ego back its mastery over lost provinces of his mental life. This pact constitutes the analytic situation.

[1940a [1938], 4983]

With the neurotics, then, we make our pact: complete candour on one side and strict discretion on the other. This looks as though we were only aiming at the post of a secular father confessor. But there is a great difference, for what we want to hear from our patient is not only what he knows and conceals from other people; he is to tell us too what he does not know. With this end in view we give him a more detailed definition of what we mean by candour. We pledge him to obey the fundamental rule of analysis, which is henceforward to govern his behaviour towards us. He is to tell us not only what he can say intentionally and willingly, what will give him relief like a confession, but everything else as well that his self-observation yields him, everything that comes into his head, even if it is disagreeable for him to say it, even if it seems to him unimportant or actually nonsensical. If he can succeed after this injunction in putting his self-criticism out of action, he will present us with a mass of material - thoughts, ideas, recollections - which are already subject to the influence of the unconscious, which are often its direct derivatives, and which thus put us in a position to conjecture his repressed unconscious material and to extend, by the information we give him, his ego's knowledge of his unconscious.

[1940a [1938], 4984]

Moreover, the relation of transference brings with it two further advantages. If the patient puts the analyst in the place of his father (or mother), he is also giving him the power which his super-ego exercises over his ego, since his parents were, as we know, the origin of his super-ego. The new super-ego now has an opportunity for a sort of after-education of the neurotic; it can correct mistakes for which his parents were responsible in educating him. But at this point a warning must be given against misusing this new influence. However much the analyst may be tempted to become a teacher, model and ideal for other people and to create men in his own image, he should not forget that that is not his task in the analytic relationship, and indeed that he will be disloyal to his task if he allows himself to be led on by his inclinations. If he does, he will only be repeating a mistake of the parents who crushed their child's independence by their influence, and he will only be replacing the patient's earlier dependence by a new one. In all his attempts at improving and educating the patient the analyst should respect his individuality. The amount of influence which he may legitimately allow himself will be determined by the degree of developmental inhibition present in the patient. Some neurotics have remained so infantile that in analysis too they can only be treated as children.

[1940a [1938], 4985]
The method by which we strengthen the weakened ego has as a starting-point an extending of its self-knowledge. That is not, of course, the whole story but it is a first step. The loss of such knowledge signifies for the ego a surrender of power and influence; it is the first tangible sign that it is being hemmed in and hampered by the demands of the id and the super-ego. Accordingly, the first part of the help we have to offer is intellectual work on our side and encouragement to the patient to collaborate in it. This first kind of activity, as we know, is intended to pave the way to another, more difficult, task. We shall not lose sight of the dynamic element in this task, even during its preliminary stage. We gather the material for our work from a variety of sources - from what is conveyed to us by the information given us by the patient and by his free associations, from what he shows us in his transferences, from what we arrive at by interpreting his dreams and from what he betrays by his slips or parapraxes. All this material helps us to make constructions about what happened to him and has been forgotten as well as about what is happening in him now without his understanding it. But in all this we never fail to make a strict distinction between our knowledge and his knowledge. We avoid telling him at once things that we have often discovered at an early stage, and we avoid telling him the whole of what we think we have discovered. We reflect carefully over when we shall impart the knowledge of one of our constructions to him and we wait for what seems to us the suitable moment - which it is not always easy to decide. As a rule we put off telling him of a construction or explanation till he himself has so nearly arrived at it that only a single step remains to be taken, though that step is in fact the decisive synthesis. If we proceeded in another way and overwhelmed him with our interpretations before he was prepared for them, our information would either produce no effect or it would provoke a violent outbreak of resistance which would make the progress of our work more difficult or might even threaten to stop it altogether. But if we have prepared everything properly, it often happens that the patient will at once confirm our construction and himself recollect the internal or external event which he had forgotten. The more exactly the construction coincides with the details of what has been forgotten the easier will it be for him to assent. On that particular matter our knowledge will then have become his knowledge as well.

[1940a [1938], 4987]
Let us once more glance over the situation which we have reached in our attempt at bringing help to the patient's neurotic ego. That ego is no longer able to fulfil the task set it by the external world (including human society). Not all of its experiences are at its disposal, a large proportion of its store of memories have escaped it. Its activity is inhibited by strict prohibitions from the super-ego, its energy is consumed in vain attempts at fending off the demands of the id. Beyond this, as a result of continuous irruptions by the id, its organization is impaired, it is no longer capable of any proper synthesis, it is torn by mutually opposed urges, by unsettled conflicts and by unsolved doubts. To start with, we get the patient's thus weakened ego to take part in the purely intellectual work of interpretation, which aims at provisionally filling the gaps in his mental assets, and to transfer to us the authority of his super-ego; we encourage it to take up the struggle over each individual demand made by the id and to conquer the resistances which arise in connection with it. At the same time we restore order in the ego by detecting the material and urges which have forced their way in from the unconscious, and expose them to criticism by tracing them back to their origin. We serve the patient in various functions, as an authority and a substitute for his parents, as a teacher and educator; and we have done the best for him if, as analysts, we raise the mental processes in his ego to a normal level, transform what has become unconscious and repressed into preconscious material and thus return it once more to the possession of his ego. On the patient's side a few rational factors work in our favour, such as the need for recovery which has its motive in his sufferings, and the intellectual interest that we may awaken in him in the theories and revelations of psycho-analysis; but of far greater force is the positive transference with which he meets us. Fighting against us, on the other hand, are the negative transference, the ego's resistance due to repression (that is, its unpleasure at having to lay itself open to the hard work imposed on it), the sense of guilt arising from its relation to the super-ego and the need to be ill due to deep-going changes in the economics of his instincts. The share taken by the last two factors decides whether the case is to be regarded as slight or severe. Apart from these, a few other factors may be discerned as having a favourable or unfavourable bearing. A certain psychical inertia, a sluggishness of the libido, which is unwilling to abandon its fixations cannot be welcome to us; the patient's capacity for sublimating his instincts plays a large part and so does his capacity for rising above the crude life of the instincts; so, too, does the relative power of his intellectual functions.

It cannot be disputed that analysts in their own personalities have not invariably come up to the standard of psychical normality to which they wish to educate their patients. Opponents of analysis often point to this fact with scorn and use it as an argument to show the uselessness of analytic exertions. We might reject this criticism as making unjustifiable demands. Analysts are people who have learned to practise a particular art; alongside of this, they may be allowed to be human beings like anyone else. After all, nobody maintains that a physician is incapable of treating internal diseases if his own internal organs are not sound; on the contrary, it may be argued that there are certain advantages in a man who is himself threatened with tuberculosis specializing in the treatment of persons suffering from that disease. But the cases are not on all fours. So long as he is capable of practising at all, a doctor suffering from disease of the lungs or heart is not handicapped either in diagnosing or treating internal complaints; whereas the special conditions of analytic work do actually cause the analyst's own defects to interfere with his making a correct assessment of the state of things in his patient and reacting to them in a useful way. It is therefore reasonable to expect of an analyst, as a part of his qualifications, a considerable degree of mental normality and correctness. In addition, he must possess some kind of superiority, so that in certain analytic situations he can act as a model for his patient and in others as a teacher. And finally we must not forget that the analytic relationship is based on a love of truth - that is, on a recognition of reality - and that it precludes any kind of sham or deceit.
The most immediate objections to this conclusion will probably be that sexual assaults on small children happen too often for them to have any aetiological importance, or that these sorts of experiences are bound to be without effect precisely because they happen to a person who is sexually undeveloped; and further, that one must beware of forcing on patients supposed reminiscences of this kind by questioning them, or of believing in the romances which they themselves invent. In reply to the latter objections we may ask that no one should form too certain judgements in this obscure field until he has made use of the only method which can throw light on it - of psycho-analysis for the purpose of making conscious what has so far been unconscious.¹ What is essential in the first objections can be disposed of by pointing out that it is not the experiences themselves which act traumatically their revival as a memory after the subject has entered on sexual maturity.

If we were in fact met by objections such as these, we might defend ourselves by appealing to the impression made by our interpretations, to the surprising connections with other elements of the dream which emerge in the course of our pursuing a single one of its ideas, and to the improbability that anything which gives such an exhaustive account of the dream could have been arrived at except by following up psychical connections which had already been laid down. We might also point out in our defence that our procedure in interpreting dreams is identical with the procedure by which we resolve hysterical symptoms; and there the correctness of our method is warranted by the coincident emergence and disappearance of the symptoms, or, to use a simile, the assertions made in the text are borne out by the accompanying illustrations. But we have no reason for evading the problem of how it is possible to reach a pre-existing goal by following the drift of an arbitrary and purposeless chain of thoughts; since, though we may not be able to solve the problem, we can completely cut the ground from under it.

In order to be able to employ the power of movement to make alterations in the external world that shall be effective, it is necessary to accumulate a great number of experiences in the mnemonic systems and a multiplicity of permanent records of the associations called up in this mnemonic material by different purposive ideas. We can now carry our hypotheses a step further. The activity of this second system, constantly feeling its way, and alternately sending out and withdrawing cathexes, needs on the one hand to have the whole of the material of memory freely at its command; but on the other hand it would be an unnecessary expenditure of energy if it sent out large quantities of cathexis along the various paths of thought and thus caused them to drain away to no useful purpose and diminish the quantity available for altering the external world. I therefore postulate that for the sake of efficiency the second system succeeds in retaining the major part of its cathexes of energy in a state of quiescence and in employing only a small part on displacement. The mechanics of these processes are quite unknown to me; anyone who wished to take these ideas seriously would have to look for physical analogies to them and find a means of picturing the movements that accompany excitation of neurones. All that I insist upon is the idea that the activity of the first Ψ-system is directed towards securing the free discharge of the quantities of excitation, while the second system, by means of the cathexes emanating from it, succeeds in inhibiting this discharge and in transforming the cathexis into a quiescent one, no doubt with a simultaneous raising of its level. I presume, therefore, that under the dominion of the second system the discharge of excitation is governed by quite different mechanical conditions from those in force under the dominion of the first system. When once the second system has concluded its exploratory thought-activity, it releases the inhibition and damming-up of the excitations and allows them to discharge themselves in movement.

¹ 1900a, 962
Those philosophers who have become aware that rational and highly complex thought-structures are possible without consciousness playing any part in them have found difficulty in assigning any function to consciousness; it has seemed to them that it can be no more than a superfluous reflected picture of the completed psychical process. We, on the other hand, are rescued from this embarrassment by the analogy between our Cs. system and the perceptual systems. We know that perception by our sense-organs has the result of directing a cathexis of attention to the paths along which the in-coming sensory excitation is spreading; the qualitative excitation of the Pcpt. system acts as a regulator of the discharge of the mobile quantity in the psychical apparatus. We can attribute the same function to the overlying sense-organ of the Cs. system. By perceiving new qualities, it makes a new contribution to directing the mobile quantities of cathexis and distributing them in an expedient fashion. By the help of its perception of pleasure and unpleasure it influences the discharge of the cathexes within what is otherwise an unconscious apparatus operating by means of the displacement of quantities. It seems probable that in the first instance the unpleasure principle regulates the displacement of cathexes automatically. But it is quite possible that consciousness of these qualities may introduce in addition a second and more discriminating regulation, which is even able to oppose the former one, and which perfects the efficiency of the apparatus by enabling it, in contradiction to its original plan, to cathect and work over even what is associated with the release of unpleasure. We learn from the psychology of the neuroses that these processes of regulation carried out by the qualitative excitation of the sense organs play a great part in the functional activity of the apparatus. The automatic domination of the primary unpleasure principle and the consequent restriction imposed upon efficiency are interrupted by the processes of sensory regulation, which are themselves in turn automatic in action. We find that repression (which, though it served a useful purpose to begin with, leads ultimately to a damaging loss of inhibition and mental control) affects memories so much more easily than perceptions because the former can receive no extra cathexis from the excitation of the psychical sense-organs. It is true on the one hand that a thought which has to be warded off cannot become conscious, because it has undergone repression; but on the other hand it sometimes happens that a thought of this kind is only repressed because for other reasons it has been withdrawn from conscious perception. Here are some hints of which we take advantage in our therapeutic procedure in order to undo repressions which have already been effected.

[1900a, 1041]

One day I discovered to my great astonishment that the view of dreams which came nearest to the truth was not the medical but the popular one, half-involved though it still was in superstition. For I had been led to fresh conclusions on the subject of dreams by applying to them a new method of psychological investigation which had done excellent service in the solution of phobias, obsessions and delusions, etc. Since then, under the name of 'psycho-analysis', it has found acceptance by a whole school of research workers. The numerous analogies that exist between dream-life and a great variety of conditions of psychical illness in waking life have indeed been correctly observed by many medical investigators. There seemed, therefore, good ground for hoping that a method of investigation which had given satisfactory results in the case of psychopathic structures would also be of use in throwing light upon dreams. Phobias and obsessions are as alien to normal consciousness as dreams are to waking consciousness; their origin is as unknown to consciousness as that of dreams. In the case of these psychopathic structures practical considerations led to an investigation of their origin and mode of development; for experience had shown that the discovery of the trains of thought which, concealed from consciousness, connect the pathological ideas with the remaining contents of the mind is equivalent to a resolution of the symptoms and has as its consequence the mastering of ideas which till then could not be inhibited. Thus psychotherapy was the starting-point of the procedure of which I made use for the explanation of dreams.

[1901a, 1053]
No one can undertake the treatment of a case of hysteria until he is convinced of the impossibility of avoiding the mention of sexual subjects, or unless he is prepared to allow himself to be convinced by experience. The right attitude is: ‘Pour faire une omlette il faut casser des œufs.’ The patients themselves are easy to convince; and there are only too many opportunities of doing so in the course of the treatment. There is no necessity for feeling any compunction at discussing the facts of normal or abnormal sexual life with them. With the exercise of a little caution all that is done is to translate into conscious ideas what was already known in the unconscious; and, after all, the whole effectiveness of the treatment is based upon our knowledge that the affect attached to an unconscious idea operates more strongly and, since it cannot be inhibited, more injuriously than the affect attached to a conscious one. There is never any danger of corrupting an inexperienced girl. For where there is no knowledge of sexual processes even in the unconscious, no hysterical symptom will arise; and where hysteria is found there can no longer be any question of ‘innocence of mind’ in the sense in which parents and educators use the phrase. With children of ten, of twelve, or of fourteen, with boys and girls alike, I have satisfied myself that the truth of this statement can invariably be relied upon. [1905e, 1386]

Nevertheless, in publishing this paper, incomplete though it is, I had two objects in view. In the first place, I wished to supplement my book on the interpretation of dreams by showing how an art, which would otherwise be useless, can be turned to account for the discovery of the hidden and repressed parts of mental life. (Incidentally, in the process of analysing the two dreams dealt with in the paper, the technique of dream-interpretation, which is similar to that of psycho-analysis, has come under consideration.) In the second place, I wished to stimulate interest in a whole group of phenomena of which science is still in complete ignorance to-day because they can only be brought to light by the use of this particular method. No one, I believe, can have had any true conception of the complexity of the psychological events in a case of hysteria - the juxtaposition of the most dissimilar tendencies, the mutual dependence of contrary ideas, the repressions and displacements, and so on. The emphasis laid by Janet upon the ‘idée fixe’ which becomes transformed into a symptom amounts to no more than an extremely meagre attempt at schematization. Moreover, it is impossible to avoid the suspicion that, when the ideas attaching to certain excitations are incapable of becoming conscious, those excitations must act upon one another differently, run a different course, and manifest themselves differently from those other excitations which we describe as ‘normal’ and which have ideas attaching to them of which we become conscious. When once things have been made clear up to this point, no obstacle can remain in the way of an understanding of a therapeutic method which removes neurotic symptoms by transforming ideas of the former kind into normal ones. [1905e, 1448]
Nor is the case of whose history and treatment I have published a fragment in these pages well calculated to put the value of psycho-analytic therapy in its true light. Not only the briefness of the treatment (which hardly lasted three months) but another factor inherent in the nature of the case prevented results being brought about such as are attainable in other instances, where the improvement will be admitted by the patient and his relatives and will approximate more or less closely to a complete recovery. Satisfactory results of this kind are reached when the symptoms are maintained solely by the internal conflict between the impulses concerned with sexuality. In such cases the patient's condition will be seen improving in proportion as he is helped towards a solution of his mental problems by the translation of pathogenic into normal material. The course of events is very different when the symptoms have become enlisted in the service of external motives, as had happened with Dora during the two preceding years. It is surprising, and might easily be misleading, to find that the patient's condition shows no noticeable alteration even though considerable progress has been made with the work of analysis. But in reality things are not as bad as they seem. It is true that the symptoms do not disappear while the work is proceeding; but they disappear a little while later, when the relations between patient and physician have been dissolved. The postponement of recovery or improvement is really only caused by the physician's own person.

¹ The longer the interval of time that separates me from the end of this analysis, the more probable it seems to me that the fault in my technique lay in this omission: I failed to discover in time and to inform the patient that her homosexual (gynaecophilic) love for Frau K. was the strongest unconscious current in her mental life. I ought to have guessed that the main source of her knowledge of sexual matters could have been no one but Frau K., the very person who later charged her with being interested in those same subjects. Her knowing all about such things and, at the same time, her always pretending not to know where her knowledge came from was really too remarkable. I ought to have attacked this riddle and looked for the motive of such an extraordinary piece of repression. If I had done this, the second dream would have given me my answer. The remorseless craving for revenge expressed in that dream was suited as nothing else was to conceal the current of feeling that ran contrary to it - the magnanimity with which she forgave the treachery of the friend she loved and concealed from every one the fact that it was this friend who had herself revealed to her the knowledge which had later been the ground of the accusations against her. Before I had learnt the importance of the homosexual current of feeling in psychoneurotics, I was often brought to a standstill in the treatment of my cases or found myself in complete perplexity.

The removal of the symptoms of hysterical patients by psycho-analysis proceeds on the supposition that those symptoms are substitutes - transcriptions as it were - for a number of emotionally cathedeted mental processes, wishes and desires, which, by the operation of a special psychical procedure (repression), have been prevented from obtaining discharge in psychical activity that is admissible to consciousness. These mental processes, therefore, being held back in a state of unconsciousness, strive to obtain an expression that shall be appropriate to their emotional importance - to obtain discharge; and in the case of hysteria they find such an expression (by means of the process of 'conversion') in somatic phenomena, that is, in hysterical symptoms. By systematically turning these symptoms back (with the help of a special technique) into emotionally cathedeted ideas - ideas that will now have become conscious - it is possible to obtain the most accurate knowledge of the nature and origin of these formerly unconscious psychical structures.
SECOND PHASE OF INFANTILE MASTURBATION  The masturbation of early infancy seems to disappear after a short time; but it may persist uninterruptedly until puberty, and this would constitute the first great deviation from the course of development laid down for civilized men. At some point of childhood after early infancy, as a rule before the fourth year, the sexual instinct belonging to the genital zone usually revives and persists again for a time until it is once more suppressed, or it may continue without interruption. This second phase of infantile sexual activity may assume a variety of different forms which can only be determined by a precise analysis of individual cases. But all its details leave behind the deepest (unconscious) impressions in the subject's memory, determine the development of his character, if he is to remain healthy, and the symptomatology of his neurosis, if he is to fall ill after puberty.¹ In the latter case we find that this sexual period has been forgotten and that the conscious memories that bear witness to it have been displaced. (I have already mentioned that I am also inclined to relate normal infantile amnesia to this infantile sexual activity.) Psychoanalytic investigation enables us to make what has been forgotten conscious and thus do away with a compulsion that arises from the unconscious psychical material.

[1905d, 1509]

The closer one comes to the deeper disturbances of psychosexual development, the more unmistakably the importance of incestuous object-choice emerges. In psychoneurotics a large portion or the whole of their psychosexual activity in finding an object remains in the unconscious as a result of their repudiation of sexuality. Girls with an exaggerated need for affection and an equally exaggerated horror of the real demands made by sexual life have an irresistible temptation on the one hand to realize the ideal of asexual love in their lives and on the other hand to conceal their libido behind an affection which they can express without self-reproaches, by holding fast throughout their lives to their infantile fondness, revived at puberty, for their parents or brothers and sisters. Psycho-analysis has no difficulty in showing persons of this kind that they are in love, in the everyday sense of the word, with these blood-relations of theirs; for, with the help of their symptoms and other manifestations of their illness, it traces their unconscious thoughts and translates them into conscious ones. In cases in which someone who has previously been healthy falls ill after an unhappy experience in love it is also possible to show with certainty that the mechanism of his illness consists in a turning-back of his libido on to those whom he preferred in his infancy.

[1905d, 1539]

The task which the psycho-analytic method seeks to perform may be formulated in different ways, which are, however, in their essence equivalent. It may, for instance, be stated thus: the task of the treatment is to remove the amnesias. When all gaps in memory have been filled in, all the enigmatic products of mental life elucidated, the continuance and even a renewal of the morbid condition are made impossible. Or the formula may be expressed in this fashion: all repressions must be undone. The mental condition is then the same as one in which all amnesias have been removed. Another formulation reaches further: the task consists in making the unconscious accessible to consciousness, which is done by overcoming the resistances. But it must be remembered that an ideal condition such as this is not present even in the normal, and further that it is only rarely possible to carry the treatment to a point approaching it. Just as health and sickness are not different from each other in essence but are only separated by a quantitative line of demarcation which can be determined in practice, so the aim of the treatment will never be anything else but the practical recovery of the patient, the restoration of his ability to lead an active life and of his capacity for enjoyment. In a treatment which is incomplete or in which success is not perfect, one may at any rate achieve a considerable improvement in the general mental condition, while the symptoms (though now of smaller importance to the patient) may continue to exist without stamping him as a sick man.

[1904a, 1559]
Finally, Gentlemen, I must confess that it is hardly fair to take up your attention for so long on the subject of psycho-analytic therapy without telling you in what this treatment consists and on what it is based. Still, as I am forced to be brief, I can only hint at this: This therapy, then, is based on the recognition that unconscious ideas - or better, the unconsciousness of certain mental processes - are the direct cause of the morbid symptoms. We share this opinion with the French school (Janet) who, by the way, owing to excessive schematization, refer the cause of hysterical symptoms to an unconscious *idée fixe*. Now please do not be afraid that this is going to land us in the depths of philosophical obscurities. Our unconscious is not quite the same thing as that of philosophers and, moreover, the majority of philosophers will hear nothing of 'unconscious mental processes'. If, however, you will look at the matter from our point of view, you will understand that the transformation of this unconscious material in the mind of the patient into conscious material must have the result of correcting his deviation from normality and of lifting the compulsion to which his mind has been subjected. For conscious will-power governs only conscious mental processes, and every mental compulsion is rooted in the unconscious. Nor need you ever fear that the patient will be harmed by the shock accompanying the introduction of the unconscious into consciousness, for you can convince yourselves theoretically that the somatic and emotional effect of an impulse that has become conscious can never be so powerful as that of an unconscious one. It is only by the application of our highest mental functions, which are bound up with consciousness, that we can control all our impulses.

There is, however, another angle from which you may seek to understand the psycho-analytic method. The uncovering and translating of the unconscious occurs in the face of a continuous resistance on the part of the patient. The process of bringing this unconscious material to light is associated with unpleasure, and because of this the patient rejects it again and again. It is for you then to interpose in this conflict in the patient's mental life. If you succeed in persuading him to accept, by virtue of a better understanding, something that up to now, in consequence of this automatic regulation by unpleasure, he has rejected (repressed), you will have accomplished something towards his education. For it is education even to induce someone who dislikes getting up early to do so all the same. Psycho-analytic treatment may in general be conceived of as such a re-education in overcoming internal resistances. Re-education of this kind is, however, in no respect more necessary to nervous patients than in regard to the mental element in their sexual life. For nowhere else have civilization and education done so much harm as in this field, and this is the point, as experience will show you, at which to look for those aetiologies of the neuroses that are amenable to influence; for the other aetiological factor, the constitutional component, consists of something fixed and unalterable. And from this it follows that one important qualification is required of the physician in this work: not only must his own character be irreproachable - 'As to morals, that goes without saying', as the hero of Vischer's novel *Auch Einer* was in the habit of declaring - but he must also have overcome in his own mind that mixture of prurience and prudery with which, unfortunately, so many people habitually consider sexual problems.

¹ Many of my neurotic patients who are under psycho-analytic treatment are regularly in the habit of confirming the fact by a laugh when I have succeeded in giving a faithful picture of their hidden unconscious to their conscious perception; and they laugh even when the content of what is unveiled would by no means justify this. This is subject, of course, to their having arrived close enough to the unconscious material to grasp it after the doctor has detected it and presented it to them.
Fräulein Zoe seems herself to have shared our view of the young archaeologist's delusion, for the satisfaction she expressed at the end of her 'frank, detailed and instructive speech of castigation' could scarcely have been based on anything but a recognition that from the very first his interest in Gradiva had related to herself. It was this which she had not expected of him, but which, in spite of all its delusional disguise, she saw for what it was. The psychical treatment she had carried out, however, had now accomplished its beneficent effect on him. He felt free, for his delusion had now been replaced by the thing of which it could only have been a distorted and inadequate copy. Nor did he any longer hesitate to remember her and to recognize her as the kind, cheerful, clever playmate who in essentials was not in any way changed. But he found something else very strange-

We ourselves were unprepared for this. Our hero was beginning to cast off his humility and to play an active part. Evidently he was completely cured of his delusion and had risen above it; and he proved this by himself tearing the last threads of the cobweb of his delusion. This, too, is just how patients behave when one has loosened the compulsion of their delusional thoughts by revealing the repressed material lying behind them. Once they have understood, they themselves bring forward the solutions of the final and most important riddles of their strange condition in a number of ideas that suddenly occur to them. We had already guessed that the Greek origin of the imaginary Gradiva was an obscure result of the Greek name 'Zoe'; but we had not ventured to approach the name 'Gradiva' itself, and had let it pass as the untrammeled creation of Norbert Hanold's imagination. But, to and behold! that very name now turns out to have been a derivative - indeed a translation - of the repressed surname of the girl he had loved in the childhood which he was supposed to have forgotten.

[1907a, 1839]
The tracing back of the delusion and its resolution were now complete. What the author now adds is no doubt designed to serve as a harmonious end to his story. We cannot but feel reassured about the future when we hear that the young man, who had earlier been obliged to play the pitiable part of a person in urgent need of treatment, advanced still further on the road to recovery and succeeded in arousing in her some of the feelings under which he himself had suffered before. Thus it was that he made her jealous by mentioning the sympathetic young lady who had previously interrupted their tête-à-tête in the House of Meleager, and by confessing that she had been the first woman for whom he had felt a very great liking. Whereupon Zoe prepared to take a chilly leave of him, remarking that everything had now returned to reason - she herself not least; he could look up Gisa Hartleben (or whatever she was now called) again and give her some scientific assistance over the purpose of her visit to Pompeii; she herself, however, must go back to the Albergo del Sole where her father was expecting her for lunch; perhaps they would meet again some time at a party in Germany or in the moon. But once more he was able to make the troublesome fly an excuse for taking possession first of her cheek and then of her lips, and to set in motion the aggressiveness which is a man's inevitable duty in love making. Once only a shadow seemed to fall on their happiness, when Zoe declared that now she really must go back to her father or he will starve at the Sole. 'Your father? . . . what will happen? . . . ' (147.) But the clever girl was able swiftly to quiet his concern. 'Probably nothing will happen. I'm not an indispensable part of his zoological collection. If I had been, perhaps I shouldn't have been so foolish as to give my heart to you.' In the exceptional event, however, of her father taking a different view from hers, there was a safe expedient. Hanold need only cross to Capri, catch a Lacerta faraglionensis there (he could practise the technique on her little finger), set the creature free over here, catch it again before the zoologist's eyes, and let him choose between a faraglionensis on the mainland and his daughter. The scheme, it is easy to see, was one in which the mockery was tinged with bitterness; it was a warning, as it were, to her fiancé not to keep too closely to the model on which she had chosen him. Here again Norbert Hanold reassures us, by showing by all sorts of apparently small signs the great transformation that had taken place in him. He proposed that he and his Zoe should come for their honeymoon to Italy and Pompeii, just as though he had never been indignant with the honeymooning Edwins and Angelinas. He had completely lost from his memory all his feelings against those happy pairs, who had so unnecessarily travelled more than a hundred miles from their German home. The author is certainly right in bringing forward a loss of memory like this as the most trustworthy sign of a change of attitude. Zoe's reply to the plan for the scene of their honeymoon suggested by 'her childhood friend who had also in a sense been dug out of the ruins again' (150.) was that she did not feel quite alive enough yet to make a geographical decision of that sort.

[1907a, 1840]

Thus the author has drawn the closest link between the clearing up of the delusion and the outbreak of a craving for love, and he has paved the way for the inevitable outcome in a courtship. He knows the essential nature of the delusion better than his critics: he knows that a component of loving desire had combined with a component of resistance to it in bringing about the delusion, and he makes the girl who undertakes the cure sensitive to the element in Hanold's delusion which is agreeable to her. It was only this knowledge which could decide her to devote herself to the treatment; it was only the certainty of being loved by him that could induce her to admit her love to him. The treatment consisted in giving him back from outside the repressed memories which he could not set free from inside; but it would have had no effect if in the course of it the therapist had not taken his feelings into account and if her ultimate translation of the delusion had not been: 'Look, all this only means that you love me.'

[1907a, 1881]
The procedure which the author makes his Zoe adopt for curing her childhood friend's delusion shows a far-reaching similarity - no, a complete agreement in its essence - with a therapeutic method which was introduced into medical practice in 1895 by Dr. Josef Breuer and myself, and to the perfecting of which I have since then devoted myself. This method of treatment, to which Breuer first gave the name of 'cathartic' but which I prefer to describe as 'analytic', consists, as applied to patients suffering from disorders analogous to Hanold's delusion, in bringing to their consciousness, to some extent forcibly, the unconscious whose repression led to their falling ill - exactly as Gradiva did with the repressed memories of their childhood relations. Gradiva, it is true, could carry out this task more easily than a doctor: in several respects she was in what may be described as an ideal position for it. The doctor, who has no pre-existing knowledge of his patient and possesses no conscious memory of what is unconsciously at work in him, must call a complicated technique to his help in order to make up for this disadvantage. He must learn how to infer with great certainty from the conscious associations and communications of the patient what is repressed in him, how to discover his unconscious as it betrays itself behind his conscious words and acts. He then brings about something like what Norbert Hanold grasped at the end of the story when he translated back the name 'Gradiva' into 'Bertgang'. The disorder vanishes while being traced back to its origin; analysis, too, brings simultaneous cure.

But the similarity between Gradiva's procedure and the analytic method of psychotherapy is not limited to these two points - the making conscious of what has been repressed and the coinciding of explanation with cure. It also extends to what turns out to be the essence of the whole change - to the awakening of feelings. Every disorder analogous to Hanold's delusion, what in scientific terms we are in the habit of calling 'psychoneuroses', has as its precondition the repression of a portion of instinctual life, or, as we can safely say, of the sexual instinct. At every attempt to introduce the unconscious and repressed causes of the illness into consciousness, the instinctual component concerned is necessarily aroused to a renewed struggle with the repressing powers, only to come to terms with them in the final outcome, often to the accompaniment of violent manifestations of reaction. The process of cure is accomplished in a relapse into love, if we combine all the many components of the sexual instinct under the term 'love'; and such a relapse is indispensable, for the symptoms on account of which the treatment has been undertaken are nothing other than precipitates of earlier struggles connected with repression or the return of the repressed, and they can only be resolved and washed away by a fresh high tide of the same passions. Every psycho-analytic treatment is an attempt at liberating repressed love which has found a meagre outlet in the compromise of a symptom. Indeed, the agreement between such treatments and the process of cure described by the author of *Gradiva* reaches its climax in the further fact that in analytic psychotherapy too the re-awakened passion, whether it is love or hate, invariably chooses as its object the figure of the doctor.

The task of the therapist, however, is the same as that of the examining magistrate. We have to uncover the hidden psychical material; and in order to do this we have invented a number of detective devices, some of which it seems that you gentlemen of the law are now about to copy from us.
It will interest you, from the point of view of your own profession, to hear how we doctors proceed in psycho-analysis. After the patient has given us a first account of his history, we ask him to give himself up to the thoughts that occur to him spontaneously and to say without any critical reserve whatever comes into his head. We start, as you see, on the assumption, which he does not share in the least, that these spontaneous thoughts will not be arbitrarily chosen but will be determined by their relation to his secret - to his ‘complex’ - and may, as it were, be regarded as derivatives of that complex. You will note that this is the same assumption as the one with the help of which you were able to interpret the association experiments. But although we have instructed the patient to follow the rule of communicating all the thoughts that occur to him, he seems to be unable to do so. He soon begins to hold back first one thought and then another. He gives various reasons to account for this: either the thought was quite unimportant, or it was irrelevant or it was totally meaningless. We thereupon demand that he shall tell us the thought in spite of these objections and shall follow it up; for the very fact of his criticism proves to us that the thought belongs to the ‘complex’ which we are seeking to uncover. We recognize in this behaviour of the patient's a manifestation of the ‘resistance’ present in him, which we are never free from through the whole duration of the treatment. I will merely indicate briefly that this concept of resistance has acquired the highest importance for us in understanding the origin of an illness as well as the mechanism of its cure.

We may justly claim that, in principle, techniques of the kind I have described enable us to make the patient conscious of what is repressed in him - of his secret - and thus to remove the psychological causation of the symptoms from which he is suffering. But before you draw any conclusions from these successful results as to the possibilities of your own work, we will examine some points of difference between the psychological situations in the two cases.

If you look more deeply into the comparison between the two situations it will become clear to you in general that psycho-analysis is concerned with a simpler, special, form of the task of uncovering what is hidden in the mind; whereas in your work the task is a more comprehensive one. That the case of the psychoneurotic is invariably concerned with a repressed sexual complex (in the widest sense) is a difference which you need not take into account. But there is something else that you must. The aim of psycho-analysis is absolutely uniform in every case: complexes have to be uncovered which have been repressed because of feelings of unpleasure and which produce signs of resistance if an attempt is made to bring them into consciousness. This resistance is as it were localized; it arises at the frontier between unconscious and conscious. In your cases what is concerned is a resistance which comes entirely from consciousness. You cannot dismiss this difference out of hand. You will first have to determine experimentally whether conscious resistance is betrayed by exactly the same indications as unconscious resistance. Further, you cannot yet be certain, in my opinion, whether you may interpret your objective indications of a complex as a ‘resistance’, as we psycho-therapists do. It may happen with your experimental subjects - even though not very frequently with criminals - that the complex you touch on is pleasurably toned; and the question then arises whether such a complex will produce the same reaction as a complex that is unpleasurably toned.
It is one of the conditions of the illness that the person who is obeying a compulsion carries it out without understanding its meaning - or at any rate its chief meaning. It is only thanks to the efforts of psycho-analytic treatment that he becomes conscious of the meaning of his obsessive action and, with it, of the motives that are impelling him to it. We express this important fact by saying that the obsessive action serves to express unconscious motives and ideas. In this, we seem to find a further departure from religious practices; but we must remember that as a rule the ordinary pious individual, too, performs a ceremonial without concerning himself with its significance, although priests and scientific investigators may be familiar with the - mostly symbolic - meaning of the ritual. In all believers, however, the motives which impel them to religious practices are unknown to them or are represented in consciousness by others which are advanced in their place.
[1907b, 1906]

Anyone who studies hysteria, therefore, soon finds his interest turned away from its symptoms to the phantasies from which they proceed. The technique of psycho-analysis enables us in the first place to infer from the symptoms what those unconscious phantasies are and then to make them conscious to the patient. By this means it has been found that the content of the hysteric's unconscious phantasies corresponds completely to the situations in which satisfaction is consciously obtained by perverts; and if anyone is at a loss for examples of such situations he has only to recall the world-famous performances of the Roman Emperors, the wild excesses of which were, of course, determined only by the enormous and unrestrained power possessed by the authors of the phantasies. The delusions of paranoics are phantasies of the same nature, though they are phantasies which have become directly conscious. They rest on the sadomasochistic components of the sexual instinct, and they, too, may find their complete counterpart in certain unconscious phantasies of hysterical subjects. We also know of cases - cases which have their practical importance as well - in which hysterics do not give expression to their phantasies in the form of symptoms but as conscious realizations, and in that way devise and stage assaults, attacks or acts of sexual aggression.
[1908a, 1935]

This method of psycho-analytic investigation, which leads from the conspicuous symptoms to the hidden unconscious phantasies, tells us everything that can be known about the sexuality of psychoneurotics, including the fact which is to be the main subject-matter of this short preliminary publication.
[1908a, 1935]

This connection between symptoms and phantasies makes it easy to arrive from a psycho-analysis of the former at a knowledge of the components of the sexual instincts which dominate the individual, as I have demonstrated in my Three Essays on the Theory of Sexuality. In some cases, however, investigation by this means yields an unexpected result. It shows that there are many symptoms where the uncovering of a sexual phantasy (or of a number of phantasies, one of which, the most significant and the earliest, is of a sexual nature) is not enough to bring about a resolution of the symptoms. To resolve it one has to have two sexual phantasies, of which one has a masculine and the other a feminine character. Thus one of these phantasies springs from a homosexual impulse. This new finding does not alter our seventh formula. It remains true that a hysterical symptom must necessarily represent a compromise between a libidinal and a repressing impulse; but it may also represent a union of two libidinal phantasies of an opposite sexual character.
[1908a, 1937]
The material on which the following synthesis is based is derived from several sources. Firstly, from the direct observation of what children say and do; secondly, from what adult neurotics consciously remember from their childhood and relate during psycho-analytic treatment; and thirdly, from the inferences and constructions, and from the unconscious memories translated into conscious material, which result from the psycho-analysis of neurotics.

[1908c, 1966]

The way in which children react to the information they are given also has its significance. In some, sexual repression has gone so far that they will not listen to anything; and these succeed in remaining ignorant even in later life - apparently ignorant, at least - until, in the psycho-analysis of neurotics, the knowledge that originated in early childhood comes to light. I also know of two boys between ten and thirteen years old who, though it is true that they listened to the sexual information, rejected it with the words: 'Your father and other people may do something like that, but I know for certain my father never would.' But however widely children's later reactions to the satisfaction of their sexual curiosity may vary, we may assume that in the first years of childhood their attitude was absolutely uniform, and we may feel certain that at that time all of them tried most eagerly to discover what it was that their parents did with each other so as to produce babies.

[1908c, 1978]

The later stage in the development of the neurotic's estrangement from his parents, begun in this manner, might be described as 'the neurotic's family romance'. It is seldom remembered consciously but can almost always be revealed by psycho-analysis. For a quite peculiarly marked imaginative activity is one of the essential characteristics of neurotics and also of all comparatively highly gifted people. This activity emerges first in children's play, and then, starting roughly from the period before puberty, takes over the topic of family relations. A characteristic example of this peculiar imaginative activity is to be seen in the familiar day-dreaming¹ which persists far beyond puberty. If these day-dreams are carefully examined, they are found to serve as the fulfilment of wishes and as a correction of actual life. They have two principal aims, an erotic and an ambitious one - though an erotic aim is usually concealed behind the latter too. At about the period I have mentioned, then, the child's imagination becomes engaged in the task of getting free from the parents of whom he now has a low opinion and of replacing them by others, who, as a rule, are of higher social standing. He will make use in this connection of any opportune coincidences from his actual experience, such as his becoming acquainted with the Lord of the Manor or some landed proprietor if he lives in the country or with some member of the aristocracy if he lives in town. Chance occurrences of this kind arouse the child's envy, which finds expression in a phantasy in which both his parents are replaced by others of better birth. The technique used in developing phantasies like this (which are, of course, conscious at this period) depends upon the ingenuity and the material which the child has at his disposal. There is also the question of whether the phantasies are worked out with greater or less effort to obtain verisimilitude. This state is reached at a time at which the child is still in ignorance of the sexual determinants of procreation.

[1909c, 1988]
But the peculiar value of this observation lies in the considerations which follow. When a physician treats an adult neurotic by psycho-analysis, the process he goes through of uncovering the psychical formations, layer by layer, eventually enables him to frame certain hypotheses as to the patient's infantile sexuality; and it is in the components of the latter that he believes he has discovered the motive forces of all the neurotic symptoms of later life. I have set out these hypotheses in my *Three Essays on the Theory of Sexuality* (1905d), and I am aware that they seem as strange to an outside reader as they seem incontrovertible to a psycho-analyst. But even a psycho-analyst may confess to the wish for a more direct and less roundabout proof of these fundamental theorems. Surely there must be a possibility of observing in children at first hand and in all the freshness of life the sexual impulses and wishes which we dig out so laboriously in adults from among their own débris - especially as it is also our belief that they are the common property of all men, a part of the human constitution, and merely exaggerated or distorted in the case of neurotics.

[1909b, 2002]

'Does the Professor talk to God,' Hans asked his father on the way home, 'as he can tell all that beforehand?' I should be extraordinarily proud of this recognition out of the mouth of a child, if I had not myself provoked it by my joking boastfulness. From the date of this consultation I received almost daily reports of the alterations in the little patient's condition. It was not to be expected that he should be freed from his anxiety at a single blow by the information I gave him; but it became apparent that a possibility had now been offered him of bringing forward his unconscious productions and of unfolding his phobia. From that time forward he carried out a programme which I was able to announce to his father in advance. [1909b, 2032]

It is true that during the analysis Hans had to be told many things that he could not say himself, that he had to be presented with thoughts which he had so far shown no signs of possessing, and that his attention had to be turned in the direction from which his father was expecting something to come. This detracts from the evidential value of the analysis; but the procedure is the same in every case. For a psycho-analysis is not an impartial scientific investigation, but a therapeutic measure. Its essence is not to prove anything, but merely to alter something. In a psycho-analysis the physician always gives his patient (sometimes to a greater and some times to a less extent) the conscious anticipatory ideas by the help of which he is put in a position to recognize and to grasp the unconscious material. For there are some patients who need more of such assistance and some who need less; but there are none who get through without some of it. Slight disorders may perhaps be brought to an end by the subject's unaided efforts, but never a neurosis - a thing which has set itself up against the ego as an element alien to it. To get the better of such an element another person must be brought in, and in so far as that other person can be of assistance the neurosis will be curable. If it is in the very nature of any neurosis to turn away from the 'other person' - and this seems to be one of the characteristics of the states grouped together under the name of dementia praecox - then for that very reason such a state will be incurable by any efforts of ours. It is true that a child, on account of the small development of his intellectual systems, requires especially energetic assistance. But, after all, the information which the physician gives his patient is itself derived in its turn from analytical experience; and indeed it is sufficiently convincing if, at the cost of this intervention by the physician, we are enabled to discover the structure of the pathogenic material and simultaneously to dissipate it. [1909b, 2089]
Little Hans's parents were determined from the very beginning of his illness that he was neither to be laughed at nor bullied, but that access must be obtained to his repressed wishes by means of psycho-analysis. The extraordinary pains taken by Hans's father were rewarded by success, and his reports will give us an opportunity of penetrating into the fabric of this type of phobia and of following the course of its analysis.

Therapeutic success, however, is not our primary aim; we endeavour rather to enable the patient to obtain a conscious grasp of his unconscious wishes. And this we can achieve by working upon the basis of the hints he throws out, and so, with the help of our interpretative technique, presenting the unconscious complex to his consciousness in our own words. There will be a certain degree of similarity between that which he hears from us and that which he is looking for, and which, in spite of all resistances, is trying to force its way through to consciousness; and it is this similarity that will enable him to discover the unconscious material. The physician is a step in front of him in knowledge; and the patient follows along his own road, until the two meet at the appointed goal. Beginners in psycho-analysis are apt to assimilate these two events, and to suppose that the moment at which one of the patient's unconscious complexes has become known to them is also the moment at which the patient himself recognizes it. They are expecting too much when they think that they will cure the patient by informing him of this piece of knowledge; for he can do no more with the information than make use of it to help himself in discovering the unconscious complex where it is anchored in his unconscious. A first success of this sort had now been achieved with Hans. Having partly mastered his castration complex, he was now able to communicate his wishes in regard to his mother. He did so, in what was still a distorted form, by means of the phantasy of the two giraffes, one of which was calling out in vain because Hans had taken possession of the other. He represented the 'taking possession of' pictorially as 'sitting down on'. His father recognized the phantasy as a reproduction of a bedroom scene which used to take place in the morning between the boy and his parents; and he quickly stripped the underlying wish of the disguise which it still wore. The boy's father and mother were the two giraffes. The reason for the choice of a giraffe-phantasy for the purposes of disguise was fully explained by a visit that the boy had paid to those same large beasts at Schönbrunn a few days earlier, by the giraffe-drawing, belonging to an earlier period, which had been preserved by his father, and also, perhaps, by an unconscious comparison based upon the giraffe's long, stiff neck.¹ It may be remarked that the giraffe, as being a large animal and interesting on account of its widdler, was a possible competitor with the horse for the role of bugbear; moreover, the fact that both his father and his mother appeared as giraffes offered a hint which had not yet been followed up, as regards the interpretation of the anxiety-horses.

¹ Even in analyses in which the physician and the patient are strangers, fear of the father plays one of the most important parts as a resistance against the reproduction of the unconscious pathogenic material. Resistances are sometimes in the nature of 'motifs'. But sometimes, as in the present instance, one piece of the unconscious material is capable from its actual content of operating as an inhibition against the reproduction of another piece.
It not at all infrequently happens that it is only after doing a certain amount of psycho-analytic work with a patient that an analyst can succeed in learning the actual content of a phobia, the precise form of words of an obsessional impulse, and so on. Repression has not only descended upon the unconscious complexes, but it is continually attacking their derivatives as well, and even prevents the patient from becoming aware of the products of the disease itself. The analyst thus finds himself in the position, curious for a doctor, of coming to the help of a disease, and of procuring it its due of attention. But only those who entirely misunderstand the nature of psycho-analysis will lay stress upon this phase of the work and suppose that on its account harm is likely to be done by analysis. The fact is that you must catch your thief before you can hang him, and that it requires some expenditure of labour to get securely hold of the pathological structures - at the destruction of which the treatment is aimed.
[1909b, 2106]

If we apply knowledge gained elsewhere to this case of childhood neurosis, we shall not be able to avoid a suspicion that in this instance as in others (that is to say, before the child had reached his sixth year) there had been conflicts and repressions, which had themselves been overtaken by amnesia, but had left behind them as a residuum the particular content of this obsessive fear. Later on we shall learn how far it is possible for us to rediscover those forgotten experiences or to reconstruct them with some degree of certainty. In the meantime stress may be laid on the fact, which is probably more than a mere coincidence, that the patient's infantile amnesia ended precisely with his sixth year.
[1909d, 2134]
'I have decided to tell you something which I consider most important and which has tormented me from the very first.' He then told me at great length the story of the last illness of his father, who had died of emphysema nine years previously. One evening, thinking that the condition was one which would come to a crisis, he had asked the doctor when the danger could be regarded as over. 'The evening of the day after to-morrow', had been the reply. It had never entered his head that his father might not survive that limit. At half-past eleven at night he had lain down for an hour's rest. He had woken up at one o'clock, and had been told by a medical friend that his father had died. He had reproached himself with not having been present at his death; and the reproach had been intensified when the nurse told him that his father had spoken his name once during the last days, and had said to her as she came up to the bed: 'Is that Paul?' He had thought he noticed that his mother and sisters had been inclined to reproach themselves in a similar way; but they had never spoken about it. At first, however, the reproach had not tormented him. For a long time he had not realized the fact of his father's death. It had constantly happened that, when he heard a good joke, he would say to himself: 'I must tell Father that.' His imagination, too, had been occupied with his father, so that often, when there was a knock at the door, he would think: 'Here comes Father', and when he walked into a room he would expect to find his father in it. And although he had never forgotten that his father was dead, the prospect of seeing a ghostly apparition of this kind had had no terrors for him; on the contrary, he had greatly desired it. It had not been until eighteen months later that the recollection of his neglect had recurred to him and begun to torment him terribly, so that he had come to treat himself as a criminal. The occasion of this happening had been the death of an aunt by marriage and of a visit of condolence that he had paid at her house. From that time forward he had extended the structure of his obsessional thoughts so as to include the next world. The immediate consequence of this development had been that he became seriously incapacitated from working.¹ He told me that the only thing that had kept him going at that time had been the consolation given him by his friend, who had always brushed his self-reproaches aside on the ground that they were grossly exaggerated. Hearing this, I took the opportunity of giving him a first glance at the underlying principles of psycho-analytic therapy. When there is a mésalliance, I began, between an affect and its ideational content (in this instance, between the intensity of the self-reproach and the occasion for it), a layman will say that the affect is too great for the occasion - that it is exaggerated and that consequently the inference following from the self-reproach (the inference that the patient is a criminal) is false. On the contrary, the physician says: 'No. The affect is justified. The sense of guilt is not in itself open to further criticism. But it belongs to some other content, which is unknown (unconscious), and which requires to be looked for. The known ideational content has only got into its actual position owing to a false connection. We are not used to feeling strong affects without their having any ideational content, and therefore, if the content is missing, we seize as a substitute upon some other content which is in some way or other suitable, much as our police, when they cannot catch the right murderer, arrest a wrong one instead. Moreover, this fact of there being a false connection is the only way of accounting for the powerlessness of logical processes to combat the tormenting idea.' I concluded by admitting that this new way of looking at the matter gave immediate rise to some hard problems; for how could he admit that his self-reproach of being a criminal towards his father was justified, when he must know that as a matter of fact he had never committed any crime against him?

[1909d, 2142]
At the next session the patient showed great interest in what I had said, but ventured, so he
told me, to bring for ward a few doubts. - How, he asked, could the information that the self-
reproach, the sense of guilt, was justified have a therapeutic effect? - I explained that it was not
the information that had this effect, but the discovery of the unknown content to which the self-
reproach was really attached. - Yes, he said, that was the precise point to which his question
had been directed. - I then made some short observations upon the psychological differences
between the conscious and the unconscious, and upon the fact that everything conscious was
subject to a process of wearing-away, while what was unconscious was relatively
unchangeable; and I illustrated my remarks by pointing to the antiques standing about in my
room. They were, in fact, I said, only objects found in a tomb, and their burial had been their
preservation: the destruction of Pompeii was only beginning now that it had been dug up. - Was
there any guarantee, he next enquired, of what one’s attitude would be towards what was
discovered? One man, he thought, would no doubt behave in such a way as to get the better of
his self-reproach, but another would not. - No, I said, it followed from the nature of the
circumstances that in every case the affect would be overcome - for the most part during the
progress of the work itself. Every effort was made to preserve Pompeii, whereas people were
anxious to be rid of tormenting ideas like his. - He had said to himself, he went on, that a self-
reproach could only arise from a breach of a person’s own inner moral principles and not from
that of any external ones. - I agreed, and said that the man who merely breaks an external law
often regards himself as a hero. - Such an occurrence, he continued, was thus only possible
where a disintegration of the personality was already present. Was there a possibility of his
effecting a reintegration of his personality? If this could be done, he thought he would be able to
make a success of his life, perhaps more of one than most people. - I replied that I was in
complete agreement with this notion of a splitting of his personality. He had only to assimilate
this new contrast, between a moral self and an evil one, with the contrast I had already
mentioned, between the conscious and the unconscious. The moral self was the conscious, the
evil self was the unconscious.¹ - He then said that, though he considered himself a moral
person, he could quite definitely remember having done things in his childhood which came
from his other self. - I remarked that here he had incidentally hit upon one of the chief
characteristics of the unconscious, namely, its relation to the infantile. The unconscious, I
explained, was the infantile; it was that part of the self which had become separated off from it
in infancy, which had not shared the later stages of its development, and which had in
consequence become repressed. It was the derivatives of this repressed unconscious that were
responsible for the involuntary thoughts which constituted his illness. He might now, I added,
discover yet another characteristic of the unconscious; it was a discovery which I should be glad
to let him make for himself. - He found nothing more to say in this immediate connection, but
instead he expressed a doubt whether it was possible to undo modifications of such long
standing. What, in particular, could be done against his idea about the next world, for it could
not be refuted by logic? - I told him I did not dispute the gravity of his case nor the significance
of his pathological constructions; but at the same time his youth was very much in his favour as
well as the intactness of his personality. In this connection I said a word or two upon the good
opinion I had formed of him, and this gave him visible pleasure.
[1909d, 2143]

We should not be justified in expecting such severe obsessional ideas as were present in this
case to be cleared up in any simpler manner or by any other means. When we reached the
solution that has been described above, the patient’s rat delirium disappeared.
[1909d, 2171]
It soon emerged, as though by chance, that this process of sweeping the mind clean could accomplish more than the merely temporary relief of her ever-recurring mental confusion. It was actually possible to bring about the disappearance of the painful symptoms of her illness, if she could be brought to remember under hypnosis, with an accompanying expression of affect, on what occasion and in what connection the symptom had first appeared. 'It was in the summer during a period of extreme heat, and the patient was suffering very badly from thirst; for, without being able to account for it in any way, she suddenly found it impossible to drink. She would take up the glass of water that she longed for, but as soon as it touched her lips she would push it away like someone suffering from hydrophobia. As she did this, she was obviously in an absence for a couple of seconds. She lived only on fruit, such as melons, etc., so as to lessen her tormenting thirst. This had lasted for some six weeks, when one day during hypnosis she grumbled about her English "lady-companion", whom she did not care for, and went on to describe, with every sign of disgust, how she had once gone into this lady's room and how her little dog - horrid creature! - had drunk out of a glass there. The patient had said nothing, as she had wanted to be polite. After giving further energetic expression to the anger she had held back, she asked for something to drink, drank a large quantity of water without any difficulty, and awoke from her hypnosis with the glass at her lips; and thereupon the disturbance vanished, never to return.'¹

A second observation of Breuer's, again, compels us to attach great importance, among the characteristics of the pathological chain of events, to states of consciousness. Breuer's patient exhibited, alongside of her normal state, a number of mental peculiarities: conditions of 'absence', confusion, and alterations of character. In her normal state she knew nothing of the pathogenic scenes or their connection with her symptoms; she had forgotten the scenes, or at all events had severed the pathogenic link. When she was put under hypnosis, it was possible, at the expense of a considerable amount of labour, to recall the scenes to her memory; and, through this work of recollecting, the symptoms were removed. The explanation of this fact would be a most awkward business, were it not that the way is pointed by experiences and experiments in hypnotism. The study of hypnotic phenomena has accustomed us to what was at first a bewildering realization that in one and the same individual there can be several mental groupings, which can remain more or less independent of one another, which can 'know nothing' of one another and which can alternate with one another in their hold upon consciousness. Cases of this kind, too, occasionally appear spontaneously, and are then described as examples of 'double conscience'.¹ If, where a splitting of the personality such as this has occurred, consciousness remains attached regularly to one of the two states, we call it the conscious mental state and the other, which is detached from it, the unconscious one. In the familiar condition known as 'post-hypnotic suggestion', a command given under hypnosis is slavishly carried out subsequently in the normal state. This phenomenon affords an admirable example of the influences which the unconscious state can exercise over the conscious one; moreover, it provides a pattern upon which we can account for the phenomena of hysteria. Breuer adopted a hypothesis that hysterical symptoms arise in peculiar mental conditions to which he gave the name of 'hypnoid'. On this view, excitations occurring during these hypnoid states can easily become pathogenic because such states do not provide opportunities for the normal discharge of the process of excitation. There consequently arises from the process of excitation an unusual product - the symptom. This finds its way, like a foreign body, into the normal state, which in turn is in ignorance of the hypnoid pathogenic situation. Wherever there is a symptom there is also an amnesia, a gap in the memory, and filling up this gap implies the removal of the conditions which led to the production of the symptom.

¹[1910a, 2203]

[1910a, 2208]
Our most valuable lesson from Breuer's observation was what it proved concerning the
relation between symptoms and pathogenic experiences or psychical traumas, and we must not
omit now to consider these discoveries from the standpoint of the theory of repression. At first
sight it really seems impossible to trace a path from repression to the formation of symptoms.
Instead of giving a complicated theoretical account, I will return here to the analogy which I
employed earlier for my explanation of repression. If you come to think of it, the removal of the
interrupter and the posting of the guardians at the door may not mean the end of the story. It
may very well be that the individual who has been expelled, and who has now become
embittered and reckless, will cause us further trouble. It is true that he is no longer among us;
we are free from his presence, from his insulting laughter and his sotto voce comments. But in
some respects, nevertheless, the repression has been unsuccessful; for now he is making an
intolerable exhibition of himself outside the room, and his shouting and banging on the door with
his fists interfere with my lecture even more than his bad behaviour did before. In these
circumstances we could not fail to be delighted if our respected president, Dr. Stanley Hall,
should be willing to assume the role of mediator and peacemaker. He would have a talk with the
unruly person outside and would then come to us with a request that he should be re-admitted
after all: he himself would guarantee that the man would now behave better. On Dr. Hall's
authority we decide to lift the repression, and peace and quiet are restored. This presents what
is really no bad picture of the physician's task in the psycho-analytic treatment of the neuroses.
[1910a, 2214]

To put the matter more directly. The investigation of hysterical patients and of other neurotics
leads us to the conclusion that their repression of the idea to which the intolerable wish is
attached has been a failure. It is true that they have driven it out of consciousness and out of
memory and have apparently saved themselves a large amount of unpleasure. But the
repressed wishful impulse continues to exist in the unconscious. It is on the look-out for an
opportunity of being activated, and when that happens it succeeds in sending into
consciousness a disguised and unrecognizable substitute for what had been repressed, and to
this there soon become attached the same feelings of unpleasure which it was hoped had been
saved by the repression. This substitute for the repressed idea - the symptom - is proof against
further attacks from the defensive ego; and in place of the short conflict an ailment now appears
which is not brought to an end by the passage of time. Alongside the indication of distortion in
the symptom, we can trace in it the remains of some kind of indirect resemblance to the idea
that was originally repressed. The paths along which the substitution was effected can be traced
in the course of the patient's psycho-analytic treatment; and in order to bring about recovery,
the symptom must be led back along the same paths and once more turned into the repressed
idea. If what was repressed is brought back again into conscious mental activity - a process
which presupposes the overcoming of considerable resistances - the resulting psychical conflict,
which the patient had tried to avoid, can, under the physician's guidance, reach a better
outcome than was offered by repression. There are a number of such opportune solutions,
which may bring the conflict and the neurosis to a happy end, and which may in certain
instances be combined. The patient's personality may be convinced that it has been wrong in
rejecting the pathogenic wish and may be led into accepting it wholly or in part; or the wish itself
may be directed to a higher and consequently unobjectionable aim (this is what we call its
'sublimation'); or the rejection of the wish may be recognized as a justifiable one, but the
automatic and therefore inefficient mechanism of repression may be replaced by a condemning
judgement with the help of the highest human mental functions - conscious control of the wish is
attained.
[1910a, 2215]
If you will now bring together the means we possess for uncovering what is concealed, forgotten and repressed in the mind (the study of the ideas occurring to patients under free association, of their dreams and of their faulty and symptomatic actions), and if you will add to these the exploitation of certain other phenomena which occur during psycho-analytic treatment and on which I shall have a few remarks to make later under the heading of 'transference' - if you bear all these in mind, you will agree with me in concluding that our technique is already efficient enough to fulfil its task, to bring the pathogenic psychical material into consciousness and so to get rid of the ailments that have been brought about by the formation of substitutive symptoms. And if, in the course of our therapeutic endeavours, we extend and deepen our knowledge of the human mind both in health and sickness, that can, of course, only be regarded as a peculiar attraction in our work.

[1910a, 2225]

Let me now proceed with my account of our findings. In another set of cases psycho-analytic investigation traces the symptoms back, it is true, not to sexual experiences but to commonplace traumatic ones. But this distinction loses its significance owing to another circumstance. For the work of analysis required for the thorough explanation and complete recovery of a case never comes to a stop at events that occurred at the time of the onset of the illness, but invariably goes back to the patient's puberty and early childhood; and it is only there that it comes upon the impressions and events which determined the later onset of the illness. It is only experiences in childhood that explain susceptibility to later traumas and it is only by uncovering these almost invariably forgotten memory-traces and by making them conscious that we acquire the power to get rid of the symptoms. And here we reach the same conclusion as in our investigation of dreams: the imperishable, repressed wishful impulses of childhood have alone provided the power for the construction of symptoms, and without them the reaction to later traumas would have taken a normal course. But these powerful wishful impulses of childhood may without exception be described as sexual.

[1910a, 2228]
Ladies and Gentlemen, from the intellectual point of view we must, I think, take into account two special obstacles to recognizing psycho-analytic trains of thought. In the first place, people are unaccustomed to reckoning with a strict and universal application of determinism to mental life; and in the second place, they are ignorant of the peculiarities which distinguish unconscious mental processes from the conscious ones that are familiar to us. One of the most widespread resistances to psycho-analytic work, in the sick and healthy alike, can be traced to the second of these two factors. People are afraid of doing harm by psycho-analysis; they are afraid of bringing the repressed sexual instincts into the patient's consciousness, as though that involved a danger of their overwhelming his higher ethical trends and of their robbing him of his cultural acquisitions. People notice that the patient has sore spots in his mind, but shrink from touching them for fear of increasing his sufferings. We can accept this analogy. It is no doubt kinder not to touch diseased spots if it can do nothing else but cause pain. But, as we know, a surgeon does not refrain from examining and handling a focus of disease, if he is intending to take active measures which he believes will lead to a permanent cure. No one thinks of blaming him for the inevitable suffering caused by the examination or for the reactions to the operation, if only it gains its end and the patient achieves a lasting recovery as a result of the temporary worsening of his state. The case is similar with psycho-analysis. It may make the same claims as surgery: the increase in suffering which it causes the patient during treatment is incomparably less than what a surgeon causes, and is quite negligible in proportion to the severity of the underlying ailment. On the other hand, the final outcome that is so much dreaded - the destruction of the patient's cultural character by the instincts which have been set free from repression - is totally impossible. For alarm on this score takes no account of what our experiences have taught us with certainty - namely that the mental and somatic power of a wishful impulse, when once its repression has failed, is far stronger if it is unconscious than if it is conscious; so that to make it conscious can only be to weaken it. An unconscious wish cannot be influenced and it is independent of any contrary tendencies, whereas a conscious one is inhibited by whatever else is conscious and opposed to it. Thus the work of psycho-analysis puts itself at the orders of precisely the highest and most valuable cultural trends, as a better substitute for the unsuccessful repression.

[1910a, 2237]

If, then, Leonardo's story about the vulture that visited him in his cradle is only a phantasy from a later period, one might suppose it could hardly be worth while spending much time on it. One might be satisfied with explaining it on the basis of his inclination, of which he makes no secret, to regard his preoccupation with the flight of birds as pre-ordained by destiny. Yet in underrating this story one would be committing just as great an injustice as if one were carelessly to reject the body of legends, traditions and interpretations found in a nation's early history. In spite of all the distortions and misunderstandings, they still represent the reality of the past: they are what a people forms out of the experience of its early days and under the dominance of motives that were once powerful and still operate to-day; and if it were only possible, by a knowledge of all the forces at work, to undo these distortions, there would be no difficulty in disclosing the historical truth lying behind the legendary material. The same holds good for the childhood memories or phantasies of an individual. What someone thinks he remembers from his childhood is not a matter of indifference; as a rule the residual memories - which he himself does not understand - cloak priceless pieces of evidence about the most important features in his mental development.¹ As we now possess in the techniques of psycho-analysis excellent methods for helping us to bring this concealed material to light, we may venture to fill in the gap in Leonardo's life story by analysing his childhood phantasy. And if in doing so we remain dissatisfied with the degree of certainty which we achieve, we shall have to console ourselves with the reflection that so many other studies of this great and enigmatic man have met with no better fate.

[1910c, 2261]
(a) Advances in our knowledge. We are, of course, still a long way from knowing all that is required for an understanding of the unconscious in our patients. It is clear that every advance in our knowledge means an increase in our therapeutic power. As long as we have understood nothing, we have accomplished nothing; the more we understand, the more we shall achieve. At its beginning psycho-analytic treatment was inexorable and exhausting. The patient had to say everything himself, and the physician's activity consisted of urging him on incessantly. To-day things have a more friendly air. The treatment is made up of two parts - what the physician infers and tells the patient, and the patient's working-over of what he has heard. The mechanism of our assistance is easy to understand: we give the patient the conscious anticipatory idea and he then finds the repressed unconscious idea in himself on the basis of its similarity to the anticipatory one. This is the intellectual help which makes it easier for him to overcome the resistances between conscious and unconscious. Incidentally, I may remark that it is not the only mechanism made use of in analytic treatment; you all know the far more powerful one which lies in the use of the 'transference'. It is my intention in the near future to deal with these various factors, which are so important for an understanding of the treatment, in an Allgemeine Methodik der Psychoanalyse. And further, in speaking to you I need not rebut the objection that the evidential value in support of the correctness of our hypotheses is obscured in our treatment as we practise it to-day; you will not forget that this evidence is to be found elsewhere, and that a therapeutic procedure cannot be carried out in the same way as a theoretical investigation. [1910d, 2307]

(b) I will hasten on to the innovations in the field of technique, where indeed nearly everything still awaits final settlement, and much is only now beginning to become clear. There are now two aims in psycho-analytic technique: to save the physician effort and to give the patient the most unrestricted access to his unconscious. As you know, our technique has undergone a fundamental transformation. At the time of the cathartic treatment what we aimed at was the elucidation of the symptoms; we then turned away from the symptoms and devoted ourselves instead to uncovering the 'complexes', to use a word which Jung has made indispensable; now, however, our work is aimed directly at finding out and overcoming the 'resistances', and we can justifiably rely on the complexes coming to light without difficulty as soon as the resistances have been recognized and removed. Some of you have since felt a need to be able to make a survey of these resistances and classify them. I will ask you to examine your material and see whether you can confirm the generalized statement that in male patients the most important resistances in the treatment seem to be derived from the father-complex and to express themselves in fear of the father, in defiance of the father and in disbelief of the father. [1910d, 2309]
Thus in the case of Schreber we find ourselves once again on the familiar ground of the father-complex.¹ The patient's struggle with Flechsig became revealed to him as a conflict with God, and we must therefore construe it as an infantile conflict with the father whom he loved; the details of that conflict (of which we know nothing) are what determined the content of his delusions. None of the material which in other cases of the sort is brought to light by analysis is absent in the present one: every element is hinted at in one way or another. In infantile experiences such as this the father appears as an interferer with the satisfaction which the child is trying to obtain; this is usually of an auto-erotic character, though at a later date it is often replaced in phantasy by some other satisfaction of a less inglorious kind.² In the final stage of Schreber's delusion a magnificent victory was scored by the infantile sexual urge; for voluptuousness became God-fearing, and God Himself (his father) never tired of demanding it from him. His father's most dreaded threat, castration, actually provided the material for his wishful phantasy (at first resisted but later accepted) of being transformed into a woman. His allusion to an offence covered by the surrogate idea 'soul-murder' could not be more transparent. The chief attendant was discovered to be identical with his neighbour von W., who, according to the voices, had falsely accused him of masturbation (108). The voices said, as though giving grounds for the threat of castration: 'For you are to be represented as being given over to voluptuous excesses.'³ (127-8.) Finally, we come to the enforced thinking (47) to which the patient submitted himself because he supposed that God would believe he had become an idiot and would withdraw from him if he ceased thinking for a moment. This is a reaction (with which we are also familiar in other connections) to the threat or fear of losing one's reason⁴ as a result of indulging in sexual practices and especially in masturbation. Considering the enormous number of delusional ideas of a hypochondriacal nature⁵ which the patient developed, no great importance should perhaps be attached to the fact that some of them coincide word for word with the hypochondriacal fears of masturbators.⁶

But in psycho-analytic relations things often happen differently from what the psychology of consciousness might lead us to expect. Experience does not speak in favour of an affective technique of this kind. Nor is it hard to see that it involves a departure from psycho-analytic principles and verges upon treatment by suggestion. It may induce the patient to bring forward sooner and with less difficulty things he already knows but would otherwise have kept back for a time through conventional resistances. But this technique achieves nothing towards the uncovering of what is unconscious to the patient. It makes him even more incapable of overcoming his deeper resistances, and in severer cases it invariably fails by encouraging the patient to be insatiable: he would like to reverse the situation, and finds the analysis of the doctor more interesting than his own. The resolution of the transference, too - one of the main tasks of the treatment - is made more difficult by an intimate attitude on the doctor's part, so that any gain there may be at the beginning is more than outweighed at the end. I have no hesitation, therefore, in condemning this kind of technique as incorrect. The doctor should be opaque to his patients and, like a mirror, should show them nothing but what is shown to him. In practice, it is true, there is nothing to be said against a psychotherapist combining a certain amount of analysis with some suggestive influence in order to achieve a perceptible result in a shorter time - as is necessary, for instance, in institutions. But one has a right to insist that he himself should be in no doubt about what he is doing and should know that his method is not that of true psycho-analysis.
This answer of course involves a condemnation of any line of behaviour which would lead us
to give the patient a translation of his symptoms as soon as we have guessed it ourselves, or
would even lead us to regard it as a special triumph to fling these 'solutions' in his face at the
first interview. It is not difficult for a skilled analyst to read the patient's secret wishes plainly
between the lines of his complaints and the story of his illness; but what a measure of self-
complacency and thoughtlessness must be possessed by anyone who can, on the shortest
acquaintance, inform a stranger who is entirely ignorant of all the tenets of analysis that he is
attached to his mother by incestuous ties, that he harbours wishes for the death of his wife
whom he appears to love, that he conceals an intention of betraying his superior, and so on! I
have heard that there are analysts who plume themselves upon these kinds of lightning
diagnoses and 'express' treatments, but I must warn everyone against following such examples.
Behaviour of this sort will completely discredit oneself and the treatment in the patient's eyes
and will arouse the most violent opposition in him, whether one's guess has been true or not;
indeed, the truer the guess the more violent will be the resistance. As a rule the therapeutic
effect will be nil; but the deterring of the patient from analysis will be final. Even in the later
stages of analysis one must be careful not to give a patient the solution of a symptom or the
translation of a wish until he is already so close to it that he has only one short step more to
make in order to get hold of the explanation for himself. In former years I often had occasion to
find that the premature communication of a solution brought the treatment to an untimely end,
on account not only of the resistances which it thus suddenly awakened but also of the relief
which the solution brought with it.
[1913c, 2492]

It is true that in the earliest days of analytic technique we took an intellectualist view of the
situation. We set a high value on the patient's knowledge of what he had forgotten, and in this
we made hardly any distinction between our knowledge of it and his. We thought it a special
piece of good luck if we were able to obtain information about the forgotten childhood trauma
from other sources - for instance, from parents or nurses or the seducer himself - as in some
cases it was possible to do; and we hastened to convey the information and the proofs of its
correctness to the patient, in the certain expectation of thus bringing the neurosis and the
treatment to a rapid end. It was a severe disappointment when the expected success was not
forthcoming. How could it be that the patient, who now knew about his traumatic experience,
nevertheless still behaved as if he knew no more about it than before? Indeed, telling and
describing his repressed trauma to him did not even result in any recollection of it coming into
his mind.
[1913c, 2493]

In one particular case the mother of a hysterical girl had confided to me the homosexual
experience which had greatly contributed to the fixation of the girl's attacks. The mother had
herself surprised the scene; but the patient had completely forgotten it, though it had occurred
when she was already approaching puberty. I was now able to make a most instructive
observation. Every time I repeated her mother's story to the girl she reacted with a hysterical
attack, and after this she forgot the story once more. There is no doubt that the patient was
expressing a violent resistance against the knowledge that was being forced upon her. Finally
she simulated feeble-mindedness and a complete loss of memory in order to protect herself
against what I had told her. After this, there was no choice but to cease attributing to the fact of
knowing, in itself, the importance that had previously been given to it and to place the emphasis
on the resistances which had in the past brought about the state of not knowing and which were
still ready to defend that state. Conscious knowledge, even if it was not subsequently driven out
again, was powerless against those resistances.
[1913c, 2493]
The strange behaviour of patients, in being able to combine a conscious knowing with not knowing, remains inexplicable by what is called normal psychology. But to psycho-analysis, which recognizes the existence of the unconscious, it presents no difficulty. The phenomenon we have described, moreover, provides some of the best support for a view which approaches mental processes from the angle of topographical differentiation. The patients now know of the repressed experience in their conscious thought, but this thought lacks any connection with the place where the repressed recollection is in some way or other contained. No change is possible until the conscious thought-process has penetrated to that place and has overcome the resistances of repression there. It is just as though a decree were promulgated by the Ministry of Justice to the effect that juvenile delinquencies should be dealt with in a certain lenient manner. As long as this decree has not come to the knowledge of the local magistrates, or in the event of their not intending to obey it but preferring to administer justice by their own lights, no change can occur in the treatment of particular youthful delinquents. For the sake of complete accuracy, however, it should be added that the communication of repressed material to the patient's consciousness is nevertheless not without effect. It does not produce the hoped-for result of putting an end to the symptoms; but it has other consequences. At first it arouses resistances, but then, when these have been overcome, it sets up a process of thought in the course of which the expected influencing of the unconscious recollection eventually takes place.

At this point I will interpolate a few remarks which every analyst has found confirmed in his observations. Forgetting impressions, scenes or experiences nearly always reduces itself to shutting them off. When the patient talks about these 'forgotten' things he seldom fails to add: 'As a matter of fact I've always known it; only I've never thought of it.' He often expresses disappointment at the fact that not enough things come into his head that he can call 'forgotten' - that he has never thought of since they happened. Nevertheless, even this desire is fulfilled, especially in the case of conversion hysterias. 'Forgetting' becomes still further restricted when we assess at their true value the screen memories which are so generally present. In some cases I have had an impression that the familiar childhood amnesia, which is theoretically so important to us, is completely counterbalanced by screen memories. Not only some but all of what is essential from childhood has been retained in these memories. It is simply a question of knowing how to extract it out of them by analysis. They represent the forgotten years of childhood as adequately as the manifest content of a dream represents the dream-thoughts.
First and foremost, the initiation of the treatment in itself brings about a change in the patient's conscious attitude to his illness. He has usually been content with lamenting it, despising it as nonsensical and under-estimating its importance; for the rest, he has extended to its manifestations the ostrich-like policy of repression which he adopted towards its origins. Thus it can happen that he does not properly know under what conditions his phobia breaks out or does not listen to the precise wording of his obsessional ideas or does not grasp the actual purpose of his obsessional impulse. The treatment, of course, is not helped by this. He must find the courage to direct his attention to the phenomena of his illness. His illness itself must no longer seem to him contemptible, but must become an enemy worthy of his mettle, a piece of his personality, which has solid ground for its existence and out of which things of value for his future life have to be derived. The way is thus paved from the beginning for a reconciliation with the repressed material which is coming to expression in his symptoms, while at the same time place is found for a certain tolerance for the state of being ill. If this new attitude towards the illness intensifies the conflicts and brings to the fore symptoms which till then had been indistinct, one can easily console the patient by pointing out that these are only necessary and temporary aggravations and that one cannot overcome an enemy who is absent or not within range. The resistance, however, may exploit the situation for its own ends and abuse the licence to be ill. It seems to say: 'See what happens if I really give way to such things. Was I not right to consign them to repression?' Young and childish people in particular are inclined to make the necessity imposed by the treatment for paying attention to their illness a welcome excuse for luxuriating in their symptoms.

The main instrument, however, for curbing the patient's compulsion to repeat and for turning it into a motive for remembering lies in the handling of the transference. We render the compulsion harmless, and indeed useful, by giving it the right to assert itself in a definite field. We admit it into the transference as a playground in which it is allowed to expand in almost complete freedom and in which it is expected to display to us everything in the way of pathogenic instincts that is hidden in the patient's mind. Provided only that the patient shows compliance enough to respect the necessary conditions of the analysis, we regularly succeed in giving all the symptoms of the illness a new transference meaning and in replacing his ordinary neurosis by a 'transference-neurosis' of which he can be cured by the therapeutic work. The transference thus creates an intermediate region between illness and real life through which the transition from the one to the other is made. The new condition has taken over all the features of the illness; but it represents an artificial illness which is at every point accessible to our intervention. It is a piece of real experience, but one which has been made possible by especially favourable conditions, and it is of a provisional nature. From the repetitive reactions which are exhibited in the transference we are led along the familiar paths to the awakening of the memories, which appear without difficulty, as it were, after the resistance has been overcome.

Every beginner in psycho-analysis probably feels alarmed at first at the difficulties in store for him when he comes to interpret the patient's associations and to deal with the reproduction of the repressed. When the time comes, however, he soon learns to look upon these difficulties as insignificant, and instead becomes convinced that the only really serious difficulties he has to meet lie in the management of the transference.
Even more decidedly, however, do I decline to fulfil the second of the expectations I have mentioned. To urge the patient to suppress, renounce or sublimate her instincts the moment she has admitted her erotic transference would be, not an analytic way of dealing with them, but a senseless one. It would be just as though, after summoning up a spirit from the underworld by cunning spells, one were to send him down again without having asked him a single question. One would have brought the repressed into consciousness, only to repress it once more in a fright. Nor should we deceive ourselves about the success of any such proceeding. As we know, the passions are little affected by sublime speeches. The patient will feel only the humiliation, and she will not fail to take her revenge for it.

If the necessary amount of patience is added to these arguments, it is usually possible to overcome the difficult situation and to continue the work with a love which has been moderated or transformed; the work then aims at uncovering the patient's infantile object-choice and the phantasies woven round it.

It was conclusively proved that hysterical symptoms are residues (reminiscences) of profoundly moving experiences, which have been withdrawn from everyday consciousness, and that their form is determined (in a manner that excludes deliberate action) by details of the traumatic effects of the experiences. On this view, the therapeutic prospects lie in the possibility of getting rid of this 'repression', so as to allow part of the unconscious psychical material to become conscious and thus to deprive it of its pathogenic power. This view is a dynamic one, in so far as it regards psychical processes as displacements of psychical energy which can be gauged by the amount of their effect on the affective elements. This is most significant in hysteria, where the process of 'conversion' creates the symptoms by transforming a quantity of mental impulses into somatic innervations.

The mind of the hysterical patient is full of active yet unconscious ideas; all her symptoms proceed from such ideas. It is in fact the most striking character of the hysterical mind to be ruled by them. If the hysterical woman vomits, she may do so from the idea of being pregnant. She has, however, no knowledge of this idea, although it can easily be detected in her mind, and made conscious to her, by one of the technical procedures of psycho-analysis. If she is executing the jerks and movements constituting her 'fit', she does not even consciously represent to herself the intended actions, and she may perceive those actions with the detached feelings of an onlooker. Nevertheless analysis will show that she was acting her part in the dramatic reproduction of some incident in her life, the memory of which was unconsciously active during the attack. The same preponderance of active unconscious ideas is revealed by analysis as the essential fact in the psychology of all other forms of neurosis.
But we are able to bring forward other motives than these, thanks to the knowledge of concealed mental impulses which we have acquired from the psycho-analytic examination of individual human beings. A woman whose psychosexual needs should find satisfaction in her marriage and her family life is often threatened with the danger of being left unsatisfied, because her marriage relation has come to a premature end and because of the uneventfulness of her emotional life. A mother, as she grows older, saves herself from this by putting herself in her children's place, by identifying herself with them; and this she does by making their emotional experiences her own. Parents are said to stay young with their children, and that is indeed one of the most precious psychological gains that parents derive from their children. Where a marriage is childless, the wife has lost one of the things which might be of most help to her in tolerating the resignation that her own marriage demands from her. A mother's sympathetic identification with her daughter can easily go so far that she herself falls in love with the man her daughter loves; and in glaring instances this may lead to severe forms of neurotic illness as a result of her violent mental struggles against this emotional situation. In any case, it very frequently happens that a mother-in-law is subject to an impulse to fall in love in this way, and this impulse itself or an opposing trend are added to the tumult of conflicting forces in her mind. And very often the unkind, sadistic components of her love are directed on to her son-in-law in order that the forbidden, affectionate ones may be the more severely suppressed.

[1912-1913, 2663]

It is in obsessional neuroses that the survival of the omnipotence of thoughts is most clearly visible and that the consequences of this primitive mode of thinking come closest to consciousness. But we must not be misled into supposing that it is a distinguishing feature of this particular neurosis, for analytic investigation reveals the same thing in the other neuroses as well. In all of them what determines the formation of symptoms is the reality not of experience but of thought. Neurotics live in a world apart, where, as I have said elsewhere, only 'neurotic currency' is legal tender; that is to say, they are only affected by what is thought with intensity and pictured with emotion, whereas agreement with external reality is a matter of no importance. What hysterics repeat in their attacks and fix by means of their symptoms are experiences which have occurred in that form only in their imagination though it is true that in the last resort those imagined experiences go back to actual events or are based upon them. To attribute the neurotic sense of guilt to real misdeeds would show an equal misunderstanding. An obsessional neurotic may be weighed down by a sense of guilt that would be appropriate in a mass-murderer, while in fact, from his childhood onwards, he has behaved to his fellow-men as the most considerate and scrupulous member of society. Nevertheless, his sense of guilt has a justification: it is founded on the intense and frequent death wishes against his fellows which are unconsciously at work in him. It has a justification if what we take into account are unconscious thoughts and not intentional deeds. Thus the omnipotence of thoughts, the overvaluation of mental processes as compared with reality, is seen to have unrestricted play in the emotional life of neurotic patients and in everything that derives from it. If one of them undergoes psycho-analytic treatment, which makes what is unconscious in him conscious, he will be unable to believe that thoughts are free and will constantly be afraid of expressing evil wishes, as though their expression would lead inevitably to their fulfilment. This behaviour, as well as the superstitions which he practises in ordinary life, reveals his resemblance to the savages who believe they can alter the external world by mere thinking.

[1912-1913, 2729]
Long before I had any opportunity of hearing about psycho-analysis, I learnt that a Russian art-connoisseur, Ivan Lermolieff,¹ had caused a revolution in the art galleries of Europe by questioning the authorship of many pictures, showing how to distinguish copies from originals with certainty, and constructing hypothetical artists for those works whose former supposed authorship had been discredited. He achieved this by insisting that attention should be diverted from the general impression and main features of a picture, and by laying stress on the significance of minor details, of things like the drawing of the fingernails, of the lobe of an ear, of halos and such unconsidered trifles which the copyist neglects to imitate and yet which every artist executes in his own characteristic way. I was then greatly interested to learn that the Russian pseudonym concealed the identity of an Italian physician called Morelli, who died in 1891 with the rank of Senator of the Kingdom of Italy. It seems to me that his method of inquiry is closely related to the technique of psycho-analysis. It, too, is accustomed to divine secret and concealed things from despised or unnoticed features, from the rubbish-heap, as it were, of our observations.

[1914b, 2854]

The view that the sexual representation of 'higher' thoughts in dreams and neurosis is nothing but an archaic mode of expression is of course irreconcilable with the fact that in neurosis these sexual complexes prove to be the bearers of the quantities of libido which have been withdrawn from utilization in real life. If it was merely a question of a sexual 'jargon', the economy of the libido could not have been altered in any way by it. Jung admits this himself in his Darstellung der psychoanalytischen Theorie and formulates the task of therapy as the detaching of libidinal catexes from these complexes. This can never be achieved, however, by directing the patient away from them and urging him to sublimate, but only by exhaustive examination of them and by making them fully and completely conscious. The first piece of reality which the patient must deal with is his illness. Efforts to spare him that task point to the physician's incapacity to help him to overcome his resistances, or else to the physician's dread of the results of the work.

[1914d, 2927]

Let us turn now to the second of the discoveries which follow from our analyses; in its case we need not fear having to make a subsequent qualification of our views. I have described to you how our first patient carried out a senseless obsessional action and how she reported an intimate memory from her past life as having some connection with it: and how afterwards I examined the connection between the two and discovered the intention of the obsessional action from its relation to the memory. But there is one factor which I have entirely neglected, though it deserves our fullest attention. However often the patient repeated her obsessional action, she knew nothing of its being derived from the experience she had had. The connection between the two was hidden from her; she could only quite truthfully reply that she did not know what it was that was making her carry out her action. Then suddenly one day, under the influence of the treatment, she succeeded in discovering the connection and reported it to me. But she still knew nothing of the intention with which she was performing the obsessional action - the intention of correcting a distressing portion of the past and of putting her beloved husband in a better light. It took a fairly long time and called for much labour before she understood and admitted to me that such a motive alone could have been the driving force of her obsessional action.

[1916-1917, 3354]
And we meet with what is in essence the same thing in our second patient. She had made a
rule that the pillow must not touch the back of the bedstead, and she had to obey this rule
though she did not know where it came from, what it meant or to what motives it owed its
power. Whether she herself regarded the rule as a matter of indifference, or whether she
struggled against it or raged against it or decided to transgress it - none of this made any
difference to her carrying it out. It had to be obeyed, and she asked herself vainly why. We must
recognize, however, that these symptoms of obsessional neurosis, these ideas and impulses
which emerge one knows not whence, which prove so resistant to every influence from an
otherwise normal mind, which give the patient himself the impression of being all-powerful
guests from an alien world, immortal beings intruding into the turmoil of mortal life - these
symptoms offer the plainest indication of there being a special region of the mind, shut off from
the rest. They lead, by a path that cannot be missed, to a conviction of the existence of the
unconscious in the mind; and that is precisely why clinical psychiatry, which is acquainted only
with a psychology of consciousness, can deal with these symptoms in no other way than by
declaring them to be signs of a special sort of degeneracy. Obsessional ideas and obsessional
impulses are not, of course, themselves unconscious, any more than the performance of
obsessional actions escapes conscious perception. They would not have become symptoms if
they had not forced their way into consciousness. But their psychical predeterminants which we
infer by means of analysis, the connections into which we insert them by interpretation, are
unconscious, at least until we have made them conscious to the patient by the work of analysis.
[1916-1917, 3355]

If, now, you consider further that the state of affairs which we have established in our two
cases is confirmed for every symptom of every neurotic illness - that always and everywhere the
sense of the symptoms is unknown to the patient and that analysis regularly shows that these
symptoms are derivatives of unconscious processes but can, subject to a variety of favourable
circumstances, be made conscious - if you consider this, you will understand that in psycho-
analysis we cannot do without what is at the same time unconscious and mental, and are
accustomed to operate with it as though it were something palpable to the senses. But you will
understand as well, perhaps, how incapable of forming a judgement on this question are all
those other people, who are only acquainted with the unconscious as a concept, who have
never carried out an analysis and have never interpreted dreams or found a sense and intention
in neurotic symptoms. To say it for our ends once again: the possibility of giving a sense to
neurotic symptoms by analytic interpretation is an unshakeable proof of the existence - or, if you
prefer it, of the necessity for the hypothesis - of unconscious mental processes.
[1916-1917, 3356]

But that is not all. Thanks to a second discovery of Breuer's, which seems to me even more
significant than the other and which he shared with no one, we learn still more of the connection
between neurotic symptoms and the unconscious. Not only is the sense of the symptoms
regularly unconscious, but there is an inseparable relation between this fact of the symptoms
being unconscious and the possibility of their existing. You will understand me in a moment. I
follow Breuer in asserting that every time we come upon a symptom we can infer that there are
certain definite unconscious processes in the patient which contain the sense of the symptom.
But it is also necessary for that sense to be unconscious in order that the symptom can come
about. Symptoms are never constructed from conscious processes; as soon as the unconscious
processes concerned have become conscious, the symptom must disappear. Here you will at
once perceive a means of approach to therapy, a way of making symptoms disappear. And in
this way Breuer did in fact restore his hysterical patient - that is, freed her from her symptoms;
he found a technique for bringing to her consciousness the unconscious processes which
contained the sense of the symptoms, and the symptoms disappeared.
[1916-1917, 3356]
The construction of a symptom is a substitute for something else that did not happen. Some particular mental processes should normally have developed to a point at which consciousness received information of them. This, however, did not take place, and instead - out of the interrupted processes, which had been somehow disturbed and were obliged to remain unconscious - the symptom emerged. Thus something in the nature of an exchange has taken place; if this can be reversed the therapy of the neurotic symptoms will have achieved its task. [1916-1917, 3357]

This discovery of Breuer's is still the foundation of psycho-analytic therapy. The thesis that symptoms disappear when we have made their unconscious predeterminants conscious has been confirmed by all subsequent research, although we meet with the strangest and most unexpected complications when we attempt to carry it through in practice. Our therapy works by transforming what is unconscious into what is conscious, and it works only in so far as it is in a position to effect that transformation. [1916-1917, 3357]

And now I must quickly make a short digression, to avoid the risk of your imagining that this therapeutic work is accomplished too easily. From what I have so far said a neurosis would seem to be the result of a kind of ignorance - a not knowing about mental events that one ought to know of. This would be a close approximation to some well-known Socratic doctrines, according to which even vices are based on ignorance. Now it would as a rule be very easy for a doctor experienced in analysis to guess what mental impulses had remained unconscious in a particular patient. So it ought not to be very difficult, either, for him to restore the patient by communicating his knowledge to him and so remedying his ignorance. One part at least of the symptom's unconscious sense could be easily dealt with in this way, though it is true that the doctor cannot guess much about the other part - the connection between the symptoms and the patient's experiences -, since he himself does not know those experiences but must wait till the patient remembers them and tells them to him. But even for this a substitute can in some instances be found. One can make enquiries about these experiences from the patient's relatives and they will often be able to recognize which of them had a traumatic effect, and they can even sometimes report experiences of which the patient himself knows nothing because they occurred at a very early period of his life. Thus, by combining these two methods, we should have a prospect of relieving the patient of his pathogenic ignorance with little expense of time or trouble. [1916-1917, 3357]

If only that was how things happened! We came upon discoveries in this connection for which we were at first unprepared. Knowledge is not always the same as knowledge: there are different sorts of knowledge, which are far from equivalent psychologically. 'Il y a fagots et fagots', as Molière has said. The doctor's knowledge is not the same as the patient's and cannot produce the same effects. If the doctor transfers his knowledge to the patient as a piece of information, it has no result. No, it would be wrong to say that. It does not have the result of removing the symptoms, but it has another one - of setting the analysis in motion, of which the first signs are often expressions of denial. The patient knows after this what he did not know before - the sense of his symptom; yet he knows it just as little as he did. Thus we learn that there is more than one kind of ignorance. We shall need to have a somewhat deeper understanding of psychology to show us in what these differences consist. But our thesis that the symptoms vanish when their sense is known remains true in spite of this. All we have to add is that the knowledge must rest on an internal change in the patient such as can only be brought about by a piece of psychical work with a particular aim. We are faced here by problems which will presently be brought together into the dynamics of the construction of symptoms. [1916-1917, 3358]
I will not go into this any further to-day. But since we still have some time to spare, I should like to direct your attention to another characteristic of our two analyses, which, once again, it will only be possible to appreciate fully later on - to the gaps in the patients' memories, their amnesias. As you have heard, the task of a psycho-analytic treatment can be expressed in this formula: its task is to make conscious everything that is pathogenically unconscious. You will perhaps be surprised to learn, then, that this formula can be replaced by another one: its task is to fill up all the gaps in the patient's memory, to remove his amnesias. This would amount to the same thing. We are thus implying that the amnesias of neurotic patients have an important connection with the origin of their symptoms. If, however, you consider the case of our first analysis you will not find this view of amnesia justified. The patient had not forgotten the scene from which her obsessive action was derived; on the contrary, she had a vivid recollection of it; nor did anything else forgotten play a part in the origin of the symptom. The position with our second patient (the girl with the obsessional ceremonial), though less clear, was on the whole analogous. She had not really forgotten her behaviour in earlier years - the fact that she had insisted on the door between her parents' bedroom and her own being left open and that she had driven her mother out of her place in her parents' bed; she remembered this very plainly, even though with hesitation and unwillingly. The only thing we can consider striking is that the first patient, in carrying out her obsessional action on countless occasions, had never once noticed its resemblance to her experience on her wedding-night, and that the memory of it did not occur to her when she was directly asked to look for the motives of her obsessional action. And the same thing applies to the girl, whose ceremonial and its causes were moreover connected with a situation which was identically repeated every evening. In both these cases there was no true amnesia, no missing memory; but a connection had been broken which ought to have led to the reproduction or re-emergence of the memory.

[1916-1917, 3359]

In psycho-analytic therapy we make use of the same technique that is familiar to you from dream-interpretation. We instruct the patient to put himself into a state of quiet, unreflecting self-observation, and to report to us whatever internal perceptions he is able to make - feelings, thoughts, memories in the order in which they occur to him. At the same time we warn him expressly against giving way to any motive which would lead him to make a selection among these associations or to exclude any of them, whether on the ground that it is too disagreeable or too indiscreet to say, or that it is too unimportant or irrelevant, or that it is nonsensical and need not be said. We urge him always to follow only the surface of his consciousness and to leave aside any criticism of what he finds, whatever shape that criticism may take; and we assure him that the success of the treatment, and above all its duration, depends on the conscientiousness with which he obeys this fundamental technical rule of analysis. We already know from the technique of dream-interpretation that the associations giving rise to the doubts and objections I have just enumerated are precisely the ones that invariably contain the material which leads to the uncovering of the unconscious.

[1916-1917, 3362]
Resistances of this kind should not be one-sidedly condemned. They include so much of the most important material from the patient's past and bring it back in so convincing a fashion that they become some of the best supports of the analysis if a skilful technique knows how to give them the right turn. Nevertheless, it remains a remarkable fact that this material is always in the service of the resistance to begin with and brings to the fore a façade that is hostile to the treatment. It may also be said that what is being mobilized for fighting against the alterations we are striving for are character-traits, attitudes of the ego. In this connection we discover that these character-traits were formed in relation to the determinants of the neurosis and in reaction against its demands, and we come upon traits which cannot normally emerge, or not to the same extent, and which may be described as latent. Nor must you get an impression that we regard the appearance of these resistances as an unforeseen risk to analytic influence. No, we are aware that these resistances are bound to come to light; in fact we are dissatisfied if we cannot provoke them clearly enough and are unable to demonstrate them to the patient. Indeed we come finally to understand that the overcoming of these resistances is the essential function of analysis and is the only part of our work which gives us an assurance that we have achieved something with the patient.
[1916-1917, 3366]

How, then, do we account for our observation that the patient fights with such energy against the removal of his symptoms and the setting of his mental processes on a normal course? We tell ourselves that we have succeeded in discovering powerful forces here which oppose any alteration of the patient's condition; they must be the same ones which in the past brought this condition about. During the construction of his symptoms something must have taken place which we can now reconstruct from our experiences during the resolution of his symptoms. We already know from Breuer's observation that there is a precondition for the existence of a symptom: some mental process must not have been brought to an end normally - so that it could become conscious. The symptom is a substitute for what did not happen at that point. We now know the point at which we must locate the operation of the force which we have surmised. A violent opposition must have started against the entry into consciousness of the questionable mental process, and for that reason it remained unconscious. As being something unconscious, it had the power to construct a symptom. This same opposition, during psychoanalytic treatment, sets itself up once more against our effort to transform what is unconscious into what is conscious. This is what we perceive as resistance. We have proposed to give the pathogenic process which is demonstrated by the resistance the name of repression.
[1916-1917, 3368]
(b) A second pointer is to be found in the analysis of the psychoneuroses, and especially of hysteria. We have seen that in this illness anxiety often appears in company with the symptoms, but that unbound anxiety appears, too, manifested as an attack or as a chronic condition. The patients cannot say what it is they are afraid of, and, by the help of an unmistakable secondary revision, link it to the first phobias that come to hand - such as dying, going mad, or having a stroke. If the situation out of which the anxiety (or the symptoms accompanied by anxiety) arose is subjected to analysis, we can as a rule discover what normal course of psychical events has failed to occur and has been replaced by phenomena of anxiety. To express it in another way: we construct the unconscious process as it would have been if it had not experienced any repression and had proceeded unhindered into consciousness. This process would have been accompanied by a particular affect, and we now learn to our surprise that this affect accompanying the normal course of events is invariably replaced by anxiety after repression has occurred, no matter what its own quality may be. Thus, when we have a hysterical anxiety-state before us, its unconscious correlate may be an impulse of a similar character - anxiety, shame, embarrassment - or, just as easily, a positive libidinal excitation or a hostile aggressive one, such as rage or anger. Anxiety is therefore the universally current coinage for which any affective impulse is or can be exchanged if the ideational content attached to it is subjected to repression.

[1916-1917, 3450]

Thus you cannot explain the therapeutic effect of psycho-analysis by its permitting a full sexual life. Look around, then, for something else. I fancy that, while I was rejecting this suggestion of yours, one remark of mine put you on the right track. What we make use of must no doubt be the replacing of what is unconscious by what is conscious, the translation of what is unconscious into what is conscious. Yes, that is it. By carrying what is unconscious on into what is conscious, we lift the repressions, we remove the preconditions for the formation of symptoms, we transform the pathogenic conflict to a normal one for which it must be possible somehow to find a solution. All that we bring about in a patient is this single psychical change: the length to which it is carried is the measure of the help we provide. Where no repressions (or analogous psychical processes) can be undone, our therapy has nothing to expect.

[1916-1917, 3477]

We can express the aim of our efforts in a variety of formulas: making conscious what is unconscious, lifting repressions, filling gaps in the memory - all these amount to the same thing. But perhaps you will be dissatisfied by this admission. You had formed a different picture of the return to health of a neurotic patient - that, after submitting to the tedious hours of a psycho-analysis, he would become another man; but the total result, so it seems, is that he has rather less that is unconscious and rather more that is conscious in him than he had before. The fact is that you are probably under-estimating the importance of an internal change of this kind. The neurotic who is cured has really become another man, though a bottom, of course, he has remained the same; that is to say, he has become what he might have become at best under the most favourable conditions. But that is a very great deal. If you now hear all that has to be done and what efforts it needs to bring about this apparently trivial change in a man's mental life, you will no doubt begin to realize the importance of this difference in psychical levels.

[1916-1917, 3477]
What, then, must we do in order to replace what is unconscious in our patients by what is conscious? There was a time when we thought this was a very simple matter: all that was necessary was for us to discover this unconscious material and communicate it to the patient. But we know already that this was a short-sighted error. Our knowledge about the unconscious material is not equivalent to his knowledge; if we communicate our knowledge to him, he does not receive it instead of his unconscious material but beside it; and that makes very little change in it. We must rather picture this unconscious material topographically, we must look for it in his memory at the place where it became unconscious owing to a repression. The repression must be got rid of - after which the substitution of the conscious material for the unconscious can proceed smoothly. How, then, do we lift a repression of this kind? Here our task enters a second phase. First, the search for the repression and then the removal of the resistance which maintains the repression.

[1916-1917, 3478]

Where the transference arises, what difficulties it raises for us, how we overcome them and what advantages we eventually derive from it - these are questions to be dealt with in a technical guide to analysis, and I shall only touch on them lightly to-day. It is out of the question for us to yield to the patient's demands deriving from the transference; it would be absurd for us to reject them in an unfriendly, still more in an indignant, manner. We overcome the transference by pointing out to the patient that his feelings do not arise from the present situation and do not apply to the person of the doctor, but that they are repeating something that happened to him earlier. In this way we oblige him to transform his repetition into a memory. By that means the transference, which, whether affectionate or hostile, seemed in every case to constitute the greatest threat to the treatment, becomes its best tool, by whose help the most secret compartments of mental life can be opened.

[1916-1917, 3485]

But here I will pause, and let you have a word; for I see an objection boiling up in you so fiercely that it would make you incapable of listening if it were not put into words: 'Ah! so you've admitted it at last! You work with the help of suggestion, just like the hypnotists! That is what we've thought for a long time. But, if so, why the roundabout road by way of memories of the past, discovering the unconscious, interpreting and translating back distortions - this immense expenditure of labour, time and money - when the one effective thing is after all only suggestion? Why do you not make direct suggestion against the symptoms, as the others do - the honest hypnotists? Moreover, if you try to excuse yourself for your long detour on the ground that you have made a number of important psychological discoveries which are hidden by direct suggestion - what about the certainty of these discoveries now? Are not they a result of suggestion too, of unintentional suggestion? Is it not possible that you are forcing on the patient what you want and what seems to you correct, in this field as well?'

[1916-1917, 3488]
Thus our therapeutic work falls into two phases. In the first, all the libido is forced from the symptoms into the transference and concentrated there; in the second, the struggle is waged around this new object and the libido is liberated from it. The change which is decisive for a favourable outcome is the elimination of repression in this renewed conflict so that the libido cannot withdraw once more from the ego by flight into the unconscious. This is made possible by the alteration of the ego which is accomplished under the influence of the doctor's suggestion. By means of the work of interpretation, which transforms what is unconscious into what is conscious, the ego is enlarged at the cost of this unconscious; by means of instruction, it is made conciliatory towards the libido and inclined to grant it some satisfaction, and its repugnance to the claims of the libido is diminished by the possibility of disposing of a portion of it by sublimation. The more closely events in the treatment coincide with this ideal description, the greater will be the success of the psycho-analytic therapy. It finds its limits in the lack of mobility of the libido, which may refuse to leave its objects, and the rigidity of narcissism, which will not allow transference on to objects to increase beyond certain bounds. Further light may perhaps be thrown on the dynamics of the process of cure if I say that we get hold of the whole of the libido which has been withdrawn from the dominance of the ego by attracting a portion of it on to ourselves by means of the transference.

[1916-1917, 3495]

'The whole process, however, only becomes possible through the single circumstance that you are mistaken in another important point as well. You feel sure that you are informed of all that goes on in your mind if it is of any importance at all, because in that case, you believe, your consciousness gives you news of it. And if you have had no information of something in your mind you confidently assume that it does not exist there. Indeed, you go so far as to regard what is "mental" as identical with what is "conscious" - that is, with what is known to you in spite of the most obvious evidence that a great deal more must constantly be going on in your mind than can be known to your consciousness. Come, let yourself be taught something on this one point! What is in your mind does not coincide with what you are conscious of; whether something is going on in your mind and whether you hear of it, are two different things. In the ordinary way, I will admit, the intelligence which reaches your consciousness is enough for your needs; and you may cherish the illusion that you learn of all the more important things. But in some cases, as in that of an instinctual conflict such as I have described, your intelligence service breaks down and your will then extends no further than your knowledge. In every case, however, the news that reaches your consciousness is incomplete and often not to be relied on. Often enough, too, it happens that you get news of events only when they are over and when you can no longer do anything to change them. Even if you are not ill, who can tell all that is stirring in your mind of which you know nothing or are falsely informed? You behave like an absolute ruler who is content with the information supplied him by his highest officials and never goes among the people to hear their voice. Turn your eyes inward, look into your own depths, learn first to know yourself! Then you will understand why you were bound to fall ill; and perhaps, you will avoid falling ill in future.'

[1917a, 3614]

We have formulated our task as physicians thus: to bring to the patient's knowledge the unconscious, repressed impulses existing in him, and, for that purpose, to uncover the resistances that oppose this extension of his knowledge about himself. Does the uncovering of these resistances guarantee that they will also be overcome? Certainly not always; but our hope is to achieve this by exploiting the patient's transference to the person of the physician, so as to induce him to adopt our conviction of the inexpediency of the repressive process established in childhood and of the impossibility of conducting life on the pleasure principle. I have set out elsewhere the dynamic conditions prevailing in the fresh conflict through which we lead the patient and which we substitute in him for his previous conflict - that of his illness. I have nothing at the moment to alter in that account.

[1919a, 3628]
The work by which we bring the repressed mental material into the patient's consciousness has been called by us psycho-analysis. Why 'analysis' - which means breaking up or separating out, and suggests an analogy with the work carried out by chemists on substances which they find in nature and bring into their laboratories? Because in an important respect there really is an analogy between the two. The patient's symptoms and pathological manifestations, like all his mental activities, are of a highly composite kind; the elements of this compound are at bottom motives, instinctual impulses. But the patient knows nothing of these elementary motives or not nearly enough. We teach him to understand the way in which these highly complicated mental formations are compounded; we trace the symptoms back to the instinctual impulses which motivate them; we point out to the patient these instinctual motives, which are present in his symptoms and of which he has hitherto been unaware, - just as a chemist isolates the fundamental substance, the chemical 'element', out of the salt in which it had been combined with other elements and in which it was unrecognizable. In the same way, as regards those of the patient's mental manifestations that were not considered pathological, we show him that he was only to a certain extent conscious of their motivation - that other instinctual impulses of which he had remained in ignorance had co-operated in producing them.

[1919a, 3629]

Let us at once agree upon what we mean by this activity. We have defined our therapeutic task as consisting of two things: making conscious the repressed material and uncovering the resistances. In that we are active enough, to be sure. But are we to leave it to the patient to deal alone with the resistances we have pointed out to him? Can we give him no other help in this besides the stimulus he gets from the transference? Does it not seem natural that we should help him in another way as well, by putting him into the mental situation most favourable to the solution of the conflict which is our aim? After all, what he can achieve depends, too, on a combination of external circumstances. Should we hesitate to alter this combination by intervening in a suitable manner? I think activity of such a kind on the part of the analysing physician is unobjectionable and entirely justified.

[1919a, 3631]

Twenty five years of intense work have had as their result that the immediate aims of psycho-analytic technique are quite other to-day than they were at the outset. At first the analysing physician could do no more than discover the unconscious material that was concealed from the patient, put it together, and, at the right moment, communicate it to him. Psychoanalysis was then first and foremost an art of interpreting. Since this did not solve the therapeutic problem, a further aim quickly came in view: to oblige the patient to confirm the analyst's construction from his own memory. In that endeavour the chief emphasis lay upon the patient's resistances: the art consisted now in uncovering these as quickly as possible, in pointing them out to the patient and in inducing him by human influence - this was where suggestion operating as 'transference' played its part - to abandon his resistances.

[1920g, 3723]
But it became ever clearer that the aim which had been set up - the aim that what was unconscious should become conscious - is not completely attainable by that method. The patient cannot remember the whole of what is repressed in him, and what he cannot remember may be precisely the essential part of it. Thus he acquires no sense of conviction of the correctness of the construction that has been communicated to him. He is obliged to repeat the repressed material as a contemporary experience instead of, as the physician would prefer to see, remembering it as something belonging to the past.¹ These reproductions, which emerge with such unwished-for exactitude, always have as their subject some portion of infantile sexual life - of the Oedipus complex, that is, and its derivatives; and they are invariably acted out in the sphere of the transference, of the patient's relation to the physician. When things have reached this stage, it may be said that the earlier neurosis has now been replaced by a fresh, 'transference neurosis'. It has been the physician's endeavour to keep this transference neurosis within the narrowest limits: to force as much as possible into the channel of memory and to allow as little as possible to emerge as repetition. The ratio between what is remembered and what is reproduced varies from case to case. The physician cannot as a rule spare his patient this phase of the treatment. He must get him to re-experience some portion of his forgotten life, but must see to it, on the other hand, that the patient retains some degree of aloofness, which will enable him, in spite of everything, to recognize that what appears to be reality is in fact only a reflection of a forgotten past. If this can be successfully achieved, the patient's sense of conviction is won, together with the therapeutic success that is dependent on it.

¹[1920g, 3723]

I cannot simplify my statement by describing my patient's death-wish against his brother-in-law as an unconscious, repressed one. For it had been made conscious during the treatment the year before and the consequences which had followed from its repression had yielded to the treatment. But it still persisted, and, though it was no longer pathogenic, it was sufficiently intense. It might be described as a 'suppressed' wish.

[1941d [1921], 3869]

The description we have given applies to the most extreme instances of this state of affairs, but in a lesser measure this factor has to be reckoned with in very many cases, perhaps in all comparatively severe cases of neurosis. In fact it may be precisely this element in the situation, the attitude of the ego ideal, that determines the severity of a neurotic illness. We shall not hesitate, therefore, to discuss rather more fully the way in which the sense of guilt expresses itself under different conditions.

[1923b, 3984]

In certain forms of obsessional neurosis the sense of guilt is over-noisy but cannot justify itself to the ego. Consequently the patient's ego rebels against the imputation of guilt and seeks the physician's support in repudiating it. It would be folly to acquiesce in this, for to do so would have no effect. Analysis eventually shows that the super-ego is being influenced by processes that have remained unknown to the ego. It is possible to discover the repressed impulses which are really at the bottom of the sense of guilt. Thus in this case the super-ego knew more than the ego about the unconscious id.

[1923b, 3985]
If a dream brings up situations that can be interpreted as referring to scenes from the dreamer's past, it seems especially important to ask whether the physician's influence can also play a part in such contents of the dream as these. And this question is most urgent of all in the case of what are called 'corroborative' dreams, dreams which, as it were, 'tag along behind' the analysis. With some patients these are the only dreams that one obtains. Such patients reproduce the forgotten experiences of their childhood only after one has constructed them from their symptoms, associations and other signs and has propounded these constructions to them. Then follow the corroborative dreams, concerning which, however, the doubt arises whether they may not be entirely without evidential value, since they may have been imagined in compliance with the physician's words instead of having been brought to light from the dreamer's unconscious. This ambiguous position cannot be escaped in the analysis, since with these patients unless one interprets, constructs and propounds, one never obtains access to what is repressed in them.

[1923c, 4036]

It looked as though our work had been made much more difficult and complicated; but the inestimable gain was that an insight was now obtained into an interplay of forces which had been concealed from the observer by the hypnotic state. It became evident that the work of uncovering what had been pathogenically forgotten had to struggle against a constant and very intense resistance. The critical objections which the patient raised in order to avoid communicating the ideas which occurred to him, and against which the fundamental rule of psycho-analysis was directed, had themselves already been manifestations of this resistance. A consideration of the phenomena of resistance led to one of the corner-stones of the psycho-analytic theory of the neuroses - the theory of repression. It was plausible to suppose that the same forces which were now struggling against the pathogenic material being made conscious had at an earlier time made the same efforts with success. A gap in the aetiology of neurotic symptoms was thus filled. The impressions and mental impulses, for which the symptoms were now serving as substitutes, had not been forgotten without reason or on account of a constitutional incapacity for synthesis (as Janet supposed); they had, though the influence of other mental forces, met with a repression the success and evidence of which was precisely their being debarred from consciousness and excluded from memory. It was only in consequence of this repression that they had become pathogenic - that is, had succeeded in manifesting themselves along unusual paths as symptoms.

[1924f, 4106]
It may seem surprising that this method of free association, carried out subject to the observation of the fundamental rule of psycho-analysis, should have achieved what was expected of it, namely the bringing into consciousness of the repressed material which was held back by resistances. We must, however, bear in mind that free association is not really free. The patient remains under the influence of the analytic situation even though he is not directing his mental activities on to a particular subject. We shall be justified in assuming that nothing will occur to him that has not some reference to that situation. His resistance against reproducing the repressed material will now be expressed in two ways. Firstly it will be shown by critical objections; and it was to deal with these that the fundamental rule of psycho-analysis was invented. But if the patient observes that rule and so overcomes his reticences, the resistance will find another means of expression. It will so arrange it that the repressed material itself will never occur to the patient but only something which approximates to it in an allusive way; and the greater the resistance, the more remote from the actual idea that the analyst is in search of will be the substitutive association which the patient has to report. The analyst, who listens composedly but without any constrained effort to the stream of associations and who, from his experience, has a general notion of what to expect, can make use of the material brought to light by the patient according to two possibilities. If the resistance is slight he will be able from the patient's allusions to infer the unconscious material itself; or if the resistance is stronger he will be able to recognize its character from the associations, as they seem to become more remote from the topic in hand, and will explain it to the patient. Uncovering the resistance, however, is the first step towards overcoming it. Thus the work of analysis involves an art of interpretation, the successful handling of which may require tact and practice but which is not hard to acquire. But it is not only in the saving of labour that the method of free association has an advantage over the earlier method. It exposes the patient to the least possible amount of compulsion, it never allows of contact being lost with the actual current situation, it guarantees to a great extent that no factor in the structure of the neurosis will be overlooked and that nothing will be introduced into it by the expectations of the analyst. It is left to the patient in all essentials to determine the course of the analysis and the arrangement of the material; any systematic handling of particular symptoms or complexes thus becomes impossible. In complete contrast to what happened with hypnotism and with the urging method, interrelated material makes its appearance at different times and at different points in the treatment. To a spectator, therefore - though in fact there must be none - an analytic treatment would seem completely obscure.

To begin with the last problem. The advance we have made is that we have gone behind reactions of anxiety to situations of danger. If we do the same thing with realistic anxiety we shall have no difficulty in solving the question. Real danger is a danger that is known, and realistic anxiety is anxiety about a known danger of this sort. Neurotic anxiety is anxiety about an unknown danger. Neurotic danger is thus a danger that has still to be discovered. Analysis has shown that it is an instinctual danger. By bringing this danger which is not known to the ego into consciousness, the analyst makes neurotic anxiety no different from realistic anxiety, so that it can be dealt with in the same way.

[1925d, 4216] [1926d, 4317]
What you say about the special personal influence of the analyst certainly deserves great attention. An influence of the kind exists and plays a large part in analysis - but not the same part as in hypnotism. It ought to be possible to convince you that the situations in the two cases are quite different. It may be enough to point out that we do not use this personal influence, the factor of 'suggestion', to suppress the symptoms of the illness, as happens with hypnotic suggestion. Further, it would be a mistake to believe that this factor is the vehicle and promoter of the treatment throughout its length. At its beginning, no doubt. But later on it opposes our analytic intentions and forces us to adopt the most far-reaching counter-measures. And I should like to show by an example how far diverting a patient's thoughts and talking him out of things are from the technique of analysis. If a patient of ours is suffering from a sense of guilt, as though he had committed a serious crime, we do not recommend him to disregard his qualms of conscience and do not emphasize his undoubted innocence; he himself has often tried to do so without success. What we do is to remind him that such a strong and persistent feeling must after all be based on something real, which it may perhaps be possible to discover. [1926e, 4333]

It is easy now to describe our therapeutic aim. We try to restore the ego, to free it from its restrictions, and to give it back the command over the id which it has lost owing to its early repressions. It is for this one purpose that we carry out analysis, our whole technique is directed to this aim. We have to seek out the repressions which have been set up and to urge the ego to correct them with our help and to deal with conflicts better than by an attempt at flight. Since these repressions belong to the very early years of childhood, the work of analysis leads us, too, back to that period. Our path to these situations of conflict, which have for the most part been forgotten and which we try to revive in the patient's memory, is pointed out to us by his symptoms, dreams and free associations. These must, however, first be interpreted - translated - for, under the influence of the psychology of the id, they have assumed forms of expression that are strange to our comprehension. We may assume that whatever associations, thoughts and memories the patient is unable to communicate to us without internal struggles are in some way connected with the repressed material or are its derivatives. By encouraging the patient to disregard his resistances to telling us these things, we are educating his ego to overcome its inclination towards attempts at flight and to tolerate an approach to what is repressed. In the end, if the situation of the repression can be successfully reproduced in his memory, his compliance will be brilliantly rewarded. The whole difference between his age then and now works in his favour; and the thing from which his childish ego fled in terror will often seem to his adult and strengthened ego no more than child's play. [1926e, 4348]

When one really practises analysis one learns all kinds of things besides. For instance: you would not find it at all such a simple matter to deduce from what the patient tells you the experiences he has forgotten and the instinctual impulses he has repressed. He says something to you which at first means as little to you as it does to him. You will have to make up your mind to look at the material which he delivers to you in obedience to the rule in a quite special way: as though it were ore, perhaps, from which its content of precious metal has to be extracted by a particular process. You will be prepared, too, to work over many tons of ore which may contain but little of the valuable material you are in search of. Here we should have a first reason for the prolonged character of the treatment. [1926e, 4361]
Oh, that is not so hard to understand. Think of the war neurotics, who do not have to serve, precisely because they are ill. In civil life illness can be used as a screen to gloss over incompetence in one's profession or in competition with other people; while in the family it can serve as a means for sacrificing the other members and extorting proofs of their love or for imposing one's will upon them. All of this lies fairly near the surface; we sum it up in the term 'gain from illness'. It is curious, however, that the patient - that is, his ego - nevertheless knows nothing of the whole concatenation of these motives and the actions which they involve. One combats the influence of these trends by compelling the ego to take cognizance of them. But there are other motives, that lie still deeper, for holding on to being ill, which are not so easily dealt with. But these cannot be understood without a fresh journey into psychological theory.
[1926e, 4364]

The therapeutic influence of psycho-analysis depends on the replacement of unconscious mental acts by conscious ones and is effective within the limits of that factor. The replacement is effected by overcoming internal resistances in the patient's mind. The future will probably attribute far greater importance to psycho-analysis as the science of the unconscious than as a therapeutic procedure.
[1926f, 4403]

¹ The best account of the meaning and content given by Dostoevsky himself, when he told his friend Strakhov that his irritability and depression after an epileptic attack were due to the fact that he seemed to himself a criminal and could not get rid of the feeling that he had a burden of unknown guilt upon him, that he had committed some great misdeed, which oppressed him. (Fülöp-Miller, 1924, 1188.) In self-accusations like these psycho-analysis sees signs of a recognition of 'psychical reality', and it endeavours to make the unknown guilt known to consciousness.
[1928b, 4563]
Now, however, another problem awaits us - at the opposite end of the ego, as we might put it. It is presented to us by an observation during the work of analysis, an observation which is actually a very old one. As not infrequently happens, it has taken a long time to come to the point of appreciating its importance. The whole theory of psycho-analysis is, as you know, in fact built up on the perception of the resistance offered to us by the patient when we attempt to make his unconscious conscious to him. The objective sign of this resistance is that his associations fail or depart widely from the topic that is being dealt with. He may also recognize the resistance subjectively by the fact that he has distressing feelings when he approaches the topic. But this last sign may also be absent. We then say to the patient that we infer from his behaviour that he is now in a state of resistance; and he replies that he knows nothing of that, and is only aware that his associations have become more difficult. It turns out that we were right; but in that case his resistance was unconscious too, just as unconscious as the repressed, at the lifting of which we were working. We should long ago have asked the question: from what part of his mind does an unconscious resistance like this arise? The beginner in psycho-analysis will be ready at once with the answer: it is, of course, the resistance of the unconscious. An ambiguous and unserviceable answer! If it means that the resistance arises from the repressed, we must rejoin: certainly not! We must rather attribute to the repressed a strong upward drive, an impulsion to break through into consciousness. The resistance can only be a manifestation of the ego, which originally put the repression into force and now wishes to maintain it. That, moreover, is the view we always took. Since we have come to assume a special agency in the ego, the super-ego, which represents demands of a restrictive and rejecting character, we may say that repression is the work of this super-ego and that it is carried out either by itself or by the ego in obedience to its orders. If then we are met by the case of the resistance in analysis not being conscious to the patient, this means either that in quite important situations the super-ego and the ego can operate unconsciously, or - and this would be still more important - that portions of both of them, the ego and the super-ego themselves, are unconscious. In both cases we have to reckon with the disagreeable discovery that on the one hand (super-) ego and conscious and on the other hand repressed and unconscious are far from coinciding.

[1933a, 4677]
You will not expect me to have much to tell you that is new about the id apart from its new name. It is the dark, inaccessible part of our personality; what little we know of it we have learnt from our study of the dream-work and of the construction of neurotic symptoms, and most of that is of a negative character and can be described only as a contrast to the ego. We approach the id with analogies: we call it a chaos, a cauldron full of seething excitations. We picture it as being open at its end to somatic influences, and as there taking up into itself instinctual needs which find their psychical expression in it, but we cannot say in what substratum. It is filled with energy reaching it from the instincts, but it has no organization, produces no collective will, but only a striving to bring about the satisfaction of the instinctual needs subject to the observance of the pleasure principle. The logical laws of thought do not apply in the id, and this is true above all of the law of contradiction. Contrary impulses exist side by side, without cancelling each other out or diminishing each other: at the most they may converge to form compromises under the dominating economic pressure towards the discharge of energy. There is nothing in the id that could be compared with negation; and we perceive with surprise an exception to the philosophical theorem that space and time are necessary forms of our mental acts. There is nothing in the id that corresponds to the idea of time; there is no recognition of the passage of time, and - a thing that is most remarkable and awaits consideration in philosophical thought - no alteration in its mental processes is produced by the passage of time. Wishful impulses which have never passed beyond the id, but impressions, too, which have been sunk into the id by repression, are virtually immortal; after the passage of decades they behave as though they had just occurred. They can only be recognized as belonging to the past, can only lose their importance and be deprived of their cathexis of energy, when they have been made conscious by the work of analysis, and it is on this that the therapeutic effect of analytic treatment rests to no small extent.

[1933a, 4682]

With the neurotics, then, we make our pact: complete candour on one side and strict discretion on the other. This looks as though we were only aiming at the post of a secular father confessor. But there is a great difference, for what we want to hear from our patient is not only what he knows and conceals from other people; he is to tell us too what he does not know. With this end in view we give him a more detailed definition of what we mean by candour. We pledge him to obey the fundamental rule of analysis, which is henceforward to govern his behaviour towards us. He is to tell us not only what he can say intentionally and willingly, what will give him relief like a confession, but everything else as well that his self-observation yields him, everything that comes into his head, even if it is disagreeable for him to say it, even if it seems to him unimportant or actually nonsensical. If he can succeed after this injunction in putting his self-criticism out of action, he will present us with a mass of material - thoughts, ideas, recollections - which are already subject to the influence of the unconscious, which are often its direct derivatives, and which thus put us in a position to conjecture his repressed unconscious material and to extend, by the information we give him, his ego's knowledge of his unconscious.

[1940a [1938], 4984]
The method by which we strengthen the weakened ego has as a starting-point an extending of its self-knowledge. That is not, of course, the whole story but it is a first step. The loss of such knowledge signifies for the ego a surrender of power and influence; it is the first tangible sign that it is being hemmed in and hampered by the demands of the id and the super-ego. Accordingly, the first part of the help we have to offer is intellectual work on our side and encouragement to the patient to collaborate in it. This first kind of activity, as we know, is intended to pave the way to another, more difficult, task. We shall not lose sight of the dynamic element in this task, even during its preliminary stage. We gather the material for our work from a variety of sources - from what is conveyed to us by the information given us by the patient and by his free associations, from what he shows us in his transferences, from what we arrive at by interpreting his dreams and from what he betrays by his slips or *parapraxes*. All this material helps us to make constructions about what happened to him and has been forgotten as well as about what is happening in him now without his understanding it. But in all this we never fail to make a strict distinction between our knowledge and his knowledge. We avoid telling him at once things that we have often discovered at an early stage, and we avoid telling him the whole of what we think we have discovered. We reflect carefully over when we shall impart the knowledge of one of our constructions to him and we wait for what seems to us the suitable moment - which it is not always easy to decide. As a rule we put off telling him of a construction or explanation till he himself has so nearly arrived at it that only a single step remains to be taken, though that step is in fact the decisive synthesis. If we proceeded in another way and overwhelmed him with our interpretations before he was prepared for them, our information would either produce no effect or it would provoke a violent outbreak of resistance which would make the progress of our work more difficult or might even threaten to stop it altogether. But if we have prepared everything properly, it often happens that the patient will at once confirm our construction and himself recollect the internal or external event which he had forgotten. The more exactly the construction coincides with the details of what has been forgotten the easier will it be for him to assent. On that particular matter our knowledge will then have become his knowledge as well.

[1940a [1938], 4987]

The further our work proceeds and the more deeply our insight penetrates into the mental life of neurotics, the more clearly two new factors force themselves on our notice, which demand the closest attention as sources of resistance. Both of them are completely unknown to the patient, neither of them could be taken into account when our pact was made; nor do they arise from the patient's ego. They may both be embraced under the single name of 'need to be ill or to suffer', but they have different origins though in other respects they are of a kindred nature. The first of these two factors is the sense of guilt or consciousness of guilt, as it is called, though the patient does not feel it and is not aware of it. It is evidently the portion of the resistance contributed by a super-ego that has become particularly severe and cruel. The patient must not become well but must remain ill, for he deserves no better. This resistance does not actually interfere with our intellectual work, but it makes it inoperative; indeed, it often allows us to remove one form of neurotic suffering, but is ready at once to replace it by another, or perhaps by some somatic illness. The sense of guilt also explains the cure or improvement of severe neuroses which we occasionally observe after real misfortunes: all that matters is that the patient should be miserable - in what way is of no consequence. The uncomplaining resignation with which such people often put up with their hard fate is most remarkable, but also revealing. In warding off this resistance we are obliged to restrict ourselves to making it conscious and attempting to bring about the slow demolition of the hostile super-ego.

[1940a [1938], 4989]
Let us once more glance over the situation which we have reached in our attempt at bringing help to the patient's neurotic ego. That ego is no longer able to fulfil the task set it by the external world (including human society). Not all of its experiences are at its disposal, a large proportion of its store of memories have escaped it. Its activity is inhibited by strict prohibitions from the super-ego, its energy is consumed in vain attempts at fending off the demands of the id. Beyond this, as a result of continuous irruptions by the id, its organization is impaired, it is no longer capable of any proper synthesis, it is torn by mutually opposed urges, by unsettled conflicts and by unsolved doubts. To start with, we get the patient's thus weakened ego to take part in the purely intellectual work of interpretation, which aims at provisionally filling the gaps in his mental assets, and to transfer to us the authority of his super-ego; we encourage it to take up the struggle over each individual demand made by the id and to conquer the resistances which arise in connection with it. At the same time we restore order in the ego by detecting the material and urges which have forced their way in from the unconscious, and expose them to criticism by tracing them back to their origin. We serve the patient in various functions, as an authority and a substitute for his parents, as a teacher and educator; and we have done the best for him if, as analysts, we raise the mental processes in his ego to a normal level, transform what has become unconscious and repressed into preconscious material and thus return it once more to the possession of his ego. On the patient's side a few rational factors work in our favour, such as the need for recovery which has its motive in his sufferings, and the intellectual interest that we may awaken in him in the theories and revelations of psycho-analysis; but of far greater force is the positive transference with which he meets us. Fighting against us, on the other hand, are the negative transference, the ego's resistance due to repression (that is, its unpleasure at having to lay itself open to the hard work imposed on it), the sense of guilt arising from its relation to the super-ego and the need to be ill due to deep-going changes in the economics of his instincts. The share taken by the last two factors decides whether the case is to be regarded as slight or severe. Apart from these, a few other factors may be discerned as having a favourable or unfavourable bearing. A certain psychical inertia, a sluggishness of the libido, which is unwilling to abandon its fixations cannot be welcome to us; the patient's capacity for sublimating his instincts plays a large part and so does his capacity for rising above the crude life of the instincts; so, too, does the relative power of his intellectual functions.

[1940a [1938], 4990]

We must first of all decide what is meant by the ambiguous phrase 'the end of an analysis'. From a practical standpoint it is easy to answer. An analysis is ended when the analyst and the patient cease to meet each other for the analytic session. This happens when two conditions have been approximately fulfilled: first, that the patient shall no longer be suffering from his symptoms and shall have overcome his anxieties and his inhibitions; and secondly, that the analyst shall judge that so much repressed material has been made conscious, so much that was unintelligible has been explained, and so much internal resistance conquered, that there is no need to fear a repetition of the pathological processes concerned. If one is prevented by external difficulties from reaching this goal, it is better to speak of an incomplete analysis rather than of an unfinished one.

[1937c, 5017]
At the moment, however, we are not concerned with the pathogenic role of the defensive mechanisms. What we are trying to discover is what influence the alteration of the ego which corresponds to them has upon our therapeutic efforts. The material for an answer to this question is given in the volume by Anna Freud to which I have already referred. The essential point is that the patient repeats these modes of reaction during the work of analysis as well, that he produces them before our eyes, as it were. In fact, it is only in this way that we get to know them. This does not mean that they make analysis impossible. On the contrary, they constitute half of our analytic task. The other half, the one which was first tackled by analysis in its early days, is the uncovering of what is hidden in the id. During the treatment our therapeutic work is constantly swinging backwards and forwards like a pendulum between a piece of id-analysis and a piece of ego-analysis. In the one case we want to make something from the id conscious, in the other we want to correct something in the ego. The crux of the matter is that the defensive mechanisms directed against former danger recur in the treatment as resistances against recovery. It follows from this that the ego treats recovery itself as a new danger.

[1937c, 5034]

The therapeutic effect depends on making conscious what is repressed, in the widest sense of the word, in the id. We prepare the way for this making conscious by interpretations and constructions, but we have interpreted only for ourselves not for the patient so long as the ego holds on to its earlier defences and does not give up its resistances. Now these resistances, although they belong to the ego, are nevertheless unconscious and in some sense separated off within the ego. The analyst recognizes them more easily than he does the hidden material in the id. One might suppose that it would be sufficient to treat them like portions of the id and, by making them conscious, bring them into connection with the rest of the ego. In this way, we should suppose, one half of the task of analysis would be accomplished; we should not reckon on meeting with a resistance against the uncovering of resistances. But what happens is this. During the work on the resistances the ego withdraws - with a greater or less degree of seriousness - from the agreement on which the analytic situation is founded. The ego ceases to support our efforts at uncovering the id; it opposes them, disobeys the fundamental rule of analysis, and allows no further derivatives of the repressed to emerge. We cannot expect the patient to have a strong conviction of the curative power of analysis. He may have brought along with him a certain amount of confidence in his analyst, which will be strengthened to an effective point by the factors of the positive transference which will be aroused in him. Under the influence of the unpleasurable impulses which he feels as a result of the fresh activation of his defensive conflicts, negative transferences may now gain the upper hand and completely annul the analytic situation. The patient now regards the analyst as no more than a stranger who is making disagreeable demands on him, and he behaves towards him exactly like a child who does not like the stranger and does not believe anything he says. If the analyst tries to explain to the patient one of the distortions made by him for the purposes of defence, and to correct it, he finds him uncomprehending and inaccessible to sound arguments. Thus we see that there is a resistance against the uncovering of resistances, and the defensive mechanisms really do deserve the name which we gave them originally, before they had been more closely examined. They are resistances not only to the making conscious of contents of the id, but also to the analysis as a whole, and thus to recovery.

[1937c, 5034]
It is familiar ground that the work of analysis aims at inducing the patient to give up the repression (using the word in the widest sense) belonging to his early development and to replace them by reactions of a sort that would correspond to a psychically mature condition. With this purpose in view he must be brought to recollect certain experiences and the affective impulses called up by them which he has for the time being forgotten. We know that his present symptoms and inhibitions are the consequences of repressions of this kind: thus that they are a substitute for these things that he has forgotten. What sort of material does he put at our disposal which we can make use of to put him on the way to recovering the lost memories? All kinds of things. He gives us fragments of these memories in his dreams, invaluable in themselves but seriously distorted as a rule by all the factors concerned in the formation of dreams. Again, he produces ideas, if he gives himself up to 'free association', in which we can discover allusions to the repressed experiences and derivatives of the suppressed affective impulses as well as of the reactions against them. And, finally, there are hints of repetitions of the affects belonging to the repressed material to be found in actions performed by the patient, some fairly important, some trivial, both inside and outside the analytic situation. Our experience has shown that the relation of transference, which becomes established towards the analyst, is particularly calculated to favour the return of these emotional connections. It is out of such raw material - if we may so describe it - that we have to put together what we are in search of. [1937d, 5050]

How this occurs in the process of the analysis - the way in which a conjecture of ours is transformed into the patient's conviction - this is hardly worth describing. All of it is familiar to every analyst from his daily experience and is intelligible without difficulty. Only one point requires investigation and explanation. The path that starts from the analyst's construction ought to end in the patient's recollection; but it does not always lead so far. Quite often we do not succeed in bringing the patient to recollect what has been repressed. Instead of that, if the analysis is carried out correctly, we produce in him an assured conviction of the truth of the construction which achieves the same therapeutic result as a recaptured memory. The problem of what the circumstances are in which this occurs and of how it is possible that what appears to be an incomplete substitute should nevertheless produce a complete result - all of this is matter for a later enquiry. [1937d, 5057]
I shall now make one or two further remarks on the picture we have just arrived at of the organization of the pathogenic material. We have said that this material behaves like a foreign body, and that the treatment, too, works like the removal of a foreign body from the living tissue. We are now in a position to see where this comparison fails. A foreign body does not enter into any relation with the layers of tissue that surround it, although it modifies them and necessitates a reactive inflammation in them. Our pathogenic psychical group, on the other hand, does not admit of being cleanly extirpated from the ego. Its external strata pass over in every direction into portions of the normal ego; and, indeed, they belong to the latter just as much as to the pathogenic organization. In analysis the boundary between the two is fixed purely conventionally, now at one point, now at another, and in some places it cannot be laid down at all. The interior layers of the pathogenic organization are increasingly alien to the ego, but once more without there being any visible boundary at which the pathogenic material begins. In fact the pathogenic organization does not behave like a foreign body, but far more like an infiltrate. In this simile the resistance must be regarded as what is infiltrating. Nor does the treatment consist in extirpating something - psychotherapy is not able to do this for the present - but in causing the resistance to melt and in thus enabling the circulation to make its way into a region that has hitherto been cut off.

Those philosophers who have become aware that rational and highly complex thought-structures are possible without consciousness playing any part in them have found difficulty in assigning any function to consciousness; it has seemed to them that it can be no more than a superfluous reflected picture of the completed psychical process. We, on the other hand, are rescued from this embarrassment by the analogy between our Cs. system and the perceptual systems. We know that perception by our sense-organs has the result of directing a cathexis of attention to the paths along which the in-coming sensory excitation is spreading: the qualitative excitation of the Pcpt. system acts as a regulator of the discharge of the mobile quantity in the psychical apparatus. We can attribute the same function to the overlying sense-organ of the Cs. system. By perceiving new qualities, it makes a new contribution to directing the mobile quantities of cathexis and distributing them in an expedient fashion. By the help of its perception of pleasure and unpleasure it influences the discharge of the cathexes within what is otherwise an unconscious apparatus operating by means of the displacement of quantities. It seems probable that in the first instance the unpleasure principle regulates the displacement of cathexes automatically. But it is quite possible that consciousness of these qualities may introduce in addition a second and more discriminating regulation, which is even able to oppose the former one, and which perfects the efficiency of the apparatus by enabling it, in contradiction to its original plan, to cathect and work over even what is associated with the release of unpleasure. We learn from the psychology of the neuroses that these processes of regulation carried out by the qualitative excitation of the sense organs play a great part in the functional activity of the apparatus. The automatic domination of the primary unpleasure principle and the consequent restriction imposed upon efficiency are interrupted by the processes of sensory regulation, which are themselves in turn automatic in action. We find that repression (which, though it served a useful purpose to begin with, leads ultimately to a damaging loss of inhibition and mental control) affects memories so much more easily than perceptions because the former can receive no extra cathexis from the excitation of the psychical sense-organs. It is true on the one hand that a thought which has to be warded off cannot become conscious, because it has undergone repression; but on the other hand it sometimes happens that a thought of this kind is only repressed because for other reasons it has been withdrawn from conscious perception. Here are some hints of which we take advantage in our therapeutic procedure in order to undo repressions which have already been effected.
No one can undertake the treatment of a case of hysteria until he is convinced of the impossibility of avoiding the mention of sexual subjects, or unless he is prepared to allow himself to be convinced by experience. The right attitude is: ‘pour faire une omelette il faut casser des œufs.’ The patients themselves are easy to convince; and there are only too many opportunities of doing so in the course of the treatment. There is no necessity for feeling any compunction at discussing the facts of normal or abnormal sexual life with them. With the exercise of a little caution all that is done is to translate into conscious ideas what was already known in the unconscious; and, after all, the whole effectiveness of the treatment is based upon our knowledge that the affect attached to an unconscious idea operates more strongly and, since it cannot be inhibited, more injuriously than the affect attached to a conscious one. There is never any danger of corrupting an inexperienced girl. For where there is no knowledge of sexual processes even in the unconscious, no hysterical symptom will arise; and where hysteria is found there can no longer be any question of ‘innocence of mind’ in the sense in which parents and educators use the phrase. With children of ten, of twelve, or of fourteen, with boys and girls alike, I have satisfied myself that the truth of this statement can invariably be relied upon.

[1905e, 1386]

The task which the psycho-analytic method seeks to perform may be formulated in different ways, which are, however, in their essence equivalent. It may, for instance, be stated thus: the task of the treatment is to remove the amnesias. When all gaps in memory have been filled in, all the enigmatic products of mental life elucidated, the continuance and even a renewal of the morbid condition are made impossible. Or the formula may be expressed in this fashion: all repressions must be undone. The mental condition is then the same as one in which all amnesias have been removed. Another formulation reaches further: the task consists in making the unconscious accessible to consciousness, which is done by overcoming the resistances. But it must be remembered that an ideal condition such as this is not present even in the normal, and further that it is only rarely possible to carry the treatment to a point approaching it. Just as health and sickness are not different from each other in essence but are only separated by a quantitative line of demarcation which can be determined in practice, so the aim of the treatment will never be anything else but the practical recovery of the patient, the restoration of his ability to lead an active life and of his capacity for enjoyment. In a treatment which is incomplete or in which success is not perfect, one may at any rate achieve a considerable improvement in the general mental condition, while the symptoms (though now of smaller importance to the patient) may continue to exist without stamping him as a sick man.

[1904a, 1559]
There is, however, another angle from which you may seek to understand the psycho-analytic method. The uncovering and translating of the unconscious occurs in the face of a continuous resistance on the part of the patient. The process of bringing this unconscious material to light is associated with unpleasure, and because of this the patient rejects it again and again. It is for you then to interpose in this conflict in the patient's mental life. If you succeed in persuading him to accept, by virtue of a better understanding, something that up to now, in consequence of this automatic regulation by unpleasure, he has rejected (repressed), you will have accomplished something towards his education. For it is education even to induce someone who dislikes getting up early to do so all the same. Psycho-analytic treatment may in general be conceived of as such a re-education in overcoming internal resistances. Re-education of this kind is, however, in no respect more necessary to nervous patients than in regard to the mental element in their sexual life. For nowhere else have civilization and education done so much harm as in this field, and this is the point, as experience will show you, at which to look for those aetiologies of the neuroses that are amenable to influence; for the other aetiological factor, the constitutional component, consists of something fixed and unalterable. And from this it follows that one important qualification is required of the physician in this work: not only must his own character be irreproachable - 'As to morals, that goes without saying', as the hero of Vischer's novel Auch Einer was in the habit of declaring - but he must also have overcome in his own mind that mixture of prurience and prudery with which, unfortunately, so many people habitually consider sexual problems.

[1905a, 1571]

To shorten analytic treatment is a justifiable wish, and its fulfilment, as we shall learn, is being attempted along various lines. Unfortunately, it is opposed by a very important factor, namely, the slowness with which deep-going changes in the mind are accomplished - in the last resort, no doubt, the 'timelessness' of our unconscious processes. When patients are faced with the difficulty of the great expenditure of time required for analysis they not infrequently manage to propose a way out of it. They divide up their ailments and describe some as unbearable, and others as secondary, and then say: 'If only you will relieve me from this one (for instance, a headache or a particular fear) I can deal with the other one on my own in my ordinary life.' In doing this, however, they over-estimate the selective power of analysis. The analyst is certainly able to do a great deal, but he cannot determine beforehand exactly what results he will effect. He sets in motion a process, that of the resolving of existing repressions. He can supervise this process, further it, remove obstacles in its way, and he can undoubtedly vitiate much of it. But on the whole, once begun, it goes its own way and does not allow either the direction it takes or the order in which it picks up its points to be prescribed for it. The analyst's power over the symptoms of the disease may thus be compared to male sexual potency. A man can, it is true, beget a whole child, but even the strongest man cannot create in the female organism a head alone or an arm or a leg; he cannot even prescribe the child's sex. He, too, only sets in motion a highly complicated process, determined by events in the remote past, which ends with the severance of the child from its mother. A neurosis as well has the character of an organism. Its component manifestations are not independent of one another; they condition one another and give one another mutual support. A person suffers from one neurosis only, never from several which have accidentally met together in a single individual. The patient freed, according to his wish, from his one unendurable symptom might easily find that a symptom which had previously been negligible had now increased and grown unendurable. The analyst who wishes the treatment to owe its success as little as possible to its elements of suggestion (i.e. to the transference) will do well to refrain from making use of even the trace of selective influence upon the results of the therapy which may perhaps be open to him. The patients who are bound to be most welcome to him are those who ask him to give them complete health, in so far as that is attainable, and who place as much time at his disposal as is necessary for the process of recovery. Such favourable conditions as these are, of course, to be looked for in only a few cases.

[1913c, 2483]
The crudest idea of these systems is the most convenient for us - a spatial one. Let us therefore compare the system of the unconscious to a large entrance hall, in which the mental impulses jostle one another like separate individuals. Adjoining this entrance hall there is a second, narrower, room - a kind of drawing-room - in which consciousness, too, resides. But on the threshold between these two rooms a watchman performs his function: he examines the different mental impulses, acts as a censor, and will not admit them into the drawing-room if they displease him. You will see at once that it does not make much difference if the watchman turns away a particular impulse at the threshold itself or if he pushes it back across the threshold after it has entered the drawing-room. This is merely a question of the degree of his watchfulness and of how early he carries out his act of recognition. If we keep to this picture, we shall be able to extend our nomenclature further. The impulses in the entrance hall of the unconscious are out of sight of the conscious, which is in the other room; to begin with they must remain unconscious. If they have already pushed their way forward to the threshold and have been turned back by the watchman, then they are inadmissible to consciousness; we speak of them as repressed. But even the impulses which the watchman has allowed to cross the threshold are not on that account necessarily conscious as well; they can only become so if they succeed in catching the eye of consciousness. We are therefore justified in calling this second room the system of the preconscious. In that case becoming conscious retains its purely descriptive sense. For any particular impulse, however, the vicissitude of repression consists in its not being allowed by the watchman to pass from the system of the unconscious into that of the preconscious. It is the same watchman whom we get to know as resistance when we try to lift the repression by means of the analytic treatment.

[1916-1917, 3369]

Thus you cannot explain the therapeutic effect of psycho-analysis by its permitting a full sexual life. Look around, then, for something else. I fancy that, while I was rejecting this suggestion of yours, one remark of mine put you on the right track. What we make use of must no doubt be the replacing of what is unconscious by what is conscious, the translation of what is unconscious into what is conscious. Yes, that is it. By carrying what is unconscious on into what is conscious, we lift the repressions, we remove the preconditions for the formation of symptoms, we transform the pathogenic conflict to a normal one for which it must be possible somehow to find a solution. All that we bring about in a patient is this single psychical change: the length to which it is carried is the measure of the help we provide. Where no repressions (or analogous psychical processes) can be undone, our therapy has nothing to expect.

[1916-1917, 3477]

We can express the aim of our efforts in a variety of formulas: making conscious what is unconscious, lifting repressions, filling gaps in the memory - all these amount to the same thing. But perhaps you will be dissatisfied by this admission. You had formed a different picture of the return to health of a neurotic patient - that, after submitting to the tedious hours of a psycho-analysis, he would become another man; but the total result, so it seems, is that he has rather less that is unconscious and rather more that is conscious in him than he had before. The fact is that you are probably under-estimating the importance of an internal change of this kind. The neurotic who is cured has really become another man, though a bottom, of course, he has remained the same; that is to say, he has become what he might have become at best under the most favourable conditions. But that is a very great deal. If you now hear all that has to be done and what efforts it needs to bring about this apparently trivial change in a man's mental life, you will no doubt begin to realize the importance of this difference in psychical levels.

[1916-1917, 3477]
What, then, must we do in order to replace what is unconscious in our patients by what is conscious? There was a time when we thought this was a very simple matter: all that was necessary was for us to discover this unconscious material and communicate it to the patient. But we know already that this was a short-sighted error. Our knowledge about the unconscious material is not equivalent to his knowledge; if we communicate our knowledge to him, he does not receive it instead of his unconscious material but beside it; and that makes very little change in it. We must rather picture this unconscious material topographically, we must look for it in his memory at the place where it became unconscious owing to a repression. The repression must be got rid of - after which the substitution of the conscious material for the unconscious can proceed smoothly. How, then, do we lift a repression of this kind? Here our task enters a second phase. First, the search for the repression and then the removal of the resistance which maintains the repression.

[1916-1917, 3478]

And now for the fact! In a whole number of nervous diseases - in hysteria, anxiety states, obsessional neurosis - our expectation is fulfilled. By searching for the repression in this way, by uncovering the resistances, by pointing out what is repressed, we really succeed in accomplishing our task - that is, in overcoming the resistances, lifting the repression and transforming the unconscious material into conscious. In doing so we gain the clearest impression of the way in which a violent struggle takes place in the patient's mind about the overcoming of each resistance - a normal mental struggle, on the same psychological ground, between the motives which seek to maintain the anticaathexis and those which are prepared to give it up. The former are the old motives which in the past put the repression into effect; among the latter are the newly arrived ones which, we may hope, will decide the conflict in our favour. We have succeeded in reviving the old conflict which led to repression and in bringing up for revision the process that was then decided. The new material that we produce includes, first the reminder that the earlier decision led to illness and the promise that a different path will lead to recovery, and, second, the enormous change in all the circumstances that has take place since the time of the original rejection. Then the ego was feeble, infantile, and may perhaps have had grounds for banning the demands of the libido as a danger. To-day it has grown strong and experienced, and moreover has a helper at and in the shape of the doctor. Thus we may expect to lead the revived conflict to a better outcome than that which ended in repression, and, as I have said, in hysteria and in the anxiety and obsessional neuroses success proves us in general to be correct.

[1916-1917, 3480]
But you will now tell me that, no matter whether we call the motive force of our analysis transference or suggestion, there is a risk that the influencing of our patient may make the objective certainty of our findings doubtful. What is advantageous to our therapy is damaging to our researches. This is the objection that is most often raised against psycho-analysis, and it must be admitted that, though it is groundless, it cannot be rejected as unreasonable. If it were justified, psycho-analysis would be nothing more than a particularly well-disguised and particularly effective form of suggestive treatment and we should have to attach little weight to all that it tells us about what influences our lives, the dynamics of the mind or the unconscious. That is what our opponents believe; and in especial they think that we have "talked" the patients into everything relating to the importance of sexual experiences - or even into those experiences themselves - after such notions have grown up in our own depraved imagination. These accusations are contradicted more easily by an appeal to experience than by the help of theory. Anyone who has himself carried out psycho-analyses will have been able to convince himself on countless occasions that it is impossible to make suggestions to a patient in that way. The doctor has no difficulty, of course, in making him a supporter of some particular theory and in thus making him share some possible error of his own. In this respect the patient is behaving like anyone else - like a pupil - but this only affects his intelligence, not his illness. After all, his conflicts will only be successfully solved and his resistances overcome if the anticipatory ideas he is given tally with what is real in him. Whatever in the doctor's conjectures is inaccurate drops out in the course of the analysis; it has to be withdrawn and replaced by something more correct. We endeavour by a careful technique to avoid the occurrence of premature successes due to suggestion; but no harm is done even if they do occur, for we are not satisfied by a first success. We do not regard an analysis as at an end until all the obscurities of the case are cleared up, the gaps in the patient's memory filled in, the precipitating causes of the repressions discovered. We look upon successes that set in too soon as obstacles rather than as a help to the work of analysis; and we put an end to such successes by constantly resolving the transference on which they are based. It is this last characteristic which is the fundamental distinction between analytic and purely suggestive therapy, and which frees the results of analysis from the suspicion of being successes due to suggestion. In every other kind of suggestive treatment the transference is carefully preserved and left untouched; in analysis it is itself subjected to treatment and is dissected in all the shapes in which it appears. At the end of an analytic treatment the transference must itself be cleared away; and if success is then obtained or continues, it rests, not on suggestion, but on the achievement by its means of an overcoming of internal resistances, on the internal change that has been brought about in the patient.

[1916-1917, 3493]
I will now complete my picture of the mechanism of cure by clothing it in the formulas of the libido theory. A neurotic is incapable of enjoyment and of efficiency - the former because his libido is not directed on to any real object and the latter because he is obliged to employ a great deal of this available energy on keeping his libido under repression and on warding off its assaults. He would become healthy if the conflict between his ego and his libido came to an end and if his ego had his libido again at its disposal. The therapeutic task consists, therefore, in freeing the libido from its present attachments, which are withdrawn from the ego, and in making it once more serviceable to the ego. Where, then, is the neurotic’s libido situated? It is easily found: it is attached to the symptoms, which yield it the only substitutive satisfaction possible at the time. We must therefore make ourselves masters of the symptoms and resolve them - which is precisely the same thing that the patient requires of us. In order to resolve the symptoms, we must go back as far as their origin, we must renew the conflict from which they arose, and, with the help of motive forces which were not at the patient’s disposal in the past, we must guide it to a different outcome. This revision of the process of repression can be accomplished only in part in connection with the memory traces of the processes which led to repression. The decisive part of the work is achieved by creating in the patient's relation to the doctor - in the ‘transference’ - new editions of the old conflicts; in these the patient would like to behave in the same way as he did in the past, while we, by summoning up every available mental force, compel him to come to a fresh decision. Thus the transference becomes the battlefield on which all the mutually struggling forces should meet one another.

Thus our therapeutic work falls into two phases. In the first, all the libido is forced from the symptoms into the transference and concentrated there; in the second, the struggle is waged around this new object and the libido is liberated from it. The change which is decisive for a favourable outcome is the elimination of repression in this renewed conflict so that the libido cannot withdraw once more from the ego by flight into the unconscious. This is made possible by the alteration of the ego which is accomplished under the influence of the doctor's suggestion. By means of the work of interpretation, which transforms what is unconscious into what is conscious, the ego is enlarged at the cost of this unconscious; by means of instruction, it is made conciliatory towards the libido and inclined to grant it some satisfaction, and its repugnance to the claims of the libido is diminished by the possibility of disposing of a portion of it by sublimation. The more closely events in the treatment coincide with this ideal description, the greater will be the success of the psycho-analytic therapy. It finds its limits in the lack of mobility of the libido, which may refuse to leave its objects, and the rigidity of narcissism, which will not allow transference on to objects to increase beyond certain bounds. Further light may perhaps be thrown on the dynamics of the process of cure if I say that we get hold of the whole of the libido which has been withdrawn from the dominance of the ego by attracting a portion of it on to ourselves by means of the transference. 

The psycho-analytic method of treatment is then able to subject this process of repression to revision and to bring about a better solution of the conflict - one that is compatible with health. Unintelligent opposition accuses us of one-sidedness in our estimate of the sexual instincts. ‘Human beings have other interests besides sexual ones,’ they say. We have not forgotten or denied this for a moment. Our one-sidedness is like that of the chemist, who traces all compounds back to the force of chemical attraction. He is not on that account denying the force of gravity; he leaves that to the physicist to deal with.
Comparison between Psycho-Analysis and Hypnotic and Suggestive Methods. - Psycho-analytic procedure differs from all methods making use of suggestion, persuasion, etc., in that it does not seek to suppress by means of authority any mental phenomenon that may occur in the patient. It endeavours to trace the causation of the phenomenon and to remove it by bringing about a permanent modification in the conditions that led to it. In psycho-analysis the suggestive influence which is inevitably exercised by the physician is diverted on to the task assigned to the patient of overcoming his resistances, that is, of carrying forward the curative process. Any danger of falsifying the products of a patient's memory by suggestion can be avoided by prudent handling of the technique; but in general the arousing of resistances is a guarantee against the misleading effects of suggestive influence. It may be laid down that the aim of the treatment is to remove the patient's resistances and to pass his repressions in review and thus to bring about the most far-reaching unification and strengthening of his ego, to enable him to save the mental energy which he is expending upon internal conflicts, to make the best of him that his inherited capacities will allow and so to make him as efficient and as capable of enjoyment as is possible. The removal of the symptoms of the illness is not specifically aimed at, but is achieved, as it were, as a by-product if the analysis is properly carried through. The analyst respects the patient's individuality and does not seek to remould him in accordance with his own - that is, according to the physician's - personal ideals; he is glad to avoid giving advice and instead to arouse the patient's power of initiative.

[1923a, 3927]

But we have arrived at the term or concept of the unconscious along another path, by considering certain experiences in which mental dynamics play a part. We have found - that is, we have been obliged to assume - that very powerful mental processes or ideas exist (and here a quantitative or economic factor comes into question for the first time) which can produce all the effects in mental life that ordinary ideas do (including effects that can in their turn become conscious as ideas), though they themselves do not become conscious. It is unnecessary to repeat in detail here what has been explained so often before. It is enough to say that at this point psycho-analytic theory steps in and asserts that the reason why such ideas cannot become conscious is that a certain force opposes them, that otherwise they could become conscious, and that it would then be apparent how little they differ from other elements which are admittedly psychical. The fact that in the technique of psycho-analysis a means has been found by which the opposing force can be removed and the ideas in question made conscious renders this theory irrefutable. The state in which the ideas existed before being made conscious is called by us repression, and we assert that the force which instituted the repression and maintains it is perceived as resistance during the work of analysis.

[1923b, 3948]

The theory of repression became the corner-stone of our understanding of the neuroses. A different view had now to be taken of the task of therapy. Its aim was no longer to 'abreact' an affect which had got on to the wrong lines but to uncover repressions and replace them by acts of judgement which might result either in the accepting or in the condemning of what had formerly been repudiated. I showed my recognition of the new situation by no longer calling my method of investigation and treatment catharsis but psycho-analysis.

[1925d, 4207]
That this is a correct account of fixation upon repression and of the retention of danger-situations that are no longer present-day ones is confirmed by the fact of analytic therapy - a fact which is modest enough in itself but which can hardly be overrated from a theoretical point of view. When, in analysis, we have given the ego assistance which is able to put it in a position to lift its repressions, it recovers its power over the repressed id and can allow the instinctual impulses to run their course as though the old situations of danger no longer existed. What we can do in this way tallies with what can be achieved in other fields of medicine; for as a rule our therapy must be content with bringing about more quickly, more reliably and with less expenditure of energy than would otherwise be the case the good result which in favourable circumstances would have occurred of itself.

It is easy now to describe our therapeutic aim. We try to restore the ego, to free it from its restrictions, and to give it back the command over the id which it has lost owing to its early repressions. It is for this one purpose that we carry out analysis, our whole technique is directed to this aim. We have to seek out the repressions which have been set up and to urge the ego to correct them with our help and to deal with conflicts better than by an attempt at flight. Since these repressions belong to the very early years of childhood, the work of analysis leads us, too, back to that period. Our path to these situations of conflict, which have for the most part been forgotten and which we try to revive in the patient's memory, is pointed out to us by his symptoms, dreams and free associations. These must, however, first be interpreted - translated - for, under the influence of the psychology of the id, they have assumed forms of expression that are strange to our comprehension. We may assume that whatever associations, thoughts and memories the patient is unable to communicate to us without internal struggles are in some way connected with the repressed material or are its derivatives. By encouraging the patient to disregard his resistances to telling us these things, we are educating his ego to overcome its inclination towards attempts at flight and to tolerate an approach to what is repressed. In the end, if the situation of the repression can be successfully reproduced in his memory, his compliance will be brilliantly rewarded. The whole difference between his age then and now works in his favour; and the thing from which his childish ego fled in terror will often seem to his adult and strengthened ego no more than child's play.

'I will add that. Thereupon he begins to talk and I listen. And what then? I infer from what he tells me the kind of impressions, experiences and wishes which he has repressed because he came across them at a time when his ego was still feeble and was afraid of them instead of dealing with them. When he has learnt this from me, he puts himself back in the old situations and with my help he manages better. The limitations to which his ego was tied then disappear, and he is cured. Is that right?'

When one really practises analysis one learns all kinds of things besides. For instance: you would not find it at all such a simple matter to deduce from what the patient tells you the experiences he has forgotten and the instinctual impulses he has repressed. He says something to you which at first means as little to you as it does to him. You will have to make up your mind to look at the material which he delivers to you in obedience to the rule in a quite special way: as though it were ore, perhaps, from which its content of precious metal has to be extracted by a particular process. You will be prepared, too, to work over many tons of ore which may contain but little of the valuable material you are in search of. Here we should have a first reason for the prolonged character of the treatment.
That is a question of tact, which can become more refined with experience. You will be making a bad mistake if, in an effort, perhaps, at shortening the analysis, you throw your interpretations at the patient's head as soon as you have found them. In that way you will draw expressions of resistance, rejection and indignation from him; but you will not enable his ego to master his repressed material. The formula is: to wait till he has come so near to the repressed material that he has only a few more steps to take under the lead of the interpretation you propose.

[1926e, 4362]

(3) By 'transference' is meant a striking peculiarity of neurotics. They develop towards their physician emotional relations, both of an affectionate and hostile character, which are not based upon the actual situation but are derived from their relations to their parents (the Oedipus complex). Transference is a proof of the fact that adults have not overcome their former childish dependence; it coincides with the force which has been named 'suggestion'; and it is only by learning to make use of it that the physician is enabled to induce the patient to overcome his internal resistances and do away with his repressions. Thus psycho-analytic treatment acts as a second education of the adult, as a corrective to his education as a child.

[1926f, 4406]

Now, however, another problem awaits us - at the opposite end of the ego, as we might put it. It is presented to us by an observation during the work of analysis, an observation which is actually a very old one. As not infrequently happens, it has taken a long time to come to the point of appreciating its importance. The whole theory of psycho-analysis is, as you know, in fact built up on the perception of the resistance offered to us by the patient when we attempt to make his unconscious conscious to him. The objective sign of this resistance is that his associations fail or depart widely from the topic that is being dealt with. He may also recognize the resistance subjectively by the fact that he has distressing feelings when he approaches the topic. But this last sign may also be absent. We then say to the patient that we infer from his behaviour that he is now in a state of resistance; and he replies that he knows nothing of that, and is only aware that his associations have become more difficult. It turns out that we were right; but in that case his resistance was unconscious too, just as unconscious as the repressed, at the lifting of which we were working. We should long ago have asked the question: from what part of his mind does an unconscious resistance like this arise? The beginner in psycho-analysis will be ready at once with the answer: it is, of course, the resistance of the unconscious. An ambiguous and unserviceable answer! If it means that the resistance arises from the repressed, we must rejoin: certainly not! We must rather attribute to the repressed a strong upward drive, an impulsion to break through into consciousness. The resistance can only be a manifestation of the ego, which originally put the repression into force and now wishes to maintain it. That, moreover, is the view we always took. Since we have come to assume a special agency in the ego, the super-ego, which represents demands of a restrictive and rejecting character, we may say that repression is the work of this super-ego and that it is carried out either by itself or by the ego in obedience to its orders. If then we are met by the case of the resistance in analysis not being conscious to the patient, this means either that in quite important situations the super-ego and the ego can operate unconsciously, or - and this would be still more important - that portions of both of them, the ego and the super-ego themselves, are unconscious. In both cases we have to reckon with the disagreeable discovery that on the one hand (super-) ego and conscious and on the other hand repressed and unconscious are far from coinciding.

[1933a, 4677]
With the mention of resistance we have reached the second and more important part of our task. We have already learnt that the ego protects itself against the invasion of undesired elements from the unconscious and repressed id by means of anticathexes, which must remain intact if it is to function normally. The more hard-pressed the ego feels, the more convulsively it clings (as though in a fright) to these anticathexes, in order to protect what remains of itself from further irruptions. But this defensive purpose does not by any means accord with the aims of our treatment. What we desire, on the contrary, is that the ego, emboldened by the certainty of our help, shall dare to take the offensive in order to reconquer what has been lost. And it is here that we become aware of the strength of these anticathexes in the form of resistances to our work. The ego draws back in alarm from such undertakings, which seem dangerous and threaten unpleasure; it must be constantly encouraged and soothed if it is not to fail us. This resistance, which persists throughout the whole treatment and is renewed at every fresh piece of work, is known, not quite correctly, as the resistance due to repression. We shall find that it is not the only one that faces us. It is interesting to notice that in this situation the party-divisions are to some extent reversed: for the ego struggles against our instigation, while the unconscious, which is ordinarily our opponent, comes to our help, since it has a natural 'upward drive' and desires nothing better than to press forward across its settled frontiers into the ego and so to consciousness. The struggle which develops, if we gain our end and can induce the ego to overcome its resistances, is carried through under our direction and with our assistance. Its outcome is a matter of indifference: whether it results in the ego accepting, after a fresh examination, an instinctual demand which it has hitherto rejected, or whether it dismisses it once more, this time for good and all. In either case a permanent danger has been disposed of, the compass of the ego has been extended and a wasteful expenditure of energy has been made unnecessary.

[1940a [1938], 4988]

The other meaning of the 'end' of an analysis is much more ambitious. In this sense of it, what we are asking is whether the analyst has had such a far-reaching influence on the patient that no further change could be expected to take place in him if his analysis were continued. It is as though it were possible by means of analysis to attain to a level of absolute psychical normality - a level, moreover, which we could feel confident would be able to remain stable, as though, perhaps, we had succeeded in resolving every one of the patient's repressions and in filling in all the gaps in his memory. We may first consult our experience to enquire whether such things do in fact happen, and then turn to our theory to discover whether there is any possibility of their happening.

[1937c, 5017]
Before we decide on an answer to this question, however, we must consider an objection whose force lies in the fact that we are probably predisposed in its favour. Our arguments, it will be said, are all deduced from the processes which take place spontaneously between the ego and the instincts, and they presuppose that analytic therapy can accomplish nothing which does not, under favourable and normal conditions, occur of itself. But is this really so? Is it not precisely the claim of our theory that analysis produces a state which never does arise spontaneously in the ego and that this newly created state constitutes the essential difference between a person who has been analysed and a person who has not? Let us bear in mind what this claim is based on. All repressions take place in early childhood; they are primitive defensive measures taken by the immature, feeble ego. In later years no fresh repressions are carried out; but the old ones persist, and their services continue to be made use of by the ego for mastering the instincts. New conflicts are disposed of by what we call 'after-repression'. We may apply to these infantile repressions our general statement that repressions depend absolutely and entirely on the relative strength of the forces involved and that they cannot hold out against an increase in the strength of the instincts. Analysis, however, enables the ego, which has attained greater maturity and strength, to undertake a revision of these old repressions; a few are demolished, while others are recognized but constructed afresh out of more solid material. These new dams are of quite a different degree of firmness from the earlier ones; we may be confident that they will not give way so easily before a rising flood of instinctual strength. Thus the real achievement of analytic therapy would be the subsequent correction of the original process of repression, a correction which puts an end to the dominance of the quantitative factor.

Applying these remarks to our present problem, I think that the answer to the question of how to explain the variable results of our analytic therapy might well be that we, too, in endeavouring to replace repressions that are insecure by reliable ego-syntonic controls, do not always achieve our aim to its full extent - that is, do not achieve it thoroughly enough. The transformation is achieved, but often only partially: portions of the old mechanisms remain untouched by the work of analysis. It is difficult to prove that this is really so; for we have no other way of judging what happens but by the outcome which we are trying to explain. Nevertheless, the impressions one receives during the work of analysis do not contradict this assumption; indeed, they seem rather to confirm it. But we must not take the clarity of our own insight as a measure of the conviction which we produce in the patient. His conviction may lack 'depth', as one might say; it is always a question of the quantitative factor, which is so easily overlooked. If this is the correct answer to our question, we may say that analysis, in claiming to cure neuroses by ensuring control over instinct, is always right in theory but not always right in practice. And this is because it does not always succeed in ensuring to a sufficient degree the foundations on which a control of instinct is based. The cause of such a partial failure is easily discovered. In the past, the quantitative factor of instinctual strength opposed the ego's defensive efforts; for that reason we called in the work of analysis to help; and now that same factor sets a limit to the efficacy of this new effort. If the strength of the instinct is excessive, the mature ego, supported by analysis, fails in its task, just as the helpless ego failed formerly. Its control over instinct is improved, but it remains imperfect because the transformation in the defensive mechanism is only incomplete. There is nothing surprising in this, since the power of the instruments with which analysis operates is not unlimited but restricted, and the final upshot always depends on the relative strength of the psychical agencies which are struggling with one another.
What we are in search of is a picture of the patient's forgotten years that shall be alike trustworthy and in all essential respects complete. But at this point we are reminded that the work of analysis consists of two quite different portions, that it is carried on in two separate localities, that it involves two people, to each of whom a distinct task is assigned. It may for a moment seem strange that such a fundamental fact should not have been pointed out long ago; but it will immediately be perceived that there was nothing being kept back in this, that it is a fact which is universally known and, as it were, self-evident and is merely being brought into relief here and separately examined for a particular purpose. We all know that the person who is being analysed has to be induced to remember something that has been experienced by him and repressed; and the dynamic determinants of this process are so interesting that the other portion of the work, the task performed by the analyst, has been pushed into the background. The analyst has neither experienced nor repressed any of the material under consideration; his task cannot be to remember anything. What then is his task? His task is to make out what has been forgotten from the traces which it has left behind or, more correctly, to construct it. The time and manner in which he conveys his constructions to the person who is being analysed, as well as the explanations with which he accompanies them, constitute the link between the two portions of the work of analysis, between his own part and that of the patient. [1937d, 5050]
And now for the fact! In a whole number of nervous diseases - in hysteria, anxiety states, obsessional neurosis - our expectation is fulfilled. By searching for the repression in this way, by uncovering the resistances, by pointing out what is repressed, we really succeed in accomplishing our task - that is, in overcoming the resistances, lifting the repression and transforming the unconscious material into conscious. In doing so we gain the clearest impression of the way in which a violent struggle takes place in the patient's mind about the overcoming of each resistance - a normal mental struggle, on the same psychological ground, between the motives which seek to maintain the anticathexis and those which are prepared to give it up. The former are the old motives which in the past put the repression into effect; among the latter are the newly arrived ones which, we may hope, will decide the conflict in our favour. We have succeeded in reviving the old conflict which led to repression and in bringing up for revision the process that was then decided. The new material that we produce includes, first the reminder that the earlier decision led to illness and the promise that a different path will lead to recovery, and, second, the enormous change in all the circumstances that has take place since the time of the original rejection. Then the ego was feeble, infantile, and may perhaps have had grounds for banning the demands of the libido as a danger. To-day it has grown strong and experienced, and moreover has a helper at and in the shape of the doctor. Thus we may expect to lead the revived conflict to a better outcome than that which ended in repression, and, as I have said, in hysteria and in the anxiety and obsessional neuroses success proves us in general to be correct.

I will now complete my picture of the mechanism of cure by clothing it in the formulas of the libido theory. A neurotic is incapable of enjoyment and of efficiency - the former because his libido is not directed on to any real object and the latter because he is obliged to employ a great deal of this available energy on keeping his libido under repression and on warding off its assaults. He would become healthy if the conflict between his ego and his libido came to an end and if his ego had his libido again at its disposal. The therapeutic task consists, therefore, in freeing the libido from its present attachments, which are withdrawn from the ego, and in making it once more serviceable to the ego. Where, then, is the neurotic's libido situated? It is easily found: it is attached to the symptoms, which yield it the only substitutive satisfaction possible at the time. We must therefore make ourselves masters of the symptoms and resolve them - which is precisely the same thing that the patient requires of us. In order to resolve the symptoms, we must go back as far as their origin, we must renew the conflict from which they arose, and, with the help of motive forces which were not at the patient's disposal in the past, we must guide it to a different outcome. This revision of the process of repression can be accomplished only in part in connection with the memory traces of the processes which led to repression. The decisive part of the work is achieved by creating in the patient's relation to the doctor - in the 'transference' - new editions of the old conflicts; in these the patient would like to behave in the same way as he did in the past, while we, by summoning up every available mental force, compel him to come to a fresh decision. Thus the transference becomes the battlefield on which all the mutually struggling forces should meet one another.

The psycho-analytic method of treatment is then able to subject this process of repression to revision and to bring about a better solution of the conflict - one that is compatible with health. Unintelligent opposition accuses us of one-sidedness in our estimate of the sexual instincts. 'Human beings have other interests besides sexual ones,' they say. We have not forgotten or denied this for a moment. Our one-sidedness is like that of the chemist, who traces all compounds back to the force of chemical attraction. He is not on that account denying the force of gravity; he leaves that to the physicist to deal with.
We have formulated our task as physicians thus: to bring to the patient's knowledge the unconscious, repressed impulses existing in him, and, for that purpose, to uncover the resistances that oppose this extension of his knowledge about himself. Does the uncovering of these resistances guarantee that they will also be overcome? Certainly not always; but our hope is to achieve this by exploiting the patient's transference to the person of the physician, so as to induce him to adopt our conviction of the inexpediency of the repressive process established in childhood and of the impossibility of conducting life on the pleasure principle. I have set out elsewhere the dynamic conditions prevailing in the fresh conflict through which we lead the patient and which we substitute in him for his previous conflict - that of his illness. I have nothing at the moment to alter in that account.

[1919a, 3628]

It is easy now to describe our therapeutic aim. We try to restore the ego, to free it from its restrictions, and to give it back the command over the id which it has lost owing to its early repressions. It is for this one purpose that we carry out analysis, our whole technique is directed to this aim. We have to seek out the repressions which have been set up and to urge the ego to correct them with our help and to deal with conflicts better than by an attempt at flight. Since these repressions belong to the very early years of childhood, the work of analysis leads us, too, back to that period. Our path to these situations of conflict, which have for the most part been forgotten and which we try to revive in the patient's memory, is pointed out to us by his symptoms, dreams and free associations. These must, however, first be interpreted - translated - for, under the influence of the psychology of the id, they have assumed forms of expression that are strange to our comprehension. We may assume that whatever associations, thoughts and memories the patient is unable to communicate to us without internal struggles are in some way connected with the repressed material or are its derivatives. By encouraging the patient to disregard his resistances to telling us these things, we are educating his ego to overcome its inclination towards attempts at flight and to tolerate an approach to what is repressed. In the end, if the situation of the repression can be successfully reproduced in his memory, his compliance will be brilliantly rewarded. The whole difference between his age then and now works in his favour; and the thing from which his childish ego fled in terror will often seem to his adult and strengthened ego no more than child's play.

[1926e, 4348]

'I will add that. Thereupon he begins to talk and I listen. And what then? I infer from what he tells me the kind of impressions, experiences and wishes which he has repressed because he came across them at a time when his ego was still feeble and was afraid of them instead of dealing with them. When he has learnt this from me, he puts himself back in the old situations and with my help he manages better. The limitations to which his ego was tied then disappear, and he is cured. Is that right?'

[1926e, 4360]
With the mention of resistance we have reached the second and more important part of our task. We have already learnt that the ego protects itself against the invasion of undesired elements from the unconscious and repressed id by means of anticathexes, which must remain intact if it is to function normally. The more hard-pressed the ego feels, the more convulsively it clings (as though in a fright) to these anticathexes, in order to protect what remains of itself from further irruptions. But this defensive purpose does not by any means accord with the aims of our treatment. What we desire, on the contrary, is that the ego, emboldened by the certainty of our help, shall dare to take the offensive in order to reconquer what has been lost. And it is here that we become aware of the strength of these anticathexes in the form of resistances to our work. The ego draws back in alarm from such undertakings, which seem dangerous and threaten unpleasure; it must be constantly encouraged and soothed if it is not to fail us. This resistance, which persists throughout the whole treatment and is renewed at every fresh piece of work, is known, not quite correctly, as the resistance due to repression. We shall find that it is not the only one that faces us. It is interesting to notice that in this situation the party-divisions are to some extent reversed: for the ego struggles against our instigation, while the unconscious, which is ordinarily our opponent, comes to our help, since it has a natural 'upward drive' and desires nothing better than to press forward across its settled frontiers into the ego and so to consciousness. The struggle which develops, if we gain our end and can induce the ego to overcome its resistances, is carried through under our direction and with our assistance. Its outcome is a matter of indifference: whether it results in the ego accepting, after a fresh examination, an instinctual demand which it has hitherto rejected, or whether it dismisses it once more, this time for good and all. In either case a permanent danger has been disposed of, the compass of the ego has been extended and a wasteful expenditure of energy has been made unnecessary.

Every analyst will have treated a few cases which have had this gratifying outcome. He has succeeded in clearing up the patient's neurotic disturbance, and it has not returned and has not been replaced by any other such disturbance. Nor are we without some insight into the determinants of these successes. The patient's ego had not been noticeably altered and the aetiology of his disturbance had been essentially traumatic. The aetiology of every neurotic disturbance is, after all, a mixed one. It is a question either of the instincts being excessively strong - that is to say, recalcitrant to taming by the ego - or of the effects of early (i.e. premature) traumas which the immature ego was unable to master. As a rule there is a combination of both factors, the constitutional and the accidental. The stronger the constitutional factor, the more readily will a trauma lead to a fixation and leave behind a developmental disturbance; the stronger the trauma, the more certainly will its injurious effects become manifest even when the instinctual situation is normal. There is no doubt that an aetiology of the traumatic sort offers by far the more favourable field for analysis. Only when a case is a predominantly traumatic one will analysis succeed in doing what it is so superlatively able to do; only then will it, thanks to having strengthened the patient's ego, succeed in replacing by a correct solution the inadequate decision made in his early life. Only in such cases can one speak of an analysis having been definitively ended. In them, analysis has done all that it should and does not need to be continued. It is true that, if the patient who has been restored in this way never produces another disorder calling for analysis, we do not know how much his immunity may not be due to a kind fate which has spared him ordeals that are too severe.
Before we decide on an answer to this question, however, we must consider an objection whose force lies in the fact that we are probably predisposed in its favour. Our arguments, it will be said, are all deduced from the processes which take place spontaneously between the ego and the instincts, and they presuppose that analytic therapy can accomplish nothing which does not, under favourable and normal conditions, occur of itself. But is this really so? Is it not precisely the claim of our theory that analysis produces a state which never does arise spontaneously in the ego and that this newly created state constitutes the essential difference between a person who has been analysed and a person who has not? Let us bear in mind what this claim is based on. All repressions take place in early childhood; they are primitive defensive measures taken by the immature, feeble ego. In later years no fresh repressions are carried out; but the old ones persist, and their services continue to be made use of by the ego for mastering the instincts. New conflicts are disposed of by what we call 'after-repression'. We may apply to these infantile repressions our general statement that repressions depend absolutely and entirely on the relative strength of the forces involved and that they cannot hold out against an increase in the strength of the instincts. Analysis, however, enables the ego, which has attained greater maturity and strength, to undertake a revision of these old repressions; a few are demolished, while others are recognized but constructed afresh out of more solid material. These new dams are of quite a different degree of firmness from the earlier ones; we may be confident that they will not give way so easily before a rising flood of instinctual strength. Thus the real achievement of analytic therapy would be the subsequent correction of the original process of repression, a correction which puts an end to the dominance of the quantitative factor. [1937c, 5024]

It is familiar ground that the work of analysis aims at inducing the patient to give up the repressions (using the word in the widest sense) belonging to his early development and to replace them by reactions of a sort that would correspond to a psychically mature condition. With this purpose in view he must be brought to recollect certain experiences and the affective impulses called up by them which he has for the time being forgotten. We know that his present symptoms and inhibitions are the consequences of repressions of this kind: thus that they are a substitute for these things that he has forgotten. What sort of material does he put at our disposal which we can make use of to put him on the way to recovering the lost memories? All kinds of things. He gives us fragments of these memories in his dreams, invaluable in themselves but seriously distorted as a rule by all the factors concerned in the formation of dreams. Again, he produces ideas, if he gives himself up to 'free association', in which we can discover allusions to the repressed experiences and derivatives of the suppressed affective impulses as well as of the reactions against them. And, finally, there are hints of repetitions of the affects belonging to the repressed material to be found in actions performed by the patient, some fairly important, some trivial, both inside and outside the analytic situation. Our experience has shown that the relation of transference, which becomes established towards the analyst, is particularly calculated to favour the return of these emotional connections. It is out of such raw material - if we may so describe it - that we have to put together what we are in search of. [1937d, 5050]
On the contrary, the only results of the analysis were that Hans recovered, that he ceased to be afraid of horses, and that he got on to rather familiar terms with his father, as the latter reported with some amusement. But whatever his father may have lost in the boy's respect he won back in his confidence: 'I thought', said Hans, 'you knew everything, as you knew that about the horse.' For analysis does not undo the effects of repression. The instincts which were formerly suppressed remain suppressed; but the same effect is produced in a different way. Analysis replaces the process of repression, which is an automatic and excessive one, by a temperate and purposeful control on the part of the highest agencies of the mind. In a word, analysis replaces repression by condemnation. This seems to bring us the long-looked-for evidence that consciousness has a biological function, and that with its entrance upon the scene an important advantage is secured.²

To put the matter more directly. The investigation of hysterical patients and of other neurotics leads us to the conclusion that their repression of the idea to which the intolerable wish is attached has been a failure. It is true that they have driven it out of consciousness and out of memory and have apparently saved themselves a large amount of unpleasure. *But the repressed wishful impulse continues to exist in the unconscious.* It is on the look-out for an opportunity of being activated, and when that happens it succeeds in sending into consciousness a disguised and unrecognizable substitute for what had been repressed, and to this there soon become attached the same feelings of unpleasure which it was hoped had been saved by the repression. This substitute for the repressed idea - the symptom - is proof against further attacks from the defensive ego; and in place of the short conflict an ailment now appears which is not brought to an end by the passage of time. Alongside the indication of distortion in the symptom, we can trace in it the remains of some kind of indirect resemblance to the idea that was originally repressed. The paths along which the substitution was effected can be traced in the course of the patient's psycho-analytic treatment; and in order to bring about recovery, the symptom must be led back along the same paths and once more turned into the repressed idea. If what was repressed is brought back again into conscious mental activity - a process which presupposes the overcoming of considerable resistances - the resulting psychical conflict, which the patient had tried to avoid, can, under the physician's guidance, reach a better outcome than was offered by repression. There are a number of such opportune solutions, which may bring the conflict and the neurosis to a happy end, and which may in certain instances be combined. The patient's personality may be convinced that it has been wrong in rejecting the pathogenic wish and may be led into accepting it wholly or in part; or the wish itself may be directed to a higher and consequently unobjectionable aim (this is what we call its 'sublimation'); or the rejection of the wish may be recognized as a justifiable one, but the automatic and therefore inefficient mechanism of repression may be replaced by a condemning judgement with the help of the highest human mental functions - conscious control of the wish is attained.

[1909b, 2121]

[1910a, 2215]
Ladies and Gentlemen, from the intellectual point of view we must, I think, take into account two special obstacles to recognizing psycho-analytic trains of thought. In the first place, people are unaccustomed to reckoning with a strict and universal application of determinism to mental life; and in the second place, they are ignorant of the peculiarities which distinguish unconscious mental processes from the conscious ones that are familiar to us. One of the most widespread resistances to psycho-analytic work, in the sick and healthy alike, can be traced to the second of these two factors. People are afraid of doing harm by psycho-analysis; they are afraid of bringing the repressed sexual instincts into the patient's consciousness, as though that involved a danger of their overwhelming his higher ethical trends and of their robbing him of his cultural acquisitions. People notice that the patient has sore spots in his mind, but shrink from touching them for fear of increasing his sufferings. We can accept this analogy. It is no doubt kinder not to touch diseased spots if it can do nothing else but cause pain. But, as we know, a surgeon does not refrain from examining and handling a focus of disease, if he is intending to take active measures which he believes will lead to a permanent cure. No one thinks of blaming him for the inevitable suffering caused by the examination or for the reactions to the operation, if only it gains its end and the patient achieves a lasting recovery as a result of the temporary worsening of his state. The case is similar with psycho-analysis. It may make the same claims as surgery: the increase in suffering which it causes the patient during treatment is incomparably less than what a surgeon causes, and is quite negligible in proportion to the severity of the underlying ailment. On the other hand, the final outcome that is so much dreaded - the destruction of the patient's cultural character by the instincts which have been set free from repression - is totally impossible. For alarm on this score takes no account of what our experiences have taught us with certainty - namely that the mental and somatic power of a wishful impulse, when once its repression has failed, is far stronger if it is unconscious than if it is conscious; so that to make it conscious can only be to weaken it. An unconscious wish cannot be influenced and it is independent of any contrary tendencies, whereas a conscious one is inhibited by whatever else is conscious and opposed to it. Thus the work of psycho-analysis puts itself at the orders of precisely the highest and most valuable cultural trends, as a better substitute for the unsuccessful repression.

[1910a, 2237]

What, then, becomes of the unconscious wishes which have been set free by psycho-analysis? Along what paths do we succeed in making them harmless to the subject's life? There are several such paths. The most frequent outcome is that, while the work is actually going on, these wishes are destroyed by the rational mental activity of the better impulses that are opposed to them. Repression is replaced by a condemning judgement carried out along the best lines. That is possible because what we have to get rid of is to a great extent only the consequences arising from earlier stages of the ego's development. The subject only succeeded in the past in repressing the unserviceable instinct because he himself was at that time still imperfectly organized and feeble. In his present-day maturity and strength, he will perhaps be able to master what is hostile to him with complete success.

[1910a, 2238]
A second outcome of the work of psycho-analysis is that it then becomes possible for the unconscious instincts revealed by it to be employed for the useful purposes which they would have found earlier if development had not been interrupted. For the extirpation of the infantile wishful impulses is by no means the ideal aim of development. Owing to their repressions, neurotics have sacrificed many sources of mental energy whose contributions would have been of great value in the formation of their character and in their activity in life. We know of a far more expedient process of development, called 'sublimation', in which the energy of the infantile wishful impulses is not cut off but remains ready for use - the unserviceable aim of the various impulses being replaced by one that is higher, and perhaps no longer sexual. It happens to be precisely the components of the sexual instinct that are specially marked by a capacity of this kind for sublimation, for exchanging their sexual aim for another one which is comparatively remote and socially valuable. It is probable that we owe our highest cultural successes to the contributions of energy made in this way to our mental functions. Premature repression makes the sublimation of the repressed instinct impossible; when the repression is lifted, the path to sublimation becomes free once more.

[1910a, 2238]

(h) Another temptation arises out of the educative activity which, in psycho-analytic treatment, devolves on the doctor without any deliberate intention on his part. When the developmental inhibitions are resolved, it happens of itself that the doctor finds himself in a position to indicate new aims for the trends that have been liberated. It is then no more than a natural ambition if he endeavours to make something specially excellent of a person whom he has been at such pains to free from his neurosis and if he prescribes high aims for his wishes. But here again the doctor should hold himself in check, and take the patient's capacities rather than his own desires as guide. Not every neurotic has a high talent for sublimation; one can assume of many of them that they would not have fallen ill at all if they had possessed the art of sublimating their instincts. If we press them unduly towards sublimation and cut them off from the most accessible and convenient instinctual satisfactions, we shall usually make life even harder for them than they feel it in any case. As a doctor, one must above all be tolerant to the weakness of a patient, and must be content if one has won back some degree of capacity for work and enjoyment for a person even of only moderate worth. Educative ambition is of as little use as therapeutic ambition. It must further be borne in mind that many people fall ill precisely from an attempt to sublimate their instincts beyond the degree permitted by their organization and that in those who have a capacity for sublimation the process usually takes place of itself as soon as their inhibitions have been overcome by analysis. In my opinion, therefore, efforts invariably to make use of the analytic treatment to bring about sublimation of instinct are, though no doubt always laudable, far from being in every case advisable.

[1912e, 2473]

One of the vicissitudes an instinctual impulse may undergo is to meet with resistances which seek to make it inoperative. Under certain conditions, which we shall presently investigate more closely, the impulse then passes into the state of 'repression' ['Verdrängung']. If what was in question was the operation of an external stimulus, the appropriate method to adopt would obviously be flight; with an instinct, flight is of no avail, for the ego cannot escape from itself. At some later period, rejection based on judgement (condemnation) will be found to be a good method to adopt against an instinctual impulse. Repression is a preliminary stage of condemnation, something between flight and condemnation; it is a concept which could not have been formulated before the time of psycho-analytic studies.

[1915d, 2977]
Thus our therapeutic work falls into two phases. In the first, all the libido is forced from the symptoms into the transference and concentrated there; in the second, the struggle is waged around this new object and the libido is liberated from it. The change which is decisive for a favourable outcome is the elimination of repression in this renewed conflict so that the libido cannot withdraw once more from the ego by flight into the unconscious. This is made possible by the alteration of the ego which is accomplished under the influence of the doctor's suggestion. By means of the work of interpretation, which transforms what is unconscious into what is conscious, the ego is enlarged at the cost of this unconscious; by means of instruction, it is made conciliatory towards the libido and inclined to grant it some satisfaction, and its repugnance to the claims of the libido is diminished by the possibility of disposing of a portion of it by sublimation. The more closely events in the treatment coincide with this ideal description, the greater will be the success of the psycho-analytic therapy. It finds its limits in the lack of mobility of the libido, which may refuse to leave its objects, and the rigidity of narcissism, which will not allow transference on to objects to increase beyond certain bounds. Further light may perhaps be thrown on the dynamics of the process of cure if I say that we get hold of the whole of the libido which has been withdrawn from the dominance of the ego by attracting a portion of it on to ourselves by means of the transference.

I cannot simplify my statement by describing my patient's death-wish against his brother-in-law as an unconscious, repressed one. For it had been made conscious during the treatment the year before and the consequences which had followed from its repression had yielded to the treatment. But it still persisted, and, though it was no longer pathogenic, it was sufficiently intense. It might be described as a 'suppressed' wish.

The psycho-analytic method of treatment is then able to subject this process of repression to revision and to bring about a better solution of the conflict - one that is compatible with health. Unintelligent opposition accuses us of one-sidedness in our estimate of the sexual instincts. 'Human beings have other interests besides sexual ones,' they say. We have not forgotten or denied this for a moment. Our one-sidedness is like that of the chemist, who traces all compounds back to the force of chemical attraction. He is not on that account denying the force of gravity; he leaves that to the physicist to deal with.

I cannot simplify my statement by describing my patient's death-wish against his brother-in-law as an unconscious, repressed one. For it had been made conscious during the treatment the year before and the consequences which had followed from its repression had yielded to the treatment. But it still persisted, and, though it was no longer pathogenic, it was sufficiently intense. It might be described as a 'suppressed' wish.
Comparison between Psycho-Analysis and Hypnotic and Suggestive Methods. - Psycho-analytic procedure differs from all methods making use of suggestion, persuasion, etc., in that it does not seek to suppress by means of authority any mental phenomenon that may occur in the patient. It endeavours to trace the causation of the phenomenon and to remove it by bringing about a permanent modification in the conditions that led to it. In psycho-analysis the suggestive influence which is inevitably exercised by the physician is diverted on to the task assigned to the patient of overcoming his resistances, that is, of carrying forward the curative process. Any danger of falsifying the products of a patient's memory by suggestion can be avoided by prudent handling of the technique; but in general the arousing of resistances is a guarantee against the misleading effects of suggestive influence. It may be laid down that the aim of the treatment is to remove the patient's resistances and to pass his repressions in review and thus to bring about the most far-reaching unification and strengthening of his ego, to enable him to save the mental energy which he is expending upon internal conflicts, to make the best of him that his inherited capacities will allow and so to make him as efficient and as capable of enjoyment as is possible. The removal of the symptoms of the illness is not specifically aimed at, but is achieved, as it were, as a by-product if the analysis is properly carried through. The analyst respects the patient's individuality and does not seek to remould him in accordance with his own - that is, according to the physician's - personal ideals; he is glad to avoid giving advice and instead to arouse the patient's power of initiative.

[Critisms and Misunderstandings of Psycho-Analysis. - Most of what is brought up against psycho-analysis, even in scientific works, is based upon insufficient information which in its turn seems to be determined by emotional resistances. Thus it is a mistake to accuse psycho-analysis of 'pan-sexualism' and to allege that it derives all mental occurrences from sexuality and traces them all back to it. On the contrary, psycho-analysis has from the very first distinguished the sexual instincts from others which it has provisionally termed 'ego instincts'. It has never dreamt of trying to explain 'everything', and even the neuroses it has traced back not to sexuality alone but to the conflict between the sexual impulses and the ego. In psycho-analysis (unlike the works of C. G. Jung) the term 'libido' does not mean psychical energy in general but the motive force of the sexual instincts. Some assertions, such as that every dream is the fulfilment of a sexual wish, have never been maintained by it at all. The charge of one-sidedness made against psycho-analysis, which, as the science of the unconscious mind, has its own definite and restricted field of work, is as inapplicable as it would be if it were made against chemistry. To believe that psycho-analysis seeks a cure for neurotic disorders by giving a free rein to sexuality is a serious misunderstanding which can only be excused by ignorance. The making conscious of repressed sexual desires in analysis makes it possible, on the contrary, to obtain a mastery over them which the previous repression had been unable to achieve. It can more truly be said that analysis sets the neurotic free from the chains of his sexuality. Moreover, it is quite unscientific to judge analysis by whether it is calculated to undermine religion, authority and morals; for, like all sciences, it is entirely non-tendentious and has only a single aim - namely to arrive at a consistent view of one portion of reality. Finally, one can only characterize as simple-minded the fear which is sometimes expressed that all the highest goods of humanity, as they are called - research, art, love, ethical and social sense - will lose their value or their dignity because psycho-analysis is in a position to demonstrate their origin in elementary and animal instinctual impulses.

[1923a, 3927]

[Critisms and Misunderstandings of Psycho-Analysis. - Most of what is brought up against psycho-analysis, even in scientific works, is based upon insufficient information which in its turn seems to be determined by emotional resistances. Thus it is a mistake to accuse psycho-analysis of 'pan-sexualism' and to allege that it derives all mental occurrences from sexuality and traces them all back to it. On the contrary, psycho-analysis has from the very first distinguished the sexual instincts from others which it has provisionally termed 'ego instincts'. It has never dreamt of trying to explain 'everything', and even the neuroses it has traced back not to sexuality alone but to the conflict between the sexual impulses and the ego. In psycho-analysis (unlike the works of C. G. Jung) the term 'libido' does not mean psychical energy in general but the motive force of the sexual instincts. Finally, one can only characterize as simple-minded the fear which is sometimes expressed that all the highest goods of humanity, as they are called - research, art, love, ethical and social sense - will lose their value or their dignity because psycho-analysis is in a position to demonstrate their origin in elementary and animal instinctual impulses.

[1923a, 3928]
The theory of repression became the corner-stone of our understanding of the neuroses. A different view had now to be taken of the task of therapy. Its aim was no longer to 'abreact' an affect which had got on to the wrong lines but to uncover repressions and replace them by acts of judgement which might result either in the accepting or in the condemning of what had formerly been repudiated. I showed my recognition of the new situation by no longer calling my method of investigation and treatment \textit{catharsis} but \textit{psycho-analysis}.

That this is a correct account of fixation upon repression and of the retention of danger-situations that are no longer present-day ones is confirmed by the fact of analytic therapy - a fact which is modest enough in itself but which can hardly be overrated from a theoretical point of view. When, in analysis, we have given the ego assistance which is able to put it in a position to lift its repressions, it recovers its power over the repressed id and can allow the instinctual impulses to run their course as though the old situations of danger no longer existed. What we can do in this way tallies with what can be achieved in other fields of medicine; for as a rule our therapy must be content with bringing about more quickly, more reliably and with less expenditure of energy than would otherwise be the case the good result which in favourable circumstances would have occurred of itself.

'I will add that. Thereupon he begins to talk and I listen. And what then? I infer from what he tells me the kind of impressions, experiences and wishes which he has repressed because he came across them at a time when his ego was still feeble and was afraid of them instead of dealing with them. When he has learnt this from me, he puts himself back in the old situations and with my help he manages better. The limitations to which his ego was tied then disappear, and he is cured. Is that right?'

That is a question of tact, which can become more refined with experience. You will be making a bad mistake if, in an effort, perhaps, at shortening the analysis, you throw your interpretations at the patient's head as soon as you have found them. In that way you will draw expressions of resistance, rejection and indignation from him; but you will not enable his ego to master his repressed material. The formula is: to wait till he has come so near to the repressed material that he has only a few more steps to take under the lead of the interpretation you propose.
Our knowledge of the historical worth of certain religious doctrines increases our respect for them, but does not invalidate our proposal that they should cease to be put forward as the reasons for the precepts of civilization. On the contrary! Those historical residues have helped us to view religious teachings, as it were, as neurotic relics, and we may now argue that the time has probably come, as it does in an analytic treatment, for replacing the effects of repression by the results of the rational operation of the intellect. We may foresee, but hardly regret, that such a process of remoulding will not stop at renouncing the solemn transfiguration of cultural precepts, but that a general revision of them will result in many of them being done away with. In this way our appointed task of reconciling men to civilization will to a great extent be achieved. We need not deplore the renunciation of historical truth when we put forward rational grounds for the precepts of civilization. The truths contained in religious doctrines are after all so distorted and systematically disguised that the mass of humanity cannot recognize them as truth. The case is similar to what happens when we tell a child that new-born babies are brought by the stork. Here, too, we are telling the truth in symbolic clothing, for we know what the large bird signifies. But the child does not know it. He hears only the distorted part of what we say, and feels that he has been deceived; and we know how often his distrust of the grown-ups and his refractoriness actually take their start from this impression. We have become convinced that it is better to avoid such symbolic disguisings of the truth in what we tell children and not to withhold from them a knowledge of the true state of affairs commensurate with their intellectual level.

[1927c, 4453]

It will be enough for my purposes if I return to two general characteristics of the phenomena of derealization. The first is that they all serve the purpose of defence; they aim at keeping something away from the ego, at disavowing it. Now, new elements, which may give occasion for defensive measures, approach the ego from two directions - from the real external world and from the internal world of thoughts and impulses that emerge in the ego. It is possible that this alternative coincides with the choice between derealizations proper and depersonalizations. There are an extraordinarily large number of methods (or mechanisms, as we say) used by our ego in the discharge of its defensive functions. An investigation is at this moment being carried on close at hand which is devoted to the study of these methods of defence: my daughter, the child analyst, is writing a book upon them. The most primitive and thorough-going of these methods, 'repression', was the starting point of the whole of our deeper understanding of psychopathology. Between repression and what may be termed the normal method of fending off what is distressing or unbearable, by means of recognizing it, considering it, making a judgement upon it and taking appropriate action about it, there lie a whole series of more or less clearly pathological methods of behaviour on the part of the ego. May I stop for a moment to remind you of a marginal case of this kind of defence? You remember the famous lament of the Spanish Moors 'Ay de mi Alhama', which tells how King Boabdil received the news of the fall of his city of Alhama. He feels that this loss means the end of his rule. But he will not 'let it be true', he determines to treat the news as 'non arrivé'. The verse runs:

[1936a, 4829]
With the mention of resistance we have reached the second and more important part of our task. We have already learnt that the ego protects itself against the invasion of undesired elements from the unconscious and repressed id by means of anticathexes, which must remain intact if it is to function normally. The more hard-pressed the ego feels, the more convulsively it clings (as though in a fright) to these anticathexes, in order to protect what remains of itself from further irruptions. But this defensive purpose does not by any means accord with the aims of our treatment. What we desire, on the contrary, is that the ego, emboldened by the certainty of our help, shall dare to take the offensive in order to reconquer what has been lost. And it is here that we become aware of the strength of these anticathexes in the form of resistances to our work. The ego draws back in alarm from such undertakings, which seem dangerous and threaten unpleasure; it must be constantly encouraged and soothed if it is not to fail us. This resistance, which persists throughout the whole treatment and is renewed at every fresh piece of work, is known, not quite correctly, as the resistance due to repression. We shall find that it is not the only one that faces us. It is interesting to notice that in this situation the party-divisions are to some extent reversed: for the ego struggles against our instigation, while the unconscious, which is ordinarily our opponent, comes to our help, since it has a natural 'upward drive' and desires nothing better than to press forward across its settled frontiers into the ego and so to consciousness. The struggle which develops, if we gain our end and can induce the ego to overcome its resistances, is carried through under our direction and with our assistance. Its outcome is a matter of indifference: whether it results in the ego accepting, after a fresh examination, an instinctual demand which it has hitherto rejected, or whether it dismisses it once more, this time for good and all. In either case a permanent danger has been disposed of, the compass of the ego has been extended and a wasteful expenditure of energy has been made unnecessary.

Every analyst will have treated a few cases which have had this gratifying outcome. He has succeeded in clearing up the patient's neurotic disturbance, and it has not returned and has not been replaced by any other such disturbance. Nor are we without some insight into the determinants of these successes. The patient's ego had not been noticeably altered and the aetiology of his disturbance had been essentially traumatic. The aetiology of every neurotic disturbance is, after all, a mixed one. It is a question either of the instincts being excessively strong - that is to say, recalcitrant to taming by the ego - or of the effects of early (i.e. premature) traumas which the immature ego was unable to master. As a rule there is a combination of both factors, the constitutional and the accidental. The stronger the constitutional factor, the more readily will a trauma lead to a fixation and leave behind a developmental disturbance; the stronger the trauma, the more certainly will its injurious effects become manifest even when the instinctual situation is normal. There is no doubt that an aetiology of the traumatic sort offers by far the more favourable field for analysis. Only when a case is a predominantly traumatic one will analysis succeed in doing what it is so superlatively able to do; only then will it, thanks to having strengthened the patient's ego, succeed in replacing by a correct solution the inadequate decision made in his early life. Only in such cases can one speak of an analysis having been definitively ended. In them, analysis has done all that it should and does not need to be continued. It is true that, if the patient who has been restored in this way never produces another disorder calling for analysis, we do not know how much his immunity may not be due to a kind fate which has spared him ordeals that are too severe.

[1940a [1938], 4988]

[1937c, 5018]
Before we decide on an answer to this question, however, we must consider an objection whose force lies in the fact that we are probably predisposed in its favour. Our arguments, it will be said, are all deduced from the processes which take place spontaneously between the ego and the instincts, and they presuppose that analytic therapy can accomplish nothing which does not, under favourable and normal conditions, occur of itself. But is this really so? Is it not precisely the claim of our theory that analysis produces a state which never does arise spontaneously in the ego and that this newly created state constitutes the essential difference between a person who has been analysed and a person who has not? Let us bear in mind what this claim is based on. All repressions take place in early childhood; they are primitive defensive measures taken by the immature, feeble ego. In later years no fresh repressions are carried out; but the old ones persist, and their services continue to be made use of by the ego for mastering the instincts. New conflicts are disposed of by what we call 'after-repression'. We may apply to these infantile repressions our general statement that repressions depend absolutely and entirely on the relative strength of the forces involved and that they cannot hold out against an increase in the strength of the instincts. Analysis, however, enables the ego, which has attained greater maturity and strength, to undertake a revision of these old repressions; a few are demolished, while others are recognized but constructed afresh out of more solid material. These new dams are of quite a different degree of firmness from the earlier ones; we may be confident that they will not give way so easily before a rising flood of instinctual strength. Thus the real achievement of analytic therapy would be the subsequent correction of the original process of repression, a correction which puts an end to the dominance of the quantitative factor.

[1937c, 5024]

Applying these remarks to our present problem, I think that the answer to the question of how to explain the variable results of our analytic therapy might well be that we, too, in endeavouring to replace repressions that are insecure by reliable ego-syntonic controls, do not always achieve our aim to its full extent - that is, do not achieve it thoroughly enough. The transformation is achieved, but often only partially: portions of the old mechanisms remain untouched by the work of analysis. It is difficult to prove that this is really so; for we have no other way of judging what happens but by the outcome which we are trying to explain. Nevertheless, the impressions one receives during the work of analysis do not contradict this assumption; indeed, they seem rather to confirm it. But we must not take the clarity of our own insight as a measure of the conviction which we produce in the patient. His conviction may lack 'depth', as one might say; it is always a question of the quantitative factor, which is so easily overlooked. If this is the correct answer to our question, we may say that analysis, in claiming to cure neuroses by ensuring control over instinct, is always right in theory but not always right in practice. And this is because it does not always succeed in ensuring to a sufficient degree the foundations on which a control of instinct is based. The cause of such a partial failure is easily discovered. In the past, the quantitative factor of instinctual strength opposed the ego's defensive efforts; for that reason we called in the work of analysis to help; and now that same factor sets a limit to the efficacy of this new effort. If the strength of the instinct is excessive, the mature ego, supported by analysis, fails in its task, just as the helpless ego failed formerly. Its control over instinct is improved, but it remains imperfect because the transformation in the defensive mechanism is only incomplete. There is nothing surprising in this, since the power of the instruments with which analysis operates is not unlimited but restricted, and the final upshot always depends on the relative strength of the psychical agencies which are struggling with one another.

[1937c, 5026]
It is familiar ground that the work of analysis aims at inducing the patient to give up the
repressions (using the word in the widest sense) belonging to his early development and to
replace them by reactions of a sort that would correspond to a psychically mature condition.
With this purpose in view he must be brought to recollect certain experiences and the affective
impulses called up by them which he has for the time being forgotten. We know that his present
symptoms and inhibitions are the consequences of repressions of this kind: thus that they are a
substitute for these things that he has forgotten. What sort of material does he put at our
disposal which we can make use of to put him on the way to recovering the lost memories? All
kinds of things. He gives us fragments of these memories in his dreams, invaluable in
themselves but seriously distorted as a rule by all the factors concerned in the formation of
dreams. Again, he produces ideas, if he gives himself up to 'free association', in which we can
discover allusions to the repressed experiences and derivatives of the suppressed affective
impulses as well as of the reactions against them. And, finally, there are hints of repetitions of
the affects belonging to the repressed material to be found in actions performed by the patient,
some fairly important, some trivial, both inside and outside the analytic situation. Our experience
has shown that the relation of transference, which becomes established towards the analyst, is
particularly calculated to favour the return of these emotional connections. It is out of such raw
material - if we may so describe it - that we have to put together what we are in search of.
[1937d, 5050]
If a furious raging against one's own integrity and one's own life can be hidden in this way behind apparently accidental clumsiness and motor inefficiency, it is not a very large step to find it possible to transfer the same view to mistakes that seriously endanger the lives and health of other people. What evidence I have to show that this view is a valid one is drawn from my experience with neurotics, and thus does not wholly meet the demands of the situation. I will give an account of a case in which something that was not strictly a faulty action but that rather deserves the name of a symptomatic or chance action gave me the clue which subsequently made it possible to resolve the patient's conflict. I once undertook the task of bringing an improvement to the marriage of a very intelligent man, whose disagreements with his fondly attached young wife could undoubtedly be shown to have a real basis, but could not, as he himself admitted, be completely accounted for in that way. He was continually occupied with the thought of a divorce, which he then dismissed once more because of his warm love for his two small children. In spite of this he constantly returned to his intention and made no attempt to find a way of making the situation tolerable to himself. Such inability to deal with a conflict is taken by me as proof that unconscious and repressed motives have lent a hand in strengthening the conscious ones which are struggling against each other, and I undertake in such cases to end the conflict by psychical analysis. One day the man told me of a small incident which had frightened him extremely. He was romping with his elder child, who was by far his favourite; he was swinging him high in the air and down again, and once he swung him so high while he was standing at a particular spot that the top of the child's head almost struck the heavy gas chandelier that was hanging there. Almost, but not quite - or perhaps just! No harm came to the child, but it was made giddy with fright. The father stood horrified with the child in his arms, and the mother had a hysterical attack. The peculiar adroitness of this imprudent movement and the violence of the parents' reaction prompted me to look for a symptomatic act in this accident - one which aimed at expressing an evil intention directed against the beloved child. I was able to remove the contradiction between this and the father's contemporary affection for his child by shifting the impulse to injure it back to the time when this child had been the only one and had been so small that its father had not yet had any reason to take an affectionate interest in it. It was then easy for me to suppose that, as he was getting little satisfaction from his wife, he may at that time have had a thought or formed a decision of this kind: 'If this little creature that means nothing at all to me dies, I shall be free and able to get a divorce.' A wish for the death of the creature that he now loved so dearly must therefore have persisted unconsciously. From this point it was easy to find the path by which this wish had become unconsciously fixated. A powerful determinant was in fact provided by a memory from the patient's childhood: namely that the death of a small brother, for which his mother blamed his father's negligence, had led to violent quarrels between the parents and threats of a divorce. The subsequent course of my patient's marriage, as well as my therapeutic success, confirmed my conjecture. [1901b, 1266]

It may be in consequence of disregarding these three preconditions that so many other psychopathic characters are as unserviceable on the stage as they are in real life. For the victim of a neurosis is someone into whose conflict we can gain no insight if we first meet it in a fully established state. But, per contra, if we recognize the conflict, we forget that he is a sick man, just as, if he himself recognizes it, he ceases to be ill. It would seem to be the dramatist's business to induce the same illness in us; and this can best be achieved if we are made to follow the development of the illness along with the sufferer. This will be especially necessary where the repression does not already exist in us but has first to be set up; and this represents a step further than Hamlet in the use of neurosis on the stage. If we are faced by an unfamiliar and fully established neurosis, we shall be inclined to send for the doctor (just as we do in real life) and pronounce the character inadmissible to the stage. [1942a [1905], 1612]
In this connection people usually overlook the one essential point - that the pathogenic conflict in neurotics is not to be confused with a normal struggle between mental impulses both of which are on the same psychological footing. In the former case the dissension is between two powers, one of which has made its way to the stage of what is preconscious or conscious while the other has been held back at the stage of the unconscious. For that reason the conflict cannot be brought to an issue; the disputants can no more come to grips than, in the familiar simile, a polar bear and a whale. A true decision can only be reached when they both meet on the same ground. To make this possible is, I think, the sole task of our therapy.

Thus you cannot explain the therapeutic effect of psycho-analysis by its permitting a full sexual life. Look around, then, for something else. I fancy that, while I was rejecting this suggestion of yours, one remark of mine put you on the right track. What we make use of must no doubt be the replacing of what is unconscious by what is conscious, the translation of what is unconscious into what is conscious. Yes, that is it. By carrying what is unconscious on into what is conscious, we lift the repressions, we remove the preconditions for the formation of symptoms, we transform the pathogenic conflict to a normal one for which it must be possible somehow to find a solution. All that we bring about in a patient is this single psychical change: the length to which it is carried is the measure of the help we provide. Where no repressions (or analogous psychical processes) can be undone, our therapy has nothing to expect.

And now for the fact! In a whole number of nervous diseases - in hysteria, anxiety states, obsessional neurosis - our expectation is fulfilled. By searching for the repression in this way, by uncovering the resistances, by pointing out what is repressed, we really succeed in accomplishing our task - that is, in overcoming the resistances, lifting the repression and transforming the unconscious material into conscious. In doing so we gain the clearest impression of the way in which a violent struggle takes place in the patient's mind about the overcoming of each resistance - a normal mental struggle, on the same psychological ground, between the motives which seek to maintain the anticathexis and those which are prepared to give it up. The former are the old motives which in the past put the repression into effect; among the latter are the newly arrived ones which, we may hope, will decide the conflict in our favour. We have succeeded in reviving the old conflict which led to repression and in bringing up for revision the process that was then decided. The new material that we produce includes, first the reminder that the earlier decision led to illness and the promise that a different path will lead to recovery, and, second, the enormous change in all the circumstances that has take place since the time of the original rejection. Then the ego was feeble, infantile, and may perhaps have had grounds for banning the demands of the libido as a danger. To-day it has grown strong and experienced, and moreover has a helper at and in the shape of the doctor. Thus we may expect to lead the revived conflict to a better outcome than that which ended in repression, and, as I have said, in hysteria and in the anxiety and obsessional neuroses success proves us in general to be correct.
I will now complete my picture of the mechanism of cure by clothing it in the formulas of the libido theory. A neurotic is incapable of enjoyment and of efficiency - the former because his libido is not directed on to any real object and the latter because he is obliged to employ a great deal of this available energy on keeping his libido under repression and on warding off its assaults. He would become healthy if the conflict between his ego and his libido came to an end and if his ego had his libido again at its disposal. The therapeutic task consists, therefore, in freeing the libido from its present attachments, which are withdrawn from the ego, and in making it once more serviceable to the ego. Where, then, is the neurotic's libido situated? It is easily found: it is attached to the symptoms, which yield it the only substitutive satisfaction possible at the time. We must therefore make ourselves masters of the symptoms and resolve them - which is precisely the same thing that the patient requires of us. In order to resolve the symptoms, we must go back as far as their origin, we must renew the conflict from which they arose, and, with the help of motive forces which were not at the patient's disposal in the past, we must guide it to a different outcome. This revision of the process of repression can be accomplished only in part in connection with the memory traces of the processes which led to repression. The decisive part of the work is achieved by creating in the patient's relation to the doctor - in the 'transference' - new editions of the old conflicts; in these the patient would like to behave in the same way as he did in the past, while we, by summoning up every available mental force, compel him to come to a fresh decision. Thus the transference becomes the battlefield on which all the mutually struggling forces should meet one another.

Thus our therapeutic work falls into two phases. In the first, all the libido is forced from the symptoms into the transference and concentrated there; in the second, the struggle is waged around this new object and the libido is liberated from it. The change which is decisive for a favourable outcome is the elimination of repression in this renewed conflict so that the libido cannot withdraw once more from the ego by flight into the unconscious. This is made possible by the alteration of the ego which is accomplished under the influence of the doctor's suggestion. By means of the work of interpretation, which transforms what is unconscious into what is conscious, the ego is enlarged at the cost of this unconscious; by means of instruction, it is made conciliatory towards the libido and inclined to grant it some satisfaction, and its repugnance to the claims of the libido is diminished by the possibility of disposing of a portion of it by sublimation. The more closely events in the treatment coincide with this ideal description, the greater will be the success of the psycho-analytic therapy. It finds its limits in the lack of mobility of the libido, which may refuse to leave its objects, and the rigidity of narcissism, which will not allow transference on to objects to increase beyond certain bounds. Further light may perhaps be thrown on the dynamics of the process of cure if I say that we get hold of the whole of the libido which has been withdrawn from the dominance of the ego by attracting a portion of it on to ourselves by means of the transference.
With this as a starting-point we go on to make our first important discovery. We learn that, when we try to understand neurotic disorders, by far the greater significance attaches to the sexual instincts; that in fact neuroses are the specific disorders, so to speak, of the sexual function; that in general whether or not a person develops a neurosis depends on the quantity of his libido, and on the possibility of satisfying it and of discharging it through satisfaction; that the form taken by the disease is determined by the way in which the individual passes through the course of development of his sexual function, or, as we put it, by the fixations his libido has undergone in the course of its development; and, further, that by a special, not very simple technique for influencing the mind we are able to throw light on the nature of some groups of neuroses and at the same time to do away with them. Our therapeutic efforts have their greatest success with a certain class of neuroses which proceed from a conflict between the ego-instincts and the sexual instincts. For in human beings it may happen that the demands of the sexual instincts, whose reach of course extends far beyond the individual, seem to the ego to constitute a danger which threatens its self-preservation or its self-esteem. The ego then assumes the defensive, denies the sexual instincts the satisfaction they desire and forces them into those by-paths of substitutive satisfaction which become manifest as nervous symptoms. [1917a, 3609]

The psycho-analytic method of treatment is then able to subject this process of repression to revision and to bring about a better solution of the conflict - one that is compatible with health. Unintelligent opposition accuses us of one-sidedness in our estimate of the sexual instincts. 'Human beings have other interests besides sexual ones,' they say. We have not forgotten or denied this for a moment. Our one-sidedness is like that of the chemist, who traces all compounds back to the force of chemical attraction. He is not on that account denying the force of gravity; he leaves that to the physicist to deal with. [1917a, 3609]

Let us at once agree upon what we mean by this activity. We have defined our therapeutic task as consisting of two things: making conscious the repressed material and uncovering the resistances. In that we are active enough, to be sure. But are we to leave it to the patient to deal alone with the resistances we have pointed out to him? Can we give him no other help in this besides the stimulus he gets from the transference? Does it not seem natural that we should help him in another way as well, by putting him into the mental situation most favourable to the solution of the conflict which is our aim? After all, what he can achieve depends, too, on a combination of external circumstances. Should we hesitate to alter this combination by intervening in a suitable manner? I think activity of such a kind on the part of the analysing physician is unobjectionable and entirely justified. [1919a, 3631]
To a physician who was to undertake psycho-analytic treatment of the girl there were many grounds for misgiving. The situation he had to deal with was not the one that analysis demands, in which alone it can demonstrate its effectiveness. As is well known, the ideal situation for analysis is when someone who is otherwise his own master is suffering from an inner conflict which he is unable to resolve alone, so that he brings his trouble to the analyst and begs for his help. The physician then works hand in hand with one portion of the pathologically divided personality, against the other party in the conflict. Any situation which differs from this is to a greater or lesser degree unfavourable for psycho-analysis and adds fresh difficulties to the internal ones already present. Situations like that of a prospective house-owner who orders an architect to build him a villa to his own tastes and requirements, or of a pious donor who commissions an artist to paint a sacred picture in the corner of which is to be a portrait of himself in adoration, are at bottom incompatible with the conditions necessary for psycho-analysis. Thus, it constantly happens that a husband instructs the physician as follows: 'My wife suffers from nerves, and for that reason gets on badly with me; please cure her, so that we may lead a happy married life again.' But often enough it turns out that such a request is impossible to fulfil - that is to say, the physician cannot bring about the result for which the husband sought the treatment. As soon as the wife is freed from her neurotic inhibitions she sets about getting a separation, for her neurosis was the sole condition under which the marriage could be maintained. Or else parents expect one to cure their nervous and unruly child. By a healthy child they mean one who never causes his parents trouble, and gives them nothing but pleasure. The physician may succeed in curing the child, but after that it goes its own way all the more decidedly, and the parents are now far more dissatisfied than before. In short, it is not a matter of indifference whether someone comes to analysis of his own accord or because he is brought to it - whether it is he himself who desires to be changed, or only his relatives, who love him (or who might be expected to love him).

Comparison between Psycho-Analysis and Hypnotic and Suggestive Methods. - Psycho-analytic procedure differs from all methods making use of suggestion, persuasion, etc., in that it does not seek to suppress by means of authority any mental phenomenon that may occur in the patient. It endeavours to trace the causation of the phenomenon and to remove it by bringing about a permanent modification in the conditions that led to it. In psycho-analysis the suggestive influence which is inevitably exercised by the physician is diverted on to the task assigned to the patient of overcoming his resistances, that is, of carrying forward the curative process. Any danger of falsifying the products of a patient's memory by suggestion can be avoided by prudent handling of the technique; but in general the arousing of resistances is a guarantee against the misleading effects of suggestive influence. It may be laid down that the aim of the treatment is to remove the patient's resistances and to pass his repressions in review and thus to bring about the most far-reaching unification and strengthening of his ego, to enable him to save the mental energy which he is expending upon internal conflicts, to make the best of him that his inherited capacities will allow and so to make him as efficient and as capable of enjoyment as is possible. The removal of the symptoms of the illness is not specifically aimed at, but is achieved, as it were, as a by-product if the analysis is properly carried through. The analyst respects the patient's individuality and does not seek to remould him in accordance with his own - that is, according to the physician's - personal ideals; he is glad to avoid giving advice and instead to arouse the patient's power of initiative.
It is easy now to describe our therapeutic aim. We try to restore the ego, to free it from its restrictions, and to give it back the command over the id which it has lost owing to its early repressions. It is for this one purpose that we carry out analysis, our whole technique is directed to this aim. We have to seek out the repressions which have been set up and to urge the ego to correct them with our help and to deal with conflicts better than by an attempt at flight. Since these repressions belong to the very early years of childhood, the work of analysis leads us, too, back to that period. Our path to these situations of conflict, which have for the most part been forgotten and which we try to revive in the patient's memory, is pointed out to us by his symptoms, dreams and free associations. These must, however, first be interpreted - translated - for, under the influence of the psychology of the id, they have assumed forms of expression that are strange to our comprehension. We may assume that whatever associations, thoughts and memories the patient is unable to communicate to us without internal struggles are in some way connected with the repressed material or are its derivatives. By encouraging the patient to disregard his resistances to telling us these things, we are educating his ego to overcome its inclination towards attempts at flight and to tolerate an approach to what is repressed. In the end, if the situation of the repression can be successfully reproduced in his memory, his compliance will be brilliantly rewarded. The whole difference between his age then and now works in his favour; and the thing from which his childish ego fled in terror will often seem to his adult and strengthened ego no more than child's play.

[1926e, 4348]

The fact that women must be regarded as having little sense of justice is no doubt related to the predominance of envy in their mental life; for the demand for justice is a modification of envy and lays down the condition subject to which one can put envy aside. We also regard women as weaker in their social interests and as having less capacity for sublimating their instincts than men. The former is no doubt derived from the dissocial quality which unquestionably characterizes all sexual relations. Lovers find sufficiency in each other, and families too resist inclusion in more comprehensive associations. The aptitude for sublimation is subject to the greatest individual variations. On the other hand I cannot help mentioning an impression that we are constantly receiving during analytic practice. A man of about thirty strikes us as a youthful, somewhat unformed individual, whom we expect to make powerful use of the possibilities for development opened up to him by analysis. A woman of the same age, however, often frightens us by her psychical rigidity and unchangeability. Her libido has taken up final positions and seems incapable of exchanging them for others. There are no paths open to further development; it is as though the whole process had already run its course and remains thenceforward insusceptible to influence - as though, indeed, the difficult development to femininity had exhausted the possibilities of the person concerned. As therapists we lament this state of things, even if we succeed in putting an end to our patient's ailment by doing away with her neurotic conflict.

[1933a, 4736]
And now let us enquire about latency, which, in view of the analogy, is bound to interest us especially. A trauma in childhood may be followed immediately by a neurotic outbreak, an infantile neurosis, with an abundance of efforts at defence, and accompanied by the formation of symptoms. This neurosis may last a considerable time and cause marked disturbances, but it may also run a latent course and be overlooked. As a rule defence retains the upper hand in it; in any case alterations of the ego, comparable to scars, are left behind. It is only rarely that an infantile neurosis continues without interruption into an adult one. Far more often it is succeeded by a period of apparently undisturbed development - a course of things which is supported or made possible by the intervention of the physiological period of latency. Not until later does the change take place with which the definitive neurosis becomes manifest as a belated effect of the trauma. This occurs either at the irruption of puberty or some while later. In the former case it happens because the instincts, intensified by physical maturation, are able now to take up the struggle again in which they were at first defeated by the defence. In the latter case it happens because the reactions and alterations of the ego brought about by the defence now prove a hindrance in dealing with the new tasks of life, so that severe conflicts come about between the demands of the real external world and the ego, which seeks to maintain the organization which it has painstakingly achieved in its defensive struggle. The phenomenon of a latency of the neurosis between the first reactions to the trauma and the later outbreak of the illness must be regarded as typical. This latter illness may also be looked upon as an attempt at cure - as an effort once more to reconcile with the rest those portions of the ego that have been split off by the influence of the trauma and to unite them into a powerful whole vis-à-vis the external world. An attempt of this kind seldom succeeds, however, unless the work of analysis comes to its help, and even then not always; it ends often enough in a complete devastation or fragmentation of the ego or in its being overwhelmed by the portion which was early split off and which is dominated by the trauma.

[1939a, 4902]

Our plan of cure is based on these discoveries. The ego is weakened by the internal conflict and we must go to its help. The position is like that in a civil war which has to be decided by the assistance of an ally from outside. The analytic physician and the patient's weakened ego, basing themselves on the real external world, have to band themselves together into a party against the enemies, the instinctual demands of the id and the conscientious demands of the super-ego. We form a pact with each other. The sick ego promises us the most complete candour - promises, that is, to put at our disposal all the material which its self-perception yields it; we assure the patient of the strictest discretion and place at his service our experience in interpreting material that has been influenced by the unconscious. Our knowledge is to make up for his ignorance and to give his ego back its mastery over lost provinces of his mental life. This pact constitutes the analytic situation.

[1940a [1938], 4983]
Moreover I am in a position to offer an ocular demonstration of the fact that the forgetting of
dreams is to a great extent a product of resistance. One of my patients will tell me he has had a
dream but has forgotten every trace of it: it is therefore just as though it had never happened.
We proceed with our work. I come up against a resistance; I therefore explain something to the
patient and help him by encouragement and pressure to come to terms with some disagreeable
thought. Hardly have I succeeded in this than he exclaims: 'Now I remember what it was I
dreamt.' The same resistance which interfered with our work that day also made him forget the
dream. By overcoming this resistance I have recalled the dream to his memory.
[1900a, 955]

The task which the psycho-analytic method seeks to perform may be formulated in different
ways, which are, however, in their essence equivalent. It may, for instance, be stated thus: the
task of the treatment is to remove the amnesias. When all gaps in memory have been filled in,
all the enigmatic products of mental life elucidated, the continuance and even a renewal of the
morbis condition are made impossible. Or the formula may be expressed in this fashion: all
repressions must be undone. The mental condition is then the same as one in which all
amnesias have been removed. Another formulation reaches further: the task consists in making
the unconscious accessible to consciousness, which is done by overcoming the resistances.
But it must be remembered that an ideal condition such as this is not present even in the
normal, and further that it is only rarely possible to carry the treatment to a point approaching it.
Just as health and sickness are not different from each other in essence but are only separated
by a quantitative line of demarcation which can be determined in practice, so the aim of the
treatment will never be anything else but the practical recovery of the patient, the restoration of
his ability to lead an active life and of his capacity for enjoyment. In a treatment which is
incomplete or in which success is not perfect, one may at any rate achieve a considerable
improvement in the general mental condition, while the symptoms (though now of smaller
importance to the patient) may continue to exist without stamping him as a sick man.
[1904a, 1559]

There is, however, another angle from which you may seek to understand the psycho-analytic
method. The uncovering and translating of the unconscious occurs in the face of a continuous
resistance on the part of the patient. The process of bringing this unconscious material to light is
associated with unpleasure, and because of this the patient rejects it again and again. It is for
you then to interpose in this conflict in the patient's mental life. If you succeed in persuading him
to accept, by virtue of a better understanding, something that up to now, in consequence of this
automatic regulation by unpleasure, he has rejected (repressed), you will have accomplished
something towards his education. For it is education even to induce someone who dislikes
getting up early to do so all the same. Psycho-analytic treatment may in general be conceived
of as such a re-education in overcoming internal resistances. Re-education of this kind is,
however, in no respect more necessary to nervous patients than in regard to the mental
element in their sexual life. For nowhere else have civilization and education done so much
harm as in this field, and this is the point, as experience will show you, at which to look for those
aetiologies of the neuroses that are amenable to influence; for the other aetiological factor, the
constitutional component, consists of something fixed and unalterable. And from this it follows
that one important qualification is required of the physician in this work: not only must his own
character be irreproachable - 'As to morals, that goes without saying', as the hero of Vischer's
novel Auch Einer was in the habit of declaring - but he must also have overcome in his own
mind that mixture of prurience and prudery with which, unfortunately, so many people habitually
consider sexual problems.
[1905a, 1571]
It will interest you, from the point of view of your own profession, to hear how we doctors proceed in psycho-analysis. After the patient has given us a first account of his history, we ask him to give himself up to the thoughts that occur to him spontaneously and to say without any critical reserve whatever comes into his head. We start, as you see, on the assumption, which he does not share in the least, that these spontaneous thoughts will not be arbitrarily chosen but will be determined by their relation to his secret - to his ‘complex’ - and may, as it were, be regarded as derivatives of that complex. You will note that this is the same assumption as the one with the help of which you were able to interpret the association experiments. But although we have instructed the patient to follow the rule of communicating all the thoughts that occur to him, he seems to be unable to do so. He soon begins to hold back first one thought and then another. He gives various reasons to account for this: either the thought was quite unimportant, or it was irrelevant or it was totally meaningless. We thereupon demand that he shall tell us the thought in spite of these objections and shall follow it up; for the very fact of his criticism proves to us that the thought belongs to the ‘complex’ which we are seeking to uncover. We recognize in this behaviour of the patient's a manifestation of the ‘resistance’ present in him, which we are never free from through the whole duration of the treatment. I will merely indicate briefly that this concept of resistance has acquired the highest importance for us in understanding the origin of an illness as well as the mechanism of its cure.

It not at all infrequently happens that it is only after doing a certain amount of psycho-analytic work with a patient that an analyst can succeed in learning the actual content of a phobia, the precise form of words of an obsessional impulse, and so on. Repression has not only descended upon the unconscious complexes, but it is continually attacking their derivatives as well, and even prevents the patient from becoming aware of the products of the disease itself. The analyst thus finds himself in the position, curious for a doctor, of coming to the help of a disease, and of procuring it its due of attention. But only those who entirely misunderstand the nature of psycho-analysis will lay stress upon this phase of the work and suppose that on its account harm is likely to be done by analysis. The fact is that you must catch your thief before you can hang him, and that it requires some expenditure of labour to get securely hold of the pathological structures - at the destruction of which the treatment is aimed.

Here the patient broke off, got up from the sofa, and begged me to spare him the recital of the details. I assured him that I myself had no taste whatever for cruelty, and certainly had no desire to torment him, but that naturally I could not grant him something which was beyond my power. He might just as well ask me to give him the moon. The overcoming of resistances was a law of the treatment, and on no consideration could it be dispensed with. (I had explained the idea of ‘resistance’ to him at the beginning of the hour, when he told me there was much in himself which he would have to overcome if he was to relate this experience of his.) I went on to say that I would do all I could, nevertheless, to guess the full meaning of any hints he gave me. Was he perhaps thinking of impalement? - ‘No, not that; . . . the criminal was tied up . . .’ - he expressed himself so indistinctly that I could not immediately guess in what position - ‘a pot was turned upside down on his buttocks . . . some rats were put into it . . . and they . . .’ - he had again got up, and was showing every sign of horror and resistance - ‘. . . bored their way in . . .’ - Into his anus, I helped him out.
It was on this idea of resistance, then, that I based my view of the course of psychical events in hysteria. In order to effect a recovery, it had proved necessary to remove these resistances. Starting out from the mechanism of cure, it now became possible to construct quite definite ideas of the origin of the illness. The same forces which, in the form of resistance, were now offering opposition to the forgotten material's being made conscious, must formerly have brought about the forgetting and must have pushed the pathogenic experiences in question out of consciousness. I gave the name of 'repression' to this hypothetical process, and I considered that it was proved by the undeniable existence of resistance.

[1910a, 2212]

(b) I will hasten on to the innovations in the field of technique, where indeed nearly everything still awaits final settlement, and much is only now beginning to become clear. There are now two aims in psycho-analytic technique: to save the physician effort and to give the patient the most unrestricted access to his unconscious. As you know, our technique has undergone a fundamental transformation. At the time of the cathartic treatment what we aimed at was the elucidation of the symptoms; we then turned away from the symptoms and devoted ourselves instead to uncovering the 'complexes', to use a word which Jung has made indispensable; now, however, our work is aimed directly at finding out and overcoming the 'resistances', and we can justifiably rely on the complexes coming to light without difficulty as soon as the resistances have been recognized and removed. Some of you have since felt a need to be able to make a survey of these resistances and classify them. I will ask you to examine your material and see whether you can confirm the generalized statement that in male patients the most important resistances in the treatment seem to be derived from the father-complex and to express themselves in fear of the father, in defiance of the father and in disbelief of the father.

[1910d, 2309]

This brings us to the technical errors which are to be seen in the doctor's procedure in this alleged case. It is a long superseded idea, and one derived from superficial appearances, that the patient suffers from a sort of ignorance, and that if one removes this ignorance by giving him information (about the causal connection of his illness with his life, about his experiences in childhood, and so on) he is bound to recover. The pathological factor is not his ignorance in itself, but the root of this ignorance in his inner resistances; it was they that first called this ignorance into being, and they still maintain it now. The task of the treatment lies in combating these resistances. Informing the patient of what he does not know because he has repressed it is only one of the necessary preliminaries to the treatment. If knowledge about the unconscious were as important for the patient as people inexperienced in psycho-analysis imagine, listening to lectures or reading books would be enough to cure him. Such measures, however, have as much influence on the symptoms of nervous illness as a distribution of menu-cards in a time of famine has upon hunger. The analogy goes even further than its immediate application; for informing the patient of his unconscious regularly results in an intensification of the conflict in him and an exacerbation of his troubles.

[1910k, 2378]

Only when these conditions have been fulfilled is it possible to recognize and to master the resistances which have led to the repression and the ignorance. Psycho-analytic intervention, therefore, absolutely requires a fairly long period of contact with the patient. Attempts to 'rush' him at first consultation, by brusquely telling him the secrets which have been discovered by the physician, are technically objectionable. And they mostly bring their own punishment by inspiring a hearty enmity towards the physician on the patient's part and cutting him off from having any further influence.

[1910k, 2379]
After it has been overcome, the overcoming of the other portions of the complex raises few further difficulties. The longer an analytic treatment lasts and the more clearly the patient realizes that distortions of the pathogenic material cannot by themselves offer any protection against its being uncovered, the more consistently does he make use of the one sort of distortion which obviously affords him the greatest advantages - distortion through transference. These circumstances tend towards a situation in which finally every conflict has to be fought out in the sphere of transference.

[1912b, 2461]

In one particular case the mother of a hysterical girl had confided to me the homosexual experience which had greatly contributed to the fixation of the girl's attacks. The mother had herself surprised the scene; but the patient had completely forgotten it, though it had occurred when she was already approaching puberty. I was now able to make a most instructive observation. Every time I repeated her mother's story to the girl she reacted with a hysterical attack, and after this she forgot the story once more. There is no doubt that the patient was expressing a violent resistance against the knowledge that was being forced upon her. Finally she simulated feeble-mindedness and a complete loss of memory in order to protect herself against what I had told her. After this, there was no choice but to cease attributing to the fact of knowing, in itself, the importance that had previously been given to it and to place the emphasis on the resistances which had in the past brought about the state of not knowing and which were still ready to defend that state. Conscious knowledge, even if it was not subsequently driven out again, was powerless against those resistances.

[1913c, 2493]

The strange behaviour of patients, in being able to combine a conscious knowing with not knowing, remains inexplicable by what is called normal psychology. But to psycho-analysis, which recognizes the existence of the unconscious, it presents no difficulty. The phenomenon we have described, moreover, provides some of the best support for a view which approaches mental processes from the angle of topographical differentiation. The patients now know of the repressed experience in their conscious thought, but this thought lacks any connection with the place where the repressed recollection is in some way or other contained. No change is possible until the conscious thought-process has penetrated to that place and has overcome the resistances of repression there. It is just as though a decree were promulgated by the Ministry of Justice to the effect that juvenile delinquencies should be dealt with in a certain lenient manner. As long as this decree has not come to the knowledge of the local magistrates, or in the event of their not intending to obey it but preferring to administer justice by their own lights, no change can occur in the treatment of particular youthful delinquents. For the sake of complete accuracy, however, it should be added that the communication of repressed material to the patient's consciousness is nevertheless not without effect. It does not produce the hoped-for result of putting an end to the symptoms; but it has other consequences. At first it arouses resistances, but then, when these have been overcome, it sets up a process of thought in the course of which the expected influencing of the unconscious recollection eventually takes place.

[1913c, 2494]
It is now time for us to take a survey of the play of forces which is set in motion by the treatment. The primary motive force in the therapy is the patient's suffering and the wish to be cured that arises from it. The strength of this motive force is subtracted from by various factors - which are not discovered till the analysis is in progress - above all, by what we have called the 'secondary gain from illness'; but it must be maintained till the end of the treatment. Every improvement effects a diminution of it. By itself, however, this motive force is not sufficient to get rid of the illness. Two things are lacking in it for this: it does not know what paths to follow to reach this end; and it does not possess the necessary quota of energy with which to oppose the resistances. The analytic treatment helps to remedy both these deficiencies. It supplies the amounts of energy that are needed for overcoming the resistances by making mobile the energies which lie ready for the transference; and, by giving the patient information at the right time, it shows him the paths along which he should direct those energies. Often enough the transference is able to remove the symptoms of the disease by itself, but only for a while - only for as long as it itself lasts. In this case the treatment is a treatment by suggestion, and not a psycho-analysis at all. It only deserves the latter name if the intensity of the transference has been utilized for the overcoming of resistances. Only then has being ill become impossible, even when the transference has once more been dissolved, which is its destined end.

[1913c, 2494]

It seems to me not unnecessary to keep on reminding students of the far-reaching changes which psycho-analytic technique has undergone since its first beginnings. In its first phase - that of Breuer's catharsis - it consisted in bringing directly into focus the moment at which the symptom was formed, and in persistently endeavouring to reproduce the mental processes involved in that situation, in order to direct their discharge along the path of conscious activity. Remembering and abreacting, with the help of the hypnotic state, were what was at that time aimed at. Next, where hypnosis had been given up, the task became one of discovering from the patient's free associations what he failed to remember. The resistance was to be circumvented by the work of interpretation and by making its results known to the patient. The situations which had given rise to the formation of the symptom and the other situations which lay behind the moment at which the illness broke out retained their place as the focus of interest; but the element of abreaction receded into the background and seemed to be replaced by the expenditure of work which the patient had to make in being obliged to overcome his criticism of his free associations, in accordance with the fundamental rule of psycho-analysis. Finally, there was evolved the consistent technique used to-day, in which the analyst gives up the attempt to bring a particular moment or problem into focus. He contents himself with studying whatever is present for the time being on the surface of the patient's mind, and he employs the art of interpretation mainly for the purpose of recognizing the resistances which appear there, and making them conscious to the patient. From this there results a new sort of division of labour: the doctor uncovers the resistances which are unknown to the patient; when these have been got the better of, the patient often relates the forgotten situations and connections without any difficulty. The aim of these different techniques has, of course, remained the same. Descriptively speaking, it is to fill in gaps in memory; dynamically speaking, it is to overcome resistances due to repression.

[1914g, 2498]
There is one special class of experiences of the utmost importance for which no memory can as a rule be recovered. These are experiences which occurred in very early childhood and were not understood at the time but which were subsequently understood and interpreted. One gains a knowledge of them through dreams and one is obliged to believe in them on the most compelling evidence provided by the fabric of the neurosis. Moreover, we can ascertain for ourselves that the patient, after his resistances have been overcome, no longer invokes the absence of any memory of them (any sense of familiarity with them) as a ground for refusing to accept them. This matter, however, calls for so much critical caution and introduces so much that is novel and startling that I shall reserve it for a separate discussion in connection with suitable material.

I might break off at this point but for the title of this paper, which obliges me to discuss a further point in analytic technique. The first step in overcoming the resistances is made, as we know, by the analyst's uncovering the resistance, which is never recognized by the patient, and acquainting him with it. Now it seems that beginners in analytic practice are inclined to look on this introductory step as constituting the whole of their work. I have often been asked to advise upon cases in which the doctor complained that he had pointed out his resistance to the patient and that nevertheless no change had set in; indeed, the resistance had become all the stronger, and the whole situation was more obscure than ever. The treatment seemed to make no headway. This gloomy foreboding always proved mistaken. The treatment was as a rule progressing most satisfactorily. The analyst had merely forgotten that giving the resistance a name could not result in its immediate cessation. One must allow the patient time to become more conversant with this resistance with which he has now become acquainted, to work through it, to overcome it, by continuing, in defiance of it, the analytic work according to the fundamental rule of analysis. Only where the resistance is at its height can the analyst, working in common with his patient, discover the repressed instinctual impulses which are feeding the resistance; and it is this kind of experience which convinces the patient of the existence and power of such impulses. The doctor has nothing else to do than to wait and let things take their course, a course which cannot be avoided nor always hastened. If he holds fast to this conviction he will often be spared the illusion of having failed when in fact he is conducting the treatment on the right lines.

This working-through of the resistances may in practice turn out to be an arduous task for the subject of the analysis and a trial of patience for the analyst. Nevertheless it is a part of the work which effects the greatest changes in the patient and which distinguishes analytic treatment from any kind of treatment by suggestion. From a theoretical point of view one may correlate it with the 'abreacting' of the quotas of affect strangulated by repression - an abreaction without which hypnotic treatment remained ineffective.

The view that the sexual representation of 'higher' thoughts in dreams and neurosis is nothing but an archaic mode of expression is of course irreconcilable with the fact that in neurosis these sexual complexes prove to be the bearers of the quantities of libido which have been withdrawn from utilization in real life. If it was merely a question of a sexual 'jargon', the economy of the libido could not have been altered in any way by it. Jung admits this himself in his Darstellung der psychoanalytischen Theorie and formulates the task of therapy as the detaching of libidinal cathexes from these complexes. This can never be achieved, however, by directing the patient away from them and urging him to sublimate, but only by exhaustive examination of them and by making them fully and completely conscious. The first piece of reality which the patient must deal with is his illness. Efforts to spare him that task point to the physician's incapacity to help him to overcome his resistances, or else to the physician's dread of the results of the work.
Resistances of this kind should not be one-sidedly condemned. They include so much of the most important material from the patient's past and bring it back in so convincing a fashion that they become some of the best supports of the analysis if a skilful technique knows how to give them the right turn. Nevertheless, it remains a remarkable fact that this material is always in the service of the resistance to begin with and brings to the fore a façade that is hostile to the treatment. It may also be said that what is being mobilized for fighting against the alterations we are striving for are character-traits, attitudes of the ego. In this connection we discover that these character-traits were formed in relation to the determinants of the neurosis and in reaction against its demands, and we come upon traits which cannot normally emerge, or not to the same extent, and which may be described as latent. Nor must you get an impression that we regard the appearance of these resistances as an unforeseen risk to analytic influence. No, we are aware that these resistances are bound to come to light; in fact we are dissatisfied if we cannot provoke them clearly enough and are unable to demonstrate them to the patient. Indeed we come finally to understand that the overcoming of these resistances is the essential function of analysis and is the only part of our work which gives us an assurance that we have achieved something with the patient.

I have now led you into the region in which the next advances in the work of analysis are to be expected. Since we have ventured to operate with the concept of ego-libido the narcissistic neuroses have become accessible to us; the task before us is to arrive at a dynamic elucidation of these disorders and at the same time to complete our knowledge of mental life by coming to understand the ego. The ego-psychology after which we are seeking must not be based on the data of our self-perceptions but (as in the case of the libido) on the analysis of disturbances and disruptions of the ego. It is likely that we shall have a low opinion of our present knowledge of the vicissitudes of the libido, which we have gained from a study of the transference neuroses, when we have achieved this greater task. But hitherto we have not made much progress with it. The narcissistic neuroses can scarcely be attacked with the technique that has served us with the transference neuroses. You will soon learn why. What always happens with them is that, after proceeding for a short distance, we come up against a wall which brings us to a stop. Even with the transference neuroses, as you know, we met with barriers of resistance, but we were able to demolish them bit by bit. In the narcissistic neuroses the resistance is unconquerable; at the most, we are able to cast an inquisitive glance over the top of the wall and spy out what is going on on the other side of it. Our technical methods must accordingly be replaced by others; and we do not know yet whether we shall succeed in finding substitute. Nevertheless, we have no lack of material with these patients either. They make a large number of remarks, even if they do not answer our questions, and for the time being it is our business to interpret these remarks with the help of the understanding we have gained from the symptoms of the transference neuroses. The agreement is great enough to guarantee us some initial advantage. It remains to be seen how far this technique will take us.
What, then, must we do in order to replace what is unconscious in our patients by what is conscious? There was a time when we thought this was a very simple matter: all that was necessary was for us to discover this unconscious material and communicate it to the patient. But we know already that this was a short-sighted error. Our knowledge about the unconscious material is not equivalent to his knowledge; if we communicate our knowledge to him, he does not receive it instead of his unconscious material but beside it; and that makes very little change in it. We must rather picture this unconscious material topographically, we must look for it in his memory at the place where it became unconscious owing to a repression. The repression must be got rid of - after which the substitution of the conscious material for the unconscious can proceed smoothly. How, then, do we lift a repression of this kind? Here our task enters a second phase. First, the search for the repression and then the removal of the resistance which maintains the repression.

[1916-1917, 3478]

And now for the fact! In a whole number of nervous diseases - in hysteria, anxiety states, obsessional neurosis - our expectation is fulfilled. By searching for the repression in this way, by uncovering the resistances, by pointing out what is repressed, we really succeed in accomplishing our task - that is, in overcoming the resistances, lifting the repression and transforming the unconscious material into conscious. In doing so we gain the clearest impression of the way in which a violent struggle takes place in the patient's mind about the overcoming of each resistance - a normal mental struggle, on the same psychological ground, between the motives which seek to maintain the anticathexis and those which are prepared to give it up. The former are the old motives which in the past put the repression into effect; among the latter are the newly arrived ones which, we may hope, will decide the conflict in our favour. We have succeeded in reviving the old conflict which led to repression and in bringing up for revision the process that was then decided. The new material that we produce includes, first the reminder that the earlier decision led to illness and the promise that a different path will lead to recovery, and, second, the enormous change in all the circumstances that has take place since the time of the original rejection. Then the ego was feeble, infantile, and may perhaps have had grounds for banning the demands of the libido as a danger. To-day it has grown strong and experienced, and moreover has a helper at and in the shape of the doctor. Thus we may expect to lead the revived conflict to a better outcome than that which ended in repression, and, as I have said, in hysteria and in the anxiety and obsessional neuroses success proves us in general to be correct.

[1916-1917, 3480]

In the light of the knowledge we have gained from psycho-analysis we can describe the difference between hypnotic and psycho-analytic suggestion as follows. Hypnotic treatment seeks to cover up and gloss over something in mental life; analytic treatment seeks to expose and get rid of something. The former acts like a cosmetic, the latter like surgery. The former makes use of suggestion in order to forbid the symptoms; it strengthens the repressions, but, apart from that, leaves all the processes that have led to the formation of the symptoms unaltered. Analytic treatment makes its impact further back towards the roots, where the conflicts are which gave rise to the symptoms, and uses suggestion in order to alter the outcome of those conflicts. Hypnotic treatment leaves the patient inert and unchanged, and for that reason, too, equally unable to resist any fresh occasion for falling ill. An analytic treatment demands from both doctor and patient the accomplishment of serious work, which is employed in lifting internal resistances. Through the overcoming of these resistances the patient's mental life is permanently changed, is raised to a high level of development and remains protected against fresh possibilities of falling ill. This work of overcoming resistances is the essential function of analytic treatment; the patient has to accomplish it and the doctor makes this possible for him with the help of suggestion operating in an educative sense. For that reason psycho-analytic treatment has justly been described as a kind of after-education.
But you will now tell me that, no matter whether we call the motive force of our analysis transference or suggestion, there is a risk that the influencing of our patient may make the objective certainty of our findings doubtful. What is advantageous to our therapy is damaging to our researches. This is the objection that is most often raised against psycho-analysis, and it must be admitted that, though it is groundless, it cannot be rejected as unreasonable. If it were justified, psycho-analysis would be nothing more than a particularly well-disguised and particularly effective form of suggestive treatment and we should have to attach little weight to all that it tells us about what influences our lives, the dynamics of the mind or the unconscious. That is what our opponents believe; and in especial they think that we have "talked" the patients into everything relating to the importance of sexual experiences - or even into those experiences themselves - after such notions have grown up in our own depraved imagination. These accusations are contradicted more easily by an appeal to experience than by the help of theory. Anyone who has himself carried out psycho-analyses will have been able to convince himself on countless occasions that it is impossible to make suggestions to a patient in that way. The doctor has no difficulty, of course, in making him a supporter of some particular theory and in thus making him share some possible error of his own. In this respect the patient is behaving like anyone else - like a pupil - but this only affects his intelligence, not his illness. After all, his conflicts will only be successfully solved and his resistances overcome if the anticipatory ideas he is given tally with what is real in him. Whatever in the doctor's conjectures is inaccurate drops out in the course of the analysis; it has to be withdrawn and replaced by something more correct. We endeavour by a careful technique to avoid the occurrence of premature successes due to suggestion; but no harm is done even if they do occur, for we are not satisfied by a first success. We do not regard an analysis as at an end until all the obscurities of the case are cleared up, the gaps in the patient's memory filled in, the precipitating causes of the repressions discovered. We look upon successes that set in too soon as obstacles rather than as a help to the work of analysis; and we put an end to such successes by constantly resolving the transference on which they are based. It is this last characteristic which is the fundamental distinction between analytic and purely suggestive therapy, and which frees the results of analysis from the suspicion of being successes due to suggestion. In every other kind of suggestive treatment the transference is carefully preserved and left untouched; in analysis it is itself subjected to treatment and is dissected in all the shapes in which it appears. At the end of an analytic treatment the transference must itself be cleared away; and if success is then obtained or continues, it rests, not on suggestion, but on the achievement by its means of an overcoming of internal resistances, on the internal change that has been brought about in the patient.

[1916-1917, 3493]
Many attempts at treatment miscarried during the early period of analysis because they were undertaken in cases which were altogether unsuited to the procedure and which we should exclude to-day on the basis of our present view of the indications for treatment. But these indications, too, could only be arrived at by experiment. In those days we did not know a priori that paranoia and dementia praecox in strongly marked forms are inaccessible, and we had a right to make trial of the method on all kinds of disorders. But most of the failures of those early years were due not to the doctor’s fault or an unsuitable choice of patients but to unfavourable external conditions. Here we have only dealt with internal resistances, those of the patient, which are inevitable and can be overcome. The external resistances which arise from the patient’s circumstances, from his environment, are of small theoretical interest but of the greatest practical importance. Psycho-analytic treatment may be compared with a surgical operation and may similarly claim to be carried out under arrangements that will be the most favourable for its success. You know the precautionary measures adopted by a surgeon: a suitable room, good lighting, assistants, exclusion of the patient’s relatives, and so on. Ask yourselves how many of these operations would turn out successfully if they had to take place in the presence of all the members of the patient’s family, who would stick their noses into the field of the operation and exclaim aloud at every incision. In psycho-analytic treatments the intervention of relatives is a positive danger and a danger one does not know how to meet. One is armed against the patient’s internal resistances which one knows are inevitable, but how can one ward off these external resistances? No kind of explanations make any impression on the patient’s relatives; they cannot be induced to keep at a distance from the whole business, and one cannot make common cause with them because of the risk of losing the confidence of the patient, who - quite rightly moreover - expects the person in whom he has put his trust to take his side. No one who has any experience of the rifts which so often divide a family will, if he is an analyst, be surprised to find that the patient’s closest relatives sometimes betray less interest in his recovering than in his remaining as he is. When, as so often, the neurosis is related to conflicts between members of a family, the healthy party will not hesitate long in choosing between his own interest and the sick party’s recovery. It is not to be wondered at, indeed, if a husband looks with disfavour on a treatment in which, as he may rightly suspect, the whole catalogue of his sins will be brought to light. Nor do we wonder at it; but we cannot in that case blame ourselves if our efforts remain unsuccessful and the treatment is broken off prematurely because the husband’s resistance is added to that of his sick wife. We had in fact undertaken something which in the prevailing circumstances was unrealizable.

[1916-1917, 3498]

We have formulated our task as physicians thus: to bring to the patient’s knowledge the unconscious, repressed impulses existing in him, and, for that purpose, to uncover the resistances that oppose this extension of his knowledge about himself. Does the uncovering of these resistances guarantee that they will also be overcome? Certainly not always; but our hope is to achieve this by exploiting the patient’s transference to the person of the physician, so as to induce him to adopt our conviction of the inexpediency of the repressive process established in childhood and of the impossibility of conducting life on the pleasure principle. I have set out elsewhere the dynamic conditions prevailing in the fresh conflict through which we lead the patient and which we substitute in him for his previous conflict - that of his illness. I have nothing at the moment to alter in that account.

[1919a, 3628]
In actual fact, indeed, the neurotic patient presents us with a torn mind, divided by resistances. As we analyse it and remove the resistances, it grows together; the great unity which we call his ego fits into itself all the instinctual impulses which before had been split off and held apart from it. The psycho-synthesis is thus achieved during analytic treatment without our intervention, automatically and inevitably. We have created the conditions for it by breaking up the symptoms into their elements and by removing the resistances. It is not true that something in the patient has been divided into its components and is now quietly waiting for us to put it somehow together again.

Let us at once agree upon what we mean by this activity. We have defined our therapeutic task as consisting of two things: making conscious the repressed material and uncovering the resistances. In that we are active enough, to be sure. But are we to leave it to the patient to deal alone with the resistances we have pointed out to him? Can we give him no other help in this besides the stimulus he gets from the transference? Does it not seem natural that we should help him in another way as well, by putting him into the mental situation most favourable to the solution of the conflict which is our aim? After all, what he can achieve depends, too, on a combination of external circumstances. Should we hesitate to alter this combination by intervening in a suitable manner? I think activity of such a kind on the part of the analysing physician is unobjectionable and entirely justified.

Twenty five years of intense work have had as their result that the immediate aims of psychoanalytic technique are quite other to-day than they were at the outset. At first the analysing physician could do no more than discover the unconscious material that was concealed from the patient, put it together, and, at the right moment, communicate it to him. Psychoanalysis was then first and foremost an art of interpreting. Since this did not solve the therapeutic problem, a further aim quickly came in view: to oblige the patient to confirm the analyst's construction from his own memory. In that endeavour the chief emphasis lay upon the patient's resistances: the art consisted now in uncovering these as quickly as possible, in pointing them out to the patient and in inducing him by human influence - this was where suggestion operating as 'transference' played its part - to abandon his resistances.
For these reasons I refrained altogether from holding out to the parents any prospect of their wish being fulfilled. I merely said I was prepared to study the girl carefully for a few weeks or months, so as then to be able to pronounce how far a continuation of the analysis would be likely to influence her. In quite a number of cases, indeed, an analysis falls into two clearly distinguishable phases. In the first, the physician procures from the patient the necessary information, makes him familiar with the premises and postulates of psycho-analysis, and unfolds to him the reconstruction of the genesis of his disorder as deduced from the material brought up in the analysis. In the second phase the patient himself gets hold of the material put before him; he works on it, recollects what he can of the apparently repressed memories, and tries to repeat the rest as if he were in some way living it over again. In this way he can confirm, supplement, and correct the inferences made by the physician. It is only during this work that he experiences, through overcoming resistances, the inner change aimed at, and acquires for himself the convictions that make him independent of the physician's authority. These two phases in the course of the analytic treatment are not always sharply divided from each other; this can only happen when the resistance obeys certain conditions. But when this is so, one may bring up as an analogy the two stages of a journey. The first comprises all the necessary preparations, to-day so complicated and hard to effect, before, ticket in hand, one can at last go on to the platform and secure a seat in the train. One then has the right, and the possibility, of travelling into a distant country; but after all these preliminary exertions one is not yet there - indeed, one is not a single mile nearer to one's goal. For this to happen one has to make the journey itself from one station to the other, and this part of the performance may well be compared with the second phase of the analysis.

[1920a, 3842]

_Development of Technique._ - After the analyst's curiosity had, as it were, been gratified by the elaboration of the technique of interpretation, it was inevitable that interest should turn to the problem of discovering the most effective way of influencing the patient. It soon became evident that the physician's immediate task was to assist the patient in getting to know, and afterwards in overcoming, the resistances which emerged in him during treatment and of which, to begin with, he himself was unaware. And it was found at the same time that the essential part of the process of cure lay in the overcoming of these resistances and that unless this was achieved no permanent mental change could be brought about in the patient. Since the analyst's efforts have in this way been directed upon the patient's resistance, analytic technique has attained a certainty and delicacy rivalling that of surgery. Consequently, everyone is strongly advised against undertaking psycho-analytic treatments without a strict training, and a physician who ventures upon them on the strength of his medical qualification is in no respect better than a layman.

[1923a, 3925]
Comparison between Psycho-Analysis and Hypnotic and Suggestive Methods. - Psycho-analytic procedure differs from all methods making use of suggestion, persuasion, etc., in that it does not seek to suppress by means of authority any mental phenomenon that may occur in the patient. It endeavours to trace the causation of the phenomenon and to remove it by bringing about a permanent modification in the conditions that led to it. In psycho-analysis the suggestive influence which is inevitably exercised by the physician is diverted on to the task assigned to the patient of overcoming his resistances, that is, of carrying forward the curative process. Any danger of falsifying the products of a patient's memory by suggestion can be avoided by prudent handling of the technique; but in general the arousing of resistances is a guarantee against the misleading effects of suggestive influence. It may be laid down that the aim of the treatment is to remove the patient's resistances and to pass his repressions in review and thus to bring about the most far-reaching unification and strengthening of his ego, to enable him to save the mental energy which he is expending upon internal conflicts, to make the best of him that his inherited capacities will allow and so to make him as efficient and as capable of enjoyment as is possible. The removal of the symptoms of the illness is not specifically aimed at, but is achieved, as it were, as a by-product if the analysis is properly carried through. The analyst respects the patient's individuality and does not seek to remould him in accordance with his own - that is, according to the physician's - personal ideals; he is glad to avoid giving advice and instead to arouse the patient's power of initiative.

[1923a, 3927]

But we have arrived at the term or concept of the unconscious along another path, by considering certain experiences in which mental dynamics play a part. We have found - that is, we have been obliged to assume - that very powerful mental processes or ideas exist (and here a quantitative or economic factor comes into question for the first time) which can produce all the effects in mental life that ordinary ideas do (including effects that can in their turn become conscious as ideas), though they themselves do not become conscious. It is unnecessary to repeat in detail here what has been explained so often before. It is enough to say that at this point psycho-analytic theory steps in and asserts that the reason why such ideas cannot become conscious is that a certain force opposes them, that otherwise they could become conscious, and that it would then be apparent how little they differ from other elements which are admittedly psychical. The fact that in the technique of psycho-analysis a means has been found by which the opposing force can be removed and the ideas in question made conscious renders this theory irrefutable. The state in which the ideas existed before being made conscious is called by us repression, and we assert that the force which instituted the repression and maintains it is perceived as resistance during the work of analysis.

[1923b, 3948]
In the further course of psycho-analytic work, however, even these distinctions have proved to be inadequate and, for practical purposes, insufficient. This has become clear in more ways than one; but the decisive instance is as follows. We have formed the idea that in each individual there is a coherent organization of mental processes; and we call this his ego. It is to this ego that consciousness is attached; the ego controls the approaches to motility - that is, to the discharge of excitations into the external world; it is the mental agency which supervises all its own constituent processes, and which goes to sleep at night, though even then it exercises the censorship on dreams. From this ego proceed the repressions, too, by means of which it is sought to exclude certain trends in the mind not merely from consciousness but also from other forms of effectiveness and activity. In analysis these trends which have been shut out stand in opposition to the ego, and the analysis is faced with the task of removing the resistances which the ego displays against concerning itself with the repressed. Now we find during analysis that, when we put certain tasks before the patient, he gets into difficulties; his associations fail when they should be coming near the repressed. We then tell him that he is dominated by a resistance; but he is quite unaware of the fact, and, even if he guesses from his unpleasurable feelings that a resistance is now at work in him, he does not know what it is or how to describe it. Since, however, there can be no question but that this resistance emanates from his ego and belongs to it, we find ourselves in an unforeseen situation. We have come upon something in the ego itself which is also unconscious, which behaves exactly like the repressed - that is, which produces powerful effects without itself being conscious and which requires special work before it can be made conscious. From the point of view of analytic practice, the consequence of this discovery is that we land in endless obscurities and difficulties if we keep to our habitual forms of expression and try, for instance, to derive neuroses from a conflict between the conscious and the unconscious. We shall have to substitute for this antithesis another, taken from our insight into the structural conditions of the mind - the antithesis between the coherent ego and the repressed which is split off from it.¹

[1923b, 3951]

It is perfectly true that psycho-analysis, like other psychotherapeutic methods, employs the instrument of suggestion (or transference). But the difference is this: that in analysis it is not allowed to play the decisive part in determining the therapeutic results. It is used instead to induce the patient to perform a piece of psychical work - the overcoming of his transference resistances - which involves a permanent alteration in his mental economy. The transference is made conscious to the patient by the analyst, and it is resolved by convincing him that in his transference-attitude he is re-experiencing emotional relations which had their origin in his earliest object-attachments during the repressed period of his childhood. In this way the transference is changed from the strongest weapon of the resistance into the best instrument of the analytic treatment. Nevertheless its handling remains the most difficult as well as the most important part of the technique of analysis.

[1925d, 4218]
We showed on an earlier occasion that the resistance that has to be overcome in analysis proceeds from the ego, which clings to its anticathexes. It is hard for the ego to direct its attention to perceptions and ideas which it has up till now made a rule of avoiding, or to acknowledge as belonging to itself impulses that are the complete opposite of those which it knows as its own. Our fight against resistance in analysis is based upon this view of the facts. If the resistance is itself unconscious, as so often happens owing to its connection with the repressed material, we make it conscious. If it is conscious, or when it has become conscious, we bring forward logical arguments against it; we promise the ego rewards and advantages if it will give up its resistance. There can be no doubt or mistake about the existence of this resistance on the part of the ego. But we have to ask ourselves whether it covers the whole state of affairs in analysis. For we find that even after the ego has decided to relinquish its resistances it still has difficulty in undoing the repressions; and we have called the period of strenuous effort which follows after its praiseworthy decision, the phase of 'working-through'. The dynamic factor which makes a working-through of this kind necessary and comprehensible is not far to seek. It must be that after the ego's resistance has been removed the power of the compulsion to repeat - the attraction exerted by the unconscious prototype upon the repressed instinctual process - has still to be overcome. There is nothing to be said against describing this factor as the resistance of the unconscious. There is no need to be discouraged by these emendations. They are to be welcomed if they add something to our knowledge, and they are no disgrace to us so long as they enrich rather than invalidate our earlier views - by limiting some statement, perhaps, that was too general or by enlarging some idea that was too narrowly formulated.

Yes, we are only beginning to appreciate the significance of all these important circumstances. That is why my description was bound to turn out so obscure. But now I can proceed. We describe all the forces that oppose the work of recovery as the patient's 'resistances'. The gain from illness is one such resistance. The 'unconscious sense of guilt' represents the super-ego's resistance; it is the most powerful factor, and the one most dreaded by us. We meet with still other resistances during the treatment. If the ego during the early period has set up a repression out of fear, then the fear still persists and manifests itself as a resistance if the ego approaches the repressed material. And finally, as you can imagine, there are likely to be difficulties if an instinctual process which has been going along a particular path for whole decades is suddenly expected to take a new path that has just been made open for it. That might be called the id's resistance. The struggle against all these resistances is our main work during an analytic treatment; the task of making interpretations is nothing compared to it. But as a result of this struggle and of the overcoming of the resistances, the patient's ego is so much altered and strengthened that we can look forward calmly to his future behaviour when the treatment is over. On the other hand, you can understand now why we need such long treatments. The length of the path of development and the wealth of the material are not the decisive factors. It is more a question of whether the path is clear. An army can be held up for weeks on a stretch of country which in peace time an express train crosses in a couple of hours - if the army has to overcome the enemy's resistance there. Such battles call for time in mental life too. I am unfortunately obliged to tell you that every effort to hasten analytic treatment appreciably has hitherto failed. The best way of shortening it seems to be to carry it out according to the rules.

[1926e, 4366]
It is a good thing you have asked me about that. This personal influence is our most powerful dynamic weapon. It is the new element which we introduce into the situation and by means of which we make it fluid. The intellectual content of our explanations cannot do it, for the patient, who shares all the prejudices of the world around him, need believe us as little as our scientific critics do. The neurotic sets to work because he has faith in the analyst, and he believes him because he acquires a special emotional attitude towards the figure of the analyst. Children, too, only believe people they are attached to. I have already told you what use we make of this particularly large 'suggestive' influence. Not for suppressing the symptoms - this distinguishes the analytic method from other psychotherapeutic procedures - but as a motive force to induce the patient to overcome his resistances.

There are at the moment two Institutes at which instruction in psycho-analysis is given. The first has been founded in Berlin by Dr. Max Eitingon, who is a member of the Society there. The second is maintained by the Vienna Psycho-Analytical Society at its own expense and at considerable sacrifice. The part played by the authorities is at present limited to the many difficulties which they put in the way of the young undertaking. A third training Institute is at this moment being opened in London by the Society there, under the direction of Dr. Ernest Jones. At these Institutes the candidates themselves are taken into analysis, receive theoretical instruction by lectures on all the subjects that are important for them, and enjoy the supervision of older and more experienced analysts when they are allowed to make their first trials with comparatively slight cases. A period of some two years is calculated for this training. Even after this period, of course, the candidate is only a beginner and not yet a master. What is still needed must be acquired by practice and by an exchange of ideas in the psycho-analytical societies in which young and old members meet together. Preparation for analytic activity is by no means so easy and simple. The work is hard, the responsibility great. But anyone who has passed through such a course of instruction, who has been analysed himself, who has mastered what can be taught to-day of the psychology of the unconscious, who is at home in the science of sexual life, who has learnt the delicate technique of psycho-analysis, the art of interpretation, of fighting resistances and of handling the transference - anyone who has accomplished all this is no longer a layman in the field of psycho-analysis. He is capable of undertaking the treatment of neurotic disorders, and will be able in time to achieve in that field whatever can be required from this form of therapy.

The therapeutic influence of psycho-analysis depends on the replacement of unconscious mental acts by conscious ones and is effective within the limits of that factor. The replacement is effected by overcoming internal resistances in the patient's mind. The future will probably attribute far greater importance to psycho-analysis as the science of the unconscious than as a therapeutic procedure.

(3) By 'transference' is meant a striking peculiarity of neurotics. They develop towards their physician emotional relations, both of an affectionate and hostile character, which are not based upon the actual situation but are derived from their relations to their parents (the Oedipus complex). Transference is a proof of the fact that adults have not overcome their former childish dependence; it coincides with the force which has been named 'suggestion'; and it is only by learning to make use of it that the physician is enabled to induce the patient to overcome his internal resistances and do away with his repressions. Thus psycho-analytic treatment acts as a second education of the adult, as a corrective to his education as a child.
With the mention of resistance we have reached the second and more important part of our task. We have already learnt that the ego protects itself against the invasion of undesired elements from the unconscious and repressed by means of anticathexes, which must remain intact if it is to function normally. The more hard-pressed the ego feels, the more convulsively it clings (as though in a fright) to these anticathexes, in order to protect what remains of itself from further irruptions. But this defensive purpose does not by any means accord with the aims of our treatment. What we desire, on the contrary, is that the ego, emboldened by the certainty of our help, shall dare to take the offensive in order to reconquer what has been lost. And it is here that we become aware of the strength of these anticathexes in the form of resistances to our work. The ego draws back in alarm from such undertakings, which seem dangerous and threaten unpleasure; it must be constantly encouraged and soothed if it is not to fail us. This resistance, which persists throughout the whole treatment and is renewed at every fresh piece of work, is known, not quite correctly, as the resistance due to repression. We shall find that it is not the only one that faces us. It is interesting to notice that in this situation the party-divisions are to some extent reversed: for the ego struggles against our instigation, while the unconscious, which is ordinarily our opponent, comes to our help, since it has a natural 'upward drive' and desires nothing better than to press forward across its settled frontiers into the ego and so to consciousness. The struggle which develops, if we gain our end and can induce the ego to overcome its resistances, is carried through under our direction and with our assistance. Its outcome is a matter of indifference: whether it results in the ego accepting, after a fresh examination, an instinctual demand which it has hitherto rejected, or whether it dismisses it once more, this time for good and all. In either case a permanent danger has been disposed of, the compass of the ego has been extended and a wasteful expenditure of energy has been made unnecessary.

The overcoming of resistances is the part of our work that requires the most time and the greatest trouble. It is worth while, however, for it brings about an advantageous alteration of the ego which will be maintained independently of the outcome of the transference and will hold good in life. We have also worked simultaneously at getting rid of the alteration of the ego which had been brought about under the influence of the unconscious; for whenever we have been able to detect any of its derivatives in the ego we have pointed out their illegitimate origin and have instigated the ego to reject them. It will be remembered that it was one of the necessary preconditions of our pact of assistance that any such alteration of the ego due to the intrusion of unconscious elements should not have gone beyond a certain amount.
Let us once more glance over the situation which we have reached in our attempt at bringing help to the patient's neurotic ego. That ego is no longer able to fulfil the task set it by the external world (including human society). Not all of its experiences are at its disposal, a large proportion of its store of memories have escaped it. Its activity is inhibited by strict prohibitions from the super-ego, its energy is consumed in vain attempts at fending off the demands of the id. Beyond this, as a result of continuous irruptions by the id, its organization is impaired, it is no longer capable of any proper synthesis, it is torn by mutually opposed urges, by unsettled conflicts and by unsolved doubts. To start with, we get the patient's thus weakened ego to take part in the purely intellectual work of interpretation, which aims at provisionally filling the gaps in his mental assets, and to transfer to us the authority of his super-ego; we encourage it to take up the struggle over each individual demand made by the id and to conquer the resistances which arise in connection with it. At the same time we restore order in the ego by detecting the material and urges which have forced their way in from the unconscious, and expose them to criticism by tracing them back to their origin. We serve the patient in various functions, as an authority and a substitute for his parents, as a teacher and educator; and we have done the best for him if, as analysts, we raise the mental processes in his ego to a normal level, transform what has become unconscious and repressed into preconscious material and thus return it once more to the possession of his ego. On the patient's side a few rational factors work in our favour, such as the need for recovery which has its motive in his sufferings, and the intellectual interest that we may awaken in him in the theories and revelations of psycho-analysis; but of far greater force is the positive transference with which he meets us. Fighting against us, on the other hand, are the negative transference, the ego's resistance due to repression (that is, its unpleasure at having to lay itself open to the hard work imposed on it), the sense of guilt arising from its relation to the super-ego and the need to be ill due to deep-going changes in the economics of his instincts. The share taken by the last two factors decides whether the case is to be regarded as slight or severe. Apart from these, a few other factors may be discerned as having a favourable or unfavourable bearing. A certain psychical inertia, a sluggishness of the libido, which is unwilling to abandon its fixations cannot be welcome to us; the patient's capacity for sublimating his instincts plays a large part and so does his capacity for rising above the crude life of the instincts; so, too, does the relative power of his intellectual functions.

We must first of all decide what is meant by the ambiguous phrase 'the end of an analysis'. From a practical standpoint it is easy to answer. An analysis is ended when the analyst and the patient cease to meet each other for the analytic session. This happens when two conditions have been approximately fulfilled: first, that the patient shall no longer be suffering from his symptoms and shall have overcome his anxieties and his inhibitions; and secondly, that the analyst shall judge that so much repressed material has been made conscious, so much that was unintelligible has been explained, and so much internal resistance conquered, that there is no need to fear a repetition of the pathological processes concerned. If one is prevented by external difficulties from reaching this goal, it is better to speak of an incomplete analysis rather than of an unfinished one.
Among the various factors, therefore, which contribute to a failure in recollection or a loss of memory, the part played by repression must not be overlooked; and it can be demonstrated not only in neurotics but (in a manner that is qualitatively the same) in normal people as well. It may be asserted quite generally that the ease (and ultimately the faithfulness, too) with which a given impression is awakened in the memory depends not only on the psychical constitution of the individual, the strength of the impression when it was fresh, the interest directed towards it at the time, the psychical constellation at the present time, the interest that is now devoted to its awakening, the connections into which the impression has been drawn, and so on - not only on such things but also on the favourable or unfavourable attitude of a particular psychical factor which refuses to reproduce anything that might liberate unpleasure, or that might subsequently lead to the liberation of unpleasure. Thus the function of memory, which we like to regard as an archive open to anyone who is curious, is in this way subjected to restriction by a trend of the will, just as is any part of our activity directed to the external world. Half the secret of hysterical amnesia is uncovered when we say that hysterical people do not know what they do not want to know; and psycho-analytic treatment, which endeavours to fill up such gaps of memory in the course of its work, leads us to the discovery that the bringing back of those lost memories is opposed by a certain resistance which has to be counterbalanced by work proportionate to its magnitude. In the case of psychical processes which are on the whole normal, it cannot, of course, be claimed that the influence of this one-sided factor in the revival of memories in any way regularly overcomes all the other factors that must be taken into account.
The Henris describe such cases as rare. In my experience, based for the most part, it is true, on neurotics, they are quite frequent. One of the subjects of the Henris' investigation made an attempt at explaining the occurrence of these mnemic images, whose innocence makes them so mysterious, and his explanation seems to me very much to the point. He thinks that in such cases the relevant scene may perhaps have been only *incompletely* retained in the memory, and that that may be why it seems so unenlightening: the parts that have been forgotten probably contained everything that made the experience noteworthy. I am able to confirm the truth of this view, though I should prefer to speak of these elements of the experience being *omitted* rather than forgotten. I have often succeeded, by means of psycho-analytic treatment, in uncovering the missing portions of a childhood experience and in thus proving that when the impression, of which no more than a torso was retained in the memory, had been restored to completeness, it did in fact agree with the presumption that it is the most important things that are recollected. This, however, provides no explanation of the remarkable choice which memory has made among the elements of the experience. We must first enquire why it should be that precisely what is important is suppressed and what is indifferent retained; and we shall not find an explanation of this until we have investigated the mechanism of these processes more deeply. We shall then form a notion that two psychical forces are concerned in bringing about memories of this sort. One of these forces takes the importance of the experience as a motive for seeking to remember it, while the other - a resistance - tries to prevent any such preference from being shown. These two opposing forces do not cancel each other out, nor does one of them (whether with or without loss to itself) overpower the other. Instead, a compromise is brought about, somewhat on the analogy of the resultant in a parallelogram of forces. And the compromise is this. What is recorded as a mnemic image is not the relevant experience itself - in this respect the resistance gets its way; what is recorded is another psychical element closely associated with the objectionable one - and in this respect the *first* principle shows its strength, the principle which endeavours to fix important impressions by establishing reproducible mnemic images. The result of the conflict is therefore that, instead of the mnemic image which would have been justified by the original event, another is produced which has been to some degree associatively *displaced* from the former one. And since the elements of the experience which aroused objection were precisely the important ones, the substituted memory will necessarily lack those important elements and will in consequence most probably strike us as trivial. It will seem incomprehensible to us because we are inclined to look for the reason for its retention in its own content, whereas in fact that retention is due to the relation holding between its own content and a different one which has been suppressed. There is a common saying among us about shams, that they are not made of gold themselves but have lain beside something that is made of gold. The same simile might well be applied to some of the experiences of childhood which have been retained in the memory.

[1899a, 490]

In my opinion we take the fact of infantile amnesia - the loss, that is, of the memories of the first years of our life - much too easily; and we fail to look upon it as a strange riddle. We forget how high are the intellectual achievements and how complicated the emotional impulses of which a child of some four years is capable, and we ought to be positively astonished that the memory of later years has as a rule preserved so little of these mental processes, especially as we have every reason to suppose that these same forgotten childhood achievements have not, as might be thought, slipped away without leaving their mark on the subject's development, but have exercised a determining influence for the whole of his later life. And in spite of this unique efficacy they have been forgotten! This suggests that there are conditions for remembering (in the sense of conscious reproducing) of a quite special kind, which have evaded recognition by us up to now. It may very well be that the forgetting of childhood can supply us with the key to the understanding of those amnesias which lie, according to our more recent discoveries, at the basis of the formation of all neurotic symptoms.

[1901b, 1140]
I next proceed to mention more particularly what is to be found in this paper and what is not to be found in it. The title of the work was originally 'Dreams and Hysteria', for it seemed to me peculiarly well-adapted for showing how dream-interpretation is woven into the history of a treatment and how it can become the means of filling in amnesias and elucidating symptoms. It was not without good reasons that in the year 1900 I gave precedence to a laborious and exhaustive study of dreams (The Interpretation of Dreams) over the publications upon the psychology of the neuroses which I had in view. And incidentally I was able to judge from its reception with what an inadequate degree of comprehension such efforts are met by other specialists at the present time. In this instance there was no validity in the objection that the material upon which had based my assertions had been withheld and that it was therefore impossible to become convinced of their truth by testing and checking them. For everyone can submit his own dreams to analytic examination, and the technique of interpreting dreams may be easily learnt from the instructions and examples which I have given. I must once more insist, just as I did at that time, that a thorough investigation of the problems of dreams is an indispensable prerequisite for any comprehension of the mental processes in hysteria and the other psychoneuroses, and that no one who wishes to shirk that preparatory labour has the smallest prospect of advancing even a few steps into this region of knowledge. Since, therefore, this case history presupposes a knowledge of the interpretation of dreams, it will seem highly unsatisfactory to any reader to whom this presupposition does not apply. Such a reader will find only bewilderment in these pages instead of the enlightenment he is in search of, and he will certainly be inclined to project the cause of his bewilderment on to the author and to pronounce his views fantastic. But in reality this bewildering character attaches to the phenomena of the neurosis itself; its presence there is only concealed by the physician's familiarity with the facts, and it comes to light again with every attempt a explaining them. It could only be completely banished if we could succeed in tracing back every single element of a neurosis to factors with which we were already familiar. But everything tends to show that, on the contrary, we shall be driven by the study of neuroses to assume the existence of many new thing which will later on gradually become the subject of more certain knowledge. What is new has always aroused bewilderment and resistance.

That this state of affairs should exist in regard to the memories relating to the history of the illness is a necessary correlate of the symptoms and one which is theoretically requisite. In the further course of the treatment the patient supplies the facts which, though he had known them all along, had been kept back by him or had not occurred to his mind. The paramnesias prove untenable, and the gaps in his memory are filled in. It is only towards the end of the treatment that we have before us all intelligible, consistent, and unbroken case history. Whereas the practical aim of the treatment is to remove all possible symptoms and to replace them by conscious thoughts, we may regard it as a second and theoretical aim to repair all the damages to the patient's memory. These two aims are coincident. When one is reached, so is the other; and the same path leads to them both.
SECOND PHASE OF INFANTILE MASTURBATION  The masturbation of early infancy seems to disappear after a short time; but it may persist uninterruptedly until puberty, and this would constitute the first great deviation from the course of development laid down for civilized men. At some point of childhood after early infancy, as a rule before the fourth year, the sexual instinct belonging to the genital zone usually revives and persists again for a time until it is once more suppressed, or it may continue without interruption. This second phase of infantile sexual activity may assume a variety of different forms which can only be determined by a precise analysis of individual cases. But all its details leave behind the deepest (unconscious) impressions in the subject's memory, determine the development of his character, if he is to remain healthy, and the symptomatology of his neurosis, if he is to fall ill after puberty.¹ In the latter case we find that this sexual period has been forgotten and that the conscious memories that bear witness to it have been displaced. (I have already mentioned that I am also inclined to relate normal infantile amnesia to this infantile sexual activity.) Psychoanalytic investigation enables us to make what has been forgotten conscious and thus do away with a compulsion that arises from the unconscious psychical material.

[1905d, 1509]

In order to secure these ideas and associations he asks the patient to 'let himself go' in what he says, 'as you would do in a conversation in which you were rambling on quite disconnectedly and at random'. Before he asks them for a detailed account of their case history he insists that they must include in it whatever comes into their heads, even if they think it unimportant or irrelevant or nonsensical; he lays special stress on their not omitting any thought or idea from their story because to relate it would be embarrassing or distressing to them. In the course of collecting this material of otherwise neglected ideas Freud made the observations which became the determining factor of his entire theory. Gaps appear in the patient's memory even while he narrates his case: actual occurrences are forgotten, the chronological order is confused, or causal connections are broken, with unintelligible results. No neurotic case history is without amnesia of some kind or other. If the patient is urged to fill these gaps in his memory by an increased application of attention, it is noticed that all the ideas which occur to him are pushed back by every possible critical expedient, until at last he feels positive discomfort when the memory really returns. From this experience Freud concludes that the amnesias are the result of a process which he calls 'repression' and the motive for which he finds in feelings of unpleasure. The psychical forces which have brought about this repression can also be detected, according to him, in the 'resistance' which operates against the recovery of the lost memories.

[1904a, 1557]
The task which the psycho-analytic method seeks to perform may be formulated in different ways, which are, however, in their essence equivalent. It may, for instance, be stated thus: the task of the treatment is to remove the amnesias. When all gaps in memory have been filled in, all the enigmatic products of mental life elucidated, the continuance and even a renewal of the morbid condition are made impossible. Or the formula may be expressed in this fashion: all repressions must be undone. The mental condition is then the same as one in which all amnesias have been removed. Another formulation reaches further: the task consists in making the unconscious accessible to consciousness, which is done by overcoming the resistances. But it must be remembered that an ideal condition such as this is not present even in the normal, and further that it is only rarely possible to carry the treatment to a point approaching it. Just as health and sickness are not different from each other in essence but are only separated by a quantitative line of demarcation which can be determined in practice, so the aim of the treatment will never be anything else but the practical recovery of the patient, the restoration of his ability to lead an active life and of his capacity for enjoyment. In a treatment which is incomplete or in which success is not perfect, one may at any rate achieve a considerable improvement in the general mental condition, while the symptoms (though now of smaller importance to the patient) may continue to exist without stamping him as a sick man.

I do not think much of the objection that neurotics are a special class of people, marked by an innate disposition that is 'degenerate', from whose childhood life we must not be allowed to infer anything about the childhood of other people. Neurotics are people much like others. They cannot be sharply differentiated from normal people, and in their childhood they are not always easily distinguishable from those who remain healthy in later life. It is one of the most valuable results of our psycho-analytic investigations to have discovered that the neuroses of such people have no special mental content that is peculiar to them, but that, as Jung has expressed it, they fall ill of the same complexes against which we healthy people struggle as well. The only difference is that healthy people know how to overcome those complexes without any gross damage demonstrable in practical life, whereas in nervous cases the suppression of the complexes succeeds only at the price of costly substitutive formations - that is to say, from a practical point of view it is a failure. In childhood neurotic and normal people naturally approximate to each other much more closely than they do in later life, so that I cannot regard it as a methodological error to make use of the communications of neurotics about their childhood for drawing conclusions by analogy about normal childhood life. But since those who later become neurotics very often have in their inborn constitution an especially strong sexual instinct and a tendency to precocity and to a premature expression of that instinct, they make it possible for us to recognize a great deal of infantile activity more sharply and clearly than our capacity for observation (which is in any case a blunted one) would enable us to do in other children. But we shall of course only be able to assess the true value of these communications made by neurotic adults when, following Havelock Ellis’s example, we shall have thought it worth while to collect the childhood memories of healthy adults as well.

If we apply knowledge gained elsewhere to this case of childhood neurosis, we shall not be able to avoid a suspicion that in this instance as in others (that is to say, before the child had reached his sixth year) there had been conflicts and repressions, which had themselves been overtaken by amnesia, but had left behind them as a residuum the particular content of this obsessive fear. Later on we shall learn how far it is possible for us to rediscover those forgotten experiences or to reconstruct them with some degree of certainty. In the meantime stress may be laid on the fact, which is probably more than a mere coincidence, that the patient's infantile amnesia ended precisely with his sixth year.
A second observation of Breuer's, again, compels us to attach great importance, among the characteristics of the pathological chain of events, to states of consciousness. Breuer's patient exhibited, alongside of her normal state, a number of mental peculiarities: conditions of 'absence', confusion, and alterations of character. In her normal state she knew nothing of the pathogenic scenes or their connection with her symptoms; she had forgotten the scenes, or at all events had severed the pathogenic link. When she was put under hypnosis, it was possible, at the expense of a considerable amount of labour, to recall the scenes to her memory; and, through this work of recollecting, the symptoms were removed. The explanation of this fact would be a most awkward business, were it not that the way is pointed by experiences and experiments in hypnotism. The study of hypnotic phenomena has accustomed us to what was at first a bewildering realization that in one and the same individual there can be several mental groupings, which can remain more or less independent of one another, which can 'know nothing' of one another and which can alternate with one another in their hold upon consciousness. Cases of this kind, too, occasionally appear spontaneously, and are then described as examples of 'double conscience'.¹ If, where a splitting of the personality such as this has occurred, consciousness remains attached regularly to one of the two states, we call it the conscious mental state and the other, which is detached from it, the unconscious one. In the familiar condition known as 'post-hypnotic suggestion', a command given under hypnosis is slavishly carried out subsequently in the normal state. This phenomenon affords an admirable example of the influences which the unconscious state can exercise over the conscious one; moreover, it provides a pattern upon which we can account for the phenomena of hysteria.

Breuer adopted a hypothesis that hysterical symptoms arise in peculiar mental conditions to which he gave the name of 'hypnoid'. On this view, excitations occurring during these hypnoid states can easily become pathogenic because such states do not provide opportunities for the normal discharge of the process of excitation. There consequently arises from the process of excitation an unusual product - the symptom. This finds its way, like a foreign body, into the normal state, which in turn is in ignorance of the hypnoid pathogenic situation. Wherever there is a symptom there is also an amnesia, a gap in the memory, and filling up this gap implies the removal of the conditions which led to the production of the symptom.

If, then, Leonardo's story about the vulture that visited him in his cradle is only a phantasy from a later period, one might suppose it could hardly be worth while spending much time on it. One might be satisfied with explaining it on the basis of his inclination, of which he makes no secret, to regard his preoccupation with the flight of birds as pre-ordained by destiny. Yet in underrating this story one would be committing just as great an injustice as if one were carelessly to reject the body of legends, traditions and interpretations found in a nation's early history. In spite of all the distortions and misunderstandings, they still represent the reality of the past: they are what a people forms out of the experience of its early days and under the dominance of motives that were once powerful and still operate to-day; and if it were only possible, by a knowledge of all the forces at work, to undo these distortions, there would be no difficulty in disclosing the historical truth lying behind the legendary material. The same holds good for the childhood memories or phantasies of an individual. What someone thinks he remembers from his childhood is not a matter of indifference; as a rule the residual memories - which he himself does not understand - cloak priceless pieces of evidence about the most important features in his mental development.¹ As we now possess in the techniques of psycho-analysis excellent methods for helping us to bring this concealed material to light, we may venture to fill in the gap in Leonardo's life story by analysing his childhood phantasy. And if in doing so we remain dissatisfied with the degree of certainty which we achieve, we shall have to console ourselves with the reflection that so many other studies of this great and enigmatic man have met with no better fate.
It seems to me not unnecessary to keep on reminding students of the far-reaching changes which psycho-analytic technique has undergone since its first beginnings. In its first phase - that of Breuer's catharsis - it consisted in bringing directly into focus the moment at which the symptom was formed, and in persistently endeavouring to reproduce the mental processes involved in that situation, in order to direct their discharge along the path of conscious activity. Remembering and abreacting, with the help of the hypnotic state, were what was at that time aimed at. Next, where hypnosis had been given up, the task became one of discovering from the patient's free associations what he failed to remember. The resistance was to be circumvented by the work of interpretation and by making its results known to the patient. The situations which had given rise to the formation of the symptom and the other situations which lay behind the moment at which the illness broke out retained their place as the focus of interest; but the element of abreaction receded into the background and seemed to be replaced by the expenditure of work which the patient had to make in being obliged to overcome his criticism of his free associations, in accordance with the fundamental rule of psycho-analysis. Finally, there was evolved the consistent technique used to-day, in which the analyst gives up the attempt to bring a particular moment or problem into focus. He contents himself with studying whatever is present for the time being on the surface of the patient's mind, and he employs the art of interpretation mainly for the purpose of recognizing the resistances which appear there, and making them conscious to the patient. From this there results a new sort of division of labour: the doctor uncovers the resistances which are unknown to the patient; when these have been got the better of, the patient often relates the forgotten situations and connections without any difficulty. The aim of these different techniques has, of course, remained the same. Descriptively speaking, it is to fill in gaps in memory; dynamically speaking, it is to overcome resistances due to repression.

[1914g, 2498]

There is another question that I might draw your attention to, which has been dealt with too little in our discussions: that of 'unconscious' masturbation. I mean masturbation during sleep, during abnormal states, or fits. You will recall the many hysterical fits in which masturbatory acts recur in a disguised or unrecognizable way, after the subject has renounced that form of satisfaction, and the many symptoms in obsessional neurosis which seek to replace and repeat this kind of sexual activity, which has formerly been forbidden. We may also speak of a therapeutic return of masturbation. A number of you will have found on occasion, as I have, that it represents a great advance if during the treatment the patient ventures to take up masturbation once more, though he may have no intention of making a permanent stop at that infantile halting-place. In this connection I may remind you that a considerable number of precisely the most severe sufferers from neurosis have avoided all recollection of masturbation during historic times, while psycho-analysis is able to prove that that species of sexual activity had by no means been strange to them during the forgotten earliest period of their lives.

[1912f, 2574]
In psycho-analytic treatments we are invariably faced by the task of filling up these gaps in the memory of childhood; and in so far as the treatment is to any extent successful - that is to say, extremely frequently - we also succeed in bringing to light the content of these forgotten years of childhood. Those impressions had never been really forgotten, they were only inaccessible, latent, and had formed part of the unconscious. But it can come about that they emerge from the unconscious spontaneously, and this happens in connection with dreams. It appears that dream-life knows how to find access to these latent, infantile experiences. Excellent examples of this have been reported in the literature and I myself have been able to provide a contribution of the kind. I once dreamt in a certain connection of a person who must have done me a service and whom I saw clearly before me. He was a one-eyed man of small stature, stout, and with his head sunk deep in his shoulders. I concluded from the context that he was a doctor. Luckily I was able to enquire from my mother, who was still alive, what the doctor at my birth-place (which I had left when I was three) had looked like; and I learnt from her that he was one-eyed, short, stout and with his head sunk deep in his shoulders; and I also learnt what the accident was for which he had come to my help and which I myself had forgotten. This fact of dreams having at their disposal the forgotten material of the first years of childhood is thus a further archaic feature.

[1916-1917, 3290]

I will not go into this any further to-day. But since we still have some time to spare, I should like to direct your attention to another characteristic of our two analyses, which, once again, it will only be possible to appreciate fully later on - to the gaps in the patients' memories, their amnesias. As you have heard, the task of a psycho-analytic treatment can be expressed in this formula: its task is to make conscious everything that is pathogenically unconscious. You will perhaps be surprised to learn, then, that this formula can be replaced by another one: its task is to fill up all the gaps in the patient's memory, to remove his amnesias. This would amount to the same thing. We are thus implying that the amnesias of neurotic patients have an important connection with the origin of their symptoms. If, however, you consider the case of our first analysis you will not find this view of amnesia justified. The patient had not forgotten the scene from which her obsessive action was derived; on the contrary, she had a vivid recollection of it; nor did anything else forgotten play a part in the origin of the symptom. The position with our second patient (the girl with the obsessional ceremonial), though less clear, was on the whole analogous. She had not really forgotten her behaviour in earlier years - the fact that she had insisted on the door between her parents' bedroom and her own being left open and that she had driven her mother out of her place in her parents' bed; she remembered this very plainly, even though with hesitation and unwillingly. The only thing we can consider striking is that the first patient, in carrying out her obsessional action on countless occasions, had never once noticed its resemblance to her experience on her wedding-night, and that the memory of it did not occur to her when she was directly asked to look for the motives of her obsessional action. And the same thing applies to the girl, whose ceremonial and its causes were moreover connected with a situation which was identically repeated every evening. In both these cases there was no true amnesia, no missing memory; but a connection had been broken which ought to have led to the reproduction or re-emergence of the memory.

[1916-1917, 3359]
A disturbance of memory of this kind is enough for obsessional neurosis; but the case is
different with hysteria. As a rule the latter neurosis is marked by amnesias on a really large
scale. In analysing each separate hysterical symptom one is usually led to a whole chain of
impressions of events, which, when they recur, are expressly described by the patient as having
been till then forgotten. On the one hand, this chain reaches back to the earliest years of life, so
that the hysterical amnesia can be recognized as an immediate continuation of the infantile
amnesia which, for us normal people, conceals the beginnings of our mental life. On the other
hand, we learn with astonishment that even the patient's most recent experiences can be
subject to forgetting, and that the occasions which precipitated the outbreak of the illness or led
to its intensification are in particular encroached upon, if not completely swallowed up, by
amnesia. It regularly happens that important details have disappeared from the total picture of a
recent recollection of this sort or that they have been replaced by falsifications of memory.
Indeed it happens with almost equal regularity that certain memories of recent experiences only
emerge shortly before the end of an analysis - memories which had been held back till that late
moment and had left perceptible gaps in the continuity of the case.
[1916-1917, 3360]

From about the sixth to the eighth year of life onwards, we can observe a halt and
retrogression in sexual development, which, in cases where it is most propitious culturally,
deserves to be called a period of latency. The latency period may also be absent; it need not
bring with it any interruption of sexual activity and sexual interests along the whole line. The
majority of experiences and mental impulses before the start of the latency period now fall
victim to infantile amnesia - the forgetting (already discussed by us) which veils our earliest
youth from us and makes us strangers to it. The task is set us in every psycho-analysis of
bringing this forgotten period back into memory. It is impossible to avoid a suspicion that the
beginnings of sexual life which are included in that period have provided the motive for its being
forgotten - that this forgetting, in fact, is an outcome of repression.
[1916-1917, 3394]

We can express the aim of our efforts in a variety of formulas: making conscious what is
unconscious, lifting repressions, filling gaps in the memory - all these amount to the same thing.
But perhaps you will be dissatisfied by this admission. You had formed a different picture of the
return to health of a neurotic patient - that, after submitting to the tedious hours of a psycho-
analysis, he would become another man; but the total result, so it seems, is that he has rather
less that is unconscious and rather more that is conscious in him than he had before. The fact is
that you are probably under-estimating the importance of an internal change of this kind. The
neurotic who is cured has really become another man, though a bottom, of course, he has
remained the same; that is to say, he has become what he might have become at best under
the most favourable conditions. But that is a very great deal. If you now hear all that has to be
done and what efforts it needs to bring about this apparently trivial change in a man's mental
life, you will no doubt begin to realize the importance of this difference in psychical levels.
[1916-1917, 3477]
Where the transference arises, what difficulties it raises for us, how we overcome them and what advantages we eventually derive from it - these are questions to be dealt with in a technical guide to analysis, and I shall only touch on them lightly to-day. It is out of the question for us to yield to the patient's demands deriving from the transference; it would be absurd for us to reject them in an unfriendly, still more in an indignant, manner. We overcome the transference by pointing out to the patient that his feelings do not arise from the present situation and do not apply to the person of the doctor, but that they are repeating something that happened to him earlier. In this way we oblige him to transform his repetition into a memory. By that means the transference, which, whether affectionate or hostile, seemed in every case to constitute the greatest threat to the treatment, becomes its best tool, by whose help the most secret compartments of mental life can be opened.

[1916-1917, 3485]

But you will now tell me that, no matter whether we call the motive force of our analysis transference or suggestion, there is a risk that the influencing of our patient may make the objective certainty of our findings doubtful. What is advantageous to our therapy is damaging to our researches. This is the objection that is most often raised against psycho-analysis, and it must be admitted that, though it is groundless, it cannot be rejected as unreasonable. If it were justified, psycho-analysis would be nothing more than a particularly well-disguised and particularly effective form of suggestive treatment and we should have to attach little weight to all that it tells us about what influences our lives, the dynamics of the mind or the unconscious. That is what our opponents believe; and in especial they think that we have 'talked' the patients into everything relating to the importance of sexual experiences - or even into those experiences themselves - after such notions have grown up in our own depraved imagination. These accusations are contradicted more easily by an appeal to experience than by the help of theory. Anyone who has himself carried out psycho-analyses will have been able to convince himself on countless occasions that it is impossible to make suggestions to a patient in that way. The doctor has no difficulty, of course, in making him a supporter of some particular theory and in thus making him share some possible error of his own. In this respect the patient is behaving like anyone else - like a pupil - but this only affects his intelligence, not his illness. After all, his conflicts will only be successfully solved and his resistances overcome if the anticipatory ideas he is given tally with what is real in him. Whatever in the doctor's conjectures is inaccurate drops out in the course of the analysis; it has to be withdrawn and replaced by something more correct. We endeavour by a careful technique to avoid the occurrence of premature successes due to suggestion; but no harm is done even if they do occur, for we are not satisfied by a first success. We do not regard an analysis as at an end until all the obscurities of the case are cleared up, the gaps in the patient's memory filled in, the precipitating causes of the repressions discovered. We look upon successes that set in too soon as obstacles rather than as a help to the work of analysis; and we put an end to such successes by constantly resolving the transference on which they are based. It is this last characteristic which is the fundamental distinction between analytic and purely suggestive therapy, and which frees the results of analysis from the suspicion of being successes due to suggestion. In every other kind of suggestive treatment the transference is carefully preserved and left untouched; in analysis it is itself subjected to treatment and is dissected in all the shapes in which it appears. At the end of an analytic treatment the transference must itself be cleared away; and if success is then obtained or continues, it rests, not on suggestion, but on the achievement by its means of an overcoming of internal resistances, on the internal change that has been brought about in the patient.

[1916-1917, 3493]
I will now complete my picture of the mechanism of cure by clothing it in the formulas of the libido theory. A neurotic is incapable of enjoyment and of efficiency - the former because his libido is not directed on to any real object and the latter because he is obliged to employ a great deal of this available energy on keeping his libido under repression and on warding off its assaults. He would become healthy if the conflict between his ego and his libido came to an end and if his ego had his libido again at its disposal. The therapeutic task consists, therefore, in freeing the libido from its present attachments, which are withdrawn from the ego, and in making it once more serviceable to the ego. Where, then, is the neurotic's libido situated? It is easily found: it is attached to the symptoms, which yield it the only substitutive satisfaction possible at the time. We must therefore make ourselves masters of the symptoms and resolve them - which is precisely the same thing that the patient requires of us. In order to resolve the symptoms, we must go back as far as their origin, we must renew the conflict from which they arose, and, with the help of motive forces which were not at the patient's disposal in the past, we must guide it to a different outcome. This revision of the process of repression can be accomplished only in part in connection with the memory traces of the processes which led to repression. The decisive part of the work is achieved by creating in the patient's relation to the doctor - in the 'transference' - new editions of the old conflicts; in these the patient would like to behave in the same way as he did in the past, while we, by summoning up every available mental force, compel him to come to a fresh decision. Thus the transference becomes the battlefield on which all the mutually struggling forces should meet one another.

² Information of this kind may, as a rule, be employed as absolutely authentic material. So it may seem tempting to take the easy course of filling up the gaps in a patient's memory by making enquiries from the older members of his family; but I cannot advise too strongly against such a technique. Any stories that may be told by relatives in reply to enquiries and requests are at the mercy of every critical misgiving that can come into play. One invariably regrets having made oneself dependent upon such information; at the same time confidence in the analysis is shaken and a court of appeal is set up over it. Whatever can be remembered at all will anyhow come to light in the further course of analysis.

¹ The Grusha scene was, as I have said, a spontaneous product of the patient's memory, and no construction or stimulation by the physician played any part in evoking it. The gaps in it were filled up by the analysis in a fashion which must be regarded as unexceptionable, if any value at all is attached to the analytic method of work. The only possible rationalistic explanation of the phobia would be the following. There is nothing extraordinary, it might be said, in a child that was inclined to be nervous having had an anxiety attack in connection with a yellow-striped butterfly, probably as a result of some inherited tendency to anxiety. (See Stanley Hall, 'A Synthetic Genetic Study of Fear', 1914.) In ignorance of the true causation of his fear, this explanation would proceed, the patient looked about for something in his childhood to which he could connect it; he made use of the chance similarity of names and the recurrence of the stripes as a ground for the construction of an imaginary adventure with the nursery-maid whom he still remembered. When, however, we observe that the trivial details of this event (which, according to this view, was in itself an innocent one) - the scrubbing, the pail and the broom - had enough power over the patient's later life to determine his object-choice permanently and compulsively, then the butterfly phobia seems to have acquired an inexplicable importance. The state of things on this hypothesis is thus seen to be at least as remarkable as on mine, and any advantage that might be claimed for a rationalistic reading of the scene has melted away. The Grusha scene is of particular value to us, since in relation to it we can prepare our judgement upon the less certain primal scene.
Strictly considered - and why should this question not be considered with all possible strictness? - analytic work deserves to be recognized as genuine psycho-analysis only when it has succeeded in removing the amnesia which conceals from the adult his knowledge of his childhood from its beginning (that is, from about the second to the fifth year). This cannot be said among analysts too emphatically or repeated too often. The motives for disregarding this reminder are, indeed, intelligible. It would be desirable to obtain practical results in a shorter period and with less trouble. But at the present time theoretical knowledge is still far more important to all of us than therapeutic success, and anyone who neglects childhood analysis is bound to fall into the most disastrous errors. The emphasis which is laid here upon the importance of the earliest experiences does not imply any underestimation of the influence of later ones. But the later impressions of life speak loudly enough through the mouth of the patient, while it is the physician who has to raise his voice on behalf of the claims of childhood. [1919e, 3646]

But it became ever clearer that the aim which had been set up - the aim that what was unconscious should become conscious - is not completely attainable by that method. The patient cannot remember the whole of what is repressed in him, and what he cannot remember may be precisely the essential part of it. Thus he acquires no sense of conviction of the correctness of the construction that has been communicated to him. He is obliged to repeat the repressed material as a contemporary experience instead of, as the physician would prefer to see, remembering it as something belonging to the past.¹ These reproductions, which emerge with such unwished-for exactitude, always have as their subject some portion of infantile sexual life - of the Oedipus complex, that is, and its derivatives; and they are invariably acted out in the sphere of the transference, of the patient's relation to the physician. When things have reached this stage, it may be said that the earlier neurosis has now been replaced by a fresh, 'transference neurosis'. It has been the physician's endeavour to keep this transference neurosis within the narrowest limits: to force as much as possible into the channel of memory and to allow as little as possible to emerge as repetition. The ratio between what is remembered and what is reproduced varies from case to case. The physician cannot as a rule spare his patient this phase of the treatment. He must get him to re-experience some portion of his forgotten life, but must see to it, on the other hand, that the patient retains some degree of aloofness, which will enable him, in spite of everything, to recognize that what appears to be reality is in fact only a reflection of a forgotten past. If this can be successfully achieved, the patient's sense of conviction is won, together with the therapeutic success that is dependent on it. [1920g, 3723]
For these reasons I refrained altogether from holding out to the parents any prospect of their wish being fulfilled. I merely said I was prepared to study the girl carefully for a few weeks or months, so as then to be able to pronounce how far a continuation of the analysis would be likely to influence her. In quite a number of cases, indeed, an analysis falls into two clearly distinguishable phases. In the first, the physician procures from the patient the necessary information, makes him familiar with the premises and postulates of psycho-analysis, and unfolds to him the reconstruction of the genesis of his disorder as deduced from the material brought up in the analysis. In the second phase the patient himself gets hold of the material put before him; he works on it, recollects what he can of the apparently repressed memories, and tries to repeat the rest as if he were in some way living it over again. In this way he can confirm, supplement, and correct the inferences made by the physician. It is only during this work that he experiences, through overcoming resistances, the inner change aimed at, and acquires for himself the convictions that make him independent of the physician's authority. These two phases in the course of the analytic treatment are not always sharply divided from each other; this can only happen when the resistance obeys certain conditions. But when this is so, one may bring up as an analogy the two stages of a journey. The first comprises all the necessary preparations, to-day so complicated and hard to effect, before, ticket in hand, one can at last go on to the platform and secure a seat in the train. One then has the right, and the possibility, of travelling into a distant country; but after all these preliminary exertions one is not yet there - indeed, one is not a single mile nearer to one's goal. For this to happen one has to make the journey itself from one station to the other, and this part of the performance may well be compared with the second phase of the analysis.

If a dream brings up situations that can be interpreted as referring to scenes from the dreamer's past, it seems especially important to ask whether the physician's influence can also play a part in such contents of the dream as these. And this question is most urgent of all in the case of what are called 'corroborative' dreams, dreams which, as it were, 'tag along behind' the analysis. With some patients these are the only dreams that one obtains. Such patients reproduce the forgotten experiences of their childhood only after one has constructed them from their symptoms, associations and other signs and has propounded these constructions to them. Then follow the corroborative dreams, concerning which, however, the doubt arises whether they may not be entirely without evidential value, since they may have been imagined in compliance with the physician's words instead of having been brought to light from the dreamer's unconscious. This ambiguous position cannot be escaped in the analysis, since with these patients unless one interprets, constructs and propounds, one never obtains access to what is repressed in them.

The situation takes a favourable turn if the analysis of a corroborative dream of this sort, which 'tags along behind', is immediately followed by feelings of remembering what has hitherto been forgotten. But even then the sceptic can fall back upon an assertion that the recollections are illusory. Moreover, such feelings are for the most part absent. The repressed material is only allowed through bit by bit; and every lack of completeness inhibits or delays the forming of a sense of conviction. Furthermore, what we are dealing with may not be the reproduction of a real and forgotten event but the bringing forward of an unconscious phantasy, about which no feeling of memory is ever to be expected, though the possibility may sometimes remain of a sense of subjective conviction.
Hypnosis had, however, performed the service of restoring to the patient's memory what he had forgotten. It was necessary to find some other technique to replace it; and the idea occurred to Freud of substituting for it the method of 'free association'. That is to say, he pledged his patients to refrain from any conscious reflection and to abandon themselves, in a state of quiet concentration, to following the ideas which occurred to them spontaneously (involuntarily) - 'to skim off the surface of their consciousness'. They were to communicate these ideas to the physician even if they felt objections to doing so, if, for instance, the thoughts seemed too disagreeable, too senseless, too unimportant or irrelevant. The choice of free association as a means of investigating the forgotten unconscious material seems so strange that a word in justification of it will not be out of place. Freud was led to it by an expectation that the so-called 'free' association would prove in fact to be unfree, since, when all conscious intellectual purposes had been suppressed, the ideas that emerged would be seen to be determined by the unconscious material. This expectation was justified by experience. When the 'fundamental rule of psycho-analysis' which has just been stated was obeyed, the course of free association produced a plentiful store of ideas which could put one on the track of what the patient had forgotten. To be sure, this material did not bring up what had actually been forgotten, but it brought up such plain and numerous hints at it that, with the help of a certain amount of supplementing and interpreting, the doctor was able to guess (to reconstruct) the forgotten material from it. Thus free association together with the art of interpretation performed the same function as had previously been performed by hypnotism.

It looked as though our work had been made much more difficult and complicated; but the inestimable gain was that an insight was now obtained into an interplay of forces which had been concealed from the observer by the hypnotic state. It became evident that the work of uncovering what had been pathogenically forgotten had to struggle against a constant and very intense resistance. The critical objections which the patient raised in order to avoid communicating the ideas which occurred to him, and against which the fundamental rule of psycho-analysis was directed, had themselves already been manifestations of this resistance. A consideration of the phenomena of resistance led to one of the corner-stones of the psychoanalytic theory of the neuroses - the theory of repression. It was plausible to suppose that the same forces which were now struggling against the pathogenic material being made conscious had at an earlier time made the same efforts with success. A gap in the aetiology of neurotic symptoms was thus filled. The impressions and mental impulses, for which the symptoms were now serving as substitutes, had not been forgotten without reason or on account of a constitutional incapacity for synthesis (as Janet supposed); they had, though the influence of other mental forces, met with a repression the success and evidence of which was precisely their being debarred from consciousness and excluded from memory. It was only in consequence of this repression that they had become pathogenic - that is, had succeeded in manifesting themselves along unusual paths as symptoms.
It is easy now to describe our therapeutic aim. We try to restore the ego, to free it from its restrictions, and to give it back the command over the id which it has lost owing to its early repressions. It is for this one purpose that we carry out analysis, our whole technique is directed to this aim. We have to seek out the repressions which have been set up and to urge the ego to correct them with our help and to deal with conflicts better than by an attempt at flight. Since these repressions belong to the very early years of childhood, the work of analysis leads us, too, back to that period. Our path to these situations of conflict, which have for the most part been forgotten and which we try to revive in the patient's memory, is pointed out to us by his symptoms, dreams and free associations. These must, however, first be interpreted - translated - for, under the influence of the psychology of the id, they have assumed forms of expression that are strange to our comprehension. We may assume that whatever associations, thoughts and memories the patient is unable to communicate to us without internal struggles are in some way connected with the repressed material or are its derivatives. By encouraging the patient to disregard his resistances to telling us these things, we are educating his ego to overcome its inclination towards attempts at flight and to tolerate an approach to what is repressed. In the end, if the situation of the repression can be successfully reproduced in his memory, his compliance will be brilliantly rewarded. The whole difference between his age then and now works in his favour; and the thing from which his childish ego fled in terror will often seem to his adult and strengthened ego no more than child's play.

Let me return to your question about certainty. We have become quite generally convinced from the direct analytic examination of children that we were right in our interpretation of what adults told us about their childhood. In a number of cases, however, another sort of confirmation has become possible. The material of the analysis of some patients has enabled us to reconstruct certain external happenings, certain impressive events of their childhood years, of which they have preserved no conscious memory. Lucky accidents, information from parents or nurses, have afterwards provided irrefutable evidence that these occurrences which we had inferred really did take place. This, of course, has not happened often, but when it has it has made an overwhelming impression. The correct reconstruction, you must know, of such forgotten experiences of childhood always has a great therapeutic effect, whether they permit of objective confirmation or not. These events owe their importance, of course, to their having occurred at such an early age, at a time when they could still produce a traumatic effect on the feeble ego.

Various sorts. In the first place, impressions capable of permanently influencing the child's budding sexual life - such as observations of sexual activities between adults, or sexual experiences of his own with an adult or another child (no rare events); or, again, overhearing conversations, understood either at the time or retrospectively, from which the child thought it could draw conclusions about mysterious or uncanny matters; or again, remarks or actions by the child himself which give evidence of significant attitudes of affection or enmity towards other people. It is of special importance in an analysis to induce a memory of the patient's own forgotten sexual activity as a child and also of the intervention by the adults which brought it to an end.

'I will add that. Thereupon he begins to talk and I listen. And what then? I infer from what he tells me the kind of impressions, experiences and wishes which he has repressed because he came across them at a time when his ego was still feeble and was afraid of them instead of dealing with them. When he has learnt this from me, he puts himself back in the old situations and with my help he manages better. The limitations to which his ego was tied then disappear, and he is cured. Is that right?''
When one really practises analysis one learns all kinds of things besides. For instance: you would not find it at all such a simple matter to deduce from what the patient tells you the experiences he has forgotten and the instinctual impulses he has repressed. He says something to you which at first means as little to you as it does to him. You will have to make up your mind to look at the material which he delivers to you in obedience to the rule in a quite special way: as though it were ore, perhaps, from which its content of precious metal has to be extracted by a particular process. You will be prepared, too, to work over many tons of ore which may contain but little of the valuable material you are in search of. Here we should have a first reason for the prolonged character of the treatment. [1926e, 4361]

We meet with the second of these facts almost every day in the course of our analytic work; and it does not imply such an important objection as the other does. One of the tasks of psycho-analysis, as you know, is to lift the veil of amnesia which hides the earliest years of childhood and to bring to conscious memory the manifestations of early infantile sexual life which are contained in them. Now these first sexual experiences of a child are linked to painful impressions of anxiety, prohibition, disappointment and punishment. We can understand their having been repressed; but, that being so, we cannot understand how it is that they have such free access to dream-life, that they provide the pattern for so many dream-phantasies and that dreams are filled with reproductions of these scenes from childhood and with allusions to them. It must be admitted that their unpleasurable character and the dream-work's wish-fulfilling purpose seem far from mutually compatible. But it may be that in this case we are magnifying the difficulty. After all, these same infantile experiences have attached to them all the imperishable, unfulfilled instinctual wishes which throughout life provide the energy for the construction of dreams, and to which we may no doubt credit the possibility, in their mighty uprush, of forcing to the surface, along with the rest, the material of distressing events. And on the other hand the manner and form in which this material is reproduced shows unmistakably the efforts of the dream-work directed to denying the unpleasure by means of distortion and to transforming disappointment into attainment. [1933a, 4641]

These three points - the very early appearance of these experiences (during the first five years of life), the fact of their being forgotten and their sexual-aggressive content - are closely interconnected. The traumas are either experiences on the subject's own body or sense perceptions, mostly of something seen and heard - that is, experiences or impressions. The interconnection of these three points is established by a theory, a product of the work of analysis which alone can bring about a knowledge of the forgotten experiences, or, to put it more vividly but also more incorrectly, bring them back to memory. The theory is that, in contrast to popular opinion, the sexual life of human beings (or what corresponds to it later on) exhibits an early efflorescence which comes to an end at about the fifth year and is followed by what is known as the period of latency (till puberty) in which there is no further development of sexuality and indeed what has been attained undergoes a retrogression. This theory is confirmed by the anatomical investigation of the growth of the internal genitalia; it leads us to suppose that the human race is descended from a species of animal which reached sexual maturity in five years and rouses a suspicion that the postponement of sexual life and its diaphasic onset are intimately connected with the history of hominization. Human beings appear to be the only animal organisms with a latency period and sexual retardation of this kind. Investigations on the primates (which, so far as I know, are not available) would be indispensable for testing this theory. It cannot be a matter of indifference psychologically that the period of infantile amnesia coincides with this early period of sexuality. It may be that this state of things provides the true determinant for the possibility of neurosis, which is in a sense a human prerogative and from this point of view appears as a vestige - a 'survival' - of pramaeval times like certain portions of our bodily anatomy. [1939a, 4900]
It has long since become common knowledge that the experiences of a person's first five years exercise a determining effect on his life, which nothing later can withstand. Much that deserves knowing might be said about the way in which these early impressions maintain themselves against any influences in more mature periods of life - but it would not be relevant here. It may, however, be less well known that the strongest compulsive influence arises from impressions which impinge upon a child at a time when we would have to regard his psychical apparatus as not yet completely receptive. The fact itself cannot be doubted; but it is so puzzling that we may make it more comprehensible by comparing it with a photographic exposure which can be developed after any interval of time and transformed into a picture. I am nevertheless glad to point out that this uncomfortable discovery of ours has been anticipated by an imaginative writer, with the boldness that is permitted to poets. E. T. A. Hoffmann used to trace back the wealth of figures that put themselves at his disposal for his creative writings to the changing images and impressions which he had experienced during a journey of some weeks in a post-chaise while he was still an infant at his mother's breast. What children have experienced at the age of two and have not understood, need never be remembered by them except in dreams; they may only come to know of it through psycho-analytic treatment. But at some later time it will break into their life with obsessional impulses, it will govern their actions, it will decide their sympathies and antipathies and will quite often determine their choice of a love-object, for which it is so frequently impossible to find a rational basis. The two points at which these facts touch upon our problem cannot be mistaken.
[1939a, 4944]

The evidence of the share taken by the unconscious id in the formation of dreams is abundant and convincing. (a) Memory is far more comprehensive in dreams than in waking life. Dreams bring up recollections which the dreamer has forgotten, which are inaccessible to him when he is awake. (b) Dreams make an unrestricted use of linguistic symbols, the meaning of which is for the most part unknown to the dreamer. Our experience, however, enables us to confirm their sense. They probably originate from earlier phases in the development of speech. (c) Memory very often reproduces in dreams impressions from the dreamer's early childhood of which we can definitely assert not only that they had been forgotten but that they had become unconscious owing to repression. That explains the help - usually indispensable - given us by dreams in the attempts we make during the analytic treatment of neuroses to reconstruct the dreamer's early life. (d) Furthermore, dreams bring to light material which cannot have originated either from the dreamer's adult life or from his forgotten childhood. We are obliged to regard it as part of the archaic heritage which a child brings with him into the world, before any experience of his own, influenced by the experiences of his ancestors. We find the counterpart of this phylogenetic material in the earliest human legends and in surviving customs. Thus dreams constitute a source of human prehistory which is not to be despised.
[1940a [1938], 4976]
The method by which we strengthen the weakened ego has as a starting-point an extending of its self-knowledge. That is not, of course, the whole story but it is a first step. The loss of such knowledge signifies for the ego a surrender of power and influence; it is the first tangible sign that it is being hemmed in and hampered by the demands of the id and the super-ego. Accordingly, the first part of the help we have to offer is intellectual work on our side and encouragement to the patient to collaborate in it. This first kind of activity, as we know, is intended to pave the way to another, more difficult, task. We shall not lose sight of the dynamic element in this task, even during its preliminary stage. We gather the material for our work from a variety of sources - from what is conveyed to us by the information given us by the patient and by his free associations, from what he shows us in his transferences, from what we arrive at by interpreting his dreams and from what he betrays by his slips or parapraxes. All this material helps us to make constructions about what happened to him and has been forgotten as well as about what is happening in him now without his understanding it. But in all this we never fail to make a strict distinction between our knowledge and his knowledge. We avoid telling him at once things that we have often discovered at an early stage, and we avoid telling him the whole of what we think we have discovered. We reflect carefully over when we shall impart the knowledge of one of our constructions to him and we wait for what seems to us the suitable moment - which it is not always easy to decide. As a rule we put off telling him of a construction or explanation till he himself has so nearly arrived at it that only a single step remains to be taken, though that step is in fact the decisive synthesis. If we proceeded in another way and overwhelmed him with our interpretations before he was prepared for them, our information would either produce no effect or it would provoke a violent outbreak of resistance which would make the progress of our work more difficult or might even threaten to stop it altogether. But if we have prepared everything properly, it often happens that the patient will at once confirm our construction and himself recollect the internal or external event which he had forgotten. The more exactly the construction coincides with the details of what has been forgotten the easier will it be for him to assent. On that particular matter our knowledge will then have become his knowledge as well.

[1940a [1938], 4987]
Let us once more glance over the situation which we have reached in our attempt at bringing help to the patient's neurotic ego. That ego is no longer able to fulfil the task set it by the external world (including human society). Not all of its experiences are at its disposal, a large proportion of its store of memories have escaped it. Its activity is inhibited by strict prohibitions from the super-ego, its energy is consumed in vain attempts at fending off the demands of the id. Beyond this, as a result of continuous irruptions by the id, its organization is impaired, it is no longer capable of any proper synthesis, it is torn by mutually opposed urges, by unsettled conflicts and by unsolved doubts. To start with, we get the patient's thus weakened ego to take part in the purely intellectual work of interpretation, which aims at provisionally filling the gaps in his mental assets, and to transfer to us the authority of his super-ego; we encourage it to take up the struggle over each individual demand made by the id and to conquer the resistances which arise in connection with it. At the same time we restore order in the ego by detecting the material and urges which have forced their way in from the unconscious, and expose them to criticism by tracing them back to their origin. We serve the patient in various functions, as an authority and a substitute for his parents, as a teacher and educator; and we have done the best for him if, as analysts, we raise the mental processes in his ego to a normal level, transform what has become unconscious and repressed into preconscious material and thus return it once more to the possession of his ego. On the patient's side a few rational factors work in our favour, such as the need for recovery which has its motive in his sufferings, and the intellectual interest that we may awaken in him in the theories and revelations of psycho-analysis; but of far greater force is the positive transference with which he meets us. Fighting against us, on the other hand, are the negative transference, the ego's resistance due to repression (that is, its unpleasure at having to lay itself open to the hard work imposed on it), the sense of guilt arising from its relation to the super-ego and the need to be ill due to deep-going changes in the economics of his instincts. The share taken by the last two factors decides whether the case is to be regarded as slight or severe. Apart from these, a few other factors may be discerned as having a favourable or unfavourable bearing. A certain psychical inertia, a sluggishness of the libido, which is unwilling to abandon its fixations cannot be welcome to us; the patient's capacity for sublimating his instincts plays a large part and so does his capacity for rising above the crude life of the instincts; so, too, does the relative power of his intellectual functions.

[1940a [1938], 4990]
It is no doubt true that the impact of the threat of castration upon a boy's budding sexual life does not always have these dreaded consequences. It will depend once again on quantitative relations how much damage is done and how much avoided. The whole occurrence, which may probably be regarded as the central experience of the years of childhood, the greatest problem of early life and the strongest source of later inadequacy, is so completely forgotten that its reconstruction during the work of analysis is met in adults by the most decided disbelief. Indeed, aversion to it is so great that people try to silence any mention of the proscribed subject and the most obvious reminders of it are overlooked by a strange intellectual blindness. One may hear it objected, for instance, that the legend of King Oedipus has in fact no connection with the construction made by analysis: the cases are quite different, since Oedipus did not know that it was his father that he killed and his mother that he married. What is overlooked in this is that a distortion of this kind is inevitable if an attempt is made at a poetic handling of the material, and that there is no introduction of extraneous material but only a skilful employment of the factors presented by the theme. The ignorance of Oedipus is a legitimate representation of the unconscious state into which, for adults, the whole experience has fallen; and the coercive power of the oracle, which makes or should make the hero innocent, is a recognition of the inevitability of the fate which has condemned every son to live through the Oedipus complex. Again it was pointed out from psycho-analytic quarters how easily the riddle of another dramatic hero, Shakespeare's procrastinator, Hamlet, can be solved by reference to the Oedipus complex, since the prince came to grief over the task of punishing someone else for what coincided with the substance of his own Oedipus wish - whereupon the general lack of understanding on the part of the literary world showed how ready is the mass of mankind to hold fast to its infantile repressions.

I myself had adopted another way of speeding up an analytic treatment even before the war. At that time I had taken on the case of a young Russian, a man spoilt by wealth, who had come to Vienna in a state of complete helplessness, accompanied by a private doctor and an attendant. In the course of a few years it was possible to give him back a large amount of his independence, to awaken his interest in life and to adjust his relations to the people most important to him. But there progress came to a stop. We advanced no further in clearing up the neurosis of his childhood, on which his later illness was based, and it was obvious that the patient found his present position highly comfortable and had no wish to take any step forward which would bring him nearer to the end of his treatment. It was a case of the treatment inhibiting itself: it was in danger of failing as a result of its - partial - success. In this predicament I resorted to the heroic measure of fixing a time limit for the analysis. At the beginning of a year's work I informed the patient that the coming year was to be the last one of his treatment, no matter what he achieved in the time still left to him. At first he did not believe me, but once he was convinced that I was in deadly earnest, the desired change set in. His resistances shrank up, and in these last months of his treatment he was able to reproduce all the memories and to discover all the connections which seemed necessary for understanding his early neurosis and mastering his present one. When he left me in the midsummer of 1914, with as little suspicion as the rest of us of what lay so shortly ahead, I believed that his cure was radical and permanent.
The other meaning of the 'end' of an analysis is much more ambitious. In this sense of it, what we are asking is whether the analyst has had such a far-reaching influence on the patient that no further change could be expected to take place in him if his analysis were continued. It is as though it were possible by means of analysis to attain to a level of absolute psychical normality - a level, moreover, which we could feel confident would be able to remain stable, as though, perhaps, we had succeeded in resolving every one of the patient's repressions and in filling in all the gaps in his memory. We may first consult our experience to enquire whether such things do in fact happen, and then turn to our theory to discover whether there is any possibility of their happening.

It is familiar ground that the work of analysis aims at inducing the patient to give up the repressions (using the word in the widest sense) belonging to his early development and to replace them by reactions of a sort that would correspond to a psychically mature condition. With this purpose in view he must be brought to recollect certain experiences and the affective impulses called up by them which he has for the time being forgotten. We know that his present symptoms and inhibitions are the consequences of repressions of this kind: thus that they are a substitute for these things that he has forgotten. What sort of material does he put at our disposal which we can make use of to put him on the way to recovering the lost memories? All kinds of things. He gives us fragments of these memories in his dreams, invaluable in themselves but seriously distorted as a rule by all the factors concerned in the formation of dreams. Again, he produces ideas, if he gives himself up to 'free association', in which we can discover allusions to the repressed experiences and derivatives of the suppressed affective impulses as well as of the reactions against them. And, finally, there are hints of repetitions of the affects belonging to the repressed material to be found in actions performed by the patient, some fairly important, some trivial, both inside and outside the analytic situation. Our experience has shown that the relation of transference, which becomes established towards the analyst, is particularly calculated to favour the return of these emotional connections. It is out of such raw material - if we may so describe it - that we have to put together what we are in search of.

What we are in search of is a picture of the patient's forgotten years that shall be alike trustworthy and in all essential respects complete. But at this point we are reminded that the work of analysis consists of two quite different portions, that it is carried on in two separate localities, that it involves two people, to each of whom a distinct task is assigned. It may for a moment seem strange that such a fundamental fact should not have been pointed out long ago; but it will immediately be perceived that there was nothing being kept back in this, that it is a fact which is universally known and, as it were, self-evident and is merely being brought into relief here and separately examined for a particular purpose. We all know that the person who is being analysed has to be induced to remember something that has been experienced by him and repressed; and the dynamic determinants of this process are so interesting that the other portion of the work, the task performed by the analyst, has been pushed into the background. The analyst has neither experienced nor repressed any of the material under consideration; his task cannot be to remember anything. What then is his task? His task is to make out what has been forgotten from the traces which it has left behind or, more correctly, to construct it. The time and manner in which he conveys his constructions to the person who is being analysed, as well as the explanations with which he accompanies them, constitute the link between the two portions of the work of analysis, between his own part and that of the patient.
It is not, however, a preliminary labour in the sense that the whole of it must be completed before the next piece of work can be begun, as, for instance, is the case with house-building, where all the walls must be erected and all the windows inserted before the internal decoration of the rooms can be taken in hand. Every analyst knows that things happen differently in an analytic treatment and that there both kinds of work are carried on side by side, the one kind being always a little ahead and the other following upon it. The analyst finishes a piece of construction and communicates it to the subject of the analysis so that it may work upon him; he then constructs a further piece out of the fresh material pouring in upon him, deals with it in the same way and proceeds in this alternating fashion until the end. If, in accounts of analytic technique, so little is said about 'constructions', that is because 'interpretations' and their effects are spoken of instead. But I think that 'construction' is by far the more appropriate description. 'Interpretation' applies to something that one does to some single element of the material, such as an association or a parapraxis. But it is a 'construction' when one lays before the subject of the analysis a piece of his early history that he has forgotten, in some such way as this: 'Up to your n th year you regarded yourself as the sole and unlimited possessor of your mother; then came another baby and brought you grave disillusionment. Your mother left you for some time, and even after her reappearance she was never again devoted to you exclusively. Your feelings towards your mother became ambivalent, your father gained a new importance for you,' ... and so on.
[1937d, 5052]

A 'No' from a person in analysis is quite as ambiguous as a 'Yes', and is indeed of even less value. In some rare cases it turns out to be the expression of a legitimate dissent. Far more frequently it expresses a resistance which may have been evoked by the subject-matter of the construction that has been put forward but which may just as easily have arisen from some other factor in the complex analytic situation. Thus, a patient's 'No' is no evidence of the correctness of a construction, though it is perfectly compatible with it. Since every such construction is an incomplete one, since it covers only a small fragment of the forgotten events, we are free to suppose that the patient is not in fact disputing what has been said to him but is basing his contradiction upon the part that has not yet been uncovered. As a rule he will not give his assent until he has learnt the whole truth - which often covers a very great deal of ground. So that the only safe interpretation of his 'No' is that it points to incompleteness; there can be no doubt that the construction has not told him everything.
[1937d, 5054]

How this occurs in the process of the analysis - the way in which a conjecture of ours is transformed into the patient's conviction - this is hardly worth describing. All of it is familiar to every analyst from his daily experience and is intelligible without difficulty. Only one point requires investigation and explanation. The path that starts from the analyst's construction ought to end in the patient's recollection; but it does not always lead so far. Quite often we do not succeed in bringing the patient to recollect what has been repressed. Instead of that, if the analysis is carried out correctly, we produce in him an assured conviction of the truth of the construction which achieves the same therapeutic result as a recaptured memory. The problem of what the circumstances are in which this occurs and of how it is possible that what appears to be an incomplete substitute should nevertheless produce a complete result - all of this is matter for a later enquiry.
[1937d, 5057]
I shall conclude this brief paper with a few remarks which open up a wider perspective. I have been struck by the manner in which, in certain analyses, the communication of an obviously apt construction has evoked in the patients a surprising and at first incomprehensible phenomenon. They have had lively recollections called up in them - which they themselves have described as 'ultra-clear' - but what they have recollected has not been the event that was the subject of the construction but details relating to that subject. For instance, they have recollected with abnormal sharpness the faces of the people involved in the construction or the rooms in which something of the sort might have happened, or, a step further away, the furniture in such rooms - on the subject of which the construction had naturally no possibility of any knowledge. This has occurred both in dreams immediately after the construction had been put forward and in waking states resembling phantasies. These recollections have themselves led to nothing further and it has seemed plausible to regard them as the product of a compromise. The 'upward drive' of the repressed, stirred into activity by the putting forward of the construction, has striven to carry the important memory-traces into consciousness; but a resistance has succeeded, not, it is true, in stopping that movement, but in displacing it on to adjacent objects of minor significance.

[1937d, 5057]

I am aware that it is of small service to handle so important a subject in the cursory fashion that I have here employed. But none the less I have not been able to resist the seduction of an analogy. The delusions of patients appear to me to be the equivalents of the constructions which we build up in the course of an analytic treatment - attempts at explanation and cure, though it is true that these, under the conditions of a psychosis, can do no more than replace the fragment of reality that is being disavowed in the present by another fragment that had already been disavowed in the remote past. It will be the task of each individual investigation to reveal the intimate connections between the material of the present disavowal and that of the original repression. Just as our construction is only effective because it recovers a fragment of lost experience, so the delusion owes its convincing power to the element of historical truth which it inserts in the place of the rejected reality. In this way a proposition which I originally asserted only of hysteria would apply also to delusions - namely, that those who are subject to them are suffering from their own reminiscences. I never intended by this short formula to dispute the complexity of the causation of the illness or to exclude the operation of many other factors.

[1937d, 5059]
It was here that I learnt for the first time, what was confirmed on countless later occasions, that when one is resolving a current hysterical delirium, the patient's communications are given in a reverse chronological order, beginning with the most recent and least important impressions and connections of thought and only at the end reaching the primary impression, which is in all probability the most important one causally.

The second auxiliary moment repeated the mechanism of the first one fairly exactly. A powerful impression temporarily reunited the patient's consciousness, and conversion once more took the path which had been opened out on the first occasion. It is interesting to notice that the second symptom to develop masked the first, so that the first was not clearly perceived until the second had been cleared out of the way. It also seems to me worth while remarking upon the reversed course which had to be followed by the analysis as well. I have had the same experience in a whole number of cases; the symptoms that had arisen later masked the earlier ones, and the key to the whole situation lay only in the last symptom to be reached by the analysis.

The discovery of the reason for the first conversion opened a second, fruitful period of the treatment. The patient surprised me soon afterwards by announcing that she now knew why it was that the pains always radiated from that particular area of the right thigh and were at their most painful there: it was in this place that her father used to rest his leg every morning, while she renewed the bandage round it, for it was badly swollen. This must have happened a good hundred times, yet she had not noticed the connection till now. In this way she gave me the explanation that I needed of the emergence of what was an atypical hysterogenic zone. Further, her painful legs began to 'join in the conversation' during our analyses. What I have in mind is the following remarkable fact. As a rule the patient was free from pain when we started work. If, then, by a question or by pressure upon her head I called up a memory, a sensation of pain would make its first appearance, and this was usually so sharp that the patient would give a start and put her hand to the painful spot. The pain that was thus aroused would persist so long as she was under the influence of the memory; it would reach its climax when she was in the act of telling me the essential and decisive part of what she had to communicate, and with the last word of this it would disappear. I came in time to use such pains as a compass to guide me; if she stopped talking but admitted that she still had a pain, I knew that she had not told me everything, and insisted on her continuing her story till the pain had been talked away. Not until then did I arouse a fresh memory.

In the first place there is an unmistakable linear chronological order which obtains within each separate theme. As an example of this I will merely quote the arrangement of the material in Breuer's analysis of Anna O. Let us take the theme of becoming deaf, of not hearing. This was differentiated according to seven sets of determinants, and under each of these seven headings ten to over a hundred individual memories were collected in chronological series (p. 35). It was as though we were examining a dossier that had been kept in good order. The analysis of my patient Emmy von N. contained similar files of memories though they were not so fully enumerated and described. These files form a quite general feature of every analysis and their contents always emerge in a chronological order which is as infallibly trustworthy as the succession of days of the week or names of the month in a mentally normal person. They make the work of analysis more difficult by the peculiarity that, in reproducing the memories, they reverse the order in which these originated. The freshest and newest experience in the file appears first, as an outer cover, and last of all comes the experience with which the series in fact began.
The knowledge I have so far gained already enables me to answer these questions. If we take a case which presents several symptoms, we arrive by means of the analysis, starting from each symptom, at a series of experiences the memories of which are linked together in association. To begin with, the chains of memories lead backwards separately from one another; but, as I have said, they ramify. From a single scene two or more memories are reached at the same time, and from these again side-chains proceed whose individual links may once more be associatively connected with links belonging to the main chain. Indeed, a comparison with the genealogical tree of a family whose members have also intermarried, is not at all a bad one. Other complications in the linkage of the chains arise from the circumstance that a single scene may be called up several times in the same chain, so that it has multiple relationships to a later scene, and exhibits both a direct connection with it and a connection established through intermediate links. In short, the concatenation is far from being a simple one; and the fact that the scenes are uncovered in a reversed chronological order (a fact which justifies our comparison of the work with the excavation of a stratified ruined site) certainly contributes nothing to a more rapid understanding of what has taken place.

But the peculiar value of this observation lies in the considerations which follow. When a physician treats an adult neurotic by psycho-analysis, the process he goes through of uncovering the psychical formations, layer by layer, eventually enables him to frame certain hypotheses as to the patient's infantile sexuality; and it is in the components of the latter that he believes he has discovered the motive forces of all the neurotic symptoms of later life. I have set out these hypotheses in my *Three Essays on the Theory of Sexuality* (1905d), and I am aware that they seem as strange to an outside reader as they seem incontrovertible to a psycho-analyst. But even a psycho-analyst may confess to the wish for a more direct and less roundabout proof of these fundamental theorems. Surely there must be a possibility of observing in children at first hand and in all the freshness of life the sexual impulses and wishes which we dig out so laboriously in adults from among their own débris - especially as it is also our belief that they are the common property of all men, a part of the human constitution, and merely exaggerated or distorted in the case of neurotics.

[1896c, 413]

[1909b, 2002]
Of the three factors which we have recognized as being decisive for the success or otherwise of analytic treatment - the influence of traumas, the constitutional strength of the instincts and alterations of the ego - what concerns us here is only the second, the strength of the instincts. A moment's reflection raises a doubt whether the restrictive use of the adjective 'constitutional' (or 'congenital') is essential. However true it may be that the constitutional factor is of decisive importance from the very beginning, it is nevertheless conceivable that a reinforcement of instinct coming later in life might produce the same effects. If so, we should have to modify our formula and say 'the strength of the instincts at the time' instead of 'the constitutional strength of the instincts'. The first of our questions was: 'Is it possible by means of analytic therapy to dispose of a conflict between an instinct and the ego, or of a pathogenic instinctual demand upon the ego, permanently and definitively?' To avoid misunderstanding it is not unnecessary, perhaps, to explain more exactly what is meant by 'permanently disposing of an instinctual demand'. Certainly not 'causing the demand to disappear so that nothing more is ever heard from it again'. This is in general impossible, nor is it at all to be desired. No, we mean something else, something which may be roughly described as a 'taming' of the instinct. That is to say, the instinct is brought completely into the harmony of the ego, becomes accessible to all the influences of the other trends in the ego and no longer seeks to go its independent way to satisfaction. If we are asked by what methods and means this result is achieved, it is not easy to find an answer. We can only say: 'So muss denn doch die Hexe dran!' - the Witch Metapsychology. Without metapsychological speculation and theorizing - I had almost said 'phantasying' - we shall not get another step forward. Unfortunately, here as elsewhere, what our Witch reveals is neither very clear nor very detailed. We have only a single clue to start from - though it is a clue of the highest value - namely, the antithesis between the primary and the secondary processes; and to that antithesis I shall at this point turn.

If now we take up our first question once more, we find that our new line of approach inevitably leads us to a particular conclusion. The question was whether it is possible to dispose of an instinctual conflict permanently and definitively - i.e. to 'tame' an instinctual demand in that fashion. Formulated in these terms, the question makes no mention at all of the strength of the instinct; but it is precisely on this that the outcome depends. Let us start from the assumption that what analysis achieves for neurotics is nothing other than what normal people bring about for themselves without its help. Everyday experience, however, teaches us that in a normal person any solution of an instinctual conflict only holds good for a particular strength of instinct, or, more correctly, only for a particular relation between the strength of the instinct and the strength of the ego.¹ If the strength of the ego diminishes, whether through illness or exhaustion, or from some similar cause, all the instincts which have so far been successfully tamed may renew their demands and strive to obtain substitutive satisfactions in abnormal ways.² Irrefutable proof of this statement is supplied by our nightly dreams; they react to the sleeping attitude assumed by the ego with an awakening of instinctual demands.

[1937c, 5022]
It is perhaps not without interest for its own sake to be able to see into the history of a psychical event of this kind, which is among the most trivial disturbances that can affect the control of the psychical apparatus and which is compatible with an otherwise untroubled state of psychical health. But the example elucidated here receives an immensely added interest when we learn that it may serve as nothing more nor less than a model for the pathological processes to which the psychical symptoms of the psychoneuroses - hysteria, obsessions and paranoia - owe their origin. In both cases we find the same elements and the same play of forces between those elements. In the same manner as here and by means of similar superficial associations, a repressed train of thought takes possession in neuroses of an innocent recent impression and draws it down with itself into repression. The same mechanism which causes the substitute names 'Botticelli' and 'Boltraffio' to emerge from 'Signorelli' (a substitution by means of intermediate or compromise ideas) also governs the formation of obsessional thoughts and paranoic paramnesias. Again, we have seen that such cases of forgetfulness have the characteristic of liberating continuous unpleasure till the moment the problem is solved - a characteristic which is unintelligible apart from this, and something which was in fact unintelligible to the person I was talking to; but there is a complete analogy to it in the way in which collections of repressed thoughts attach their capacity for producing affect to some symptom whose psychical content seems to our judgement totally unsuited to such a liberation of affect. Finally, the resolution of the whole tension by a communication of the correct name from an external quarter is itself a good example of the efficacy of psycho-analytic therapy, which aims at correcting the repressions and displacements and which removes the symptoms by re-instating the genuine psychical object.

¹ They share this character of indestructibility with all other mental acts which are truly unconscious, i.e. which belong to the system Ucs. only. These are paths which have been laid down once and for all, which never fall into disuse and which, whenever an unconscious excitation re-cathects them, are always ready to conduct the excitatory process to discharge. If I may use a simile, they are only capable of annihilation in the same sense as the ghosts in the underworld of the Odyssey - ghosts which awoke to new life as soon as they tasted blood. Processes which are dependent on the preconscious system are destructible in quite another sense. The psychotherapy of the neuroses is based on this distinction.

It is perfectly true that unconscious wishes always remain active. They represent paths which can always be traversed, whenever a quantity of excitation makes use of them. Indeed it is a prominent feature of unconscious processes that they are indestructible. In the unconscious nothing can be brought to an end, nothing is past or forgotten. This is brought most vividly home to one in studying the neuroses, and especially hysteria. The unconscious path of thoughts, which leads to discharge in a hysterical attack, immediately becomes traversable once more, when sufficient excitation has accumulated. A humiliation that was experienced thirty years ago acts exactly like a fresh one throughout the thirty years, as soon as it has obtained access to the unconscious sources of emotion. As soon as the memory of it is touched, it springs into life again and shows itself cathected with excitation which finds a motor discharge in an attack. This is precisely the point at which psychotherapy has to intervene. Its task is to make it possible for the unconscious processes to be dealt with finally and be forgotten. For the fading of memories and the emotional weakness of impressions which are no longer recent, which we are inclined to regard as self-evident and to explain as a primary effect of time upon mental memory-traces, are in reality secondary modifications which are only brought about by laborious work. What performs this work is the preconscious, and psychotherapy can pursue no other course than to bring the Ucs. under the domination of the Pcs.
If the dream that I analyse is not my own, but someone else's, the conclusion will be the same, though the grounds for believing it will be different. If the dreamer is a healthy person, there is no other means open to me of obliging him to recognize the repressed ideas that have been discovered than by pointing out the context of the dream-thoughts; and I cannot help it if he refuses to recognize them. If, however, I am dealing with a neurotic patient, with a hysteric for instance, he will find the acceptance of the repressed thought forced upon him, owing to its connection with the symptoms of his illness, and owing to the improvement he experiences when he exchanges those symptoms for the repressed ideas. In the case, for instance, of the woman patient who had the dream I have just quoted about the three theatre tickets which cost 1 florin 50 kreuzers, the analysis led to the inevitable conclusion that she had a low estimate of her husband (cf. her idea that she could have got one 'a hundred times better'), that she regretted having married him, and that she would have liked to exchange him for another one. It is true that she asserted that she loved her husband, and that her emotional life knew nothing of any such low estimate of him, but all her symptoms led to the same conclusion as the dream. And after her repressed memories had been revived of a particular period during which she had consciously not loved her husband, her symptoms cleared up and her resistance against the interpretation of the dream disappeared.

[1901a, 1086]

The procedure which the author makes his Zoe adopt for curing her childhood friend's delusion shows a far-reaching similarity - no, a complete agreement in its essence - with a therapeutic method which was introduced into medical practice in 1895 by Dr. Josef Breuer and myself, and to the perfecting of which I have since then devoted myself. This method of treatment, to which Breuer first gave the name of 'cathartic' but which I prefer to describe as 'analytic', consists, as applied to patients suffering from disorders analogous to Hanold's delusion, in bringing to their consciousness, to some extent forcibly, the unconscious whose repression led to their falling ill - exactly as Gradiva did with the repressed memories of their childhood relations. Gradiva, it is true, could carry out this task more easily than a doctor: in several respects she was in what may be described as an ideal position for it. The doctor, who has no pre-existing knowledge of his patient and possesses no conscious memory of what is unconsciously at work in him, must call a complicated technique to his help in order to make up for this disadvantage. He must learn how to infer with great certainty from the conscious associations and communications of the patient what is repressed in him, how to discover his unconscious as it betrays itself behind his conscious words and acts. He then brings about something like what Norbert Hanold grasped at the end of the story when he translated back the name 'Gradiva' into 'Bertgang'. The disorder vanishes while being traced back to its origin; analysis, too, brings simultaneous cure.

[1907a, 1881]
But the similarity between Gradiva's procedure and the analytic method of psychotherapy is not limited to these two points - the making conscious of what has been repressed and the coinciding of explanation with cure. It also extends to what turns out to be the essence of the whole change - to the awakening of feelings. Every disorder analogous to Hanold's delusion, what in scientific terms we are in the habit of calling 'psychoneuroses', has as its precondition the repression of a portion of instinctual life, or, as we can safely say, of the sexual instinct. At every attempt to introduce the unconscious and repressed causes of the illness into consciousness, the instinctual component concerned is necessarily aroused to a renewed struggle with the repressing powers, only to come to terms with them in the final outcome, often to the accompaniment of violent manifestations of reaction. The process of cure is accomplished in a relapse into love, if we combine all the many components of the sexual instinct under the term 'love'; and such a relapse is indispensable, for the symptoms on account of which the treatment has been undertaken are nothing other than precipitates of earlier struggles connected with repression or the return of the repressed, and they can only be resolved and washed away by a fresh high tide of the same passions. Every psycho-analytic treatment is an attempt at liberating repressed love which has found a meagre outlet in the compromise of a symptom. Indeed, the agreement between such treatments and the process of cure described by the author of Gradiva reaches its climax in the further fact that in analytic psychotherapy too the re-awakened passion, whether it is love or hate, invariably chooses as its object the figure of the doctor.

[1907a, 1881]

It is here that the differences begin, which made the case of Gradiva an ideal one which medical technique cannot attain. Gradiva was able to return the love which was making its way from the unconscious into consciousness, but the doctor cannot. Gradiva had herself been the object of the earlier, repressed love; her figure at once offered the liberated current of love a desirable aim. The doctor has been a stranger, and must endeavour to become a stranger once more after the cure; he is often at a loss what advice to give the patients he has cured as to how in real life they can use their recovered capacity to love. To indicate the expediencies and substitutes of which the doctor therefore makes use to help him to approximate with more or less success to the model of a cure by love which has been shown us by our author - all this would take us much too far away from the task before us.

[1907a, 1882]

And now for the final question, whose answer we have already evaded more than once. Our views on repression, on the genesis of delusions and allied disorders, on the formation and solution of dreams, on the part played by erotic life, and on the method by which such disorders are cured, are far from being the common property of science, let alone the assured possession of educated people. If the insight which has enabled the author to construct his 'phantasy' in such a way that we have been able to dissect it like a real case history is in the nature of knowledge, we should be curious to learn what were the sources of that knowledge. One of our circle - the one who, as I said at the beginning, was interested in the dreams in Gradiva and their possible interpretation - approached the author with the direct question whether he knew anything of such scientific theories as these. The author replied, as was to be expected, in the negative, and, indeed, somewhat brusquely. His imagination, he said, had inspired Gradiva, and he had enjoyed it; if there was anyone whom it did not please, let him simply leave it alone. He had no suspicion of how greatly it had in fact pleased his readers.

[1907a, 1882]

We should not be justified in expecting such severe obsessional ideas as were present in this case to be cleared up in any simpler manner or by any other means. When we reached the solution that has been described above, the patient's rat delirium disappeared.

[1909d, 2171]
What, then, becomes of the unconscious wishes which have been set free by psycho-analysis? Along what paths do we succeed in making them harmless to the subject's life? There are several such paths. The most frequent outcome is that, while the work is actually going on, these wishes are destroyed by the rational mental activity of the better impulses that are opposed to them. Repression is replaced by a condemning judgement carried out along the best lines. That is possible because what we have to get rid of is to a great extent only the consequences arising from earlier stages of the ego's development. The subject only succeeded in the past in repressing the unserviceable instinct because he himself was at that time still imperfectly organized and feeble. In his present-day maturity and strength, he will perhaps be able to master what is hostile to him with complete success.

[1910a, 2238]

A second outcome of the work of psycho-analysis is that it then becomes possible for the unconscious instincts revealed by it to be employed for the useful purposes which they would have found earlier if development had not been interrupted. For the extirpation of the infantile wishful impulses is by no means the ideal aim of development. Owing to their repressions, neurotics have sacrificed many sources of mental energy whose contributions would have been of great value in the formation of their character and in their activity in life. We know of a far more expedient process of development, called 'sublimation', in which the energy of the infantile wishful impulses is not cut off but remains ready for use - the unserviceable aim of the various impulses being replaced by one that is higher, and perhaps no longer sexual. It happens to be precisely the components of the sexual instinct that are specially marked by a capacity of this kind for sublimation, for exchanging their sexual aim for another one which is comparatively remote and socially valuable. It is probable that we owe our highest cultural successes to the contributions of energy made in this way to our mental functions. Premature repression makes the sublimation of the repressed instinct impossible; when the repression is lifted, the path to sublimation becomes free once more.

[1910a, 2238]

We must not omit to consider the third of the possible outcomes of the work of psycho-analysis. A certain portion of the repressed libidinal impulses has a claim to direct satisfaction and ought to find it in life. Our civilized standards make life too difficult for the majority of human organizations. Those standards consequently encourage the retreat from reality and the generating of neuroses, without achieving any surplus of cultural gain by this excess of sexual repression. We ought not to exalt ourselves so high as completely to neglect what was originally animal in our nature. Nor should we forget that the satisfaction of the individual's happiness cannot be erased from among the aims of our civilization. The plasticity of the components of sexuality, shown by their capacity for sublimation, may indeed offer a great temptation to strive for still greater cultural achievements by still further sublimation. But, just as we do not count on our machines converting more than a certain fraction of the heat consumed into useful mechanical work, we ought not to seek to alienate the whole amount of the energy of the sexual instinct from its proper ends. We cannot succeed in doing so; and if the restriction upon sexuality were to be carried too far it would inevitably bring with it all the evils of soil-exhaustion.

[1910a, 2239]
In place of a single sick person let us put society - suffering as a whole from neuroses, though composed of sick and healthy members; and in place of individual acceptance in the one case let us put general recognition in the other. A little reflection will then show you that this substitution cannot in any way alter the outcome. The success which the treatment can have with the individual must occur equally with the community. Sick people will not be able to let their various neuroses become known - their anxious over-tenderness which is meant to conceal their hatred, their agoraphobia which tells of disappointed ambition, their obsessive actions which represent self-reproaches for evil intentions and precautions against them - if all their relatives and every stranger from whom they wish to conceal their mental processes know the general meaning of such symptoms, and if they themselves know that in the manifestations of their illness they are producing nothing that other people cannot instantly interpret. The effect, however, will not be limited to the concealment of the symptoms which, incidentally, it is often impossible to carry out; for this necessity for concealment destroys the use of being ill. Disclosure of the secret will have attacked, at its most sensitive point, the 'aetiological equation' from which neuroses arise - it will have made the gain from the illness illusory; and consequently the final outcome of the changed situation brought about by the physician's indiscretion can only be that the production of the illness will be brought to a stop.

If this hope seems Utopian to you, you may remember that neurotic phenomena have actually been dispelled already by this means, although only in quite isolated instances. Think how common hallucinations of the Virgin Mary used to be among peasant girls in former times. So long as such a phenomenon brought a flock of believers and might lead to a chapel being built on the sacred spot, the visionary state of these girls was inaccessible to influence. To-day even our clergy have changed their attitude to such things; they allow police and doctors to examine the visionary, and now the Virgin makes only very rare appearances.

Are we, then, to abandon our efforts to explain the hidden meaning of neurosis as being in the last resort dangerous to the individual and harmful to the workings of society? Are we to give up drawing the practical conclusion from a piece of scientific insight? No; I think that in spite of this our duty lies in the other direction. The gain from illness provided by the neuroses is nevertheless on the whole and in the end detrimental to individuals as well as to society. The unhappiness that our work of enlightenment may cause will after all only affect some individuals. The change-over to a more realistic and creditable attitude on the part of society will not be bought too dearly by these sacrifices. But above all, all the energies which are to-day consumed in the production of neurotic symptoms serving the purposes of a world of phantasy isolated from reality, will, even if they cannot at once be put to uses in life, help to strengthen the clamour for the changes in our civilization through which alone we can look for the well-being of future generations.
The sun, therefore, is nothing but another sublimated symbol for the father; and in pointing this out I must disclaim all responsibility for the monotony of the solutions provided by psycho-analysis. In this instance symbolism overrides grammatical gender - at least so far as German goes,¹ for in most other languages the sun is masculine. Its counterpart in this picture of the two parents is 'Mother Earth' as she is generally called. We frequently come upon confirmations of this assertion in resolving the pathogenic phantasies of neurotics by psycho-analysis. I can make no more than the barest allusion to the relation of all this to cosmic myths. One of my patients, who had lost his father at a very early age, was always seeking to rediscover him in what was grand and sublime in Nature. Since I have known this, it has seemed to me probable that Nietzsche's hymn 'Vor Sonnenaufgang' ['Before Sunrise'] is an expression of the same longing.² Another patient, who became neurotic after his father's death, was seized with his first attack of anxiety and giddiness while the sun shone upon him as he was working in the garden with a spade. He spontaneously put forward as an interpretation that he had become frightened because his father had looked at him while he was at work upon his mother with a sharp instrument. When I ventured upon a mild remonstrance, he gave an air of greater plausibility to his view by telling me that even in his father's lifetime he had compared him with the sun, though then it had been in a satirical sense. Whenever he had been asked where his father was going to spend the summer he had replied in these sonorous words from the 'Prologue in Heaven':

[1911c, 2426]

An analysis such as this of someone who is practically healthy will, as may be imagined, remain incomplete. Anyone who can appreciate the high value of the self-knowledge and increase in self-control thus acquired will, when it is over, continue the analytic examination of his personality in the form of a self-analysis, and be content to realize that, within himself as well as in the external world, he must always expect to find something new. But anyone who has scorned to take the precaution of being analysed himself will not merely be punished by being incapable of learning more than a certain amount from his patients, he will risk a more serious danger and one which may become a danger to others. He will easily fall into the temptation of projecting outwards some of the peculiarities of his own personality, which he has dimly perceived, into the field of science, as a theory having universal validity; he will bring the psycho-analytic method into discredit, and lead the inexperienced astray.

[1912e, 2471]
(h) Another temptation arises out of the educative activity which, in psycho-analytic treatment, devolves on the doctor without any deliberate intention on his part. When the developmental inhibitions are resolved, it happens of itself that the doctor finds himself in a position to indicate new aims for the trends that have been liberated. It is then no more than a natural ambition if he endeavours to make something specially excellent of a person whom he has been at such pains to free from his neurosis and if he prescribes high aims for his wishes. But here again the doctor should hold himself in check, and take the patient's capacities rather than his own desires as guide. Not every neurotic has a high talent for sublimation; one can assume of many of them that they would not have fallen ill at all if they had possessed the art of sublimating their instincts. If we press them unduly towards sublimation and cut them off from the most accessible and convenient instinctual satisfactions, we shall usually make life even harder for them than they feel it in any case. As a doctor, one must above all be tolerant to the weakness of a patient, and must be content if one has won back some degree of capacity for work and enjoyment for a person even of only moderate worth. Educative ambition is of as little use as therapeutic ambition. It must further be borne in mind that many people fall ill precisely from an attempt to sublimate their instincts beyond the degree permitted by their organization and that in those who have a capacity for sublimation the process usually takes place of itself as soon as their inhibitions have been overcome by analysis. In my opinion, therefore, efforts invariably to make use of the analytic treatment to bring about sublimation of instinct are, though no doubt always laudable, far from being in every case advisable.

[1912e, 2473]

As far as the middle classes are concerned, the expense involved in psycho-analysis is excessive only in appearance. Quite apart from the fact that no comparison is possible between restored health and efficiency on the one hand and a moderate financial outlay on the other, when we add up the unceasing costs of nursing-homes and medical treatment and contrast them with the increase of efficiency and earning capacity which results from a successfully completed analysis, we are entitled to say that the patients have made a good bargain. Nothing in life is so expensive as illness - and stupidity.

[1913c, 2486]

The sexual ideal may enter into an interesting auxiliary relation to the ego ideal. It may be used for substitutive satisfaction where narcissistic satisfaction encounters real hindrances. In that case a person will love in conformity with the narcissistic type of object-choice, will love what he once was and no longer is, or else what possesses the excellences which he never had at all (cf. (c)). The formula parallel to the one there stated runs thus: what possesses the excellence which the ego lacks for making it an ideal, is loved. This expedient is of special importance for the neurotic, who, on account of his excessive object-cathexes, is impoverished in his ego and is incapable of fulfilling his ego ideal. He then seeks a way back to narcissism from his prodigal expenditure of libido upon objects, by choosing a sexual ideal after the narcissistic type which possesses the excellences to which he cannot attain. This is the cure by love, which he generally prefers to cure by analysis. Indeed, he cannot believe in any other mechanism of cure; he usually brings expectations of this sort with him to the treatment and directs them towards the person of the physician. The patient's incapacity for love, resulting from his extensive repressions, naturally stands in the way of a therapeutic plan of this kind. An unintended result is often met with when, by means of the treatment, he has been partially freed from his repressions: he withdraws from further treatment in order to choose a love-object, leaving his cure to be continued by a life with someone he loves. We might be satisfied with this result, if it did not bring with it all the dangers of a crippling dependence upon his helper in need.

[1914c, 2954]
But you must not conclude from my eagerness in defending myself against the charge that neurotics are encouraged in analytic treatment to live a full life - you must not conclude from this that we influence them in favour of conventional virtue. That is at least as far from being the case. It is true that we are not reformers but merely observers; nevertheless, we cannot help observing with a critical eye and we have found it impossible to side with conventional sexual morality or to form a very high opinion of the manner in which society attempts the practical regulation of the problems of sexual life. We can present society with a blunt calculation that what is described as its morality calls for a bigger sacrifice than it is worth and that its proceedings are not based on honesty and do not display wisdom. We do not keep such criticisms from our patients' ears, we accustom them to giving unprejudiced consideration to sexual matters no less than to any others; and if, having grown independent after the completion of their treatment, they decide on their own judgement in favour of some midway position between living a full life and absolute asceticism, we feel our conscience clear whatever their choice. We tell ourselves that anyone who has succeeded in educating himself to truth about himself is permanently defended against the danger of immorality, even though his standard of morality may differ in some respect from that which is customary in society. Moreover, we must guard against over-estimating the importance of the part played by the question of abstinence in influencing neuroses. Only in a minority of cases can the pathogenic situation of frustration and the subsequent damming-up of libido be brought to an end by the sort of sexual intercourse that can be procured without much trouble.

[1916-1917, 3477]

We can express the aim of our efforts in a variety of formulas: making conscious what is unconscious, lifting repressions, filling gaps in the memory - all these amount to the same thing. But perhaps you will be dissatisfied by this admission. You had formed a different picture of the return to health of a neurotic patient - that, after submitting to the tedious hours of a psycho-analysis, he would become another man; but the total result, so it seems, is that he has rather less that is unconscious and rather more that is conscious in him than he had before. The fact is that you are probably under-estimating the importance of an internal change of this kind. The neurotic who is cured has really become another man, though a bottom, of course, he has remained the same; that is to say, he has become what he might have become at best under the most favourable conditions. But that is a very great deal. If you now hear all that has to be done and what efforts it needs to bring about this apparently trivial change in a man's mental life, you will no doubt begin to realize the importance of this difference in psychical levels.

[1916-1917, 3477]
And now for the fact! In a whole number of nervous diseases - in hysteria, anxiety states, obsessional neurosis - our expectation is fulfilled. By searching for the repression in this way, by uncovering the resistances, by pointing out what is repressed, we really succeed in accomplishing our task - that is, in overcoming the resistances, lifting the repression and transforming the unconscious material into conscious. In doing so we gain the clearest impression of the way in which a violent struggle takes place in the patient's mind about the overcoming of each resistance - a normal mental struggle, on the same psychological ground, between the motives which seek to maintain the anticaathexis and those which are prepared to give it up. The former are the old motives which in the past put the repression into effect; among the latter are the newly arrived ones which, we may hope, will decide the conflict in our favour. We have succeeded in reviving the old conflict which led to repression and in bringing up for revision the process that was then decided. The new material that we produce includes, first the reminder that the earlier decision led to illness and the promise that a different path will lead to recovery, and, second, the enormous change in all the circumstances that has take place since the time of the original rejection. Then the ego was feeble, infantile, and may perhaps have had grounds for banning the demands of the libido as a danger. To-day it has grown strong and experienced, and moreover has a helper at and in the shape of the doctor. Thus we may expect to lead the revived conflict to a better outcome than that which ended in repression, and, as I have said, in hysteria and in the anxiety and obsessional neuroses success proves us in general to be correct.

[1916-1917, 3480]

Let us hope that the doctor is modest enough to attribute his patient's high opinion of him to the hopes he can rouse in him and to the widening of his intellectual horizon by the surprising and liberating enlightenment that the treatment brings with it. Under these conditions the analysis makes fine progress too. The patient understands what is interpreted to him and becomes engrossed in the tasks set him by the treatment; the material of memories and associations floods in upon him in plenty, the certainty and appositeness of his interpretations are a surprise to the doctor, and the latter can only take note with satisfaction that here is a patient who readily accepts all the psychological novelties which are apt to provoke the most bitter contradiction among healthy people in the outside world. Moreover the cordial relations that prevail during the work of analysis are accompanied by an objective improvement, which is recognized on all sides, in the patient's illness.

[1916-1917, 3482]
But I should like to say a few words to you to relieve you of your surprise at the emergence of this unexpected phenomenon. We must not forget that the patient's illness, which we have undertaken to analyse, is not something which has been rounded off and become rigid but that it is still growing and developing like a living organism. The beginning of the treatment does not put an end to this development; when, however, the treatment has obtained mastery over the patient, what happens is that the whole of his illness's new production is concentrated upon a single point - his relation to the doctor. Thus the transference may be compared to the cambium layer in a tree between the wood and the bark, from which the new formation of tissue and the increase in the girth of the trunk derive. When the transference has risen to this significance, work upon the patient's memories retreats far into the background. Thereafter it is not incorrect to say that we are no longer concerned with the patient's earlier illness but with a newly created and transformed neurosis which has taken the former's place. We have followed this new edition of the old disorder from its start, we have observed its origin and growth, and we are especially well able to find our way about in it since, as its object, we are situated at its very centre. All the patient's symptoms have abandoned their original meaning and have take on a new sense which lies in a relation to the transference; or only such symptoms have persisted as are capable of undergoing such a transformation. But the mastering of this new, artificial neurosis coincides with getting rid of the illness which was originally brought to the treatment - with the accomplishment of our therapeutic task. A person who has become normal and free from the operation of repressed instinctual impulse in his relation to the doctor will remain so in his own life after the doctor has once more withdrawn from it.

I will now complete my picture of the mechanism of cure by clothing it in the formulas of the libido theory. A neurotic is incapable of enjoyment and of efficiency - the former because his libido is not directed on to any real object and the latter because he is obliged to employ a great deal of this available energy on keeping his libido under repression and on warding off its assaults. He would become healthy if the conflict between his ego and his libido came to an end and if his ego had his libido again at its disposal. The therapeutic task consists, therefore, in freeing the libido from its present attachments, which are withdrawn from the ego, and in making it once more serviceable to the ego. Where, then, is the neurotic's libido situated? It is easily found: it is attached to the symptoms, which yield it the only substitutive satisfaction possible at the time. We must therefore make ourselves masters of the symptoms and resolve them - which is precisely the same thing that the patient requires of us. In order to resolve the symptoms, we must go back as far as their origin, we must renew the conflict from which they arose, and, with the help of motive forces which were not at the patient's disposal in the past, we must guide it to a different outcome. This revision of the process of repression can be accomplished only in part in connection with the memory traces of the processes which led to repression. The decisive part of the work is achieved by creating in the patient's relation to the doctor - in the 'transference' - new editions of the old conflicts; in these the patient would like to behave in the same way as he did in the past, while we, by summoning up every available mental force, compel him to come to a fresh decision. Thus the transference becomes the battlefield on which all the mutually struggling forces should meet one another.
Thus our therapeutic work falls into two phases. In the first, all the libido is forced from the symptoms into the transference and concentrated there; in the second, the struggle is waged around this new object and the libido is liberated from it. The change which is decisive for a favourable outcome is the elimination of repression in this renewed conflict so that the libido cannot withdraw once more from the ego by flight into the unconscious. This is made possible by the alteration of the ego which is accomplished under the influence of the doctor's suggestion. By means of the work of interpretation, which transforms what is unconscious into what is conscious, the ego is enlarged at the cost of this unconscious; by means of instruction, it is made conciliatory towards the libido and inclined to grant it some satisfaction, and its repugnance to the claims of the libido is diminished by the possibility of disposing of a portion of it by sublimation. The more closely events in the treatment coincide with this ideal description, the greater will be the success of the psycho-analytic therapy. It finds its limits in the lack of mobility of the libido, which may refuse to leave its objects, and the rigidity of narcissism, which will not allow transference on to objects to increase beyond certain bounds. Further light may perhaps be thrown on the dynamics of the process of cure if I say that we get hold of the whole of the libido which has been withdrawn from the dominance of the ego by attracting a portion of it on to ourselves by means of the transference.

The patient with whom I am here concerned remained for a long time unassailably entrenched behind an attitude of 'obliging apathy'. He listened, understood, and remained unapproachable. His unimpeachable intelligence was, as it were, cut off from the instinctual forces which governed his behaviour in the few relations of life that remained to him. It required a long education to induce him to take an independent share in the work; and when as a result of this exertion he began for the first time to feel relief, he immediately gave up working in order to avoid any further changes, and in order to remain comfortably in the situation which had been thus established. His shrinking from a self-sufficient existence was so great as to outweigh all the vexations of his illness. Only one way was to be found of overcoming it. I was obliged to wait until his attachment to myself had become strong enough to counter-balance this shrinking, and then played off this one factor against the other. I determined - but not until trustworthy signs had led me to judge that the right moment had come - that the treatment must be brought to an end at a particular fixed date, no matter how far it had advanced. I was resolved to keep to the date; and eventually the patient came to see that I was in earnest. Under the inexorable pressure of this fixed limit his resistance and his fixation to the illness gave way, and now in a disproportionately short time the analysis produced all the material which made it possible to clear up his inhibitions and remove his symptoms. All the information, too, which enabled me to understand his infantile neurosis is derived from this last period of the work, during which resistance temporarily disappeared and the patient gave an impression of lucidity which is usually attainable only in hypnosis.

The psycho-analytic method of treatment is then able to subject this process of repression to revision and to bring about a better solution of the conflict - one that is compatible with health. Unintelligent opposition accuses us of one-sidedness in our estimate of the sexual instincts. 'Human beings have other interests besides sexual ones,' they say. We have not forgotten or denied this for a moment. Our one-sidedness is like that of the chemist, who traces all compounds back to the force of chemical attraction. He is not on that account denying the force of gravity; he leaves that to the physicist to deal with.
This well-founded comparison of medical psycho-analytic activity with a chemical procedure might suggest a new direction for our therapy. We have *analysed* the patient - that is, separated his mental processes into their elementary constituents and demonstrated these instinctual elements in him singly and in isolation; what could be more natural than to expect that we should also help him to make a new and a better combination of them? You know that this demand has actually been put forward. We have been told that after an analysis of a sick mind a synthesis of it must follow. And, close upon this, concern has been expressed that the patient might be given too much analysis and too little synthesis; and there has then followed a move to put all the weight on this synthesis as the main factor in the psychotherapeutic effect, to see in it a kind of restoration of something that had been destroyed - destroyed, as it were, by vivisection.

[1919a, 3629]

Now let us assume that by some kind of organization we succeeded in increasing our numbers to an extent sufficient for treating a considerable mass of the population. On the other hand, it is possible to foresee that at some time or other the conscience of society will awake and remind it that the poor man should have just as much right to assistance for his mind as he now has to the life-saving help offered by surgery; and that the neuroses threaten public health no less than tuberculosis, and can be left as little as the latter to the impotent care of individual members of the community. When this happens, institutions or out-patient clinics will be started, to which analytically-trained physicians will be appointed, so that men who would otherwise give way to drink, women who have nearly succumbed under their burden of privations, children for whom there is no choice but between running wild or neurosis, may be made capable, by analysis, of resistance and of efficient work. Such treatments will be free. It may be a long time before the State comes to see these duties as urgent. Present conditions may delay its arrival even longer. Probably these institutions will first be started by private charity. Some time or other, however, it must come to this.

[1919a, 3635]

For these reasons I refrained altogether from holding out to the parents any prospect of their wish being fulfilled. I merely said I was prepared to study the girl carefully for a few weeks or months, so as then to be able to pronounce how far a continuation of the analysis would be likely to influence her. In quite a number of cases, indeed, an analysis falls into two clearly distinguishable phases. In the first, the physician procures from the patient the necessary information, makes him familiar with the premises and postulates of psycho-analysis, and unfolds to him the reconstruction of the genesis of his disorder as deduced from the material brought up in the analysis. In the second phase the patient himself gets hold of the material put before him; he works on it, recollects what he can of the apparently repressed memories, and tries to repeat the rest as if he were in some way living it over again. In this way he can confirm, supplement, and correct the inferences made by the physician. It is only during this work that he experiences, through overcoming resistances, the inner change aimed at, and acquires for himself the convictions that make him independent of the physician's authority. These two phases in the course of the analytic treatment are not always sharply divided from each other; this can only happen when the resistance obeys certain conditions. But when this is so, one may bring up as an analogy the two stages of a journey. The first comprises all the necessary preparations, to-day so complicated and hard to effect, before, ticket in hand, one can at last go on to the platform and secure a seat in the train. One then has the right, and the possibility, of travelling into a distant country; but after all these preliminary exertions one is not yet there - indeed, one is not a single mile nearer to one's goal. For this to happen one has to make the journey itself from one station to the other, and this part of the performance may well be compared with the second phase of the analysis.

[1920a, 3842]
Comparison between Psycho-Analysis and Hypnotic and Suggestive Methods. - Psycho-analytic procedure differs from all methods making use of suggestion, persuasion, etc., in that it does not seek to suppress by means of authority any mental phenomenon that may occur in the patient. It endeavours to trace the causation of the phenomenon and to remove it by bringing about a permanent modification in the conditions that led to it. In psycho-analysis the suggestive influence which is inevitably exercised by the physician is diverted on to the task assigned to the patient of overcoming his resistances, that is, of carrying forward the curative process. Any danger of falsifying the products of a patient's memory by suggestion can be avoided by prudent handling of the technique; but in general the arousing of resistances is a guarantee against the misleading effects of suggestive influence. It may be laid down that the aim of the treatment is to remove the patient's resistances and to pass his repressions in review and thus to bring about the most far-reaching unification and strengthening of his ego, to enable him to save the mental energy which he is expending upon internal conflicts, to make the best of him that his inherited capacities will allow and so to make him as efficient and as capable of enjoyment as is possible. The removal of the symptoms of the illness is not specifically aimed at, but is achieved, as it were, as a by-product if the analysis is properly carried through. The analyst respects the patient's individuality and does not seek to remould him in accordance with his own - that is, according to the physician's - personal ideals; he is glad to avoid giving advice and instead to arouse the patient's power of initiative.
[1923a, 3927]

Criticisms and Misunderstandings of Psycho-Analysis. - Most of what is brought up against psycho-analysis, even in scientific works, is based upon insufficient information which in its turn seems to be determined by emotional resistances. Thus it is a mistake to accuse psycho-analysis of 'pan-sexualism' and to allege that it derives all mental occurrences from sexuality and traces them all back to it. On the contrary, psycho-analysis has from the very first distinguished the sexual instincts from others which it has provisionally termed 'ego instincts'. It has never dreamt of trying to explain 'everything', and even the neuroses it has traced back not to sexuality alone but to the conflict between the sexual impulses and the ego. In psycho-analysis (unlike the works of C. G. Jung) the term ‘libido’ does not mean psychical energy in general but the motive force of the sexual instincts. Some assertions, such as that every dream is the fulfilment of a sexual wish, have never been maintained by it at all. The charge of one-sidedness made against psycho-analysis, which, as the science of the unconscious mind, has its own definite and restricted field of work, is as inapplicable as it would be if it were made against chemistry. To believe that psycho-analysis seeks a cure for neurotic disorders by giving a free rein to sexuality is a serious misunderstanding which can only be excused by ignorance. The making conscious of repressed sexual desires in analysis makes it possible, on the contrary, to obtain a mastery over them which the previous repression had been unable to achieve. It can more truly be said that analysis sets the neurotic free from the chains of his sexuality. Moreover, it is quite unscientific to judge analysis by whether it is calculated to undermine religion, authority and morals; for, like all sciences, it is entirely non-tendentious and has only a single aim - namely to arrive at a consistent view of one portion of reality. Finally, one can only characterize as simple-minded the fear which is sometimes expressed that all the highest goods of humanity, as they are called - research, art, love, ethical and social sense - will lose their value or their dignity because psycho-analysis is in a position to demonstrate their origin in elementary and animal instinctual impulses.
[1923a, 3928]
That this is a correct account of fixation upon repression and of the retention of danger-situations that are no longer present-day ones is confirmed by the fact of analytic therapy - a fact which is modest enough in itself but which can hardly be overrated from a theoretical point of view. When, in analysis, we have given the ego assistance which is able to put it in a position to lift its repressions, it recovers its power over the repressed id and can allow the instinctual impulses to run their course as though the old situations of danger no longer existed. What we can do in this way tallies with what can be achieved in other fields of medicine; for as a rule our therapy must be content with bringing about more quickly, more reliably and with less expenditure of energy than would otherwise be the case the good result which in favourable circumstances would have occurred of itself.

[1926d, 4308]

You will not expect me to have much to tell you that is new about the id apart from its new name. It is the dark, inaccessible part of our personality; what little we know of it we have learnt from our study of the dream-work and of the construction of neurotic symptoms, and most of that is of a negative character and can be described only as a contrast to the ego. We approach the id with analogies: we call it a chaos, a cauldron full of seething excitations. We picture it as being open at its end to somatic influences, and as there taking up into itself instinctual needs which find their psychical expression in it, but we cannot say in what substratum. It is filled with energy reaching it from the instincts, but it has no organization, produces no collective will, but only a striving to bring about the satisfaction of the instinctual needs subject to the observance of the pleasure principle. The logical laws of thought do not apply in the id, and this is true above all of the law of contradiction. Contrary impulses exist side by side, without cancelling each other out or diminishing each other: at the most they may converge to form compromises under the dominating economic pressure towards the discharge of energy. There is nothing in the id that could be compared with negation; and we perceive with surprise an exception to the philosophical theorem that space and time are necessary forms of our mental acts. There is nothing in the id that corresponds to the idea of time; there is no recognition of the passage of time, and - a thing that is most remarkable and awaits consideration in philosophical thought - no alteration in its mental processes is produced by the passage of time. Wishful impulses which have never passed beyond the id, but impressions, too, which have been sunk into the id by repression, are virtually immortal; after the passage of decades they behave as though they had just occurred. They can only be recognized as belonging to the past, can only lose their importance and be deprived of their cathectic of energy, when they have been made conscious by the work of analysis, and it is on this that the therapeutic effect of analytic treatment rests to no small extent.

[1933a, 4682]

We may mention, though only as an incidental consideration, an indirect way in which the upbringing of children may be helped by analysis and which may with time acquire a greater influence. Parents who have themselves experienced an analysis and owe much to it, including an insight into the faults of their own upbringing, will treat their children with better understanding and will spare them much of what they themselves were not spared.

[1933a, 4750]
Compared with the other psychotherapeutic procedures psycho-analysis is beyond any doubt the most powerful. It is just and fair, too, that this should be so for it is also the most laborious and time-consuming; it would not be used on slight cases. In suitable cases it is possible by its means to get rid of disturbances and bring about changes for which in pre-analytic times one would not have ventured to hope. But it has its very appreciable limits. The therapeutic ambition of some of my adherents has made the greatest efforts to overcome these obstacles so that every sort of neurotic disorder might be curable by psycho-analysis. They have endeavoured to compress the work of analysis into a shorter duration, to intensify transference so that it may be able to overcome any resistance, to unite other forms of influence with it so as to compel a cure. These efforts are certainly praiseworthy, but, in my opinion, they are vain. They bring with them, too, a danger of being oneself forced away from analysis and drawn into a boundless course of experimentation. The expectation that every neurotic phenomenon can be cured may, I suspect, be derived from the layman's belief that the neuroses are something quite unnecessary which have no right whatever to exist. Whereas in fact they are severe, constitutionally fixed illnesses, which rarely restrict themselves to only a few attacks but persist as a rule over long periods or throughout life. Our analytic experience that they can be extensively influenced, if the historical precipitating causes and accidental auxiliary factors of the illness can be dealt with, has led us to neglect the constitutional factor in our therapeutic practice, and in any case we can do nothing about it; but in theory we ought always to bear it in mind. The radical inaccessibility of the psychoses to analytic treatment should, in view of their close relationship to the neuroses, restrict our pretensions in regard to these latter. The therapeutic effectiveness of psycho-analysis remains cramped by a number of weighty and scarcely assailable factors. In the case of children, where one might count on the greatest successes, the difficulties are the external ones connected with their relation to their parents, though these difficulties are after all a necessary part of being a child. In the case of adults the difficulties arise in the first instance from two factors: the amount of psychical rigidity present and the form of the illness with all that covers in the way of deeper determinants.

[1933a, 4752]

I am afraid these detailed discussions are exhausting your interest. But I should be still more sorry if you were to think it is my intention to lower your opinion of psycho-analysis as a therapy. Perhaps I really made a clumsy start. For I wanted to do the opposite: to excuse the therapeutic limitations of analysis by pointing out their inevitability. With the same aim in view I turn to another point: the reproach against analytic treatment that it takes a disproportionately long time. On this it must be said that psychical changes do in fact only take place slowly; if they occur rapidly, suddenly, that is a bad sign. It is true that the treatment of a fairly severe neurosis may easily extend over several years; but consider, in case of success, how long the illness would have lasted. A decade, probably, for every year of treatment: the illness, that is to say (as we see so often in untreated cases), would not have ended at all. In some cases we have reasons for resuming an analysis many years afterwards. Life had developed fresh pathological reactions to fresh precipitating causes; but in the meantime our patient had been well. The first analysis had not in fact brought to light all his pathological dispositions, and it was natural for the analysis to have been stopped when success was achieved. There are also severely handicapped people who are kept under analytic supervision all through their lives and are taken back into analysis from time to time. But these people would otherwise have been altogether incapable of existence and we must feel glad that they can be kept on their feet by this piecemeal and recurrent treatment. The analysis of character disorders also calls for long periods of treatment; but it is often successful; and do you know of any other therapy with which such a task could even be approached? Therapeutic ambition may feel unsatisfied by such results; but we have learnt from the example of tuberculosis and lupus that success can only be obtained when the treatment has been adapted to the characteristics of the illness.

[1933a, 4755]
Let us once more glance over the situation which we have reached in our attempt at bringing help to the patient's neurotic ego. That ego is no longer able to fulfil the task set it by the external world (including human society). Not all of its experiences are at its disposal, a large proportion of its store of memories have escaped it. Its activity is inhibited by strict prohibitions from the super-ego, its energy is consumed in vain attempts at fending off the demands of the id. Beyond this, as a result of continuous irruptions by the id, its organization is impaired, it is no longer capable of any proper synthesis, it is torn by mutually opposed urges, by unsettled conflicts and by unsolved doubts. To start with, we get the patient's thus weakened ego to take part in the purely intellectual work of interpretation, which aims at provisionally filling the gaps in his mental assets, and to transfer to us the authority of his super-ego; we encourage it to take up the struggle over each individual demand made by the id and to conquer the resistances which arise in connection with it. At the same time we restore order in the ego by detecting the material and urges which have forced their way in from the unconscious, and expose them to criticism by tracing them back to their origin. We serve the patient in various functions, as an authority and a substitute for his parents, as a teacher and educator; and we have done the best for him if, as analysts, we raise the mental processes in his ego to a normal level, transform what has become unconscious and repressed into preconscious material and thus return it once more to the possession of his ego. On the patient's side a few rational factors work in our favour, such as the need for recovery which has its motive in his sufferings, and the intellectual interest that we may awaken in him in the theories and revelations of psycho-analysis; but of far greater force is the positive transference with which he meets us. Fighting against us, on the other hand, are the negative transference, the ego's resistance due to repression (that is, its unpleasure at having to lay itself open to the hard work imposed on it), the sense of guilt arising from its relation to the super-ego and the need to be ill due to deep-going changes in the economics of his instincts. The share taken by the last two factors decides whether the case is to be regarded as slight or severe. Apart from these, a few other factors may be discerned as having a favourable or unfavourable bearing. A certain psychical inertia, a sluggishness of the libido, which is unwilling to abandon its fixations cannot be welcome to us; the patient's capacity for sublimating his instincts plays a large part and so does his capacity for rising above the crude life of the instincts; so, too, does the relative power of his intellectual functions.

Experience has taught us that psycho-analytic therapy - the freeing of someone from his neurotic symptoms, inhibitions and abnormalities of character - is a time-consuming business. Hence, from the very first, attempts have been made to shorten the duration of analyses. Such endeavours required no justification; they could claim to be based on the strongest considerations of reason and expediency. But there was probably still at work in them as well some trace of the impatient contempt with which the medical science of an earlier day regarded the neuroses as being uncalled-for consequences of invisible injuries. If it had now become necessary to attend to them, they should at least be disposed of as quickly as possible.

We must first of all decide what is meant by the ambiguous phrase 'the end of an analysis'. From a practical standpoint it is easy to answer. An analysis is ended when the analyst and the patient cease to meet each other for the analytic session. This happens when two conditions have been approximately fulfilled: first, that the patient shall no longer be suffering from his symptoms and shall have overcome his anxieties and his inhibitions; and secondly, that the analyst shall judge that so much repressed material has been made conscious, so much that was unintelligible has been explained, and so much internal resistance conquered, that there is no need to fear a repetition of the pathological processes concerned. If one is prevented by external difficulties from reaching this goal, it is better to speak of an incomplete analysis rather than of an unfinished one.
Every analyst will have treated a few cases which have had this gratifying outcome. He has
succeeded in clearing up the patient's neurotic disturbance, and it has not returned and has not
been replaced by any other such disturbance. Nor are we without some insight into the
determinants of these successes. The patient's ego had not been noticeably altered and the
aetiology of his disturbance had been essentially traumatic. The aetiology of every neurotic
disturbance is, after all, a mixed one. It is a question either of the instincts being excessively
strong - that is to say, recalcitrant to taming by the ego - or of the effects of early (i.e.
premature) traumas which the immature ego was unable to master. As a rule there is a
combination of both factors, the constitutional and the accidental. The stronger the constitutional
factor, the more readily will a trauma lead to a fixation and leave behind a developmental
disturbance; the stronger the trauma, the more certainly will its injurious effects become
manifest even when the instinctual situation is normal. There is no doubt that an aetiology of the
traumatic sort offers by far the more favourable field for analysis. Only when a case is a
predominantly traumatic one will analysis succeed in doing what it is so superlatively able to do;
only then will it, thanks to having strengthened the patient's ego, succeed in replacing by a
correct solution the inadequate decision made in his early life. Only in such cases can one
speak of an analysis having been definitively ended. In them, analysis has done all that it should
and does not need to be continued. It is true that, if the patient who has been restored in this
way never produces another disorder calling for analysis, we do not know how much his
immunity may not be due to a kind fate which has spared him ordeals that are too severe.
[1937c, 5018]

I now pass on to my second example, which raises the same problem. An unmarried woman,
no longer young, had been cut off from life since puberty by an inability to walk, owing to severe
pains in the legs. Her condition was obviously of a hysterical nature, and it had defied many
kinds of treatment. An analysis lasting three-quarters of a year removed the trouble and
restored to the patient, an excellent and worthy person, her right to a share in life. In the years
following her recovery she was consistently unfortunate. There were disasters in her family, and
financial losses, and, as she grew older, she saw every hope of happiness in love and marriage
vanish. But the one-time invalid stood up to all this valiantly and was a support to her family in
difficult times. I cannot remember whether it was twelve or fourteen years after the end of her
analysis that, owing to profuse haemorrhages, she was obliged to undergo a gynaecological
examination. A myoma was found, which made a complete hysterectomy advisable. From the
time of this operation, the woman became ill once more. She fell in love with her surgeon,
wallowed in masochistic phantasies about the fearful changes in her inside - phantasies with
which she concealed her romance - and proved inaccessible to a further attempt at analysis.
She remained abnormal to the end of her life. The successful analytic treatment took place so
long ago that we cannot expect too much from it; it was in the earliest years of my work as an
analyst. No doubt the patient's second illness may have sprung from the same source as her
first one which had been successfully overcome: it may have been a different manifestation of
the same repressed impulses, which the analysis had only incompletely resolved. But I am
inclined to think that, were it not for the new trauma, there would have been no fresh outbreak of
neurosis.
[1937c, 5020]
If now we take up our first question once more, we find that our new line of approach inevitably leads us to a particular conclusion. The question was whether it is possible to dispose of an instinctual conflict permanently and definitively - i.e. to ‘tame’ an instinctual demand in that fashion. Formulated in these terms, the question makes no mention at all of the strength of the instinct; but it is precisely on this that the outcome depends. Let us start from the assumption that what analysis achieves for neurotics is nothing other than what normal people bring about for themselves without its help. Everyday experience, however, teaches us that in a normal person any solution of an instinctual conflict only holds good for a particular strength of instinct, or, more correctly, only for a particular relation between the strength of the instinct and the strength of the ego.¹ If the strength of the ego diminishes, whether through illness or exhaustion, or from some similar cause, all the instincts which have so far been successfully tamed may renew their demands and strive to obtain substitutive satisfactions in abnormal ways.² Irrefutable proof of this statement is supplied by our nightly dreams; they react to the sleeping attitude assumed by the ego with an awakening of instinctual demands.

Before we decide on an answer to this question, however, we must consider an objection whose force lies in the fact that we are probably predisposed in its favour. Our arguments, it will be said, are all deduced from the processes which take place spontaneously between the ego and the instincts, and they presuppose that analytic therapy can accomplish nothing which does not, under favourable and normal conditions, occur of itself. But is this really so? Is it not precisely the claim of our theory that analysis produces a state which never does arise spontaneously in the ego and that this newly created state constitutes the essential difference between a person who has been analysed and a person who has not? Let us bear in mind what this claim is based on. All repressions take place in early childhood; they are primitive defensive measures taken by the immature, feeble ego. In later years no fresh repressions are carried out; but the old ones persist, and their services continue to be made use of by the ego for mastering the instincts. New conflicts are disposed of by what we call 'after-repression'. We may apply to these infantile repressions our general statement that repressions depend absolutely and entirely on the relative strength of the forces involved and that they cannot hold out against an increase in the strength of the instincts. Analysis, however, enables the ego, which has attained greater maturity and strength, to undertake a revision of these old repressions; a few are demolished, while others are recognized but constructed afresh out of more solid material. These new dams are of quite a different degree of firmness from the earlier ones; we may be confident that they will not give way so easily before a rising flood of instinctual strength. Thus the real achievement of analytic therapy would be the subsequent correction of the original process of repression, a correction which puts an end to the dominance of the quantitative factor.

Thus far our theory, which we cannot give up except under irresistible compulsion. And what does our experience have to say to this? Perhaps our experience is not yet wide enough for us to come to a settled conclusion. It confirms our expectations often enough, but not always. One has an impression that one ought not to be surprised if it should turn out in the end that the difference between a person who has not been analysed and a person after he has been analysed is not so thorough-going as we aim at making it and as we expect and maintain it to be. If this is so, it would mean that analysis sometimes succeeds in eliminating the influence of an increase in instinct, but not invariably, or that the effect of analysis is limited to increasing the power of resistance of the inhibitions, so that they are equal to much greater demands than before the analysis or if no analysis had taken place. I really cannot commit myself to a decision on this point, nor do I know whether a decision is possible at the present time.
Applying these remarks to our present problem, I think that the answer to the question of how to explain the variable results of our analytic therapy might well be that we, too, in endeavouring to replace repressions that are insecure by reliable ego-syntonic controls, do not always achieve our aim to its full extent - that is, do not achieve it thoroughly enough. The transformation is achieved, but often only partially: portions of the old mechanisms remain untouched by the work of analysis. It is difficult to prove that this is really so; for we have no other way of judging what happens but by the outcome which we are trying to explain. Nevertheless, the impressions one receives during the work of analysis do not contradict this assumption; indeed, they seem rather to confirm it. But we must not take the clarity of our own insight as a measure of the conviction which we produce in the patient. His conviction may lack 'depth', as one might say; it is always a question of the quantitative factor, which is so easily overlooked. If this is the correct answer to our question, we may say that analysis, in claiming to cure neuroses by ensuring control over instinct, is always right in theory but not always right in practice. And this is because it does not always succeed in ensuring to a sufficient degree the foundations on which a control of instinct is based. The cause of such a partial failure is easily discovered. In the past, the quantitative factor of instinctual strength opposed the ego's defensive efforts; for that reason we called in the work of analysis to help; and now that same factor sets a limit to the efficacy of this new effort. If the strength of the instinct is excessive, the mature ego, supported by analysis, fails in its task, just as the helpless ego failed formerly. Its control over instinct is improved, but it remains imperfect because the transformation in the defensive mechanism is only incomplete. There is nothing surprising in this, since the power of the instruments with which analysis operates is not unlimited but restricted, and the final upshot always depends on the relative strength of the psychical agencies which are struggling with one another.

[1937c, 5026]
It is perfectly true that unconscious wishes always remain active. They represent paths which can always be traversed, whenever a quantity of excitation makes use of them. Indeed it is a prominent feature of unconscious processes that they are indestructible. In the unconscious nothing can be brought to an end, nothing is past or forgotten. This is brought most vividly home to one in studying the neuroses, and especially hysteria. The unconscious path of thoughts, which leads to discharge in a hysterical attack, immediately becomes traversable once more, when sufficient excitation has accumulated. A humiliation that was experienced thirty years ago acts exactly like a fresh one throughout the thirty years, as soon as it has obtained access to the unconscious sources of emotion. As soon as the memory of it is touched, it springs into life again and shows itself cathected with excitation which finds a motor discharge in an attack. This is precisely the point at which psychotherapy has to intervene. Its task is to make it possible for the unconscious processes to be dealt with finally and be forgotten. For the fading of memories and the emotional weakness of impressions which are no longer recent, which we are inclined to regard as self-evident and to explain as a primary effect of time upon mental memory-traces, are in reality secondary modifications which are only brought about by laborious work. What performs this work is the preconscious, and *psychotherapy can pursue no other course than to bring the Ucs. under the domination of the Pcs.*

[1900a, 1007]

Thus there are two possible outcomes for any particular unconscious excitatory process. Either it may be left to itself, in which case it eventually forces its way through at some point and on this single occasion finds discharge for its excitation in movement; or it may come under the influence of the preconscious, and its excitation, instead of being discharged, may be bound by the preconscious. *This second alternative is the one which occurs in the process of dreaming.* The cathexis from the Pcs. which goes halfway to meet the dream after it has become perceptual, having been directed on to it by the excitation in consciousness, binds the dream's unconscious excitation and makes it powerless to act as a disturbance. If it is true that the dreamer wakes for an instant, yet he really *has* brushed away the fly that was threatening to disturb his sleep. It begins to dawn on us that it actually *is* more expedient and economical to allow the unconscious wish to take its course, to leave the path to regression open to it so that it can construct a dream, and then to bind the dream and dispose of it with a small expenditure of preconscious work - rather than to continue keeping a tight rein on the unconscious throughout the whole period of sleep. It was indeed to be expected that dreaming, even though it may originally have been a process without a useful purpose, would have procured itself some function in the interplay of mental forces. And we can now see what that function is. Dreaming has taken on the task of bringing back under control of the preconscious the excitation in the Ucs. which has been left free; in so doing, it discharges the Ucs. excitation, serves it as a safety valve and at the same time preserves the sleep of the preconscious in return for a small expenditure of waking activity. Thus, like all the other psychical structures in the series of which it is a member, it constitutes a compromise; it is in the service of both of the two systems since it fulfills the two wishes in so far as they are compatible with each other. If we turn back to the 'excretion theory' of dreams put forward by Robert, which I explained on p. 586 ff., we shall see at a glance that in its essence we must accept his account of the *function* of dreams, though differing from him in his premises and in his view of the dream-process itself.¹

[1900a, 1007]
The procedure which the author makes his Zoe adopt for curing her childhood friend's delusion shows a far-reaching similarity - no, a complete agreement in its essence - with a therapeutic method which was introduced into medical practice in 1895 by Dr. Josef Breuer and myself, and to the perfecting of which I have since then devoted myself. This method of treatment, to which Breuer first gave the name of 'cathartic' but which I prefer to describe as 'analytic', consists, as applied to patients suffering from disorders analogous to Hanold's delusion, in bringing to their consciousness, to some extent forcibly, the unconscious whose repression led to their falling ill - exactly as Gradiva did with the repressed memories of their childhood relations. Gradiva, it is true, could carry out this task more easily than a doctor: in several respects she was in what may be described as an ideal position for it. The doctor, who has no pre-existing knowledge of his patient and possesses no conscious memory of what is unconsciously at work in him, must call a complicated technique to his help in order to make up for this disadvantage. He must learn how to infer with great certainty from the conscious associations and communications of the patient what is repressed in him, how to discover his unconscious as it betrays itself behind his conscious words and acts. He then brings about something like what Norbert Hanold grasped at the end of the story when he translated back the name 'Gradiva' into 'Bertgang'. The disorder vanishes while being traced back to its origin; analysis, too, brings simultaneous cure.

[1907a, 1881]

To shorten analytic treatment is a justifiable wish, and its fulfilment, as we shall learn, is being attempted along various lines. Unfortunately, it is opposed by a very important factor, namely, the slowness with which deep-going changes in the mind are accomplished - in the last resort, no doubt, the 'timelessness' of our unconscious processes. When patients are faced with the difficulty of the great expenditure of time required for analysis they not infrequently manage to propose a way out of it. They divide up their ailments and describe some as unbearable, and others as secondary, and then say: 'If only you will relieve me from this one (for instance, a headache or a particular fear) I can deal with the other one on my own in my ordinary life.' In doing this, however, they over-estimate the selective power of analysis. The analyst is certainly able to do a great deal, but he cannot determine beforehand exactly what results he will effect. He sets in motion a process, that of the resolving of existing repressions. He can supervise this process, further it, remove obstacles in its way, and he can undoubtedly vitiate much of it. But on the whole, once begun, it goes its own way and does not allow either the direction it takes or the order in which it picks up its points to be prescribed for it. The analyst's power over the symptoms of the disease may thus be compared to male sexual potency. A man can, it is true, beget a whole child, but even the strongest man cannot create in the female organism a head alone or an arm or a leg; he cannot even prescribe the child's sex. He, too, only sets in motion a highly complicated process, determined by events in the remote past, which ends with the severance of the child from its mother. A neurosis as well has the character of an organism. Its component manifestations are not independent of one another; they condition one another and give one another mutual support. A person suffers from one neurosis only, never from several which have accidentally met together in a single individual. The patient freed, according to his wish, from his one unendurable symptom might easily find that a symptom which had previously been negligible had now increased and grown unendurable. The analyst who wishes the treatment to owe its success as little as possible to its elements of suggestion (i.e. to the transference) will do well to refrain from making use of even the trace of selective influence upon the results of the therapy which may perhaps be open to him. The patients who are bound to be most welcome to him are those who ask him to give them complete health, in so far as that is attainable, and who place as much time at his disposal as is necessary for the process of recovery. Such favourable conditions as these are, of course, to be looked for in only a few cases.

[1913c, 2483]
First and foremost, the initiation of the treatment in itself brings about a change in the patient's conscious attitude to his illness. He has usually been content with lamenting it, despising it as nonsensical and under-estimating its importance; for the rest, he has extended to its manifestations the ostrich-like policy of repression which he adopted towards its origins. Thus it can happen that he does not properly know under what conditions his phobia breaks out or does not listen to the precise wording of his obsessional ideas or does not grasp the actual purpose of his obsessional impulse. The treatment, of course, is not helped by this. He must find the courage to direct his attention to the phenomena of his illness. His illness itself must no longer seem to him contemptible, but must become an enemy worthy of his mettle, a piece of his personality, which has solid ground for its existence and out of which things of value for his future life have to be derived. The way is thus paved from the beginning for a reconciliation with the repressed material which is coming to expression in his symptoms, while at the same time place is found for a certain tolerance for the state of being ill. If this new attitude towards the illness intensifies the conflicts and brings to the fore symptoms which till then had been indistinct, one can easily console the patient by pointing out that these are only necessary and temporary aggravations and that one cannot overcome an enemy who is absent or not within range. The resistance, however, may exploit the situation for its own ends and abuse the licence to be ill. It seems to say: ‘See what happens if I really give way to such things. Was I not right to consign them to repression?’ Young and childish people in particular are inclined to make the necessity imposed by the treatment for paying attention to their illness a welcome excuse for luxuriating in their symptoms.

I have already let it be understood that analytic technique requires of the physician that he should deny to the patient who is craving for love the satisfaction she demands. The treatment must be carried out in abstinence. By this I do not mean physical abstinence alone, nor yet the deprivation of everything that the patient desires, for perhaps no sick person could tolerate this. Instead, I shall state it as a fundamental principle that the patient's need and longing should be allowed to persist in her, in order that they may serve as forces impelling her to do work and to make changes, and that we must beware of appeasing those forces by means of surrogates. And what we could offer would never be anything else than a surrogate, for the patient's condition is such that, until her repressions are removed, she is incapable of getting real satisfaction.

Thus you cannot explain the therapeutic effect of psycho-analysis by its permitting a full sexual life. Look around, then, for something else. I fancy that, while I was rejecting this suggestion of yours, one remark of mine put you on the right track. What we make use of must no doubt be the replacing of what is unconscious by what is conscious, the translation of what is unconscious into what is conscious. Yes, that is it. By carrying what is unconscious on into what is conscious, we lift the repressions, we remove the preconditions for the formation of symptoms, we transform the pathogenic conflict to a normal one for which it must be possible somehow to find a solution. All that we bring about in a patient is this single psychical change: the length to which it is carried is the measure of the help we provide. Where no repressions (or analogous psychical processes) can be undone, our therapy has nothing to expect.
We can express the aim of our efforts in a variety of formulas: making conscious what is unconscious, lifting repressions, filling gaps in the memory - all these amount to the same thing. But perhaps you will be dissatisfied by this admission. You had formed a different picture of the return to health of a neurotic patient - that, after submitting to the tedious hours of a psycho-analysis, he would become another man; but the total result, so it seems, is that he has rather less that is unconscious and rather more that is conscious in him than he had before. The fact is that you are probably under-estimating the importance of an internal change of this kind. The neurotic who is cured has really become another man, though a bottom, of course, he has remained the same; that is to say, he has become what he might have become at best under the most favourable conditions. But that is a very great deal. If you now hear all that has to be done and what efforts it needs to bring about this apparently trivial change in a man's mental life, you will no doubt begin to realize the importance of this difference in psychical levels.

What, then, must we do in order to replace what is unconscious in our patients by what is conscious? There was a time when we thought this was a very simple matter: all that was necessary was for us to discover this unconscious material and communicate it to the patient. But we know already that this was a short-sighted error. Our knowledge about the unconscious material is not equivalent to his knowledge; if we communicate our knowledge to him, he does not receive it instead of his unconscious material but beside it; and that makes very little change in it. We must rather picture this unconscious material topographically, we must look for it in his memory at the place where it became unconscious owing to a repression. The repression must be got rid of - after which the substitution of the conscious material for the unconscious can proceed smoothly. How, then, do we lift a repression of this kind? Here our task enters a second phase. First, the search for the repression and then the removal of the resistance which maintains the repression.

And now for the fact! In a whole number of nervous diseases - in hysteria, anxiety states, obsessional neurosis - our expectation is fulfilled. By searching for the repression in this way, by uncovering the resistances, by pointing out what is repressed, we really succeed in accomplishing our task - that is, in overcoming the resistances, lifting the repression and transforming the unconscious material into conscious. In doing so we gain the clearest impression of the way in which a violent struggle takes place in the patient's mind about the overcoming of each resistance - a normal mental struggle, on the same psychological ground, between the motives which seek to maintain the anticathexis and those which are prepared to give it up. The former are the old motives which in the past put the repression into effect; among the latter are the newly arrived ones which, we may hope, will decide the conflict in our favour. We have succeeded in reviving the old conflict which led to repression and in bringing up for revision the process that was then decided. The new material that we produce includes, first the reminder that the earlier decision led to illness and the promise that a different path will lead to recovery, and, second, the enormous change in all the circumstances that has take place since the time of the original rejection. Then the ego was feeble, infantile, and may perhaps have had grounds for banning the demands of the libido as a danger. To-day it has grown strong and experienced, and moreover has a helper at and in the shape of the doctor. Thus we may expect to lead the revived conflict to a better outcome than that which ended in repression, and, as I have said, in hysteria and in the anxiety and obsessional neuroses success proves us in general to be correct.
But you will now tell me that, no matter whether we call the motive force of our analysis transference or suggestion, there is a risk that the influencing of our patient may make the objective certainty of our findings doubtful. What is advantageous to our therapy is damaging to our researches. This is the objection that is most often raised against psycho-analysis, and it must be admitted that, though it is groundless, it cannot be rejected as unreasonable. If it were justified, psycho-analysis would be nothing more than a particularly well-disguised and particularly effective form of suggestive treatment and we should have to attach little weight to all that it tells us about what influences our lives, the dynamics of the mind or the unconscious. That is what our opponents believe; and in especial they think that we have "talked" the patients into everything relating to the importance of sexual experiences - or even into those experiences themselves - after such notions have grown up in our own depraved imagination. These accusations are contradicted more easily by an appeal to experience than by the help of theory. Anyone who has himself carried out psycho-analyses will have been able to convince himself on countless occasions that it is impossible to make suggestions to a patient in that way. The doctor has no difficulty, of course, in making him a supporter of some particular theory and in thus making him share some possible error of his own. In this respect the patient is behaving like anyone else - like a pupil - but this only affects his intelligence, not his illness. After all, his conflicts will only be successfully solved and his resistances overcome if the anticipatory ideas he is given tally with what is real in him. Whatever in the doctor's conjectures is inaccurate drops out in the course of the analysis; it has to be withdrawn and replaced by something more correct. We endeavour by a careful technique to avoid the occurrence of premature successes due to suggestion; but no harm is done even if they do occur, for we are not satisfied by a first success. We do not regard an analysis as at an end until all the obscurities of the case are cleared up, the gaps in the patient's memory filled in, the precipitating causes of the repressions discovered. We look upon successes that set in too soon as obstacles rather than as a help to the work of analysis; and we put an end to such successes by constantly resolving the transference on which they are based. It is this last characteristic which is the fundamental distinction between analytic and purely suggestive therapy, and which frees the results of analysis from the suspicion of being successes due to suggestion. In every other kind of suggestive treatment the transference is carefully preserved and left untouched; in analysis it is itself subjected to treatment and is dissected in all the shapes in which it appears. At the end of an analytic treatment the transference must itself be cleared away; and if success is then obtained or continues, it rests, not on suggestion, but on the achievement by its means of an overcoming of internal resistances, on the internal change that has been brought about in the patient.

[1916-1917, 3493]
Thus our therapeutic work falls into two phases. In the first, all the libido is forced from the symptoms into the transference and concentrated there; in the second, the struggle is waged around this new object and the libido is liberated from it. The change which is decisive for a favourable outcome is the elimination of repression in this renewed conflict so that the libido cannot withdraw once more from the ego by flight into the unconscious. This is made possible by the alteration of the ego which is accomplished under the influence of the doctor's suggestion. By means of the work of interpretation, which transforms what is unconscious into what is conscious, the ego is enlarged at the cost of this unconscious; by means of instruction, it is made conciliatory towards the libido and inclined to grant it some satisfaction, and its repugnance to the claims of the libido is diminished by the possibility of disposing of a portion of it by sublimation. The more closely events in the treatment coincide with this ideal description, the greater will be the success of the psycho-analytic therapy. It finds its limits in the lack of mobility of the libido, which may refuse to leave its objects, and the rigidity of narcissism, which will not allow transference on to objects to increase beyond certain bounds. Further light may perhaps be thrown on the dynamics of the process of cure if I say that we get hold of the whole of the libido which has been withdrawn from the dominance of the ego by attracting a portion of it on to ourselves by means of the transference.

The psycho-analytic method of treatment is then able to subject this process of repression to revision and to bring about a better solution of the conflict - one that is compatible with health. Unintelligent opposition accuses us of one-sidedness in our estimate of the sexual instincts. 'Human beings have other interests besides sexual ones,' they say. We have not forgotten or denied this for a moment. Our one-sidedness is like that of the chemist, who traces all compounds back to the force of chemical attraction. He is not on that account denying the force of gravity; he leaves that to the physicist to deal with.

We have formulated our task as physicians thus: to bring to the patient's knowledge the unconscious, repressed impulses existing in him, and, for that purpose, to uncover the resistances that oppose this extension of his knowledge about himself. Does the uncovering of these resistances guarantee that they will also be overcome? Certainly not always; but our hope is to achieve this by exploiting the patient's transference to the person of the physician, so as to induce him to adopt our conviction of the inexpediency of the repressive process established in childhood and of the impossibility of conducting life on the pleasure principle. I have set out elsewhere the dynamic conditions prevailing in the fresh conflict through which we lead the patient and which we substitute in him for his previous conflict - that of his illness. I have nothing at the moment to alter in that account.
The work by which we bring the repressed mental material into the patient's consciousness has been called by us psycho-analysis. Why 'analysis' - which means breaking up or separating out, and suggests an analogy with the work carried out by chemists on substances which they find in nature and bring into their laboratories? Because in an important respect there really is an analogy between the two. The patient's symptoms and pathological manifestations, like all his mental activities, are of a highly composite kind; the elements of this compound are at bottom motives, instinctual impulses. But the patient knows nothing of these elementary motives or not nearly enough. We teach him to understand the way in which these highly complicated mental formations are compounded; we trace the symptoms back to the instinctual impulses which motivate them; we point out to the patient these instinctual motives, which are present in his symptoms and of which he has hitherto been unaware, - just as a chemist isolates the fundamental substance, the chemical 'element', out of the salt in which it had been combined with other elements and in which it was unrecognizable. In the same way, as regards those of the patient's mental manifestations that were not considered pathological, we show him that he was only to a certain extent conscious of their motivation - that other instinctual impulses of which he had remained in ignorance had co-operated in producing them.

[1919a, 3629]

Let us at once agree upon what we mean by this activity. We have defined our therapeutic task as consisting of two things: making conscious the repressed material and uncovering the resistances. In that we are active enough, to be sure. But are we to leave it to the patient to deal alone with the resistances we have pointed out to him? Can we give him no other help in this besides the stimulus he gets from the transference? Does it not seem natural that we should help him in another way as well, by putting him into the mental situation most favourable to the solution of the conflict which is our aim? After all, what he can achieve depends, too, on a combination of external circumstances. Should we hesitate to alter this combination by intervening in a suitable manner? I think activity of such a kind on the part of the analysing physician is unobjectionable and entirely justified.

[1919a, 3631]

Twenty five years of intense work have had as their result that the immediate aims of psycho-analytic technique are quite other to-day than they were at the outset. At first the analysing physician could do no more than discover the unconscious material that was concealed from the patient, put it together, and, at the right moment, communicate it to him. Psychoanalysis was then first and foremost an art of interpreting. Since this did not solve the therapeutic problem, a further aim quickly came in view: to oblige the patient to confirm the analyst's construction from his own memory. In that endeavour the chief emphasis lay upon the patient's resistances: the art consisted now in uncovering these as quickly as possible, in pointing them out to the patient and in inducing him by human influence - this was where suggestion operating as 'transference' played its part - to abandon his resistances.

[1920g, 3723]
But it became ever clearer that the aim which had been set up - the aim that what was unconscious should become conscious - is not completely attainable by that method. The patient cannot remember the whole of what is repressed in him, and what he cannot remember may be precisely the essential part of it. Thus he acquires no sense of conviction of the correctness of the construction that has been communicated to him. He is obliged to repeat the repressed material as a contemporary experience instead of, as the physician would prefer to see, remembering it as something belonging to the past.¹ These reproductions, which emerge with such unwished-for exactitude, always have as their subject some portion of infantile sexual life - of the Oedipus complex, that is, and its derivatives; and they are invariably acted out in the sphere of the transference, of the patient's relation to the physician. When things have reached this stage, it may be said that the earlier neurosis has now been replaced by a fresh, 'transference neurosis'. It has been the physician's endeavour to keep this transference neurosis within the narrowest limits: to force as much as possible into the channel of memory and to allow as little as possible to emerge as repetition. The ratio between what is remembered and what is reproduced varies from case to case. The physician cannot as a rule spare his patient this phase of the treatment. He must get him to re-experience some portion of his forgotten life, but must see to it, on the other hand, that the patient retains some degree of aloofness, which will enable him, in spite of everything, to recognize that what appears to be reality is in fact only a reflection of a forgotten past. If this can be successfully achieved, the patient's sense of conviction is won, together with the therapeutic success that is dependent on it.

[1920g, 3723]

Comparison between Psycho-Analysis and Hypnotic and Suggestive Methods. - Psycho-analytic procedure differs from all methods making use of suggestion, persuasion, etc., in that it does not seek to suppress by means of authority any mental phenomenon that may occur in the patient. It endeavours to trace the causation of the phenomenon and to remove it by bringing about a permanent modification in the conditions that led to it. In psycho-analysis the suggestive influence which is inevitably exercised by the physician is diverted on to the task assigned to the patient of overcoming his resistances, that is, of carrying forward the curative process. Any danger of falsifying the products of a patient's memory by suggestion can be avoided by prudent handling of the technique; but in general the arousing of resistances is a guarantee against the misleading effects of suggestive influence. It may be laid down that the aim of the treatment is to remove the patient's resistances and to pass his repressions in review and thus to bring about the most far-reaching unification and strengthening of his ego, to enable him to save the mental energy which he is expending upon internal conflicts, to make the best of him that his inherited capacities will allow and so to make him as efficient and as capable of enjoyment as is possible. The removal of the symptoms of the illness is not specifically aimed at, but is achieved, as it were, as a by-product if the analysis is properly carried through. The analyst respects the patient's individuality and does not seek to remould him in accordance with his own - that is, according to the physician's - personal ideals; he is glad to avoid giving advice and instead to arouse the patient's power of initiative.

[1923a, 3927]
Criticisms and Misunderstandings of Psycho-Analysis. - Most of what is brought up against psycho-analysis, even in scientific works, is based upon insufficient information which in its turn seems to be determined by emotional resistances. Thus it is a mistake to accuse psycho-analysis of 'pan-sexualism' and to allege that it derives all mental occurrences from sexuality and traces them all back to it. On the contrary, psycho-analysis has from the very first distinguished the sexual instincts from others which it has provisionally termed 'ego instincts'. It has never dreamt of trying to explain 'everything', and even the neuroses it has traced back not to sexuality alone but to the conflict between the sexual impulses and the ego. In psycho-analysis (unlike the works of C. G. Jung) the term 'libido' does not mean psychical energy in general but the motive force of the sexual instincts. Some assertions, such as that every dream is the fulfilment of a sexual wish, have never been maintained by it at all. The charge of one-sidedness made against psycho-analysis, which, as the science of the unconscious mind, has its own definite and restricted field of work, is as inapplicable as it would be if it were made against chemistry. To believe that psycho-analysis seeks a cure for neurotic disorders by giving a free rein to sexuality is a serious misunderstanding which can only be excused by ignorance. The making conscious of repressed sexual desires in analysis makes it possible, on the contrary, to obtain a mastery over them which the previous repression had been unable to achieve. It can more truly be said that analysis sets the neurotic free from the chains of his sexuality. Moreover, it is quite unscientific to judge analysis by whether it is calculated to undermine religion, authority and morals; for, like all sciences, it is entirely non-tendentious and has only a single aim - namely to arrive at a consistent view of one portion of reality. Finally, one can only characterize as simple-minded the fear which is sometimes expressed that all the highest goods of humanity, as they are called - research, art, love, ethical and social sense - will lose their value or their dignity because psycho-analysis is in a position to demonstrate their origin in elementary and animal instinctual impulses.

[1923a, 3928]

But we have arrived at the term or concept of the unconscious along another path, by considering certain experiences in which mental dynamics play a part. We have found - that is, we have been obliged to assume - that very powerful mental processes or ideas exist (and here a quantitative or economic factor comes into question for the first time) which can produce all the effects in mental life that ordinary ideas do (including effects that can in their turn become conscious as ideas), though they themselves do not become conscious. It is unnecessary to repeat in detail here what has been explained so often before. It is enough to say that at this point psycho-analytic theory steps in and asserts that the reason why such ideas cannot become conscious is that a certain force opposes them, that otherwise they could become conscious, and that it would then be apparent how little they differ from other elements which are admittedly psychical. The fact that in the technique of psycho-analysis a means has been found by which the opposing force can be removed and the ideas in question made conscious renders this theory irrefutable. The state in which the ideas existed before being made conscious is called by us repression, and we assert that the force which instituted the repression and maintains it is perceived as resistance during the work of analysis.

[1923b, 3948]
In the further course of psycho-analytic work, however, even these distinctions have proved to be inadequate and, for practical purposes, insufficient. This has become clear in more ways than one; but the decisive instance is as follows. We have formed the idea that in each individual there is a coherent organization of mental processes; and we call this his ego. It is to this ego that consciousness is attached; the ego controls the approaches to motility - that is, to the discharge of excitations into the external world; it is the mental agency which supervises all its own constituent processes, and which goes to sleep at night, though even then it exercises the censorship on dreams. From this ego proceed the repressions, too, by means of which it is sought to exclude certain trends in the mind not merely from consciousness but also from other forms of effectiveness and activity. In analysis these trends which have been shut out stand in opposition to the ego, and the analysis is faced with the task of removing the resistances which the ego displays against concerning itself with the repressed. Now we find during analysis that, when we put certain tasks before the patient, he gets into difficulties; his associations fail when they should be coming near the repressed. We then tell him that he is dominated by a resistance; but he is quite unaware of the fact, and, even if he guesses from his unpleasurable feelings that a resistance is now at work in him, he does not know what it is or how to describe it. Since, however, there can be no question but that this resistance emanates from his ego and belongs to it, we find ourselves in an unforeseen situation. We have come upon something in the ego itself which is also unconscious, which behaves exactly like the repressed - that is, which produces powerful effects without itself being conscious and which requires special work before it can be made conscious. From the point of view of analytic practice, the consequence of this discovery is that we land in endless obscurities and difficulties if we keep to our habitual forms of expression and try, for instance, to derive neuroses from a conflict between the conscious and the unconscious. We shall have to substitute for this antithesis another, taken from our insight into the structural conditions of the mind - the antithesis between the coherent ego and the repressed which is split off from it.¹

[1923b, 3951]

The theory of repression became the corner-stone of our understanding of the neuroses. A different view had now to be taken of the task of therapy. Its aim was no longer to 'abreact' an affect which had got on to the wrong lines but to uncover repressions and replace them by acts of judgement which might result either in the accepting or in the condemning of what had formerly been repudiated. I showed my recognition of the new situation by no longer calling my method of investigation and treatment catharsis but psycho-analysis.

[1925d, 4207]
It may seem surprising that this method of free association, carried out subject to the observation of the fundamental rule of psycho-analysis, should have achieved what was expected of it, namely the bringing into consciousness of the repressed material which was held back by resistances. We must, however, bear in mind that free association is not really free. The patient remains under the influence of the analytic situation even though he is not directing his mental activities on to a particular subject. We shall be justified in assuming that nothing will occur to him that has not some reference to that situation. His resistance against reproducing the repressed material will now be expressed in two ways. Firstly it will be shown by critical objections; and it was to deal with these that the fundamental rule of psycho-analysis was invented. But if the patient observes that rule and so overcomes his reticences, the resistance will find another means of expression. It will so arrange it that the repressed material itself will never occur to the patient but only something which approximates to it in an allusive way; and the greater the resistance, the more remote from the actual idea that the analyst is in search of will be the substitutive association which the patient has to report. The analyst, who listens composedly but without any constrained effort to the stream of associations and who, from his experience, has a general notion of what to expect, can make use of the material brought to light by the patient according to two possibilities. If the resistance is slight he will be able from the patient's allusions to infer the unconscious material itself; or if the resistance is stronger he will be able to recognize its character from the associations, as they seem to become more remote from the topic in hand, and will explain it to the patient. Uncovering the resistance, however, is the first step towards overcoming it. Thus the work of analysis involves an art of interpretation, the successful handling of which may require tact and practice but which is not hard to acquire. But it is not only in the saving of labour that the method of free association has an advantage over the earlier method. It exposes the patient to the least possible amount of compulsion, it never allows of contact being lost with the actual current situation, it guarantees to a great extent that no factor in the structure of the neurosis will be overlooked and that nothing will be introduced into it by the expectations of the analyst. It is left to the patient in all essentials to determine the course of the analysis and the arrangement of the material; any systematic handling of particular symptoms or complexes thus becomes impossible. In complete contrast to what happened with hypnosis and with the urging method, interrelated material makes its appearance at different times and at different points in the treatment. To a spectator, therefore - though in fact there must be none - an analytic treatment would seem completely obscure.

That this is a correct account of fixation upon repression and of the retention of danger-situations that are no longer present-day ones is confirmed by the fact of analytic therapy - a fact which is modest enough in itself but which can hardly be overrated from a theoretical point of view. When, in analysis, we have given the ego assistance which is able to put it in a position to lift its repressions, it recovers its power over the repressed id and can allow the instinctual impulses to run their course as though the old situations of danger no longer existed. What we can do in this way tallies with what can be achieved in other fields of medicine; for as a rule our therapy must be content with bringing about more quickly, more reliably and with less expenditure of energy than would otherwise be the case the good result which in favourable circumstances would have occurred of itself.
It is easy now to describe our therapeutic aim. We try to restore the ego, to free it from its restrictions, and to give it back the command over the id which it has lost owing to its early repressions. It is for this one purpose that we carry out analysis, our whole technique is directed to this aim. We have to seek out the repressions which have been set up and to urge the ego to correct them with our help and to deal with conflicts better than by an attempt at flight. Since these repressions belong to the very early years of childhood, the work of analysis leads us, too, back to that period. Our path to these situations of conflict, which have for the most part been forgotten and which we try to revive in the patient's memory, is pointed out to us by his symptoms, dreams and free associations. These must, however, first be interpreted - translated for, under the influence of the psychology of the id, they have assumed forms of expression that are strange to our comprehension. We may assume that whatever associations, thoughts and memories the patient is unable to communicate to us without internal struggles are in some way connected with the repressed material or are its derivatives. By encouraging the patient to disregard his resistances to telling us these things, we are educating his ego to overcome its inclination towards attempts at flight and to tolerate an approach to what is repressed. In the end, if the situation of the repression can be successfully reproduced in his memory, his compliance will be brilliantly rewarded. The whole difference between his age then and now works in his favour; and the thing from which his childish ego fled in terror will often seem to his adult and strengthened ego no more than child's play.

'I will add that. Thereupon he begins to talk and I listen. And what then? I infer from what he tells me the kind of impressions, experiences and wishes which he has repressed because he came across them at a time when his ego was still feeble and was afraid of them instead of dealing with them. When he has learnt this from me, he puts himself back in the old situations and with my help he manages better. The limitations to which his ego was tied then disappear, and he is cured. Is that right?'

When one really practises analysis one learns all kinds of things besides. For instance: you would not find it at all such a simple matter to deduce from what the patient tells you the experiences he has forgotten and the instinctual impulses he has repressed. He says something to you which at first means as little to you as it does to him. You will have to make up your mind to look at the material which he delivers to you in obedience to the rule in a quite special way: as though it were ore, perhaps, from which its content of precious metal has to be extracted by a particular process. You will be prepared, too, to work over many tons of ore which may contain but little of the valuable material you are in search of. Here we should have a first reason for the prolonged character of the treatment.

That is a question of tact, which can become more refined with experience. You will be making a bad mistake if, in an effort, perhaps, at shortening the analysis, you throw your interpretations at the patient's head as soon as you have found them. In that way you will draw expressions of resistance, rejection and indignation from him; but you will not enable his ego to master his repressed material. The formula is: to wait till he has come so near to the repressed material that he has only a few more steps to take under the lead of the interpretation you propose.
(3) By 'transference' is meant a striking peculiarity of neurotics. They develop towards their physician emotional relations, both of an affectionate and hostile character, which are not based upon the actual situation but are derived from their relations to their parents (the Oedipus complex). Transference is a proof of the fact that adults have not overcome their former childish dependence; it coincides with the force which has been named 'suggestion'; and it is only by learning to make use of it that the physician is enabled to induce the patient to overcome his internal resistances and do away with his repressions. Thus psycho-analytic treatment acts as a second education of the adult, as a corrective to his education as a child.

[1926f, 4406]

You will not expect me to have much to tell you that is new about the id apart from its new name. It is the dark, inaccessible part of our personality; what little we know of it we have learnt from our study of the dream-work and of the construction of neurotic symptoms, and most of that is of a negative character and can be described only as a contrast to the ego. We approach the id with analogies: we call it a chaos, a cauldron full of seething excitations. We picture it as being open at its end to somatic influences, and as there taking up into itself instinctual needs which find their psychical expression in it, but we cannot say in what substratum. It is filled with energy reaching it from the instincts, but it has no organization, produces no collective will, but only a striving to bring about the satisfaction of the instinctual needs subject to the observance of the pleasure principle. The logical laws of thought do not apply in the id, and this is true above all of the law of contradiction. Contrary impulses exist side by side, without cancelling each other out or diminishing each other: at the most they may converge to form compromises under the dominating economic pressure towards the discharge of energy. There is nothing in the id that could be compared with negation; and we perceive with surprise an exception to the philosophical theorem that space and time are necessary forms of our mental acts. There is nothing in the id that corresponds to the idea of time; there is no recognition of the passage of time, and - a thing that is most remarkable and awaits consideration in philosophical thought - no alteration in its mental processes is produced by the passage of time. Wishful impulses which have never passed beyond the id, but impressions, too, which have been sunk into the id by repression, are virtually immortal; after the passage of decades they behave as though they had just occurred. They can only be recognized as belonging to the past, can only lose their importance and be deprived of their cathexis of energy, when they have been made conscious by the work of analysis, and it is on this that the therapeutic effect of analytic treatment rests to no small extent.

[1933a, 4682]
With the mention of resistance we have reached the second and more important part of our task. We have already learnt that the ego protects itself against the invasion of undesired elements from the unconscious and repressed id by means of anticathexes, which must remain intact if it is to function normally. The more hard-pressed the ego feels, the more convulsively it clings (as though in a fright) to these anticathexes, in order to protect what remains of itself from further irruptions. But this defensive purpose does not by any means accord with the aims of our treatment. What we desire, on the contrary, is that the ego, emboldened by the certainty of our help, shall dare to take the offensive in order to reconquer what has been lost. And it is here that we become aware of the strength of these anticathexes in the form of resistances to our work. The ego draws back in alarm from such undertakings, which seem dangerous and threaten unpleasure; it must be constantly encouraged and soothed if it is not to fail us. This resistance, which persists throughout the whole treatment and is renewed at every fresh piece of work, is known, not quite correctly, as the resistance due to repression. We shall find that it is not the only one that faces us. It is interesting to notice that in this situation the party-divisions are to some extent reversed: for the ego struggles against our instigation, while the unconscious, which is ordinarily our opponent, comes to our help, since it has a natural 'upward drive' and desires nothing better than to press forward across its settled frontiers into the ego and so to consciousness. The struggle which develops, if we gain our end and can induce the ego to overcome its resistances, is carried through under our direction and with our assistance. Its outcome is a matter of indifference: whether it results in the ego accepting, after a fresh examination, an instinctual demand which it has hitherto rejected, or whether it dismisses it once more, this time for good and all. In either case a permanent danger has been disposed of, the compass of the ego has been extended and a wasteful expenditure of energy has been made unnecessary.

[1940a [1938], 4988]
Let us once more glance over the situation which we have reached in our attempt at bringing help to the patient's neurotic ego. That ego is no longer able to fulfil the task set it by the external world (including human society). Not all of its experiences are at its disposal, a large proportion of its store of memories have escaped it. Its activity is inhibited by strict prohibitions from the super-ego, its energy is consumed in vain attempts at fending off the demands of the id. Beyond this, as a result of continuous irruptions by the id, its organization is impaired, it is no longer capable of any proper synthesis, it is torn by mutually opposed urges, by unsettled conflicts and by unsolved doubts. To start with, we get the patient's thus weakened ego to take part in the purely intellectual work of interpretation, which aims at provisionally filling the gaps in his mental assets, and to transfer to us the authority of his super-ego; we encourage it to take up the struggle over each individual demand made by the id and to conquer the resistances which arise in connection with it. At the same time we restore order in the ego by detecting the material and urges which have forced their way in from the unconscious, and expose them to criticism by tracing them back to their origin. We serve the patient in various functions, as an authority and a substitute for his parents, as a teacher and educator; and we have done the best for him if, as analysts, we raise the mental processes in his ego to a normal level, transform what has become unconscious and repressed into preconscious material and thus return it once more to the possession of his ego. On the patient's side a few rational factors work in our favour, such as the need for recovery which has its motive in his sufferings, and the intellectual interest that we may awaken in him in the theories and revelations of psycho-analysis; but of far greater force is the positive transference with which he meets us. Fighting against us, on the other hand, are the negative transference, the ego's resistance due to repression (that is, its unpleasure at having to lay itself open to the hard work imposed on it), the sense of guilt arising from its relation to the super-ego and the need to be ill due to deep-going changes in the economics of his instincts. The share taken by the last two factors decides whether the case is to be regarded as slight or severe. Apart from these, a few other factors may be discerned as having a favourable or unfavourable bearing. A certain psychical inertia, a sluggishness of the libido, which is unwilling to abandon its fixations cannot be welcome to us; the patient's capacity for sublimating his instincts plays a large part and so does his capacity for rising above the crude life of the instincts; so, too, does the relative power of his intellectual functions.

[1940a [1938], 4990]

We must first of all decide what is meant by the ambiguous phrase 'the end of an analysis'. From a practical standpoint it is easy to answer. An analysis is ended when the analyst and the patient cease to meet each other for the analytic session. This happens when two conditions have been approximately fulfilled: first, that the patient shall no longer be suffering from his symptoms and shall have overcome his anxieties and his inhibitions; and secondly, that the analyst shall judge that so much repressed material has been made conscious, so much that was unintelligible has been explained, and so much internal resistance conquered, that there is no need to fear a repetition of the pathological processes concerned. If one is prevented by external difficulties from reaching this goal, it is better to speak of an incomplete analysis rather than of an unfinished one.

[1937c, 5017]
The other meaning of the ‘end’ of an analysis is much more ambitious. In this sense of it, what we are asking is whether the analyst has had such a far-reaching influence on the patient that no further change could be expected to take place in him if his analysis were continued. It is as though it were possible by means of analysis to attain to a level of absolute psychical normality - a level, moreover, which we could feel confident would be able to remain stable, as though, perhaps, we had succeeded in resolving every one of the patient's repressions and in filling in all the gaps in his memory. We may first consult our experience to enquire whether such things do in fact happen, and then turn to our theory to discover whether there is any possibility of their happening.

[1937c, 5017]

At the moment, however, we are not concerned with the pathogenic role of the defensive mechanisms. What we are trying to discover is what influence the alteration of the ego which corresponds to them has upon our therapeutic efforts. The material for an answer to this question is given in the volume by Anna Freud to which I have already referred. The essential point is that the patient repeats these modes of reaction during the work of analysis as well, that he produces them before our eyes, as it were. In fact, it is only in this way that we get to know them. This does not mean that they make analysis impossible. On the contrary, they constitute half of our analytic task. The other half, the one which was first tackled by analysis in its early days, is the uncovering of what is hidden in the id. During the treatment our therapeutic work is constantly swinging backwards and forwards like a pendulum between a piece of id-analysis and a piece of ego-analysis. In the one case we want to make something from the id conscious, in the other we want to correct something in the ego. The crux of the matter is that the defensive mechanisms directed against former danger recur in the treatment as resistances against recovery. It follows from this that the ego treats recovery itself as a new danger.

[1937c, 5034]
The therapeutic effect depends on making conscious what is repressed, in the widest sense of the word, in the id. We prepare the way for this making conscious by interpretations and constructions, but we have interpreted only for ourselves not for the patient so long as the ego holds on to its earlier defences and does not give up its resistances. Now these resistances, although they belong to the ego, are nevertheless unconscious and in some sense separated off within the ego. The analyst recognizes them more easily than he does the hidden material in the id. One might suppose that it would be sufficient to treat them like portions of the id and, by making them conscious, bring them into connection with the rest of the ego. In this way, we should suppose, one half of the task of analysis would be accomplished; we should not reckon on meeting with a resistance against the uncovering of resistances. But what happens is this. During the work on the resistances the ego withdraws - with a greater or less degree of seriousness - from the agreement on which the analytic situation is founded. The ego ceases to support our efforts at uncovering the id; it opposes them, disobeys the fundamental rule of analysis, and allows no further derivatives of the repressed to emerge. We cannot expect the patient to have a strong conviction of the curative power of analysis. He may have brought along with him a certain amount of confidence in his analyst, which will be strengthened to an effective point by the factors of the positive transference which will be aroused in him. Under the influence of the unpleasurable impulses which he feels as a result of the fresh activation of his defensive conflicts, negative transferences may now gain the upper hand and completely annul the analytic situation. The patient now regards the analyst as no more than a stranger who is making disagreeable demands on him, and he behaves towards him exactly like a child who does not like the stranger and does not believe anything he says. If the analyst tries to explain to the patient one of the distortions made by him for the purposes of defence, and to correct it, he finds him uncomprehending and inaccessible to sound arguments. Thus we see that there is a resistance against the uncovering of resistances, and the defensive mechanisms really do deserve the name which we gave them originally, before they had been more closely examined. They are resistances not only to the making conscious of contents of the id, but also to the analysis as a whole, and thus to recovery.

[1937c, 5034]

It is familiar ground that the work of analysis aims at inducing the patient to give up the repressions (using the word in the widest sense) belonging to his early development and to replace them by reactions of a sort that would correspond to a psychically mature condition. With this purpose in view he must be brought to recollect certain experiences and the affective impulses called up by them which he has for the time being forgotten. We know that his present symptoms and inhibitions are the consequences of repressions of this kind: thus that they are a substitute for these things that he has forgotten. What sort of material does he put at our disposal which we can make use of to put him on the way to recovering the lost memories? All kinds of things. He gives us fragments of these memories in his dreams, invaluable in themselves but seriously distorted as a rule by all the factors concerned in the formation of dreams. Again, he produces ideas, if he gives himself up to ‘free association’, in which we can discover allusions to the repressed experiences and derivatives of the suppressed affective impulses as well as of the reactions against them. And, finally, there are hints of repetitions of the affects belonging to the repressed material to be found in actions performed by the patient, some fairly important, some trivial, both inside and outside the analytic situation. Our experience has shown that the relation of transference, which becomes established towards the analyst, is particularly calculated to favour the return of these emotional connections. It is out of such raw material - if we may so describe it - that we have to put together what we are in search of.

[1937d, 5050]
What we are in search of is a picture of the patient's forgotten years that shall be alike trustworthy and in all essential respects complete. But at this point we are reminded that the work of analysis consists of two quite different portions, that it is carried on in two separate localities, that it involves two people, to each of whom a distinct task is assigned. It may for a moment seem strange that such a fundamental fact should not have been pointed out long ago; but it will immediately be perceived that there was nothing being kept back in this, that it is a fact which is universally known and, as it were, self-evident and is merely being brought into relief here and separately examined for a particular purpose. We all know that the person who is being analysed has to be induced to remember something that has been experienced by him and repressed; and the dynamic determinants of this process are so interesting that the other portion of the work, the task performed by the analyst, has been pushed into the background. The analyst has neither experienced nor repressed any of the material under consideration; his task cannot be to remember anything. What then is his task? His task is to make out what has been forgotten from the traces which it has left behind or, more correctly, to construct it. The time and manner in which he conveys his constructions to the person who is being analysed, as well as the explanations with which he accompanies them, constitute the link between the two portions of the work of analysis, between his own part and that of the patient.

[1937d, 5050]
It is easy now to describe our therapeutic aim. We try to restore the ego, to free it from its restrictions, and to give it back the command over the id which it has lost owing to its early repressions. It is for this one purpose that we carry out analysis, our whole technique is directed to this aim. We have to seek out the repressions which have been set up and to urge the ego to correct them with our help and to deal with conflicts better than by an attempt at flight. Since these repressions belong to the very early years of childhood, the work of analysis leads us, too, back to that period. Our path to these situations of conflict, which have for the most part been forgotten and which we try to revive in the patient's memory, is pointed out to us by his symptoms, dreams and free associations. These must, however, first be interpreted - translated - for, under the influence of the psychology of the id, they have assumed forms of expression that are strange to our comprehension. We may assume that whatever associations, thoughts and memories the patient is unable to communicate to us without internal struggles are in some way connected with the repressed material or are its derivatives. By encouraging the patient to disregard his resistances to telling us these things, we are educating his ego to overcome its inclination towards attempts at flight and to tolerate an approach to what is repressed. In the end, if the situation of the repression can be successfully reproduced in his memory, his compliance will be brilliantly rewarded. The whole difference between his age then and now works in his favour; and the thing from which his childish ego fled in terror will often seem to his adult and strengthened ego no more than child's play.

[1926e, 4348]
That this is a correct account of fixation upon repression and of the retention of danger-
situations that are no longer present-day ones is confirmed by the fact of analytic therapy - a
fact which is modest enough in itself but which can hardly be overrated from a theoretical point
of view. When, in analysis, we have given the ego assistance which is able to put it in a position
to lift its repressions, it recovers its power over the repressed id and can allow the instinctual
impulses to run their course as though the old situations of danger no longer existed. What we
can do in this way tallies with what can be achieved in other fields of medicine; for as a rule our
therapy must be content with bringing about more quickly, more reliably and with less
expenditure of energy than would otherwise be the case the good result which in favourable
circumstances would have occurred of itself.

[1926d, 4308]

It is easy now to describe our therapeutic aim. We try to restore the ego, to free it from its
restrictions, and to give it back the command over the id which it has lost owing to its early
repressions. It is for this one purpose that we carry out analysis, our whole technique is directed
to this aim. We have to seek out the repressions which have been set up and to urge the ego to
correct them with our help and to deal with conflicts better than by an attempt at flight. Since
these repressions belong to the very early years of childhood, the work of analysis leads us,
too, back to that period. Our path to these situations of conflict, which have for the most part
been forgotten and which we try to revive in the patient's memory, is pointed out to us by his
symptoms, dreams and free associations. These must, however, first be interpreted - translated
- for, under the influence of the psychology of the id, they have assumed forms of expression
that are strange to our comprehension. We may assume that whatever associations, thoughts
and memories the patient is unable to communicate to us without internal struggles are in some
way connected with the repressed material or are its derivatives. By encouraging the patient to
disregard his resistances to telling us these things, we are educating his ego to overcome its
inclination towards attempts at flight and to tolerate an approach to what is repressed. In the
end, if the situation of the repression can be successfully reproduced in his memory, his
compliance will be brilliantly rewarded. The whole difference between his age then and now
works in his favour; and the thing from which his childish ego fled in terror will often seem to his
adult and strengthened ego no more than child's play.

[1926e, 4348]

'I will add that. Thereupon he begins to talk and I listen. And what then? I infer from what he
tells me the kind of impressions, experiences and wishes which he has repressed because he
came across them at a time when his ego was still feeble and was afraid of them instead of
dealing with them. When he has learnt this from me, he puts himself back in the old situations
and with my help he manages better. The limitations to which his ego was tied then disappear,
and he is cured. Is that right?'

[1926e, 4360]

That is a question of tact, which can become more refined with experience. You will be
making a bad mistake if, in an effort, perhaps, at shortening the analysis, you throw your
interpretations at the patient's head as soon as you have found them. In that way you will draw
expressions of resistance, rejection and indignation from him; but you will not enable his ego to
master his repressed material. The formula is: to wait till he has come so near to the repressed
material that he has only a few more steps to take under the lead of the interpretation you
propose.

[1926e, 4362]
Again, I attach no great importance to the argument that a lay analyst, because he must be prepared to consult a doctor, will have no authority in the eyes of his patients and will be treated with no more respect than such people as bone-setters or masseurs. Once again, the analogy is an imperfect one - quite apart from the fact that what governs patients in their recognition of authority is usually their emotional transference and that the possession of a medical diploma does not impress them nearly so much as doctors believe. A professional lay analyst will have no difficulty in winning as much respect as is due to a secular pastoral worker. Indeed, the words, 'secular pastoral worker', might well serve as a general formula for describing the function which the analyst, whether he is a doctor or a layman, has to perform in his relation to the public. Our friends among the protestant clergy, and more recently among the catholic clergy as well, are often able to relieve their parishioners of the inhibitions of their daily life by confirming their faith - after having first offered them a little analytic information about the nature of their conflicts. Our opponents, the Adlerian 'individual psychologists', endeavour to produce a similar result in people who have become unstable and inefficient by arousing their interest in the social community after having first thrown some light upon a single corner of their mental life and shown them the part played in their illness by their egoistic and distrustful impulses. Both of these procedures, which derive their power from being based on analysis, have their place in psychotherapy. We who are analysts set before us as our aim the most complete and profoundest possible analysis of whoever may be our patient. We do not seek to bring him relief by receiving him into the catholic, protestant or socialist community. We seek rather to enrich him from his own internal sources, by putting at the disposal of his ego those energies which, owing to repression, are inaccessibly confined in his unconscious, as well as those which his ego is obliged to squander in the fruitless task of maintaining these repressions. Such activity as this is pastoral work in the best sense of the words. Have we set ourselves too high an aim? Are the majority of our patients worth the pains that this work requires of us? Would it not be more economical to prop up their weaknesses from without rather than to rebuild them from within? I cannot say; but there is something else that I do know. In psycho-analysis there has existed from the very first an inseparable bond between cure and research. Knowledge brought therapeutic success. It was impossible to treat a patient without learning something new; it was impossible to gain fresh insight without perceiving its beneficent results. Our analytic procedure is the only one in which this precious conjunction is assured. It is only by carrying on our analytic pastoral work that we can deepen our dawning comprehension of the human mind. This prospect of scientific gain has been the proudest and happiest feature of analytic work. Are we to sacrifice it for the sake of any considerations of a practical sort? [1926e, 4396]
And here is another warning, to conclude these remarks, which have certainly been exacting and not, perhaps, very illuminating. In thinking of this division of the personality into an ego, a super-ego and an id, you will not, of course, have pictured sharp frontiers like the artificial ones drawn in political geography. We cannot do justice to the characteristics of the mind by linear outlines like those in a drawing or in primitive painting, but rather by areas of colour melting into one another as they are presented by modern artists. After making the separation we must allow what we have separated to merge together once more. You must not judge too harshly a first attempt at giving a pictorial representations of something so intangible as psychical processes. It is highly probable that the development of these divisions is subject to great variations in different individuals; it is possible that in the course of actual functioning they may change and go through a temporary phase of involution. Particularly in the case of what is phylogenetically the last and most delicate of these divisions - the differentiation between the ego and the super-ego - something of the sort seems to be true. There is no question but that the same thing results from psychical illness. It is easy to imagine, too, that certain mystical practices may succeed in upsetting the normal relations between the different regions of the mind, so that, for instance, perception may be able to grasp happenings in the depths of the ego and in the id which were otherwise inaccessible to it. It may safely be doubted, however, whether this road will lead us to the ultimate truths from which salvation is to be expected. Nevertheless it may be admitted that the therapeutic efforts of psycho-analysis have chosen a similar line of approach. Its intention is, indeed, to strengthen the ego, to make it more independent of the super-ego, to widen its field of perception and enlarge its organization, so that it can appropriate fresh portions of the id. Where id was, there ego shall be. It is a work of culture - not unlike the draining of the Zuider Zee.

[1933a, 4687]

Our plan of cure is based on these discoveries. The ego is weakened by the internal conflict and we must go to its help. The position is like that in a civil war which has to be decided by the assistance of an ally from outside. The analytic physician and the patient's weakened ego, basing themselves on the real external world, have to band themselves together into a party against the enemies, the instinctual demands of the id and the conscientious demands of the super-ego. We form a pact with each other. The sick ego promises us the most complete candour - promises, that is, to put at our disposal all the material which its self-perception yields it; we assure the patient of the strictest discretion and place at his service our experience in interpreting material that has been influenced by the unconscious. Our knowledge is to make up for his ignorance and to give his ego back its mastery over lost provinces of his mental life. This pact constitutes the analytic situation.

[1940a [1938], 4983]
The method by which we strengthen the weakened ego has as a starting-point an extending of its self-knowledge. That is not, of course, the whole story but it is a first step. The loss of such knowledge signifies for the ego a surrender of power and influence; it is the first tangible sign that it is being hemmed in and hampered by the demands of the id and the super-ego. Accordingly, the first part of the help we have to offer is intellectual work on our side and encouragement to the patient to collaborate in it. This first kind of activity, as we know, is intended to pave the way to another, more difficult, task. We shall not lose sight of the dynamic element in this task, even during its preliminary stage. We gather the material for our work from a variety of sources - from what is conveyed to us by the information given us by the patient and by his free associations, from what he shows us in his transferences, from what we arrive at by interpreting his dreams and from what he betrays by his slips or parapraxes. All this material helps us to make constructions about what happened to him and has been forgotten as well as about what is happening in him now without his understanding it. But in all this we never fail to make a strict distinction between our knowledge and his knowledge. We avoid telling him at once things that we have often discovered at an early stage, and we avoid telling him the whole of what we think we have discovered. We reflect carefully over when we shall impart the knowledge of one of our constructions to him and we wait for what seems to us the suitable moment - which it is not always easy to decide. As a rule we put off telling him of a construction or explanation till he himself has so nearly arrived at it that only a single step remains to be taken, though that step is in fact the decisive synthesis. If we proceeded in another way and overwhelmed him with our interpretations before he was prepared for them, our information would either produce no effect or it would provoke a violent outbreak of resistance which would make the progress of our work more difficult or might even threaten to stop it altogether. But if we have prepared everything properly, it often happens that the patient will at once confirm our construction and himself recollect the internal or external event which he had forgotten. The more exactly the construction coincides with the details of what has been forgotten the easier will it be for him to assent. On that particular matter our knowledge will then have become his knowledge as well.

[1940a [1938], 4987]
With the mention of resistance we have reached the second and more important part of our task. We have already learnt that the ego protects itself against the invasion of undesired elements from the unconscious and repressed id by means of anticathexes, which must remain intact if it is to function normally. The more hard-pressed the ego feels, the more convulsively it clings (as though in a fright) to these anticathexes, in order to protect what remains of itself from further irruptions. But this defensive purpose does not by any means accord with the aims of our treatment. What we desire, on the contrary, is that the ego, emboldened by the certainty of our help, shall dare to take the offensive in order to reconquer what has been lost. And it is here that we become aware of the strength of these anticathexes in the form of resistances to our work. The ego draws back in alarm from such undertakings, which seem dangerous and threaten unpleasure; it must be constantly encouraged and soothed if it is not to fail us. This resistance, which persists throughout the whole treatment and is renewed at every fresh piece of work, is known, not quite correctly, as the resistance due to repression. We shall find that it is not the only one that faces us. It is interesting to notice that in this situation the party-divisions are to some extent reversed: for the ego struggles against our instigation, while the unconscious, which is ordinarily our opponent, comes to our help, since it has a natural 'upward drive' and desires nothing better than to press forward across its settled frontiers into the ego and so to consciousness. The struggle which develops, if we gain our end and can induce the ego to overcome its resistances, is carried through under our direction and with our assistance. Its outcome is a matter of indifference: whether it results in the ego accepting, after a fresh examination, an instinctual demand which it has hitherto rejected, or whether it dismisses it once more, this time for good and all. In either case a permanent danger has been disposed of, the compass of the ego has been extended and a wasteful expenditure of energy has been made unnecessary.

[1940a [1938], 4988]
Let us once more glance over the situation which we have reached in our attempt at bringing help to the patient's neurotic ego. That ego is no longer able to fulfil the task set it by the external world (including human society). Not all of its experiences are at its disposal, a large proportion of its store of memories have escaped it. Its activity is inhibited by strict prohibitions from the super-ego, its energy is consumed in vain attempts at fending off the demands of the id. Beyond this, as a result of continuous irruptions by the id, its organization is impaired, it is no longer capable of any proper synthesis, it is torn by mutually opposed urges, by unsettled conflicts and by unsolved doubts. To start with, we get the patient's thus weakened ego to take part in the purely intellectual work of interpretation, which aims at provisionally filling the gaps in his mental assets, and to transfer to us the authority of his super-ego; we encourage it to take up the struggle over each individual demand made by the id and to conquer the resistances which arise in connection with it. At the same time we restore order in the ego by detecting the material and urges which have forced their way in from the unconscious, and expose them to criticism by tracing them back to their origin. We serve the patient in various functions, as an authority and a substitute for his parents, as a teacher and educator; and we have done the best for him if, as analysts, we raise the mental processes in his ego to a normal level, transform what has become unconscious and repressed into preconscious material and thus return it once more to the possession of his ego. On the patient's side a few rational factors work in our favour, such as the need for recovery which has its motive in his sufferings, and the intellectual interest that we may awaken in him in the theories and revelations of psychoanalysis; but of far greater force is the positive transference with which he meets us. Fighting against us, on the other hand, are the negative transference, the ego's resistance due to repression (that is, its unpleasure at having to lay itself open to the hard work imposed on it), the sense of guilt arising from its relation to the super-ego and the need to be ill due to deep-going changes in the economics of his instincts. The share taken by the last two factors decides whether the case is to be regarded as slight or severe. Apart from these, a few other factors may be discerned as having a favourable or unfavourable bearing. A certain psychical inertia, a sluggishness of the libido, which is unwilling to abandon its fixations cannot be welcome to us; the patient's capacity for sublimating his instincts plays a large part and so does his capacity for rising above the crude life of the instincts; so, too, does the relative power of his intellectual functions.

[1940a [1938], 4990]
During the work of treatment we have to consider the distribution of the patient's libido; we look for the object presentations to which it is bound and free it from them, so as to place it at the disposal of the ego. In the course of this, we have come to form a very curious picture of the original, primal distribution of libido in human beings. We have been driven to assume that at the beginning of the development of the individual all his libido (all his erotic tendencies, all his capacity for love) is tied to himself - that as we say, it cathects his own ego. It is only later that, being attached to the satisfaction of the major vital needs, the libido flows over from the ego on to external objects. Not till then are we able to recognize the libidinal instincts as such and distinguish them from the ego instincts. It is possible for the libido to become detached from these objects and withdrawn again into the ego.

[1917a, 3609]

**Criticisms and Misunderstandings of Psycho-Analysis.** - Most of what is brought up against psycho-analysis, even in scientific works, is based upon insufficient information which in its turn seems to be determined by emotional resistances. Thus it is a mistake to accuse psycho-analysis of 'pan-sexualism' and to allege that it derives all mental occurrences from sexuality and traces them all back to it. On the contrary, psycho-analysis has from the very first distinguished the sexual instincts from others which it has provisionally termed 'ego instincts'. It has never dreamt of trying to explain 'everything', and even the neuroses it has traced back not to sexuality alone but to the conflict between the sexual impulses and the ego. In psycho-analysis (unlike the works of C. G. Jung) the term 'libido' does not mean psychical energy in general but the motive force of the sexual instincts. Some assertions, such as that every dream is the fulfilment of a sexual wish, have never been maintained by it at all. The charge of one-sidedness made against psycho-analysis, which, as the science of the unconscious mind, has its own definite and restricted field of work, is as inapplicable as it would be if it were made against chemistry. To believe that psycho-analysis seeks a cure for neurotic disorders by giving a free rein to sexuality is a serious misunderstanding which can only be excused by ignorance. The making conscious of repressed sexual desires in analysis makes it possible, on the contrary, to obtain a mastery over them which the previous repression had been unable to achieve. It can more truly be said that analysis sets the neurotic free from the chains of his sexuality. Moreover, it is quite unscientific to judge analysis by whether it is calculated to undermine religion, authority and morals; for, like all sciences, it is entirely non-tendentious and has only a single aim - namely to arrive at a consistent view of one portion of reality. Finally, one can only characterize as simple-minded the fear which is sometimes expressed that all the highest goods of humanity, as they are called - research, art, love, ethical and social sense - will lose their value or their dignity because psycho-analysis is in a position to demonstrate their origin in elementary and animal instinctual impulses.

[1923a, 3928]
I will hasten on to the innovations in the field of technique, where indeed nearly everything still awaits final settlement, and much is only now beginning to become clear. There are now two aims in psycho-analytic technique: to save the physician effort and to give the patient the most unrestricted access to his unconscious. As you know, our technique has undergone a fundamental transformation. At the time of the cathartic treatment what we aimed at was the elucidation of the symptoms; we then turned away from the symptoms and devoted ourselves instead to uncovering the 'complexes', to use a word which Jung has made indispensable; now, however, our work is aimed directly at finding out and overcoming the 'resistances', and we can justifiably rely on the complexes coming to light without difficulty as soon as the resistances have been recognized and removed. Some of you have since felt a need to be able to make a survey of these resistances and classify them. I will ask you to examine your material and see whether you can confirm the generalized statement that in male patients the most important resistances in the treatment seem to be derived from the father-complex and to express themselves in fear of the father, in defiance of the father and in disbelief of the father.

In the light of the knowledge we have gained from psycho-analysis we can describe the difference between hypnotic and psycho-analytic suggestion as follows. Hypnotic treatment seeks to cover up and gloss over something in mental life; analytic treatment seeks to expose and get rid of something. The former acts like a cosmetic, the latter like surgery. The former makes use of suggestion in order to forbid the symptoms; it strengthens the repressions, but, apart from that, leaves all the processes that have led to the formation of the symptoms unaltered. Analytic treatment makes its impact further back towards the roots, where the conflicts are which gave rise to the symptoms, and uses suggestion in order to alter the outcome of those conflicts. Hypnotic treatment leaves the patient inert and unchanged, and for that reason, too, equally unable to resist any fresh occasion for falling ill. An analytic treatment demands from both doctor and patient the accomplishment of serious work, which is employed in lifting internal resistances. Through the overcoming of these resistances the patient's mental life is permanently changed, is raised to a high level of development and remains protected against fresh possibilities of falling ill. This work of overcoming resistances is the essential function of analytic treatment; the patient has to accomplish it and the doctor makes this possible for him with the help of suggestion operating in an educative sense. For that reason psycho-analytic treatment has justly been described as a kind of after-education.
But you will now tell me that, no matter whether we call the motive force of our analysis transference or suggestion, there is a risk that the influencing of our patient may make the objective certainty of our findings doubtful. What is advantageous to our therapy is damaging to our researches. This is the objection that is most often raised against psycho-analysis, and it must be admitted that, though it is groundless, it cannot be rejected as unreasonable. If it were justified, psycho-analysis would be nothing more than a particularly well-disguised and particularly effective form of suggestive treatment and we should have to attach little weight to all that it tells us about what influences our lives, the dynamics of the mind or the unconscious. That is what our opponents believe; and in especial they think that we have 'talked' the patients into everything relating to the importance of sexual experiences - or even into those experiences themselves - after such notions have grown up in our own depraved imagination. These accusations are contradicted more easily by an appeal to experience than by the help of theory. Anyone who has himself carried out psycho-analyses will have been able to convince himself on countless occasions that it is impossible to make suggestions to a patient in that way. The doctor has no difficulty, of course, in making him a supporter of some particular theory and in thus making him share some possible error of his own. In this respect the patient is behaving like anyone else - like a pupil - but this only affects his intelligence, not his illness. After all, his conflicts will only be successfully solved and his resistances overcome if the anticipatory ideas he is given tally with what is real in him. Whatever in the doctor's conjectures is inaccurate drops out in the course of the analysis; it has to be withdrawn and replaced by something more correct. We endeavour by a careful technique to avoid the occurrence of premature successes due to suggestion; but no harm is done even if they do occur, for we are not satisfied by a first success. We do not regard an analysis as at an end until all the obscurities of the case are cleared up, the gaps in the patient's memory filled in, the precipitating causes of the repressions discovered. We look upon successes that set in too soon as obstacles rather than as a help to the work of analysis; and we put an end to such successes by constantly resolving the transference on which they are based. It is this last characteristic which is the fundamental distinction between analytic and purely suggestive therapy, and which frees the results of analysis from the suspicion of being successes due to suggestion. In every other kind of suggestive treatment the transference is carefully preserved and left untouched; in analysis it is itself subjected to treatment and is dissected in all the shapes in which it appears. At the end of an analytic treatment the transference must itself be cleared away; and if success is then obtained or continues, it rests, not on suggestion, but on the achievement by its means of an overcoming of internal resistances, on the internal change that has been brought about in the patient.

[1916-1917, 3493]

In actual fact, indeed, the neurotic patient presents us with a torn mind, divided by resistances. As we analyse it and remove the resistances, it grows together; the great unity which we call his ego fits into itself all the instinctual impulses which before had been split off and held apart from it. The psycho-synthesis is thus achieved during analytic treatment without our intervention, automatically and inevitably. We have created the conditions for it by breaking up the symptoms into their elements and by removing the resistances. It is not true that something in the patient has been divided into its components and is now quietly waiting for us to put it somehow together again.

[1919a, 3630]
Twenty five years of intense work have had as their result that the immediate aims of psychoanalytic technique are quite other to-day than they were at the outset. At first the analysing physician could do no more than discover the unconscious material that was concealed from the patient, put it together, and, at the right moment, communicate it to him. Psychoanalysis was then first and foremost an art of interpreting. Since this did not solve the therapeutic problem, a further aim quickly came in view: to oblige the patient to confirm the analyst's construction from his own memory. In that endeavour the chief emphasis lay upon the patient's resistances: the art consisted now in uncovering these as quickly as possible, in pointing them out to the patient and in inducing him by human influence - this was where suggestion operating as 'transference' played its part - to abandon his resistances.

For these reasons I refrained altogether from holding out to the parents any prospect of their wish being fulfilled. I merely said I was prepared to study the girl carefully for a few weeks or months, so as then to be able to pronounce how far a continuation of the analysis would be likely to influence her. In quite a number of cases, indeed, an analysis falls into two clearly distinguishable phases. In the first, the physician procures from the patient the necessary information, makes him familiar with the premises and postulates of psycho-analysis, and unfolds to him the reconstruction of the genesis of his disorder as deduced from the material brought up in the analysis. In the second phase the patient himself gets hold of the material put before him; he works on it, recollects what he can of the apparently repressed memories, and tries to repeat the rest as if he were in some way living it over again. In this way he can confirm, supplement, and correct the inferences made by the physician. It is only during this work that he experiences, through overcoming resistances, the inner change aimed at, and acquires for himself the convictions that make him independent of the physician's authority. These two phases in the course of the analytic treatment are not always sharply divided from each other; this can only happen when the resistance obeys certain conditions. But when this is so, one may bring up as an analogy the two stages of a journey. The first comprises all the necessary preparations, to-day so complicated and hard to effect, before, ticket in hand, one can at last go on to the platform and secure a seat in the train. One then has the right, and the possibility, of travelling into a distant country; but after all these preliminary exertions one is not yet there - indeed, one is not a single mile nearer to one's goal. For this to happen one has to make the journey itself from one station to the other, and this part of the performance may well be compared with the second phase of the analysis.

**Development of Technique.** - After the analyst's curiosity had, as it were, been gratified by the elaboration of the technique of interpretation, it was inevitable that interest should turn to the problem of discovering the most effective way of influencing the patient. It soon became evident that the physician's immediate task was to assist the patient in getting to know, and afterwards in overcoming, the resistances which emerged in him during treatment and of which, to begin with, he himself was unaware. And it was found at the same time that the essential part of the process of cure lay in the overcoming of these resistances and that unless this was achieved no permanent mental change could be brought about in the patient. Since the analyst's efforts have in this way been directed upon the patient's resistance, analytic technique has attained a certainty and delicacy rivalling that of surgery. Consequently, everyone is strongly advised against undertaking psycho-analytic treatments without a strict training, and a physician who ventures upon them on the strength of his medical qualification is in no respect better than a layman.
Comparison between Psycho-Analysis and Hypnotic and Suggestive Methods. - Psycho-analytic procedure differs from all methods making use of suggestion, persuasion, etc., in that it does not seek to suppress by means of authority any mental phenomenon that may occur in the patient. It endeavours to trace the causation of the phenomenon and to remove it by bringing about a permanent modification in the conditions that led to it. In psycho-analysis the suggestive influence which is inevitably exercised by the physician is diverted on to the task assigned to the patient of overcoming his resistances, that is, of carrying forward the curative process. Any danger of falsifying the products of a patient's memory by suggestion can be avoided by prudent handling of the technique; but in general the arousing of resistances is a guarantee against the misleading effects of suggestive influence. It may be laid down that the aim of the treatment is to remove the patient's resistances and to pass his repressions in review and thus to bring about the most far-reaching unification and strengthening of his ego, to enable him to save the mental energy which he is expending upon internal conflicts, to make the best of him that his inherited capacities will allow and so to make him as efficient and as capable of enjoyment as is possible. The removal of the symptoms of the illness is not specifically aimed at, but is achieved, as it were, as a by-product if the analysis is properly carried through. The analyst respects the patient's individuality and does not seek to remould him in accordance with his own - that is, according to the physician's - personal ideals; he is glad to avoid giving advice and instead to arouse the patient's power of initiative.

[1923a, 3927]

It is perfectly true that psycho-analysis, like other psychotherapeutic methods, employs the instrument of suggestion (or transference). But the difference is this: that in analysis it is not allowed to play the decisive part in determining the therapeutic results. It is used instead to induce the patient to perform a piece of psychical work - the overcoming of his transference resistances - which involves a permanent alteration in his mental economy. The transference is made conscious to the patient by the analyst, and it is resolved by convincing him that in his transference-attitude he is re-experiencing emotional relations which had their origin in his earliest object-attachments during the repressed period of his childhood. In this way the transference is changed from the strongest weapon of the resistance into the best instrument of the analytic treatment. Nevertheless its handling remains the most difficult as well as the most important part of the technique of analysis.

[1925d, 4218]
Yes, we are only beginning to appreciate the significance of all these important circumstances. That is why my description was bound to turn out so obscure. But now I can proceed. We describe all the forces that oppose the work of recovery as the patient's 'resistances'. The gain from illness is one such resistance. The 'unconscious sense of guilt' represents the super-ego's resistance; it is the most powerful factor, and the one most dreaded by us. We meet with still other resistances during the treatment. If the ego during the early period has set up a repression out of fear, then the fear still persists and manifests itself as a resistance if the ego approaches the repressed material. And finally, as you can imagine, there are likely to be difficulties if an instincntual process which has been going along a particular path for whole decades is suddenly expected to take a new path that has just been made open for it. That might be called the id's resistance. The struggle against all these resistances is our main work during an analytic treatment; the task of making interpretations is nothing compared to it. But as a result of this struggle and of the overcoming of the resistances, the patient's ego is so much altered and strengthened that we can look forward calmly to his future behaviour when the treatment is over. On the other hand, you can understand now why we need such long treatments. The length of the path of development and the wealth of the material are not the decisive factors. It is more a question of whether the path is clear. An army can be held up for weeks on a stretch of country which in peace time an express train crosses in a couple of hours - if the army has to overcome the enemy's resistance there. Such battles call for time in mental life too. I am unfortunately obliged to tell you that every effort to hasten analytic treatment appreciably has hitherto failed. The best way of shortening it seems to be to carry it out according to the rules.

[1926e, 4366]

(3) By 'transference' is meant a striking peculiarity of neurotics. They develop towards their physician emotional relations, both of an affectionate and hostile character, which are not based upon the actual situation but are derived from their relations to their parents (the Oedipus complex). Transference is a proof of the fact that adults have not overcome their former childish dependence; it coincides with the force which has been named 'suggestion'; and it is only by learning to make use of it that the physician is enabled to induce the patient to overcome his internal resistances and do away with his repressions. Thus psycho-analytic treatment acts as a second education of the adult, as a corrective to his education as a child.

[1926f, 4406]
With the mention of resistance we have reached the second and more important part of our task. We have already learnt that the ego protects itself against the invasion of undesired elements from the unconscious and repressed id by means of anticathexes, which must remain intact if it is to function normally. The more hard-pressed the ego feels, the more convulsively it clings (as though in a fright) to these anticathexes, in order to protect what remains of itself from further irruptions. But this defensive purpose does not by any means accord with the aims of our treatment. What we desire, on the contrary, is that the ego, emboldened by the certainty of our help, shall dare to take the offensive in order to reconquer what has been lost. And it is here that we become aware of the strength of these anticathexes in the form of resistances to our work. The ego draws back in alarm from such undertakings, which seem dangerous and threaten unpleasure; it must be constantly encouraged and soothed if it is not to fail us. This resistance, which persists throughout the whole treatment and is renewed at every fresh piece of work, is known, not quite correctly, as the resistance due to repression. We shall find that it is not the only one that faces us. It is interesting to notice that in this situation the party-divisions are to some extent reversed: for the ego struggles against our instigation, while the unconscious, which is ordinarily our opponent, comes to our help, since it has a natural 'upward drive' and desires nothing better than to press forward across its settled frontiers into the ego and so to consciousness. The struggle which develops, if we gain our end and can induce the ego to overcome its resistances, is carried through under our direction and with our assistance. Its outcome is a matter of indifference: whether it results in the ego accepting, after a fresh examination, an instinctual demand which it has hitherto rejected, or whether it dismisses it once more, this time for good and all. In either case a permanent danger has been disposed of, the compass of the ego has been extended and a wasteful expenditure of energy has been made unnecessary.

The overcoming of resistances is the part of our work that requires the most time and the greatest trouble. It is worth while, however, for it brings about an advantageous alteration of the ego which will be maintained independently of the outcome of the transference and will hold good in life. We have also worked simultaneously at getting rid of the alteration of the ego which had been brought about under the influence of the unconscious; for whenever we have been able to detect any of its derivatives in the ego we have pointed out their illegitimate origin and have instigated the ego to reject them. It will be remembered that it was one of the necessary preconditions of our pact of assistance that any such alteration of the ego due to the intrusion of unconscious elements should not have gone beyond a certain amount.

We must first of all decide what is meant by the ambiguous phrase 'the end of an analysis'. From a practical standpoint it is easy to answer. An analysis is ended when the analyst and the patient cease to meet each other for the analytic session. This happens when two conditions have been approximately fulfilled: first, that the patient shall no longer be suffering from his symptoms and shall have overcome his anxieties and his inhibitions; and secondly, that the analyst shall judge that so much repressed material has been made conscious, so much that was unintelligible has been explained, and so much internal resistance conquered, that there is no need to fear a repetition of the pathological processes concerned. If one is prevented by external difficulties from reaching this goal, it is better to speak of an incomplete analysis rather than of an unfinished one.
The sexual causes, too, are the ones which most readily offer the physician a foothold for his therapeutic influence. Heredity is no doubt an important factor, when it is present; it enables a strong pathological effect to come about where otherwise only a very slight one would have resulted. But heredity is inaccessible to the physician's influence; everyone is born with his own hereditary tendencies to illness, and we can do nothing to change them. Nor should we forget that it is precisely in regard to the aetiology of the neurasthenias that we must necessarily deny the first place to heredity. Neurasthenia (in both its forms) is one of those affections which anyone may easily acquire without having any hereditary taint. If it were otherwise, the enormous increase in neurasthenia, of which all the authorities complain, would be unthinkable. In what concerns civilization, among whose sins people so often include responsibility for neurasthenia, these authorities may indeed be right (although the way in which this comes about is probably quite different from what they imagine). Yet the state of our civilization is, once again, something that is unalterable for the individual. Moreover this factor, being common to all the members of the same society, can never explain the fact of selectivity in the incidence of the illness. The physician who is not neurasthenic is exposed to the same influence of an allegedly detrimental civilization as the neurasthenic patient whom he has to treat. Subject to these limitations, the factors of exhaustion retain their significance. But the element of 'overwork', which physicians are so fond of producing to their patients as the cause of their neurosis, is too often unduly misused. It is quite true that anyone who, owing to sexual noxae, has made himself disposed to neurasthenia, tolerates intellectual work and the psychical exigencies of life badly; but no one ever becomes neurotic through work or excitement alone. Intellectual work is rather a protection against falling ill of neurasthenia; it is precisely the most unremitting intellectual workers who remain exempt from neurasthenia, and what neurasthenics complain of as 'overwork that is making them ill' does not as a rule deserve to be called 'intellectual work' at all, either in its quality or quantity. Physicians will have to become accustomed to explaining to an office-worker who has been 'overworked' at his desk or to a housewife for whom her domestic activities have become too heavy, that they have fallen ill, not because they have tried to carry out duties which are in fact easily performed by a civilized brain, but because all the while they have been grossly neglecting and damaging their sexual life.

[1897b, 463]
As regards the second kind of emotional reaction, which is not directed against me this time, but against my patient - supposing that my view of her is correct - and which regards the perverse nature of her phantasies as horrible, I should like to say emphatically that a medical man has no business to indulge in such passionate condemnation. I may also remark in passing that it seems to me superfluous for a physician who is writing upon the aberrations of the sexual instincts to seize every opportunity of inserting into the text expressions of his personal repugnance at such revolting things. We are faced by a fact; and it is to be hoped that we shall grow accustomed to it, when we have put our own tastes on one side. We must learn to speak without indignation of what we call the sexual perversions - instances in which the sexual function has extended its limits in respect either to the part of the body concerned or to the sexual object chosen. The uncertainty in regard to the boundaries of what is to be called normal sexual life, when we take different races and different epochs into account, should in itself be enough to cool the zealot's ardour. We surely ought not to forget that the perversion which is the most repellant to us, the sensual love of a man for a man, was not only tolerated by a people so far our superiors in cultivation as were the Greeks, but was actually entrusted by them with important social functions. The sexual life of each one of us extends to a slight degree - now in this direction, now in that - beyond the narrow lines imposed as the standard of normality. The perversions are neither bestial nor degenerate in the emotional sense of the word. They are a development of germs all of which are contained in the undifferentiated sexual disposition of the child, and which, by being suppressed or by being diverted to higher, asexual aims - by being 'sublimated' - are destined to provide the energy for a great number of our cultural achievements. When, therefore, any one has become a gross and manifest pervert, it would be more correct to say that he has remained one, for he exhibits a certain stage of inhibited development. All psychoneurotics are persons with strongly marked perverse tendencies, which have been repressed in the course of their development and have become unconscious. Consequently their unconscious phantasies show precisely the same content as the documentarily recorded actions of perverts - even though they have not read Krafft-Ebing's Psychopathia Sexualis, to which simple-minded people attribute such a large share of the responsibility for the production of perverse tendencies. Psychoneuroses are, so to speak, the negative of perversions. In neurotics their sexual constitution, under which the effects of heredity are included, operates in combination with any accidental influences in their life which may disturb the development of normal sexuality. A stream of water which meets with an obstacle in the river-bed is dammed up and flows back into old channels which had formerly seemed fated to run dry. The motive forces leading to the formation of hysterical symptoms draw their strength not only from repressed normal sexuality but also from unconscious perverse activities.
The same holds true of seeing - an activity that is ultimately derived from touching. Visual impressions remain the most frequent pathway along which libidinal excitation is aroused; indeed, natural selection counts upon the accessibility of this pathway - if such a teleological form of statement is permissible - when it encourages the development of beauty in the sexual object. The progressive concealment of the body which goes along with civilization keeps sexual curiosity awake. This curiosity seeks to complete the sexual object by revealing its hidden parts. It can, however, be diverted ('sublimated') in the direction of art, if its interest can be shifted away from the genitals on to the shape of the body as a whole.¹ It is usual for most normal people to linger to some extent over the intermediate sexual aim of a looking that has a sexual tinge to it; indeed, this offers them a possibility of directing some proportion of their libido on to higher artistic aims. On the other hand, this pleasure in looking becomes a perversion (a) if it is restricted exclusively to the genitals, or (b) if it is connected with the overriding of disgust (as in the case of voyeurs or people who look on at excretory functions), or (c) if, instead of being preparatory to the normal sexual aim, it supplants it. This last is markedly true of exhibitionists, who, if I may trust the findings of several analyses, exhibit their own genitals in order to obtain a reciprocal view of the genitals of the other person.²

REACTION-FORMATION AND SUBLIMATION What is it that goes to the making of these constructions which are so important for the growth of a civilized and normal individual? They probably emerge at the cost of the infantile sexual impulses themselves. Thus the activity of those impulses does not cease even during this period of latency, though their energy is diverted, wholly or in great part, from their sexual use and directed to other ends. Historians of civilization appear to be at one in assuming that powerful components are acquired for every kind of cultural achievement by this diversion of sexual instinctual forces from sexual aims and their direction to new ones - a process which deserves the name of 'sublimation'. To this we would add, accordingly, that the same process plays a part in the development of the individual and we would place its beginning in the period of sexual latency of childhood.¹

It is possible further to form some idea of the mechanism of this process of sublimation. On the one hand, it would seem, the sexual impulses cannot be utilized during these years of childhood, since the reproductive functions have been deferred - a fact which constitutes the main feature of the period of latency. On the other hand, these impulses would seem in themselves to be perverse - that is, to arise from erotogenic zones and to derive their activity from instincts which, in view of the direction of the subject's development, can only arouse unpleasurable feelings. They consequently evoke opposing mental forces (reacting impulses) which, in order to suppress this unpleasure effectively, build up the mental dams that have already mentioned - disgust, shame and morality.²

² [Footnote added 1915:] In the case which I am here discussing, the sublimation of sexual instinctual forces takes place along the path of reaction-formation. But in general it is possible to distinguish the concepts of sublimation and reaction-formation from each other as two different processes. Sublimation can also take place by other and simpler mechanisms.

[1905d, 1483]

[1905d, 1500]
The same pathways, however, along which sexual disturbances trench upon the other somatic functions must also perform another important function in normal health. They must serve as paths for the attraction of sexual instincital forces to aims that are other than sexual, that is to say, for the sublimation of sexuality. But we must end with a confession that very little is as yet known with certainty of these pathways, though they certainly exist and can probably be traversed in both directions.

[1905d, 1523]

SUBLIMATION The third alternative result of an abnormal constitutional disposition is made possible by the process of sublimation. This enables excessively strong excitations arising from particular sources of sexuality to find an outlet and use in other fields, so that a not inconsiderable increase in psychical efficiency results from a disposition which is itself perilous. Here we have one of the origins of artistic activity; and, according to the completeness or incompleteness of the sublimation, a characterological analysis of a highly gifted individual, and in particular of one with an artistic disposition, may reveal a mixture, in every proportion, of efficiency, perversion and neurosis. A sub-species of sublimation is to be found in suppression by reaction-formation, which, as we have seen, begins during a child's period of latency and continues in favourable cases throughout his whole life. What we describe as a person's 'character' is built up to a considerable extent from the material of sexual excitations and is composed of instincts that have been fixed since childhood, of constructions achieved by means of sublimation, and of other constructions, employed for effectively holding in check perverse impulses which have been recognized as being unutilizable.¹ The multifariously perverse sexual disposition of childhood can accordingly be regarded as the source of a number of our virtues, in so far as through reaction-formation it stimulates their development.²

[1905d, 1549]

ACCIDENTAL EXPERIENCES No other influences on the course of sexual development can compare in importance with releases of sexuality, waves of repression and sublimations - the two latter being processes of which the inner causes are quite unknown to us. It might be possible to include repressions and sublimations as a part of the constitutional disposition, by regarding them as manifestations of it in life; and anyone who does so is justified in asserting that the final shape taken by sexual life is principally the outcome of the innate constitution. No one with perception will, however, dispute that an interplay of factors such as this also leaves room for the modifying effects of accidental events experienced in childhood and later. It is not easy to estimate the relative efficacy of the constitutional and accidental factors. In theory one is always inclined to overestimate the former; therapeutic practice emphasizes the importance of the latter. It should, however, of no account be forgotten that the relation between the two is a co-operative and not a mutually exclusive one. The constitutional factor must await experiences before it can make itself felt; the accidental factor must have a constitutional basis in order to come into operation. To cover the majority of cases we can picture what has been described as a 'complemental series', in which the diminishing intensity of one factor is balanced by the increasing intensity of the other; there is, however, no reason to deny the existence of extreme cases at the two ends of the series.

[1905d, 1550]
Unconscious phantasies have either been unconscious all along and have been formed in the unconscious; or - as is more often the case - they were once conscious phantasies, daydreams, and have since been purposely forgotten and have become unconscious through 'repression'. Their content may afterwards either have remained the same or have undergone alterations, so that the present unconscious phantasies are derivatives of the once conscious ones. Now an unconscious phantasy has a very important connection with the subject's sexual life; for it is identical with the phantasy which served to give him sexual satisfaction during a period of masturbation. At that time the masturbatory act (in the widest sense of the term) was compounded of two parts. One was the evocation of a phantasy and the other some active behaviour for obtaining self-gratification at the height of the phantasy. This compound, as we know, was itself merely soldered together.¹ Originally the action was a purely auto-erotic procedure for the purpose of obtaining pleasure from some particular part of the body, which could be described as erotogenic. Later, this action became merged with a wishful idea from the sphere of object-love and served as a partial realization of the situation in which the phantasy culminated. When, subsequently, the subject renounces this type of satisfaction, composed of masturbation and phantasy, the action is given up, while the phantasy, from being conscious, becomes unconscious. If no other mode of sexual satisfaction supervenes, the subject remains abstinent; and if he does not succeed in sublimating his libido - that is, in deflecting his sexual excitation to higher aims - , the condition is now fulfilled for his unconscious phantasy to be revived and to proliferate, and, at least as regards some part of its content, to put itself into effect, with the whole force of his need for love, in the form of a pathological symptom. [1908a, 1934]

I know that no one is prepared to believe in a state of things so long as it appears to be unintelligible and to offer no angle from which an explanation can be attempted. But we can at least bring the underlying factors nearer to our understanding by the help of the postulates I laid down in my Three Essays on the Theory of Sexuality in 1905. I there attempted to show that the sexual instinct of man is highly complex and is put together from contributions made by numerous constituents and component instincts. Important contributions to 'sexual excitation' are furnished by the peripheral excitations of certain specially designated parts of the body (the genitals, mouth, anus, urethra), which therefore deserve to be described as 'erotogenic zones'. But the amounts of excitation coming in from these parts of the body do not all undergo the same vicissitudes, nor is the fate of all of them the same at every period of life. Generally speaking, only a part of them is made use of in sexual life; another part is deflected from sexual aims and directed towards others - a process which deserves the name of 'sublimation'. During the period of life which may be called the period of 'sexual latency' - i.e. from the completion of the fifth year to the first manifestations of puberty (round about the eleventh year) - reaction-formations, or counter-forces, such as shame, disgust and morality, are created in the mind. They are actually formed at the expense of the excitations proceeding from the erotogenic zones, and they rise like dams to oppose the later activity of the sexual instincts. Now anal erotism is one of the components of the instinct which, in the course of development and in accordance with the education demanded by our present civilization, have become unserviceable for sexual aims. It is therefore plausible to suppose that these character-traits of orderliness, parsimony and obstinacy, which are so often prominent in people who were formerly anal erotics, are to be regarded as the first and most constant results of the sublimation of anal erotism.² [1908b, 1943]
We ought in general to consider whether other character complexes, too, do not exhibit a connection with the excitations of particular erotogenic zones. At present I only know of the intense "burning" ambition of people who earlier suffered from enuresis. We can at any rate lay down a formula for the way in which character in its final shape is formed out of the constituent instincts: the permanent character-traits are either unchanged prolongations of the original instincts, or sublimations of those instincts, or reaction-formations against them.

[1908b, 1945]

The sexual instinct - or, more correctly, the sexual instincts, for analytic investigation teaches us that the sexual instinct is made up of many separate constituents or component instincts - is probably more strongly developed in man than in most of the higher animals; it is certainly more constant, since it has almost entirely overcome the periodicity to which it is tied in animals. It places extraordinarily large amounts of force at the disposal of civilized activity, and it does this in virtue of its especially marked characteristic of being able to displace its aim without materially diminishing in intensity. This capacity to exchange its originally sexual aim for another one, which is no longer sexual but which is psychically related to the first aim, is called the capacity for sublimation. In contrast to this displaceability, in which its value for civilization lies, the sexual instinct may also exhibit a particularly obstinate fixation which renders it unserviceable and which sometimes causes it to degenerate into what are described as abnormalities. The original strength of the sexual instinct probably varies in each individual; certainly the proportion of it which is suitable for sublimation varies. It seems to us that it is the innate constitution of each individual which decides in the first instance how large a part of his sexual instinct it will be possible to sublimate and make use of. In addition to this, the effects of experience and the intellectual influences upon his mental apparatus succeed in bringing about the sublimation of a further portion of it. To extend this process of displacement indefinitely is, however, certainly not possible, any more than is the case with the transformation of heat into mechanical energy in our machines. A certain amount of direct sexual satisfaction seems to be indispensable for most organizations, and a deficiency in this amount, which varies from individual to individual, is visited by phenomena which, on account of their detrimental effects on functioning and their subjective quality of unpleasure, must be regarded as an illness.

[1908d, 1952]

In the first place (disregarding people whose sexual instinct is altogether excessive and uninhibitable) there are the different varieties perverts, in whom an infantile fixation to a preliminary sexual aim has prevented the primacy of the reproductive function from being established, and the homosexuals or inverts, in whom, in a manner that is not yet quite understood, the sexual aim has been deflected away from the opposite sex. If the injurious effects of these two kinds of developmental disturbance are less than might be expected, this mitigation can be ascribed precisely to the complex way in which the sexual instinct is put together, which makes it possible for a person's sexual life to reach a serviceable final form even if one or more components of the instinct have been shut off from development. The constitution of people suffering from inversion - the homosexuals - is, indeed, often distinguished by their sexual instinct's possessing a special aptitude for cultural sublimation.

[1908d, 1953]
The answer to the first question touches on a problem which has often been discussed and cannot be exhaustively treated here - that of sexual abstinence. Our third stage of civilization demands of individuals of both sexes that they shall practise abstinence until they are married and that all who do not contract a legal marriage shall remain abstinent throughout their lives. The position, agreeable to all the authorities, that sexual abstinence is not harmful and not difficult to maintain, has also been widely supported by the medical profession. It may be asserted, however, that the task of mastering such a powerful impulse as that of the sexual instinct by any other means than satisfying it is one which can call for the whole of a man's forces. Mastering it by sublimation, by deflecting the sexual instinctual forces away from their sexual aim to higher cultural aims, can be achieved by a minority and then only intermittently, and least easily during the period of ardent and vigorous youth. Most of the rest become neurotic or are harmed in one way or another. Experience shows that the majority of the people who make up our society are constitutionally unfit to face the task of abstinence. Those who would have fallen ill under milder sexual restrictions fall ill all the more readily and more severely before the demands of our cultural sexual morality of to-day; for we know no better safe-guard against the threat to normal sexual life offered by defective innate dispositions or disturbances of development than sexual satisfaction itself. The more a person is disposed to neurosis, the less he can tolerate abstinence; instincts which have been withdrawn from normal development, in the sense in which it has been described above, become at the same time all the more uninhibitible. But even those people who would have retained their health under the requirements of the second stage of civilization will now succumb to neurosis in great numbers. For the psychical value of sexual satisfaction increases with its frustration. The dammed-up libido is now put in a position to detect one or other of the weaker spots which are seldom absent in the structure of sexual life, and there to break through and obtain substitutive satisfaction of a neurotic kind in the form of pathological symptoms. Anyone who is able to penetrate the determinants of nervous illness will soon become convinced that its increase in our society arises from the intensification of sexual restrictions.

[1908d, 1956]
This brings us to the question whether sexual intercourse in legal marriage can offer full compensation for the restrictions imposed before marriage. There is such an abundance of material supporting a reply in the negative that we can give only the briefest summary of it. It must above all be borne in mind that our cultural sexual morality restricts sexual intercourse even in marriage itself, since it imposes on married couples the necessity of contenting themselves, as a rule, with a very few procreative acts. As a consequence of this consideration, satisfying sexual intercourse in marriage takes place only for a few years; and we must subtract from this, of course, the intervals of abstention necessitated by regard for the wife's health. After these three, four or five years, the marriage becomes a failure in so far as it has promised the satisfaction of sexual needs. For all the devices hitherto invented for preventing conception impair sexual enjoyment, hurt the fine susceptibilities of both partners and even actually cause illness. Fear of the consequences of sexual intercourse first brings the married couple's physical affection to an end; and then, as a remoter result, it usually puts a stop as well to the mental sympathy between them, which should have been the successor to their original passionate love. The spiritual disillusionment and bodily deprivation to which most marriages are thus doomed puts both partners back in the state they were in before their marriage, except for being the poorer by the loss of an illusion, and they must once more have recourse to their fortitude in mastering and deflecting their sexual instinct. We need not enquire how far men, by then in their maturer years, succeed in this task. Experience shows that they very frequently avail themselves of the degree of sexual freedom which is allowed them - although only with reluctance and under a veil of silence - by even the strictest sexual code. The 'double' sexual morality which is valid for men in our society is the plainest admission that society itself does not believe in the possibility of enforcing the precepts which it itself has laid down. But experience shows as well that women, who, as being the actual vehicle of the sexual interests of mankind, are only endowed in a small measure with the gift of sublimating their instincts, and who, though they may find a sufficient substitute for the sexual object in an infant at the breast, do not find one in a growing child - experience shows, I repeat, that women, when they are subjected to the disillusionments of marriage, fall ill of severe neuroses which permanently darken their lives. (Under the cultural conditions of to-day, marriage has long ceased to be a panacea for the nervous troubles of women; and if we doctors still advise marriage in such cases, we are nevertheless aware that, on the contrary, a girl must be very healthy if she is to be able to tolerate it, and we urgently advise our male patients not to marry any girl who has had nervous trouble before marriage. On the contrary, the cure for nervous illness arising from marriage would be marital unfaithfulness. But the more strictly a woman has been brought up and the more sternly she has submitted to the demands of civilization, the more she is afraid of taking this way out; and in the conflict between her desires and her sense of duty, she once more seeks refuge in a neurosis. Nothing protects her virtue as securely as an illness. Thus the married state, which is held out as a consolation to the sexual instinct of the civilized person in his youth, proves to be inadequate even to the demands of the actual period of life covered by it. There is no question of its being able to compensate for the deprivation which precedes it. [1908d, 1957]
The retardation of sexual development and sexual activity at which our education and civilization aim is certainly not injurious to begin with. It is seen to be a necessity, when one considers the late age at which young people of the educated classes reach independence and are able to earn a living. (This reminds one, incidentally, of the intimate interconnection between all our cultural institutions and of the difficulty of altering any part of them without regard to the whole.) But abstinence continued long after the age of twenty is no longer unobjectionable for a young man; and it leads to other damage even when it does not lead to neurosis. People say, to be sure, that the struggle against such a powerful instinct, and the strengthening of all the ethical and aesthetic forces which are necessary for this struggle, 'steel' the character; and this is true for a few specially favourably organized natures. It must also be admitted that the differentiation of individual character, which is so marked in our day, has only become possible with the existence of sexual restriction. But in the vast majority of cases the struggle against sexuality eats up the energy available in a character and this at the very time when a young man is in need of all his forces in order to win his share and place in society. The relationship between the amount of sublimation possible and the amount of sexual activity necessary naturally varies very much from person to person and even from one calling to another. An abstinent artist is hardly conceivable; but an abstinent young savant is certainly no rarity. The latter can, by his self-restraint, liberate forces for his studies; while the former probably finds his artistic achievements powerfully stimulated by his sexual experience. In general I have not gained the impression that sexual abstinence helps to bring about energetic and self-reliant men of action or original thinkers or bold emancipators and reformers. Far more often it goes to produce well-behaved weaklings who later become lost in the great mass of people that tends to follow, unwillingly, the leads given by strong individuals. [1908d, 1958]

¹ Hans's father even observed that simultaneously with this repression a certain amount of sublimation set in. From the time of the beginning of his anxiety Hans began to show an increased interest in music and to develop his inherited musical gift. [1909b, 2117]
To this unimpeachable body of evidence we shall be able to add fresh material, if we turn to the history of the masturbatory side of our patient’s sexual activities. There is a conflict between the opinions of doctors and patients on this subject which has not hitherto been properly appreciated. The patients are unanimous in their belief that masturbation, by which they mean masturbation during puberty, is the root and origin of all their troubles. The doctors are, upon the whole, unable to decide what line to take; but, influenced by the knowledge that not only neurotics but most normal people pass through a period of masturbation during their puberty, the majority of them are inclined to dismiss the patients’ assertions as gross exaggerations. In my opinion the patients are once again nearer to a correct view than the doctors; for the patients have some glimmering notion of the truth, while the doctors are in danger of overlooking an essential point. The thesis propounded by the patients certainly does not correspond to the facts in the sense in which they themselves construe it, namely, that masturbation during puberty (which may almost be described as a typical occurrence) is responsible for all neurotic disturbances. Their thesis requires interpretation. The masturbation of puberty is in fact no more than a revival of the masturbation of infancy, a subject which has hitherto invariably been neglected. Infantile masturbation reaches a kind of climax, as a rule, between the ages of three and four or five; and it is the clearest expression of a child’s sexual constitution, in which the aetiology of subsequent neuroses must be sought. In this disguised way, therefore, the patients are putting the blame for their illnesses upon their infantile sexuality; and they are perfectly right in doing so. On the other hand, the problem of masturbation becomes insoluble if we attempt to treat it as a clinical unit, and forget that it can represent the discharge of every variety of sexual component and of every sort of phantasy to which such components can give rise. The injurious effects of masturbation are only in a very small degree autonomous - that is to say, determined by its own nature. They are in substance merely part and parcel of the pathogenic significance of the subject’s sexual life as a whole. The fact that so many people can tolerate masturbation - that is, a certain amount of it - without injury merely shows that their sexual constitution and the course of development of their sexual life have been such as to allow them to exercise the sexual function within the limits of what is culturally permissible; whereas other people, because their sexual constitution has been less favourable or their development has been disturbed, fall ill as a result of their sexuality - they cannot, that is, achieve the necessary suppression or sublimation of their sexual components without having recourse to inhibitions or substitutes.¹

[1909d, 2159]
To put the matter more directly. The investigation of hysterical patients and of other neurotics leads us to the conclusion that their repression of the idea to which the intolerable wish is attached has been a failure. It is true that they have driven it out of consciousness and out of memory and have apparently saved themselves a large amount of unpleasure. But the repressed wishful impulse continues to exist in the unconscious. It is on the look-out for an opportunity of being activated, and when that happens it succeeds in sending into consciousness a disguised and unrecognizable substitute for what had been repressed, and to this there soon become attached the same feelings of unpleasure which it was hoped had been saved by the repression. This substitute for the repressed idea - the symptom - is proof against further attacks from the defensive ego; and in place of the short conflict an ailment now appears which is not brought to an end by the passage of time. Alongside the indication of distortion in the symptom, we can trace in it the remains of some kind of indirect resemblance to the idea that was originally repressed. The paths along which the substitution was effected can be traced in the course of the patient's psycho-analytic treatment; and in order to bring about recovery, the symptom must be led back along the same paths and once more turned into the repressed idea. If what was repressed is brought back again into conscious mental activity - a process which presupposes the overcoming of considerable resistances - the resulting psychical conflict, which the patient had tried to avoid, can, under the physician's guidance, reach a better outcome than was offered by repression. There are a number of such opportune solutions, which may bring the conflict and the neurosis to a happy end, and which may in certain instances be combined. The patient's personality may be convinced that it has been wrong in rejecting the pathogenic wish and may be led into accepting it wholly or in part; or the wish itself may be directed to a higher and consequently unobjectionable aim (this is what we call its 'sublimation'); or the rejection of the wish may be recognized as a justifiable one, but the automatic and therefore inefficient mechanism of repression may be replaced by a condemning judgement with the help of the highest human mental functions - conscious control of the wish is attained.

[1910a, 2215]

A second outcome of the work of psycho-analysis is that it then becomes possible for the unconscious instincts revealed by it to be employed for the useful purposes which they would have found earlier if development had not been interrupted. For the extirpation of the infantile wishful impulses is by no means the ideal aim of development. Owing to their repressions, neurotics have sacrificed many sources of mental energy whose contributions would have been of great value in the formation of their character and in their activity in life. We know of a far more expedient process of development, called 'sublimation', in which the energy of the infantile wishful impulses is not cut off but remains ready for use - the unserviceable aim of the various impulses being replaced by one that is higher, and perhaps no longer sexual. It happens to be precisely the components of the sexual instinct that are specially marked by a capacity of this kind for sublimation, for exchanging their sexual aim for another one which is comparatively remote and socially valuable. It is probable that we owe our highest cultural successes to the contributions of energy made in this way to our mental functions. Premature repression makes the sublimation of the repressed instinct impossible; when the repression is lifted, the path to sublimation becomes free once more.

[1910a, 2238]
We must not omit to consider the third of the possible outcomes of the work of psycho-
analysis. A certain portion of the repressed libidinal impulses has a claim to direct satisfaction
and ought to find it in life. Our civilized standards make life too difficult for the majority of human
organizations. Those standards consequently encourage the retreat from reality and the
generating of neuroses, without achieving any surplus of cultural gain by this excess of sexual
repression. We ought not to exalt ourselves so high as completely to neglect what was originally
animal in our nature. Nor should we forget that the satisfaction of the individual's happiness
cannot be erased from among the aims of our civilization. The plasticity of the components of
sexuality, shown by their capacity for sublimation, may indeed offer a great temptation to strive
for still greater cultural achievements by still further sublimation. But, just as we do not count on
our machines converting more than a certain fraction of the heat consumed into useful
mechanical work, we ought not to seek to alienate the whole amount of the energy of the sexual
instinct from its proper ends. We cannot succeed in doing so; and if the restriction upon
sexuality were to be carried too far it would inevitably bring with it all the evils of soil-exhaustion.
[1910a, 2239]

A conversion of psychical instinctual force into various forms of activity can perhaps no more
be achieved without loss than a conversion of physical forces. The example of Leonardo
teaches us how many other things we have to take into account in connection with these
processes. The postponement of loving until full knowledge is acquired ends in a substitution of
the latter for the former. A man who has won his way to a state of knowledge cannot properly be
said to love and hate; he remains beyond love and hatred. He has investigated instead of
loving. And that is perhaps why Leonardo's life was so much poorer in love than that of other
great men, and of other artists. The stormy passions of a nature that inspires and consumes,
passions in which other men have enjoyed their richest experience, appear not to have touched
him. [1910c, 2252]

Observation of men's daily lives shows us that most people succeed in directing very
considerable portions of their sexual instinctual forces to their professional activity. The sexual
instinct is particularly well fitted to make contributions of this kind since it is endowed with a
capacity for sublimation: that is, it has the power to replace its immediate aim by other aims
which may be valued more highly and which are not sexual. We accept this process as proved
whenever the history of a person's childhood - that is, the history of his mental development -
shows that in childhood this over-powerful instinct was in the service of sexual interests. We find
further confirmation if a striking atrophy occurs in the sexual life of maturity, as though a portion
of sexual activity had now been replaced by the activity of the over-powerful instinct.
[1910c, 2254]

In virtue of a special disposition, the third type, which is the rarest and most perfect, escapes
both inhibition of thought and neurotic compulsive thinking. It is true that here too sexual
repression comes about, but it does not succeed in relegating a component instinct of sexual
desire to the unconscious. Instead, the libido evades the fate of repression by being sublimated
from the very beginning into curiosity and by becoming attached to the powerful instinct for
research as a reinforcement. Here, too, the research becomes to some extent compulsive and a
substitute for sexual activity; but owing to the complete difference in the underlying psychical
processes (sublimation instead of an irruption from the unconscious ) the quality of neurosis is
absent; there is no attachment to the original complexes of infantile sexual research, and the
instinct can operate freely in the service of intellectual interest. Sexual repression, which has
made the instinct so strong through the addition to it of sublimated libido, is still taken into
account by the instinct, in that it avoids any concern with sexual themes. [1910c, 2257]
A powerful wave of repression brought this childhood excess to an end, and established the dispositions which were to become manifest in the years of puberty. The most obvious result of the transformation was the avoidance of every crudely sensual activity; Leonardo was enabled to live in abstinence and to give the impression of being an asexual human being. When the excitements of puberty came in their flood upon the boy they did not, however, make him ill by forcing him to develop substitutive structures of a costly and harmful kind. Owing to his very early inclination towards sexual curiosity the greater portion of the needs of his sexual instinct could be sublimated into a general urge to know, and thus evaded repression. A much smaller portion of his libido continued to be devoted to sexual aims and represented a stunted adult sexual life. Because his love for his mother had been repressed, this portion was driven to take up a homosexual attitude and manifested itself in ideal love for boys. The fixation on his mother and on the blissful memories of his relations with her continued to be preserved in the unconscious, but for the time being it remained in an inactive state. In this way repression, fixation and sublimation all played their part in disposing of the contributions which the sexual instinct made to Leonardo's mental life.

Leonardo emerges from the obscurity of his boyhood as an artist, a painter and a sculptor, owing to a specific talent which may have been reinforced by the precocious awakening in the first years of childhood of his scopophilic instinct. We should be most glad to give an account of the way in which artistic activity derives from the primal instincts of the mind if it were not just here that our capacities fail us. We must be content to emphasize the fact - which it is hardly any longer possible to doubt - that what an artist creates provides at the same time an outlet for his sexual desire; and in Leonardo's case we can point to the information which comes from Vasari, that heads of laughing women and beautiful boys - in other words, representations of his sexual objects - were notable among his first artistic endeavours. In the bloom of his youth Leonardo appears at first to have worked without inhibition. Just as he modelled himself on his father in the outward conduct of his life, so too he passed through a period of masculine creative power and artistic productiveness in Milan, where a kindly fate enabled him to find a father substitute in the duke Lodovico Moro. But soon we and confirmation of our experience that the almost total repression of a real sexual life does not provide the most favourable conditions for the exercise of sublimated sexual trends. The pattern imposed by sexual life made itself felt. His activity and his ability to form quick decisions began to fail; his tendency towards deliberation and delay was already noticeable as a disturbing element in the 'Last Supper', and by influencing his technique it had a decisive effect on the fate of that great painting. Slowly there occurred in him a process which can only be compared to the regressions in neurotics. The development that turned him into an artist at puberty was overtaken by the process which led him to be an investigator, and which had its determinants in early infancy. The second sublimation of his erotic instinct gave place to the original sublimation for which the way had been prepared on the occasion of the first repression. He became an investigator, at first still in the service of his art, but later independently of it and away from it. With the loss of his patron, the substitute for his father, and with the increasingly sombre colours which his life took on, this regressive shift assumed larger and larger proportions. He became 'impacientissimo al pennello',¹ as we are told by a correspondent of the Countess Isabella d'Este, who was extremely eager to possess a painting from his hand. His infantile past had gained control over him. But the research which now took the place of artistic creation seems to have contained some of the features which distinguish the activity of unconscious instincts - insatiability, unyielding rigidity and the lack of an ability to adapt to real circumstances.

[1910c, 2301]
But even if the historical material at our disposal were very abundant, and if the psychical mechanisms could be dealt with with the greatest assurance, there are two important points at which a psycho-analytic enquiry would not be able to make us understand how inevitable it was that the person concerned should have turned out in the way he did and in no other way. In Leonardo’s case we have had to maintain the view that the accident of his illegitimate birth and the excessive tenderness of his mother had the most decisive influence on the formation of his character and on his later fortune, since the sexual repression which set in after this phase of childhood caused him to sublimate his libido into the urge to know, and established his sexual inactivity for the whole of his later life. But this repression after the first erotic satisfactions of childhood need not necessarily have taken place; in someone else it might perhaps not have taken place or might have assumed much less extensive proportions. We must recognize here a degree of freedom which cannot be resolved any further by psycho-analytic means. Equally, one has no right to claim that the consequence of this wave of repression was the only possible one. It is probable that another person would not have succeeded in withdrawing the major portion of his libido from repression by sublimating it into a craving for knowledge; under the same influences he would have sustained a permanent injury to his intellectual activity or have acquired an insurmountable disposition to obsessional neurosis. We are left, then, with these two characteristics of Leonardo which are inexplicable by the efforts of psycho-analysis: his quite special tendency towards instinctual repressions, and his extraordinary capacity for sublimating the primitive instincts. [1910c, 2303]

Thus we may perhaps be forced to become reconciled to the idea that it is quite impossible to adjust the claims of the sexual instinct to the demands of civilization; that in consequence of its cultural development renunciation and suffering, as well as the danger of extinction in the remotest future, cannot be avoided by the human race. This gloomy prognosis rests, it is true, on the single conjecture that the non-satisfaction that goes with civilization is the necessary consequence of certain peculiarities which the sexual instinct has assumed under the pressure of culture. The very incapacity of the sexual instinct to yield complete satisfaction as soon as it submits to the first demands of civilization becomes the source, however, of the noblest cultural achievements which are brought into being by ever more extensive sublimation of its instinctual components. For what motive would men have for putting sexual instinctual forces to other uses if, by any distribution of those forces, they could obtain fully satisfying pleasure? They would never abandon that pleasure and they would never make any further progress. It seems, therefore, that the irreconcilable difference between the demands of the two instincts - the sexual and the egoistic - has made men capable of ever higher achievements, though subject, it is true, to a constant danger, to which, in the form of neurosis, the weaker are succumbing today. [1912d, 2346]
If, then, as we have learnt, psychogenic disturbances of vision depend on certain ideas connected with seeing being cut off from consciousness, we must, on the psycho-analytic view, assume that these ideas have come into opposition to other, more powerful ones, for which we use the collective concept of the 'ego'- a compound which is made up variously at different times - and have for that reason come under repression. But what can be the origin of this opposition, which makes for repression, between the ego and various groups of ideas? You will no doubt notice that it was not possible to frame such a question before the advent of psycho-analysis, for nothing was known earlier of psychical conflict and repression. Our researches, however, have put us in a position to give us the desired answer. Our attention has been drawn to the importance of the instincts in ideational life. We have discovered that every instinct tries to make itself effective by activating ideas that are in keeping with its aims. These instincts are not always compatible with one another; their interests often come into conflict. Opposition between ideas is only an expression of struggles between the various instincts. From the point of view of our attempted explanation, a quite specially important part is played by the undeniable opposition between the instincts which subserve sexuality, the attainment of sexual pleasure, and those other instincts, which have as their aim the self-preservation of the individual - the ego-instincts. As the poet has said, all the organic instincts that operate in our mind may be classified as 'hunger' or 'love'. We have traced the 'sexual instinct' from its first manifestations in children to its final form, which is described as 'normal'. We have found that it is put together from numerous 'component instincts' which are attached to excitations of regions of the body; and we have come to see that these separate instincts have to pass through a complicated development before they can be brought effectively to serve the aims of reproduction. The light thrown by psychology on the evolution of our civilization has shown us that it originates mainly at the cost of the sexual component instincts, and that these must be suppressed, restricted, transformed and directed to higher aims, in order that the mental constructions of civilization may be established. We have been able to recognize as a valuable outcome of these researches something that our colleagues have not yet been willing to believe, namely that the human ailments known as 'neuroses' are derived from the many different ways in which these processes of transformation in the sexual component instincts may miscarry. The 'ego' feels threatened by the claims of the sexual instincts and fends them off by repressions; these, however, do not always have the desired result, but lead to the formation of dangerous substitutes for the repressed and to burdensome reactions on the part of the ego. From these two classes of phenomena taken together there emerge what we call the symptoms of neuroses.

[1910i, 2368]
Let us start with the latter, the scientific errors. The doctor's advice to the lady shows clearly in what sense he understands the expression 'sexual life' - in the popular sense, namely, in which by sexual needs nothing is meant but the need for coitus or analogous acts producing orgasm and emission of the sexual substances. He cannot have remained unaware, however, that psycho-analysis is commonly reproached with having extended the concept of what is sexual far beyond its usual range. The fact is undisputed; I shall not discuss here whether it may justly be used as a reproach. In psycho-analysis the concept of what is sexual comprises far more; it goes lower and also higher than its popular sense. This extension is justified genetically; we reckon as belonging to 'sexual life' all the activities of the tender feelings which have primitive sexual impulses as their source, even when those impulses have become inhibited in regard to their original sexual aim or have exchanged this aim for another which is no longer sexual. For this reason we prefer to speak of psychosexuality, thus laying stress on the point that the mental factor in sexual life should not be overlooked or underestimated. We use the word 'sexuality' in the same comprehensive sense as that in which the German language uses the word lieben ['to love']. We have long known, too, that mental absence of satisfaction with all its consequences can exist where there is no lack of normal sexual intercourse; and as therapists we always bear in mind that the unsatisfied sexual trends (whose substitutive satisfactions in the form of nervous symptoms we combat) can often find only very inadequate outlet in coitus or other sexual acts.

[1910k, 2375]

After the stage of heterosexual object-choice has been reached, the homosexual tendencies are not, as might be supposed, done away with or brought to a stop; they are merely deflected from their sexual aim and applied to fresh uses. They now combine with portions of the ego-instincts and, as 'attached' components, help to constitute the social instincts, thus contributing an erotic factor to friendship and comradeship, to esprit de corps and to the love of mankind in general. How large a contribution is in fact derived from erotic sources (with the sexual aim inhibited) could scarcely be guessed from the normal social relations of mankind. But it is not irrelevant to note that it is precisely manifest homosexuals, and among them again precisely those that set themselves against an indulgence in sensual acts, who are distinguished by taking a particularly active share in the general interests of humanity - interests which have themselves sprung from a sublimation of erotic instincts.

[1911c, 2431]
(h) Another temptation arises out of the educative activity which, in psycho-analytic treatment, devolves on the doctor without any deliberate intention on his part. When the developmental inhibitions are resolved, it happens of itself that the doctor finds himself in a position to indicate new aims for the trends that have been liberated. It is then no more than a natural ambition if he endeavours to make something specially excellent of a person whom he has been at such pains to free from his neurosis and if he prescribes high aims for his wishes. But here again the doctor should hold himself in check, and take the patient's capacities rather than his own desires as guide. Not every neurotic has a high talent for sublimation; one can assume of many of them that they would not have fallen ill at all if they had possessed the art of sublimating their instincts. If we press them unduly towards sublimation and cut them off from the most accessible and convenient instinctual satisfactions, we shall usually make life even harder for them than they feel it in any case. As a doctor, one must above all be tolerant to the weakness of a patient, and must be content if one has won back some degree of capacity for work and enjoyment for a person even of only moderate worth. Educative ambition is of as little use as therapeutic ambition. It must further be borne in mind that many people fall ill precisely from an attempt to sublimate their instincts beyond the degree permitted by their organization and that in those who have a capacity for sublimation the process usually takes place of itself as soon as their inhibitions have been overcome by analysis. In my opinion, therefore, efforts invariably to make use of the analytic treatment to bring about sublimation of instinct are, though no doubt always laudable, far from being in every case advisable.

[1912e, 2473]

Researches into the sexual activity of children have led to a further conception of the sexual instinct, based not on its purposes but on its sources. The sexual instinct possesses in a high degree the capacity for being diverted from direct sexual aims and for being directed towards higher aims which are no longer sexual ('sublimation'). The instinct is thus enabled to make most important contributions to the social and artistic achievements of humanity.

[1913m, 2547]

Thus with this type, to which, no doubt, the majority of human beings on the whole belong, the possibility of falling ill arises only when there is abstinence. And it may be judged from this what an important part in the causation of neuroses may be played by the limitation imposed by civilization on the field of accessible satisfactions. Frustration has a pathogenic effect because it dams up libido, and so submits the subject to a test as to how long he can tolerate this increase in psychical tension and as to what methods he will adopt for dealing with it. There are only two possibilities for remaining healthy when there is a persistent frustration of satisfaction in the real world. The first is by transforming the psychical tension into active energy which remains directed towards the external world and eventually extorts a real satisfaction of the libido from it. The second is by renouncing libidinal satisfaction, sublimating the dammed-up libido and turning it to the attainment of aims which are no longer erotic and which escape frustration. That these two possibilities are realized in men's lives proves that unhappiness does not coincide with neurosis and that frustration does not alone decide whether its victim remains healthy or falls ill. The immediate effect of frustration lies in its bringing into play the dispositional factors which have hitherto been inoperative.

[1912c, 2560]
Just as the third type has brought the dispositional determinant before us almost in isolation, so the fourth type, which now follows, draws our attention to another factor, which comes into consideration in every single case and might easily for that very reason be overlooked in a theoretical discussion. We see people fall ill who have hitherto been healthy, who have met with no fresh experience and whose relation to the external world has undergone no change, so that the onset of their illness inevitably gives an impression of spontaneity. A closer consideration of such cases, however, shows us that none the less a change has taken place in them whose importance we must rate very highly as a cause of illness. As a result of their having reached a particular period of life, and in conformity with regular biological processes, the quantity of libido in their mental economy has experienced an increase which is in itself enough to upset the equilibrium of their health and to set up the necessary conditions for a neurosis. It is well known that more or less sudden increases of libido of this kind are habitually associated with puberty and the menopause - with the attainment of a certain age in women; in some people they may in addition be manifested in periodicities that are still unknown. Here the damming-up of libido is the primary factor; it becomes pathogenic as a consequence of a relative frustration on the part of the external world, which would still have granted satisfaction to a smaller claim by the libido. The unsatisfied and dammed-up libido can once again open up paths to regression and kindle the same conflicts which we have demonstrated in the case of absolute external frustration. We are reminded in this way that the quantitative factor should not be left out of account in any consideration of the precipitating causes of illness. All the other factors - frustration, fixation, developmental inhibition - remain ineffective unless they affect a certain amount of libido and bring about a damming-up of libido of a certain height. It is true that we are unable to measure this amount of libido which seems to us indispensable for a pathogenic effect; we can only postulate it after the resulting illness has started. There is only one direction in which we can determine it more precisely. We may assume that it is not a question of an absolute quantity, but of the relation between the quota of libido in operation and the quantity of libido which the individual ego is able to deal with - that is, to hold under tension, to sublimate or to employ directly. For this reason a relative increase in the quantity of libido may have the same effects as an absolute one. An enfeeblement of the ego owing to organic illness or owing to some special demand upon its energy will be able to cause the emergence of neuroses which would otherwise have remained latent in spite of any disposition that might be present.

[1912c, 2563]

Just as Adler's investigation brought something new to psycho-analysis - a contribution to the psychology of the ego - and then expected us to pay too high a price for this gift by throwing over all the fundamental theories of analysis, so in the same way Jung and his followers paved the way for their fight against psycho-analysis by presenting it with a new acquisition. They traced in detail (as Pfister did before them) the way in which the material of sexual ideas belonging to the family-complex and incestuous object-choice is made use of in representing the highest ethical and religious interests of man - that is, they have illuminated an important instance of the sublimation of the erotic instinctual forces and of their transformation into trends which can no longer be called erotic. This was in complete harmony with all the expectations of psycho-analysis, and would have agreed very well with the view that in dreams and neurosis a regressive dissolution of this sublimation, as of all others, becomes visible. But the world would have risen in indignation and protested that ethics and religion were being sexualized. Now I cannot refrain from thinking teleologically for once and concluding that these discoverers were not equal to meeting such a storm of indignation. Perhaps it even began to rage in their own bosoms. The theological prehistory of so many of the Swiss throws no less light on their attitude to psycho-analysis than does Adler's socialist prehistory on the development of his psychology. One is reminded of Mark Twain's famous story of all the things that happened to his watch and of his concluding words: 'And he used to wonder what became of all the unsuccessful tinkers, and gunsmiths, and shoemakers, and blacksmiths; but nobody could ever tell him.'

[1914d, 2924]
We are naturally led to examine the relation between this forming of an ideal and sublimation. Sublimation is a process that concerns object-libido and consists in the instinct's directing itself towards an aim other than, and remote from, that of sexual satisfaction; in this process the accent falls upon deflection from sexuality. Idealization is a process that concerns the object; by it that object, without any alteration in its nature, is aggrandized and exalted in the subject's mind. Idealization is possible in the sphere of ego-libido as well as in that of object-libido. For example, the sexual overvaluation of an object is an idealization of it. In so far as sublimation describes something that has to do with the instinct and idealization something to do with the object, the two concepts are to be distinguished from each other.

The formation of an ego ideal is often confused with the sublimation of instinct, to the detriment of our understanding of the facts. A man who has exchanged his narcissism for homage to a high ego ideal has not necessarily on that account succeeded in sublimating his libidinal instincts. It is true that the ego ideal demands such sublimation, but it cannot enforce it; sublimation remains a special process which may be prompted by the ideal but the execution of which is entirely independent of any such prompting. It is precisely in neurotics that we find the highest differences of potential between the development of their ego ideal and the amount of sublimation of their primitive libidinal instincts; and in general it is far harder to convince an idealist of the inexpedient location of his libido than a plain man whose pretensions have remained more moderate. Further, the formation of an ego ideal and sublimation are quite differently related to the causation of neurosis. As we have learnt, the formation of an ideal heightens the demands of the ego and is the most powerful factor favouring repression; sublimation is a way out, a way by which those demands can be met without involving repression.

The ego ideal opens up an important avenue for the understanding of group psychology. In addition to its individual side, this ideal has a social side; it is also the common ideal of a family, a class or a nation. It binds not only a person's narcissistic libido, but also a considerable amount of his homosexual libido, which is in this way turned back into the ego. The want of satisfaction which arises from the non-fulfilment of this ideal liberates homosexual libido, and this is transformed into a sense of guilt (social anxiety). Originally this sense of guilt was a fear of punishment by the parents, or, more correctly, the fear of losing their love; later the parents are replaced by an indefinite number of fellow-men. The frequent causation of paranoia by an injury to the ego, by a frustration of satisfaction within the sphere of the ego ideal, is thus made more intelligible, as is the convergence of ideal-formation and sublimation in the ego ideal, as well as the involution of sublimations and the possible transformation of ideals in paraphrenic disorders.
This much can be said by way of a general characterization of the sexual instincts. They are numerous, emanate from a great variety of organic sources, act in the first instance independently of one another and only achieve a more or less complete synthesis at a late stage. The aim which each of them strives for is the attainment of 'organ-pleasure'; only when synthesis is achieved do they enter the service of the reproductive function and thereupon become generally recognizable as sexual instincts. At their first appearance they are attached to the instincts of self-preservation, from which they only gradually become separated; in their choice of object, too, they follow the paths that are indicated to them by the ego-instincts. A portion of them remains associated with the ego-instincts throughout life and furnishes them with libidinal components, which in normal functioning easily escape notice and are revealed clearly only by the onset of illness. They are distinguished by possessing the capacity to act vicariously for one another to a wide extent and by being able to change their objects readily. In consequence of the latter properties they are capable of functions which are far removed from their original purposive actions - capable, that is, of 'sublimation'.

[1915c, 2963]

Co-operation between a preconscious and an unconscious impulse, even when the latter is intensely repressed, may come about if there is a situation in which the unconscious impulse can act in the same sense as one of the dominant trends. The repression is removed in this instance, and the repressed activity is admitted as a reinforcement of the one intended by the ego. The unconscious becomes ego-syntonic in respect of this single conjunction without any change taking place in its repression apart from this. In this co-operation the influence of the Ucs. is unmistakable: the reinforced tendencies reveal themselves as being nevertheless different from the normal; they make specially perfect functioning possible, and they manifest a resistance in the face of opposition which is similar to that offered, for instance, by obsessional symptoms.

[1915e, 3017]

Thus our therapeutic work falls into two phases. In the first, all the libido is forced from the symptoms into the transference and concentrated there; in the second, the struggle is waged around this new object and the libido is liberated from it. The change which is decisive for a favourable outcome is the elimination of repression in this renewed conflict so that the libido cannot withdraw once more from the ego by flight into the unconscious. This is made possible by the alteration of the ego which is accomplished under the influence of the doctor's suggestion. By means of the work of interpretation, which transforms what is unconscious into what is conscious, the ego is enlarged at the cost of this unconscious; by means of instruction, it is made conciliatory towards the libido and inclined to grant it some satisfaction, and its repugnance to the claims of the libido is diminished by the possibility of disposing of a portion of it by sublimation. The more closely events in the treatment coincide with this ideal description, the greater will be the success of the psycho-analytic therapy. It finds its limits in the lack of mobility of the libido, which may refuse to leave its objects, and the rigidity of narcissism, which will not allow transference on to objects to increase beyond certain bounds. Further light may perhaps be thrown on the dynamics of the process of cure if I say that we get hold of the whole of the libido which has been withdrawn from the dominance of the ego by attracting a portion of it on to ourselves by means of the transference.

[1916-1917, 3495]
It would, however, be a great mistake to suppose that after the removal of the obsessional symptoms no permanent effects of the obsessional neurosis remained behind. The process had led to a victory for the faith of piety over the rebelliousness of critical research, and had had the repression of the homosexual attitude as its necessary condition. Lasting disadvantages resulted from both these factors. His intellectual activity remained seriously impaired after this first great defeat. He developed no zeal for learning, he showed no more of the acuteness with which at the tender age of five he had criticized and dissected the doctrines of religion. The repression of his over-powerful homosexuality, which was accomplished during the anxiety-dream, reserved that important impulse for the unconscious, kept it directed towards its original aim, and withdrew it from all the sublimations to which it is susceptible in other circumstances. For this reason the patient was without all those social interests which give a content to life. It was only when, during the analytic treatment, it became possible to liberate his shackled homosexuality that this state of affairs showed any improvement; and it was a most remarkable experience to see how (without any direct advice from the physician) each piece of homosexual libido which was set free sought out some application in life and some attachment to the great common concerns of mankind.

[1918b, 3553]
The sexual instinct - or, more correctly, the sexual instincts, for analytic investigation teaches us that the sexual instinct is made up of many separate constituents or component instincts - is probably more strongly developed in man than in most of the higher animals; it is certainly more constant, since it has almost entirely overcome the periodicity to which it is tied in animals. It places extraordinarily large amounts of force at the disposal of civilized activity, and it does this in virtue of its especially marked characteristic of being able to displace its aim without materially diminishing in intensity. This capacity to exchange its originally sexual aim for another one, which is no longer sexual but which is psychically related to the first aim, is called the capacity for sublimation. In contrast to this displaceability, in which its value for civilization lies, the sexual instinct may also exhibit a particularly obstinate fixation which renders it unserviceable and which sometimes causes it to degenerate into what are described as abnormalities. The original strength of the sexual instinct probably varies in each individual; certainly the proportion of it which is suitable for sublimation varies. It seems to us that it is the innate constitution of each individual which decides in the first instance how large a part of his sexual instinct it will be possible to sublimate and make use of. In addition to this, the effects of experience and the intellectual influences upon his mental apparatus succeed in bringing about the sublimation of a further portion of it. To extend this process of displacement indefinitely is, however, certainly not possible, any more than is the case with the transformation of heat into mechanical energy in our machines. A certain amount of direct sexual satisfaction seems to be indispensable for most organizations, and a deficiency in this amount, which varies from individual to individual, is visited by phenomena which, on account of their detrimental effects on functioning and their subjective quality of unpleasure, must be regarded as an illness.

The answer to the first question touches on a problem which has often been discussed and cannot be exhaustively treated here - that of sexual abstinence. Our third stage of civilization demands of individuals of both sexes that they shall practise abstinence until they are married and that all who do not contract a legal marriage shall remain abstinent throughout their lives. The position, agreeable to all the authorities, that sexual abstinence is not harmful and not difficult to maintain, has also been widely supported by the medical profession. It may be asserted, however, that the task of mastering such a powerful impulse as that of the sexual instinct by any other means than satisfying it is one which can call for the whole of a man's forces. Mastering it by sublimation, by deflecting the sexual instinctual forces away from their sexual aim to higher cultural aims, can be achieved by a minority and then only intermittently, and least easily during the period of ardent and vigorous youth. Most of the rest become neurotic or are harmed in one way or another. Experience shows that the majority of the people who make up our society are constitutionally unfit to face the task of abstinence. Those who would have fallen ill under milder sexual restrictions fall ill all the more readily and more severely before the demands of our cultural sexual morality of to-day; for we know no better safe-guard against the threat to normal sexual life offered by defective innate dispositions or disturbances of development than sexual satisfaction itself. The more a person is disposed to neurosis, the less can he tolerate abstinence; instincts which have been withdrawn from normal development, in the sense in which it has been described above, become at the same time all the more uninhibitible. But even those people who would have retained their health under the requirements of the second stage of civilization will now succumb to neurosis in great numbers. For the psychical value of sexual satisfaction increases with its frustration. The dammed-up libido is now put in a position to detect one or other of the weaker spots which are seldom absent in the structure of sexual life, and there to break through and obtain substitutive satisfaction of a neurotic kind in the form of pathological symptoms. Anyone who is able to penetrate the determinants of nervous illness will soon become convinced that its increase in our society arises from the intensification of sexual restrictions.

[1908d, 1952]
The retardation of sexual development and sexual activity at which our education and civilization aim is certainly not injurious to begin with. It is seen to be a necessity, when one considers the late age at which young people of the educated classes reach independence and are able to earn a living. (This reminds one, incidentally, of the intimate interconnection between all our cultural institutions and of the difficulty of altering any part of them without regard to the whole.) But abstinence continued long after the age of twenty is no longer unobjectionable for a young man; and it leads to other damage even when it does not lead to neurosis. People say, to be sure, that the struggle against such a powerful instinct, and the strengthening of all the ethical and aesthetic forces which are necessary for this struggle, 'steel' the character; and this is true for a few specially favourably organized natures. It must also be admitted that the differentiation of individual character, which is so marked in our day, has only become possible with the existence of sexual restriction. But in the vast majority of cases the struggle against sexuality eats up the energy available in a character and this at the very time when a young man is in need of all his forces in order to win his share and place in society. The relationship between the amount of sublimation possible and the amount of sexual activity necessary naturally varies very much from person to person and even from one calling to another. An abstinent artist is hardly conceivable; but an abstinent young savant is certainly no rarity. The latter can, by his self-restraint, liberate forces for his studies; while the former probably finds his artistic achievements powerfully stimulated by his sexual experience. In general I have not gained the impression that sexual abstinence helps to bring about energetic and self-reliant men of action or original thinkers or bold emancipators and reformers. Far more often it goes to produce well-behaved weaklings who later become lost in the great mass of people that tends to follow, unwillingly, the leads given by strong individuals.

[1908d, 1958]

We must not omit to consider the third of the possible outcomes of the work of psychoanalysis. A certain portion of the repressed libidinal impulses has a claim to direct satisfaction and ought to find it in life. Our civilized standards make life too difficult for the majority of human organizations. Those standards consequently encourage the retreat from reality and the generating of neuroses, without achieving any surplus of cultural gain by this excess of sexual repression. We ought not to exalt ourselves so high as completely to neglect what was originally animal in our nature. Nor should we forget that the satisfaction of the individual's happiness cannot be erased from among the aims of our civilization. The plasticity of the components of sexuality, shown by their capacity for sublimation, may indeed offer a great temptation to strive for still greater cultural achievements by still further sublimation. But, just as we do not count on our machines converting more than a certain fraction of the heat consumed into useful mechanical work, we ought not to seek to alienate the whole amount of the energy of the sexual instinct from its proper ends. We cannot succeed in doing so; and if the restriction upon sexuality were to be carried too far it would inevitably bring with it all the evils of soil-exhaustion.

[1910a, 2239]
Another temptation arises out of the educative activity which, in psycho-analytic treatment, devolves on the doctor without any deliberate intention on his part. When the developmental inhibitions are resolved, it happens of itself that the doctor finds himself in a position to indicate new aims for the trends that have been liberated. It is then no more than a natural ambition if he endeavours to make something specially excellent of a person whom he has been at such pains to free from his neurosis and if he prescribes high aims for his wishes. But here again the doctor should hold himself in check, and take the patient's capacities rather than his own desires as guide. Not every neurotic has a high talent for sublimation; one can assume of many of them that they would not have fallen ill at all if they had possessed the art of sublimating their instincts. If we press them unduly towards sublimation and cut them off from the most accessible and convenient instinctual satisfactions, we shall usually make life even harder for them than they feel it in any case. As a doctor, one must above all be tolerant to the weakness of a patient, and must be content if one has won back some degree of capacity for work and enjoyment for a person even of only moderate worth. Educative ambition is of as little use as therapeutic ambition. It must further be borne in mind that many people fall ill precisely from an attempt to sublimate their instincts beyond the degree permitted by their organization and that in those who have a capacity for sublimation the process usually takes place of itself as soon as their inhibitions have been overcome by analysis. In my opinion, therefore, efforts invariably to make use of the analytic treatment to bring about sublimation of instinct are, though no doubt always laudable, far from being in every case advisable.

[1912e, 2473]

Think it over! You have learnt all that is essential about the determinants of falling ill as well as all the factors that come into effect after the patient has fallen ill. Where do these leave room for any therapeutic influence? In the first place there is hereditary disposition. We have not talked about it very often because it is emphatically stressed from other directions and we have nothing new to say about it. But do not suppose that we underestimate it; precisely as therapists we come to realize its power clearly enough. In any case we can do nothing to alter it; we too must take it as something given, which sets a limit to our efforts. Next there is the influence of early experiences in childhood, to which we are in the habit of giving prominence in analysis: they belong to the past and we cannot undo them. Then comes everything that we have summarized as 'real frustration' - the misfortunes of life from which arise deprivation of love, poverty, family quarrels, ill-judged choice of a partner in marriage, unfavourable social circumstances, and the strictness of the ethical standards to whose pressure the individual is subject. Here, to be sure, there would be handles enough for a very effective therapy, but it would have to be of the kind which Viennese folklore attributes to the Emperor Joseph - the benevolent interference of a powerful personage before whose will people bow and difficulties vanish. But who are we, that we should be able to adopt benevolence of this kind as an instrument of our therapy? Poor ourselves and socially powerless, and compelled to earn our livelihood from our medical activity, we are not even in a position to extend our efforts to people without means, as other doctors with other methods of treatment are after all able to do. Our therapy is too time-consuming and too laborious for that to be possible. Perhaps, however, you are clutching at one of the factors I have mentioned and believe that there you have found the point at which our influence can make its attack. If the ethical restrictions demanded by society play a part in the deprivation imposed on the patient, treatment can, after all, give him the courage, or perhaps a direct injunction, to disregard those barriers and achieve satisfaction and recovery while forgoing the fulfilment of an ideal that is exalted, but so often not adhered to, by society. The patient will thus become healthy by 'living a full life' sexually. This, it is true, casts a shadow on analytic treatment for not serving general morality. What it has given to the individual it will have taken from the community.

[1916-1917, 3475]
Thus our therapeutic work falls into two phases. In the first, all the libido is forced from the symptoms into the transference and concentrated there; in the second, the struggle is waged around this new object and the libido is liberated from it. The change which is decisive for a favourable outcome is the elimination of repression in this renewed conflict so that the libido cannot withdraw once more from the ego by flight into the unconscious. This is made possible by the alteration of the ego which is accomplished under the influence of the doctor's suggestion. By means of the work of interpretation, which transforms what is unconscious into what is conscious, the ego is enlarged at the cost of this unconscious; by means of instruction, it is made conciliatory towards the libido and inclined to grant it some satisfaction, and its repugnance to the claims of the libido is diminished by the possibility of disposing of a portion of it by sublimation. The more closely events in the treatment coincide with this ideal description, the greater will be the success of the psycho-analytic therapy. It finds its limits in the lack of mobility of the libido, which may refuse to leave its objects, and the rigidity of narcissism, which will not allow transference on to objects to increase beyond certain bounds. Further light may perhaps be thrown on the dynamics of the process of cure if I say that we get hold of the whole of the libido which has been withdrawn from the dominance of the ego by attracting a portion of it on to ourselves by means of the transference.

[1916-1917, 3495]
I cannot simplify my statement by describing my patient's death-wish against his brother-in-law as an unconscious, repressed one. For it had been made conscious during the treatment the year before and the consequences which had followed from its repression had yielded to the treatment. But it still persisted, and, though it was no longer pathogenic, it was sufficiently intense. It might be described as a 'suppressed' wish.
[1941d [1921], 3869]
REACTION-FORMATION AND SUBLIMATION

What is it that goes to the making of these constructions which are so important for the growth of a civilized and normal individual? They probably emerge at the cost of the infantile sexual impulses themselves. Thus the activity of those impulses does not cease even during this period of latency, though their energy is diverted, wholly or in great part, from their sexual use and directed to other ends. Historians of civilization appear to be at one in assuming that powerful components are acquired for every kind of cultural achievement by this diversion of sexual instinctual forces from sexual aims and their direction to new ones - a process which deserves the name of 'sublimation'. To this we would add, accordingly, that the same process plays a part in the development of the individual and we would place its beginning in the period of sexual latency of childhood.¹

² [Footnote added 1915:] In the case which I am here discussing, the sublimation of sexual instinctual forces takes place along the path of reaction-formation. But in general it is possible to distinguish the concepts of sublimation and reaction-formation from each other as two different processes. Sublimation can also take place by other and simpler mechanisms.

A powerful wave of repression brought this childhood excess to an end, and established the dispositions which were to become manifest in the years of puberty. The most obvious result of the transformation was the avoidance of every crudely sensual activity; Leonardo was enabled to live in abstinence and to give the impression of being an asexual human being. When the excitations of puberty came in their flood upon the boy they did not, however, make him ill by forcing him to develop substitutive structures of a costly and harmful kind. Owing to his very early inclination towards sexual curiosity the greater portion of the needs of his sexual instinct could be sublimated into a general urge to know, and thus evaded repression. A much smaller portion of his libido continued to be devoted to sexual aims and represented a stunted adult sexual life. Because his love for his mother had been repressed, this portion was driven to take up a homosexual attitude and manifested itself in ideal love for boys. The fixation on his mother and on the blissful memories of his relations with her continued to be preserved in the unconscious, but for the time being it remained in an inactive state. In this way repression, fixation and sublimation all played their part in disposing of the contributions which the sexual instinct made to Leonardo's mental life.

¹ [1905d, 1500]

² [1910c, 2301]
Our most valuable lesson from Breuer's observation was what it proved concerning the relation between symptoms and pathogenic experiences or psychical traumas, and we must not omit now to consider these discoveries from the standpoint of the theory of repression. At first sight it really seems impossible to trace a path from repression to the formation of symptoms. Instead of giving a complicated theoretical account, I will return here to the analogy which I employed earlier for my explanation of repression. If you come to think of it, the removal of the interrupter and the posting of the guardians at the door may not mean the end of the story. It may very well be that the individual who has been expelled, and who has now become embittered and reckless, will cause us further trouble. It is true that he is no longer among us; we are free from his presence, from his insulting laughter and his sotto voce comments. But in some respects, nevertheless, the repression has been unsuccessful; for now he is making an intolerable exhibition of himself outside the room, and his shouting and banging on the door with his fists interfere with my lecture even more than his bad behaviour did before. In these circumstances we could not fail to be delighted if our respected president, Dr. Stanley Hall, should be willing to assume the role of mediator and peacemaker. He would have a talk with the unruly person outside and would then come to us with a request that he should be re-admitted after all: he himself would guarantee that the man would now behave better. On Dr. Hall's authority we decide to lift the repression, and peace and quiet are restored. This presents what is really no bad picture of the physician's task in the psycho-analytic treatment of the neuroses. [1910a, 2214]

In this connection people usually overlook the one essential point - that the pathogenic conflict in neurotics is not to be confused with a normal struggle between mental impulses both of which are on the same psychological footing. In the former case the dissension is between two powers, one of which has made its way to the stage of what is preconscious or conscious while the other has been held back at the stage of the unconscious. For that reason the conflict cannot be brought to an issue; the disputants can no more come to grips than, in the familiar simile, a polar bear and a whale. A true decision can only be reached when they both meet on the same ground. To make this possible is, I think, the sole task of our therapy. [1916-1917, 3476]

That this is a correct account of fixation upon repression and of the retention of danger-situations that are no longer present-day ones is confirmed by the fact of analytic therapy - a fact which is modest enough in itself but which can hardly be overrated from a theoretical point of view. When, in analysis, we have given the ego assistance which is able to put it in a position to lift its repressions, it recovers its power over the repressed id and can allow the instinctual impulses to run their course as though the old situations of danger no longer existed. What we can do in this way tallies with what can be achieved in other fields of medicine; for as a rule our therapy must be content with bringing about more quickly, more reliably and with less expenditure of energy than would otherwise be the case the good result which in favourable circumstances would have occurred of itself. [1926d, 4308]
It is perhaps not without interest for its own sake to be able to see into the history of a psychical event of this kind, which is among the most trivial disturbances that can affect the control of the psychical apparatus and which is compatible with an otherwise untroubled state of psychical health. But the example elucidated here receives an immensely added interest when we learn that it may serve as nothing more nor less than a model for the pathological processes to which the psychical symptoms of the psychoneuroses - hysteria, obsessions and paranoia - owe their origin. In both cases we find the same elements and the same play of forces between those elements. In the same manner as here and by means of similar superficial associations, a repressed train of thought takes possession in neuroses of an innocent recent impression and draws it down with itself into repression. The same mechanism which causes the substitute names 'Botticelli' and 'Boltraffio' to emerge from 'Signorelli' (a substitution by means of intermediate or compromise ideas) also governs the formation of obsessional thoughts and paranoic paramnesias. Again, we have seen that such cases of forgetfulness have the characteristic of liberating continuous unpleasure till the moment the problem is solved - a characteristic which is unintelligible apart from this, and something which was in fact unintelligible to the person I was talking to; but there is a complete analogy to it in the way in which collections of repressed thoughts attach their capacity for producing affect to some symptom whose psychical content seems to our judgement totally unsuited to such a liberation of affect. Finally, the resolution of the whole tension by a communication of the correct name from an external quarter is itself a good example of the efficacy of psycho-analytic therapy, which aims at correcting the repressions and displacements and which removes the symptoms by re-instating the genuine psychical object.
[1898b, 482]
I will without delay add some factual details and some commentary to the result I have announced, in order to combat the scepticism with which I expect to meet. I have been able to carry out a complete psycho-analysis in thirteen cases of hysteria, three of that number being true combinations of hysteria and obsessional neurosis. (I do not speak of hysteria with obsessions.) In none of these cases was an event of the kind defined above missing. It was represented either by a brutal assault committed by an adult or by a seduction less rapid and less repulsive, but reaching the same conclusion. In seven out of the thirteen cases the intercourse was between children on both sides - sexual relations between a little girl and a boy a little older (most often her brother) who had himself been the victim of an earlier seduction. These relations sometimes continued for years, until the little guilty parties reached puberty; the boy would repeat the same practices with the little girl over and over again and without alteration - practices to which he himself had been subjected by some female servant or governess and which on account of their origin were often of a disgusting sort. In a few cases there was a combination of an assault and relations between children or a repetition of a brutal abuse.

[1896a, 376]

Without wishing to lay special stress on the point, I will add that in a number of cases therapeutic evidence of the genuineness of the infantile scenes can also be brought forward. There are cases in which a complete or partial cure can be obtained without our having to go as deep as the infantile experiences. And there are others in which no success at all is obtained until the analysis has come to its natural end with the uncovering of the earliest traumas. In the former cases we are not, I believe, secure against relapses; and my expectation is that a complete psycho-analysis implies a radical cure of the hysteria. We must not, however, be led into forestalling the lessons of observation.

[1896c, 420]

There is another kind of fausse reconnaissance which not infrequently makes its appearance at the close of a treatment, much to the physician's satisfaction. After he has succeeded in forcing the repressed event (whether it was of a real or of a psychical nature) upon the patient's acceptance in the teeth of all resistances, and has succeeded, as it were, in rehabilitating it - the patient may say: 'Now I feel as though I had known it all the time.' With this the work of the analysis has been completed.

[1914a, 2842]
But you will now tell me that, no matter whether we call the motive force of our analysis transference or suggestion, there is a risk that the influencing of our patient may make the objective certainty of our findings doubtful. What is advantageous to our therapy is damaging to our researches. This is the objection that is most often raised against psycho-analysis, and it must be admitted that, though it is groundless, it cannot be rejected as unreasonable. If it were justified, psycho-analysis would be nothing more than a particularly well-disguised and particularly effective form of suggestive treatment and we should have to attach little weight to all that it tells us about what influences our lives, the dynamics of the mind or the unconscious. That is what our opponents believe; and in especial they think that we have "talked" the patients into everything relating to the importance of sexual experiences - or even into those experiences themselves - after such notions have grown up in our own depraved imagination. These accusations are contradicted more easily by an appeal to experience than by the help of theory. Anyone who has himself carried out psycho-analyses will have been able to convince himself on countless occasions that it is impossible to make suggestions to a patient in that way. The doctor has no difficulty, of course, in making him a supporter of some particular theory and in thus making him share some possible error of his own. In this respect the patient is behaving like anyone else - like a pupil - but this only affects his intelligence, not his illness. After all, his conflicts will only be successfully solved and his resistances overcome if the anticipatory ideas he is given tally with what is real in him. Whatever in the doctor's conjectures is inaccurate drops out in the course of the analysis; it has to be withdrawn and replaced by something more correct. We endeavour by a careful technique to avoid the occurrence of premature successes due to suggestion; but no harm is done even if they do occur, for we are not satisfied by a first success. We do not regard an analysis as at an end until all the obscurities of the case are cleared up, the gaps in the patient's memory filled in, the precipitating causes of the repressions discovered. We look upon successes that set in too soon as obstacles rather than as a help to the work of analysis; and we put an end to such successes by constantly resolving the transference on which they are based. It is this last characteristic which is the fundamental distinction between analytic and purely suggestive therapy, and which frees the results of analysis from the suspicion of being successes due to suggestion. In every other kind of suggestive treatment the transference is carefully preserved and left untouched; in analysis it is itself subjected to treatment and is dissected in all the shapes in which it appears. At the end of an analytic treatment the transference must itself be cleared away; and if success is then obtained or continues, it rests, not on suggestion, but on the achievement by its means of an overcoming of internal resistances, on the internal change that has been brought about in the patient. [1916-1917, 3493]
I am afraid these detailed discussions are exhausting your interest. But I should be still more sorry if you were to think it is my intention to lower your opinion of psycho-analysis as a therapy. Perhaps I really made a clumsy start. For I wanted to do the opposite: to excuse the therapeutic limitations of analysis by pointing out their inevitability. With the same aim in view I turn to another point: the reproach against analytic treatment that it takes a disproportionately long time. On this it must be said that psychical changes do in fact only take place slowly; if they occur rapidly, suddenly, that is a bad sign. It is true that the treatment of a fairly severe neurosis may easily extend over several years; but consider, in case of success, how long the illness would have lasted. A decade, probably, for every year of treatment: the illness, that is to say (as we see so often in untreated cases), would not have ended at all. In some cases we have reasons for resuming an analysis many years afterwards. Life had developed fresh pathological reactions to fresh precipitating causes; but in the meantime our patient had been well. The first analysis had not in fact brought to light all his pathological dispositions, and it was natural for the analysis to have been stopped when success was achieved. There are also severely handicapped people who are kept under analytic supervision all through their lives and are taken back into analysis from time to time. But these people would otherwise have been altogether incapable of existence and we must feel glad that they can be kept on their feet by this piecemeal and recurrent treatment. The analysis of character disorders also calls for long periods of treatment; but it is often successful; and do you know of any other therapy with which such a task could even be approached? Therapeutic ambition may feel unsatisfied by such results; but we have learnt from the example of tuberculosis and lupus that success can only be obtained when the treatment has been adapted to the characteristics of the illness.

[1933a, 4755]

The discussion of the technical problem of how to accelerate the slow progress of an analysis leads us to another, more deeply interesting question: is there such a thing as a natural end to an analysis - is there any possibility at all of bringing an analysis to such an end? To judge by the common talk of analysts it would seem to be so, for we often hear them say, when they are deploring or excusing the recognized imperfections of some fellow-mortal: 'His analysis was not finished' or 'he was never analysed to the end.'

[1937c, 5017]

We must first of all decide what is meant by the ambiguous phrase 'the end of an analysis'. From a practical standpoint it is easy to answer. An analysis is ended when the analyst and the patient cease to meet each other for the analytic session. This happens when two conditions have been approximately fulfilled: first, that the patient shall no longer be suffering from his symptoms and shall have overcome his anxieties and his inhibitions; and secondly, that the analyst shall judge that so much repressed material has been made conscious, so much that was unintelligible has been explained, and so much internal resistance conquered, that there is no need to fear a repetition of the pathological processes concerned. If one is prevented by external difficulties from reaching this goal, it is better to speak of an incomplete analysis rather than of an unfinished one.

[1937c, 5017]

The other meaning of the 'end' of an analysis is much more ambitious. In this sense of it, what we are asking is whether the analyst has had such a far-reaching influence on the patient that no further change could be expected to take place in him if his analysis were continued. It is as though it were possible by means of analysis to attain to a level of absolute psychical normality - a level, moreover, which we could feel confident would be able to remain stable, as though, perhaps, we had succeeded in resolving every one of the patient's repressions and in filling in all the gaps in his memory. We may first consult our experience to enquire whether such things do in fact happen, and then turn to our theory to discover whether there is any possibility of their happening.

[1937c, 5017]
Every analyst will have treated a few cases which have had this gratifying outcome. He has succeeded in clearing up the patient's neurotic disturbance, and it has not returned and has not been replaced by any other such disturbance. Nor are we without some insight into the determinants of these successes. The patient's ego had not been noticeably altered and the aetiology of his disturbance had been essentially traumatic. The aetiology of every neurotic disturbance is, after all, a mixed one. It is a question either of the instincts being excessively strong - that is to say, recalcitrant to taming by the ego - or of the effects of early (i.e. premature) traumas which the immature ego was unable to master. As a rule there is a combination of both factors, the constitutional and the accidental. The stronger the constitutional factor, the more readily will a trauma lead to a fixation and leave behind a developmental disturbance; the stronger the trauma, the more certainly will its injurious effects become manifest even when the instinctual situation is normal. There is no doubt that an aetiology of the traumatic sort offers by far the more favourable field for analysis. Only when a case is a predominantly traumatic one will analysis succeed in doing what it is so superlatively able to do; only then will it, thanks to having strengthened the patient's ego, succeed in replacing by a correct solution the inadequate decision made in his early life. Only in such cases can one speak of an analysis having been definitively ended. In them, analysis has done all that it should and does not need to be continued. It is true that, if the patient who has been restored in this way never produces another disorder calling for analysis, we do not know how much his immunity may not be due to a kind fate which has spared him ordeals that are too severe. [1937c, 5018]

A constitutional strength of instinct and an unfavourable alteration of the ego acquired in its defensive struggle in the sense of its being dislocated and restricted - these are the factors which are prejudicial to the effectiveness of analysis and which may make its duration interminable. One is tempted to make the first factor - strength of instinct - responsible as well for the emergence of the second - the alteration of the ego; but it seems that the latter too has an aetiology of its own. And, indeed, it must be admitted that our knowledge of these matters is as yet insufficient. They are only now becoming the subject of analytic study. In this field the interest of analysts seems to me to be quite wrongly directed. Instead of an enquiry into how a cure by analysis comes about (a matter which I think has been sufficiently elucidated) the question should be asked of what are the obstacles that stand in the way of such a cure. [1937c, 5019]

In 1927, Ferenczi read an instructive paper on the problem of the termination of analyses. It ends with a comforting assurance that 'analysis is not an endless process, but one which can be brought to a natural end with sufficient skill and patience on the analyst's part'. The paper as a whole, however, seems to me to be in the nature of a warning not to aim at shortening analysis but at deepening it. Ferenczi makes the further important point that success depends very largely on the analyst's having learnt sufficiently from his own 'errors and mistakes' and having got the better of 'the weak points in his own personality'. This provides an important supplement to our theme. Among the factors which influence the prospects of analytic treatment and add to its difficulties in the same manner as the resistances, must be reckoned not only the nature of the patient's ego but the individuality of the analyst. [1937c, 5041]
Unfortunately something else happens as well. In trying to describe this, one can only rely on impressions. Hostility on the one side and partisanship on the other create an atmosphere which is not favourable to objective investigation. It seems that a number of analysts learn to make use of defensive mechanisms which allow them to divert the implications and demands of analysis from themselves (probably by directing them on to other people), so that they themselves remain as they are and are able to withdraw from the critical and corrective influence of analysis. Such an event may justify the words of the writer who warns us that when a man is endowed with power it is hard for him not to misuse it.¹ Sometimes, when we try to understand this, we are driven into drawing a disagreeable analogy with the effect of X-rays on people who handle them without taking special precautions. It would not be surprising if the effect of a constant preoccupation with all the repressed material which struggles for freedom in the human mind were to stir up in the analyst as well all the instinctual demands which he is otherwise able to keep under suppression. These, too, are 'dangers of analysis', though they threaten, not the passive but the active partner in the analytic situation; and we ought not to neglect to meet them. There can be no doubt how this is to be done. Every analyst should periodically - at intervals of five years or so - submit himself to analysis once more, without feeling ashamed of taking this step. This would mean, then, that not only the therapeutic analysis of patients but his own analysis would change from a terminable into an interminable task.

[1937c, 5043]

At this point, however, we must guard against a misconception. I am not intending to assert that analysis is altogether an endless business. Whatever one's theoretical attitude to the question may be, the termination of an analysis is, I think a practical matter. Every experienced analyst will be able to recall a number of cases in which he has bidden his patient a permanent farewell rebus bene gestis². In cases of what is known as character-analysis there is a far smaller discrepancy between theory and practice. Here it is not easy to foresee a natural end, even if one avoids any exaggerated expectations and sets the analysis no excessive tasks. Our aim will not be to rub off every peculiarity of human character for the sake of a schematic 'normality', nor yet to demand that the person who has been 'thoroughly analysed' shall feel no passions and develop no internal conflicts. The business of the analysis is to secure the best possible psychological conditions for the functions of the ego; with that it has discharged its task.

[1937c, 5043]

But we also learn from this that it is not important in what form the resistance appears, whether as a transference or not. The decisive thing remains that the resistance prevents any change from taking place - that everything stays as it was. We often have the impression that with the wish for a penis and the masculine protest we have penetrated through all the psychological strata and have reached bedrock, and that thus our activities are at an end. This is probably true, since, for the psychical field, the biological field does in fact play the part of the underlying bedrock. The repudiation of femininity can be nothing else than a biological fact, a part of the great riddle of sex.¹ It would be hard to say whether and when we have succeeded in mastering this factor in an analytic treatment. We can only console ourselves with the certainty that we have given the person analysed every possible encouragement to re-examine and alter his attitude to it.

[1937c, 5046]
The patient with whom I am here concerned remained for a long time unassailably entrenched behind an attitude of 'obliging apathy'. He listened, understood, and remained unapproachable. His unimpeachable intelligence was, as it were, cut off from the instinctual forces which governed his behaviour in the few relations of life that remained to him. It required a long education to induce him to take an independent share in the work; and when as a result of this exertion he began for the first time to feel relief, he immediately gave up working in order to avoid any further changes, and in order to remain comfortably in the situation which had been thus established. His shrinking from a self-sufficient existence was so great as to outweigh all the vexations of his illness. Only one way was to be found of overcoming it. I was obliged to wait until his attachment to myself had become strong enough to counter-balance this shrinking, and then played off this one factor against the other. I determined - but not until trustworthy signs had led me to judge that the right moment had come - that the treatment must be brought to an end at a particular fixed date, no matter how far it had advanced. I was resolved to keep to the date; and eventually the patient came to see that I was in earnest. Under the inexorable pressure of this fixed limit his resistance and his fixation to the illness gave way, and now in a disproportionately short time the analysis produced all the material which made it possible to clear up his inhibitions and remove his symptoms. All the information, too, which enabled me to understand his infantile neurosis is derived from this last period of the work, during which resistance temporarily disappeared and the patient gave an impression of lucidity which is usually attainable only in hypnosis.

[1918b, 3507]

The manifestations of a compulsion to repeat (which we have described as occurring in the early activities of infantile mental life as well as among the events of psycho-analytic treatment) exhibit to a high degree an instinctual character and, when they act in opposition to the pleasure principle, give the appearance of some 'daemonic' force at work. In the case of children's play we seemed to see that children repeat unpleasurable experiences for the additional reason that they can master a powerful impression far more thoroughly by being active than they could by merely experiencing it passively. Each fresh repetition seems to strengthen the mastery they are in search of. Nor can children have their pleasurable experiences repeated often enough, and they are inexorable in their insistence that the repetition shall be an identical one. This character trait disappears later on. If a joke is heard for a second time it produces almost no effect; a theatrical production never creates so great an impression the second time as the first; indeed, it is hardly possible to persuade an adult who has very much enjoyed reading a book to re-read it immediately. Novelty is always the condition of enjoyment. But children will never tire of asking an adult to repeat a game that he has shown them or played with them, till he is too exhausted to go on. And if a child has been told a nice story, he will insist on hearing it over and over again rather than a new one; and he will remorselessly stipulate that the repetition shall be an identical one and will correct any alterations of which the narrator may be guilty - though they may actually have been made in the hope of gaining fresh approval. None of this contradicts the pleasure principle; repetition, the re-experiencing of something identical, is clearly in itself a source of pleasure. In the case of a person in analysis, on the contrary, the compulsion to repeat the events of his childhood in the transference evidently disregards the pleasure principle in every way. The patient behaves in a purely infantile fashion and thus shows us that the repressed memory-traces of his primaeval experiences are not present in him in a bound state and are indeed in a sense incapable of obeying the secondary process. It is to this fact of not being bound, moreover, that they owe their capacity for forming, in conjunction with the residues of the previous day, a wishful phantasy that emerges in a dream. This same compulsion to repeat frequently meets us as an obstacle to our treatment when at the end of an analysis we try to induce the patient to detach himself completely from his physician. It may be presumed, too, that when people unfamiliar with analysis feel an obscure fear - a dread of rousing something that, so they feel, is better left sleeping - what they are afraid of at bottom is the emergence of this compulsion with its hint of possession by some 'daemonic' power.

[1920g, 3738]
In the case of our patient, it was not doubt but the affective factor of revenge against her father that made her cool reserve possible, that divided the analysis into two distinct phases, and rendered the results of the first phase so complete and perspicuous. It seemed, further, as though nothing resembling a transference to the physician had been effected. That, however, is of course absurd, or, at least, is a loose way of expressing things. For some kind of relation to the analyst must come into being, and this relation is almost always transferred from an infantile one. In reality she transferred to me the sweeping repudiation of men which had dominated her ever since the disappointment she had suffered from her father. Bitterness against men is as a rule easy to gratify upon the physician; it need not evoke any violent emotional manifestations, it simply expresses itself by rendering futile all his endeavours and - by clinging to the illness. I know from experience how difficult it is to make a patient understand just precisely this mute kind of symptomatic behaviour and to make him aware of this latent, and often exceedingly strong, hostility without endangering the treatment. As soon, therefore, as I recognized the girl's attitude to her father, I broke off the treatment and advised her parents that if they set store by the therapeutic procedure it should be continued by a woman doctor. The girl had in the meanwhile promised her father that at any rate she would give up seeing the 'lady', and I do not know whether my advice, the reasons for which are obvious, will be followed.

[1920a, 3853]
Instead of a number of cases I will give a detailed report of only a single example from my medical experience. A young married woman broke her leg below the knee in a carriage accident, so that she was bed-ridden for weeks; what was striking was the absence of any expressions of pain and the calmness with which she bore her misfortune. This accident introduced a long and severe neurotic illness of which she was finally cured by psycho-analysis. In treating her I learnt of the circumstances surrounding the accident and of certain events that had preceded it. The young woman was staying with her very jealous husband on the estate of a married sister, in company with her numerous other sisters and brothers with their husbands and wives. One evening in this intimate circle she showed off one of her accomplishments: she gave an accurate performance of the can-can, which was received with hearty applause by her relatives but with scanty satisfaction by her husband, who afterwards whispered to her: 'Carrying on like a tart again!' The remark struck home - we will not enquire whether it was only on account of the dancing display. She spent a restless night. Next morning she felt a desire to go for a drive. She selected the horses herself, refusing one pair and asking for another. Her youngest sister wanted her baby and its nurse to go in the carriage with her; my patient vigorously opposed this. During the drive she showed signs of nerves; she warned the coachman that the horses were growing skittish, and when the restless animals were really causing a moment's difficulty she jumped out in a fright and broke her leg, while the others who stayed in the carriage were unharmed. Although after learning these details we can hardly remain in doubt that this accident was really contrived, we cannot fail to admire the skill which forced chance to mete out a punishment that fitted the crime so well. For it had now been made impossible for her to dance the can-can for quite a long time.

[1901b, 1259]

While I was speaking, the boy stopped kneading and, as I was on the point of describing what the king did in his garden and had reached the words 'silently struck', he made a lightning movement and tore the head off his little man. He had therefore understood me and had seen that he had been understood by me. I could now question him directly, I gave him the information he needed, and in a short time we had brought the neurosis to an end.

[1901b, 1277]

Nor is the case of whose history and treatment I have published a fragment in these pages well calculated to put the value of psycho-analytic therapy in its true light. Not only the briefness of the treatment (which hardly lasted three months) but another factor inherent in the nature of the case prevented results being brought about such as are attainable in other instances, where the improvement will be admitted by the patient and his relatives and will approximate more or less closely to a complete recovery. Satisfactory results of this kind are reached when the symptoms are maintained solely by the internal conflict between the impulses concerned with sexuality. In such cases the patient's condition will be seen improving in proportion as he is helped towards a solution of his mental problems by the translation of pathogenic into normal material. The course of events is very different when the symptoms have become enlisted in the service of external motives, as had happened with Dora during the two preceding years. It is surprising, and might easily be misleading, to find that the patient's condition shows no noticeable alteration even though considerable progress has been made with the work of analysis. But in reality things are not as bad as they seem. It is true that the symptoms do not disappear while the work is proceeding; but they disappear a little while later, when the relations between patient and physician have been dissolved. The postponement of recovery or improvement is really only caused by the physician's own person.

[1905e, 1449]
In Dora’s second dream there are several clear allusions to transference. At the time she was telling me the dream I was still unaware (and did not learn until two days later) that we had only two hours more work before us. This was the same length of time which she had spent in front of the Sistine Madonna, and which (by making a correction and putting ‘two hours’ instead of ‘two and a half hours’) she had taken as the length of the walk which she had not made round the lake. The striving and waiting in the dream, which related to the young man in Germany, and had their origin in her waiting till Herr K. could marry her, had been expressed in the transference a few days before. The treatment, she had thought, was too long for her; she would never have the patience to wait so long. And yet in the first few weeks she had had discernment enough to listen without making any such objections when I informed her that her complete recovery would require perhaps a year. Her refusing in the dream to be accompanied, and preferring to go alone, also originated from her visit to the gallery at Dresden, and I was myself to experience them on the appointed day. What they meant was, no doubt: ‘Men are all so detestable that I would rather not marry. This is my revenge.’¹

The task which the psycho-analytic method seeks to perform may be formulated in different ways, which are, however, in their essence equivalent. It may, for instance, be stated thus: the task of the treatment is to remove the amnesias. When all gaps in memory have been filled in, all the enigmatic products of mental life elucidated, the continuance and even a renewal of the morbid condition are made impossible. Or the formula may be expressed in this fashion: all repressions must be undone. The mental condition is then the same as one in which all amnesias have been removed. Another formulation reaches further: the task consists in making the unconscious accessible to consciousness, which is done by overcoming the resistances. But it must be remembered that an ideal condition such as this is not present even in the normal, and further that it is only rarely possible to carry the treatment to a point approaching it. Just as health and sickness are not different from each other in essence but are only separated by a quantitative line of demarcation which can be determined in practice, so the aim of the treatment will never be anything else but the practical recovery of the patient, the restoration of his ability to lead an active life and of his capacity for enjoyment. In a treatment which is incomplete or in which success is not perfect, one may at any rate achieve a considerable improvement in the general mental condition, while the symptoms (though now of smaller importance to the patient) may continue to exist without stamping him as a sick man.

As far as the middle classes are concerned, the expense involved in psycho-analysis is excessive only in appearance. Quite apart from the fact that no comparison is possible between restored health and efficiency on the one hand and a moderate financial outlay on the other, when we add up the unceasing costs of nursing-homes and medical treatment and contrast them with the increase of efficiency and earning capacity which results from a successfully completed analysis, we are entitled to say that the patients have made a good bargain. Nothing in life is so expensive as illness - and stupidity.

[1905e, 1453]
[1904a, 1559]
[1913c, 2486]
But I should like to say a few words to you to relieve you of your surprise at the emergence of this unexpected phenomenon. We must not forget that the patient's illness, which we have undertaken to analyse, is not something which has been rounded off and become rigid but that it is still growing and developing like a living organism. The beginning of the treatment does not put an end to this development; when, however, the treatment has obtained mastery over the patient, what happens is that the whole of his illness's new production is concentrated upon a single point - his relation to the doctor. Thus the transference may be compared to the cambium layer in a tree between the wood and the bark, from which the new formation of tissue and the increase in the girth of the trunk derive. When the transference has risen to this significance, work upon the patient's memories retreats far into the background. Thereafter it is not incorrect to say that we are no longer concerned with the patient's earlier illness but with a newly created and transformed neurosis which has taken the former's place. We have followed this new edition of the old disorder from its start, we have observed its origin and growth, and we are especially well able to find our way about in it since, as its object, we are situated at its very centre. All the patient's symptoms have abandoned their original meaning and have take on a new sense which lies in a relation to the transference; or only such symptoms have persisted as are capable of undergoing such a transformation. But the mastering of this new, artificial neurosis coincides with getting rid of the illness which was originally brought to the treatment - with the accomplishment of our therapeutic task. A person who has become normal and free from the operation of repressed instinctual impulse in his relation to the doctor will remain so in his own life after the doctor has once more withdrawn from it.

[1916-1917, 3486]
But you will now tell me that, no matter whether we call the motive force of our analysis transference or suggestion, there is a risk that the influencing of our patient may make the objective certainty of our findings doubtful. What is advantageous to our therapy is damaging to our researches. This is the objection that is most often raised against psycho-analysis, and it must be admitted that, though it is groundless, it cannot be rejected as unreasonable. If it were justified, psycho-analysis would be nothing more than a particularly well-disguised and particularly effective form of suggestive treatment and we should have to attach little weight to all that it tells us about what influences our lives, the dynamics of the mind or the unconscious. That is what our opponents believe; and in especial they think that we have ‘talked’ the patients into everything relating to the importance of sexual experiences - or even into those experiences themselves - after such notions have grown up in our own depraved imagination. These accusations are contradicted more easily by an appeal to experience than by the help of theory. Anyone who has himself carried out psycho-analyses will have been able to convince himself on countless occasions that it is impossible to make suggestions to a patient in that way. The doctor has no difficulty, of course, in making him a supporter of some particular theory and in thus making him share some possible error of his own. In this respect the patient is behaving like anyone else - like a pupil - but this only affects his intelligence, not his illness. After all, his conflicts will only be successfully solved and his resistances overcome if the anticipatory ideas he is given tally with what is real in him. Whatever in the doctor's conjectures is inaccurate drops out in the course of the analysis; it has to be withdrawn and replaced by something more correct. We endeavour by a careful technique to avoid the occurrence of premature successes due to suggestion; but no harm is done even if they do occur, for we are not satisfied by a first success. We do not regard an analysis as at an end until all the obscurities of the case are cleared up, the gaps in the patient's memory filled in, the precipitating causes of the repressions discovered. We look upon successes that set in too soon as obstacles rather than as a help to the work of analysis; and we put an end to such successes by constantly resolving the transference on which they are based. It is this last characteristic which is the fundamental distinction between analytic and purely suggestive therapy, and which frees the results of analysis from the suspicion of being successes due to suggestion. In every other kind of suggestive treatment the transference is carefully preserved and left untouched; in analysis it is itself subjected to treatment and is dissected in all the shapes in which it appears. At the end of an analytic treatment the transference must itself be cleared away; and if success is then obtained or continues, it rests, not on suggestion, but on the achievement by its means of an overcoming of internal resistances, on the internal change that has been brought about in the patient.

[1916-1917, 3493]
Thus our therapeutic work falls into two phases. In the first, all the libido is forced from the symptoms into the transference and concentrated there; in the second, the struggle is waged around this new object and the libido is liberated from it. The change which is decisive for a favourable outcome is the elimination of repression in this renewed conflict so that the libido cannot withdraw once more from the ego by flight into the unconscious. This is made possible by the alteration of the ego which is accomplished under the influence of the doctor's suggestion. By means of the work of interpretation, which transforms what is unconscious into what is conscious, the ego is enlarged at the cost of this unconscious; by means of instruction, it is made conciliatory towards the libido and inclined to grant it some satisfaction, and its repugnance to the claims of the libido is diminished by the possibility of disposing of a portion of it by sublimation. The more closely events in the treatment coincide with this ideal description, the greater will be the success of the psycho-analytic therapy. It finds its limits in the lack of mobility of the libido, which may refuse to leave its objects, and the rigidity of narcissism, which will not allow transference on to objects to increase beyond certain bounds. Further light may perhaps be thrown on the dynamics of the process of cure if I say that we get hold of the whole of the libido which has been withdrawn from the dominance of the ego by attracting a portion of it on to ourselves by means of the transference.

[1916-1917, 3495]
Many attempts at treatment miscarried during the early period of analysis because they were undertaken in cases which were altogether unsuited to the procedure and which we should exclude to-day on the basis of our present view of the indications for treatment. But these indications, too, could only be arrived at by experiment. In those days we did not know a priori that paranoia and dementia praecox in strongly marked forms are inaccessible, and we had a right to make trial of the method on all kinds of disorders. But most of the failures of those early years were due not to the doctor's fault or an unsuitable choice of patients but to unfavourable external conditions. Here we have only dealt with internal resistances, those of the patient, which are inevitable and can be overcome. The external resistances which arise from the patient's circumstances, from his environment, are of small theoretical interest but of the greatest practical importance. Psycho-analytic treatment may be compared with a surgical operation and may similarly claim to be carried out under arrangements that will be the most favourable for its success. You know the precautionary measures adopted by a surgeon: a suitable room, good lighting, assistants, exclusion of the patient's relatives, and so on. Ask yourselves now how many of these operations would turn out successfully if they had to take place in the presence of all the members of the patient's family, who would stick their noses into the field of the operation and exclaim aloud at every incision. In psycho-analytic treatments the intervention of relatives is a positive danger and a danger one does not know how to meet. One is armed against the patient's internal resistances which one knows are inevitable, but how can one ward off these external resistances? No kind of explanations make any impression on the patient's relatives; they cannot be induced to keep at a distance from the whole business, and one cannot make common cause with them because of the risk of losing the confidence of the patient, who - quite rightly moreover - expects the person in whom he has put his trust to take his side. No one who has any experience of the rifts which so often divide a family will, if he is an analyst, be surprised to find that the patient's closest relatives sometimes betray less interest in his recovering than in his remaining as he is. When, as so often, the neurosis is related to conflicts between members of a family, the healthy party will not hesitate long in choosing between his own interest and the sick party's recovery. It is not to be wondered at, indeed, if a husband looks with disfavour on a treatment in which, as he may rightly suspect, the whole catalogue of his sins will be brought to light. Nor do we wonder at it; but we cannot in that case blame ourselves if our efforts remain unsuccessful and the treatment is broken off prematurely because the husband's resistance is added to that of his sick wife. We had in fact undertaken something which in the prevailing circumstances was unrealizable.
This presents a gloomy prospect for the effectiveness of psycho-analysis as a therapy - does it not? - even though we are able to explain the great majority of our failures by attributing them to interfering external factors. Friends of analysis have advised us to meet the threatened publication of our failures with statistics of our successes drawn up by ourselves. I did not agree to this. I pointed out that statistics are worthless if the items assembled in them are too heterogeneous; and the cases of neurotic illness which we had taken into treatment were in fact incomparable in a great variety of respects. Moreover, the period of time that could be covered was too short to make it possible to judge the durability of the cures. And it was altogether impossible to report on many of the cases: they concerned people who had kept both their illness and its treatment secret, and their recovery had equally to be kept secret. But the strongest reason for holding back lay in the realization that in matters of therapy people behave highly irrationally, so that one has no prospect of accomplishing anything with them by rational means. A therapeutic novelty is either received with delirious enthusiasm - as, for instance, when Koch introduced his first tuberculin against tuberculosis to the public - or it is treated with abysmal distrust - like Jenner's vaccination, which was in fact a blessing and which even to-day has its irreconcilable opponents. There was obviously a prejudice against psycho-analysis. If one had cured a severe case, one might hear people say: 'That proves nothing. He would have recovered on his own account by this time.' And when a woman patient, who had already passed through four cycles of depression and mania, came to be treated by me during an interval after an attack of melancholia and three weeks later started on a phase of mania, all the members of her family and a high medical authority, too, who was called in for consultation - were convinced that the fresh attack could only be the result of my attempted analysis. Nothing can be done against prejudices. You can see it again to-day in the prejudices which each group of nations at war has developed against the other. The most sensible thing to do is to wait, and to leave such prejudices to the eroding effects of time. One day the same people begin to think about the same things in quite a different way from before; why they did not think so earlier remains a dark mystery.

[1916-1917, 3500]
There is, however, another angle from which we can approach this problem of the variability in the effect of analysis. We know that the first step towards attaining intellectual mastery of our environment is to discover generalizations, rules and laws which bring order into chaos. In doing this we simplify the world of phenomena; but we cannot avoid falsifying it, especially if we are dealing with processes of development and change. What we are concerned with is discerning a qualitative alteration, and as a rule in doing so we neglect, at any rate to begin with, a quantitative factor. In the real world, transitions and intermediate stages are far more common than sharply differentiated opposite states. In studying developments and changes we direct our attention solely to the outcome; we readily overlook the fact that such processes are usually more or less incomplete - that is to say, that they are in fact only partial alterations. A shrewd satirist of old Austria, Johann Nestroy, once said: 'Every step forward is only half as big as it looks at first.' It is tempting to attribute a quite general validity to this malicious dictum. There are nearly always residual phenomena, a partial hanging-back. When an open-handed Maecenas surprises us by some isolated trait of miserliness, or when a person who is consistently over-kind suddenly indulges in a hostile action, such 'residual phenomena' are invaluable for genetic research. They show us that these praiseworthy and precious qualities are based on compensation and overcompensation which, as was to have been expected, have not been absolutely and fully successful. Our first account of the development of the libido was that an original oral phase gave way to a sadistic-anal phase and that this was in turn succeeded by a phallic-genital one. Later research has not contradicted this view, but it has corrected it by adding that these replacements do not take place all of a sudden but gradually, so that portions of the earlier organization always persist alongside of the more recent one, and even in normal development the transformation is never complete and residues of earlier libidinal fixations may still be retained in the final configuration. The same thing is to be seen in quite other fields. Of all the erroneous and superstitious beliefs of mankind that have supposedly been surmounted there is not one whose residues do not live on among us to-day in the lower strata of civilized peoples or even in the highest strata of cultural society. What has once come to life clings tenaciously to its existence. One feels inclined to doubt sometimes whether the dragons of primaeval days are really extinct.

[1937c, 5025]
Applying these remarks to our present problem, I think that the answer to the question of how to explain the variable results of our analytic therapy might well be that we, too, in endeavouring to replace repressions that are insecure by reliable ego-syntonic controls, do not always achieve our aim to its full extent - that is, do not achieve it thoroughly enough. The transformation is achieved, but often only partially: portions of the old mechanisms remain untouched by the work of analysis. It is difficult to prove that this is really so; for we have no other way of judging what happens but by the outcome which we are trying to explain. Nevertheless, the impressions one receives during the work of analysis do not contradict this assumption; indeed, they seem rather to confirm it. But we must not take the clarity of our own insight as a measure of the conviction which we produce in the patient. His conviction may lack 'depth', as one might say; it is always a question of the quantitative factor, which is so easily overlooked. If this is the correct answer to our question, we may say that analysis, in claiming to cure neuroses by ensuring control over instinct, is always right in theory but not always right in practice. And this is because it does not always succeed in ensuring to a sufficient degree the foundations on which a control of instinct is based. The cause of such a partial failure is easily discovered. In the past, the quantitative factor of instinctual strength opposed the ego's defensive efforts; for that reason we called in the work of analysis to help; and now that same factor sets a limit to the efficacy of this new effort. If the strength of the instinct is excessive, the mature ego, supported by analysis, fails in its task, just as the helpless ego failed formerly. Its control over instinct is improved, but it remains imperfect because the transformation in the defensive mechanism is only incomplete. There is nothing surprising in this, since the power of the instruments with which analysis operates is not unlimited but restricted, and the final upshot always depends on the relative strength of the psychical agencies which are struggling with one another.

[1937c, 5026]
It might be objected that, in cases of hysteria like this, in which the illness has run its course, the residual symptoms in any case pass away spontaneously. It may be said in reply, however, that a spontaneous cure of this kind is very often neither rapid nor complete enough and that it can be assisted to an extraordinary degree by our therapeutic intervention. We may readily leave it for the moment as an unresolved question whether by means of the cathartic therapy we cure only what is capable of spontaneous cure or sometimes also what would not have been cleared up spontaneously.

It would be more dignified as well as more helpful to the patient - who, after all, has to come to terms with his ailments - for the doctor to tell the truth, as he knows it from his daily practice. The psychoneuroses as a genus are by no means mild illnesses. When hysteria sets in, no one can foretell when it will come to an end. We mostly comfort ourselves with the vain prophecy that ‘one day it will suddenly disappear’. Recovery often enough turns out to be merely an agreement to mutual toleration between the sick part of the patient and the healthy part; or it is the result of the transformation of a symptom into a phobia. A girl's hysteria, calmed down with difficulty, revives in her as a wife after the short interruption of young married happiness. The only difference is that another person, the husband, is now driven by his own interests to keep silence about her condition. Even if an illness of this kind leads to no manifest incapacity on the patients' part to carry on their life, it nearly always prevents free unfolding of their mental powers. Obsessions recur throughout their lives; and phobias and other restrictions upon the will have hitherto been unamenable to treatment of any kind. All this is kept from the knowledge of the layman. The father of a hysterical girl is consequently horrified if, for instance, he is asked to agree to her being given a year's treatment, when she has perhaps only been ill for a few months. The layman is, as it were, deeply convinced in himself that all these psychoneuroses are unnecessary; so he has no patience with the processes of the illness and no readiness to make sacrifices for its treatment. If, in face of a case of typhus which lasts three weeks, or of a broken leg which takes six months to mend, he adopts a more understanding attitude, and if, as soon as his child shows the first signs of a curvature of the spine, he finds it reasonable that orthopaedic treatment should be carried on over several years, the difference in his behaviour is due to the better knowledge on the part of the physicians who pass on their knowledge honestly to the layman. Honesty on the part of the physician and willing acquiescence on the part of the layman will be established for the neuroses too, as soon as an insight into the nature of those affections becomes common property in the medical world. Radical treatment of these disorders will no doubt always require special training and will be incompatible with other kinds of medical activity. On the other hand, this class of physicians, which will, I believe, be a large one in the future, has the prospect of achieving noteworthy results and of obtaining a satisfying insight into the mental life of mankind.
I will pass over the details which showed how entirely correct all of this was, and I will instead add a few general remarks upon the part played in hysteria by the motives of illness. A motive for being ill is sharply to be distinguished as a concept from a potentiality for illness - from the material out of which symptoms are formed. The motives have no share in the formation of symptoms, and indeed are not present at the beginning of the illness. They only appear secondarily to it; but it is not until they have appeared that the disease is fully constituted.¹ Their presence can be reckoned upon in every case in which there is real suffering and which is of fairly long standing. A symptom comes into the patient's mental life at first as an unwelcome guest; it has everything against it; and that is why it may vanish so easily, apparently of its own accord, under the influence of time. To begin with there is no use to which it can be put in the domestic economy of the mind; but very often it succeeds in finding one secondarily. Some psychical current or other finds it convenient to make use of it, and in that way the symptom manages to obtain a secondary function and remains, as it were, anchored fast in the patient's mental life. And so it happens that any one who tries to make him well is to his astonishment brought up against a powerful resistance, which teaches him that the patient's intention of getting rid of his complaint is not so entirely and completely serious as it seemed.² Let us imagine a workman, a bricklayer, let us say, who has fallen off a house and been crippled, and now earns his livelihood by begging at the street-corner. Let us then suppose that a miracle-worker comes along and promises him to make his crooked leg straight and capable of walking. It would be unwise, I think, to look forward to seeing an expression of peculiar bliss upon the man's features. No doubt at the time of the accident he felt he was extremely unlucky, when he realized that he would never be able to do any more work and would have to starve or live upon charity. But since then the very thing which in the first instance threw him out of employment has become his source of income: he lives by his disablement. If that is taken from him he may become totally helpless. He has in the meantime forgotten his trade and lost his habits of industry; he has grown accustomed to idleness, and perhaps to drink as well.

It is in combating the motives of illness that the weak point in every kind of therapeutic treatment of hysteria lies. This in quite generally true, and it applies equally to psycho-analysis. Destiny has an easier time of it in this respect: it need not concern itself either with the patient's constitution or with his pathogenic material; it has only to take away a motive for being ill, and the patient is temporarily or perhaps even permanently freed from his illness. How many fewer miraculous cures and spontaneous disappearances of symptoms should we physicians have to register in cases of hysteria, if we were more often given a sight of the human interests which the patient keeps hidden from us! In one case, some stated period of time has elapsed; in a second, consideration for some other person has ceased to operate; in a third, the situation has been fundamentally changed by some external event - and the whole disorder which up till then had shown the greatest obstinacy, vanishes at a single blow, apparently of its own accord, but really because it has been deprived of its most powerful motive, one of the uses to which it has been put in the patient's life.
An opportunity very soon occurred for interpreting Dora's nervous cough in this way by means of an imagined sexual situation. She had once again been insisting that Frau K. only loved her father because he was 'ein vermögender Mann' ['a man of means']. Certain details of the way in which she expressed herself (which I pass over here, like most other purely technical parts of the analysis) led me to see that behind this phrase its opposite lay concealed, namely, that her father was 'ein unvermögender Mann' ['a man without means']. This could only be meant in a sexual sense - that her father, as a man, was without means, was impotent.¹ Dora confirmed this interpretation from her conscious knowledge; whereupon I pointed out the contradiction she was involved in if on the one hand she continued to insist that her father's relation with Frau K. was a common love-affair, and on the other hand maintained that her father was impotent, or in other words incapable of carrying on an affair of such a kind. Her answer showed that she had no need to admit the contradiction. She knew very well, she said, that there was more than one way of obtaining sexual gratification. (The source of this piece of knowledge, however, was once more untraceable.) I questioned her further, whether she referred to the use of organs other than the genitals for the purpose of sexual intercourse, and she replied in the affirmative. I could then go on to say that in that case she must be thinking of precisely those parts of the body which in her case were in a state of irritation, - the throat and the oral cavity. To be sure, she would not hear of going so far as this in recognizing her own thoughts; and indeed, if the occurrence of the symptom was to be made possible at all, it was essential that she should not be completely clear on the subject. But the conclusion was inevitable that with her spasmodic cough, which, as is usual, was referred for its exciting stimulus to a tickling in her throat, she pictured to herself a scene of sexual gratification per os between the two people whose love-affair occupied her mind so incessantly. A very short time after she had tacitly accepted this explanation her cough vanished - which fitted in very well with my view; but I do not wish to lay too much stress upon this development, since her cough had so often before disappeared spontaneously.

[1905e, 1384]

Nor do I know whether Herr K. would have done any better if it had been revealed to him that the slap Dora gave him by no means signified a final 'No' on her part, but that it expressed the jealousy which had lately been roused in her, while her strongest feelings were still on his side. If he had disregarded that first 'No', and had continued to press his suit with a passion which left room for no doubts, the result might very well have been a triumph of the girl's affection for him over all her internal difficulties. But I think she might just as well have been merely provoked into satisfying her craving for revenge upon him all the more thoroughly. It is never possible to calculate towards which side the decision will incline in such a conflict of motives: whether towards the removal of the repression or towards its reinforcement. Incapacity for meeting a real erotic demand is one of the most essential features of a neurosis. Neurotics are dominated by the opposition between reality and phantasy. If what they long for the most intensely in their phantasies is presented to them in reality, they none the less flee from it; and they abandon themselves to their phantasies the most readily where they need no longer fear to see them realized. Nevertheless, the barrier erected by repression can fall before the onslaught of a violent emotional excitement produced by a real cause; it is possible for a neurosis to be overcome by reality. But we have no general means of calculating through what person or what event such a cure can be effected.¹

[1905e, 1445]
(c) From certain of my remarks you will have gathered that there are many characteristics in
the analytic method which prevent it from being an ideal form of therapy. *Tuto, cito, jucunde*:
investigation and probing do not indicate speedy results, and the resistance I have mentioned
would prepare you to expect unpleasantness of various kinds. Psycho-analytic treatment
certainly makes great demands upon the patient as well as upon the physician. From the patient
it requires perfect sincerity - a sacrifice in itself; it absorbs time and is therefore also costly; for
the physician it is no less time-absorbing, and the technique which he must study and practise
is fairly laborious. I consider it quite justifiable to resort to more convenient methods of treatment
as long as there is any prospect of achieving anything by their means. That, after all, is the only
point at issue. If the more difficult and lengthy method accomplishes considerably more than the
short and easy one, then, in spite of everything, the use of the former is justified. Only consider,
Gentlemen, how much more inconvenient and costly is the Finsen therapy of lupus than the
method of cauterizing and scraping previously employed; and yet the use of the former signifies
a great advance, for it performs a radical cure. Although I do not wish to carry this comparison
to extremes, the psycho-analytic method may claim a similar privilege. Actually, I have been
able to elaborate and to test my therapeutic method only on severe, indeed on the severest
cases; at first my material consisted entirely of patients who had tried everything else without
success, and had spent long years in sanatoria. I have scarcely been able to bring together
sufficient material to enable me to say how my method works with those slighter, episodic cases
which we see recovering under all kinds of influences and even spontaneously. Psycho-analytic
therapy was created through and for the treatment of patients permanently unfit for existence,
and its triumph has been that it has made a satisfactorily large number of these permanently fit
for existence. In the face of such an achievement all the effort expended seems trivial. We
cannot conceal from ourselves what, as physicians, we are in the habit of denying to our
patients, namely, that a severe neurosis is no less serious for the sufferer than any cachexia or
any of the dreaded major diseases.
[1905a, 1568]

There are many very effective mental procedures which the physician is obliged to renounce.
He either has not the power or has not the right to invoke them. This applies in particular to the
provocation of strong affects - the most powerful of all the means by which the mind affects the
body. The vicissitudes of life often cure illnesses through the experience of great joy, through
the satisfaction of needs or the fulfilment of wishes. The physician, who is often impotent
outside his profession, cannot compete along these lines. It might be more within his power to
employ fear and fright for therapeutic ends; but, except in the case of children, he must have the
gravest doubts about the use of such double-edged tools. On the other hand, the physician
must rule out any relations with his patient that are bound up with tender feelings, owing to their
implications in practical life. Thus from the first his power to bring about mental changes in his
patients seems so restricted that mental treatment conducted on a deliberate plan would seem
to offer no advantages over the earlier haphazard method.
[1890a, 1595]
It is true that during the analysis Hans had to be told many things that he could not say himself, that he had to be presented with thoughts which he had so far shown no signs of possessing, and that his attention had to be turned in the direction from which his father was expecting something to come. This detracts from the evidential value of the analysis; but the procedure is the same in every case. For a psycho-analysis is not an impartial scientific investigation, but a therapeutic measure. Its essence is not to prove anything, but merely to alter something. In a psycho-analysis the physician always gives his patient (sometimes to a greater and some times to a less extent) the conscious anticipatory ideas by the help of which he is put in a position to recognize and to grasp the unconscious material. For there are some patients who need more of such assistance and some who need less; but there are none who get through without some of it. Slight disorders may perhaps be brought to an end by the subject's unaided efforts, but never a neurosis - a thing which has set itself up against the ego as an element alien to it. To get the better of such an element another person must be brought in, and in so far as that other person can be of assistance the neurosis will be curable. If it is in the very nature of any neurosis to turn away from the 'other person' - and this seems to be one of the characteristics of the states grouped together under the name of dementia praecox - then for that very reason such a state will be incurable by any efforts of ours. It is true that a child, on account of the small development of his intellectual systems, requires especially energetic assistance. But, after all, the information which the physician gives his patient is itself derived in its turn from analytical experience; and indeed it is sufficiently convincing if, at the cost of this intervention by the physician, we are enabled to discover the structure of the pathogenic material and simultaneously to dissipate it.

We may give as instances of disorders that are accessible to psycho-analytic treatment hysterical convulsions and paralyses as well as the various symptoms of obsessional neurosis (obsessive ideas and actions). All of these are conditions which are occasionally subject to spontaneous recovery and are dependent on the personal influence of the physician in a haphazard fashion which has not yet been explained. Psycho-analysis has no therapeutic effect on the severer forms of mental disorder properly so called. But - for the first time in the history of medicine - psycho-analysis has made it possible to get some insight into the origin and mechanism alike of the neuroses and psychoses.

And now an explanation, given in writing by a doctor who was a stranger to her, was expected to effect what all the most important experiences of her later life had failed to do! Probably a regular analysis continued for a considerable time would have succeeded in this. As things were, I was obliged to content myself with writing to her that I was convinced she was suffering from the after-effects of a strong emotional tie binding her to her father and from a corresponding identification with her mother, but that I did not myself expect that this explanation would help her. Spontaneous cures of neurosis usually leave scars behind, and these become painful again from time to time. We are very proud of our art if we achieve a cure through psycho-analysis, yet here too we cannot always prevent the formation of a painful scar as an outcome.
Psycho-analysis leads to less simple and satisfactory conclusions. What I have to say in this connection has long been familiar and I have nothing new to add. If the ego succeeds in protecting itself from a dangerous instinctual impulse, through, for instance, the process of repression, it has certainly inhibited and damaged the particular part of the id concerned; but it has at the same time given it some independence and has renounced some of its own sovereignty. This is inevitable from the nature of repression, which is, fundamentally, an attempt at flight. The repressed is now, as it were, an outlaw; it is excluded from the great organization of the ego and is subject only to the laws which govern the realm of the unconscious. If, now, the danger-situation changes so that the ego has no reason for fending off a new instinctual impulse analogous to the repressed one, the consequence of the restriction of the ego which has taken place will become manifest. The new impulse will run its course under an automatic influence - or, as I should prefer to say, under the influence of the compulsion to repeat. It will follow the same path as the earlier, repressed impulse, as though the danger-situation that had been overcome still existed. The fixating factor in repression, then, is the unconscious id's compulsion to repeat - a compulsion which in normal circumstances is only done away with by the freely mobile function of the ego. The ego may occasionally manage to break down the barriers of repression which it has itself put up and to recover its influence over the instinctual impulse and direct the course of the new impulse in accordance with the changed danger-situation. But in point of fact the ego very seldom succeeds in doing this: it cannot undo its repressions. It is possible that the way the struggle will go depends upon quantitative relations. In some cases one has the impression that the outcome is an enforced one: the regressive attraction exerted by the repressed impulse and the strength of the repression are so great that the new impulse has no choice but to obey the compulsion to repeat. In other cases we perceive a contribution from another play of forces: the attraction exerted by the repressed prototype is reinforced by a repulsion coming from the direction of difficulties in real life which stand in the way of any different course that might be taken by the new instinctual impulse.

That this is a correct account of fixation upon repression and of the retention of danger-situations that are no longer present-day ones is confirmed by the fact of analytic therapy - a fact which is modest enough in itself but which can hardly be overrated from a theoretical point of view. When, in analysis, we have given the ego assistance which is able to put it in a position to lift its repressions, it recovers its power over the repressed id and can allow the instinctual impulses to run their course as though the old situations of danger no longer existed. What we can do in this way tallies with what can be achieved in other fields of medicine; for as a rule our therapy must be content with bringing about more quickly, more reliably and with less expenditure of energy than would otherwise be the case the good result which in favourable circumstances would have occurred of itself.
Frau Cäcilie suffered among other things from an extremely violent facial neuralgia which appeared suddenly two or three times a year, lasted for from five to ten days, resisted any kind of treatment and then ceased abruptly. It was limited to the second and third branches of one trigeminal, and since an abnormal excretion of urates was undoubtedly present and a not quite clearly defined 'acute rheumatism' played some part in the patient's history, a diagnosis of gouty neuralgia was plausible enough. This diagnosis was confirmed by the different consultants who were called in at each attack. Treatment of the usual kind was ordered: the electric brush, alkaline water, purges; but each time the neuralgia remained unaffected until it chose to give place to another symptom. Earlier in her life - the neuralgia was fifteen years old - her teeth were accused of being responsible for it. They were condemned to extraction, and one fine day, under narcosis, the sentence was carried out on seven of the criminals. This was not such an easy matter; her teeth were so firmly attached that the roots of most of them had to be left behind. This cruel operation had no result, either temporary or permanent. At that time the neuralgia raged for months on end. Even at the time of my treatment, at each attack of neuralgia the dentist was called in. On each occasion he diagnosed the presence of diseased roots and began to get to work on them; but as a rule he was soon interrupted. For the neuralgia would suddenly cease, and at the same time the demand for the dentist's services. During the interval her teeth did not ache at all. One day, when an attack was raging once more, the patient got me to give her hypnotic treatment. I laid a very energetic prohibition on her pains, and from that moment they ceased. I began at that time to harbour doubts of the genuineness of the neuralgia.

(4) Where we meet with an acute hysteria, a case which is passing through the period of the most active production of hysterical symptoms and in which the ego is being constantly overwhelmed by the products of the illness (i.e. during a hysterical psychosis), even the cathartic method will make little change in the appearance and course of the disorder. In such circumstances we find ourselves in the same position as regards the neurosis as a physician faced by an acute infectious disease. The aetiological factors have performed their work sufficiently, at a time which has now passed and is beyond the reach of any influence; and now, after the period of incubation has elapsed, they have become manifest. The illness cannot be broken off short. We must wait for it to run its course and in the mean time make the patient's circumstances as favourable as possible. If, during an acute period like this, we get rid of the products of the illness, the freshly generated hysterical symptoms, we must also be prepared to find that those that have been got rid of will promptly be replaced by others. The physician will not be spared the depressing feeling of being faced by a Sisyphean task. The immense expenditure of labour, and the dissatisfaction of the patient's family, to whom the inevitable length of an acute neurosis is not likely to be as familiar as the analogous case of an acute infectious disease - these and other difficulties will probably make a systematic application of the cathartic method as a rule impossible in any given case. Nevertheless, it remains a matter for serious consideration whether it may not be true that even in an acute hysteria the regular clearing up of the products of the illness exercises a curative influence, by supporting the patient's normal ego which is engaged in the work of defence, and by preserving it from being overwhelmed and falling into a psychosis and even perhaps into a permanent state of confusion.

[1895d, 159]

[1895d, 233]
In conclusion I may point out that combinations of a phobia and an obsession proper may co-exist, and that indeed this is a very frequent occurrence. We may find that a phobia had developed at the beginning of the disease as a symptom of anxiety neurosis. The idea which constitutes the phobia and which is associated with the state of fear may be replaced by another idea or rather by the protective procedure that seemed to relieve the fear. Case 7 (obsessive speculating) presents a neat example of this group: a phobia along with a true substitutive obsession.

[1895c, 324]

(10) Several of the symptoms I have mentioned, which accompany or take the place of an anxiety attack, also appear in a chronic form. In that case they are still less easy to recognize, since the anxious sensation which goes with them is less clear than in an anxiety attack. This is especially true of diarrhoea, vertigo and paraesthesias. Just as an attack of vertigo can be replaced by a fainting fit, so chronic vertigo can be replaced by a constant feeling of great feebleness, lassitude and so on.

[1895b, 335]

(3) The anamnesis of patients often discloses that the symptoms of anxiety neurosis have at some definite time succeeded the symptoms of some other neurosis - neurasthenia, perhaps - and have taken their place. In these instances it can quite regularly be shown that, shortly before this change of the picture, a corresponding change has occurred in the form of the sexual noxa.

[1895b, 340]

It would be more dignified as well as more helpful to the patient - who, after all, has to come to terms with his ailments - for the doctor to tell the truth, as he knows it from his daily practice. The psychoneuroses as a genus are by no means mild illnesses. When hysteria sets in, no one can foretell when it will come to an end. We mostly comfort ourselves with the vain prophecy that 'one day it will suddenly disappear'. Recovery often enough turns out to be merely an agreement to mutual toleration between the sick part of the patient and the healthy part; or it is the result of the transformation of a symptom into a phobia. A girl's hysteria, calmed down with difficulty, revives in her as a wife after the short interruption of young married happiness. The only difference is that another person, the husband, is now driven by his own interests to keep silence about her condition. Even if an illness of this kind leads to no manifest incapacity on the patients' part to carry on their life, it nearly always prevents free unfolding of their mental powers. Obsessions recur throughout their lives; and phobias and other restrictions upon the will have hitherto been unamenable to treatment of any kind. All this is kept from the knowledge of the layman. The father of a hysterical girl is consequently horrified if, for instance, he is asked to agree to her being given a year's treatment, when she has perhaps only been ill for a few months. The layman is, as it were, deeply convinced in himself that all these psychoneuroses are unnecessary; so he has no patience with the processes of the illness and no readiness to make sacrifices for its treatment. If, in face of a case of typhus which lasts three weeks, or of a broken leg which takes six months to mend, he adopts a more understanding attitude, and if, as soon as his child shows the first signs of a curvature of the spine, he finds it reasonable that orthopaedic treatment should be carried on over several years, the difference in his behaviour is due to the better knowledge on the part of the physicians who pass on their knowledge honestly to the layman. Honesty on the part of the physician and willing acquiescence on the part of the layman will be established for the neuroses too, as soon as an insight into the nature of those affections becomes common property in the medical world. Radical treatment of these disorders will no doubt always require special training and will be incompatible with other kinds of medical activity. On the other hand, this class of physicians, which will, I believe, be large one in the future, has the prospect of achieving noteworthy results and of obtaining a satisfying insight into the mental life of mankind.

[1897b, 475]
I have observed that this method is very often confused with hypnotic treatment by suggestion; I have noticed this because it happens comparatively often that colleagues who do not ordinarily confide their cases to me send me patients refractory patients, of course - with a request that I should hypnotize them. Now I have not used hypnosis for therapeutic purposes for some eight years (except for a few special experiments) so that I habitually send back these cases with the recommendation that anyone who relies upon hypnosis may employ it himself. There is, actually, the greatest possible antithesis between suggestive and analytic technique - the same antithesis which, in regard to the fine arts, the great Leonardo da Vinci summed up in the formulas: *per via di porre* and *per via di levare*. Painting, says Leonardo, works *per via di porre*, for it applies a substance - particles of colour - where there was no thing before, on the colourless canvas; sculpture, however, proceeds *per via di levare*, since it takes away from the block of stone all that hides the surface of the statue contained in it. In a similar way, the technique of suggestion aims at proceeding *per via di porre*; it is not concerned with the origin, strength and meaning of the morbid symptoms, but instead, it superimposes something - a suggestion - in the expectation that it will be strong enough to restrain the pathogenic idea from coming to expression. Analytic therapy, on the other hand, does not seek to add or to introduce anything new, but to take away something, to bring out something; and to this end concerns itself with the genesis of the morbid symptoms and the psychical context of the pathogenic idea which it seeks to remove. It is by the use of this mode of investigation that analytic therapy has increased our knowledge so notably. I gave up the suggestive technique, and with it hypnosis, so early in my practice because I despaired of making suggestion powerful and enduring enough to effect permanent cures. In every severe case I saw the suggestions which had been applied crumble away again; after which the disease or some substitute for it was back once more. Besides all this I have another reproach to make against this method, namely, that it conceals from us all insight into the play of mental forces; it does not permit us, for example, to recognize the resistance with which the patient clings to his disease and thus even fights against his own recovery; yet it is this phenomenon of resistance which alone makes it possible to understand his behaviour in daily life.

[1905a, 1566]
This one-sided attitude of medicine towards the body has undergone a gradual change in the course of the last decade and a half, a change brought about directly by clinical experience. There are a large number of patients, suffering from affections of greater or less severity, whose disorders and complaints make great demands on the skill of their physicians, but in whom no visible or observable signs of a pathological process can be discovered either during their life or after their death, in spite of all the advances in the methods of investigation made by scientific medicine. One group of these patients are distinguished by the copiousness and variety of their symptoms: they are incapable of intellectual work because of headaches or inability to concentrate their attention, their eyes ache when they read, their legs become fatigued when they walk, develop dull pains or go to sleep, their digestion is disturbed by distressing sensations, by eructations or gastric spasms, they cannot defaecate without aperients, they are subject to sleeplessness, and so on. They may suffer from all these disorders simultaneously or in succession, or from only a selection of them; but in every case the illness is evidently the same. Moreover, its signs are often variable and replace one another. A patient who has hitherto been incapacitated by headaches but has had a fairly good digestion may next day enjoy a clear head but may thenceforward be unable to manage most kinds of food. Again, his sufferings may suddenly cease if there is a marked change in the circumstances of his existence. If he is travelling he may feel perfectly well and be able to enjoy the most varied diet without any ill effects, but when he gets home he may once more have to restrict himself to sour milk. In a few cases the disorder - whether it is a pain or a weakness resembling a paralysis - may suddenly pass from one side of the body to the other: it may jump from his right side to the corresponding part of the body on his left side. But in every instance it is to be observed that the symptoms are very clearly influenced by excitement, emotion, worry, etc., and also that they can disappear and give place to perfect health without leaving any traces, even if they have persisted over a long period.

[1890a, 1587]
To shorten analytic treatment is a justifiable wish, and its fulfilment, as we shall learn, is being attempted along various lines. Unfortunately, it is opposed by a very important factor, namely, the slowness with which deep-going changes in the mind are accomplished - in the last resort, no doubt, the 'timelessness' of our unconscious processes. When patients are faced with the difficulty of the great expenditure of time required for analysis they not infrequently manage to propose a way out of it. They divide up their ailments and describe some as unbearable, and others as secondary, and then say: 'If only you will relieve me from this one (for instance, a headache or a particular fear) I can deal with the other one on my own in my ordinary life.' In doing this, however, they over-estimate the selective power of analysis. The analyst is certainly able to do a great deal, but he cannot determine beforehand exactly what results he will effect. He sets in motion a process, that of the resolving of existing repressions. He can supervise this process, further it, remove obstacles in its way, and he can undoubtedly vitiate much of it. But on the whole, once begun, it goes its own way and does not allow either the direction it takes or the order in which it picks up its points to be prescribed for it. The analyst's power over the symptoms of the disease may thus be compared to male sexual potency. A man can, it is true, beget a whole child, but even the strongest man cannot create in the female organism a head alone or an arm or a leg; he cannot even prescribe the child's sex. He, too, only sets in motion a highly complicated process, determined by events in the remote past, which ends with the severance of the child from its mother. A neurosis as well has the character of an organism. Its component manifestations are not independent of one another; they condition one another and give one another mutual support. A person suffers from one neurosis only, never from several which have accidentally met together in a single individual. The patient freed, according to his wish, from his one unendurable symptom might easily find that a symptom which had previously been negligible had now increased and grown unendurable. The analyst who wishes the treatment to owe its success as little as possible to its elements of suggestion (i.e. to the transference) will do well to refrain from making use of even the trace of selective influence upon the results of the therapy which may perhaps be open to him. The patients who are bound to be most welcome to him are those who ask him to give them complete health, in so far as that is attainable, and who place as much time at his disposal as is necessary for the process of recovery. Such favourable conditions as these are, of course, to be looked for in only a few cases.

[1913c, 2483]
But I should like to say a few words to you to relieve you of your surprise at the emergence of this unexpected phenomenon. We must not forget that the patient's illness, which we have undertaken to analyse, is not something which has been rounded off and become rigid but that it is still growing and developing like a living organism. The beginning of the treatment does not put an end to this development; when, however, the treatment has obtained mastery over the patient, what happens is that the whole of his illness's new production is concentrated upon a single point - his relation to the doctor. Thus the transference may be compared to the cambium layer in a tree between the wood and the bark, from which the new formation of tissue and the increase in the girth of the trunk derive. When the transference has risen to this significance, work upon the patient's memories retreats far into the background. Thereafter it is not incorrect to say that we are no longer concerned with the patient's earlier illness but with a newly created and transformed neurosis which has taken the former's place. We have followed this new edition of the old disorder from its start, we have observed its origin and growth, and we are especially well able to find our way about in it since, as its object, we are situated at its very centre. All the patient's symptoms have abandoned their original meaning and have take on a new sense which lies in a relation to the transference; or only such symptoms have persisted as are capable of undergoing such a transformation. But the mastering of this new, artificial neurosis coincides with getting rid of the illness which was originally brought to the treatment - with the accomplishment of our therapeutic task. A person who has become normal and free from the operation of repressed instinctual impulse in his relation to the doctor will remain so in his own life after the doctor has once more withdrawn from it.

Let us begin with the former. I was a pupil of Bernheim's, whom I visited at Nancy in 1889 and whose book on suggestion I translated into German. I practised hypnotic treatment for many years, at first by prohibitory suggestion and later in combination with Breuer's method of questioning the patient. I can therefore speak of the results of hypnotic or suggestive therapy on the basis of a wide experience. If, in the words of the old medical aphorism, an ideal therapy should be rapid, reliable and not disagreeable for the patient, Bernheim's method fulfilled at least two of these requirements. It could be carried through much quicker - or, rather, infinitely quicker - than analytic treatment and it caused the patient neither trouble nor unpleasantness. For the doctor it became, in the long run, monotonous: in each case, in the same way, with the same ceremonial, forbidding the most variegated symptoms to exist, without being able to learn anything of their sense and meaning. It was hackwork and not a scientific activity, and it recalled magic, incantations and hocus-pocus. That could not weigh, however, against the patient's interest. But the third quality was lacking: the procedure was not reliable in any respect. It could be used with one patient, but not with another; it achieved a great deal with one and very little with another, and one never knew why. Worse than the capriciousness of the procedure was the lack of permanence in its successes. If, after a short time, one had news of the patient once more, the old ailment was back again or its place had been taken by a new one. One might hypnotize him again. But in the background there was the warning given by experienced workers against robbing the patient of his self-reliance by frequently repeated hypnosis and so making him an addict to this kind of therapy as though it were a narcotic. Admittedly sometimes things went entirely as one would wish: after a few efforts, success was complete and permanent. But the conditions determining such a favourable outcome remained unknown. On one occasion a severe condition in a woman, which I had entirely got rid of by a short hypnotic treatment, returned unchanged after the patient had, through no action on my part, got annoyed with me; after a reconciliation, I removed the trouble again and far more thoroughly; yet it returned once more after she had fallen foul of me a second time. On another occasion a woman patient, whom I had repeatedly helped out of neurotic states by hypnosis, suddenly, during the treatment of a specially obstinate situation, threw her arms round my neck. After this one could scarcely avoid, whether one wanted to or not, investigating the question of the nature and origin of one's authority in suggestive treatment.

[1916-1917, 3486]

[1916-1917, 3491]
All the libido, as well as everything opposing it, is made to converge solely on the relation with the doctor. In this process the symptoms are inevitably divested of libido. In place of his patient's true illness there appears the artificially constructed transference illness, in place of the various unreal objects of the libido there appears a single, and once more imaginary, object in the person of the doctor. But, by the help of he doctor's suggestion, the new struggle around this object is lifted to the highest psychical level: it takes place as a normal mental conflict. Since a fresh repression is avoided, the alienation between ego and libido is brought to an end and the subject's mental unity is restored. When the libido is released once more from its temporary object in the person of the doctor, it cannot return to its earlier objects, but is at the disposal of the ego. The forces against which we have been struggling during our work of therapy are, on the one hand, the ego's antipathy to certain trends of the libido - an antipathy expressed in a tendency to repression - and, on the other hand, the tenacity or adhesiveness of the libido, which dislikes leaving objects that it has once cathected. 

As far as I can see, the danger threatens from two directions in especial. On the one hand, when the illness has been broken down by the analysis, the patient makes the most assiduous efforts to create for himself in place of his symptoms new substitutive satisfactions, which now lack the feature of suffering. He makes use of the enormous capacity for displacement possessed by the now partly liberated libido, in order to cathect with libido and promote to the position of substitutive satisfactions the most diverse kinds of activities, preferences and habits, not excluding some that have been his already. He continually finds new distractions of this kind, into which the energy necessary to carrying on the treatment escapes, and he knows how to keep them secret for a time. It is the analyst's task to detect these divergent paths and to require him every time to abandon them, however harmless the activity which leads to satisfaction may be in itself. The half-recovered patient may also enter on less harmless paths - as when, for instance, if he is a man, he seeks prematurely to attach himself to a woman. It may be observed, incidentally, that unhappy marriage and physical infirmity are the two things that most often supersede a neurosis. They satisfy in particular the sense of guilt (need for punishment) which makes many patients cling so fast to their neuroses. By a foolish choice in marriage they punish themselves; they regard a long organic illness as a punishment by fate and thereafter often cease to keep up their neurosis.
But it became ever clearer that the aim which had been set up - the aim that what was unconscious should become conscious - is not completely attainable by that method. The patient cannot remember the whole of what is repressed in him, and what he cannot remember may be precisely the essential part of it. Thus he acquires no sense of conviction of the correctness of the construction that has been communicated to him. He is obliged to repeat the repressed material as a contemporary experience instead of, as the physician would prefer to see, remembering it as something belonging to the past.¹ These reproductions, which emerge with such unwished-for exactitude, always have as their subject some portion of infantile sexual life - of the Oedipus complex, that is, and its derivatives; and they are invariably acted out in the sphere of the transference, of the patient's relation to the physician. When things have reached this stage, it may be said that the earlier neurosis has now been replaced by a fresh, 'transference neurosis'. It has been the physician's endeavour to keep this transference neurosis within the narrowest limits: to force as much as possible into the channel of memory and to allow as little as possible to emerge as repetition. The ratio between what is remembered and what is reproduced varies from case to case. The physician cannot as a rule spare his patient this phase of the treatment. He must get him to re-experience some portion of his forgotten life, but must see to it, on the other hand, that the patient retains some degree of aloofness, which will enable him, in spite of everything, to recognize that what appears to be reality is in fact only a reflection of a forgotten past. If this can be successfully achieved, the patient's sense of conviction is won, together with the therapeutic success that is dependent on it.

[1920g, 3723]

Let us keep to a habit of our technique and consider first the extreme and unmistakably pathological form of this masochism. I have described elsewhere¹ how in analytic treatment we come across patients to whom, owing to their behaviour towards its therapeutic influence, we are obliged to ascribe an 'unconscious' sense of guilt. I pointed out the sign by which such people can be recognized (a 'negative therapeutic reaction') and I did not conceal the fact that the strength of such an impulse constitutes one of the most serious resistances and the greatest danger to the success of our medical or educative aims. The satisfaction of this unconscious sense of guilt is perhaps the most powerful bastion in the subject's (usually composite) gain from illness - in the sum of forces which struggle against his recovery and refuse to surrender his state of illness. The suffering entailed by neuroses is precisely the factor that makes them valuable to the masochistic trend. It is instructive, too, to find, contrary to all theory and expectation, that a neurosis which has defied every therapeutic effort may vanish if the subject becomes involved in the misery of an unhappy marriage, or loses all his money, or develops a dangerous organic disease. In such instances one form of suffering has been replaced by another; and we see that all that mattered was that it should be possible to maintain a certain amount of suffering.

[1924c, 4078]
We have travelled somewhat far from our basis. I will tell you in retrospect the starting-point of these reflections on the theory of the instincts. It was the same as that which led us to revise the relation between the ego and the unconscious - the impression derived from the work of analysis that the patient who puts up a resistance is so often unaware of that resistance. Not only the fact of the resistance is unconscious to him, however, but its motives as well. We were obliged to search out these motives or motive, and to our surprise we found them in a powerful need for punishment which we could only class with masochistic wishes. The practical significance of this discovery is not less than its theoretical one, for the need for punishment is the worst enemy of our therapeutic efforts. It is satisfied by the suffering which is linked to the neurosis, and for that reason holds fast to being ill. It seems that this factor, an unconscious need for punishment, has a share in every neurotic illness. And here those cases in which the neurotic suffering can be replaced by suffering of another kind are wholly convincing. I will report an experience of this kind. [1933a, 4712]

The further our work proceeds and the more deeply our insight penetrates into the mental life of neurotics, the more clearly two new factors force themselves on our notice, which demand the closest attention as sources of resistance. Both of them are completely unknown to the patient, neither of them could be taken into account when our pact was made; nor do they arise from the patient's ego. They may both be embraced under the single name of 'need to be ill or to suffer', but they have different origins though in other respects they are of a kindred nature. The first of these two factors is the sense of guilt or consciousness of guilt, as it is called, though the patient does not feel it and is not aware of it. It is evidently the portion of the resistance contributed by a super-ego that has become particularly severe and cruel. The patient must not become well but must remain ill, for he deserves no better. This resistance does not actually interfere with our intellectual work, but it makes it inoperative; indeed, it often allows us to remove one form of neurotic suffering, but is ready at once to replace it by another, or perhaps by some somatic illness. The sense of guilt also explains the cure or improvement of severe neuroses which we occasionally observe after real misfortunes: all that matters is that the patient should be miserable - in what way is of no consequence. The uncomplaining resignation with which such people often put up with their hard fate is most remarkable, but also revealing. In warding off this resistance we are obliged to restrict ourselves to making it conscious and attempting to bring about the slow demolition of the hostile super-ego. [1940a [1938], 4989]
Dora had listened to me without any of her usual contradictions. She seemed to be moved; she said good-bye to me very warmly, with the heartiest wishes for the New Year, and - came no more. Her father, who called on me two or three times afterwards, assured me that she would come back again, and said it was easy to see that she was eager for the treatment to continue. But it must be confessed that Dora's father was never entirely straightforward. He had given his support to the treatment so long as he could hope that I should 'talk' Dora out of her belief that there was something more than a friendship between him and Frau K. His interest faded when he observed that it was not my intention to bring about that result. I knew Dora would not come back again. Her breaking off so unexpectedly, just when my hopes of a successful termination of the treatment were at their highest, and her thus bringing those hopes to nothing - this was an unmistakable act of vengeance on her part. Her purpose of self-injury also profited by this action. No one who, like me, conjures up the most evil of those half-tamed demons that inhabit the human breast, and seeks to wrestle with them, can expect to come through the struggle unscathed. Might I perhaps have kept the girl under my treatment if I myself had acted a part, if I had exaggerated the importance to me of her staying on, and had shown a warm personal interest in her - a course which, even after allowing for my position as her physician, would have been tantamount to providing her with a substitute for the affection she longed for? I do not know. Since in every case a portion of the factors that are encountered under the form of resistance remains unknown, I have always avoided acting a part, and have contented myself with practising the humbler arts of psychology. In spite of every theoretical interest and of every endeavour to be of assistance as a physician, I keep the fact in mind that there must be some limits set to the extent to which psychological influence may be used, and I respect as one of these limits the patient's own will and understanding.

(2) To be quite safe, one should limit one's choice of patients to those who possess a normal mental condition, since in the psycho-analytic method this is used as a foothold from which to obtain control of the morbid manifestations. Psychoses, states of confusion and deeply-rooted (I might say toxic) depression are therefore not suitable for psycho-analysis; at least not for the method as it has been practised up to the present. I do not regard it as by any means impossible that by suitable changes in the method we may succeed in overcoming this contraindication - and so be able to initiate a psychotherapy of the psychoses.

By this time you will have formed an impression that the field of analytic psychotherapy is a very narrow one, since you have in fact heard nothing from me except indications that point against it. There remain, however, cases and types of disease enough on which this therapy may be tested - as, for instance, all chronic forms of hysteria with residual manifestations, the broad field of obsessive conditions, aboulias, and the like.
You are perhaps aware that I have never been a therapeutic enthusiast; there is no danger of my misusing this lecture by indulging in eulogies. I would rather say too little than too much. During the period at which I was the only analyst, people who were ostensibly friendly to my ideas used to say to me: 'That's all very nice and clever; but show me a case that you have cured by analysis.' This was one of the many formulas which in the course of time have succeeded one another in performing the function of pushing the uncomfortable novelty aside. To-day it is as out of date as many others: the analyst, too, has a heap of letters in his files from grateful patients who have been cured. The analogy does not stop at that. Psycho-analysis is really a method of treatment like others. It has its triumphs and its defeats, its difficulties, its limitations, its indications. At one time a complaint was made against analysis that it was not to be taken seriously as a treatment since it did not dare to issue any statistics of its successes. Since then, the Psycho-Analytic Institute in Berlin, which was founded by Dr. Max Eitingon, has published a statement of its results during its first ten years. Its therapeutic successes give grounds neither for boasting nor for being ashamed. But statistics of that kind are in general uninstructive; the material worked upon is so heterogeneous that only very large numbers would show anything. It is wiser to examine one's individual experiences. And here I should like to add that I do not think our cures can compete with those of Lourdes. There are so many more people who believe in the miracles of the Blessed Virgin than in the existence of the unconscious. If we turn to mundane competitors, we must compare psycho-analytic treatment with other kinds of psychotherapy. To-day organic physical methods of treating neurotic states need scarcely be mentioned. Analysis as a psycho-therapeutic procedure does not stand in opposition to other methods used in this specialized branch of medicine; it does not diminish their value nor exclude them. There is no theoretical inconsistency in a doctor who likes to call himself a psychotherapist using analysis on his patients alongside of any other method of treatment according to the peculiarities of the case and the favourable or unfavourable external circumstances. It is in fact technique that necessitates the specialization in medical practice. Thus in the same way surgery and orthopaedics were obliged to separate. Psycho-analytic activity is arduous and exacting; it cannot well be handled like a pair of glasses that one puts on for reading and takes off when one goes for a walk. As a rule psycho-analysis possesses a doctor either entirely or not at all. Those psychotherapists who make use of analysis among other methods, occasionally, do not to my knowledge stand on firm analytic ground; they have not accepted the whole of analysis but have watered it down - have drawn its fangs, perhaps; they cannot be counted as analysts. This is, I think, to be regretted. But co-operation in medical practice between an analyst and a psychotherapist who restricts himself to other techniques would serve quite a useful purpose. [1933a, 4751]
Compared with the other psychotherapeutic procedures psycho-analysis is beyond any doubt the most powerful. It is just and fair, too, that this should be so for it is also the most laborious and time-consuming; it would not be used on slight cases. In suitable cases it is possible by its means to get rid of disturbances and bring about changes for which in pre-analytic times one would not have ventured to hope. But it has its very appreciable limits. The therapeutic ambition of some of my adherents has made the greatest efforts to overcome these obstacles so that every sort of neurotic disorder might be curable by psycho-analysis. They have endeavoured to compress the work of analysis into a shorter duration, to intensify transference so that it may be able to overcome any resistance, to unite other forms of influence with it so as to compel a cure. These efforts are certainly praiseworthy, but, in my opinion, they are vain. They bring with them, too, a danger of being oneself forced away from analysis and drawn into a boundless course of experimentation. The expectation that every neurotic phenomenon can be cured may, I suspect, be derived from the layman’s belief that the neuroses are something quite unnecessary which have no right whatever to exist. Whereas in fact they are severe, constitutionally fixed illnesses, which rarely restrict themselves to only a few attacks but persist as a rule over long periods or throughout life. Our analytic experience that they can be extensively influenced, if the historical precipitating causes and accidental auxiliary factors of the illness can be dealt with, has led us to neglect the constitutional factor in our therapeutic practice, and in any case we can do nothing about it; but in theory we ought always to bear it in mind. The radical inaccessibility of the psychoses to analytic treatment should, in view of their close relationship to the neuroses, restrict our pretensions in regard to these latter. The therapeutic effectiveness of psycho-analysis remains cramped by a number of weighty and scarcely assailable factors. In the case of children, where one might count on the greatest successes, the difficulties are the external ones connected with their relation to their parents, though these difficulties are after all a necessary part of being a child. In the case of adults the difficulties arise in the first instance from two factors: the amount of psychical rigidity present and the form of the illness with all that covers in the way of deeper determinants.

The second limitation upon analytic successes is given by the form of the illness. You know already that the field of application of analytic therapy lies in the transference neuroses - phobias, hysteria, obsessional neurosis - and further, abnormalities of character which have been developed in place of these illnesses. Everything differing from these, narcissistic and psychotic conditions, is unsuitable to a greater or less extent. It would be entirely legitimate to guard against failures by carefully excluding such cases. This precaution would lead to a great improvement in the statistics of analysis. There is, however, a pitfall here. Our diagnoses are very often made only after the event. They resemble the Scottish King’s test for identifying witches that I read about in Victor Hugo. This king declared that he was in possession of an infallible method of recognizing a witch. He had the women stewed in a cauldron of boiling water and then tasted the broth. Afterwards he was able to say: ‘That was a witch’, or ‘No, that was not one.’ It is the same with us, except that we are the sufferers. We cannot judge the patient who comes for treatment (or, in the same way, the candidate who comes for training) till we have studied him analytically for a few weeks or months. We are in fact buying a pig in a poke. The patient brings along indefinite general ailments which do not admit of a conclusive diagnosis. After this period of testing it may turn out that the case is an unsuitable one. If so we send him away if he is a candidate, or continue the trial a little longer if he is a patient on the chance that we may yet see things in a more favourable light. The patient has his revenge by adding to our list of failures, and the rejected candidate does so perhaps, if he is paranoid, by writing books on psycho-analysis himself. As you see, our precautions have been of no avail.
I am afraid these detailed discussions are exhausting your interest. But I should be still more sorry if you were to think it is my intention to lower your opinion of psycho-analysis as a therapy. Perhaps I really made a clumsy start. For I wanted to do the opposite: to excuse the therapeutic limitations of analysis by pointing out their inevitability. With the same aim in view I turn to another point: the reproach against analytic treatment that it takes a disproportionately long time. On this it must be said that psychical changes do in fact only take place slowly; if they occur rapidly, suddenly, that is a bad sign. It is true that the treatment of a fairly severe neurosis may easily extend over several years; but consider, in case of success, how long the illness would have lasted. A decade, probably, for every year of treatment: the illness, that is to say (as we see so often in untreated cases), would not have ended at all. In some cases we have reasons for resuming an analysis many years afterwards. Life had developed fresh pathological reactions to fresh precipitating causes; but in the meantime our patient had been well. The first analysis had not in fact brought to light all his pathological dispositions, and it was natural for the analysis to have been stopped when success was achieved. There are also severely handicapped people who are kept under analytic supervision all through their lives and are taken back into analysis from time to time. But these people would otherwise have been altogether incapable of existence and we must feel glad that they can be kept on their feet by this piecemeal and recurrent treatment. The analysis of character disorders also calls for long periods of treatment; but it is often successful; and do you know of any other therapy with which such a task could even be approached? Therapeutic ambition may feel unsatisfied by such results; but we have learnt from the example of tuberculosis and lupus that success can only be obtained when the treatment has been adapted to the characteristics of the illness.

[1933a, 4755]

The two further questions - whether, while we are treating one instinctual conflict, we can protect a patient from future conflicts, and whether it is feasible and expedient, for prophylactic purposes, to stir up a conflict which is not at the time manifest - must be treated together; for obviously the first task can only be carried out in so far as the second one is - that is, in so far as a possible future conflict is turned into an actual present one upon which influence is then brought to bear. This new way of stating the problem is at bottom only an extension of the earlier one. Whereas in the first instance we were considering how to guard against a return of the same conflict, we are now considering how to guard against its possible replacement by another conflict. This sounds a very ambitious proposal, but all we are trying to do is to make clear what limits are set to the efficacy of analytic therapy.

[1937c, 5027]
However much our therapeutic ambition may be tempted to undertake such tasks, experience flatly rejects the notion. If an instinctual conflict is not a currently active one, is not manifesting itself, we cannot influence it even by analysis. The warning that we should let sleeping dogs lie, which we have so often heard in connection with our efforts to explore the psychical underworld, is peculiarly inapposite when applied to the conditions of mental life. For if the instincts are causing disturbances, it is a proof that the dogs are not sleeping; and if they seem really to be sleeping, it is not in our power to awaken them. This last statement, however, does not seem to be quite accurate and calls for a more detailed discussion. Let us consider what means we have at our disposal for turning an instinctual conflict which is at the moment latent into one which is currently active. Obviously there are only two things that we can do. We can bring about situations in which the conflict does become currently active, or we can content ourselves with discussing it in the analysis and pointing out the possibility of its arising. The first of these two alternatives can be carried out in two ways: in reality, or in the transference - in either case by exposing the patient to a certain amount of real suffering through frustration and the damming up of libido. Now it is true that we already make use of a technique of this kind in our ordinary analytic procedure. What would otherwise be the meaning of the rule that analysis must be carried out ‘in a state of frustration’? But this is a technique which we use in treating a conflict which is already currently active. We seek to bring this conflict to a head, to develop it to its highest pitch, in order to increase the instinctual force available for its solution. Analytic experience has taught us that the better is always the enemy of the good and that in every phase of the patient's recovery we have to fight against his inertia, which is ready to be content with an incomplete solution.

[1937c, 5027]
(4) Where we meet with an acute hysteria, a case which is passing through the period of the most active production of hysterical symptoms and in which the ego is being constantly overwhelmed by the products of the illness (i.e. during a hysterical psychosis), even the cathartic method will make little change in the appearance and course of the disorder. In such circumstances we find ourselves in the same position as regards the neurosis as a physician faced by an acute infectious disease. The aetiological factors have performed their work sufficiently, at a time which has now passed and is beyond the reach of any influence; and now, after the period of incubation has elapsed, they have become manifest. The illness cannot be broken off short. We must wait for it to run its course and in the mean time make the patient's circumstances as favourable as possible. If, during an acute period like this, we get rid of the products of the illness, the freshly generated hysterical symptoms, we must also be prepared to find that those that have been got rid of will promptly be replaced by others. The physician will not be spared the depressing feeling of being faced by a Sisyphean task. The immense expenditure of labour, and the dissatisfaction of the patient's family, to whom the inevitable length of an acute neurosis is not likely to be as familiar as the analogous case of an acute infectious disease - these and other difficulties will probably make a systematic application of the cathartic method as a rule impossible in any given case. Nevertheless, it remains a matter for serious consideration whether it may not be true that even in an acute hysteria the regular clearing up of the products of the illness exercises a curative influence, by supporting the patient's normal ego which is engaged in the work of defence, and by preserving it from being overwhelmed and falling into a psychosis and even perhaps into a permanent state of confusion.

[1895d, 233]
I return now to my earlier assertion that, in judging the neuroses, their full importance is not as a rule taken into account. I do not mean by this the undervaluation of these states shown in their frivolous dismissal by relatives and in the boasting assurances by doctors that a few weeks of cold water treatment or a few months of rest and convalescence will cure the condition. These are merely the opinions of quite ignorant doctors and laymen and are mostly no more than words intended to give the sufferer a short-lived consolation. It is, on the contrary, a well-known fact that a chronic neurosis, even if it does not totally put an end to the subject's capacity for existence, represents a severe handicap in his life, of the same order, perhaps, as tuberculosis or a cardiac defect. The situation would even be tolerable if neurotic illness were to exclude from civilized activities only a number of individuals who were in any case of the weaker sort, and allowed the rest to play their part in it at the cost of troubles that were merely subjective. But, far from this being so, I must insist upon the view that neuroses, whatever their extent and wherever they occur, always succeed in frustrating the purposes of civilization, and in that way actually perform the work of the suppressed mental forces that are hostile to civilization. Thus, when society pays for obedience to its far-reaching regulations by an increase in nervous illness, it cannot claim to have purchased a gain at the price of sacrifices; it cannot claim a gain at all. Let us, for instance, consider the very common case of a woman who does not love her husband, because, owing to the conditions under which she entered marriage, she has no reason to love him, but who very much wants to love him, because that alone corresponds to the ideal of marriage to which she has been brought up. She will in that case suppress every impulse which would express the truth and contradict her endeavours to fulfil her ideal, and she will make special efforts to play the part of a loving, affectionate and attentive wife. The outcome of this self-suppression will be a neurotic illness; and this neurosis will in a short time have taken revenge on the unloved husband and have caused him just as much lack of satisfaction and worry as would have resulted from an acknowledgement of the true state of affairs. This example is completely typical of what a neurosis achieves. A similar failure to obtain compensation is to be seen after the suppression of impulses inimical to civilization which are not directly sexual. If a man, for example, has become over-kind as a result of a violent suppression of a constitutional inclination to harshness and cruelty, he often loses so much energy in doing this that he fails to carry out all that his compensatory impulses require, and he may, after all, do less good on the whole than he would have done without the suppression.

[1908d, 1962]
Ladies and Gentlemen, from the intellectual point of view we must, I think, take into account two special obstacles to recognizing psycho-analytic trains of thought. In the first place, people are unaccustomed to reckoning with a strict and universal application of determinism to mental life; and in the second place, they are ignorant of the peculiarities which distinguish unconscious mental processes from the conscious ones that are familiar to us. One of the most widespread resistances to psycho-analytic work, in the sick and healthy alike, can be traced to the second of these two factors. People are afraid of doing harm by psycho-analysis: they are afraid of bringing the repressed sexual instincts into the patient's consciousness, as though that involved a danger of their overwhelming his higher ethical trends and of their robbing him of his cultural acquisitions. People notice that the patient has sore spots in his mind, but shrink from touching them for fear of increasing his sufferings. We can accept this analogy. It is no doubt kinder not to touch diseased spots if it can do nothing else but cause pain. But, as we know, a surgeon does not refrain from examining and handling a focus of disease, if he is intending to take active measures which he believes will lead to a permanent cure. No one thinks of blaming him for the inevitable suffering caused by the examination or for the reactions to the operation, if only it gains its end and the patient achieves a lasting recovery as a result of the temporary worsening of his state. The case is similar with psycho-analysis. It may make the same claims as surgery: the increase in suffering which it causes the patient during treatment is incomparably less than what a surgeon causes, and is quite negligible in proportion to the severity of the underlying ailment. On the other hand, the final outcome that is so much dreaded - the destruction of the patient's cultural character by the instincts which have been set free from repression - is totally impossible. For alarm on this score takes no account of what our experiences have taught us with certainty - namely that the mental and somatic power of a wishful impulse, when once its repression has failed, is far stronger if it is unconscious than if it is conscious; so that to make it conscious can only be to weaken it. An unconscious wish cannot be influenced and it is independent of any contrary tendencies, whereas a conscious one is inhibited by whatever else is conscious and opposed to it. Thus the work of psycho-analysis puts itself at the orders of precisely the highest and most valuable cultural trends, as a better substitute for the unsuccessful repression.
[1910a, 2237]
Hitherto, this authority, with its enormous weight of suggestion, has been against us. All our therapeutic successes have been achieved in the face of this suggestion: it is surprising that any successes at all could be gained in such circumstances. I must not let myself be led into describing my agreeable experiences during the period when I alone represented psycho-analysis. I can only say that when I assured my patients that I knew how to relieve them permanently of their sufferings they looked round my modest abode, reflected on my lack of fame and title, and regarded me like the possessor of an infallible system at a gambling-resort, of whom people say that if he could do what he professes he would look very different himself. Nor was it really pleasant to carry out a psychical operation while the colleagues whose duty it should have been to assist took particular pleasure in spitting into the field of operation, and while at the first signs of blood or restlessness in the patient his relatives began threatening the operating surgeon. An operation is surely entitled to produce reactions; in surgery we became accustomed to that long ago. People simply did not believe me, just as even to-day people do not much believe any of us. Under such conditions not a few attempts were bound to fail. To estimate the increase in our therapeutic prospects when we have received general recognition, you should think of the position of a gynaecologist in Turkey and in the West. In Turkey, all he may do is to feel the pulse of all arm stretched out to him through a hole in the wall: and his medical achievements are in proportion to the inaccessibility of their object. Our opponents in the West wish to allow us much the same degree of access to our patient's minds. But now that the force of social suggestion drives sick women to the gynaecologist, he has become their helper and saviour. I trust you will not say that the fact of the authority of society coming to our aid and increasing our successes so greatly would do nothing to prove the validity of our hypotheses - arguing as you might that, since suggestion is supposed to be able to do anything, our successes would then be successes of suggestion and not of psycho-analysis. Social suggestion is at present favourable to treating nervous patients by hydropathy, dieting and electro-therapy, but that does not enable such measures to get the better of neuroses. Time will show whether psycho-analytic treatment can accomplish more.

[1910d, 2311]

As the combined result of lack of insight on the part of patients and disingenuousness on the part of doctors, analysis finds itself expected to fulfil the most boundless demands, and that in the shortest time. Let me, as an example, give some details from a letter which I received a few days ago from a lady in Russia. She is 53 years old, her illness began twenty-three years ago and for the last ten years she has no longer been able to do any continuous work. 'Treatment in a number of institutions for nervous cases' have not succeeded in making an 'active life' possible for her. She hopes to be completely cured by psycho-analysis, which she has read about, but her illness has already cost her family so much money that she cannot manage to come to Vienna for longer than six weeks or two months. Another added difficulty is that she wishes from the very start to 'explain' herself in writing only, since any discussion of her complexes would cause an explosion of feeling in her or 'render her temporarily unable to speak'. - No one would expect a man to lift a heavy table with two fingers as if it were a light stool, or to build a large house in the time it would take to put up a wooden hut; but as soon as it becomes a question of the neuroses - which do not seem so far to have found a proper place in human thought - even intelligent people forget that a necessary proportion must be observed between time, work and success. This, incidentally, is an understandable result of the deep ignorance which prevails about the aetiology of the neuroses. Thanks to this ignorance, neurosis is looked or as a kind of 'maiden from afar'. 'None knew whence she came'; so they expected that one day she would vanish.

[1913c, 2481]
Doctors lend support to these fond hopes. Even the informed among them often fail to estimate properly the severity of nervous disorders. A friend and colleague of mine, to whose great credit I account it that after several decades of scientific work on other principles he became converted to the merits of psycho-analysis, once wrote to me: 'What we need is a short, convenient, out-patient treatment for obsessional neurosis.' I could not supply him with it and felt ashamed; so I tried to excuse myself with the remark that specialists in internal diseases, too, would probably be very glad of a treatment for tuberculosis or carcinoma which combined these advantages.

[1913c, 2482]

The lay public, about whose attitude to psycho-analysis I spoke at the outset, will doubtless seize upon this discussion of transference-love as another opportunity for directing the attention of the world to the serious danger of this therapeutic method. The psycho-analyst knows that he is working with highly explosive forces and that he needs to proceed with as much caution and conscientiousness as a chemist. But when have chemists ever been forbidden, because of the danger, from handling explosive substances, which are indispensable, on account of their effects? It is remarkable that psycho-analysis has to win for itself afresh all the liberties which have long since been accorded to other medical activities. I am certainly not in favour of giving up the harmless methods of treatment. For many cases they are sufficient, and, when all is said, human society has no more use for the furor sanandi¹ than for any other fanaticism. But to believe that the psychoneuroses are to be conquered by operating with harmless little remedies is grossly to under-estimate those disorders both as to their origin and their practical importance. No; in medical practice there will always be room for the 'ferrum' and the 'ignis' side by side with the 'medicina'; and in the same way we shall never be able to do without a strictly regular, undiluted psycho-analysis which is not afraid to handle the most dangerous mental impulses and to obtain mastery over them for the benefit of the patient.

[1915a, 2520]
I am to put before you, then, the psycho-analytic view of the phenomena of neurosis. In doing so, the best plan would seem to be to make a start in connection with the phenomena we have already dealt with, for the sake both of analogy and contrast; and I will begin with a symptomatic action which I have seen many people perform during my consulting hours. We analysts cannot do much for the people who come to us in our consulting-room to lay before us in a quarter of an hour the miseries of a long lifetime. Our deeper knowledge makes it difficult for us to give the kind of opinion another doctor would - 'There's nothing wrong with you' - with the added advice: 'You should arrange for a mild hydropathic treatment.' One of my colleagues who was asked what he did with his consultation patients shrugged his shoulders and replied: 'I fine them so-and-so many Kronen for a frivolous waste of time.' So you will not be surprised to hear that even in the case of busy psycho-analysts their consulting hours are not apt to be very lively. I have had the ordinary door between my waiting-room and my consulting- and treatment-room doubled and given a baize lining. There can be no doubt about the purpose of this arrangement. Now it constantly happens that a person whom I have brought in from the waiting-room omits to shut the door behind him and almost always he leaves both doors open. As soon as I notice this I insist in a rather unfriendly tone on his or her going back and making good the omission even if the person concerned is a well-dressed gentleman or a fashionable lady. This makes an impression of uncalled-for pedantry. Occasionally, too, I have put myself in a foolish position by making this request when it has turned out to be a person who cannot touch a door-handle himself and is glad if someone with him spares him the necessity. But in the majority of cases I have been right; for anyone who behaves like this and leaves the door open between a doctor's waiting-room and consulting-room is ill-mannered and deserves an unfriendly reception. But do not take sides over this till you have heard the sequel. For this carelessness on the part of the patient only occurs when he has been alone in the waiting-room and has therefore left an empty room behind him; it never happens if other people, strangers to him, have been waiting with him. In this latter case he knows quite well that it is in his interest not to be overheard while he is talking to the doctor, and he never fails to shut both the doors carefully.

[1916-1917, 3329]
Compared with the other psychotherapeutic procedures psycho-analysis is beyond any doubt the most powerful. It is just and fair, too, that this should be so for it is also the most laborious and time-consuming; it would not be used on slight cases. In suitable cases it is possible by its means to get rid of disturbances and bring about changes for which in pre-analytic times one would not have ventured to hope. But it has its very appreciable limits. The therapeutic ambition of some of my adherents has made the greatest efforts to overcome these obstacles so that every sort of neurotic disorder might be curable by psycho-analysis. They have endeavoured to compress the work of analysis into a shorter duration, to intensify transference so that it may be able to overcome any resistance, to unite other forms of influence with it so as to compel a cure. These efforts are certainly praiseworthy, but, in my opinion, they are vain. They bring with them, too, a danger of being oneself forced away from analysis and drawn into a boundless course of experimentation. The expectation that every neurotic phenomenon can be cured may, I suspect, be derived from the layman's belief that the neuroses are something quite unnecessary which have no right whatever to exist. Whereas in fact they are severe, constitutionally fixed illnesses, which rarely restrict themselves to only a few attacks but persist as a rule over long periods or throughout life. Our analytic experience that they can be extensively influenced, if the historical precipitating causes and accidental auxiliary factors of the illness can be dealt with, has led us to neglect the constitutional factor in our therapeutic practice, and in any case we can do nothing about it; but in theory we ought always to bear it in mind. The radical inaccessibility of the psychoses to analytic treatment should, in view of their close relationship to the neuroses, restrict our pretensions in regard to these latter. The therapeutic effectiveness of psycho-analysis remains cramped by a number of weighty and scarcely assailable factors. In the case of children, where one might count on the greatest successes, the difficulties are the external ones connected with their relation to their parents, though these difficulties are after all a necessary part of being a child. In the case of adults the difficulties arise in the first instance from two factors: the amount of psychical rigidity present and the form of the illness with all that covers in the way of deeper determinants.

I am afraid these detailed discussions are exhausting your interest. But I should be still more sorry if you were to think it is my intention to lower your opinion of psycho-analysis as a therapy. Perhaps I really made a clumsy start. For I wanted to do the opposite: to excuse the therapeutic limitations of analysis by pointing out their inevitability. With the same aim in view I turn to another point: the reproach against analytic treatment that it takes a disproportionately long time. On this it must be said that psychical changes do in fact only take place slowly; if they occur rapidly, suddenly, that is a bad sign. It is true that the treatment of a fairly severe neurosis may easily extend over several years; but consider, in case of success, how long the illness would have lasted. A decade, probably, for every year of treatment: the illness, that is to say (as we see so often in untreated cases), would not have ended at all. In some cases we have reasons for resuming an analysis many years afterwards. Life had developed fresh pathological reactions to fresh precipitating causes; but in the meantime our patient had been well. The first analysis had not in fact brought to light all his pathological dispositions, and it was natural for the analysis to have been stopped when success was achieved. There are also severely handicapped people who are kept under analytic supervision all through their lives and are taken back into analysis from time to time. But these people would otherwise have been altogether incapable of existence and we must feel glad that they can be kept on their feet by this piecemeal and recurrent treatment. The analysis of character disorders also calls for long periods of treatment; but it is often successful; and do you know of any other therapy with which such a task could even be approached? Therapeutic ambition may feel unsatisfied by such results; but we have learnt from the example of tuberculosis and lupus that success can only be obtained when the treatment has been adapted to the characteristics of the illness.

[1933a, 4752, 4755]
(4) Where we meet with an acute hysteria, a case which is passing through the period of the most active production of hysterical symptoms and in which the ego is being constantly overwhelmed by the products of the illness (i.e. during a hysterical psychosis), even the cathartic method will make little change in the appearance and course of the disorder. In such circumstances we find ourselves in the same position as regards the neurosis as a physician faced by an acute infectious disease. The aetiological factors have performed their work sufficiently, at a time which has now passed and is beyond the reach of any influence; and now, after the period of incubation has elapsed, they have become manifest. The illness cannot be broken off short. We must wait for it to run its course and in the mean time make the patient's circumstances as favourable as possible. If, during an acute period like this, we get rid of the products of the illness, the freshly generated hysterical symptoms, we must also be prepared to find that those that have been got rid of will promptly be replaced by others. The physician will not be spared the depressing feeling of being faced by a Sisyphean task. The immense expenditure of labour, and the dissatisfaction of the patient's family, to whom the inevitable length of an acute neurosis is not likely to be as familiar as the analogous case of an acute infectious disease - these and other difficulties will probably make a systematic application of the cathartic method as a rule impossible in any given case. Nevertheless, it remains a matter for serious consideration whether it may not be true that even in an acute hysteria the regular clearing up of the products of the illness exercises a curative influence, by supporting the patient's normal ego which is engaged in the work of defence, and by preserving it from being overwhelmed and falling into a psychosis and even perhaps into a permanent state of confusion.

[1895d, 233]

We can express the aim of our efforts in a variety of formulas: making conscious what is unconscious, lifting repressions, filling gaps in the memory - all these amount to the same thing. But perhaps you will be dissatisfied by this admission. You had formed a different picture of the return to health of a neurotic patient - that, after submitting to the tedious hours of a psycho-analysis, he would become another man; but the total result, so it seems, is that he has rather less that is unconscious and rather more that is conscious in him than he had before. The fact is that you are probably under-estimating the importance of an internal change of this kind. The neurotic who is cured has really become another man, though a bottom, of course, he has remained the same; that is to say, he has become what he might have become at best under the most favourable conditions. But that is a very great deal. If you now hear all that has to be done and what efforts it needs to bring about this apparently trivial change in a man's mental life, you will no doubt begin to realize the importance of this difference in psychical levels.

[1916-1917, 3477]
In our opinion the therapeutic advantages of this procedure are considerable. It is of course true that we do not cure hysteria in so far as it is a matter of disposition. We can do nothing against the recurrence of hypnoid states. Moreover, during the productive stage of an acute hysteria our procedure cannot prevent the phenomena which have been so laboriously removed from being at once replaced by fresh ones. But once this acute stage is past, any residues which may be left in the form of chronic symptoms or attacks are often removed, and permanently so, by our method, because it is a radical one; in this respect it seems to us far superior in its efficacy to removal through direct suggestion, as it is practised to-day by psychotherapists.

[1895d, 19]

The therapeutic success on the whole was considerable; but it was not a lasting one. The patient's tendency to fall ill in a similar way under the impact of fresh traumas was not got rid of. Anyone who wanted to undertake the definitive cure of a case of hysteria such as this would have to enter more thoroughly into the complex of phenomena than I attempted to do. Frau von N. was undoubtedly a personality with a severe neuropathic heredity. It seems likely that there can be no hysteria apart from a disposition of this kind. But on the other hand disposition alone does not make hysteria. There must be reasons that bring it about, and, in my opinion, these reasons must be appropriate: the aetiology is of a specific character. I have already mentioned that in Frau von N. the affects of a great number of traumatic experiences had been retained and that the lively activity of her memory brought now one and now another of these traumas to the surface of her mind. I shall now venture to put forward an explanation of the reason why she retained the affects in this way. That reason, it is true, was connected with her hereditary disposition. For, on the one hand, her feelings were very intense; she was of a vehement nature, capable of the strongest passions. On the other hand, since her husband's death, she had lived in complete mental solitude; her persecution by her relatives had made her suspicious of friends and she was jealously on guard against anyone acquiring too much influence over her actions. The circle of her duties was very wide, and she performed the whole of the mental work which they imposed on her by herself, without a friend or confidant, almost isolated from her family and handicapped by her conscientiousness, her tendency to tormenting herself and often, too, by the natural helplessness of a woman. In short the mechanism of the retention of large sums of excitation, apart from everything else, cannot be overlooked in this case. It was based partly on the circumstances of her life and partly on her natural disposition. Her dislike, for instance, of saying anything about herself was so great, that, as I noticed to my astonishment in 1891, none of the daily visitors to her house recognized that she was ill or were aware that I was her doctor.

[1895d, 92]

Without wishing to lay special stress on the point, I will add that in a number of cases therapeutic evidence of the genuineness of the infantile scenes can also be brought forward. There are cases in which a complete or partial cure can be obtained without our having to go as deep as the infantile experiences. And there are others in which no success at all is obtained until the analysis has come to its natural end with the uncovering of the earliest traumas. In the former cases we are not, I believe, secure against relapses; and my expectation is that a complete psycho-analysis implies a radical cure of the hysteria. We must not, however, be led into forestalling the lessons of observation.

[1896c, 420]
The treatment described in this paper was broken off on December 31st, 1899. My account of it was written during the two weeks immediately following, but was not published until 1905. It is not to be expected that after more than twenty years of uninterrupted work I should see nothing to alter in my view of such a case and in my presentment of it; but it would obviously be absurd to bring the case history 'up to date' by means of emendations and additions. In all essentials, therefore, I have left it as it was, and in the text I have merely corrected a few oversights and inaccuracies to which my excellent English translators, Mr. and Mrs. James Strachey, have directed my attention. Such critical remarks as I have thought it permissible to add I have incorporated in these additional notes: so that the reader will be justified in assuming that I still hold to the opinions expressed in the text unless he finds them contradicted in the footnotes. The problem of medical discretion which I have discussed in this preface does not touch the remaining case histories contained in this volume; for three of them were published with the express assent of the patients (or rather, as regards little Hans, with that of his father), while in the fourth case (that of Schreber) the subject of the analysis was not actually a person but a book produced by him. In Dora's case the secret was kept until this year. I had long been out of touch with her, but a short while ago I heard that she had recently fallen ill again from other causes, and had confided to her physician that she had been analysed by me when she was a girl. This disclosure made it easy for my well-informed colleague to recognize her as the Dora of 1899. No fair judge of analytic therapy will make it a reproach that the three months' treatment she received at that time effected no more than the relief of her current conflict and was unable to give her protection against subsequent illnesses.

The task which the psycho-analytic method seeks to perform may be formulated in different ways, which are, however, in their essence equivalent. It may, for instance, be stated thus: the task of the treatment is to remove the amnesias. When all gaps in memory have been filled in, all the enigmatic products of mental life elucidated, the continuance and even a renewal of the morbid condition are made impossible. Or the formula may be expressed in this fashion: all repressions must be undone. The mental condition is then the same as one in which all amnesias have been removed. Another formulation reaches further: the task consists in making the unconscious accessible to consciousness, which is done by overcoming the resistances. But it must be remembered that an ideal condition such as this is not present even in the normal, and further that it is only rarely possible to carry the treatment to a point approaching it. Just as health and sickness are not different from each other in essence but are only separated by a quantitative line of demarcation which can be determined in practice, so the aim of the treatment will never be anything else but the practical recovery of the patient, the restoration of his ability to lead an active life and of his capacity for enjoyment. In a treatment which is incomplete or in which success is not perfect, one may at any rate achieve a considerable improvement in the general mental condition, while the symptoms (though now of smaller importance to the patient) may continue to exist without stamping him as a sick man.

In spite of all these limitations, the number of persons suitable for psycho-analytic treatment is extraordinarily large and the extension which has come to our therapeutic powers from this method is, according to Freud, very considerable. Freud requires long periods, six months to three years, for an effective treatment; yet he informs us that up to the present, owing to various circumstances which can easily be guessed, he has for the most part been in a position to try his treatment only on very severe cases: patients have come to him after many years of illness, completely incapacitated for life, and, after being disappointed by all kinds of treatments, have had recourse as a last resort to a method which is novel and has been greeted with many doubts. In cases of less severe illness the duration of the treatment might well be much shorter, and very great advantage in the direction of future prevention might be achieved.
(c) From certain of my remarks you will have gathered that there are many characteristics in the analytic method which prevent it from being an ideal form of therapy. *Tuto, cito, jucunde*: investigation and probing do not indicate speedy results, and the resistance I have mentioned would prepare you to expect unpleasantness of various kinds. Psycho-analytic treatment certainly makes great demands upon the patient as well as upon the physician. From the patient it requires perfect sincerity - a sacrifice in itself; it absorbs time and is therefore also costly; for the physician it is no less time-absorbing, and the technique which he must study and practise is fairly laborious. I consider it quite justifiable to resort to more convenient methods of treatment as long as there is any prospect of achieving anything by their means. That, after all, is the only point at issue. If the more difficult and lengthy method accomplishes considerably more than the short and easy one, then, in spite of everything, the use of the former is justified. Only consider, Gentlemen, how much more inconvenient and costly is the Finsen therapy of lupus than the method of cauterizing and scraping previously employed; and yet the use of the former signifies a great advance, for it performs a radical cure. Although I do not wish to carry this comparison to extremes, the psycho-analytic method may claim a similar privilege. Actually, I have been able to elaborate and to test my therapeutic method only on severe, indeed on the severest cases; at first my material consisted entirely of patients who had tried everything else without success, and had spent long years in sanatoria. I have scarcely been able to bring together sufficient material to enable me to say how my method works with those slighter, episodic cases which we see recovering under all kinds of influences and even spontaneously. Psycho-analytic therapy was created through and for the treatment of patients permanently unfit for existence, and its triumph has been that it has made a satisfactorily large number of these permanently fit for existence. In the face of such an achievement all the effort expended seems trivial. We cannot conceal from ourselves what, as physicians, we are in the habit of denying to our patients, namely, that a severe neurosis is no less serious for the sufferer than any cachexia or any of the dreaded major diseases. [1905a, 1568]
Furthermore, let me say in Hans's favour (and I frankly admit my partisan attitude) that he is not the only child who has been overtaken by a phobia at some time or other in his childhood. Troubles of that kind are well known to be quite extraordinarily frequent, even in children the strictness of whose upbringing has left nothing to be desired. In later life these children either become neurotic or remain healthy. Their phobias are shouted down in the nursery because they are inaccessible to treatment and are decidedly inconvenient. In the course of months or years they diminish, and the child seems to recover; but no one can tell what psychological changes are necessitated by such a recovery, or what alterations in character are involved in it. When, however, an adult neurotic patient comes to us for psycho-analytic treatment (and let us assume that his illness has only become manifest after he has reached maturity), we find regularly that his neurosis has as its point of departure an infantile anxiety such as we have been discussing, and is in fact a continuation of it; so that, as it were, a continuous and undisturbed thread of psychical activity, taking its start from the conflicts of his childhood, has been spun through his life - irrespective of whether the first symptom of those conflicts has persisted or has retreated under the pressure of circumstances. I think, therefore, that Hans's illness may perhaps have been no more serious than that of many other children who are not branded as 'degenerates'; but since he was brought up without being intimidated, and with as much consideration and as little coercion as possible, his anxiety dared to show itself more boldly. With him there was no place for such motives as a bad conscience or a fear of punishment, which with other children must no doubt contribute to making the anxiety less. It seems to me that we concentrate too much upon symptoms and concern ourselves too little with their causes. In bringing up children we aim only at being left in peace and having no difficulties, in short, at training up a model child, and we pay very little attention to whether such a course of development is for the child's good as well. I can therefore quite imagine that it may have been to Hans's advantage to have produced this phobia. For it directed his parents' attention to the unavoidable difficulties by which a child is confronted when in the course of his cultural training he is called upon to overcome the innate instinctual components of his mind; and his trouble brought his father to his assistance. It may be that Hans now enjoys an advantage over other children, in that he no longer carries within him that seed in the shape of repressed complexes which must always be of some significance for a child's later life, and which undoubtedly brings with it a certain degree of deformity of character if not a predisposition to a subsequent neurosis. I am inclined to think that this is so, but I do not know if many others will share my opinion; nor do I know whether experience will prove me right.

[1909b, 2120]
I refer to the omnipotence which he ascribed to his thoughts and feelings, and to his wishes, whether good or evil. It is, I must admit, decidedly tempting to declare that this idea was a delusion and that it oversteps the limits of obsessional neurosis. I have, however, come across the same conviction in another obsessional patient; and he was long ago restored to health and is leading a normal life. Indeed, all obsessional neurotics behave as though they shared this conviction. It will be our business to throw some light upon these patients' over-estimation of their powers. Assuming, without more ado, that this belief is a frank acknowledgement of a relic of the old megalomania of infancy, we will proceed to ask our patient for the grounds of his conviction. In reply, he adduces two experiences. When he returned for a second visit to the hydropathic establishment at which his disorder had been relieved for the first and only time, he asked to be given his old room, for its position had facilitated his relations with one of the nurses. He was told that the room was already taken and that it was occupied by an old professor. This piece of news considerably diminished his prospects of successful treatment, and he reacted to it with the unamiable thought: 'I wish he may be struck dead for it!' A fortnight later he was woken up from his sleep by the disturbing idea of a corpse; and in the morning he heard that the professor had really had a stroke, and that he had been carried up into his room at about the time he himself had woken up. The second experience related to an unmarried woman, no longer young, though with a great desire to be loved, who had paid him a great deal of attention and had once asked him point blank whether he could not love her. He had given her an evasive answer. A few days afterwards he heard that she had thrown herself out of a window. He then began to reproach himself, and said to himself that it would have been in his power to save her life by giving her his love. In this way he became convinced of the omnipotence of his love and of his hatred. Without denying the omnipotence of love we may point out that both these instances were concerned with death, and we may adopt the obvious explanation that, like other obsessional neurotics, our patient was compelled to overestimate the effects of his hostile feelings upon the external world, because a large part of their internal, mental effects escaped his conscious knowledge. His love - or rather his hatred - was in truth overpowering; it was precisely they that created the obsessional thoughts, of which he could not understand the origin and against which he strove in vain to defend himself.¹

¹ (Footnote added 1923:) The patient's mental health was restored to him by the analysis which I have reported upon in these pages. Like so many other young men of value and promise, he perished in the Great War.

Let us remember, however, that our attitude to life ought not to be that of a fanatic for hygiene or therapy. We must admit that the ideal prevention of neurotic illnesses which we have in mind would not be of advantage to every individual. A good number of those who now take flight into illness would not, under the conditions we have assumed, support the conflict but would rapidly succumb or would cause a mischief greater than their own neurotic illness. Neuroses have in fact their biological function as a protective contrivance and they have their social justification: the 'gain from illness' they provide is not always a purely subjective one. Is there one of you who has not at some time looked into the causation of a neurosis and had to allow that it was the mildest possible outcome of the situation? And should such heavy sacrifices be made in order to eradicate the neuroses in particular, when the world is full of other unavoidable misery?

¹ [1909d, 2183]
In the light of the knowledge we have gained from psycho-analysis we can describe the difference between hypnotic and psycho-analytic suggestion as follows. Hypnotic treatment seeks to cover up and gloss over something in mental life; analytic treatment seeks to expose and get rid of something. The former acts like a cosmetic, the latter like surgery. The former makes use of suggestion in order to forbid the symptoms; it strengthens the repressions, but, apart from that, leaves all the processes that have led to the formation of the symptoms unaltered. Analytic treatment makes its impact further back towards the roots, where the conflicts are which gave rise to the symptoms, and uses suggestion in order to alter the outcome of those conflicts. Hypnotic treatment leaves the patient inert and unchanged, and for that reason, too, equally unable to resist any fresh occasion for falling ill. An analytic treatment demands from both doctor and patient the accomplishment of serious work, which is employed in lifting internal resistances. Through the overcoming of these resistances the patient's mental life is permanently changed, is raised to a high level of development and remains protected against fresh possibilities of falling ill. This work of overcoming resistances is the essential function of analytic treatment; the patient has to accomplish it and the doctor makes this possible for him with the help of suggestion operating in an educative sense. For that reason psycho-analytic treatment has justly been described as a kind of after-education.

I am afraid these detailed discussions are exhausting your interest. But I should be still more sorry if you were to think it is my intention to lower your opinion of psycho-analysis as a therapy. Perhaps I really made a clumsy start. For I wanted to do the opposite: to excuse the therapeutic limitations of analysis by pointing out their inevitability. With the same aim in view I turn to another point: the reproach against analytic treatment that it takes a disproportionately long time. On this it must be said that psychical changes do in fact only take place slowly; if they occur rapidly, suddenly, that is a bad sign. It is true that the treatment of a fairly severe neurosis may easily extend over several years; but consider, in case of success, how long the illness would have lasted. A decade, probably, for every year of treatment: the illness, that is to say (as we see so often in untreated cases), would not have ended at all. In some cases we have reasons for resuming an analysis many years afterwards. Life had developed fresh pathological reactions to fresh precipitating causes; but in the meantime our patient had been well. The first analysis had not in fact brought to light all his pathological dispositions, and it was natural for the analysis to have been stopped when success was achieved. There are also severely handicapped people who are kept under analytic supervision all through their lives and are taken back into analysis from time to time. But these people would otherwise have been altogether incapable of existence and we must feel glad that they can be kept on their feet by this piecemeal and recurrent treatment. The analysis of character disorders also calls for long periods of treatment; but it is often successful; and do you know of any other therapy with which such a task could even be approached? Therapeutic ambition may feel unsatisfied by such results; but we have learnt from the example of tuberculosis and lupus that success can only be obtained when the treatment has been adapted to the characteristics of the illness.

[1916-1917, 3492] [1933a, 4755]
Every analyst will have treated a few cases which have had this gratifying outcome. He has succeeded in clearing up the patient's neurotic disturbance, and it has not returned and has not been replaced by any other such disturbance. Nor are we without some insight into the determinants of these successes. The patient's ego had not been noticeably altered and the aetiology of his disturbance had been essentially traumatic. The aetiology of every neurotic disturbance is, after all, a mixed one. It is a question either of the instincts being excessively strong - that is to say, recalcitrant to taming by the ego - or of the effects of early (i.e. premature) traumas which the immature ego was unable to master. As a rule there is a combination of both factors, the constitutional and the accidental. The stronger the constitutional factor, the more readily will a trauma lead to a fixation and leave behind a developmental disturbance; the stronger the trauma, the more certainly will its injurious effects become manifest even when the instinctual situation is normal. There is no doubt that an aetiology of the traumatic sort offers by far the more favourable field for analysis. Only when a case is a predominantly traumatic one will analysis succeed in doing what it is so superlatively able to do; only then will it, thanks to having strengthened the patient's ego, succeed in replacing by a correct solution the inadequate decision made in his early life. Only in such cases can one speak of an analysis having been definitively ended. In them, analysis has done all that it should and does not need to be continued. It is true that, if the patient who has been restored in this way never produces another disorder calling for analysis, we do not know how much his immunity may not be due to a kind fate which has spared him ordeals that are too severe. [1937c, 5018]

This brings me to two problems which arise directly out of analytic practice, as I hope to show by the following examples. A certain man, who had himself practised analysis with great success, came to the conclusion that his relations both to men and women - to the men who were his competitors and to the woman whom he loved - were nevertheless not free from neurotic impediments; and he therefore made himself the subject of an analysis by someone else whom he regarded as superior to himself. This critical illumination of his own self had a completely successful result. He married the woman he loved and turned into a friend and teacher of his supposed rivals. Many years passed in this way, during which his relations with his former analyst also remained unclouded. But then, for no assignable external reason, trouble arose. The man who had been analysed became antagonistic to the analyst and reproached him for having failed to give him a complete analysis. The analyst, he said, ought to have known and to have taken into account the fact that a transference-relation can never be purely positive; he should have given his attention to the possibilities of a negative transference. The analyst defended himself by saying that, at the time of the analysis, there was no sign of a negative transference. But even if he had failed to observe some very faint signs of it - which was not altogether ruled out, considering the limited horizon of analysis in those early days - it was still doubtful, he thought, whether he would have had the power to activate a topic (or, as we say, a ‘complex’) by merely pointing it out, so long as it was not currently active in the patient himself at the time. To activate it would certainly have required some unfriendly piece of behaviour in reality on the analyst's part. Furthermore, he added, not every good relation between an analyst and his subject during and after analysis was to be regarded as a transference; there were also friendly relations which were based on reality and which proved to be viable. [1937c, 5019]
I now pass on to my second example, which raises the same problem. An unmarried woman, no longer young, had been cut off from life since puberty by an inability to walk, owing to severe pains in the legs. Her condition was obviously of a hysterical nature, and it had defied many kinds of treatment. An analysis lasting three-quarters of a year removed the trouble and restored to the patient, an excellent and worthy person, her right to a share in life. In the years following her recovery she was consistently unfortunate. There were disasters in her family, and financial losses, and, as she grew older, she saw every hope of happiness in love and marriage vanish. But the one-time invalid stood up to all this valiantly and was a support to her family in difficult times. I cannot remember whether it was twelve or fourteen years after the end of her analysis that, owing to profuse haemorrhages, she was obliged to undergo a gynaecological examination. A myoma was found, which made a complete hysterectomy advisable. From the time of this operation, the woman became ill once more. She fell in love with her surgeon, wallowed in masochistic phantasies about the fearful changes in her inside - phantasies with which she concealed her romance - and proved inaccessible to a further attempt at analysis. She remained abnormal to the end of her life. The successful analytic treatment took place so long ago that we cannot expect too much from it; it was in the earliest years of my work as an analyst. No doubt the patient's second illness may have sprung from the same source as her first one which had been successfully overcome: it may have been a different manifestation of the same repressed impulses, which the analysis had only incompletely resolved. But I am inclined to think that, were it not for the new trauma, there would have been no fresh outbreak of neurosis.

[1937c, 5020]

These two examples, which have been purposely selected from a large number of similar ones, will suffice to start a discussion of the topics we are considering. The sceptical, the optimistic and the ambitious will take quite different views of them. The first will say that it is now proved that even a successful analytic treatment does not protect the patient, who at the time has been cured, from falling ill later on of another neurosis - for, indeed, of a neurosis derived from the same instinctual root - that is to say, from a recurrence of his old trouble. The others will consider that this is not proved. They will object that the two examples date from the early days of analysis, twenty and thirty years ago, respectively; and that since then we have acquired deeper insight and wider knowledge, and that our technique has changed in accordance with our new discoveries. To-day, they will say, we may demand and expect that an analytic cure shall prove permanent, or at least that if a patient falls ill again, his new illness shall not turn out to be a revival of his earlier instinctual disturbance, manifesting itself in new forms. Our experience, they will maintain, does not oblige us to restrict so materially the demands that can be made upon our therapeutic method.

[1937c, 5021]

My reason for choosing these two examples is, of course, precisely because they lie so far back in the past. It is obvious that the more recent the successful outcome of an analysis is, the less utilizable it is for our discussion, since we have no means of predicting what the later history of the recovery will be. The optimists' expectations clearly presuppose a number of things which are not precisely self-evident. They assume, firstly, that there really is a possibility of disposing of an instinctual conflict (or, more correctly, a conflict between the ego and an instinct) definitively and for all time; secondly, that while we are treating someone for one instinctual conflict we can, as it were, inoculate him against the possibility of any other such conflicts; and thirdly, that we have the power, for purposes of prophylaxis, to stir up a pathogenic conflict of this sort which is not betraying itself at the time by any indications, and that it is wise to do so. I throw out these questions without proposing to answer them now. Perhaps it may not be possible at present to give any certain answer to them at all.

[1937c, 5021]
Of the three factors which we have recognized as being decisive for the success or otherwise of analytic treatment - the influence of traumas, the constitutional strength of the instincts and alterations of the ego - what concerns us here is only the second, the strength of the instincts. A moment's reflection raises a doubt whether the restrictive use of the adjective 'constitutional' (or 'congenital') is essential. However true it may be that the constitutional factor is of decisive importance from the very beginning, it is nevertheless conceivable that a reinforcement of instinct coming later in life might produce the same effects. If so, we should have to modify our formula and say 'the strength of the instincts at the time' instead of 'the constitutional strength of the instincts'. The first of our questions was: 'Is it possible by means of analytic therapy to dispose of a conflict between an instinct and the ego, or of a pathogenic instinctual demand upon the ego, permanently and definitively?' To avoid misunderstanding it is not unnecessary, perhaps, to explain more exactly what is meant by 'permanently disposing of an instinctual demand'. Certainly not 'causing the demand to disappear so that nothing more is ever heard from it again'. This is in general impossible, nor is it at all to be desired. No, we mean something else, something which may be roughly described as a 'taming' of the instinct. That is to say, the instinct is brought completely into the harmony of the ego, becomes accessible to all the influences of the other trends in the ego and no longer seeks to go its independent way to satisfaction. If we are asked by what methods and means this result is achieved, it is not easy to find an answer. We can only say: 'So muss denn doch die Hexe dran!' - the Witch Metapsychology. Without metapsychological speculation and theorizing - I had almost said 'phantasying' - we shall not get another step forward. Unfortunately, here as elsewhere, what our Witch reveals is neither very clear nor very detailed. We have only a single clue to start from - though it is a clue of the highest value - namely, the antithesis between the primary and the secondary processes; and to that antithesis I shall at this point turn.

If now we take up our first question once more, we find that our new line of approach inevitably leads us to a particular conclusion. The question was whether it is possible to dispose of an instinctual conflict permanently and definitively - i.e. to 'tame' an instinctual demand in that fashion. Formulated in these terms, the question makes no mention at all of the strength of the instinct; but it is precisely on this that the outcome depends. Let us start from the assumption that what analysis achieves for neurotics is nothing other than what normal people bring about for themselves without its help. Everyday experience, however, teaches us that in a normal person any solution of an instinctual conflict only holds good for a particular strength of instinct, or, more correctly, only for a particular relation between the strength of the instinct and the strength of the ego.¹ If the strength of the ego diminishes, whether through illness or exhaustion, or from some similar cause, all the instincts which have so far been successfully tamed may renew their demands and strive to obtain substitutive satisfactions in abnormal ways.² Irrefutable proof of this statement is supplied by our nightly dreams; they react to the sleeping attitude assumed by the ego with an awakening of instinctual demands.

The two further questions - whether, while we are treating one instinctual conflict, we can protect a patient from future conflicts, and whether it is feasible and expedient, for prophylactic purposes, to stir up a conflict which is not at the time manifest - must be treated together; for obviously the first task can only be carried out in so far as the second one is - that is, in so far as a possible future conflict is turned into an actual present one upon which influence is then brought to bear. This new way of stating the problem is at bottom only an extension of the earlier one. Whereas in the first instance we were considering how to guard against a return of the same conflict, we are now considering how to guard against its possible replacement by another conflict. This sounds a very ambitious proposal, but all we are trying to do is to make clear what limits are set to the efficacy of analytic therapy.
However much our therapeutic ambition may be tempted to undertake such tasks, experience flatly rejects the notion. If an instinctual conflict is not a currently active one, is not manifesting itself, we cannot influence it even by analysis. The warning that we should let sleeping dogs lie, which we have so often heard in connection with our efforts to explore the psychical underworld, is peculiarly inapposite when applied to the conditions of mental life. For if the instincts are causing disturbances, it is a proof that the dogs are not sleeping; and if they seem really to be sleeping, it is not in our power to awaken them. This last statement, however, does not seem to be quite accurate and calls for a more detailed discussion. Let us consider what means we have at our disposal for turning an instinctual conflict which is at the moment latent into one which is currently active. Obviously there are only two things that we can do. We can bring about situations in which the conflict does become currently active, or we can content ourselves with discussing it in the analysis and pointing out the possibility of its arising. The first of these two alternatives can be carried out in two ways: in reality, or in the transference - in either case by exposing the patient to a certain amount of real suffering through frustration and the damming up of libido. Now it is true that we already make use of a technique of this kind in our ordinary analytic procedure. What would otherwise be the meaning of the rule that analysis must be carried out 'in a state of frustration'? But this is a technique which we use in treating a conflict which is already currently active. We seek to bring this conflict to a head, to develop it to its highest pitch, in order to increase the instinctual force available for its solution. Analytic experience has taught us that the better is always the enemy of the good and that in every phase of the patient's recovery we have to fight against his inertia, which is ready to be content with an incomplete solution.

[1937c, 5027]

If, however, what we are aiming at is a prophylactic treatment of instinctual conflicts that are not currently active but merely potential, it will not be enough to regulate sufferings which are already present in the patient and which he cannot avoid. We should have to make up our minds to provoke fresh sufferings in him; and this we have hitherto quite rightly left to fate. We should receive admonitions from all sides against the presumption of vying with fate in subjecting poor human creatures to such cruel experiments. And what sort of experiments would they be? Could we, for purposes of prophylaxis, take the responsibility of destroying a satisfactory marriage, or causing a patient to give up a post upon which his livelihood depends? Fortunately, we never find ourselves in the position of having to consider whether such interventions in the patient's real life are justified; we do not possess the plenary powers which they would necessitate, and the subject of our therapeutic experiment would certainly refuse to co-operate in it. In practice, then, such a procedure is virtually excluded; but there are, besides, theoretical objections to it. For the work of analysis proceeds best if the patient's pathogenic experiences belong to the past, so that his ego can stand at a distance from them. In states of acute crisis analysis is to all intents and purposes unusable. The ego's whole interest is taken up by the painful reality and it withholds itself from analysis, which is attempting to go below the surface and uncover the influences of the past. To create a fresh conflict would thus only be to make the work of analysis longer and more difficult.

[1937c, 5028]
We started from the question of how we can shorten the inconveniently long duration of analytic treatment, and, still with this question of time in mind, we went on to consider whether it is possible to achieve a permanent cure or even to prevent future illness by prophylactic treatment. In doing so, we found that the factors which were decisive for the success of our therapeutic efforts were the influence of traumatic aetiology, the relative strength of the instincts which have to be controlled, and something which we have called an alteration of the ego. Only the second of these factors has been discussed by us in any detail, and in connection with it we have had occasion to recognize the paramount importance of the quantitative factor and to stress the claim of the metapsychological line of approach to be taken into account in any attempt at explanation.

[1937c, 5030]
This brings me to two problems which arise directly out of analytic practice, as I hope to show by the following examples. A certain man, who had himself practised analysis with great success, came to the conclusion that his relations both to men and women - to the men who were his competitors and to the woman whom he loved - were nevertheless not free from neurotic impediments; and he therefore made himself the subject of an analysis by someone else whom he regarded as superior to himself. This critical illumination of his own self had a completely successful result. He married the woman he loved and turned into a friend and teacher of his supposed rivals. Many years passed in this way, during which his relations with his former analyst also remained unclouded. But then, for no assignable external reason, trouble arose. The man who had been analysed became antagonistic to the analyst and reproached him for having failed to give him a complete analysis. The analyst, he said, ought to have known and to have taken into account the fact that a transference-relation can never be purely positive; he should have given his attention to the possibilities of a negative transference. The analyst defended himself by saying that, at the time of the analysis, there was no sign of a negative transference. But even if he had failed to observe some very faint signs of it - which was not altogether ruled out, considering the limited horizon of analysis in those early days - it was still doubtful, he thought, whether he would have had the power to activate a topic (or, as we say, a 'complex') by merely pointing it out, so long as it was not currently active in the patient himself at the time. To activate it would certainly have required some unfriendly piece of behaviour in reality on the analyst's part. Furthermore, he added, not every good relation between an analyst and his subject during and after analysis was to be regarded as a transference; there were also friendly relations which were based on reality and which proved to be viable.

My reason for choosing these two examples is, of course, precisely because they lie so far back in the past. It is obvious that the more recent the successful outcome of an analysis is, the less utilizable it is for our discussion, since we have no means of predicting what the later history of the recovery will be. The optimists' expectations clearly presuppose a number of things which are not precisely self-evident. They assume, firstly, that there really is a possibility of disposing of an instinctual conflict (or, more correctly, a conflict between the ego and an instinct) definitively and for all time; secondly, that while we are treating someone for one instinctual conflict we can, as it were, inoculate him against the possibility of any other such conflicts; and thirdly, that we have the power, for purposes of prophylaxis, to stir up a pathogenic conflict of this sort which is not betraying itself at the time by any indications, and that it is wise to do so. I throw out these questions without proposing to answer them now. Perhaps it may not be possible at present to give any certain answer to them at all.

The two further questions - whether, while we are treating one instinctual conflict, we can protect a patient from future conflicts, and whether it is feasible and expedient, for prophylactic purposes, to stir up a conflict which is not at the time manifest - must be treated together; for obviously the first task can only be carried out in so far as the second one is - that is, in so far as a possible future conflict is turned into an actual present one upon which influence is then brought to bear. This new way of stating the problem is at bottom only an extension of the earlier one. Whereas in the first instance we were considering how to guard against a return of the same conflict, we are now considering how to guard against its possible replacement by another conflict. This sounds a very ambitious proposal, but all we are trying to do is to make clear what limits are set to the efficacy of analytic therapy.
However much our therapeutic ambition may be tempted to undertake such tasks, experience flatly rejects the notion. If an instinctual conflict is not a currently active one, is not manifesting itself, we cannot influence it even by analysis. The warning that we should let sleeping dogs lie, which we have so often heard in connection with our efforts to explore the psychical underworld, is peculiarly inapposite when applied to the conditions of mental life. For if the instincts are causing disturbances, it is a proof that the dogs are not sleeping; and if they seem really to be sleeping, it is not in our power to awaken them. This last statement, however, does not seem to be quite accurate and calls for a more detailed discussion. Let us consider what means we have at our disposal for turning an instinctual conflict which is at the moment latent into one which is currently active. Obviously there are only two things that we can do. We can bring about situations in which the conflict does become currently active, or we can content ourselves with discussing it in the analysis and pointing out the possibility of its arising. The first of these two alternatives can be carried out in two ways: in reality, or in the transference - in either case by exposing the patient to a certain amount of real suffering through frustration and the damming up of libido. Now it is true that we already make use of a technique of this kind in our ordinary analytic procedure. What would otherwise be the meaning of the rule that analysis must be carried out 'in a state of frustration'? But this is a technique which we use in treating a conflict which is already currently active. We seek to bring this conflict to a head, to develop it to its highest pitch, in order to increase the instinctual force available for its solution. Analytic experience has taught us that the better is always the enemy of the good and that in every phase of the patient's recovery we have to fight against his inertia, which is ready to be content with an incomplete solution.

[1937c, 5027]
Thus there are two possible outcomes for any particular unconscious excitatory process. Either it may be left to itself, in which case it eventually forces its way through at some point and on this single occasion finds discharge for its excitation in movement; or it may come under the influence of the preconscious, and its excitation, instead of being discharged, may be bound by the preconscious. This second alternative is the one which occurs in the process of dreaming. The cathexis from the Pcs. which goes halfway to meet the dream after it has become perceptual, having been directed on to it by the excitation in consciousness, binds the dream's unconscious excitation and makes it powerless to act as a disturbance. If it is true that the dreamer wakes for an instant, yet he really has brushed away the fly that was threatening to disturb his sleep. It begins to dawn on us that it actually is more expedient and economical to allow the unconscious wish to take its course, to leave the path to regression open to it so that it can construct a dream, and then to bind the dream and dispose of it with a small expenditure of preconscious work - rather than to continue keeping a tight rein on the unconscious throughout the whole period of sleep. It was indeed to be expected that dreaming, even though it may originally have been a process without a useful purpose, would have procured itself some function in the interplay of mental forces. And we can now see what that function is. Dreaming has taken on the task of bringing back under control of the preconscious the excitation in the Ucs. which has been left free; in so doing, it discharges the Ucs. excitation, serves it as a safety valve and at the same time preserves the sleep of the preconscious in return for a small expenditure of waking activity. Thus, like all the other psychical structures in the series of which it is a member, it constitutes a compromise: it is in the service of both of the two systems since it fulfils the two wishes in so far as they are compatible with each other. If we turn back to the 'excretion theory' of dreams put forward by Robert, which I explained on p. 586 ff., we shall see at a glance that in its essence we must accept his account of the function of dreams, though differing from him in his premises and in his view of the dream-process itself.¹

[1900a, 1007]

However much our therapeutic ambition may be tempted to undertake such tasks, experience flatly rejects the notion. If an instinctual conflict is not a currently active one, is not manifesting itself, we cannot influence it even by analysis. The warning that we should let sleeping dogs lie, which we have so often heard in connection with our efforts to explore the psychical underworld, is peculiarly inapposite when applied to the conditions of mental life. For if the instincts are causing disturbances, it is a proof that the dogs are not sleeping; and if they seem really to be sleeping, it is not in our power to awaken them. This last statement, however, does not seem to be quite accurate and calls for a more detailed discussion. Let us consider what means we have at our disposal for turning an instinctual conflict which is at the moment latent into one which is currently active. Obviously there are only two things that we can do. We can bring about situations in which the conflict does become currently active, or we can content ourselves with discussing it in the analysis and pointing out the possibility of its arising. The first of these two alternatives can be carried out in two ways: in reality, or in the transference - in either case by exposing the patient to a certain amount of real suffering through frustration and the damming up of libido. Now it is true that we already make use of a technique of this kind in our ordinary analytic procedure. What would otherwise be the meaning of the rule that analysis must be carried out 'in a state of frustration'? But this is a technique which we use in treating a conflict which is already currently active. We seek to bring this conflict to a head, to develop it to its highest pitch, in order to increase the instinctual force available for its solution. Analytic experience has taught us that the better is always the enemy of the good and that in every phase of the patient's recovery we have to fight against his inertia, which is ready to be content with an incomplete solution.

[1937c, 5027]
If, however, what we are aiming at is a prophylactic treatment of instinctual conflicts that are not currently active but merely potential, it will not be enough to regulate sufferings which are already present in the patient and which he cannot avoid. We should have to make up our minds to provoke fresh sufferings in him; and this we have hitherto quite rightly left to fate. We should receive admonitions from all sides against the presumption of vying with fate in subjecting poor human creatures to such cruel experiments. And what sort of experiments would they be? Could we, for purposes of prophylaxis, take the responsibility of destroying a satisfactory marriage, or causing a patient to give up a post upon which his livelihood depends? Fortunately, we never find ourselves in the position of having to consider whether such interventions in the patient's real life are justified; we do not possess the plenary powers which they would necessitate, and the subject of our therapeutic experiment would certainly refuse to co-operate in it. In practice, then, such a procedure is virtually excluded; but there are, besides, theoretical objections to it. For the work of analysis proceeds best if the patient's pathogenic experiences belong to the past, so that his ego can stand at a distance from them. In states of acute crisis analysis is to all intents and purposes unusable. The ego's whole interest is taken up by the painful reality and it withholds itself from analysis, which is attempting to go below the surface and uncover the influences of the past. To create a fresh conflict would thus only be to make the work of analysis longer and more difficult.

It will be objected that these remarks are quite unnecessary. Nobody thinks of purposely conjuring up new situations of suffering in order to make it possible for a latent instinctual conflict to be treated. This would not be much to boast of as a prophylactic achievement. We know, for instance, that a patient who has recovered from scarlet fever is immune to a return of the same illness; yet it never occurs to a doctor to take a healthy person who may possibly fall ill of scarlet fever and infect him with scarlet fever in order to make him immune to it. The protective measure must not produce the same situation of danger as is produced by the illness itself, but only something very much slighter, as is the case with vaccination against small-pox and many other similar procedures. In analytic prophylaxis against instinctual conflicts, therefore, the only methods which come into consideration are the other two which we have mentioned: the artificial production of new conflicts in the transference (conflicts which, after all, lack the character of reality), and the arousing of such conflicts in the patient's imagination by talking to him about them and making him familiar with their possibility.

I do not know whether we can assert that the first of these two milder procedures is altogether ruled out in analysis. No experiments have been particularly made in this direction. But difficulties at once suggest themselves, which do not throw a very promising light on such an undertaking. In the first place, the choice of such situations for the transference is very limited. The patients cannot themselves bring all their conflicts into the transference; nor is the analyst able to call out all their possible instinctual conflicts from the transference situation. He may make them jealous or cause them to experience disappointments in love; but no technical purpose is required to bring this about. Such things happen of themselves in any case in most analyses. In the second place, we must not overlook the fact that all measures of this sort would oblige the analyst to behave in an unfriendly way to the patient, and this would have a damaging effect upon the affectionate attitude - upon the positive transference - which is the strongest motive for the patient's taking a share in the joint work of analysis. Thus we should on no account expect very much from this procedure.
This therefore leaves only the one method open to us - the one which was in all probability the only one originally contemplated. We tell the patient about the possibilities of other instinctual conflicts, and we arouse his expectation that such conflicts may occur in him. What we hope is that this information and this warning will have the effect of activating in him one of the conflicts we have indicated, in a modest degree and yet sufficiently for treatment. But this time experience speaks with no uncertain voice. The expected result does not come about. The patient hears our message, but there is no response. He may think to himself: 'This is very interesting, but I feel no trace of it.' We have increased his knowledge, but altered nothing else in him. The situation is much the same as when people read psycho-analytic writings. The reader is 'stimulated' only by those passages which he feels apply to himself - that is, which concern conflicts that are active in him at the time. Everything else leaves him cold. We can have analogous experiences, I think, when we give children sexual enlightenment. I am far from maintaining that this is a harmful or unnecessary thing to do, but it is clear that the prophylactic effect of this liberal measure has been greatly over-estimated. After such enlightenment, children know something they did not know before, but they make no use of the new knowledge that has been presented to them. We come to see that they are not even in so great a hurry to sacrifice for this new knowledge the sexual theories which might be described as a natural growth and which they have constructed in harmony with, and dependence on, their imperfect libidinal organization - theories about the part played by the stork, about the nature of sexual intercourse and about the way in which babies are made. For a long time after they have been given sexual enlightenment they behave like primitive races who have had Christianity thrust upon them and who continue to worship their old idols in secret.

[1937c, 5029]
It is impossible to pursue an aetiological investigation based on anamneses if we accept those anamneses as the patients present them, or are content with what they are willing to volunteer. If syphilidologists still depended on the statements of their patients for tracing back an initial infection of the genitals to sexual intercourse, they would be able to attribute an imposing number of chancreas in allegedly virginal persons to catching a chill; and gynaecologists would have little difficulty in confirming the miracle of parthenogenesis among their unmarried lady clients. I hope that one day the idea will prevail that neuropathologists, too, in collecting the anamneses of major neuroses, may proceed upon aetiological prejudices of a similar kind. [1895f, 357]
It turned out to be quite impracticable to shorten the work by trying to elicit in her memory straight away the first provoking cause of her symptoms. She was unable to find it, grew confused, and things proceeded even more slowly than if she was allowed quietly and steadily to follow back the thread of memories on which she had embarked. Since the latter method, however, took too long in the evening hypnosis, owing to her being over-strained and distraught by ‘talking out’ the two other sets of experiences - and owing, too, to the reminiscences needing time before they could attain sufficient vividness - we evolved the following procedure. I used to visit her in the morning and hypnotize her. (Very simple methods of doing this were arrived at empirically.) I would next ask her to concentrate her thoughts on the symptom we were treating at the moment and to tell me the occasions on which it had appeared. The patient would proceed to describe in rapid succession and under brief headings the external events concerned and these I would jot down. During her subsequent evening hypnosis she would then, with the help of my notes, give me a fairly detailed account of these circumstances.

Only when these conditions have been fulfilled is it possible to recognize and to master the resistances which have led to the repression and the ignorance. Psycho-analytic intervention, therefore, absolutely requires a fairly long period of contact with the patient. Attempts to ‘rush’ him at first consultation, by brusquely telling him the secrets which have been discovered by the physician, are technically objectionable. And they mostly bring their own punishment by inspiring a hearty enmity towards the physician on the patient’s part and cutting him off from having any further influence.
To shorten analytic treatment is a justifiable wish, and its fulfilment, as we shall learn, is being attempted along various lines. Unfortunately, it is opposed by a very important factor, namely, the slowness with which deep-going changes in the mind are accomplished - in the last resort, no doubt, the 'timelessness' of our unconscious processes. When patients are faced with the difficulty of the great expenditure of time required for analysis they not infrequently manage to propose a way out of it. They divide up their ailments and describe some as unbearable, and others as secondary, and then say: 'If only you will relieve me from this one (for instance, a headache or a particular fear) I can deal with the other one on my own in my ordinary life.' In doing this, however, they over-estimate the selective power of analysis. The analyst is certainly able to do a great deal, but he cannot determine beforehand exactly what results he will effect. He sets in motion a process, that of the resolving of existing repressions. He can supervise this process, further it, remove obstacles in its way, and he can undoubtedly vitiate much of it. But on the whole, once begun, it goes its own way and does not allow either the direction it takes or the order in which it picks up its points to be prescribed for it. The analyst's power over the symptoms of the disease may thus be compared to male sexual potency. A man can, it is true, beget a whole child, but even the strongest man cannot create in the female organism a head alone or an arm or a leg; he cannot even prescribe the child's sex. He, too, only sets in motion a highly complicated process, determined by events in the remote past, which ends with the severance of the child from its mother. A neurosis as well has the character of an organism. Its component manifestations are not independent of one another; they condition one another and give one another mutual support. A person suffers from one neurosis only, never from several which have accidentally met together in a single individual. The patient freed, according to his wish, from his one unendurable symptom might easily find that a symptom which had previously been negligible had now increased and grown unendurable. The analyst who wishes the treatment to owe its success as little as possible to its elements of suggestion (i.e. to the transference) will do well to refrain from making use of even the trace of selective influence upon the results of the therapy which may perhaps be open to him. The patients who are bound to be most welcome to him are those who ask him to give them complete health, in so far as that is attainable, and who place as much time at his disposal as is necessary for the process of recovery. Such favourable conditions as these are, of course, to be looked for in only a few cases.
[1913c, 2483]

But at this point an objection will be raised. Is it, then, our task to lengthen the treatment and not, rather, to bring it to an end as rapidly as possible? Are not the patient's ailments due to his lack of knowledge and understanding and is it not a duty to enlighten him as soon as possible - that is, as soon as the doctor himself knows the explanations? The answer to this question calls for a short digression on the meaning of knowledge and the mechanism of cure in analysis.
[1913c, 2492]
I might break off at this point but for the title of this paper, which obliges me to discuss a further point in analytic technique. The first step in overcoming the resistances is made, as we know, by the analyst's uncovering the resistance, which is never recognized by the patient, and acquainting him with it. Now it seems that beginners in analytic practice are inclined to look on this introductory step as constituting the whole of their work. I have often been asked to advise upon cases in which the doctor complained that he had pointed out his resistance to the patient and that nevertheless no change had set in; indeed, the resistance had become all the stronger, and the whole situation was more obscure than ever. The treatment seemed to make no headway. This gloomy foreboding always proved mistaken. The treatment was as a rule progressing most satisfactorily. The analyst had merely forgotten that giving the resistance a name could not result in its immediate cessation. One must allow the patient time to become more conversant with this resistance with which he has now become acquainted, to work through it, to overcome it, by continuing, in defiance of it, the analytic work according to the fundamental rule of analysis. Only where the resistance is at its height can the analyst, working in common with his patient, discover the repressed instinctual impulses which are feeding the resistance; and it is this kind of experience which convinces the patient of the existence and power of such impulses. The doctor has nothing else to do than to wait and let things take their course, a course which cannot be avoided nor always hastened. If he holds fast to this conviction he will often be spared the illusion of having failed when in fact he is conducting the treatment on the right lines.

[1914g, 2506]

Another characteristic which makes the present analysis noteworthy is connected with the severity of the illness and the duration of the treatment. Analyses which lead to a favourable conclusion in a short time are of value in ministering to the therapeutist's self-esteem and substantiate the medical importance of psycho-analysis; but they remain for the most part insignificant as regards the advancement of scientific knowledge. Nothing new is learnt from them. In fact they only succeed so quickly because everything that was necessary for their accomplishment was already known. Something new can only be gained from analyses that present special difficulties, and to the overcoming of these a great deal of time has to be devoted. Only in such cases do we succeed in descending into the deepest and most primitive strata of mental development and in gaining from there solutions for the problems of the later formations. And we feel afterwards that, strictly speaking, only an analysis which has penetrated so far deserves the name. Naturally a single case does not give us all the information that we should like to have. Or, to put it more correctly, it might teach us everything, if we were only in a position to make everything out, and if we were not compelled by the inexperience of our own perception to content ourselves with a little.

[1918b, 3506]

As regards these fertile difficulties the case I am about to discuss left nothing to be desired. The first years of the treatment produced scarcely any change. Owing to a fortunate concatenation, all the external circumstances nevertheless combined to make it possible to proceed with the therapeutic experiment. I can easily believe that in less favourable circumstances the treatment would have been given up after a short time. Of the physician's point of view I can only declare that in a case of this kind he must behave as 'timelessly' as the unconscious itself, if he wishes to learn anything or to achieve anything. And in the end he will succeed in doing so, if he has the strength to renounce any short-sighted therapeutic ambition. It is not to be expected that the amount of patience, adaptability, insight, and confidence demanded of the patient and his relatives will be forthcoming in many other cases. But the analyst has a right to feel that the results which he has attained from such lengthy work in one case will help substantially to reduce the length of the treatment in a subsequent case of equal severity, and that by submitting on a single occasion
The patient with whom I am here concerned remained for a long time unassailably entrenched behind an attitude of 'obliging apathy'. He listened, understood, and remained unapproachable. His unimpeachable intelligence was, as it were, cut off from the instinctual forces which governed his behaviour in the few relations of life that remained to him. It required a long education to induce him to take an independent share in the work; and when as a result of this exertion he began for the first time to feel relief, he immediately gave up working in order to avoid any further changes, and in order to remain comfortably in the situation which had been thus established. His shrinking from a self-sufficient existence was so great as to outweigh all the vexations of his illness. Only one way was to be found of overcoming it. I was obliged to wait until his attachment to myself had become strong enough to counter-balance this shrinking, and then played off this one factor against the other. I determined - but not until trustworthy signs had led me to judge that the right moment had come - that the treatment must be brought to an end at a particular fixed date, no matter how far it had advanced. I was resolved to keep to the date; and eventually the patient came to see that I was in earnest. Under the inexorable pressure of this fixed limit his resistance and his fixation to the illness gave way, and now in a disproportionately short time the analysis produced all the material which made it possible to clear up his inhibitions and remove his symptoms. All the information, too, which enabled me to understand his infantile neurosis is derived from this last period of the work, during which resistance temporarily disappeared and the patient gave an impression of lucidity which is usually attainable only in hypnosis.

Strictly considered - and why should this question not be considered with all possible strictness? - analytic work deserves to be recognized as genuine psycho-analysis only when it has succeeded in removing the amnesia which conceals from the adult his knowledge of his childhood from its beginning (that is, from about the second to the fifth year). This cannot be said among analysts too emphatically or repeated too often. The motives for disregarding this reminder are, indeed, intelligible. It would be desirable to obtain practical results in a shorter period and with less trouble. But at the present time theoretical knowledge is still far more important to all of us than therapeutic success, and anyone who neglects childhood analysis is bound to fall into the most disastrous errors. The emphasis which is laid here upon the importance of the earliest experiences does not imply any underestimation of the influence of later ones. But the later impressions of life speak loudly enough through the mouth of the patient, while it is the physician who has to raise his voice on behalf of the claims of childhood.

That is a question of tact, which can become more refined with experience. You will be making a bad mistake if, in an effort, perhaps, at shortening the analysis, you throw your interpretations at the patient's head as soon as you have found them. In that way you will draw expressions of resistance, rejection and indignation from him; but you will not enable his ego to master his repressed material. The formula is: to wait till he has come so near to the repressed material that he has only a few more steps to take under the lead of the interpretation you propose.
Yes, we are only beginning to appreciate the significance of all these important circumstances. That is why my description was bound to turn out so obscure. But now I can proceed. We describe all the forces that oppose the work of recovery as the patient's 'resistances'. The gain from illness is one such resistance. The 'unconscious sense of guilt' represents the super-ego's resistance; it is the most powerful factor, and the one most dreaded by us. We meet with still other resistances during the treatment. If the ego during the early period has set up a repression out of fear, then the fear still persists and manifests itself as a resistance if the ego approaches the repressed material. And finally, as you can imagine, there are likely to be difficulties if an instinctual process which has been going along a particular path for whole decades is suddenly expected to take a new path that has just been made open for it. That might be called the id's resistance. The struggle against all these resistances is our main work during an analytic treatment; the task of making interpretations is nothing compared to it. But as a result of this struggle and of the overcoming of the resistances, the patient's ego is so much altered and strengthened that we can look forward calmly to his future behaviour when the treatment is over. On the other hand, you can understand now why we need such long treatments. The length of the path of development and the wealth of the material are not the decisive factors. It is more a question of whether the path is clear. An army can be held up for weeks on a stretch of country which in peace time an express train crosses in a couple of hours - if the army has to overcome the enemy's resistance there. Such battles call for time in mental life too. I am unfortunately obliged to tell you that every effort to hasten analytic treatment appreciably has hitherto failed. The best way of shortening it seems to be to carry it out according to the rules.

Compared with the other psychotherapeutic procedures psycho-analysis is beyond any doubt the most powerful. It is just and fair, too, that this should be so for it is also the most laborious and time-consuming; it would not be used on slight cases. In suitable cases it is possible by its means to get rid of disturbances and bring about changes for which in pre-analytic times one would not have ventured to hope. But it has its very appreciable limits. The therapeutic ambition of some of my adherents has made the greatest efforts to overcome these obstacles so that every sort of neurotic disorder might be curable by psycho-analysis. They have endeavoured to compress the work of analysis into a shorter duration, to intensify transference so that it may be able to overcome any resistance, to unite other forms of influence with it so as to compel a cure. These efforts are certainly praiseworthy, but, in my opinion, they are vain. They bring with them, too, a danger of being oneself forced away from analysis and drawn into a boundless course of experimentation. The expectation that every neurotic phenomenon can be cured may, I suspect, be derived from the layman's belief that the neuroses are something quite unnecessary which have no right whatever to exist. Whereas in fact they are severe, constitutionally fixed illnesses, which rarely restrict themselves to only a few attacks but persist as a rule over long periods or throughout life. Our analytic experience that they can be extensively influenced, if the historical precipitating causes and accidental auxiliary factors of the illness can be dealt with, has led us to neglect the constitutional factor in our therapeutic practice, and in any case we can do nothing about it; but in theory we ought always to bear it in mind. The radical inaccessibility of the psychoses to analytic treatment should, in view of their close relationship to the neuroses, restrict our pretensions in regard to these latter. The therapeutic effectiveness of psycho-analysis remains cramped by a number of weighty and scarcely assailable factors. In the case of children, where one might count on the greatest successes, the difficulties are the external ones connected with their relation to their parents, though these difficulties are after all a necessary part of being a child. In the case of adults the difficulties arise in the first instance from two factors: the amount of psychical rigidity present and the form of the illness with all that that covers in the way of deeper determinants.
Experience has taught us that psycho-analytic therapy - the freeing of someone from his 
neurotic symptoms, inhibitions and abnormalities of character - is a time-consuming business. 
Hence, from the very first, attempts have been made to shorten the duration of analyses. Such 
endeavours required no justification; they could claim to be based on the strongest 
considerations of reason and expediency. But there was probably still at work in them as well 
some trace of the impatient contempt with which the medical science of an earlier day regarded 
the neuroses as being uncalled-for consequences of invisible injuries. If it had now become 
necessary to attend to them, they should at least be disposed of as quickly as possible. 
[1937c, 5014]

I myself had adopted another way of speeding up an analytic treatment even before the war. 
At that time I had taken on the case of a young Russian, a man spoilt by wealth, who had come 
to Vienna in a state of complete helplessness, accompanied by a private doctor and an 
attendant.¹ In the course of a few years it was possible to give him back a large amount of his 
independence, to awaken his interest in life and to adjust his relations to the people most 
important to him. But there progress came to a stop. We advanced no further in clearing up the 
neurosis of his childhood, on which his later illness was based, and it was obvious that the 
patient found his present position highly comfortable and had no wish to take any step forward 
which would bring him nearer to the end of his treatment. It was a case of the treatment 
inhibiting itself: it was in danger of failing as a result of its - partial - success. In this predicament 
I resorted to the heroic measure of fixing a time limit for the analysis. At the beginning of a 
year's work I informed the patient that the coming year was to be the last one of his treatment, 
no matter what he achieved in the time still left to him. At first he did not believe me, but once he 
was convinced that I was in deadly earnest, the desired change set in. His resistances shrank 
up, and in these last months of his treatment he was able to reproduce all the memories and to 
discover all the connections which seemed necessary for understanding his early neurosis and 
mastering his present one. When he left me in the midsummer of 1914, with as little suspicion 
as the rest of us of what lay so shortly ahead, I believed that his cure was radical and 
permanent. 
[1937c, 5015]

I have subsequently employed this fixing of a time-limit in other cases as well, and I have also 
taken the experiences of other analysts into account. There can be only one verdict about the 
value of this blackmailing device: it is effective provided that one hits the right time for it. But it 
cannot guarantee to accomplish the task completely. On the contrary, we may be sure that, 
while part of the material will become accessible under the pressure of the threat, another part 
will be kept back and thus become buried, as it were, and lost to our therapeutic efforts. For 
once the analyst has fixed the time-limit he cannot extend it; otherwise the patient would lose all 
faith in him. The most obvious way out would be for the patient to continue his treatment with 
another analyst, although we know that such a change will involve a fresh loss of time and 
abandoning fruits of work already done. Nor can any general rule be laid down as to the right 
time for resorting to this forcible technical device; the decision must be left to the analyst's tact. 
A miscalculation cannot be rectified. The saying that a lion only springs once must apply here. 
[1937c, 5016]

The discussion of the technical problem of how to accelerate the slow progress of an analysis 
leads us to another, more deeply interesting question: is there such a thing as a natural end to 
an analysis - is there any possibility at all of bringing an analysis to such an end? To judge by 
the common talk of analysts it would seem to be so, for we often hear them say, when they are 
deploring or excusing the recognized imperfections of some fellow-mortal: 'His analysis was not 
finished' or 'he was never analysed to the end.' 
[1937c, 5017]
Some light may probably be thrown on them by theoretical considerations. But another point has already become clear: if we wish to fulfil the more exacting demands upon analytic therapy, our road will not lead us to, or by way of, a shortening of its duration.

[1937c, 5021]

An analytic experience which now extends over several decades, and a change which has taken place in the nature and mode of my activity, encourage me to attempt to answer the questions before us. In earlier days I treated quite a large number of patients, who, as was natural, wanted to be dealt with as quickly as possible. Of late years I have been mainly engaged in training analyses; a relatively small number of severe cases of illness remained with me for continuous treatment, interrupted, however, by longer or shorter intervals. With them, the therapeutic aim was no longer the same. There was no question of shortening the treatment; the purpose was radically to exhaust the possibilities of illness in them and to bring about a deep-going alteration of their personality.

[1937c, 5022]

No doubt it is desirable to shorten the duration of analytic treatment, but we can only achieve our therapeutic purpose by increasing the power of analysis to come to the assistance of the ego. Hypnotic influence seemed to be an excellent instrument for our purposes; but the reasons for our having to abandon it are well known. No substitute for hypnosis has yet been found. From this point of view we can understand how such a master of analysis as Ferenczi came to devote the last years of his life to therapeutic experiments, which, unhappily, proved to be vain.

[1937c, 5026]

We started from the question of how we can shorten the inconveniently long duration of analytic treatment, and, still with this question of time in mind, we went on to consider whether it is possible to achieve a permanent cure or even to prevent future illness by prophylactic treatment. In doing so, we found that the factors which were decisive for the success of our therapeutic efforts were the influence of traumatic aetiology, the relative strength of the instincts which have to be controlled, and something which we have called an alteration of the ego. Only the second of these factors has been discussed by us in any detail, and in connection with it we have had occasion to recognize the paramount importance of the quantitative factor and to stress the claim of the metapsychological line of approach to be taken into account in any attempt at explanation.

[1937c, 5030]
But you will now tell me that, no matter whether we call the motive force of our analysis transference or suggestion, there is a risk that the influencing of our patient may make the objective certainty of our findings doubtful. What is advantageous to our therapy is damaging to our researches. This is the objection that is most often raised against psycho-analysis, and it must be admitted that, though it is groundless, it cannot be rejected as unreasonable. If it were justified, psycho-analysis would be nothing more than a particularly well-disguised and particularly effective form of suggestive treatment and we should have to attach little weight to all that it tells us about what influences our lives, the dynamics of the mind or the unconscious. That is what our opponents believe; and in especial they think that we have "talked" the patients into everything relating to the importance of sexual experiences - or even into those experiences themselves - after such notions have grown up in our own depraved imagination. These accusations are contradicted more easily by an appeal to experience than by the help of theory. Anyone who has himself carried out psycho-analyses will have been able to convince himself on countless occasions that it is impossible to make suggestions to a patient in that way. The doctor has no difficulty, of course, in making him a supporter of some particular theory and in thus making him share some possible error of his own. In this respect the patient is behaving like anyone else - like a pupil - but this only affects his intelligence, not his illness. After all, his conflicts will only be successfully solved and his resistances overcome if the anticipatory ideas he is given tally with what is real in him. Whatever in the doctor's conjectures is inaccurate drops out in the course of the analysis; it has to be withdrawn and replaced by something more correct. We endeavour by a careful technique to avoid the occurrence of premature successes due to suggestion; but no harm is done even if they do occur, for we are not satisfied by a first success. We do not regard an analysis as at an end until all the obscurities of the case are cleared up, the gaps in the patient's memory filled in, the precipitating causes of the repressions discovered. We look upon successes that set in too soon as obstacles rather than as a help to the work of analysis; and we put an end to such successes by constantly resolving the transference on which they are based. It is this last characteristic which is the fundamental distinction between analytic and purely suggestive therapy, and which frees the results of analysis from the suspicion of being successes due to suggestion. In every other kind of suggestive treatment the transference is carefully preserved and left untouched; in analysis it is itself subjected to treatment and is dissected in all the shapes in which it appears. At the end of an analytic treatment the transference must itself be cleared away; and if success is then obtained or continues, it rests, not on suggestion, but on the achievement by its means of an overcoming of internal resistances, on the internal change that has been brought about in the patient.

Another characteristic which makes the present analysis noteworthy is connected with the severity of the illness and the duration of the treatment. Analyses which lead to a favourable conclusion in a short time are of value in ministering to the therapeutist's self-esteem and substantiate the medical importance of psycho-analysis; but they remain for the most part insignificant as regards the advancement of scientific knowledge. Nothing new is learnt from them. In fact they only succeed so quickly because everything that was necessary for their accomplishment was already known. Something new can only be gained from analyses that present special difficulties, and to the overcoming of these a great deal of time has to be devoted. Only in such cases do we succeed in descending into the deepest and most primitive strata of mental development and in gaining from there solutions for the problems of the later formations. And we feel afterwards that, strictly speaking, only an analysis which has penetrated so far deserves the name. Naturally a single case does not give us all the information that we should like to have. Or, to put it more correctly, it might teach us everything, if we were only in a position to make everything out, and if we were not compelled by the inexperience of our own perception to content ourselves with a little.
You will remember that it was a frustration that made the patient ill, and that his symptoms serve him as substitutive satisfactions. It is possible to observe during the treatment that every improvement in his condition reduces the rate at which he recovers and diminishes the instinctual force impelling him towards recovery. But this instinctual force is indispensible; reduction of it endangers our aim - the patient's restoration to health. What, then, is the conclusion that forces itself inevitably upon us? Cruel though it may sound, we must see to it that the patient's suffering, to a degree that is in some way or other effective, does not come to an end prematurely. If, owing to the symptoms having been taken apart and having lost their value, his suffering becomes mitigated, we must reinstate it elsewhere in the form of some appreciable privation; otherwise we run the danger of never achieving any improvements except quite insignificant and transitory ones.

Let us take as an example the so-called dreams of recovery. If a patient has had a dream of this kind, in which he seems to abandon the restrictions of his neurosis - if, for instance, he overcomes some phobia or gives up some emotional attachment - we are inclined to think that he has made a great step forward, that he is ready to take his place in a new state of life, that he has begun to reckon on his recovery, etc. This may often be true, but quite as often such dreams of recovery only have the value of dreams of convenience: they signify a wish to be well at last, in order to avoid another portion of the work of analysis which is felt to lie ahead. In this sense, dreams of recovery very frequently occur, for instance, when the patient is about to enter upon a new and disagreeable phase of the transference. He is behaving in this just like some neurotics who after a few hours of analysis declare they have been cured - because they want to escape all the unpleasantness that is bound to come up for discussion in the analysis. Sufferers from war neuroses, too, who gave up their symptoms because the therapy adopted by the army doctors succeeded in making being ill even more uncomfortable than serving at the front - these sufferers, too, were following the same economic laws and in both cases alike the cures have proved to be only temporary.

I myself had adopted another way of speeding up an analytic treatment even before the war. At that time I had taken on the case of a young Russian, a man spoilt by wealth, who had come to Vienna in a state of complete helplessness, accompanied by a private doctor and an attendant.¹ In the course of a few years it was possible to give him back a large amount of his independence, to awaken his interest in life and to adjust his relations to the people most important to him. But there progress came to a stop. We advanced no further in clearing up the neurosis of his childhood, on which his later illness was based, and it was obvious that the patient found his present position highly comfortable and had no wish to take any step forward which would bring him nearer to the end of his treatment. It was a case of the treatment inhibiting itself: it was in danger of failing as a result of its - partial - success. In this predicament I resorted to the heroic measure of fixing a time limit for the analysis. At the beginning of a year's work I informed the patient that the coming year was to be the last one of his treatment, no matter what he achieved in the time still left to him. At first he did not believe me, but once he was convinced that I was in deadly earnest, the desired change set in. His resistances shrank up, and in these last months of his treatment he was able to reproduce all the memories and to discover all the connections which seemed necessary for understanding his early neurosis and mastering his present one. When he left me in the midsummer of 1914, with as little suspicion as the rest of us of what lay so shortly ahead, I believed that his cure was radical and permanent.

[1919a, 3632]

[1923c, 4033]

[1937c, 5015]
We are also now coming to the opinion that analytic technique must be modified in certain ways according to the nature of the disease and the dominant instinctual trends in the patient. We started out from the treatment of conversion hysteria; in anxiety hysteria (phobias) we must to some extent alter our procedure. For these patient cannot bring out the material necessary for resolving their phobia so long as they feel protected by obeying the condition which it lays down. One cannot, of course, succeed in getting them to give up their protective measures and work under the influence of anxiety from the beginning of the treatment. One must therefore help them by interpreting their unconscious to them until they can make up their minds to do without the protection of their phobia and expose themselves to a now greatly mitigated anxiety. Only after they have done so does the material become accessible, which, when it has been mastered, leads to a solution of the phobia. Other modifications of technique, which seem to me not yet ripe for discussion, will be required in the treatment of obsessional neurosis. In this connection very important questions arise, which have not hitherto been elucidated: how far the instincts which the patient is combating are to be allowed some satisfaction during the treatment, and what difference it makes whether these impulses are active (sadistic) or passive (masochistic) in their nature.

[1910d, 2310]

I have now led you into the region in which the next advances in the work of analysis are to be expected. Since we have ventured to operate with the concept of ego-libido the narcissistic neuroses have become accessible to us; the task before us is to arrive at a dynamic elucidation of these disorders and at the same time to complete our knowledge of mental life by coming to understand the ego. The ego-psychology after which we are seeking must not be based on the data of our self-perceptions but (as in the case of the libido) on the analysis of disturbances and disruptions of the ego. It is likely that we shall have a low opinion of our present knowledge of the vicissitudes of the libido, which we have gained from a study of the transference neuroses, when we have achieved this greater task. But hitherto we have not made much progress with it. The narcissistic neuroses can scarcely be attacked with the technique that has served us with the transference neuroses. You will soon learn why. What always happens with them is that, after proceeding for a short distance, we come up against a wall which brings us to a stop. Even with the transference neuroses, as you know, we met with barriers of resistance, but we were able to demolish them bit by bit. In the narcissistic neuroses the resistance is unconquerable; at the most, we are able to cast an inquisitive glance over the top of the wall and spy out what is going on on the other side of it. Our technical methods must accordingly be replaced by others; and we do not know yet whether we shall succeed in finding substitute. Nevertheless, we have no lack of material with these patients either. They make a large number of remarks, even if they do not answer our questions, and for the time being it is our business to interpret these remarks with the help of the understanding we have gained from the symptoms of the transference neuroses. The agreement is great enough to guarantee us some initial advantage. It remains to be seen how far this technique will take us.

[1916-1917, 3467]
Lastly, another quite different kind of activity is necessitated by the gradually growing appreciation that the various forms of disease treated by us cannot all be dealt with by the same technique. It would be premature to discuss this in detail, but I can give two examples of the way in which a new kind of activity comes into question. Our technique grew up in the treatment of hysteria and is still directed principally to the cure of that affection. But the phobias have already made it necessary for us to go beyond our former limits. One can hardly master a phobia if one waits till the patient lets the analysis influence him to give it up. He will never in that case bring into the analysis the material indispensable for a convincing resolution of the phobia. One must proceed differently. Take the example of agoraphobia; there are two classes of it, one mild, the other severe. Patients belonging to the first class suffer from anxiety when they go into the street by themselves, but they have not yet given up going out alone on that account; the others protect themselves from the anxiety by altogether ceasing to go about alone. With these last one succeeds only when one can induce them by the influence of the analysis to behave like phobic patients of the first class - that is, to go into the street and to struggle with their anxiety while they make the attempt. One starts, therefore, by moderating the phobia so far; and it is only when that has been achieved at the physician's demand that the associations and memories come into the patient's mind which enable the phobia to be resolved.

[1919a, 3634]

In severe cases of obsessive acts a passive waiting attitude seems even less indicated. Indeed in general these cases incline to an 'asymptotic' process of recovery, an interminable protraction of the treatment. Their analysis is always in danger of bringing to light a great deal and changing nothing. I think there is little doubt that here the correct technique can only be to wait until the treatment itself has become a compulsion, and then with this counter-compulsion forcibly to suppress the compulsion of the disease. You will understand, however, that these two instances I have given you are only samples of the new developments towards which our therapy is tending.

[1919a, 3634]

We shall then be faced by the task of adapting our technique to the new conditions. I have no doubt that the validity of our psychological assumptions will make its impression on the uneducated too, but we shall need to look for the simplest and most easily intelligible ways of expressing our theoretical doctrines. We shall probably discover that the poor are even less ready to part with their neuroses than the rich, because the hard life that awaits them if they recover offers them no attraction, and illness gives them one more claim to social help. Often, perhaps, we may only be able to achieve anything by combining mental assistance with some material support, in the manner of the Emperor Joseph. It is very probable, too, that the large-scale application of our therapy will compel us to alloy the pure gold of analysis freely with the copper of direct suggestion; and hypnotic influence, too, might find a place in it again, as it has in the treatment of war neuroses. But, whatever form this psychotherapy for the people may take, whatever the elements out of which it is compounded, its most effective and most important ingredients will assuredly remain those borrowed from strict and untendentious psycho-analysis.

[1919a, 3635]
We had no misgivings over applying analytic treatment to children who either exhibited unambiguous neurotic symptoms or who were on the road to an unfavourable development of character. The apprehension expressed by opponents of analysis that the child would be injured by it proved unfounded. What we gained from these undertakings was that we were able to confirm on the living subject what we had inferred (from historical documents, as it were) in the case of adults. But the gain for the children was also very satisfactory. It turned out that a child is a very favourable subject for analytic therapy; the results are thorough and lasting. The technique of treatment worked out for adults must, of course, be largely altered for children. A child is psychologically a different object from an adult. As yet he possesses no super-ego, the method of free association does not carry far with him, transference (since the real parents are still on the spot) plays a different part. The internal resistances against which we struggle in adults are replaced for the most part in children by external difficulties. If the parents make themselves vehicles of the resistance, the aim of the analysis - and even the analysis itself - is often imperilled. Hence it is often necessary to combine with a child's analysis a certain amount of analytic influencing of his parents. On the other hand, the inevitable deviations of analyses of children from those of adults are diminished by the circumstance that some of our patients have retained so many infantile character traits that the analyst (once again adapting himself to his subject) cannot avoid making use with them of certain of the techniques of child-analysis. It has automatically happened that child-analysis has become the domain of women analysts, and no doubt this will remain true.

[1933a, 4748]
We have appended to it a series of case histories, the selection of which could not unfortunately be determined on purely scientific grounds. Our experience is derived from private practice in an educated and literate social class, and the subject matter with which we deal often touches upon our patients' most intimate lives and histories. It would be a grave breach of confidence to publish material of this kind, with the risk of the patients being recognized and their acquaintances becoming informed of facts which were confided only to the physician. It has therefore been impossible for us to make use of some of the most instructive and convincing of our observations. This of course applies especially to all those cases in which sexual and marital relations play an important aetiological part. Thus it comes about that we are only able to produce very incomplete evidence in favour of our view that sexuality seems to play a principal part in the pathogenesis of hysteria as a source of psychical traumas and as a motive for 'defence' - that is, for repressing ideas from consciousness. It is precisely observations of a markedly sexual nature that we have been obliged to leave unpublished.

It is a quite regular thing for the mood attaching to an experience and the subject-matter of that experience to come into different relations to the primary consciousness. This was shown in the case of another patient, Frau Cäcilie M., whom I got to know far more thoroughly than any of the other patients mentioned in these studies. I collected from her very numerous and convincing proofs of the existence of a psychical mechanism of hysterical phenomena such as I have put forward above. Personal considerations unfortunately make it impossible for me to give a detailed case history of this patient, though I shall have occasion to refer to it from time to time. Frau Cäcilie had latterly been in a peculiar hysterical state. This state was certainly not a unique one, though I do not know if it has hitherto been recognized. It might be called a 'hysterical psychosis for the payment of old debts'. The patient had experienced numerous psychical traumas and had spent many years in a chronic hysteria which was attended by a great variety of manifestations. The causes of all these states of hers were unknown to her and everyone else. Her remarkably well-stocked memory showed the most striking gaps. She herself complained that it was as though her life was chopped in pieces. One day an old memory suddenly broke in upon her clear and tangible and with all the freshness of a new sensation. For nearly three years after this she once again lived through all the traumas of her life - long-forgotten, as they seemed to her, and some, indeed, never remembered at all - accompanied by the acutest suffering and by the return of all the symptoms she had ever had. The 'old debts' which were thus paid covered a period of thirty-three years and made it possible to discover the origins, often very complicated, of all her abnormal states. The only way of relieving her was to give her an opportunity of talking off under hypnosis the particular reminiscence which was tormenting her at the moment, together with all its accompanying load of feelings and their physical expression. When I was prevented from doing so, so that she was obliged to say these things to a person in whose presence she felt embarrassed, it sometimes happened that she would tell him her story quite calmly and would subsequently, in hypnosis, produce for me all the tears, all the expressions of despair, with which she would have wished to accompany her recital. For a few hours after a purgation of this kind during hypnosis she used to be quite well and on the spot. After a short interval the next reminiscence of the series would break its way in. But this reminiscence would be preceded some hours earlier by the mood which was proper to it. She would become anxious or irritable or despairing without ever suspecting that this mood did not belong to the present moment but to the state to which she would next be subject. During this transition period she would habitually make a false connection to which she would obstinately cling until her next hypnosis. For instance, she once greeted me with the question: 'Am I not a worthless person? Is it not a sign of worthlessness that I said to you what I did yesterday?' What she had actually said to me the day before did not in fact seem to me to justify this damning verdict. After a short discussion, she clearly recognized this; but her next hypnosis brought to light a recollection of an occasion, twelve years earlier, which had aroused severe self-reproaches in her - though, incidentally, she no longer subscribed to them in the least.

[1895d, 65]
Even if I ignore the ill-will of narrow-minded critics such as these, the presentation of my case histories remains a problem which is hard for me to solve. The difficulties are partly of a technical kind, but are partly due to the nature of the circumstances themselves. If it is true that the causes of hysterical disorders are to be found in the intimacies of the patients' psychosexual life, and that hysterical symptoms are the expression of their most secret and repressed wishes, then the complete elucidation of a case of hysteria is bound to involve the revelation of those intimacies and the betrayal of those secrets. It is certain that the patients would never have spoken if it had occurred to them that their admissions might possibly be put to scientific uses; and it is equally certain that to ask them themselves for leave to publish their case would be quite unavailing. In such circumstances persons of delicacy, as well as those who were merely timid, would give first place to the duty of medical discretion and would declare with regret that the matter was one upon which they could offer science no enlightenment. But in my opinion the physician has taken upon himself duties not only towards the individual patient but towards science as well; and his duties towards science mean ultimately nothing else than his duties towards the many other patients who are suffering or will some day suffer from the same disorder. Thus it becomes the physician's duty to publish what he believes he knows of the causes and structure of hysteria, and it becomes a disgraceful piece of cowardice on his part to neglect doing so, as long as he can avoid causing direct personal injury to the single patient concerned. I think I have taken every precaution to prevent my patient from suffering any such injury. I have picked out a person the scenes of whose life were laid not in Vienna but in a remote provincial town, and whose personal circumstances must therefore be practically unknown in Vienna. I have from the very beginning kept the fact of her being under my treatment such a careful secret that only one other physician - and one in whose discretion I have complete confidence - can be aware that the girl was a patient of mine. I have waited for four whole years since the end of the treatment and have postponed publication till hearing that a change has taken place in the patient's life of such a character as allows me to suppose that her own interest in the occurrences and psychological events which are to be related here may now have grown faint. Needless to say, I have allowed no name to stand which could put a nonmedical reader upon the scent; and the publication of the case in a purely scientific, and technical periodical should, further, afford a guarantee against unauthorized readers of this sort. I naturally cannot prevent the patient herself from being pained if her own case history should accidentally fall into her hands. But she will learn nothing from it that she does not already know; and she may ask herself who besides her could discover from it that she is the subject of this paper.

[1905e, 1351]

I am aware that - in this city, at least - there are many physicians who (revolting though it may seem) choose to read a case history of this kind not as a contribution to the psychopathology of the neuroses, but as a roman à clef designed for their private delectation. I can assure readers of this species that every case history which I may have occasion to publish in the future will be secured against their perspicacity by similar guarantees of secrecy, even though this resolution is bound to put quite extraordinary restrictions upon my choice of material.

[1905e, 1352]
Now in this case history - the only one which I have hitherto succeeded in forcing through the limitations imposed by medical discretion and unfavourable circumstances - sexual questions will be discussed with all possible frankness, the organs and functions of sexual life will be called by their proper names, and the pure-minded reader can convince himself from my description that I have not hesitated to converse upon such subjects in such language even with a young woman. Am I then, to defend myself upon this score as well? I will simply claim for myself the rights of the gynaecologist - or rather, much more modest ones - and add that it would be the mark of a singular and perverse prurience to suppose that conversations of this kind are a good means of exciting or of gratifying sexual desire. For the rest, I feel inclined to express my opinion on this subject in a few borrowed words:
[1905e, 1352]

I will now describe the way in which I have overcome the technical difficulties of drawing up the report of this case history. The difficulties are very considerable when the physician has to conduct six or eight psychotherapeutic treatments of the sort in a day, and cannot make notes during the actual session with the patient for fear of shaking the patient's confidence and of disturbing his own view of the material under observation. Indeed, I have not yet succeeded in solving the problem of how to record for publication the history of a treatment of long duration. As regards the present case, two circumstances have come to my assistance. In the first place the treatment did not last for more than three months; and in the second place the material which elucidated the case was grouped around two dreams (one related in the middle of the treatment and one at the end). The wording of these dreams was recorded immediately after the session, and they thus afforded a secure point of attachment for the chain of interpretations and recollections which proceeded from them. The case history itself was only committed to writing from memory after the treatment was at an end, but while my recollection of the case was still fresh and was heightened by my interest in its publication. Thus the record is not absolutely - phonographically - exact, but it can claim to possess a high degree of trustworthiness. Nothing of any importance has been altered in it except in some places the order in which the explanations are given; and this has been done for the sake of presenting the case in a more connected form.
[1905e, 1352]

While the case history before us seems particularly favoured as regards the utilization of dreams, in other respects it has turned out poorer than I could have wished. But its shortcomings are connected with the very circumstances which have made its publication possible. As I have already said, I should not have known how to deal with the material involved in the history of a treatment which had lasted, perhaps, for a whole year. The present history, which covers only three months could be recollected and reviewed; but its results remain incomplete in more than one respect. The treatment was not carried through to its appointed end, but was broken off at the patient's own wish when it had reached a certain point. At that time some of the problems of the case had not even been attacked and others had only been imperfectly elucidated; whereas, if the work had been continued, we should no doubt have obtained the fullest possible enlightenment upon every particular of the case. In the following pages, therefore, I can present only a fragment of an analysis.
[1905e, 1354]
The treatment described in this paper was broken off on December 31st, 1899. My account of it was written during the two weeks immediately following, but was not published until 1905. It is not to be expected that after more than twenty years of uninterrupted work I should see nothing to alter in my view of such a case and in my presentment of it; but it would obviously be absurd to bring the case history 'up to date' by means of emendations and additions. In all essentials, therefore, I have left it as it was, and in the text I have merely corrected a few oversights and inaccuracies to which my excellent English translators, Mr. and Mrs. James Strachey, have directed my attention. Such critical remarks as I have thought it permissible to add I have incorporated in these additional notes: so that the reader will be justified in assuming that I still hold to the opinions expressed in the text unless he finds them contradicted in the footnotes. The problem of medical discretion which I have discussed in this preface does not touch the remaining case histories contained in this volume; for three of them were published with the express assent of the patients (or rather, as regards little Hans, with that of his father), while in the fourth case (that of Schreber) the subject of the analysis was not actually a person but a book produced by him. In Dora's case the secret was kept until this year. I had long been out of touch with her, but a short while ago I heard that she had recently fallen ill again from other causes, and had confided to her physician that she had been analysed by me when she was a girl. This disclosure made it easy for my well-informed colleague to recognize her as the Dora of 1899. No fair judge of analytic therapy will make it a reproach that the three months' treatment she received at that time effected no more than the relief of her current conflict and was unable to give her protection against subsequent illnesses.

It is true that I have introduced this paper as a fragment of an analysis; but the reader will have discovered that it is incomplete to a far greater degree than its title might have led him to expect. It is therefore only proper that I should attempt to give a reason for the omissions - which are by no means accidental.
A number of the results of the analysis have been omitted, because at the time when work was broken off they had either not been established with sufficient certainty or they required further study before any general statement could be made about them. At other points, where it seemed to be permissible, I have indicated the direction along which some particular solution would probably have been found to lie. I have in this paper left entirely out of account the technique, which does not at all follow as a matter of course, but by whose means alone the pure metal of valuable unconscious thoughts can be extracted from the raw material of the patient's associations. This brings with it the disadvantage of the reader being given no opportunity of testing the correctness of my procedure in the course of this exposition of the case. I found it quite impracticable, however, to deal simultaneously with the technique of analysis and with the internal structure of a case of hysteria: I could scarcely have accomplished such a task, and if I had, the result would have been almost unreadable. The technique of analysis demands an entirely separate exposition, which would have to be illustrated by numerous examples chosen from a very great variety of cases and which would not have to take the results obtained in each particular case into account. Nor have I attempted in this paper to substantiate the psychological postulates which will be seen to underlie my descriptions of mental phenomena. A cursory attempt to do so would have effected nothing; an exhaustive one would have been a volume in itself. I can only assure the reader that I approached the study of the phenomena revealed by observation of the psychoneuroses without being pledged to any particular psychological system, and that I then proceeded to adjust my views until they seemed adapted for giving an account of the collection of facts which had been observed. I take no pride in having avoided speculation; the material for my hypotheses was collected by the most extensive and laborious series of observations. The decidedness of my attitude on the subject of the unconscious is perhaps specially likely to cause offence, for I handle unconscious ideas, unconscious trains of thought, and unconscious impulses as though they were no less valid and unimpeachable psychological data than conscious ones. But of this I am certain - that any one who sets out to investigate the same region of phenomena and employs the same method will find himself compelled to take up the same position, however much philosophers may expostulate.

[1905e, 1446]
A singular thing. I can remember, when I first began to meddle in the conflict of scientific opinions twenty-two years ago, with what derision the older generation of neurologists and psychiatrists of those days received assertions about suggestion and its effects. Since then the situation has fundamentally changed. The former aversion has been converted into an only too ready acceptance; and this has happened not only as a consequence of the impression which the work of Liébeault and Bernheim and their pupils could not fail to create in the course of these two decades, but also because it has since been discovered how great an economy of thought can be effected by the use of the catchword 'suggestion'. Nobody knows and nobody cares what suggestion is, where it comes from, or when it arises, - it is enough that everything awkward in the region of psychology can be labelled 'suggestion'. I do not share the view which is at present fashionable that assertions made by children are invariably arbitrary and untrustworthy. The arbitrary has no existence in mental life. The untrustworthiness of the assertions of children is due to the predominance of their imagination, just as the untrustworthiness of the assertions of grown-up people is due to the predominance of their prejudices. For the rest, even children do not lie without a reason, and on the whole they are more inclined to a love of truth than are their elders. If we were to reject little Hans's statements root and branch we should certainly be doing him a grave injustice. On the contrary, we can quite clearly distinguish from one another the occasions on which he was falsifying the facts or keeping them back under the compelling force of a resistance, the occasions on which, being undecided himself, he agreed with his father (so that what he said must not be taken as evidence), and the occasions on which, freed from every pressure, he burst into a flood of information about what was really going on inside him and about things which until then no one but himself had known. Statements made by adults offer no greater certainty. It is a regrettable fact that no account of a psycho-analysis can reproduce the impressions received by the analyst as he conducts it, and that a final sense of conviction can never be obtained from reading about it but only from directly experiencing it. But this disability attaches in an equal degree to analyses of adults.

[1909b, 2088]

A programme of this kind seems to me to require some justification. For it might otherwise be thought that I regard this method of making a communication as perfectly correct and as one to be imitated; whereas in reality I am only accommodating myself to obstacles, some external and others inherent in the subject, and I should gladly have communicated more if it had been right or possible for me to do so. I cannot give a complete history of the treatment, because that would involve my entering in detail into the circumstances of my patient's life. The importunate interest of a capital city, focused with particular attention upon my medical activities, forbids my giving a faithful picture of the case. On the other hand I have come more and more to regard the distortions usually resorted to in such circumstances as useless and objectionable. If the distortions are slight, they fail in their object of protecting the patient from indiscreet curiosity; while if they go beyond this they require too great a sacrifice, for they destroy the intelligibility of the material, which depends for its coherence precisely upon the small details of real life. And from this latter circumstance follows the paradoxical truth that it is far easier to divulge the patient's most intimate secrets than the most innocent and trivial facts about him; for, whereas the former would not throw any light on his identity, the latter, by which he is generally recognized, would make it obvious to every one.

[1909d, 2127]
Such is my excuse for having curtailed so drastically the history of this case and its treatment. And I can offer still more cogent reasons for having confined myself to the statement only of some disconnected results of the psycho-analytic investigation of obsessional neuroses. I must confess that I have not yet succeeded in completely penetrating the complicated texture of a severe case of obsessional neurosis, and that, if I were to reproduce the analysis, it would be impossible for me to make the structure, such as by the help of analysis we know or suspect it to be, visible to others through the mass of therapeutic work superimposed upon it. What add so greatly to the difficulty of doing this are the resistances of the patients and the forms in which they are expressed. But even apart from this it must be admitted that an obsessional neurosis is in itself not an easy thing to understand - much less so than a case of hysteria. Actually, indeed, we should have expected to find the contrary. The language of an obsessional neurosis - the means by which it expresses its secret thoughts - is, as it were, only a dialect of the language of hysteria; but it is a dialect in which we ought to be able to find our way about more easily, since it is more nearly related to the forms of expression adopted by our conscious thought than is the language of hysteria. Above all, it does not involve the leap from a mental process to a somatic innervation - hysterical conversion - which can never be fully comprehensible to us.

I have already asserted that obsessional thoughts have undergone a distortion similar to that undergone by dream-thoughts before they become the manifest content of a dream. The technique of this distortion may therefore be of interest to us, and there should be nothing to prevent our exhibiting its various modes by means of a series of obsessions which have been translated and made clear. But here again the conditions governing the publication of this case make it impossible for me to give more than a few specimens. Not all of the patient's obsessions were so complicated in their structure and so difficult to solve as the great rat idea. In some of the others a very simple technique was employed - namely, that of distortion by omission or ellipsis. This technique is pre-eminently applicable to jokes, but in our present case, too, it did useful work as a means of protecting things from being understood.

Taking notes during the session with the patient might be justified by an intention of publishing a scientific study of the case. On general grounds this can scarcely be denied. Nevertheless it must be borne in mind that exact reports of analytic case histories are of less value than might be expected. Strictly speaking, they only possess the ostensible exactness of which 'modern' psychiatry affords us some striking examples. They are, as a rule, fatiguing to the reader and yet do not succeed in being a substitute for his actual presence at an analysis. Experience invariably shows that if readers are willing to believe an analyst they will have confidence in any slight revision to which he has submitted his material; if, on the other hand, they are unwilling to take analysis and the analyst seriously, they will pay no attention to accurate verbatim records of the treatment either. This is not the way, it seems, to remedy the lack of convincing evidence to be found in psycho-analytic reports.
Unfortunately I am unable, for familiar reasons, to enter into the history of the case as far as I should like, and I must restrict myself to the account which follows. Up to the time of her falling ill the patient had been a happy and almost completely satisfied wife. She wanted to have children, from motives based on an infantile fixation of her wishes, and she fell ill when she learned that it was impossible for her to have any by the husband who was the only object of her love. The anxiety hysteria with which she reacted to this frustration corresponded, as she herself soon learned to understand, to the repudiation of phantasies of seduction in which her firmly implanted wish for a child found expression. She now did all she could to prevent her husband from guessing that she had fallen ill owing to the frustration of which he was the cause. But I have had good reason for asserting that everyone possesses in his own unconscious an instrument with which he can interpret the utterances of the unconscious in other people. Her husband understood, without any admission or explanation on her part, what his wife's anxiety meant; he felt hurt, without showing it, and in his turn reacted neurotically by - for the first time - failing in sexual intercourse with her. Immediately afterwards he started on a journey. His wife believed that he had become permanently impotent, and produced her first obsessional symptoms on the day before his expected return.

(Before I continue the account, I must confess that I have altered the milieu of the case in order to preserve the incognito of the people concerned, but that I have altered nothing else. I consider it a wrong practice, however excellent the motive may be, to alter any detail in the presentation of a case. One can never tell what aspect of a case may be picked out by a reader of independent judgement, and one runs the risk of leading him astray.)

For reasons which will be easily understood I cannot communicate very much about these or other case histories. Nor do I propose to go into the obvious analogy between deformities of character resulting from protracted sickliness in childhood and the behaviour of whole nations whose past history has been full of suffering. Instead, however, I will take the opportunity of pointing to a figure created by the greatest of poets - a figure in whose character the claim to be an exception is closely bound up with and is motivated by the circumstance of congenital disadvantage.

Analytic work has no difficulty in showing us that it is forces of conscience which forbid the subject to gain the long hoped for advantage from the fortunate change in reality. It is a difficult task, however, to discover the essence and origin of these judging and punishing trends, which so often surprise us by their existence where we do not expect to find them. For the usual reasons I shall not discuss what we know or conjecture on the point in relation to cases of clinical observation, but in relation to figures which great writers have created from the wealth of their knowledge of the mind.

I shall give you only two examples of the analysis of an obsessional symptom: one an old observation which I cannot find a better one to replace, and another recently met with. I limit myself to this small number, because it is impossible in such reports to avoid being very diffuse and entering into every detail.
Only this infantile neurosis will be the subject of my communication. In spite of the patient's direct request, I have abstained from writing a complete history of his illness, of his treatment, and of his recovery, because I recognized that such a task was technically impracticable and socially impermissible. This at the same time removes the possibility of demonstrating the connection between his illness in childhood and his later and permanent one. As regards the latter I can only say that on account of it the patient spent a long time in German sanatoria, and was at that period classified in the most authoritative quarters as a case of 'manic-depressive insanity'. This diagnosis was certainly applicable to the patient's father, whose life with its wealth of activity and interests, was disturbed by repeated attacks of severe depression. But in the son I was never able, during an observation which lasted several years, to detect any changes of mood which were disproportionate to the manifest psychological situation either in their intensity or in the circumstances of their appearance. I have formed the opinion that this case, like many others which clinical psychiatry has labelled with the most multifarious and shifting diagnoses, is to be regarded as a condition following on an obsessional neurosis which has come to an end spontaneously, but has left a defect behind it after recovery.

A third peculiarity of the analysis which is to be described in these pages has only increased my difficulty in deciding to make a report upon it. On the whole its results have coincided in the most satisfactory manner with our previous knowledge, or have been easily embodied into it. Many details, however, seemed to me myself to be so extraordinary and incredible that I felt some hesitation in asking other people to believe them. I requested the patient to make the strictest criticism of his recollections, but he found nothing improbable in his statements and adhered closely to them. Readers may at all events rest assured that I myself am only reporting what I came upon as an independent experience, uninfluenced by my expectation. So that there was nothing left for me but to remember the wise saying that there are more things in heaven and earth than are dreamed of in our philosophy. Anyone who could succeed in eliminating his pre-existing convictions even more thoroughly could no doubt discover even more such things.

I am unable to give either a purely historical or a purely thematic account of my patient's story; I can write a history neither of the treatment nor of the illness, but I shall find myself obliged to combine the two methods of presentation. It is well known that no means has been found of in any way introducing into the reproduction of an analysis the sense of conviction which results from the analysis itself. Exhaustive verbatim reports of the proceedings during the hours of analysis would certainly be of no help at all; and in any case the technique of the treatment makes it impossible to draw them up. So analyses such as this are not published in order to produce conviction in the minds of those whose attitude has hitherto been recusant and sceptical. The intention is only to bring forward some new facts for investigators who have already been convinced by their own clinical experiences.

The diffuseness and elaboration of this commentary have been forced on me by the effort to present the reader with some sort of equivalent for the convincing power of an analysis carried through by oneself; perhaps they may also serve to discourage him from asking for the publication of analyses which have stretched over several years.
I do not know if the reader of this report of an analysis will have succeeded in forming a clear picture of the origin and development of the patient's illness. I fear that, on the contrary, this will not have been the case. But though on other occasions I have said very little on behalf of my powers in the art of exposition, I should like in the present instance to plead mitigating circumstances. The description of such early phases and of such deep strata of mental life has been a task which has never before been attacked; and it is better to perform that task badly than to take flight before it - a proceeding which would moreover (or so we are told) involve the coward in risks of a certain kind. I prefer, therefore, to put a bold face on it and show that I have not allowed myself to be held back by a sense of my own inferiority.

[1918b, 3582]

The case itself was not a particularly favourable one. The advantage of having a wealth of information about the patient's childhood (an advantage which was made possible by the fact that the child could be studied through the medium of the adult) had to be purchased at the expense of the analysis being most terribly disjointed and of the exposition showing corresponding gaps. Personal peculiarities in the patient and a national character that was foreign to ours made the task of feeling one's way into his mind a laborious one. The contrast between the patient's agreeable and affable personality, his acute intelligence and his nicemindedness on the one hand, and his completely unbridled instinctual life on the other, necessitated an excessively long process of preparatory education, and this made a general perspective more difficult. But the patient himself has no responsibility for that feature of the case which put the severest obstacles in the way of any description of it. In the psychology of adults we have fortunately reached the point of being able to divide mental processes into conscious and unconscious and of being able to give a clearly-worded description of both. With children this distinction leaves us almost completely in the lurch. It is often embarrassing to decide what one would choose to call conscious and what unconscious. Processes which have become the dominant ones, and which from their subsequent behaviour must be equated with conscious ones, have nevertheless not been conscious in the child. It is easy to understand why. In children the conscious has not yet acquired all its characteristics; it is still in process of development, and it does not as yet fully possess the capacity for transposing itself into verbal images. We are constantly guilty of making a confusion between the phenomenon of emergence as a perception in consciousness and the fact of belonging to a hypothetical psychical system to which we ought to assign some conventional name, but which we in fact also call 'consciousness' (the system Cs.). This confusion does no harm when we are giving a psychological description of an adult, but it is misleading when we are dealing with that of a young child. Nor should we be much assisted here if we introduced the 'preconscious'; for a child's preconscious may, in just the same way, fail to coincide with an adult's. We must be content, therefore, with having clearly recognized the obscurity.

[1918b, 3582]

Homosexuality in women, which is certainly not less common than in men, although much less glaring, has not only been ignored by the law, but has also been neglected by psycho-analytic research. The narration of a single case, not too pronounced in type, in which it was possible to trace its origin and development in the mind with complete certainty and almost without a gap may, therefore, have a certain claim to attention. If this presentation of it furnishes only the most general outlines of the various events concerned and of the conclusions reached from a study of the case, while suppressing all the characteristic details on which the interpretation is founded, this limitation is easily to be explained by the medical discretion necessary in discussing a recent case.

[1920a, 3837]
Linear presentation is not a very adequate means of describing complicated mental processes going on in different layers of the mind. I am therefore obliged to pause in the discussion of the case and treat more fully and deeply some of the points brought forward above. [1920a, 3850]

For obvious reasons the details of these cases must be withheld from publication; I cannot, therefore, show in what way accidental circumstances have contributed to the choice of a fetish. The most extraordinary case seemed to me to be one in which a young man had exalted a certain sort of 'shine on the nose' into a fetishistic precondition. The surprising explanation of this was that the patient had been brought up in an English nursery but had later come to Germany, where he forgot his mother-tongue almost completely. The fetish, which originated from his earliest childhood, had to be understood in English, not German. The 'shine on the nose' - was in reality a 'glance at the nose'. The nose was thus the fetish, which, incidentally, he endowed at will with the luminous shine which was not perceptible to others. [1927e, 4535]
The adoption of the required attitude of mind towards ideas that seem to emerge 'of their own free will' and the abandonment of the critical function that is normally in operation against them seem to be hard of achievement for some people. The 'involuntary thoughts' are liable to release a most violent resistance, which seeks to prevent their emergence. If we may trust that great poet and philosopher Friedrich Schiller, however, poetic creation must demand an exactly similar attitude. In a passage in his correspondence with Körner - we have to thank Otto Rank for unearthing it - Schiller (writing on December 1, 1788) replies to his friend's complaint of insufficient productivity: 'The ground for your complaint seems to me to lie in the constraint imposed by your reason upon your imagination. I will make my idea more concrete by a simile. It seems a bad thing and detrimental to the creative work of the mind if Reason makes too close an examination of the ideas as they come pouring in - at the very gateway, as it were. Looked at in isolation, a thought may seem very trivial or very fantastic; but it may be made important by another thought that comes after it, and, in conjunction with other thoughts that may seem equally absurd, it may turn out to form a most effective link. Reason cannot form any opinion upon all this unless it retains the thought long enough to look at it in connection with the others. On the other hand, where there is a creative mind, Reason - so it seems to me - relaxes its watch upon the gates, and the ideas rush in pell-mell, and only then does it look them through and examine them in a mass. - You critics, or whatever else you may call yourselves, are ashamed or frightened of the momentary and transient extravagances which are to be found in all truly creative minds and whose longer or shorter duration distinguishes the thinking artist from the dreamer. You complain of your unfruitfulness because you reject too soon and discriminate too severely.'

[1900a, 605]

No one should expect that an interpretation of his dreams will fall into his lap like manna from the skies. Practice is needed even for perceiving endoptic phenomena or other sensations from which our attention is normally withheld; and this is so even though there is no psychical motive fighting against such perceptions. It is decidedly more difficult to get hold of 'involuntary ideas.' Anyone who seeks to do so must familiarize himself with the expectations raised in the present volume and must, in accordance with the rules laid down in it, endeavour during the work to refrain from any criticism, any parti pris, and any emotional or intellectual bias. He must bear in mind Claude Bernard's advice to experimenters in a physiological laboratory: 'travailler comme une bête' - he must work, that is, with as much persistence as an animal and with as much disregard of the result. If this advice is followed, the task will no longer be a hard one.

[1900a, 957]
But perhaps all we need is a new idea in order to help us out of our dilemma and lead to valuable results. The idea is this. As we know from Breuer, hysterical symptoms can be resolved if, starting from them, we are able to find the path back to the memory of a traumatic experience. If the memory which we have uncovered does not answer our expectations, it may be that we ought to pursue the same path a little further; perhaps behind the first traumatic scene there may be concealed the memory of a second, which satisfies our requirements better and whose reproduction has a greater therapeutic effect; so that the scene that was first discovered only has the significance of a connecting link in the chain of associations. And perhaps this situation may repeat itself; inoperative scenes may be interpolated more than once, as necessary transitions in the process of reproduction, until we finally make our way from the hysterical symptom to the scene which is really operative traumatically and which is satisfactory in every respect, both therapeutically and analytically. Well, Gentlemen, this supposition is correct. If the first-discovered scene is unsatisfactory, we tell our patient that this experience explains nothing, but that behind it there must be hidden a more significant, earlier, experience; and we direct his attention by the same technique to the associative thread which connects the two memories - the one that has been discovered and the one that has still to be discovered.¹ A continuation of the analysis then leads in every instance to the reproduction of new scenes of the character we expect. For example, let us take once again the case of hysterical vomiting which I selected before, and in which the analysis first led back to a fright from a railway accident - a scene which lacked suitability as a determinant. Further analysis showed that this accident had aroused in the patient the memory of another, earlier accident, which, it is true, he had not himself experienced but which had been the occasion of his having a ghastly and revolting sight of a dead body. It is as though the combined operation of the two scenes made the fulfilment of our postulates possible, the one experience supplying, through fright, the traumatic force and the other, from its content, the determining effect. The other case, in which the vomiting was traced back to eating an apple which had partly gone bad, was amplified by the analysis somewhat in the following way. The bad apple reminded the patient of an earlier experience: while he was picking up windfalls in an orchard he had accidentally come upon a dead animal in a revolting state.

³ If a patient exhibits doubts in the course of his narrative, an empirical rule teaches us to disregard such expressions of his judgement entirely. If the narrative wavers between two versions, we should incline to regard the first one as correct and the second as a product of repression.
In 1896, shortly after the appearance of my *Studies on Hysteria* (written in conjunction with Dr. J. Breuer, 1895), I asked an eminent fellow-specialist for his opinion on the psychological theory of hysteria put forward in that work. He bluntly replied that he considered it an unjustifiable generalization of conclusions which might hold good for a few cases. Since then I have seen an abundance of cases of hysteria, and I have been occupied with each case for a number of days, weeks, or years. In not a single one of them have I failed to discover the psychological determinants which were postulated in the *Studies*, namely, a psychical trauma, a conflict of affects, and an additional factor which I brought forward in later publications - a disturbance in the sphere of sexuality. It is of course not to be expected that the patient will come to meet the physician half-way with material which has become pathogenic for the very reason of its efforts to lie concealed; nor must the enquirer rest content with the first 'No' that crosses his path.¹

[1905e, 1364]

When a patient brings forward a sound and incontestable train of argument during psycho-analytic treatment, the physician is liable to feel a moment's embarrassment, and the patient may take advantage of it by asking: 'This is all perfectly correct and true, isn't it? What do you want to change in now that I've told it you?' But it soon becomes evident that the patient is using thoughts of this kind, which the analysis cannot attack, for the purpose of cloaking others which are anxious to escape from criticism and from consciousness. A string of reproaches against other people leads one to suspect the existence of a string of self-reproaches with the same content. All that need be done is to turn back each particular reproach on to the speaker himself. There is something undeniably automatic about this method of defending oneself against a self-reproach by making the same reproach against some one else. A model of it is to be found in the *tu quoque* arguments of children; if one of them is accused of being a liar, he will reply without an instant's hesitation: 'You're another.' A grown-up person who wanted to throw back abuse would look for some really exposed spot in his antagonist and would not necessarily lay the chief stress upon the same content being repeated. In paranoia the projection of a reproach on to another person without any alteration in its content and therefore without any consideration for reality becomes manifest as the process of forming delusions.

[1905e, 1373]
Her other reproach against her father was that his ill-health was only a pretext and that he exploited it for his own purposes. This reproach, too, concealed a whole section of her own secret history. One day she complained of a professedly new symptom, which consisted of piercing gastric pains. ‘Whom are you copying now?’ I asked her, and found I had hit the mark. The day before she had visited her cousins, the daughters of the aunt who had died. The younger one had become engaged, and this had given occasion to the elder one for falling ill with gastric pains, and she was to be sent off to Semmering. Dora thought it was all just envy on the part of the elder sister; she always got ill when she wanted something, and what she wanted now was to be away from home so as not to have to look on at her sister’s happiness.¹ But Dora’s own gastric pains proclaimed the fact that she identified herself with her cousin, who, according to her, was a malingerer. Her grounds for this identification were either that she too envied the luckier girl her love, or that she saw her own story reflected in that of the elder sister, who had recently had a love-affair which had ended unhappily.² But she had also learned from observing Frau K. what useful things illnesses could become. Herr K. spent part of the year in travelling. Whenever he came back, he used to find his wife in bad health, although, as Dora knew, she had been quite well only the day before. Dora realized that the presence of the husband had the effect of making his wife ill, and that she was glad to be ill so as to be able to escape the conjugal duties which she so much detested. At this point in the discussion Dora suddenly brought in an allusion to her own alternations between poor and bad health during the first years of her girlhood at B--; and I was thus driven to suspect that her states of health were to be regarded as depending upon something else, in the same way as Frau K.’s. (It is a rule of psycho-analytic technique that an internal connection which is still undisclosed will announce its presence by means of a contiguity - a temporal proximity of associations; just as in writing, if ‘a’ and ‘b’ are put side by side, it means that the syllable ‘ab’ is to be formed out of them.) Dora had had a very large number of attacks of coughing accompanied by loss of voice. Could it be that the presence or absence of the man she loved had had an influence upon the appearance and disappearance of the symptoms of her illness? If this were so, it must be possible to discover some coincidence or other which would betray the fact. I asked her what the average length of these attacks had been. 'From three to six weeks, perhaps.' How long had Herr K.’s absences lasted? 'Three to six weeks, too', she was obliged to admit. Her illness was therefore a demonstration of her love for K., just as his wife’s was a demonstration of her dislike. It was only necessary to suppose that her behaviour had been the opposite of Frau K.’s and that she had been ill when he was absent and well when he had come back. And this really seemed to have been so, at least during the first period of the attacks. Later on it no doubt became necessary to obscure the coincidence between her attacks of illness and the absence of the man she secretly loved, lest its regularity should betray her secret. The length of the attacks would then remain as a trace of their original significance.

[1905e, 1376]
This short piece of the analysis may perhaps have excited in the medical reader - apart from the scepticism to which he is entitled - feelings of astonishment and horror; and I am prepared at this point to look into these two reactions so as to discover whether they are justifiable. The astonishment is probably caused by my daring to talk about such delicate and unpleasant subjects to a young girl - or, for that matter, to any woman who is sexually active. The horror is aroused, no doubt, by the possibility that an inexperienced girl could know about practices of such a kind and could occupy her imagination with them. I would advise recourse to moderation and reasonableness upon both points. There is no cause for indignation either in the one case or in the other. It is possible for a man to talk to girls and women upon sexual matters of every kind without doing them harm and without bringing suspicion upon himself, so long as, in the first place, he adopts a particular way of doing it, and, in the second place, can make them feel convinced that it is unavoidable. A gynaecologist, after all, under the same conditions, does not hesitate to make them submit to uncovering every possible part of their body. The best way of speaking about such things is to be dry and direct; and that is at the same time the method furthest removed from the prurience with which the same subjects are handled in 'society', and to which girls and women alike are so thoroughly accustomed. I call bodily organs and processes by their technical names, and I tell these to the patient if they - the names, I mean - happen to be unknown to her. J'appelle un chat un chat. I have certainly heard of some people - doctors and laymen - who are scandalized by a therapeutic method in which conversations of this sort occur, and who appear to envy either me or my patients the titillation which, according to their notions, such a method must afford. But I am too well acquainted with the respectability of these gentry to excite myself over them. I shall avoid the temptation of writing a satire upon them. But there is one thing that I will mention: often, after I have for some time treated a patient who had not at first found it easy to be open about sexual matters, I have had the satisfaction of hearing her exclaim: 'Why, after all, your treatment is far more respectable than Mr. X.'s conversation!'

When I told Dora that I could not avoid supposing that her affection for her father must at a very early moment have amounted to her being completely in love with him, she of course gave me her usual reply: 'I don't remember that.' But she immediately went on to tell me something analogous about a seven-year-old girl who was her cousin (on her mother's side) and in whom she often thought she saw a kind of reflection of her own childhood. This little girl had (not for the first time) been the witness of a heated dispute between her parents, and, when Dora happened to come in on a visit soon afterwards, whispered in her ear: 'You can't think how I hate that person!' (pointing to her mother), 'and when she's dead I shall marry Daddy.' I am in the habit of regarding associations such as this, which bring forward something that agrees with the content of an assertion of mine, as a confirmation from the unconscious of what I have said. No other kind of 'Yes' can be extracted from the unconscious; there is no such thing at all as an unconscious 'No'.¹

¹ [Footnote added 1923:] There is another very remarkable and entirely trustworthy form of confirmation from the unconscious, which I had not recognized at the time this was written: namely, an exclamation on the part of the patient of 'I didn't think that', or 'I didn't think of that'. This can be translated point-blank into: 'Yes, I was unconscious of that.'
My expectations were by no means disappointed when this explanation of mine was met by Dora with a most emphatic negative. The 'No' uttered by a patient after a repressed thought has been presented to his conscious perception for the first time does no more than register the existence of a repression and its severity; it acts, as it were, as a gauge of the repression's strength. If this 'No', instead of being regarded as the expression of an impartial judgement (of which, indeed, the patient is incapable), is ignored, and if work is continued, the first evidence soon begins to appear that in such a case 'No' signifies the desired 'Yes'. Dora admitted that she found it impossible to be as angry with Herr K. as he had deserved. She told me that one day she had met Herr K. in the street while she was walking with a cousin of hers who did not know him. The other girl had exclaimed all at once: 'Why, Dora, what's wrong with you? You've gone as white as a sheet!' She herself had felt nothing of this change of colour; but I explained to her that the expression of emotion and the play of features obey the unconscious rather than the conscious, and are a means of betraying the former. Another time Dora came to me in the worst of tempers after having been uniformly cheerful for several days. She could give no explanation of this. She felt so contrary to-day, she said; it was her uncle's birthday, and she could not bring herself to congratulate him. She did not know why. My powers of interpretation were at a low ebb that day; I let her go on talking, and she suddenly recollected that it was Herr K.'s birthday too - a fact which I did not fail to use against her. And it was then no longer hard to explain why the handsome presents she had had on her own birthday a few days before had given her no pleasure. One gift was missing, and that was Herr K.'s, the gift which had plainly once been the most prized of all.

Here, therefore (and quite in accordance with the rules), was a piece of material information coming to light in the middle of the analysis and helping to solve problems which had previously been raised. I was able to say to Dora: 'Now I know your motive for the slap in the face with which you answered Herr K.'s proposal. It was not that you were offended at his suggestions; you were actuated by jealousy and revenge. At the time when the governess was telling you her story you were still able to make use of your gift for putting on one side everything that is not agreeable to your feelings. But at the moment when Herr K. used the words "I get nothing out of my wife" - which were the same words he had used to the governess - fresh emotions were aroused in you and tipped the balance. "Does he dare", you said to yourself, "to treat me like a governess, like a servant?" Wounded pride added to jealousy and to the conscious motives of common sense - it was too much. To prove to you how deeply impressed you were by the governess's story, let me draw your attention to the repeated occasions upon which you have identified yourself with her both in your dream and in your conduct. You told your parents what happened - a fact which we have hitherto been unable to account for - just as the governess wrote and told her parents. You give me a fortnight's notice, just like a governess. The letter in the dream which gave you leave to go home is the counterpart of the governess's letter from her parents forbidding her to do so.'
I have been obliged to speak of transference, for it is only by means of this factor that I can elucidate the peculiarities of Dora's analysis. Its great merit, namely, the unusual clarity which makes it seem so suitable as a first introductory publication, is closely bound up with its great defect, which led to its being broken off prematurely. I did not succeed in mastering the transference in good time. Owing to the readiness with which Dora put one part of the pathogenic material at my disposal during the treatment, I neglected the precaution of looking out for the first signs of transference, which was being prepared in connection with another part of the same material a part of which I was in ignorance. At the beginning it was clear that I was replacing her father in her imagination, which was not unlikely, in view of the difference between our ages. She was even constantly comparing me with him consciously, and kept anxiously trying to make sure whether I was being quite straightforward with her, for her father 'always preferred secrecy and roundabout ways'. But when the first dream came, in which she gave herself the warning that she had better leave my treatment just as she had formerly left Herr K.'s house, I ought to have listened to the warning myself. 'Now,' I ought to have said to her, 'it is from Herr K. that you have made a transference on to me. Have you noticed anything that leads you to suspect me of evil intentions similar (whether openly or in some sublimated form) to Herr K.'s? Or have you been struck by anything about me or got to know anything about me which has caught your fancy, as happened previously with Herr K.' Her attention would then have been turned to some detail in our relations, or in my person or circumstances, behind which there lay concealed something analogous but immeasurably more important concerning Herr K. And when this transference had been cleared up, the analysis would have obtained access to new memories, dealing, probably, with actual events. But I was deaf to this first note of warning, thinking I had ample time before me, since no further stages of transference developed and the material for the analysis had not yet run dry. In this way the transference took me unawares, and, because of the unknown quantity in me which reminded Dora of Herr K., she took her revenge on me as she wanted to take her revenge on him, and deserted me as she believed herself to have been deceived and deserted by him. Thus she acted out an essential part of her recollections and phantasies instead of reproducing it in the treatment. What this unknown quantity was I naturally cannot tell. I suspect that it had to do with money, or with jealousy of another patient who had kept up relations with my family after her recovery. When it is possible to work transferences into the analysis at an early stage, the course of the analysis is retarded and obscured, but its existence is better guaranteed against sudden and overwhelming resistances.

³ The longer the interval of time that separates me from the end of this analysis, the more probable it seems to me that the fault in my technique lay in this omission: I failed to discover in time and to inform the patient that her homosexual (gynaecophilic) love for Frau K. was the strongest unconscious current in her mental life. I ought to have guessed that the main source of her knowledge of sexual matters could have been no one but Frau K. - the very person who later on charged her with being interested in those same subjects. Her knowing all about such things and, at the same time, her always pretending not to know where her knowledge came from was really too remarkable. I ought to have attacked this riddle and looked for the motive of such an extraordinary piece of repression. If I had done this, the second dream would have given me my answer. The remorseless craving for revenge expressed in that dream was suited as nothing else was to conceal the current of feeling that ran contrary to it - the magnanimity with which she forgave the treachery of the friend she loved and concealed from every one the fact that it was this friend who had herself revealed to her the knowledge which had later been the ground of the accusations against her. Before I had learnt the importance of the homosexual current of feeling in psychoneurotics, I was often brought to a standstill in the treatment of my cases or found myself in complete perplexity.
Freud has developed on this basis an art of interpretation which takes on the task of, as it were, extracting the pure metal of the repressed thoughts from the ore of the unintentional ideas. This work of interpretation is applied not only to the patient's ideas but also to his dreams, which open up the most direct approach to a knowledge of the unconscious, to his unintentional as well as to his purposeless actions (symptomatic acts) and to the blunders he makes in everyday life (slips of the tongue, bungled actions, and so on). The details of this technique of interpretation or translation have not yet been published by Freud. According to indications he has given, they comprise a number of rules, reached empirically, of how the unconscious material may be reconstructed from the associations, directions on how to know what it means when the patient's ideas cease to flow, and experiences of the most important typical resistances that arise in the course of such treatments. A bulky volume called The Interpretation of Dreams, published by Freud in 1900, may be regarded as the forerunner of an initiation into his technique. [1904a, 1558]

The therapeutic procedure remains the same, apart from insignificant modifications, for all the various clinical pictures that may be presented in hysteria, and all forms of obsessional neurosis. This does not imply, however, that it can have an unlimited application. The nature of the psycho-analytic method involves indications and contra-indications with respect to the person to be treated as well as with respect to the clinical picture. Chronic cases of psychoneuroses without any very violent or dangerous symptoms are the most favourable ones for psycho-analysis: thus in the first place every species of obsessional neurosis, obsessive thinking and acting, and cases of hysteria in which phobias and aboulias play the most important part; further, all somatic expressions of hysteria whenever they do not, as in anorexia, require the physician to attend promptly to the speedy removal of symptoms. In acute cases of hysteria it will be necessary to wait for a calmer stage; in all cases where nervous exhaustion dominates the clinical picture a treatment which in itself demands effort, brings only slow improvement and for a time cannot take the persistence of the symptoms into account, will have to be avoided. [1904a, 1559]

In psycho-analytic treatment it is very important to be prepared for a symptom's having a bisexual meaning. We need not then be surprised or misled if a symptom seems to persist undiminished although we have already resolved one of its sexual meanings; for it is still being maintained by the - perhaps unsuspected - one belonging to the opposite sex. In the treatment of such cases, moreover, one may observe how the patient avails himself, during the analysis of the one sexual meaning, of the convenient possibility of constantly switching his associations, as though on to an adjoining track, into the field of the contrary meaning. [1908a, 1939]

¹ In point of fact there was nothing more to be got out of it than Hans's verbal association, and this had escaped his father. Here is a good instance of conditions under which an analyst's efforts are wasted. [1909b, 2048]
At this point I must put in a few words. Hans's father was asking too many questions, and was pressing the inquiry along his own lines instead of allowing the little boy to express his thoughts. For this reason the analysis began to be obscure and uncertain. Hans went his own way and would produce nothing if attempts were made to draw him off it. For the moment his interest was evidently centred upon lumf and widdle, but we cannot tell why. Just as little satisfactory light was thrown upon the business of the row as upon that of the yellow and black drawers. I suspect that the boy's sharp ears had clearly detected the difference between the sounds made by a man micturating and a woman. The analysis succeeded in forcing the material somewhat artificially into an expression of the distinction between the two different calls of nature. I can only advise those of my readers who have not as yet themselves conducted an analysis not to try to understand everything at once, but to give a kind of unbiased attention to every point that arises and to await further developments.

[1909b, 2052]

Hans was now beginning to bring fuel to the analysis in the shape of spontaneous utterances of his own. This remark of his established the connection between his two last phantasies - that of the plumber who unscrewed the bath and that of the unsuccessful journey to Gmunden. His father had correctly inferred from the latter that Hans had some aversion to Gmunden. This, by the way, is another good reminder of the fact that what emerges from the unconscious is to be understood in the light not of what goes before but of what comes after.

[1909b, 2054]

¹ Well done, little Hans! I could wish for no better understanding of psycho-analysis from any grown-up.

[1909b, 2059]

Immediately after the giraffe story Hans produced two minor phantasies: one of his forcing his way into a forbidden space at Schönbrunn, and the other of his smashing a railway-carriage window on the Stadtbahn. In each case the punishable nature of the action was emphasized, and in each his father appeared as an accomplice. Unluckily his father failed to interpret either of these phantasies, so that Hans himself gained nothing from telling them. In an analysis, however, a thing which has not been understood inevitably reappears; like an unlaid ghost, it cannot rest until the mystery has been solved and the spell broken.

[1909b, 2104]

It not at all infrequently happens that it is only after doing a certain amount of psycho-analytic work with a patient that an analyst can succeed in learning the actual content of a phobia, the precise form of words of an obsessional impulse, and so on. Repression has not only descended upon the unconscious complexes, but it is continually attacking their derivatives as well, and even prevents the patient from becoming aware of the products of the disease itself. The analyst thus finds himself in the position, curious for a doctor, of coming to the help of a disease, and of procuring it its due of attention. But only those who entirely misunderstand the nature of psycho-analysis will lay stress upon this phase of the work and suppose that on its account harm is likely to be done by analysis. The fact is that you must catch your thief before you can hang him, and that it requires some expenditure of labour to get securely hold of the pathological structures - at the destruction of which the treatment is aimed.

[1909b, 2106]

While the analysis of a case is in progress it is impossible to obtain any clear impression of the structure and development of the neurosis. That is the business of a synthetic process which must be performed subsequently. In attempting to carry out such a synthesis of little Hans's phobia we shall take as our basis the account of his mental constitution, of his governing sexual wishes, and of his experiences up to the time of his sister's birth, which we have given in an earlier part of this paper.

[1909b, 2112]
In other cases of this kind there would be a great deal more to be said upon the structure, the development, and the diffusion of the neurosis. But the history of little Hans's attack was very short; almost as soon as it had begun, its place was taken by the history of its treatment. And although during the treatment the phobia appeared to develop further and to extend over new objects and to lay down new conditions, his father, since he was himself treating the case, naturally had sufficient penetration to see that it was merely a question of the emergence of material that was already in existence, and not of fresh productions for which the treatment might be held responsible. In the treatment of other cases it would not always be possible to count upon so much penetration.

[1909b, 2116]

¹ Dr. Alfred Adler, who was formerly an analyst, once drew attention in a privately delivered paper to the peculiar importance which attaches to the very first communications made by patients. Here is an instance of this. The patient's opening words laid stress upon the influence exercised over him by men, that is to say, upon the part played in his life by homosexual object-choice; but immediately afterwards they touched upon a second motif, which was to become of great importance later on, namely, the conflict between man and woman and the opposition of their interests. Even the fact that he remembered his first pretty governess by her surname, which happened to be a man's first name, must be taken into account in this connection. In middle-class circles in Vienna it is more usual to call a governess by her first name, and it is by that name that she is more commonly remembered.

[1909d, 2131]

The reader must not expect to hear at once what light I have to throw upon the patient's strange and senseless obsessions about the rats. The true technique of psycho-analysis requires the physician to suppress his curiosity and leaves the patient complete freedom in choosing the order in which topics shall succeed each other during the treatment. At the fourth session, accordingly, I received the patient with the question: 'And how do you intend to proceed to-day?'

[1909d, 2142]
He admitted that all of this sounded quite plausible, but he was naturally not in the very least convinced by it. He would venture to ask, he said, how it was that an idea of this kind could have remissions, how it could appear for a moment when he was twelve years old, and again when he was twenty, and then once more two years later, this time for good. He could not believe that his hostility had been extinguished in the intervals, and yet during them there had been no sign of self-reproaches. - To this I replied that whenever any one asked a question like that, he was already prepared with an answer; he needed only to be encouraged to go on talking. - He then proceeded, somewhat disconnectedly as it seemed, to say that he had been his father's best friend, and that his father had been his. Except on a few subjects, upon which fathers and sons usually hold aloof from one another - (What could he mean by that?) -, there had been a greater intimacy between them than there now was between him and his best friend. As regards the lady for whose sake he had sacrificed his father in that idea of his, it was true that he had loved her very much, but he had never felt really sensual wishes towards her, such as he had constantly had in his childhood. Altogether, in his childhood his sensual impulses had been much stronger than during his puberty. - At this I told him I thought he had now produced the answer we were waiting for, and had at the same time discovered the third great characteristic of the unconscious. The source from which his hostility to his father derived its indestructibility was evidently something in the nature of sensual desires, and in that connection he must have felt his father as in some way or other an interference. A conflict of this kind, I added, between sensuality and childish love was entirely typical. The remissions he had spoken of had occurred because the premature explosion of his sensual feelings had had as its immediate consequence a considerable diminution of their violence. It was not until he was once more seized with intense erotic desires that his hostility reappeared again owing to the revival of the old situation. I then got him to agree that I had not led him on to the subject either of childhood or of sex, but that he had raised them both of his own free will. - He then went on to ask why he had not simply come to a decision, at the time he was in love with the lady, that his father's interference with that love could not for a moment weigh against his love of his father. - I replied that it was scarcely possible to destroy a person in absentia. Such a decision would only have been possible if the wish that he took objection to had made its first appearance on that occasion; whereas, as a matter of fact, it was a long-repressed wish, towards which he could not behave otherwise than he had formerly done, and which was consequently immune from destruction. This wish (to get rid of his father as being an interference) must have originated at a time when circumstances had been very different - at a time, perhaps, when he had not loved his father more than the person whom he desired sensually, or when he was incapable of making a clear decision. It must have been in his very early childhood, therefore, before he had reached the age of six, and before the date at which his memory became continuous; and things must have remained in the same state ever since. - With this piece of construction our discussion was broken off for the time being.

[1909d, 2145]
In psycho-analyses we frequently come across occurrences of this kind, dating back to the earliest years of the patient's childhood, in which his infantile sexual activity appears to reach its climax and often comes to a catastrophic end owing to some misfortune or punishment. Such occurrences are apt to appear in a shadowy way in dreams. Often they will become so clear that the analyst thinks he has a firm hold of them, and will nevertheless evade any final elucidation; and unless he proceeds with the greatest skill and caution he may be compelled to leave it undecided whether the scene in question actually took place or not. It will help to put us upon the right track in interpreting it, if we recognize that more than one version of the scene (each often differing greatly from the other) may be detected in the patient's unconscious phantasies. If we do not wish to go astray in our judgement of their historical reality, we must above all bear in mind that people's 'childhood memories' are only consolidated at a later period, usually at the age of puberty; and that this involves a complicated process of remodelling, analogous in every way to the process by which a nation constructs legends about its early history. It at once becomes evident that in his phantasies about his infancy the individual as he grows up strives to efface the recollection of his auto-erotic activities; and this he does by exalting their memory-traces to the level of object-love, just as a real historian will view the past in the light of the present. This explains why these phantasies abound in seductions and assaults, where the facts will have been confined to auto-erotic activities and the caresses or punishments that stimulated them. Furthermore, it becomes clear that in constructing phantasies about his childhood the individual sexualizes his memories; that is, he brings commonplace experiences into relation with his sexual activity, and extends his sexual interest to them - though in doing this he is probably following upon the traces of a really existing connection. No one who remembers my 'Analysis of a Phobia in a Five-Year-Old Boy' will need to be told that it is not my intention in these remarks to detract from the importance which I have hitherto attached to infantile sexuality by reducing it to nothing more than sexual interest at the age of puberty. I merely wish to give some technical advice that may help to clear up a class of phantasy which is calculated to falsify the picture of infantile sexual activity.

Every one of you will know from his own experience what a very different attitude he has towards a new case of illness when once he has thoroughly grasped the structure of a few typical cases. Imagine that we had arrived at a succinct formula of the factors regularly concerned in constructing the various forms of neuroses, as we have so far succeeded in doing for the construction of hysterical symptoms, and consider how firmly it would establish our prognostic judgement! Just as an obstetrician can tell by examining the placenta whether it has been completely expelled or whether noxious fragments of it still remain, so should we, independently of the outcome and of the patient's condition at the moment, be able to say whether our work had been definitely successful or whether we had to expect relapses and fresh onsets of illness.

Let us suppose, therefore, that her doctor spoke to the patient exactly as she reported. Everyone will at once bring us the criticism that if a physician thinks it necessary to discuss the question of sexuality with a woman he must do so with tact and consideration. Compliance with this demand, however, coincides with carrying out certain technical rules of psycho-analysis. Moreover, the physician in question was ignorant of a number of the scientific theories of psycho-analysis or had misapprehended them, and thus showed how little he had penetrated into an understanding of its nature and purposes.

Since, however, psycho-analysis cannot dispense with giving this information, it lays down that this shall not be done before two conditions have been fulfilled. First, the patient must, through preparation, himself have reached the neighbourhood of what he has repressed, and secondly, he must have formed a sufficient attachment (transference) to the physician for his emotional relationship to him to make a fresh flight impossible.
Only when these conditions have been fulfilled is it possible to recognize and to master the resistances which have led to the repression and the ignorance. Psycho-analytic intervention, therefore, absolutely requires a fairly long period of contact with the patient. Attempts to 'rush' him at first consultation, by brusquely telling him the secrets which have been discovered by the physician, are technically objectionable. And they mostly bring their own punishment by inspiring a hearty enmity towards the physician on the patient's part and cutting him off from having any further influence.

Besides all this, one may sometimes make a wrong surmise, and one is never in a position to discover the whole truth. Psycho-analysis provides these definite technical rules to replace the indefinable 'medical tact' which is looked upon as some special gift.

Anyone coming from dream-interpretation to analytic practice will retain his interest in the content of dreams, and his inclination will be to interpret as fully as possible every dream related by the patient. But he will soon remark that he is now working under quite different conditions, and that if he attempts to carry out his intention he will come into collision with the most immediate tasks of the treatment. Even if a patient's first dream proves to be admirably suited for the introduction of the first explanations to be given, other dreams will promptly appear, so long and so obscure that the full meaning cannot be extracted from them in the limited session of one day's work. If the doctor continues the work of interpretation during the following days, fresh dreams will be produced in the meantime and these will have to be put aside until he can regard the first dream as finally resolved. The production of dreams is at times so copious, and the patient's progress towards comprehension of them so hesitant, that a suspicion will force itself on the analyst that the appearance of the material in this manner may be simply a manifestation of the patient's resistance taking advantage of the discovery that the method is unable to master what is so presented. Moreover, the treatment will meanwhile have fallen quite a distance behind the present and have lost touch with actuality. In opposition to such a technique stands the rule that it is of the greatest importance for the treatment that the analyst should always be aware of the surface of the patient's mind at any given moment, that he should know what complexes and resistances are active in him at the time and what conscious reaction to them will govern his behaviour. It is scarcely ever right to sacrifice this therapeutic aim to an interest in dream-interpretation.

[1910k, 2379]

[1911e, 2450]
What then, if we bear this rule in mind, is to be our attitude to interpreting dreams in analysis? More or less as follows: The amount of interpretation which can be achieved in one session should be taken as sufficient and it is not to be regarded as a loss if the content of the dream is not fully discovered. On the following day, the interpretation of the dream is not to be taken up again as a matter of course, until it has become evident that nothing else has meanwhile forced its way into the foreground of the patient's thoughts. Thus no exception in favour of an interrupted dream-interpretation is to be made to the rule that the first thing that comes into the patient's head is the first thing to be dealt with. If fresh dreams occur before the earlier ones have been disposed of, the more recent productions are to be attended to, and no uneasiness need be felt about neglecting the older ones. If the dreams become altogether too diffuse and voluminous, all hope of completely unravelling them should tacitly be given up from the start. One must in general guard against displaying very special interest in the interpretation of dreams, or arousing an idea in the patient that the work would come to a standstill if he were to bring up no dreams; otherwise there is a danger of the resistance being directed to the production of dreams, with a consequent cessation of them. The patient must be brought to believe, on the contrary, that the analysis invariably finds material for its continuation, regardless of whether or no he brings up dreams or what amount of attention is devoted to them.

[1911e, 2451]

It will now be asked whether we shall not be giving up too much valuable material which might throw light on the unconscious if dream-interpretation is only to be carried out subject to such restrictions of method. The answer to this is that the loss is by no means so great as might appear from a superficial view of the matter. To begin with, it must be recognized that in cases of severe neurosis any elaborate dream-productions must from the nature of things be regarded as incapable of complete solution. A dream of this kind is often based on the entire pathogenic material of the case, as yet unknown to both doctor and patient (so called 'programme-dreams' and biographical dreams), and is sometimes equivalent to a translation into dream-language of the whole content of the neurosis. In the attempt to interpret such a dream all the latent, as yet untouched, resistances will be roused to activity and soon set a limit to its understanding. The full interpretation of such a dream will coincide with the completion of the whole analysis; if a note is made of it at the beginning, it may be possible to understand it at the end, many months later. It is the same as with the elucidation of a single symptom (the main symptom, perhaps). The whole analysis is needed to explain it; in the course of the treatment one must endeavour to lay hold first of this, then of that, fragment of the symptom's meaning, one after another, until they can all be pieced together. Similarly, no more can be expected of a dream occurring in the early stages of the analysis; one must be content if the attempt at interpretation brings a single pathogenic wishful impulse to light.

[1911e, 2451]
There would be nothing more to discuss or worry about in this behaviour of transference, if it were not that two points remain unexplained about it which are of particular interest to psycho-analysis. Firstly, we do not understand why transference is so much more intense with neurotic subjects in analysis than it is with other such people who are not being analysed; and secondly, it remains a puzzle why in analysis transference emerges as the most powerful resistance to the treatment, whereas outside analysis it must be regarded as the vehicle of cure and the condition of success. For our experience has shown us - and the fact can be confirmed as often as we please - that if a patient's free associations fail¹ the stoppage can invariably be removed by an assurance that he is being dominated at the moment by an association which is concerned with the doctor himself or with something connected with him. As soon as this explanation is given, the stoppage is removed, or the situation is changed from one in which the associations fail into one in which they are being kept back. At first sight it appears to be an immense disadvantage in psycho-analysis as a method that what is elsewhere the strongest factor towards success is changed in it into the most powerful medium of resistance. If, however, we examine the situation more closely, we can at least clear away the first of our two problems. It is not a fact that transference emerges with greater intensity and lack of restraint during psycho-analysis than outside it. In institutions in which nerve patients are treated non-analytically, we can observe transference occurring with the greatest intensity and in the most unworthy forms, extending to nothing less than mental bondage, and moreover showing the plainest erotic colouring. Gabriele Reuter, with her sharp powers of observation, described this at a time when there was no such thing as psycho-analysis, in a remarkable book which betrays in every respect the clearest insight into the nature and genesis of neuroses.² These characteristics of transference are therefore to be attributed not to psycho-analysis but to neurosis itself.

The technical rules which I am putting forward here have been arrived at from my own experience in the course of many years after unfortunate results had led me to abandon other methods. It will easily be seen that they (or at least many of them) may be summed up in a single precept. My hope is that observance of them will spare physicians practising analysis much unnecessary effort and guard them against some oversights. I must however make it clear that what I am asserting is that this technique is the only one suited to my individuality; I do not venture to deny that a physician quite differently constituted might find himself driven to adopt a different attitude to his patients and to the task before him.

(a) The first problem confronting an analyst who is treating more than one patient in the day will seem to him the hardest. It is the task of keeping in mind all the innumerable names, dates, detailed memories and pathological products which each patient communicates in the course of months and years of treatment, and of not confusing them with similar material produced by other patients under treatment simultaneously or previously. If one is required to analyse six, eight, or even more patients daily, the feat of memory involved in achieving this will provoke incredulity, astonishment or even commiseration in uninformed observers. Curiosity will in any case be felt about the technique which makes it possible to master such an abundance of material, and the expectation will be that some special expedients are required for the purpose.

¹ [1912b, 2458]
² [1912e, 2467]
The technique, however, is a very simple one. As we shall see, it rejects the use of any special expedient (even that of taking notes). It consists simply in not directing one’s notice to anything in particular and in maintaining the same 'evenly-suspended attention' (as I have called it) in the face of all that one hears. In this way we spare ourselves a strain on our attention which could not in any case be kept up for several hours daily, and we avoid a danger which is inseparable from the exercise of deliberate attention. For as soon as anyone deliberately concentrates his attention to a certain degree, he begins to select from the material before him; one point will be fixed in his mind with particular clearness and some other will be correspondingly disregarded, and in making this selection he will be following his expectations or inclinations. This, however, is precisely what must not be done. In making the selection, if he follows his expectations he is in danger of never finding anything but what he already knows; and if he follows his inclinations he will certainly falsify what he may perceive. It must not be forgotten that the things one hears are for the most part things whose meaning is only recognized later on.

[1912e, 2467]

It will be seen that the rule of giving equal notice to everything is the necessary counterpart to the demand made on the patient that he should communicate everything that occurs to him without criticism or selection. If the doctor behaves otherwise, he is throwing away most of the advantage which results from the patient's obeying the 'fundamental rule of psycho- analysis'. The rule for the doctor may be expressed: 'He should withhold all conscious influences from his capacity to attend, and give himself over completely to his "unconscious memory".' Or, to put it purely in terms of technique: 'He should simply listen, and not bother about whether he is keeping anything in mind.'

[1912e, 2468]

What is achieved in this manner will be sufficient for all requirements during the treatment. Those elements of the material which already form a connected context will be at the doctor's conscious disposal; the rest, as yet unconnected and in chaotic disorder, seems at first to be submerged, but rises readily into recollection as soon as the patient brings up something new to which it can be related and by which it can be continued. The undeserved compliment of having 'a remarkably good memory' which the patient pays one when one reproduces some detail after a year and a day can then be accepted with a smile, whereas a conscious determination to recollect the point would probably have resulted in failure. Mistakes in this process of remembering occur only at times and places at which one is disturbed by some personal consideration (see below) - that is, when one has fallen seriously below the standard of an ideal analyst. Confusion with material brought up by other patients occurs very rarely. Where there is a dispute with the patient as to whether or how he has said some particular thing, the doctor is usually in the right.

[1912e, 2468]

¹ A patient will often assert that he has already told the doctor something on a previous occasion, while the doctor can assure him with a quiet feeling of superiority that it has come up now for the first time. It then turns out that the patient had previously had the intention of saying it, but had been prevented from performing his intention by a resistance which was still present. His recollection of his intention is indistinguishable to him from a recollection of its performance.

[1912e, 2468]
(b) I cannot advise the taking of full notes, the keeping of a shorthand record, etc., during analytic sessions. Apart from the unfavourable impression which this makes on some patients, the same considerations as have been advanced with regard to attention apply here too. A detrimental selection from the material will necessarily be made as one writes the notes or shorthand, and part of one’s own mental activity is tied up in this way, which would be better employed in interpreting what one has heard. No objection can be raised to making exceptions to this rule in the case of dates, the text of dreams, or particular noteworthy events which can easily be detached from their context and are suitable for independent use as instances. But I am not in the habit of doing this either. As regards instances, I write them down from memory in the evening after work is over; as regards texts of dreams to which I attach importance, I get the patient to repeat them to me after he has related them so that I can fix them in my mind.

[1912e, 2469]

(c) Taking notes during the session with the patient might be justified by an intention of publishing a scientific study of the case. On general grounds this can scarcely be denied. Nevertheless it must be borne in mind that exact reports of analytic case histories are of less value than might be expected. Strictly speaking, they only possess the ostensible exactness of which ‘modern’ psychiatry affords us some striking examples. They are, as a rule, fatiguing to the reader and yet do not succeed in being a substitute for his actual presence at an analysis. Experience invariably shows that if readers are willing to believe an analyst they will have confidence in any slight revision to which he has submitted his material; if, on the other hand, they are unwilling to take analysis and the analyst seriously, they will pay no attention to accurate verbatim records of the treatment either. This is not the way, it seems, to remedy the lack of convincing evidence to be found in psycho-analytic reports.

[1912e, 2469]

(d) One of the claims of psycho-analysis to distinction is, no doubt, that in its execution research and treatment coincide; nevertheless, after a certain point, the technique required for the one opposes that required for the other. It is not a good thing to work on a case scientifically while treatment is still proceeding - to piece together its structure, to try to foretell its further progress, and to get a picture from time to time of the current state of affairs, as scientific interest would demand. Cases which are devoted from the first to scientific purposes and are treated accordingly suffer in their outcome; while the most successful cases are those in which one proceeds, as it were, without any purpose in view, allows oneself to be taken by surprise by any new turn in them, and always meets them with an open mind, free from any presuppositions. The correct behaviour for an analyst lies in swinging over according to need from the one mental attitude to the other, in avoiding speculation or brooding over cases while they are in analysis, and in submitting the material obtained to a synthetic process of thought only after the analysis is concluded. The distinction between the two attitudes would be meaningless if we already possessed all the knowledge (or at least the essential knowledge) about the psychology of the unconscious and about the structure of the neuroses that we can obtain from psycho-analytic work. At present we are still far from that goal and we ought not to cut ourselves off from the possibility of testing what we have already learnt and of extending our knowledge further.

[1912e, 2469]
(e) I cannot advise my colleagues too urgently to model themselves during psycho-analytic treatment on the surgeon, who puts aside all his feelings, even his human sympathy, and concentrates his mental forces on the simple aim of performing the operation as skilfully as possible. Under present-day conditions the feeling that is most dangerous to a psycho-analyst is the therapeutic ambition to achieve by this novel and much disputed method something that will produce a convincing effect upon other people. This will not only put him into a state of mind which is unfavourable for his work, but will make him helpless against certain resistances of the patient, whose recovery, as we know, primarily depends on the interplay of forces in him. The justification for requiring this emotional coldness in the analyst is that it creates the most advantageous conditions for both parties: for the doctor a desirable protection for his own emotional life and for the patient the largest amount of help that we can give him to-day. A surgeon of earlier times took as his motto the words: 'Je le pansai, Dieu le guérit.'¹ The analyst should be content with something similar.

(f) It is easy to see upon what aim the different rules I have brought forward converge. They are all intended to create for the doctor a counterpart to the 'fundamental rule of psycho-analysis' which is laid down for the patient. Just as the patient must relate everything that his self-observation can detect, and keep back all the logical and affective objections that seek to induce him to make a selection from among them, so the doctor must put himself in a position to make use of everything he is told for the purposes of interpretation and of recognizing the concealed unconscious material without substituting a censorship of his own for the selection that the patient has forgone. To put it in a formula: he must turn his own unconscious like a receptive organ towards the transmitting unconscious of the patient. He must adjust himself to the patient as a telephone receiver is adjusted to the transmitting microphone. Just as the receiver converts back into sound waves the electric oscillations in the telephone line which were set up by sound waves, so the doctor's unconscious is able, from the derivatives of the unconscious which are communicated to him, to reconstruct that unconscious, which has determined the patient's free associations.

But if the doctor is to be in a position to use his unconscious in this way as an instrument in the analysis, he must himself fulfil one psychological condition to a high degree. He may not tolerate any resistances in himself which hold back from his consciousness what has been perceived by his unconscious; otherwise he would introduce into the analysis a new species of selection and distortion which would be far more detrimental than that resulting from concentration of conscious attention. It is not enough for this that he himself should be an approximately normal person. It may be insisted, rather, that he should have undergone a psycho-analytic purification and have become aware of those complexes of his own which would be apt to interfere with his grasp of what the patient tells him. There can be no reasonable doubt about the disqualifying effect of such defects in the doctor; every unresolved repression in him constitutes what has been aptly described by Stekel as a 'blind spot' in his analytic perception.

(g) I shall now add a few other rules, that will serve as a transition from the attitude of the doctor to the treatment of the patient.
Young and eager psycho-analysts will no doubt be tempted to bring their own individuality freely into the discussion, in order to carry the patient along with them and lift him over the barriers of his own narrow personality. It might be expected that it would be quite allowable and indeed useful, with a view to overcoming the patient's existing resistances, for the doctor to afford him a glimpse of his own mental defects and conflicts and, by giving him intimate information about his own life, enable him to put himself on an equal footing. One confidence deserves another, and anyone who demands intimacy from someone else must be prepared to give it in return.

[1912e, 2472]

But in psycho-analytic relations things often happen differently from what the psychology of consciousness might lead us to expect. Experience does not speak in favour of an affective technique of this kind. Nor is it hard to see that it involves a departure from psycho-analytic principles and verges upon treatment by suggestion. It may induce the patient to bring forward sooner and with less difficulty things he already knows but would otherwise have kept back for a time through conventional resistances. But this technique achieves nothing towards the uncovering of what is unconscious to the patient. It makes him even more incapable of overcoming his deeper resistances, and in severer cases it invariably fails by encouraging the patient to be insatiable: he would like to reverse the situation, and finds the analysis of the doctor more interesting than his own. The resolution of the transference, too - one of the main tasks of the treatment - is made more difficult by an intimate attitude on the doctor's part, so that any gain there may be at the beginning is more than outweighed at the end. I have no hesitation, therefore, in condemning this kind of technique as incorrect. The doctor should be opaque to his patients and, like a mirror, should show them nothing but what is shown to him. In practice, it is true, there is nothing to be said against a psychotherapist combining a certain amount of analysis with some suggestive influence in order to achieve a perceptible result in a shorter time - as is necessary, for instance, in institutions. But one has a right to insist that he himself should be in no doubt about what he is doing and should know that his method is not that of true psycho-analysis.

[1912e, 2472]

(h) Another temptation arises out of the educative activity which, in psycho-analytic treatment, devolves on the doctor without any deliberate intention on his part. When the developmental inhibitions are resolved, it happens of itself that the doctor finds himself in a position to indicate new aims for the trends that have been liberated. It is then no more than a natural ambition if he endeavours to make something specially excellent of a person whom he has been at such pains to free from his neurosis and if he prescribes high aims for his wishes. But here again the doctor should hold himself in check, and take the patient's capacities rather than his own desires as guide. Not every neurotic has a high talent for sublimation; one can assume of many of them that they would not have fallen ill at all if they had possessed the art of sublimating their instincts. If we press them unduly towards sublimation and cut them off from the most accessible and convenient instinctual satisfactions, we shall usually make life even harder for them than they feel it in any case. As a doctor, one must above all be tolerant to the weakness of a patient, and must be content if one has won back some degree of capacity for work and enjoyment for a person even of only moderate worth. Educative ambition is of as little use as therapeutic ambition. It must further be borne in mind that many people fall ill precisely from an attempt to sublimate their instincts beyond the degree permitted by their organization and that in those who have a capacity for sublimation the process usually takes place of itself as soon as their inhibitions have been overcome by analysis. In my opinion, therefore, efforts invariably to make use of the analytic treatment to bring about sublimation of instinct are, though no doubt always laudable, far from being in every case advisable.

[1912e, 2473]
(i) To what extent should the patient's intellectual co-operation be sought for in the treatment? It is difficult to say anything of general applicability on this point: the patient's personality is the determining factor. But in any case caution and self-restraint must be observed in this connection. It is wrong to set a patient tasks, such as collecting his memories or thinking over some particular period of his life. On the contrary, he has to learn above all - what never comes easily to anyone - that mental activities such as thinking something over or concentrating the attention solve none of the riddles of a neurosis; that can only be done by patiently obeying the psycho-analytic rule, which enjoins the exclusion of all criticism of the unconscious or of its derivatives. One must be especially unyielding about obedience to that rule with patients who practise the art of sheering off into intellectual discussion during their treatment, who speculate a great deal and often very wisely about their condition and in that way avoid doing anything to overcome it. For this reason I dislike making use of analytic writings as an assistance to my patients; I require them to learn by personal experience, and I assure them that they will acquire wider and more valuable knowledge than the whole literature of psycho-analysis could teach them. I recognize, however, that under institutional conditions it may be of great advantage to employ reading as a preparation for patients in analysis and as a means of creating an atmosphere of influence.

[1912e, 2474]

I must give a most earnest warning against any attempt to gain the confidence or support of parents or relatives by giving them psycho-analytic books to read, whether of an introductory or an advanced kind. This well-meant step usually has the effect of bringing on prematurely the natural opposition of the relatives to the treatment - an opposition which is bound to appear sooner or later - so that the treatment is never ever begun.

[1912e, 2474]

Let me express a hope that the increasing experience of psycho-analysts will soon lead to agreement on questions of technique and on the most effective method of treating neurotic patients. As regards the treatment of their relatives I must confess myself utterly at a loss, and I have in general little faith in any individual treatment of them.

[1912e, 2474]

Anyone who hopes to learn the noble game of chess from book will soon discover that only the openings and end-games admit of an exhaustive systematic presentation and that the infinite variety of moves which develop after the opening defy any such description. This gap in instruction can only be filled by a diligent study of games fought out by masters. The rules which can be laid down for the practice of psycho-analytic treatment are subject to similar limitations.

[1913c, 2477]

In what follows I shall endeavour to collect together for the use of practising analysts some of the rules for the beginning of the treatment. Among them there are some which may seem to be petty details, as, indeed, they are. Their justification is that they are simply rules of the game which acquire their importance from their relation to the general plan of the game. I think I am well-advised, however, to call these rules 'recommendations' and not to claim any unconditional acceptance for them. The extraordinary diversity of the psychical constellations concerned, the plasticity of all mental processes and the wealth of determining factors oppose any mechanization of the technique; and they bring it about that a course of action that is as a rule justified may at times prove ineffective, whilst one that is usually mistaken may once in a while lead to the desired end. These circumstances, however, do not prevent us from laying down a procedure for the physician which is effective on the average.

[1913c, 2477]
Some years ago I set out the most important indications for selecting patients¹ and I shall therefore not repeat them here. They have in the meantime been approved by other psychoanalysts. But I may add that since then I have made it my habit, when I know little about a patient, only to take him on at first provisionally, for a period of one to two weeks. If one breaks off within this period one spares the patient the distressing impression of an attempted cure having failed. One has only been undertaking a 'sounding' in order to get to know the case and to decide whether it is a suitable one for psycho-analysis. No other kind of preliminary examination but this procedure is at our disposal; the most lengthy discussions and questionings in ordinary consultations would offer no substitute. This preliminary experiment, however, is itself the beginning of a psycho-analysis and must conform to its rules. There may perhaps be this distinction made, that in it one lets the patient do nearly all the talking and explains nothing more than what is absolutely necessary to get him to go on with what he is saying.

There are also diagnostic reasons for beginning the treatment with a trial period of this sort lasting for one or two weeks. Often enough, when one sees a neurosis with hysterical or obsessional symptoms, which is not excessively marked and has not been in existence for long - just the type of case, that is, that one would regard as suitable for treatment - one has to, reckon with the possibility that it may be a preliminary stage of what is known as dementia praecox ('schizophrenia', in Bleuler's terminology; 'paraphrenia', as I have proposed to call it), and that sooner or later it will show a well-marked picture of that affection. I do not agree that it is always possible to make the distinction so easily. I am aware that there are psychiatrists who hesitate less often in their differential diagnosis, but I have become convinced that just as often they make mistakes. To make a mistake, moreover, is of far greater moment for the psychoanalyst than it is for the clinical psychiatrist, as he is called. For the latter is not attempting to do anything that will be of use, whichever kind of case it may be. He merely runs the risk of making a theoretical mistake, and his diagnosis is of no more than academic interest. Where the psychoanalyst is concerned, however, if the case is unfavourable he has committed a practical error; he has been responsible for wasted expenditure and has discredited his method of treatment. He cannot fulfil his promise of cure if the patient is suffering, not from hysteria or obsessional neurosis, but from paraphrenia, and he therefore has particularly strong motives for avoiding mistakes in diagnosis. In an experimental treatment of a few weeks he will often observe suspicious signs which may determine him not to pursue the attempt any further. Unfortunately I cannot assert that an attempt of this kind always enables us to arrive at a certain decision; it is only one wise precaution the more.

Lengthy preliminary discussions before the beginning of the analytic treatment, previous treatment by another method and also previous acquaintance between the doctor and the patient who is to be analysed, have special disadvantageous consequences for which one must be prepared. They result in the patient's meeting the doctor with a transference attitude which is already established and which the doctor must first slowly uncover instead of having the opportunity to observe the growth and development of the transference from the outset. In this way the patient gains a temporary start upon us which we do not willingly grant him in the treatment.

One must mistrust all prospective patients who want to make a delay before beginning their treatment. Experience show that when the time agreed upon has arrived they fail to put in an appearance, even though the motive for the delay - i.e. their rationalization of their intention - seems to the uninitiated to be above suspicion.
Special difficulties arise when the analyst and his new patient or their families are on terms of friendship or have social ties with one another. The psycho-analyst who is asked to undertake the treatment of the wife or child of a friend must be prepared for it to cost him that friendship, no matter what the outcome of the treatment may be: nevertheless he must make the sacrifice if he cannot find a trustworthy substitute.

Both lay public and doctors - still ready to confuse psycho-analysis with treatment by suggestion - are inclined to attribute great importance to the expectations which the patient brings to the new treatment. They often believe in the case of one patient that he will not give much trouble, because he has great confidence in psycho-analysis and is fully convinced of its truth and efficacy; whereas in the case of another, they think that he will undoubtedly prove more difficult, because he has a sceptical outlook and will not believe anything until he has experienced its successful results on his own person. Actually, however, this attitude on the part of the patient has very little importance. His initial trust or distrust is almost negligible compared with the internal resistances which hold the neurosis firmly in place. It is true that the patient's happy trustfulness makes our earliest relationship with him a very pleasant one; we are grateful to him for that, but we warn him that his favourable prepossession will be shattered by the first difficulty that arises in the analysis. To the sceptic we say that the analysis requires no faith, that he may be as critical and suspicious as he pleases and that we do not regard his attitude as the effect of his judgement at all, for he is not in a position to form a reliable judgement on these matters; his distrust is only a symptom like his other symptoms and it will not be an interference, provided he conscientiously carries out what the rule of the treatment requires of him.

No one who is familiar with the nature of neurosis will be astonished to hear that even a man who is very well able to carry out an analysis on other people can behave like any other mortal and be capable of producing the most intense resistances as soon as he himself becomes the object of analytic investigation. When this happens we are once again reminded of the dimension of depth in the mind, and it does not surprise us to find that the neurosis has its roots in psychical strata to which an intellectual knowledge of analysis has not penetrated.

Points of importance at the beginning of the analysis are arrangements about time and money.
In regard to time, I adhere strictly to the principle of leasing a definite hour. Each patient is allotted a particular hour of my available working day; it belongs to him and he is liable for it, even if he does not make use of it. This arrangement, which is taken as a matter of course for teachers of music or languages in good society, may perhaps seem too rigorous in a doctor, or even unworthy of his profession. There will be an inclination to point to the many accidents which may prevent the patient from attending every day at the same hour and it will be expected that some allowance shall be made for the numerous intercurrent ailments which may occur in the course of a longish analytic treatment. But my answer is: no other way is practicable. Under a less stringent régime the 'occasional' non-attendances increase so greatly that the doctor finds his material existence threatened; whereas when the arrangement is adhered to, it turns out that accidental hindrances do not occur at all and intercurrent illnesses only very seldom. The analyst is hardly ever put in the position of enjoying a leisure hour which he is paid for and would be ashamed of; and he can continue his work without interruptions, and is spared the distressing and bewildering experience of finding that a break for which he cannot blame himself is always bound to happen just when the work promises to be especially important and rich in content. Nothing brings home to one so strongly the significance of the psychogenic factor in the daily life of men, the frequency of malingering and the non-existent of chance, as a few years' practice of psycho-analysis on the strict principle of leasing by the hour. In cases of undoubted organic illnesses, which, after all, cannot be excluded by the patient's having a psychical interest in attending, I break off the treatment, consider myself entitled to dispose elsewhere of the hour which becomes free, and take the patient back again as soon as he has recovered and I have another hour vacant.

I work with my patients every day except on Sundays and public holidays - that is, as a rule, six days a week. For slight cases or the continuation of a treatment which is already well advanced, three days a week will be enough. Any restrictions of time beyond this bring no advantage either to the doctor or the patient; and at the beginning of an analysis they are quite out of the question. Even short interruptions have a slightly, obscuring effect on the work. We used to speak jokingly of the 'Monday crust' when we began work again after the rest on Sunday. When the hours of work are less frequent, there is a risk of not being able to keep pace with the patient's real life and of the treatment losing contact with the present and being forced into by-paths. Occasionally, too, one comes across patients to whom one must give more than the average time of one hour a day, because the best part of an hour is gone before they begin to open up and to become communicative at all.

An unwelcome question which the patient asks the doctor at the outset is: 'How long will the treatment take? How much time will you need to relieve me of my trouble?' If one has proposed a trial treatment of a few weeks one can avoid giving a direct answer to this question by promising to make a more reliable pronouncement at the end of the trial period. Our answer is like the answer given by the Philosopher to the Wayfarer in Aesop's fable. When the Wayfarer asked how long a journey lay ahead, the Philosopher merely answered 'Walk!' and afterwards explained his apparently unhelpful reply on the ground that he must know the length of the Wayfarer's stride before he could tell how long his journey would take. This expedient helps one over the first difficulties; but the comparison is not a good one, for the neurotic can easily alter his pace and may at times make only very slow progress. In point of fact, the question as to the probable duration of a treatment is almost unanswerable.
To speak more plainly, psycho-analysis is always a matter of long periods of time, of half a year or whole years - of longer periods than the patient expects. It is therefore our duty to tell the patient this before he finally decides upon the treatment. I consider it altogether more honourable, and also more expedient, to draw his attention - without trying to frighten him off, but at the very beginning - to the difficulties and sacrifices which analytic treatment involves, and in this way to deprive him of any right to say later on that he has been inveigled into a treatment whose extent and implications he did not realize. A patient who lets himself be dissuaded by this information would in any case have shown himself unsuitable later on. It is a good thing to institute a selection of this kind before the beginning of the treatment. With the progress of understanding among patients the number of those who successfully meet this first test increases.

[1913c, 2482]

I do not bind patients to continue the treatment for a certain length of time; I allow each one to break off whenever he likes. But I do not hide it from him that if the treatment is stopped after only a small amount of work has been done it will not be successful and may easily, like an unfinished operation, leave him in an unsatisfactory state. In the early years of my psycho-analytic practice I used to have the greatest difficulty in prevailing on my patients to continue their analysis. This difficulty has long since been shifted, and I now have to take the greatest pains to induce them to give it up.

[1913c, 2482]

The next point that must be decided at the beginning of the treatment is the one of money, of the doctor's fee. An analyst does not dispute that money is to be regarded in the first instance as a medium for self-preservation and for obtaining power; but he maintains that, besides this, powerful sexual factors are involved in the value set upon it. He can point out the money matters are treated by civilized people in the same way as sexual matters - with the same inconsistency, prudishness and hypocrisy. The analyst is therefore determined from the first not to fall in with this attitude, but, in his dealings with his patients, to treat of money matters with the same matter-of-course frankness to which he wishes to educate them in things relating to sexual life. He shows them that he himself has cast off false shame on these topics, by voluntarily telling them the price at which he values his time. Ordinary good sense cautions him, furthermore, not to allow large sums of money to accumulate, but to ask for payment at fairly short regular intervals - monthly, perhaps. (It is a familiar fact that the value of the treatment is not enhanced in the patient's eyes if a very low fee is asked.) This is, of course, not the usual practice of nerve specialists or other physicians in our European society. But the psycho-analyst may put himself in the position of a surgeon, who is frank and expensive because he has at his disposal methods of treatment which can be of use. It seems to me more respectable and ethically less objectionable to acknowledge one's actual claims and needs rather than, as is still the practice among physicians, to act the part of the disinterested philanthropist - a position which one is not, in fact, able to fill, with the result that one is secretly aggrieved, or complains aloud, at the lack of consideration and the desire for exploitation evinced by one's patients. In fixing his fee the analyst must also allow for the fact that, hard as he may work, he can never earn as much as other medical specialists.

[1913c, 2484]
For the same reason he should also refrain from giving treatment free, and make no
exceptions to this in favour of his colleagues or their families. This last recommendation will
seem to offend against professional amenities. It must be remembered, however, that a
gratuitous treatment means much more to a psycho-analyst than to any other medical man; it
means the sacrifice of a considerable portion - an eighth or a seventh part, perhaps - of the
working time available to him for earning his living, over a period of many months. A second
free treatment carried on at the same time would already deprive him of a quarter or a third of
his earning capacity, and this would be comparable to the damage inflicted by a severe
accident.
[1913c, 2485]

The question then arises whether the advantage gained by the patient would not to some
extent counterbalance the sacrifice made by the physician. I may venture to form a judgement
about this, since for ten years or so I set aside one hour a day, and sometimes two, for
gratuitous treatments, because I wanted, in order to find my way about in the neuroses, to work
in the face of as little resistance as possible. The advantages I sought by this means were not
forthcoming. Free treatment enormously increases some of a neurotic's resistances - in young
women, for instance, the temptation which is inherent in their transference-relation, and in
young men, their opposition to an obligation to feel grateful, an opposition which arises from
their father-complex and which presents one of the most troublesome hindrances to the
acceptance of medical help. The absence of the regulating effect offered by the payment of a
fee to the doctor makes itself very painfully felt; the whole relationship is removed from the real
world, and the patient is deprived of a strong motive for endeavouring to bring the treatment to
an end.
[1913c, 2485]

Before I wind up these remarks on beginning analytic treatment, I must say a word about a
certain ceremonial which concerns the position in which the treatment is carried out. I hold to
the plan of getting the patient to lie on a sofa while I sit behind him out of his sight. This
arrangement has a historical basis; it is the remnant of the hypnotic method out of which
psycho-analysis was evolved. But it deserves to be maintained for many reasons. The first is a
personal motive, but one which others may share with me. I cannot put up with being stared at
by other people for eight hours a day (or more). Since, while I am listening to the patient, I, too,
give myself over to the current of my unconscious thoughts, I do not wish my expressions of
face to give the patient material for interpretations or to influence him in what he tells me. The
patient usually regards being made to adopt this position as a hardship and rebels against it,
especially if the instinct for looking (scopophilia) plays an important part in his neurosis. I insist
on this procedure, however, for its purpose and result are to prevent the transference from
mingling with the patient's associations imperceptibly, to isolate the transference and to allow it
to come forward in due course sharply defined as a resistance. I know that many analysts work
in a different way, but I do not know whether this deviation is due more to a craving for doing
things differently or to some advantage which they find they gain by it.
[1913c, 2487]

The conditions of treatment having been regulated in this manner, the question arises at what
point and with what material is the treatment to begin?
[1913c, 2487]

What the material is with which one starts the treatment is on the whole a matter of
indifference - whether it is the patient's life-history or the history of his illness or his recollections
of childhood. But in any case the patient must be left to do the talking and must be free to
choose at what point he shall begin. We therefore say to him: 'Before I can say anything to you I
must know a great deal about you; please tell me what you know about yourself.'
[1913c, 2487]
The only exception to this is in regard to the fundamental rule of psycho-analytic technique which the patient has to observe. This must be imparted to him at the very beginning: 'One more thing before you start. What you tell me must differ in one respect from an ordinary conversation. Ordinarily you rightly try to keep a connecting thread running through your remarks and you exclude any intrusive ideas that may occur to you and any side-issues, so as not to wander too far from the point. But in this case you must proceed differently. You will notice that as you relate things various thoughts will occur to you which you would like to put aside on the ground of certain criticisms and objections. You will be tempted to say to yourself that this or that is irrelevant here, or is quite up important, or nonsensical, so that there is no need to say it. You must never give in to these criticisms, but must say it in spite of them - indeed, you must say it precisely because you feel an aversion to doing so. Later on you will find out and understand the reason for this injunction, which is really the only one you have to follow. So say whatever goes through your mind. Act as though, for instance, you were a traveller sitting next to the window of a railway carriage and describing to someone inside the carriage the changing views which you see outside. Finally, never forget that you have promised to be absolutely honest, and never leave anything out because, for some reason or other, it is unpleasant to tell it.'¹

¹ Much might be said about our experiences with the fundamental rule of psycho-analysis. One occasionally comes across people who behave as if they had made this rule for themselves. Others offend against it from the very beginning. It is indispensable, and also advantageous, to lay down the rule in the first stages of the treatment. Later, under the dominance of the resistances, obedience to it weakens, and there comes a time in every analysis when the patient disregards it. We must remember from our own self-analysis how irresistible the temptation is to yield to these pretexts put forward by critical judgement for rejecting certain ideas. How small is the effect of such agreements as one makes with the patient in laying down the fundamental rule is regularly demonstrated when something intimate about a third person comes up in his mind for the first time. He knows that he is supposed to say everything, but he turns discretion about other people into a new obstacle! 'Must I really say everything? I thought that only applied to things that concern myself.' It is naturally impossible to carry out analysis if the patient's relations with other people and his thoughts about them are excluded. Pour faire une omelette il faut casser des œufs. An honourable man readily forgets such of the private affairs of strangers as do not seem to him important to know. Nor can an exception be made in the case of names. Otherwise the patient's narratives became a little shadowy, like the scenes in Goethe's play Die natürliche Tochter [The Natural Daughter], and do not lodge in the doctor's memory. Moreover, the names that are withheld screen the approach to all sorts of important connections. But one may perhaps allow names to be left on one side until the patient has become more familiar with the doctor and the procedure of analysis. It is very remarkable how the whole task becomes impossible if a reservation is allowed at any single place. But we have only to reflect what would happen if the right of asylum existed at any one point in a town; how long would it be before all the riff-raff of the town had collected there? I once treated a high official who was bound by his oath of office not to communicate certain things because they were state secrets, and the analysis came to grief as a consequence of this restriction. Psycho-analytic treatment must have no regard for any consideration, because the neurosis and its resistances are themselves without any such regard.

Patients who date their illness from a particular moment usually concentrate upon its precipitating cause. Others, who themselves recognize the connection between their neurosis and their childhood, often begin with an account of their whole life-history. A systematic narrative should never be expected and nothing should be done to encourage it. Every detail of the story will have to be told afresh later on, and it is only with these repetitions that additional material will appear which will supply the important connections that are unknown to the patient.

[1913c, 2488]
There are patients who from the very first hours carefully prepare what they are going to communicate, ostensibly so as to be sure of making better use of the time devoted to the treatment. What is thus disguising itself as eagerness is resistance. Any preparation of this sort should be disrecommended, for it is only employed to guard against unwelcome thoughts cropping up.¹ However genuinely the patient may believe in his excellent intentions, the resistance will play its part in this deliberate method of preparation and will see to it that the most valuable material escapes communication. One will soon find that the patient devises yet other means by which what is required may be withheld from the treatment. He may talk over the treatment every day with some intimate friend, and bring into this discussion all the thoughts which should come forward in the presence of the doctor. The treatment thus has a leak which lets through precisely what is most valuable. When this happens, the patient must, without much delay, be advised to treat his analysis as a matter between himself and his doctor and to exclude everyone else from sharing in the knowledge of it, no matter how close to him they may be, or how inquisitive. In later stages of the treatment the patient is usually not subjected to temptations of this sort.

[1913c, 2489]

Certain patients want their treatment to be kept secret, often because they have kept their neurosis secret; and I put no obstacle in their way. That in consequence the world hears nothing of some of the most successful cures is, of course, a consideration that cannot be taken into account. It is obvious that a patient's decision in favour of secrecy already reveals a feature of his secret history.

[1913c, 2489]

In advising the patient at the beginning of the treatment to tell as few people as possible about it, we also protect him to some extent from the many hostile influences that will seem to entice him away from analysis. Such influences may be very mischievous at the outset of the treatment; later, they are usually immaterial, or even useful in bringing to the fore resistances which are trying to conceal themselves.

[1913c, 2490]

If during the course of the analysis the patient should temporarily need some other medical or specialist treatment, it is far wiser to call in a non-analytic colleague than to give this other treatment oneself. Combined treatments for neurotic disorders which have a powerful organic basis are nearly always impracticable. The patients withdraw their interest from analysis as soon as they are shown more than one path that promises to lead them to health. The best plan is to postpone the organic treatment until the psychical treatment is finished; if the former were tried first it would in most cases meet with no success.

[1913c, 2490]
To return to the beginning of the treatment. Patients are occasionally met with who start the treatment by assuring us that they cannot think of anything to say, although the whole field of their life-history and the story of their illness is open to them to choose from. Their request that we should tell them what to talk about must not be granted on this first occasion any more than on any later one. We must bear in mind what is involved here. A strong resistance has come to the front in order to defend the neurosis; we must take up the challenge then and there and come to grips with it. Energetic and repeated assurances to the patient that it is impossible for no ideas at all to occur to him at the beginning, and that what is in question is a resistance against the analysis, soon oblige him to make the expected admissions or to uncover a first piece of his complexes. It is a bad sign if he has to confess that while he was listening to the fundamental rule of analysis he made a mental reservation that he would nevertheless keep this or that to himself; it is not so serious if all he has to tell us is how mistrustful he is of analysis or the horrifying things he has heard about it. If he denies these and similar possibilities when they are put before him, he can be driven by our insistence to acknowledge that he has nevertheless overlooked certain thoughts which were occupying his mind. He had thought of the treatment itself, though nothing definite about it, or he had been occupied with the picture of the room in which he was, or he could not help thinking of the objects in the consulting room and of the fact that he was lying here on a sofa - all of which he has replaced by the word 'nothing'. These indications are intelligible enough: everything connected with the present situation represents a transference to the doctor, which proves suitable to serve as a first resistance. We are thus obliged to begin by uncovering this transference; and a path from it will give rapid access to the patient's pathogenic material. Women who are prepared by events in their past history to be subjected to sexual aggression and men with over-strong repressed homosexuality are the most apt thus to withhold the ideas that occur to them at the outset of their analysis.

The patient's first symptoms or chance actions, like his first resistance, may possess a special interest and may betray a complex which governs his neurosis. A clever young philosopher with exquisite aesthetic sensibilities will hasten to put the creases of his trousers straight before lying down for his first hour; he is revealing himself as a former coprophilic of the highest refinement - which was to be expected from the later aesthete. A young girl will at the same juncture hurriedly pull the hem of her skirt over her exposed ankles; in doing this she is giving away the gist of what her analysis will uncover later: her narcissistic pride in her physical beauty and her inclinations to exhibitionism.

A particularly large number of patients object to being asked to lie down, while the doctor sits out of sight behind them. They ask to be allowed to go through the treatment in some other position, for the most part because they are anxious not to be deprived of a view of the doctor. Permission is regularly refused, but one cannot prevent them from contriving to say a few sentences before the beginning of the actual 'session' or after one has signified that it is finished and they have got up from the sofa. In this way they divide the treatment in their own view into an official portion, in which they mostly behave in a very inhibited manner, and an informal 'friendly' portion, in which they speak really freely and say all sorts of things which they themselves do not regard as being part of the treatment. The doctor does not accept this division for long. He takes note of what is said before or after the session and he brings it forward at the first opportunity, thus pulling down the partition which the patient has tried to erect. This partition, once again, will have been put together from the material of a transference-resistance.

[1913c, 2490]
So long as the patient's communications and ideas run on without any obstruction, the theme of transference should be left untouched. One must wait until the transference, which is the most delicate of all procedures, has become a resistance.

[1913c, 2491]

The next question with which we are faced raises a matter of principle. It is this: When are we to begin making our communications to the patient? When is the moment for disclosing to him the hidden meaning of the ideas that occur to him, and for initiating him into the postulates and technical procedures of analysis?

[1913c, 2491]

But at this point an objection will be raised. Is it, then, our task to lengthen the treatment and not, rather, to bring it to an end as rapidly as possible? Are not the patient's ailments due to his lack of knowledge and understanding and is it not a duty to enlighten him as soon as possible - that is, as soon as the doctor himself knows the explanations? The answer to this question calls for a short digression on the meaning of knowledge and the mechanism of cure in analysis.

[1913c, 2492]

The strange behaviour of patients, in being able to combine a conscious knowing with not knowing, remains inexplicable by what is called normal psychology. But to psycho-analysis, which recognizes the existence of the unconscious, it presents no difficulty. The phenomenon we have described, moreover, provides some of the best support for a view which approaches mental processes from the angle of topographical differentiation. The patients now know of the repressed experience in their conscious thought, but this thought lacks any connection with the place where the repressed recollection is in some way or other contained. No change is possible until the conscious thought-process has penetrated to that place and has overcome the resistances of repression there. It is just as though a decree were promulgated by the Ministry of Justice to the effect that juvenile delinquencies should be dealt with in a certain lenient manner. As long as this decree has not come to the knowledge of the local magistrates, or in the event of their not intending to obey it but preferring to administer justice by their own lights, no change can occur in the treatment of particular youthful delinquents. For the sake of complete accuracy, however, it should be added that the communication of repressed material to the patient's consciousness is nevertheless not without effect. It does not produce the hoped-for result of putting an end to the symptoms; but it has other consequences. At first it arouses resistances, but then, when these have been overcome, it sets up a process of thought in the course of which the expected influencing of the unconscious recollection eventually takes place.

[1913c, 2494]
It is now time for us to take a survey of the play of forces which is set in motion by the treatment. The primary motive force in the therapy is the patient's suffering and the wish to be cured that arises from it. The strength of this motive force is subtracted from by various factors - which are not discovered till the analysis is in progress - above all, by what we have called the 'secondary gain from illness'; but it must be maintained till the end of the treatment. Every improvement effects a diminution of it. By itself, however, this motive force is not sufficient to get rid of the illness. Two things are lacking in it for this: it does not know what paths to follow to reach this end; and it does not possess the necessary quota of energy with which to oppose the resistances. The analytic treatment helps to remedy both these deficiencies. It supplies the amounts of energy that are needed for overcoming the resistances by making mobile the energies which lie ready for the transference; and, by giving the patient information at the right time, it shows him the paths along which he should direct those energies. Often enough the transference is able to remove the symptoms of the disease by itself, but only for a while - only for as long as it itself lasts. In this case the treatment is a treatment by suggestion, and not a psycho-analysis at all. It only deserves the latter name if the intensity of the transference has been utilized for the overcoming of resistances. Only then has being ill become impossible, even when the transference has once more been dissolved, which is its destined end.

In the course of the treatment yet another helpful factor is aroused. This is the patient's intellectual interest and understanding. But this alone hardly comes into consideration in comparison with the other forces that are engaged in the struggle; for it is always in danger of losing its value, as a result of the clouding of judgement that arises from the resistances. Thus the new sources of strength for which the patient is indebted to his analyst are reducible to transference and instruction (through the communications made to him). The patient, however, only makes use of the instruction in so far as he is induced to do so by the transference; and it is for this reason that our first communication should be withheld until a strong transference has been established. And this, we may add, holds good of every subsequent communication. In each case we must wait until the disturbance of the transference by the successive emergence of transference-resistances has been removed.

The tactics to be adopted by the physician in this situation are easily justified. For him, remembering in the old manner - reproduction in the psychical field - is the aim to which he adheres, even though he knows that such an aim cannot be achieved in the new technique. He is prepared for a perpetual struggle with his patient to keep in the psychical sphere all the impulses which the patient would like to direct into the motor sphere; and he celebrates it as a triumph for the treatment if he can bring it about that something that the patient wishes to discharge in action is disposed of through the work of remembering. If the attachment through transference has grown into something at all serviceable, the treatment is able to prevent the patient from executing any of the more important repetitive actions and to utilize his intention to do so in statu nascendi as material for the therapeutic work. One best protects the patient from injuries brought about through carrying out one of his impulses by making him promise not to take any important decisions affecting his life during the time of his treatment - for instance, not to choose any profession or definitive love-object - but to postpone all such plans until after his recovery.
At the same time one willingly leaves untouched as much of the patient's personal freedom as is compatible with these restrictions, nor does one hinder him from carrying out unimportant intentions, even if they are foolish; one does not forget that it is in fact only through his own experience and mishaps that a person learns sense. There are also people whom one cannot restrain from plunging into some quite undesirable project during the treatment and who only afterwards become ready for, and accessible to, analysis. Occasionally, too, it is bound to happen that the untamed instincts assert themselves before there is time to put the reins of the transference on them, or that the bonds which attach the patient to the treatment are broken by him in a repetitive action. As an extreme example of this, I may cite the case of an elderly lady who had repeatedly fled from her house and her husband in a twilight state and gone no one knew where, without ever having become conscious of her motive for decamping in this way. She came to treatment with a marked affectionate transference which grew in intensity with uncanny rapidity in the first few days; by the end of the week she had decamped from me, too, before I had had time to say anything to her which might have prevented this repetition.

I might break off at this point but for the title of this paper, which obliges me to discuss a further point in analytic technique. The first step in overcoming the resistances is made, as we know, by the analyst's uncovering the resistance, which is never recognized by the patient, and acquainting him with it. Now it seems that beginners in analytic practice are inclined to look on this introductory step as constituting the whole of their work. I have often been asked to advise upon cases in which the doctor complained that he had pointed out his resistance to the patient and that nevertheless no change had set in; indeed, the resistance had become all the stronger, and the whole situation was more obscure than ever. The treatment seemed to make no headway. This gloomy foreboding always proved mistaken. The treatment was as a rule progressing most satisfactorily. The analyst had merely forgotten that giving the resistance a name could not result in its immediate cessation. One must allow the patient time to become more conversant with this resistance with which he has now become acquainted, to work through it, to overcome it, by continuing, in defiance of it, the analytic work according to the fundamental rule of analysis. Only where the resistance is at its height can the analyst, working in common with his patient, discover the repressed instinctual impulses which are feeding the resistance; and it is this kind of experience which convinces the patient of the existence and power of such impulses. The doctor has nothing else to do than to wait and let things take their course, a course which cannot be avoided nor always hastened. If he holds fast to this conviction he will often be spared the illusion of having failed when in fact he is conducting the treatment on the right lines.

It has come to my knowledge that some doctors who practise analysis frequently prepare their patients for the emergence of the erotic transference or even urge them to 'go ahead and fall in love with the doctor so that the treatment may make progress'. I can hardly imagine a more senseless proceeding. In doing so, an analyst robs the phenomenon of the element of spontaneity which is so convincing and lays up obstacles for himself in the future which are hard to overcome.
If one looks into the situation more closely one recognizes the influence of motives which further complicate things - of which some are connected with being in love and others are particular expressions of resistance. Of the first kind are the patient's endeavour to assure herself of her irresistibility, to destroy the doctor's authority by bringing him down to the level of a lover and to gain all the other promised advantages incidental to the satisfaction of love. As regards the resistance, we may suspect that on occasion it makes use of a declaration of love on the patient's part as a means of putting her analyst's severity to the test, so that, if he should show signs of compliance, he may expect to be taken to task for it. But above all one gets an impression that the resistance is acting as an agent provocateur; it heightens the patient's state of being in love and exaggerates her readiness for sexual surrender in order to justify the workings of repression all the more emphatically, by pointing to the dangers of such licentiousness. All these accessory motives, which in simpler cases may not be present, have, as we know, been regarded by Adler as the essential part of the whole process.

[1915a, 2513]

But how is the analyst to behave in order not to come to grief over this situation, supposing he is convinced that the treatment should be carried on in spite of this erotic transference and should take it in its stride?

[1915a, 2513]

It would be easy for me to lay stress on the universally accepted standards of morality and to insist that the analyst must never under any circumstances accept or return the tender feelings that are offered him: that, instead, he must consider that the time has come for him to put before the woman who is in love with him the demands of social morality and the necessity for renunciation, and to succeed in making her give up her desires, and, having surmounted the animal side of herself, go on with the work of analysis.

[1915a, 2513]

Even more decidedly, however, do I decline to fulfil the second of the expectations I have mentioned. To urge the patient to suppress, renounce or sublimate her instincts the moment she has admitted her erotic transference would be, not an analytic way of dealing with them, but a senseless one. It would be just as though, after summoning up a spirit from the underworld by cunning spells, one were to send him down again without having asked him a single question. One would have brought the repressed into consciousness, only to repress it once more in a fright. Nor should we deceive ourselves about the success of any such proceeding. As we know, the passions are little affected by sublime speeches. The patient will feel only the humiliation, and she will not fail to take her revenge for it.

[1915a, 2514]
Just as little can I advocate a middle course, which would recommend itself to some people as being specially ingenious. This would consist in declaring that one returns the patient's fond feelings but at the same time in avoiding any physical implementation of this fondness until one is able to guide the relationship into calmer channels and raise it to a highest level. My objection to this expedient is that psycho-analytic treatment is founded on truthfulness. In this fact lies a great part of its educative effect and its ethical value. It is dangerous to depart from this foundation. Anyone who has become saturated in the analytic technique will no longer be able to make use of the lies and pretences which a doctor normally finds unavoidable; and if, with the best intentions, he does attempt to do so, he is very likely to betray himself. Since we demand strict truthfulness from our patients, we jeopardize our whole authority if we let ourselves be caught out by them in a departure from the truth. Besides, the experiment of letting oneself go a little way in tender feelings for the patient is not altogether without danger. Our control over ourselves is not so complete that we may not suddenly one day go further than we had intended. In my opinion, therefore, we ought not to give up the neutrality towards the patient, which we have acquired through keeping the counter-transference in check.

[1915a, 2514]

I have already let it be understood that analytic technique requires of the physician that he should deny to the patient who is craving for love the satisfaction she demands. The treatment must be carried out in abstinence. By this I do not mean physical abstinence alone, nor yet the deprivation of everything that the patient desires, for perhaps no sick person could tolerate this. Instead, I shall state it as a fundamental principle that the patient's need and longing should be allowed to persist in her, in order that they may serve as forces impelling her to do work and to make changes, and that we must beware of appeasing those forces by means of surrogates. And what we could offer would never be anything else than a surrogate, for the patient's condition is such that, until her repressions are removed, she is incapable of getting real satisfaction.

[1915a, 2515]

If he has been guided by the calculation that this compliance on his part will ensure his domination over his patient and thus enable him to influence her to perform the tasks required by the treatment, and in this way to liberate herself permanently from her neurosis - then experience would inevitably show him that his calculation was wrong. The patient would achieve her aim, but he would never achieve his. What would happen to the doctor and the patient would only be what happened, according to the amusing anecdote, to the pastor and the insurance agent. The insurance agent, a free-thinker, lay at the point of death and his relatives insisted on bringing in a man of God to convert him before he died. The interview lasted so long that those who were waiting outside began to have hopes. At last the door of the sick-chamber opened. The free-thinker had not been converted; but the pastor went away insured.

[1915a, 2515]
However, contradictions of a certain kind - replacements by the precise opposite - offer no serious difficulty to the work of analytic interpretation. We shall not appeal here to the fact that contraries are so often represented by one and the same element in the modes of expression used by the unconscious, as for instance in dreams. But we shall remember that there are motive forces in mental life which bring about replacement by the opposite in the form of what is known as reaction-formation; and it is precisely in the revelation of such hidden forces as these that we look for the reward of this enquiry. The Moerae were created as a result of a discovery that warned man that he too is a part of nature and therefore subject to the immutable law of death. Something in man was bound to struggle against this subjection, for it is only with extreme unwillingness that he gives up his claim to an exceptional position. Man, as we know, makes use of his imaginative activity in order to satisfy the wishes that reality does not satisfy. So his imagination rebelled against the recognition of the truth embodied in the myth of the Moerae, and constructed instead the myth derived from it, in which the Goddess of Death was replaced by the Goddess of Love and by what was equivalent to her in human shape. The third of the sisters was no longer Death; she was the fairest, best, most desirable and most lovable of women. Nor was this substitution in any way technically difficult: it was prepared for by an ancient ambivalence, it was carried out along a primaeval line of connection which could not long have been forgotten. The Goddess of Love herself, who now took the place of the Goddess of Death, had once been identical with her. Even the Greek Aphrodite had not wholly relinquished her connection with the underworld, although she had long surrendered her chthonic role to other divine figures, to Persephone, or to the tri-form Artemis-Hecate. The great Mother-goddesses of the oriental peoples, however, all seem to have been both creators and destroyers - both goddesses of life and fertility and goddesses of death. Thus the replacement by a wishful opposite in our theme harks back to a primaeval identity.

We should not think lightly of such episodes in the life of children. It would be a serious mistake to read into childish misdemeanours like these a prognosis of the development of a bad character. Nevertheless, they are intimately connected with the most powerful motive forces in children's minds, and give notice of dispositions that will lead to later eventualities in their lives or to future neuroses.

I must now mention two secessions which have taken place among the adherents of psycho-analysis; the first occurred between the founding of the Association in 1910 and the Weimar Congress in 1911; the second took place after this and became manifest at Munich in 1913. The disappointment that they caused me might have been averted if I had paid more attention to the reactions of patients under analytic treatment. I knew very well of course that anyone may take to flight at his first approach to the unwelcome truths of analysis; I had always myself maintained that everyone's understanding of it is limited by his own repressions (or rather, by the resistances which sustain them) so that he cannot go beyond a particular point in his relation to analysis. But I had not expected that anyone who had reached a certain depth in his understanding of analysis could renounce that understanding and lose it. And yet daily experience with patients had shown that total rejection of analytic knowledge may result whenever a specially strong resistance arises at any depth in the mind; one may have succeeded in laboriously bringing a patient to grasp some parts of analytic knowledge and to handle them like possessions of his own, and yet one may see him, under the domination of the very next resistance, throw all he has learnt to the winds and stand on the defensive as he did in the days when he was a carefree beginner. I had to learn that the very same thing can happen with psycho-analysts as with patients in analysis.
Moreover, I can assure you that you are misinformed if you suppose that advice and guidance in the affairs of life play an integral part in analytic influence. On the contrary, so far as possible we avoid the role of a mentor such as this and there is nothing we would rather bring about than the patient should make his decisions for himself. With this purpose, too, we require him to postpone for the term of his treatment any vital decisions on choice of a profession, business undertakings, marriage or divorce, and only to put them in practice when the treatment is finished. You must admit that all this is different from what you pictured. Only in the case of some very youthful or quite helpless or unstable individuals are we unable to put the desired limitation of our role into effect. With them we have to combine the functions of a doctor and an educator; but when this is so we are quite conscious of our responsibility and behave with the necessary caution.

[1916-1917, 3476]

Many attempts at treatment miscarried during the early period of analysis because they were undertaken in cases which were altogether unsuited to the procedure and which we should exclude to-day on the basis of our present view of the indications for treatment. But these indications, too, could only be arrived at by experiment. In those days we did not know a priori that paranoia and dementia praecox in strongly marked forms are inaccessible, and we had a right to make trial of the method on all kinds of disorders. But most of the failures of those early years were due not to the doctor's fault or an unsuitable choice of patients but to unfavourable external conditions. Here we have only dealt with internal resistances, those of the patient, which are inevitable and can be overcome. The external resistances which arise from the patient's circumstances, from his environment, are of small theoretical interest but of the greatest practical importance. Psycho-analytic treatment may be compared with a surgical operation and may similarly claim to be carried out under arrangements that will be the most favourable for its success. You know the precautionary measures adopted by a surgeon: a suitable room, good lighting, assistants, exclusion of the patient's relatives, and so on. Ask yourselves now how many of these operations would turn out successfully if they had to take place in the presence of all the members of the patient's family, who would stick their noses into the field of the operation and exclaim aloud at every incision. In psycho-analytic treatments the intervention of relatives is a positive danger and a danger one does not know how to meet. One is armed against the patient's internal resistances which one knows are inevitable, but how can one ward off these external resistances? No kind of explanations make any impression on the patient's relatives; they cannot be induced to keep at a distance from the whole business, and one cannot make common cause with them because of the risk of losing the confidence of the patient, who - quite rightly moreover - expects the person in whom he has put his trust to take his side. No one who has any experience of the rifts which so often divide a family will, if he is an analyst, be surprised to find that the patient's closest relatives sometimes betray less interest in his recovering than in his remaining as he is. When, as so often, the neurosis is related to conflicts between members of a family, the healthy party will not hesitate long in choosing between his own interest and the sick party's recovery. It is not to be wondered at, indeed, if a husband looks with disfavour on a treatment in which, as he may rightly suspect, the whole catalogue of his sins will be brought to light. Nor do we wonder at it; but we cannot in that case blame ourselves if our efforts remain unsuccessful and the treatment is broken off prematurely because the husband's resistance is added to that of his sick wife. We had in fact undertaken something which in the prevailing circumstances was unrealizable.

[1916-1917, 3498]
In the years before the war, when arrivals from many foreign countries made me independent of the favour or disfavour of my own city, I followed a rule of not taking on patient for treatment unless he was *sui juris*, not dependent on anyone else in the essential relations of his life. This is not possible, however, for every psycho-analyst. Perhaps you may conclude from my warning against relatives that patients designed for psycho-analysis should be removed from their families and that this kind of treatment should accordingly be restricted to inmates of hospitals for nervous diseases. I could not, however, follow you in that. It is much more advantageous for patients, (in so far as they are not in a phase of severe exhaustion) to remain during the treatment in the conditions in which they have to struggle with the tasks that face them. But the patients' relatives ought not to cancel out this advantage by their conduct and should not offer any hostile opposition to the doctor's efforts. But how do you propose to influence in that direction factors like these which are inaccessible to us? And you will guess, of course, how much the prospects of a treatment are determined by the patient's social *milieu* and the cultural level of his family.

[1916-1917, 3500]

It is possible that the prejudice against analytic treatment is already diminishing. The constant spread of analytic teachings, the increasing number of doctors practising analysis in a number of countries seems to vouch for this. When I was a young doctor, I found myself in a similar storm of indignation on the doctors' part against treatment by hypnotic suggestion, which is now held up in contrast to analysis by people of 'moderate' views. Hypnotism, however, has not fulfilled its original promise as a therapeutic agent. We psycho-analysts may claim to be its legitimate heirs and we do not forget how much encouragement and theoretical clarification we owe to it. The damaging results attributed to psycho-analysis are restricted essentially to passing manifestations of increased conflict if an analysis is clumsily carried out or if it is broken off in the middle. You have heard an account of what we do with our patients and can form your own judgement as to whether our efforts are calculated to lead to any lasting damage. Abuse of analysis is possible in various directions; in particular, the transference is a dangerous instrument in the hands of an unconscientious doctor. But no medical instrument or procedure is guaranteed against abuse; if a knife does not cut, it cannot be used for healing either.

[1916-1917, 3501]

As regards these fertile difficulties the case I am about to discuss left nothing to be desired. The first years of the treatment produced scarcely any change. Owing to a fortunate concatenation, all the external circumstances nevertheless combined to make it possible to proceed with the therapeutic experiment. I can easily believe that in less favourable circumstances the treatment would have been given up after a short time. Of the physician's point of view I can only declare that in a case of this kind he must behave as 'timelessly' as the unconscious itself, if he wishes to learn anything or to achieve anything. And in the end he will succeed in doing so, if he has the strength to renounce any short-sighted therapeutic ambition. It is not to be expected that the amount of patience, adaptability, insight, and confidence demanded of the patient and his relatives will be forthcoming in many other cases. But the analyst has a right to feel that the results which he has attained from such lengthy work in one case will help substantially to reduce the length of the treatment in a subsequent case of equal severity, and that by submitting on a single occasion

[1918b, 3506]

² Information of this kind may, as a rule, be employed as absolutely authentic material. So it may seem tempting to take the easy course of filling up the gaps in a patient's memory by making enquiries from the older members of his family; but I cannot advise too strongly against such a technique. Any stories that may be told by relatives in reply to enquiries and requests are at the mercy of every critical misgiving that can come into play. One invariably regrets having made oneself dependent upon such information; at the same time confidence in the analysis is shaken and a court of appeal is set up over it. Whatever can be remembered at all will anyhow come to light in the further course of analysis.

[1918b, 3509]
It happens in many analyses that as one approaches their end new recollections emerge which have hitherto been kept carefully concealed. Or it may be that on one occasion some unpretentious remark is thrown out in an indifferent tone of voice as though it were superfluous; that then, on another occasion, something further is added, which begins to make the physician prick his ears; and that at last he comes to recognize this despised fragment of a memory as the key to the weightiest secrets that the patient's neurosis has veiled.

[1918b, 3571]

The analysis would be unsatisfactory if it failed to explain the phrase used by the patient for summing up the troubles of which he complained. The world, he said, was hidden from him by a veil; and our psycho-analytic training forbids our assuming that these words can have been without significance or have been chosen at haphazard. The veil was torn, strange to say, in one situation only; and that was at the moment when, as a result of an enema, he passed a motion through his anus. He then felt well again, and for a very short while he saw the world clearly. The interpretation of this 'veil' progressed with as much difficulty as we met with in clearing up his fear of the butterfly. Nor did he keep to the veil. It became still more elusive, as a feeling of twilight, 'ténèbres', and of other impalpable things.

[1918b, 3579]

In every psycho-analytic investigation of a life-history it is always possible to explain the meaning of the earliest childhood memories along these lines. Indeed, it usually happens that the very recollection to which the patient gives precedence, which he relates first, with which he introduces the story of his life, proves to be the most important, the very one that holds the key to the secret pages of his mind. But the little childish episode related in Dichtung und Wahrheit does not rise to our expectations. The ways and means that with our patients lead to interpretation are of course not available to us here; the episode does not seem in itself to admit of any traceable connection with important impressions at a later date. A mischievous trick with damaging effects on the household economy, carried out under the spur of outside encouragement, is certainly no fitting headpiece for all that Goethe has to tell us of his richly filled life. An impression of utter innocence and irrelevance clings to this childish memory, and it might be taken as a warning not to stretch the claims of psycho-analysis too far nor to apply it in unsuitable places.

[1917b, 3619]

After hearing this statement I threw all doubts to the winds. When in analysis two things are brought out one immediately after the other, as though in one breath, we have to interpret this proximity as a connection of thought. It was, therefore, as if the patient had said, 'Because I found that I had got a new brother, I shortly afterwards threw these things into the street.' The act of flinging the brushes, shoes and so on, out of the window must be recognized as a reaction to the birth of the brother. Nor is it a matter for regret that in this instance the objects thrown out were not crockery but other things, probably, anything the child could reach at the moment. - The hurling out (through the window into the street) thus proves to be the essential thing in the act, while the pleasure in the smashing and the noise, and the class of object on which 'execution is done', are variable and unessential points.

[1917b, 3623]
You will remember that it was a frustration that made the patient ill, and that his symptoms serve him as substitutive satisfactions. It is possible to observe during the treatment that every improvement in his condition reduces the rate at which he recovers and diminishes the instinctual force impelling him towards recovery. But this instinctual force is indispensible; reduction of it endangers our aim - the patient's restoration to health. What, then, is the conclusion that forces itself inevitably upon us? Cruel though it may sound, we must see to it that the patient's suffering, to a degree that is in some way or other effective, does not come to an end prematurely. If, owing to the symptoms having been taken apart and having lost their value, his suffering becomes mitigated, we must reinstate it elsewhere in the form of some appreciable privation; otherwise we run the danger of never achieving any improvements except quite insignificant and transitory ones.

[1919a, 3632]

As far as I can see, the danger threatens from two directions in especial. On the one hand, when the illness has been broken down by the analysis, the patient makes the most assiduous efforts to create for himself in place of his symptoms new substitutive satisfactions, which now lack the feature of suffering. He makes use of the enormous capacity for displacement possessed by the now partly liberated libido, in order to cathect with libido and promote to the position of substitutive satisfactions the most diverse kinds of activities, preferences and habits, not excluding some that have been his already. He continually finds new distractions of this kind, into which the energy necessary to carrying on the treatment escapes, and he knows how to keep them secret for a time. It is the analyst's task to detect these divergent paths and to require him every time to abandon them, however harmless the activity which leads to satisfaction may be in itself. The half-recovered patient may also enter on less harmless paths - as when, for instance, if he is a man, he seeks prematurely to attach himself to a woman. It may be observed, incidentally, that unhappy marriage and physical infirmity are the two things that most often supersede a neurosis. They satisfy in particular the sense of guilt (need for punishment) which makes many patients cling so fast to their neuroses. By a foolish choice in marriage they punish themselves; they regard a long organic illness as a punishment by fate and thereafter often cease to keep up their neurosis.

[1919a, 3632]

I do not think I have exhausted the range of desirable activity on the part of the physician in saying that a condition of privation is to be kept up during the treatment. Activity in another direction during analytic treatment has already, as you will remember, been a point at issue between us and the Swiss school. We refused most emphatically to turn a patient who puts himself into our hands in search of help into our private property, to decide his fate for him, to force our own ideals upon him, and with the pride of a Creator to form him in our own image and see that it is good. I still adhere to this refusal, and I think that this is the proper place for the medical discretion which we have had to ignore in other connections. I have learnt by experience, too, that such a far-reaching activity towards patients is not in the least necessary for therapeutic purposes. For I have been able to help people with whom I had nothing in common - neither race, education, social position nor outlook upon life in general - without affecting their individuality. At the time of the controversy I have just spoken of, I had the impression, to be sure, that the objections of our spokesmen - I think it was Ernest Jones who took the chief part - were too harsh and uncompromising. We cannot avoid taking some patients for treatment who are so helpless and incapable of ordinary life that for them one has to combine analytic with educative influence; and even with the majority, occasions now and then arise in which the physician is bound to take up the position of teacher and mentor. But it must always be done with great caution, and the patient should be educated to liberate and fulfil his own nature, not to resemble ourselves.

[1919a, 3633]
In the further course of psycho-analytic work, however, even these distinctions have proved to be inadequate and, for practical purposes, insufficient. This has become clear in more ways than one; but the decisive instance is as follows. We have formed the idea that in each individual there is a coherent organization of mental processes; and we call this his ego. It is to this ego that consciousness is attached; the ego controls the approaches to motility - that is, to the discharge of excitations into the external world; it is the mental agency which supervises all its own constituent processes, and which goes to sleep at night, though even then it exercises the censorship on dreams. From this ego proceed the repressions, too, by means of which it is sought to exclude certain trends in the mind not merely from consciousness but also from other forms of effectiveness and activity. In analysis these trends which have been shut out stand in opposition to the ego, and the analysis is faced with the task of removing the resistances which the ego displays against concerning itself with the repressed. Now we find during analysis that, when we put certain tasks before the patient, he gets into difficulties; his associations fail when they should be coming near the repressed. We then tell him that he is dominated by a resistance; but he is quite unaware of the fact, and, even if he guesses from his unpleasurable feelings that a resistance is now at work in him, he does not know what it is or how to describe it. Since, however, there can be no question but that this resistance emanates from his ego and belongs to it, we find ourselves in an unforeseen situation. We have come upon something in the ego itself which is also unconscious, which behaves exactly like the repressed - that is, which produces powerful effects without itself being conscious and which requires special work before it can be made conscious. From the point of view of analytic practice, the consequence of this discovery is that we land in endless obscurities and difficulties if we keep to our habitual forms of expression and try, for instance, to derive neuroses from a conflict between the conscious and the unconscious. We shall have to substitute for this antithesis another, taken from our insight into the structural conditions of the mind - the antithesis between the coherent ego and the repressed which is split off from it.¹

[1923b, 3951]

The description we have given applies to the most extreme instances of this state of affairs, but in a lesser measure this factor has to be reckoned with in very many cases, perhaps in all comparatively severe cases of neurosis. In fact it may be precisely this element in the situation, the attitude of the ego ideal, that determines the severity of a neurotic illness. We shall not hesitate, therefore, to discuss rather more fully the way in which the sense of guilt expresses itself under different conditions.
[1923b, 3984]
I should like to consider the historical argument a moment longer. Since it is with me personally that we are concerned, I can throw a little light, for anyone who may be interested, on my own motives. After forty-one years of medical activity, my self-knowledge tells me that I have never really been a doctor in the proper sense. I became a doctor through being compelled to deviate from my original purpose; and the triumph of my life lies in my having, after a long and roundabout journey, found my way back to my earliest path. I have no knowledge of having had any craving in my early childhood to help suffering humanity. My innate sadistic disposition was not a very strong one, so that I had no need to develop this one of its derivatives. Nor did I ever play the 'doctor game'; my infantile curiosity evidently chose other paths. In my youth I felt an overpowering need to understand something of the riddles of the world in which we live and perhaps even to contribute something to their solution. The most hopeful means of achieving this end seemed to be to enrol myself in the medical faculty; but even after that I experimented - unsuccessfully - with zoology and chemistry, till at last, under the influence of Brücke, who carried more weight with me than any one else in my whole life, I settled down to physiology, though in those days it was too narrowly restricted to histology. By that time I had already passed all my medical examinations; but I took no interest in anything to do with medicine till the teacher whom I so deeply respected warned me that in view of my impoverished material circumstances I could not possibly take up a theoretical career. Thus I passed from the histology of the nervous system to neuropathology and then, prompted by fresh influences, I began to be concerned with the neuroses. I scarcely think, however, that my lack of a genuine medical temperament has done much damage to my patients. For it is not greatly to the advantage of patients if their doctor's therapeutic interest has too marked an emotional emphasis. They are best helped if he carries out his task coolly and keeping as closely as possible to the rules.

The first objection we meet with is to the effect that it is an impertinence on the part of science to make religion a subject for its investigations, for religion is something sublime, superior to any operation of the human intellect, something which may not be approached with hair-splitting criticisms. In other words, science is not qualified to judge religion: it is quite serviceable and estimable otherwise, so long as it keeps to its own sphere. But religion is not its sphere, and it has no business there. If we do not let ourselves be put off by this brusque repulse and enquire further what is the basis of this claim to a position exceptional among all human concerns, the reply we receive (if we are thought worthy of any reply) is that religion cannot be measured by human measurements, for it is of divine origin and was given us as a revelation by a Spirit which the human spirit cannot comprehend. One would have thought that there was nothing earlier than the refutation of this argument: it is a clear case of *petitio principii*, of 'begging the question' - I know of no good German equivalent expression. The actual question raised is whether there *is* a divine spirit and a revelation by it; and the matter is certainly not decided by saying that this question cannot be asked, since the deity may not be put in question. The position here is what it occasionally is during the work of analysis. If a usually sensible patient rejects some particular suggestion on specially foolish grounds, this logical weakness is evidence of the existence of a specially strong motive for the denial - a motive which can only be of an affective nature, an emotional tie.

[1926e, 4394]

[1933a, 4767]
The first of these is that we have here dealt with only a single instance from the copious phenomenology of religions and have thrown no light on any others. I must regretfully admit that I am unable to give more than this one example and that my expert knowledge is insufficient to complete the enquiry. From my limited information I may perhaps add that the case of the founding of the Mahommedan religion seems to me like an abbreviated repetition of the Jewish one, of which it emerged as an imitation. It appears, indeed, that the Prophet intended originally to accept Judaism completely for himself and his people. The recapture of the single great primal father brought the Arabs an extraordinary exaltation of their self-confidence, which led to great worldly successes but exhausted itself in them. Allah showed himself far more grateful to his chosen people than Yahweh did to his. But the internal development of the new religion soon came to a stop, perhaps because it lacked the depth which had been caused in the Jewish case by the murder of the founder of their religion. The apparently rationalistic religions of the East are in their core ancestor-worship and so come to a halt, too, at an early stage of the reconstruction of the past. If it is true that in primitive peoples of to-day the recognition of a supreme being is the only content of their religion, we can only regard this as an atrophy of religious development and bring it into relation with the countless cases of rudimentary neuroses which are to be observed in the other field. Why it is that in the one case just as in the other things have gone no further, our knowledge is in both cases insufficient to tell us. We can only attribute the responsibility to the individual endowment of these peoples, the direction taken by their activity and their general social condition. Moreover, it is a good rule in the work of analysis to be content to explain what is actually before one and not to seek to explain what has not happened.

We think it most undesirable if the patient acts outside the transference instead of remembering. The ideal conduct for our purposes would be that he should behave as normally as possible outside the treatment and express his abnormal reactions only in the transference.

It has always seemed to me to be greatly to the credit of a certain well-known man of science that he treated psycho-analysis fairly at a time when most other people felt themselves under no such obligation. On one occasion, nevertheless, he gave expression to an opinion upon analytic technique which was at once derogatory and unjust. He said that in giving interpretations to a patient we treat him upon the famous principle of 'Heads I win, tails you lose.' That is to say, if the patient agrees with us, then the interpretation is right; but if he contradicts us, that is only a sign of his resistance, which again shows that we are right. In this way we are always in the right against the poor helpless wretch whom we are analysing, no matter how he may respond to what we put forward. Now, since it is in fact true that a 'No' from one of our patients is not as a rule enough to make us abandon an interpretation as incorrect, a revelation such as this of the nature of our technique has been most welcome to the opponents of analysis. It is therefore worth while to give a detailed account of how we are accustomed to arrive at an assessment of the 'Yes' or 'No' of our patients during analytic treatment - of their expression of agreement or of denial. The practising analyst will naturally learn nothing in the course of this apologia that he does not know already.
Previous writers have had less justification in devoting so much space to the doubt with which our judgement receives accounts of dreams. For this doubt has no intellectual warrant. There is in general no guarantee of the correctness of our memory; and yet we yield to the compulsion to attach belief to its data far more often than is objectively justified. Doubt whether a dream or certain of its details have been correctly reported is once more a derivative of the dream-censorship, of resistance to the penetration of the dream-thoughts into consciousness. This resistance has not been exhausted even by the displacements and substitutions it has brought about; it persists in the form of doubt attaching to the material which has been allowed through. We are especially inclined to misunderstand this doubt since it is careful never to attack the more intense elements of a dream but only the weak and indistinct ones. As we already know, however, a complete reversal of all psychical values takes place between the dream-thoughts and the dream. Distortion is only made possible by a withdrawal of psychical value; it habitually expresses itself by that means and is occasionally content to require nothing more. If, then, an indistinct element of a dream's content is in addition attacked by doubt, we have a sure indication that we are dealing with a comparatively direct derivative of one of the proscribed dream-thoughts. The state of things is what it was after some sweeping revolution in one of the republics of antiquity or the Renaissance. The noble and powerful families which had previously dominated the scene were sent into exile and all the high offices were filled by newcomers. Only the most impoverished and powerless members of the vanquished families, or their remote dependants, were allowed to remain in the city; and even so they did not enjoy full civic rights and were viewed with distrust. The distrust in this analogy corresponds to the doubt in the case we are considering. That is why in analysing a dream I insist that the whole scale of estimates of certainty shall be abandoned and that the faintest possibility that something of this or that sort may have occurred in the dream shall be treated as complete certainty. In tracing any element of a dream it will be found that unless this attitude is firmly adopted the analysis will come to a standstill. If any doubt is thrown upon the value of the element in question, the psychical result in the patient is that none of the involuntary ideas underlying that element comes into his head. This result is not a self-evident one. It would not make nonsense if someone were to say: 'I don't know for certain whether such and such a thing came into the dream, but here is what occurs to me in connection with it.' But in fact no one ever does say this; and it is precisely the fact that doubt produces this interrupting effect upon an analysis that reveals it as a derivative and tool of psychical resistance. Psycho-analysis is justly suspicious. One of its rules is that whatever interrupts the progress of analytic work is a resistance.¹

¹ [Footnote added 1925:] The proposition laid down in these peremptory terms - 'whatever interrupts the progress of analytic work is a resistance' is easily open to misunderstanding. It is of course only to be taken as a technical rule, as a warning to analysts. It cannot be disputed that in the course of an analysis various events may occur the responsibility for which cannot be laid upon the patient's intentions. His father may die without his having murdered him; or a war may break out which brings the analysis to an end. But behind its obvious exaggeration the proposition is asserting something both true and new. Even if the interrupting event is a real one and independent of the patient, it often depends on him how great an interruption it causes; and resistance shows itself unmistakably in the readiness with which he accepts an occurrence of this kind or the exaggerated use which he makes of it.
Anyone coming from dream-interpretation to analytic practice will retain his interest in the content of dreams, and his inclination will be to interpret as fully as possible every dream related by the patient. But he will soon remark that he is now working under quite different conditions, and that if he attempts to carry out his intention he will come into collision with the most immediate tasks of the treatment. Even if a patient's first dream proves to be admirably suited for the introduction of the first explanations to be given, other dreams will promptly appear, so long and so obscure that the full meaning cannot be extracted from them in the limited session of one day's work. If the doctor continues the work of interpretation during the following days, fresh dreams will be produced in the meantime and these will have to be put aside until he can regard the first dream as finally resolved. The production of dreams is at times so copious, and the patient's progress towards comprehension of them so hesitant, that a suspicion will force itself on the analyst that the appearance of the material in this manner may be simply a manifestation of the patient's resistance taking advantage of the discovery that the method is unable to master what is so presented. Moreover, the treatment will meanwhile have fallen quite a distance behind the present and have lost touch with actuality. In opposition to such a technique stands the rule that it is of the greatest importance for the treatment that the analyst should always be aware of the surface of the patient's mind at any given moment, that he should know what complexes and resistances are active in him at the time and what conscious reaction to them will govern his behaviour. It is scarcely ever right to sacrifice this therapeutic aim to an interest in dream-interpretation.

If you further consider that the patient makes all the chance events that occur during his analysis into interferences with it, that he uses as reasons for slackening his efforts every diversion outside the analysis, every comment by a person of authority in his environment who is hostile to analysis, any chance organic illness or any that complicates his neurosis and, even, every improvement in his condition - if you consider all this, you will have obtained an approximate, though still incomplete, picture of the forms and methods of the resistance, the struggle against which accompanies every analysis.

Let us take as an example the so-called dreams of recovery. If a patient has had a dream of this kind, in which he seems to abandon the restrictions of his neurosis - if, for instance, he overcomes some phobia or gives up some emotional attachment - we are inclined to think that he has made a great step forward, that he is ready to take his place in a new state of life, that he has begun to reckon on his recovery, etc. This may often be true, but quite as often such dreams of recovery only have the value of dreams of convenience: they signify a wish to be well at last, in order to avoid another portion of the work of analysis which is felt to lie ahead. In this sense, dreams of recovery very frequently occur, for instance, when the patient is about to enter upon a new and disagreeable phase of the transference. He is behaving in this just like some neurotics who after a few hours of analysis declare they have been cured - because they want to escape all the unpleasantness that is bound to come up for discussion in the analysis. Sufferers from war neuroses, too, who gave up their symptoms because the therapy adopted by the army doctors succeeded in making being ill even more uncomfortable than serving at the front - these sufferers, too, were following the same economic laws and in both cases alike the cures have proved to be only temporary.
The manner in which our patients bring forward their associations during the work of analysis gives us an opportunity for making some interesting observations. 'Now you'll think I mean to say something insulting, but really I've no such intention.' we realize that this is a rejection, by projection, of an idea that has just come up. Or: 'You ask who this person in the dream can be. It's not my mother.' We emend this to: 'So it is his mother.' In our interpretation, we take the liberty of disregarding the negation and of picking out the subject-matter alone of the association. It is as though the patient had said: 'It's true that my mother came into my mind as I thought of this person, but I don't feel inclined to let the association count.'

There is a very convenient method by which we can sometimes obtain a piece of information we want about unconscious repressed material. 'What', we ask, 'would you consider the most unlikely imaginable thing in that situation? What do you think was furthest from your mind at that time?' If the patient falls into the trap and says what he thinks is most incredible, he almost always makes the right admission. A neat counterpart to this experiment is often met with in an obsessional neurotic who has already been initiated into the meaning of his symptoms. 'I've got a new obsessive idea,' he says, 'and it occurred to me at once that it might mean so and so. But no; that can't be true, or it couldn't have occurred to me.' What he is repudiating, on grounds picked up from his treatment, is, of course, the correct meaning of the obsessive idea.

Thus the content of a repressed image or idea can make its way into consciousness, on condition that it is negated. Negation is a way of taking cognizance of what is repressed; indeed it is already a lifting of the repression, though not, of course, an acceptance of what is repressed. We can see how in this the intellectual function is separated from the affective process. With the help of negation only one consequence of the process of repression is undone - the fact, namely, of the ideational content of what is repressed not reaching consciousness. The outcome of this is a kind of intellectual acceptance of the repressed, while at the same time what is essential to the repression persists.¹ In the course of analytic work we often produce a further, very important and somewhat strange variant of this situation. We succeed in conquering the negation as well, and in bringing about a full intellectual acceptance of the repressed; but the repressive process itself is not yet removed by this.

Since to affirm or negate the content of thoughts is the task of the function of intellectual judgement, what we have just been saying has led us to the psychological origin of that function. To negate something in a judgement is, at bottom, to say: 'This is something which I should prefer to repress.' A negative judgement is the intellectual substitute for repression; its 'no' is the hall-mark of repression, a certificate of origin like, let us say, 'Made in Germany'. With the help of the symbol of negation, thinking frees itself from the restrictions of repression and enriches itself with material that is indispensable for its proper functioning.

¹ The same process is at the root of the familiar superstition that boasting is dangerous. 'How nice not to have had one of my headaches for so long.' But this is in fact the first announcement of an attack, of whose approach the subject is already sensible, although he is as yet unwilling to believe it.
The study of judgement affords us, perhaps for the first time, an insight into the origin of an intellectual function from the interplay of the primary instinctual impulses. Judging is a continuation, along lines of expediency, of the original process by which the ego took things into itself or expelled them from itself, according to the pleasure principle. The polarity of judgement appears to correspond to the opposition of the two groups of instincts which we have supposed to exist. Affirmation - as a substitute for uniting - belongs to Eros; negation - the successor to expulsion - belongs to the instinct of destruction. The general wish to negate, the negativism which is displayed by some psychotics, is probably to be regarded as a sign of a defusion of instincts that has taken place through a withdrawal of the libidinal components. But the performance of the function of judgement is not made possible until the creation of the symbol of negation has endowed thinking with a first measure of freedom from the consequences of repression and, with it, from the compulsion of the pleasure principle.

[1925h, 4143]

This view of negation fits in very well with the fact that in analysis we never discover a 'no' in the unconscious and that recognition of the unconscious on the part of the ego is expressed in a negative formula. There is no stronger evidence that we have been successful in our effort to uncover the unconscious than when the patient reacts to it with the words 'I didn't think that', or 'I didn't (ever) think of that'.

[1925h, 4143]
In the course of my psycho-analyses of neurotics I must already have analysed over a thousand dreams; but I do not propose to make use of this material in my present introduction to the technique and theory of dream-interpretation. Apart from the fact that such a course would be open to the objection that these are the dreams of neuropaths, from which no valid inferences could be made as to the dreams of normal people, there is quite another reason which forces this decision upon me. The subject to which these dreams of my patients lead up is always, of course, the case history which underlies their neurosis. Each dream would therefore necessitate a lengthy introduction and an investigation of the nature and aetiological determinants of the psychoneuroses. But these questions are in themselves novelties and highly bewildering and would distract attention from the problem of dreams. On the contrary, it is my intention to make use of my present elucidation of dreams as a preliminary step towards solving the more difficult problems of the psychology of the neuroses. If, however, I forego my principal material, the dreams of my neurotic patients, I must not be too particular about what is left to me. All that remains are such dreams as have been reported to me from time to time by normal persons of my acquaintance, and such others as have been quoted as instances in the literature dealing with dream-life. Unluckily, however, none of these dreams are accompanied by the analysis without which I cannot discover a dream's meaning. My procedure is not so convenient as the popular decoding method which translates any given piece of a dream's content by a fixed key. I, on the contrary, am prepared to find that the same piece of content may conceal a different meaning when it occurs in various people or in various contexts. Thus it comes about that I am led to my own dreams, which offer a copious and convenient material, derived from an approximately normal person and relating to multifarious occasions of daily life. No doubt I shall be met by doubts of the trustworthiness of 'self-analyses' of this kind; and I shall be told that they leave the door open to arbitrary conclusions. In my judgement the situation is in fact more favourable in the case of self-observation than in that of other people; at all events we may make the experiment and see how far self-analysis takes us with the interpretation of dreams. But I have other difficulties to overcome, which lie within myself. There is some natural hesitation about revealing so many intimate facts about one's mental life; nor can there be any guarantee against misinterpretation by strangers. But it must be possible to overcome such hesitations. 'Tout psychologue, writes Delboeuf, 'est obligé de faire l'avoué même de ses faiblesses s'il croit par là jeter du jour sur quelque problème obscur.'¹ And it is safe to assume that my readers too will very soon find their initial interest in the indiscretions which I am bound to make replaced by an absorbing immersion in the psychological problems upon which they throw light.²

We are also now coming to the opinion that analytic technique must be modified in certain ways according to the nature of the disease and the dominant instinctual trends in the patient. We started out from the treatment of conversion hysteria; in anxiety hysteria (phobias) we must to some extent alter our procedure. For these patient cannot bring out the material necessary for resolving their phobia so long as they feel protected by obeying the condition which it lays down. One cannot, of course, succeed in getting them to give up their protective measures and work under the influence of anxiety from the beginning of the treatment. One must therefore help them by interpreting their unconscious to them until they can make up their minds to do without the protection of their phobia and expose themselves to a now greatly mitigated anxiety. Only after they have done so does the material become accessible, which, when it has been mastered, leads to a solution of the phobia. Other modifications of technique, which seem to me not yet ripe for discussion, will be required in the treatment of obsessional neurosis. In this connection very important questions arise, which have not hitherto been elucidated: how far the instincts which the patient is combating are to be allowed some satisfaction during the treatment, and what difference it makes whether these impulses are active (sadistic) or passive (masochistic) in their nature.

¹[1900a, 606]
²[1910d, 2310]
I have already let it be understood that analytic technique requires of the physician that he should deny to the patient who is craving for love the satisfaction she demands. The treatment must be carried out in abstinence. By this I do not mean physical abstinence alone, nor yet the deprivation of everything that the patient desires, for perhaps no sick person could tolerate this. Instead, I shall state it as a fundamental principle that the patient's need and longing should be allowed to persist in her, in order that they may serve as forces impelling her to do work and to make changes, and that we must beware of appeasing those forces by means of surrogates. And what we could offer would never be anything else than a surrogate, for the patient's condition is such that, until her repressions are removed, she is incapable of getting real satisfaction.

Let us admit that this fundamental principle of the treatment being carried out in abstinence extends far beyond the single case we are considering here, and that it needs to be thoroughly discussed in order that we may define the limits of its possible application. We will not enter into this now, however, but will keep as close as possible to the situation from which we started out. What would happen if the doctor were to behave differently and, supposing both parties were free, if he were to avail himself of that freedom in order to return the patient's love and to still her need for affection?

If the patient's advances were returned it would be a great triumph for her, but a complete defeat for the treatment. She would have succeeded in what all patients strive for in analysis - she would have succeeded in acting out, in repeating in real life, what she ought only to have remembered, to have reproduced as psychical material and to have kept within the sphere of psychical events.¹ In the further course of the love-relationship she would bring out all the inhibitions and pathological reactions of her erotic life, without there being any possibility of correcting them; and the distressing episode would end in remorse and a great strengthening of her propensity to repression. The love-relationship in fact destroys the patient's susceptibility to influence from analytic treatment. A combination of the two would be an impossibility.

You will observe that this opens up a new field of analytic technique the working over of which will require close application and which will lead to quite definite rules of procedure. I shall not attempt to-day to introduce you to this new technique, which is still in the course of being evolved, but will content myself with enunciating a fundamental principle which will probably dominate our work in this field. It runs as follows: Analytic treatment should be carried through, as far as is possible, under privation - in a state of abstinence.

How far it is possible to show that I am right in this must be left to a more detailed discussion. By abstinence, however, is not to be understood doing without any and every satisfaction - that would of course not be practicable; nor do we mean what it popularly connotes, refraining from sexual intercourse; it means something else which has far more to do with the dynamics of falling ill and recovering.
You will remember that it was a *frustration* that made the patient ill, and that his symptoms 
serve him as substitutive satisfactions. It is possible to observe during the treatment that every 
improvement in his condition reduces the rate at which he recovers and diminishes the 
instinctual force impelling him towards recovery. But this instinctual force is indispensible; 
reduction of it endangers our aim - the patient's restoration to health. What, then, is the 
conclusion that forces itself inevitably upon us? Cruel though it may sound, we must see to it 
that the patient's suffering, to a degree that is in some way or other effective, does not come to 
an end prematurely. If, owing to the symptoms having been taken apart and having lost their 
value, his suffering becomes mitigated, we must reinstate it elsewhere in the form of some 
appreciable privation; otherwise we run the danger of never achieving any improvements except 
quite insignificant and transitory ones.

[1919a, 3632]

As far as I can see, the danger threatens from two directions in especial. On the one hand, 
when the illness has been broken down by the analysis, the patient makes the most assiduous 
efforts to create for himself in place of his symptoms new substitutive satisfactions, which now 
lack the feature of suffering. He makes use of the enormous capacity for displacement 
possessed by the now partly liberated libido, in order to cathect with libido and promote to the 
position of substitutive satisfactions the most diverse kinds of activities, preferences and habits, 
not excluding some that have been his already. He continually finds new distractions of this 
kind, into which the energy necessary to carrying on the treatment escapes, and he knows how 
to keep them secret for a time. It is the analyst's task to detect these divergent paths and to 
require him every time to abandon them, however harmless the activity which leads to 
satisfaction may be in itself. The half-recovered patient may also enter on less harmless paths - 
as when, for instance, if he is a man, he seeks prematurely to attach himself to a woman. It may 
be observed, incidentally, that unhappy marriage and physical infirmity are the two things that 
most often supersede a neurosis. They satisfy in particular the sense of guilt (need for 
punishment) which makes many patients cling so fast to their neuroses. By a foolish choice in 
marrige they punish themselves; they regard a long organic illness as a punishment by fate 
and thereafter often cease to keep up their neurosis.

[1919a, 3632]

In all such situations activity on the part of the physician must take the form of energetic 
opposition to premature substitutive satisfactions. It is easier for him, however, to prevent the 
second danger which jeopardizes the propelling force of the analysis, though it is not one to be 
under-estimated. The patient looks for his substitutive satisfactions above all in the treatment 
itself, in his transference-relationship with the physician; and he may even strive to compensate 
himself by this means for all the other privations laid upon him. Some concessions must of 
course be made to him, greater or less, according to the nature of the case and the patient's 
individuality. But it is not good to let them become too great. Any analyst who out of the fullness 
of his heart, perhaps, and his readiness to help, extends to the patient all that one human being 
may hope to receive from another, commits the same economic error as that of which our non-
analytic institutions for nervous patients are guilty. Their one aim is to make everything as 
pleasant as possible for the patient, so that he may feel well there and be glad to take refuge 
there again from the trials of life. In so doing they make no attempt to give him more strength for 
facing life and more capacity for carrying out his actual tasks in it. In analytic treatment all such 
spoiling must be avoided. As far as his relations with the physician are concerned, the patient 
must be left with unfulfilled wishes in abundance. It is expedient to deny him precisely those 
satisfactions which he desires most intensely and expresses most importantly.

[1919a, 3633]
I do not think I have exhausted the range of desirable activity on the part of the physician in saying that a condition of privation is to be kept up during the treatment. Activity in another direction during analytic treatment has already, as you will remember, been a point at issue between us and the Swiss school. We refused most emphatically to turn a patient who puts himself into our hands in search of help into our private property, to decide his fate for him, to force our own ideals upon him, and with the pride of a Creator to form him in our own image and see that it is good. I still adhere to this refusal, and I think that this is the proper place for the medical discretion which we have had to ignore in other connections. I have learnt by experience, too, that such a far-reaching activity towards patients is not in the least necessary for therapeutic purposes. For I have been able to help people with whom I had nothing in common - neither race, education, social position nor outlook upon life in general - without affecting their individuality. At the time of the controversy I have just spoken of, I had the impression, to be sure, that the objections of our spokesmen - I think it was Ernest Jones who took the chief part - were too harsh and uncompromising. We cannot avoid taking some patients for treatment who are so helpless and incapable of ordinary life that for them one has to combine analytic with educative influence; and even with the majority, occasions now and then arise in which the physician is bound to take up the position of teacher and mentor. But it must always be done with great caution, and the patient should be educated to liberate and fulfil his own nature, not to resemble ourselves.

[1919a, 3633]

And now for the other side of the situation. Since the transference reproduces the patient's relation with his parents, it takes over the ambivalence of that relation as well. It almost inevitably happens that one day his positive attitude towards the analyst changes over into the negative, hostile one. This too is as a rule a repetition of the past. His obedience to his father (if it is his father that is in question), his courting of his father's favour, had its roots in an erotic wish directed towards him. Some time or other that demand will press its way forward in the transference as well and insist on being satisfied. In the analytic situation it can only meet with frustration. Real sexual relations between patients and analysts are out of the question, and even the subtler methods of satisfaction, such as the giving of preference, intimacy and so on, are only sparingly granted by the analyst. A rejection of this kind is taken as the occasion for the change-over; probably things happened in the same way in the patient's childhood.

[1940a [1938], 4986]
The next day I made him pledge himself to submit to the one and only condition of the treatment - namely, to say everything that came into his head, even if it was unpleasant to him, or seemed unimportant or irrelevant or senseless. I then gave him leave to start his communications with any subject he pleased, and he began thus:

It will now be asked whether we shall not be giving up too much valuable material which might throw light on the unconscious if dream-interpretation is only to be carried out subject to such restrictions of method. The answer to this is that the loss is by no means so great as might appear from a superficial view of the matter. To begin with, it must be recognized that in cases of severe neurosis any elaborate dream-productions must from the nature of things be regarded as incapable of complete solution. A dream of this kind is often based on the entire pathogenic material of the case, as yet unknown to both doctor and patient (so called 'programme-dreams' and biographical dreams), and is sometimes equivalent to a translation into dream-language of the whole content of the neurosis. In the attempt to interpret such a dream all the latent, as yet untouched, resistances will be roused to activity and soon set a limit to its understanding. The full interpretation of such a dream will coincide with the completion of the whole analysis; if a note is made of it at the beginning, it may be possible to understand it at the end, many months later. It is the same as with the elucidation of a single symptom (the main symptom, perhaps). The whole analysis is needed to explain it; in the course of the treatment one must endeavour to lay hold first of this, then of that, fragment of the symptom's meaning, one after another, until they can all be pieced together. Similarly, no more can be expected of a dream occurring in the early stages of the analysis; one must be content if the attempt at interpretation brings a single pathogenic wishful impulse to light.
To shorten analytic treatment is a justifiable wish, and its fulfilment, as we shall learn, is being attempted along various lines. Unfortunately, it is opposed by a very important factor, namely, the slowness with which deep-going changes in the mind are accomplished - in the last resort, no doubt, the 'timelessness' of our unconscious processes. When patients are faced with the difficulty of the great expenditure of time required for analysis they not infrequently manage to propose a way out of it. They divide up their ailments and describe some as unbearable, and others as secondary, and then say: 'If only you will relieve me from this one (for instance, a headache or a particular fear) I can deal with the other one on my own in my ordinary life.' In doing this, however, they over-estimate the selective power of analysis. The analyst is certainly able to do a great deal, but he cannot determine beforehand exactly what results he will effect. He sets in motion a process, that of the resolving of existing repressions. He can supervise this process, further it, remove obstacles in its way, and he can undoubtedly vitiate much of it. But on the whole, once begun, it goes its own way and does not allow either the direction it takes or the order in which it picks up its points to be prescribed for it. The analyst's power over the symptoms of the disease may thus be compared to male sexual potency. A man can, it is true, beget a whole child, but even the strongest man cannot create in the female organism a head alone or an arm or a leg; he cannot even prescribe the child's sex. He, too, only sets in motion a highly complicated process, determined by events in the remote past, which ends with the severance of the child from its mother. A neurosis as well has the character of an organism. Its component manifestations are not independent of one another; they condition one another and give one another mutual support. A person suffers from one neurosis only, never from several which have accidentally met together in a single individual. The patient freed, according to his wish, from his one unendurable symptom might easily find that a symptom which had previously been negligible had now increased and grown unendurable. The analyst who wishes the treatment to owe its success as little as possible to its elements of suggestion (i.e. to the transference) will do well to refrain from making use of even the trace of selective influence upon the results of the therapy which may perhaps be open to him. The patients who are bound to be most welcome to him are those who ask him to give them complete health, in so far as that is attainable, and who place as much time at his disposal as is necessary for the process of recovery. Such favourable conditions as these are, of course, to be looked for in only a few cases. [1913c, 2483]

The analysis of these torments did not proceed so simply as that of our earlier patient's obsessional action. I was obliged to give the girl hints and propose interpretations, which were always rejected with a decided 'no' or accepted with contemptuous doubt. But after this first reaction of rejection there followed a time during which she occupied herself with the possibilities put before her, collected associations to them, produced recollections and made connections, until by her own work she had accepted all the interpretations. In proportion as this happened, she relaxed the performance of her obsessional measures, and even before the end of the treatment she had given up the whole ceremonial. You must understand, too, that the work of analysis as we carry it out to-day quite excludes the systematic treatment of any individual symptom till it has been entirely cleared up. We are, on the contrary, obliged to keep on leaving any particular topic, in the certain expectation of coming back to it again in other connections. The interpretation of her symptoms which I am about to give you is accordingly a synthesis of findings which were arrived at, interrupted by other work, over a period of weeks and months. [1916-1917, 3346]
I will digress for a moment to ask if you know what is meant by a causal therapy. That is how we describe procedure which does not take the symptoms of an illness as its point of attack but sets about removing its causes. Well, then, is our psycho-analytic method a causal therapy or not? The reply is not a simple one, but it may perhaps give us an opportunity of realizing the worthlessness of a question framed in this way. In so far as analytic therapy does not make it its first task to remove the symptoms, it is behaving like a causal therapy. In another respect, you may say, it is not. For we long ago traced the causal chain back through the repressions to the instinctual dispositions, their relative intensities in the constitution and the deviations in the course of their development. Supposing, now, that it was possible, by some chemical means, perhaps, to interfere in this mechanism, to increase or diminish the quantity of libido present at a given time or to strengthen one instinct at the cost of another - this then would be a causal therapy in the true sense of the word, for which our analysis would have carried out the indispensable preliminary work of reconnaissance. At present, as you know, there is no question of any such method of influencing libidinal processes; with our psychical therapy we attack at a different point in the combination - not exactly at what we know are the roots of the phenomena, but nevertheless far enough away from the symptoms, at a point which has been made accessible to us by some very remarkable circumstances.

[1916-1917, 3478]

Comparison between Psycho-Analysis and Hypnotic and Suggestive Methods. - Psycho-analytic procedure differs from all methods making use of suggestion, persuasion, etc., in that it does not seek to suppress by means of authority any mental phenomenon that may occur in the patient. It endeavours to trace the causation of the phenomenon and to remove it by bringing about a permanent modification in the conditions that led to it. In psycho-analysis the suggestive influence which is inevitably exercised by the physician is diverted on to the task assigned to the patient of overcoming his resistances, that is, of carrying forward the curative process. Any danger of falsifying the products of a patient's memory by suggestion can be avoided by prudent handling of the technique; but in general the arousing of resistances is a guarantee against the misleading effects of suggestive influence. It may be laid down that the aim of the treatment is to remove the patient's resistances and to pass his repressions in review and thus to bring about the most far-reaching unification and strengthening of his ego, to enable him to save the mental energy which he is expending upon internal conflicts, to make the best of him that his inherited capacities will allow and so to make him as efficient and as capable of enjoyment as is possible. The removal of the symptoms of the illness is not specifically aimed at, but is achieved, as it were, as a by-product if the analysis is properly carried through. The analyst respects the patient's individuality and does not seek to remould him in accordance with his own - that is, according to the physician's personal ideals; he is glad to avoid giving advice and instead to arouse the patient's power of initiative.

[1923a, 3927]
It may seem surprising that this method of free association, carried out subject to the observation of the fundamental rule of psycho-analysis, should have achieved what was expected of it, namely the bringing into consciousness of the repressed material which was held back by resistances. We must, however, bear in mind that free association is not really free. The patient remains under the influence of the analytic situation even though he is not directing his mental activities on to a particular subject. We shall be justified in assuming that nothing will occur to him that has not some reference to that situation. His resistance against reproducing the repressed material will now be expressed in two ways. Firstly it will be shown by critical objections; and it was to deal with these that the fundamental rule of psycho-analysis was invented. But if the patient observes that rule and so overcomes his reticences, the resistance will find another means of expression. It will so arrange it that the repressed material itself will never occur to the patient but only something which approximates to it in an allusive way; and the greater the resistance, the more remote from the actual idea that the analyst is in search of will be the substitutive association which the patient has to report. The analyst, who listens composedly but without any constrained effort to the stream of associations and who, from his experience, has a general notion of what to expect, can make use of the material brought to light by the patient according to two possibilities. If the resistance is slight he will be able from the patient's allusions to infer the unconscious material itself; or if the resistance is stronger he will be able to recognize its character from the associations, as they seem to become more remote from the topic in hand, and will explain it to the patient. Uncovering the resistance, however, is the first step towards overcoming it. Thus the work of analysis involves an art of interpretation, the successful handling of which may require tact and practice but which is not hard to acquire. But it is not only in the saving of labour that the method of free association has an advantage over the earlier method. It exposes the patient to the least possible amount of compulsion, it never allows of contact being lost with the actual current situation, it guarantees to a great extent that no factor in the structure of the neurosis will be overlooked and that nothing will be introduced into it by the expectations of the analyst. It is left to the patient in all essentials to determine the course of the analysis and the arrangement of the material; any systematic handling of particular symptoms or complexes thus becomes impossible. In complete contrast to what happened with hypnosis and with the urging method, interrelated material makes its appearance at different times and at different points in the treatment. To a spectator, therefore - though in fact there must be none - an analytic treatment would seem completely obscure.

[1925d, 4216]
I will now describe the way in which I have overcome the technical difficulties of drawing up the report of this case history. The difficulties are very considerable when the physician has to conduct six or eight psychotherapeutic treatments of the sort in a day, and cannot make notes during the actual session with the patient for fear of shaking the patient's confidence and of disturbing his own view of the material under observation. Indeed, I have not yet succeeded in solving the problem of how to record for publication the history of a treatment of long duration. As regards the present case, two circumstances have come to my assistance. In the first place the treatment did not last for more than three months; and in the second place the material which elucidated the case was grouped around two dreams (one related in the middle of the treatment and one at the end). The wording of these dreams was recorded immediately after the session, and they thus afforded a secure point of attachment for the chain of interpretations and recollections which proceeded from them. The case history itself was only committed to writing from memory after the treatment was at an end, but while my recollection of the case was still fresh and was heightened by my interest in its publication. Thus the record is not absolutely phonographically exact, but it can claim to possess a high degree of trustworthiness. Nothing of any importance has been altered in it except in some places the order in which the explanations are given; and this has been done for the sake of presenting the case in a more connected form.

¹ What follows is based upon notes made on the evening of the day of treatment, and adheres as closely as possible to my recollection of the patient's words. I feel obliged to offer a warning against the practice of noting down what the patient says during the actual time of treatment. The consequent withdrawal of the physician's attention does the patient more harm than can be made up for by any increase in accuracy that may be achieved in the reproduction of his case history.

The technique, however, is a very simple one. As we shall see, it rejects the use of any special expedient (even that of taking notes). It consists simply in not directing one's notice to anything in particular and in maintaining the same 'evenly-suspended attention' (as I have called it) in the face of all that one hears. In this way we spare ourselves a strain on our attention which could not in any case be kept up for several hours daily, and we avoid a danger which is inseparable from the exercise of deliberate attention. For as soon as anyone deliberately concentrates his attention to a certain degree, he begins to select from the material before him; one point will be fixed in his mind with particular clearness and some other will be correspondingly disregarded, and in making this selection he will be following his expectations or inclinations. This, however, is precisely what must not be done. In making the selection, if he follows his expectations he is in danger of never finding anything but what he already knows; and if he follows his inclinations he will certainly falsify what he may perceive. It must not be forgotten that the things one hears are for the most part things whose meaning is only recognized later on.

(b) I cannot advise the taking of full notes, the keeping of a shorthand record, etc., during analytic sessions. Apart from the unfavourable impression which this makes on some patients, the same considerations as have been advanced with regard to attention apply here too. A detrimental selection from the material will necessarily be made as one writes the notes or shorthand, and part of one's own mental activity is tied up in this way, which would be better employed in interpreting what one has heard. No objection can be raised to making exceptions to this rule in the case of dates, the text of dreams, or particular noteworthy events which can easily be detached from their context and are suitable for independent use as instances. But I am not in the habit of doing this either. As regards instances, I write them down from memory in the evening after work is over; as regards texts of dreams to which I attach importance, I get the patient to repeat them to me after he has related them so that I can fix them in my mind.
(c) Taking notes during the session with the patient might be justified by an intention of publishing a scientific study of the case. On general grounds this can scarcely be denied. Nevertheless it must be borne in mind that exact reports of analytic case histories are of less value than might be expected. Strictly speaking, they only possess the *ostensible* exactness of which 'modern' psychiatry affords us some striking examples. They are, as a rule, fatiguing to the reader and yet do not succeed in being a substitute for his actual presence at an analysis. Experience invariably shows that if readers are willing to believe an analyst they will have confidence in any slight revision to which he has submitted his material; if, on the other hand, they are unwilling to take analysis and the analyst seriously, they will pay no attention to accurate verbatim records of the treatment either. This is not the way, it seems, to remedy the lack of convincing evidence to be found in psycho-analytic reports.

[1912e, 2469]
(b) It seems to me that there is a widespread and erroneous impression among my colleagues that this technique of searching for the origins of an illness and removing its manifestations by that means is an easy one which can be practised off-hand, as it were. I conclude this from the fact that not one of all the people who have shown an interest in my therapy and passed definite judgements upon it has ever asked me how I actually go about it. There can be only one reason for this: that they think there is nothing to enquire about, that the thing is perfectly self-evident. Again, I am now and then astonished to hear that in this or that department of a hospital a young assistant has received an order from his chief to undertake a 'psycho-analysis' of a hysterical patient. I am sure he would not be allowed to examine an extirpated tumour unless he had convinced his chiefs that he was conversant with histological technique. Similarly, reports reach my ears that this or that colleague has arranged appointments with a patient in order to undertake a mental treatment of the case, though I am certain he knows nothing of the technique of any such therapy. His expectation must be therefore that the patient will make him a present of his secrets, or perhaps that he is looking for salvation in some sort of confession or confidence. I should not be surprised if a patient were injured rather than benefited by being treated in such a fashion. For it is not so easy to play upon the instrument of the mind. I am reminded on such occasions of the words of a world-famous neurotic - though it is true that he was never treated by a physician but existed only in a poet's imagination - Hamlet, Prince of Denmark. The King has ordered two courtiers, Rosenkranz and Guildenstern, to follow him, to question him and drag the secret of his depression out of him. He wards them off. Then some recorders are brought on the stage and Hamlet, taking one of them, begs one of his tormentors to play upon it, telling him that it is as easy as lying. The courtier excuses himself, for he knows no touch of the instrument, and when he cannot be persuaded to try it, Hamlet finally breaks out with these words: 'Why, look you now, how unworthy a thing you make of me! You would play upon me; . . . you would pluck out the heart of my mystery; you would sound me from my lowest note to the top of my compass; and there is much music, excellent voice, in this little organ; yet you cannot make it speak. 'Sblood, do you think I am easier to be played on than a pipe? Call me what instrument you will, though you can fret me, you cannot play upon me.' (Act III, Scene 2.) [1905a, 1567]
Ladies and Gentlemen, from the intellectual point of view we must, I think, take into account two special obstacles to recognizing psycho-analytic trains of thought. In the first place, people are unaccustomed to reckoning with a strict and universal application of determinism to mental life; and in the second place, they are ignorant of the peculiarities which distinguish unconscious mental processes from the conscious ones that are familiar to us. One of the most widespread resistances to psycho-analytic work, in the sick and healthy alike, can be traced to the second of these two factors. People are afraid of doing harm by psycho-analysis; they are afraid of bringing the repressed sexual instincts into the patient's consciousness, as though that involved a danger of their overwhelming his higher ethical trends and of their robbing him of his cultural acquisitions. People notice that the patient has sore spots in his mind, but shrink from touching them for fear of increasing his sufferings. We can accept this analogy. It is no doubt kinder not to touch diseased spots if it can do nothing else but cause pain. But, as we know, a surgeon does not refrain from examining and handling a focus of disease, if he is intending to take active measures which he believes will lead to a permanent cure. No one thinks of blaming him for the inevitable suffering caused by the examination or for the reactions to the operation, if only it gains its end and the patient achieves a lasting recovery as a result of the temporary worsening of his state. The case is similar with psycho-analysis. It may make the same claims as surgery: the increase in suffering which it causes the patient during treatment is incomparably less than what a surgeon causes, and is quite negligible in proportion to the severity of the underlying ailment. On the other hand, the final outcome that is so much dreaded - the destruction of the patient's cultural character by the instincts which have been set free from repression - is totally impossible. For alarm on this score takes no account of what our experiences have taught us with certainty - namely that the mental and somatic power of a wishful impulse, when once its repression has failed, is far stronger if it is unconscious than if it is conscious; so that to make it conscious can only be to weaken it. An unconscious wish cannot be influenced and it is independent of any contrary tendencies, whereas a conscious one is inhibited by whatever else is conscious and opposed to it. Thus the work of psycho-analysis puts itself at the orders of precisely the highest and most valuable cultural trends, as a better substitute for the unsuccessful repression. 
[1910a, 2237]
Hitherto, this authority, with its enormous weight of suggestion, has been against us. All our therapeutic successes have been achieved in the face of this suggestion: it is surprising that any successes at all could be gained in such circumstances. I must not let myself be led into describing my agreeable experiences during the period when I alone represented psycho-analysis. I can only say that when I assured my patients that I knew how to relieve them permanently of their sufferings they looked round my modest abode, reflected on my lack of fame and title, and regarded me like the possessor of an infallible system at a gambling-resort, of whom people say that if he could do what he professes he would look very different himself. Nor was it really pleasant to carry out a psychical operation while the colleagues whose duty it should have been to assist took particular pleasure in spitting into the field of operation, and while at the first signs of blood or restlessness in the patient his relatives began threatening the operating surgeon. An operation is surely entitled to produce reactions; in surgery we became accustomed to that long ago. People simply did not believe me, just as even to-day people do not much believe any of us. Under such conditions not a few attempts were bound to fail. To estimate the increase in our therapeutic prospects when we have received general recognition, you should think of the position of a gynaecologist in Turkey and in the West. In Turkey, all he may do is to feel the pulse of all arm stretched out to him through a hole in the wall: and his medical achievements are in proportion to the inaccessibility of their object. Our opponents in the West wish to allow us much the same degree of access to our patient's minds. But now that the force of social suggestion drives sick women to the gynaecologist, he has become their helper and saviour. I trust you will not say that the fact of the authority of society coming to our aid and increasing our successes so greatly would do nothing to prove the validity of our hypotheses - arguing as you might that, since suggestion is supposed to be able to do anything, our successes would then be successes of suggestion and not of psycho-analysis. Social suggestion is at present favourable to treating nervous patients by hydropathy, dieting and electro-therapy, but that does not enable such measures to get the better of neuroses. Time will show whether psycho-analytic treatment can accomplish more.

Neither I myself nor my friends and co-workers find it agreeable to claim a monopoly in this way in the use of a medical technique. But in face of the dangers to patients and to the cause of psycho-analysis which are inherent in the practice that is to be foreseen of a 'wild' psycho-analysis, we have had no other choice. In the spring of 1910 we founded an International Psycho-Analytical Association, to which its members declare their adherence by the publication of their names, in order to be able to repudiate responsibility for what is done by those who do not belong to us and yet call their medical procedure 'psycho-analysis'. For as a matter of fact 'wild' analysts of this kind do more harm to the cause of psycho-analysis than to individual patients. I have often found that a clumsy procedure like this, even if at first it produced an exacerbation of the patient's condition, led to a recovery in the end. Not always but still often. When he has abused the physician enough and feels far enough away from his influence, his symptoms give way, or he decides to take some step which leads along the path to recovery. The final improvement then comes about 'of itself', or is ascribed to some totally indifferent treatment by some other doctor to whom the patient has later turned. In the case of the lady whose complaint against her physician we have heard, I should say that, despite everything, the 'wild' psycho-analyst did more for her than some highly respected authority who might have told her she was suffering from a 'vasomotor neurosis'. He forced her attention to the real cause of her trouble, or in that direction, and in spite of all her opposition this intervention of his cannot be without some favourable results. But he has done himself harm and helped to intensify the prejudices which patients feel, owing to their natural affective resistances, against the methods of psycho-analysis. And this can be avoided.

[1910d, 2311]

[1910k, 2380]
Many attempts at treatment miscarried during the early period of analysis because they were undertaken in cases which were altogether unsuited to the procedure and which we should exclude to-day on the basis of our present view of the indications for treatment. But these indications, too, could only be arrived at by experiment. In those days we did not know a priori that paranoia and dementia praecox in strongly marked forms are inaccessible, and we had a right to make trial of the method on all kinds of disorders. But most of the failures of those early years were due not to the doctor's fault or an unsuitable choice of patients but to unfavourable external conditions. Here we have only dealt with internal resistances, those of the patient, which are inevitable and can be overcome. The external resistances which arise from the patient's circumstances, from his environment, are of small theoretical interest but of the greatest practical importance. Psycho-analytic treatment may be compared with a surgical operation and may similarly claim to be carried out under arrangements that will be the most favourable for its success. You know the precautionary measures adopted by a surgeon: a suitable room, good lighting, assistants, exclusion of the patient's relatives, and so on. Ask yourselves now how many of these operations would turn out successfully if they had to take place in the presence of all the members of the patient's family, who would stick their noses into the field of the operation and exclaim aloud at every incision. In psycho-analytic treatments the intervention of relatives is a positive danger and a danger one does not know how to meet. One is armed against the patient's internal resistances which one knows are inevitable, but how can one ward off these external resistances? No kind of explanations make any impression on the patient's relatives; they cannot be induced to keep at a distance from the whole business, and one cannot make common cause with them because of the risk of losing the confidence of the patient, who - quite rightly moreover - expects the person in whom he has put his trust to take his side. No one who has any experience of the rifts which so often divide a family will, if he is an analyst, be surprised to find that the patient's closest relatives sometimes betray less interest in his recovering than in his remaining as he is. When, as so often, the neurosis is related to conflicts between members of a family, the healthy party will not hesitate long in choosing between his own interest and the sick party's recovery. It is not to be wondered at, indeed, if a husband looks with disfavour on a treatment in which, as he may rightly suspect, the whole catalogue of his sins will be brought to light. Nor do we wonder at it; but we cannot in that case blame ourselves if our efforts remain unsuccessful and the treatment is broken off prematurely because the husband's resistance is added to that of his sick wife. We had in fact undertaken something which in the prevailing circumstances was unrealizable.
[1916-1917, 3498]

It is possible that the prejudice against analytic treatment is already diminishing. The constant spread of analytic teachings, the increasing number of doctors practising analysis in a number of countries seems to vouch for this. When I was a young doctor, I found myself in a similar storm of indignation on the doctors' part against treatment by hypnotic suggestion, which is now held up in contrast to analysis by people of 'moderate' views. Hypnotism, however, has not fulfilled its original promise as a therapeutic agent. We psycho-analysts may claim to be its legitimate heirs and we do not forget how much encouragement and theoretical clarification we owe to it. The damaging results attributed to psycho-analysis are restricted essentially to passing manifestations of increased conflict if an analysis is clumsily carried out or if it is broken off in the middle. You have heard an account of what we do with our patients and can form your own judgement as to whether our efforts are calculated to lead to any lasting damage. Abuse of analysis is possible in various directions; in particular, the transference is a dangerous instrument in the hands of an unconscientious doctor. But no medical instrument or procedure is guaranteed against abuse; if a knife does not cut, it cannot be used for healing either.
[1916-1917, 3501]
But I cannot think, Gentlemen, that any new task is set us by this psycho-synthesis. If I allowed myself to be frank and uncivil I should say it was nothing but an empty phrase. I will limit myself to remarking that it is merely pushing a comparison so far that it ceases to have any meaning, or, if you prefer, that it is an unjustifiable exploitation of a name. A name, however, is only a label applied to distinguish a thing from other similar things, not a syllabus, a description of its content or a definition. And the two objects compared need only coincide at a single point and may be entirely different from each other in everything else. What is psychical is something so unique and peculiar to itself that no one comparison can reflect its nature. The work of psycho-analysis suggests analogies with chemical analysis, but it does so just as much with the intervention of a surgeon or the manipulations of an orthopaedist or the influence of an educator. The comparison with chemical analysis has its limitation: for in mental life we have to deal with trends that are under a compulsion towards unification and combination. Whenever we succeed in analysing a symptom into its elements, in freeing an instinctual impulse from one nexus, it does not remain in isolation, but immediately enters into a new one.¹

[1919a, 3630]

Development of Technique. - After the analyst's curiosity had, as it were, been gratified by the elaboration of the technique of interpretation, it was inevitable that interest should turn to the problem of discovering the most effective way of influencing the patient. It soon became evident that the physician's immediate task was to assist the patient in getting to know, and afterwards in overcoming, the resistances which emerged in him during treatment and of which, to begin with, he himself was unaware. And it was found at the same time that the essential part of the process of cure lay in the overcoming of these resistances and that unless this was achieved no permanent mental change could be brought about in the patient. Since the analyst's efforts have in this way been directed upon the patient's resistance, analytic technique has attained a certainty and delicacy rivalling that of surgery. Consequently, everyone is strongly advised against undertaking psycho-analytic treatments without a strict training, and a physician who ventures upon them on the strength of his medical qualification is in no respect better than a layman.

[1923a, 3925]
There are many ways and means of practising psychotherapy. All that lead to recovery are good. Our usual word of comfort, which we dispense so liberally to our patients - 'You'll soon be all right again' -, corresponds to one of these psychotherapeutic methods; but now that we have deeper insight into the neuroses, we are no longer obliged to confine ourselves to the word of comfort. We have developed the technique of hypnotic suggestion, and psychotherapy by mental distraction, by exercise, and by eliciting suitable affects. I despise none of these methods and would use them all in appropriate circumstances. If I have actually come to confine myself to one form of treatment, to the method which Breuer called cathartic, but which I myself prefer to call 'analytic', it is because I have allowed myself to be influenced by purely subjective motives. Because of the part I have played in founding this therapy, I feel a personal obligation to devote myself to closer investigation of it and to the development of its technique. And I may say that the analytic method of psychotherapy is the one that penetrates most deeply and carries farthest, the one by means of which the most extensive transformations can be effected in patients. Putting aside for a moment the therapeutic point of view, I may also say of it that it is the most interesting method, the only one which informs us at all about the origin and inter-relation of morbid phenomena. Owing to the insight which we gain into mental illness by this method, it alone should be capable of leading us beyond its own limits and of pointing out the way to other forms of therapeutic influence.

[1905a, 1565]

_Psycho-Analysis as a Therapeutic Procedure._ - Psycho-analysis has never set itself up as a panacea and has never claimed to perform miracles. In one of the most difficult spheres of medical activity it is the only possible method of treatment for certain illnesses and for others it is the method which yields the best or the most permanent results - though never without a corresponding expenditure of time and trouble. A physician who is not wholly absorbed in the work of giving help will find his labours amply repaid by obtaining an unhoped-for insight into the complications of mental life and the interrelations between the mental and the physical. Where at present it cannot offer help but only theoretical understanding, it may perhaps be preparing the way for some later, more direct means of influencing neurotic disorders. Its province is above all the two transference neuroses, hysteria and obsessional neurosis, in which it has contributed to the discovery of their internal structure and operative mechanisms; and, beyond them, all kinds of phobias, inhibitions, deformities of character, sexual perversions and difficulties in erotic life. Some analysts (Jelliffe, Groddeck, Felix Deutsch) have reported too that the analytic treatment of gross organic diseases is not unpromising, since a mental factor not infrequently contributes to the origin and continuance of such illnesses. Since psycho-analysis demands a certain amount of psychical plasticity from its patients, some kind of age-limit must be laid down in their selection; and since it necessitates the devotion of long and intense attention to the individual patient, it would be uneconomical to squander such expenditure upon completely worthless persons who happen to be neurotic. Experience upon material in clinics can alone show what modifications may be necessary in order to make psycho-analytic treatment accessible to wider strata of the population or to adapt it to weaker intelligences.

[1923a, 3926]
Compared with the other psychotherapeutic procedures psycho-analysis is beyond any doubt the most powerful. It is just and fair, too, that this should be so for it is also the most laborious and time-consuming; it would not be used on slight cases. In suitable cases it is possible by its means to get rid of disturbances and bring about changes for which in pre-analytic times one would not have ventured to hope. But it has its very appreciable limits. The therapeutic ambition of some of my adherents has made the greatest efforts to overcome these obstacles so that every sort of neurotic disorder might be curable by psycho-analysis. They have endeavoured to compress the work of analysis into a shorter duration, to intensify transference so that it may be able to overcome any resistance, to unite other forms of influence with it so as to compel a cure. These efforts are certainly praiseworthy, but, in my opinion, they are vain. They bring with them, too, a danger of being oneself forced away from analysis and drawn into a boundless course of experimentation. The expectation that every neurotic phenomenon can be cured may, I suspect, be derived from the layman's belief that the neuroses are something quite unnecessary which have no right whatever to exist. Whereas in fact they are severe, constitutionally fixed illnesses, which rarely restrict themselves to only a few attacks but persist as a rule over long periods or throughout life. Our analytic experience that they can be extensively influenced, if the historical precipitating causes and accidental auxiliary factors of the illness can be dealt with, has led us to neglect the constitutional factor in our therapeutic practice, and in any case we can do nothing about it; but in theory we ought always to bear it in mind. The radical inaccessibility of the psychoses to analytic treatment should, in view of their close relationship to the neuroses, restrict our pretensions in regard to these latter. The therapeutic effectiveness of psycho-analysis remains cramped by a number of weighty and scarcely assailable factors. In the case of children, where one might count on the greatest successes, the difficulties are the external ones connected with their relation to their parents, though these difficulties are after all a necessary part of being a child. In the case of adults the difficulties arise in the first instance from two factors: the amount of psychical rigidity present and the form of the illness with all that that covers in the way of deeper determinants.

[1933a, 4752]
A chance observation has led us, over a number of years, to investigate a great variety of different forms and symptoms of hysteria, with a view to discovering their precipitating cause - the event which provoked the first occurrence, often many years earlier, of the phenomenon in question. In the great majority of cases it is not possible to establish the point of origin by a simple interrogation of the patient, however thoroughly it may be carried out. This is in part because what is in question is often some experience which the patient dislikes discussing; but principally because he is genuinely unable to recollect it and often has no suspicion of the causal connection between the precipitating event and the pathological phenomenon. As a rule it is necessary to hypnotize the patient and to arouse his memories under hypnosis of the time at which the symptom made its first appearance; when this has been done, it becomes possible to demonstrate the connection in the clearest and most convincing fashion.

In our opinion the therapeutic advantages of this procedure are considerable. It is of course true that we do not cure hysteria in so far as it is a matter of disposition. We can do nothing against the recurrence of hypnoid states. Moreover, during the productive stage of an acute hysteria our procedure cannot prevent the phenomena which have been so laboriously removed from being at once replaced by fresh ones. But once this acute stage is past, any residues which may be left in the form of chronic symptoms or attacks are often removed, and permanently so, by our method, because it is a radical one; in this respect it seems to us far superior in its efficacy to removal through direct suggestion, as it is practised to-day by psychotherapists.

Her confession seemed to offer even less help towards the cure of her illness than it did towards its explanation. It was not easy to see what beneficent influence Fräulein Elisabeth could derive from recapitulating the tale of her sufferings of recent years - with which all the members of her family were so familiar - to a stranger who received it with only a moderate sympathy. Nor was there any sign of the confession producing a curative effect of this kind. During this first period of her treatment she never failed to repeat that she was still feeling ill and that her pains were as bad as ever; and, when she looked at me as the said this with a sly look of satisfaction at my discomfiture, I could not help being reminded of old Herr von R.'s judgement about his favourite daughter - that she was often 'cheeky' and 'ill-behaved'. But I was obliged to admit that she was in the right.
There is one other advantage in the use of this procedure which I must emphasize. I know of no better way of getting to understand a severe case of complicated neurosis with a greater or lesser admixture of hysteria than by submitting it to an analysis by Breuer's method. The first thing that happens is the disappearance of whatever exhibits a hysterical mechanism. In the meantime I have learnt in the course of the analysis to interpret the residual phenomena and to trace their aetiology; and in this way I have secured a firm basis for deciding which of the weapons in the therapeutic armoury against the neuroses is indicated in the case concerned. When I reflect on the difference that I usually find between my judgement on a case of neurosis before and after an analysis of this kind, I am almost inclined to regard an analysis as essential for the understanding of a neurotic illness. Moreover, I have adopted the habit of combining cathartic psychotherapy with a rest-cure which can, if need be, be extended into a complete treatment of feeding-up on Weir Mitchell lines. This gives me the advantage of being able on the one hand to avoid the very disturbing introduction of new psychical impressions during a psychotherapy, and on the other hand to remove the boredom of a rest-cure, in which the patients not infrequently fall into the habit of harmful day-dreaming. It might be expected that the often very considerable psychical work imposed on the patients during a cathartic treatment, and the excitations resulting from the reproduction of traumatic experiences, would run counter to the intentions of the Weir Mitchell rest cure and would hinder the successes which we are accustomed to see it bring about. But the opposite is in fact the case. A combination such as this between the Breuer and Weir Mitchell procedures produces all the physical improvement that we expect from the latter, as well as having a far-reaching psychical influence such as never results from a rest-cure without psychotherapy.

I have now given enough indications, I think, of the way in which these analyses have been carried out and of the observations that I have made in the course of them. What I have said may perhaps make some things seem more complicated than they are. Many problems answer themselves when we find ourselves engaged in such work. I did not enumerate the difficulties of the work in order to create an impression that, in view of the demands a cathartic analysis makes on physician and patient alike, it is only worth while undertaking one in the rarest cases. I allow my medical activities to be governed by the contrary assumption, though I cannot, it is true, lay down the most definite indications for the application of the therapeutic method described in these pages without entering into an examination of the more important and comprehensive topic of the treatment of the neuroses in general. I have often in my own mind compared cathartic psychotherapy with surgical intervention. I have described my treatments as psychotherapeutic operations; and I have brought out their analogy with the opening up of a cavity filled with pus, the scraping out of a carious region, etc. An analogy of this kind finds its justification not so much in the removal of what is pathological as in the establishment of conditions that are more likely to lead the course of the process in the direction of recovery.

I have no desire to depreciate the aetiological importance of these stock agents. Since they are very various, occur very frequently and are most often named by patients themselves, they become more prominent than the specific causes of the neuroses - an aetiology which is either hidden or unknown. Fairly frequently they fulfil the function of agents provocateurs which render manifest a neurosis that has previously been latent; and a practical interest attaches to them, for a consideration of these stock causes may offer lines of approach to a therapy which does not aim at a radical cure and is content with repressing the illness to its former state of latency.
How is it possible to remain convinced of the reality of these analytic confessions which claim to be memories preserved from the earliest childhood? and how is one to arm oneself against the tendency to lies and the facility of invention which are attributed to hysterical subjects? I should accuse myself of blame-worthy credulity if I did not possess more conclusive evidence. But the fact is that these patients never repeat these stories spontaneously, nor do they ever in the course of a treatment suddenly present the physician with the complete recollection of a scene of this kind. One only succeeds in awakening the psychical trace of a precocious sexual event under the most energetic pressure of the analytic procedure, and against an enormous resistance. Moreover, the memory must be extracted from them piece by piece, and while it is being awakened in their consciousness they become the prey to an emotion which it would be hard to counterfeit.

[1896a, 377]

I cannot say for certain what the upper age-limit is below which sexual injury plays a part in the aetiology of hysteria; but I doubt whether sexual passivity can bring on repression later than between the eighth and tenth years, unless it is enabled to do so by previous experiences. The lower limit extends as far back as memory itself - that is, therefore, to the tender age of one and a half or two years! (I have had two cases of this.) In a number of my cases the sexual trauma (or series of traumas) occurred in the third and fourth years of life. I should not lend credence to these extraordinary findings myself if their complete reliability were not proved by the development of the subsequent neurosis. In every case a number of pathological symptoms, habits and phobias are only to be accounted for by going back to these experiences in childhood, and the logical structure of the neurotic manifestations makes it impossible to reject these faithfully preserved memories which emerge from childhood life. True, it would be useless to try to elicit these childhood traumas from a hysteric by questioning him outside psycho-analysis; their traces are never present in conscious memory, only in the symptoms of the illness.

[1896b, 386]

GENTLEMEN, - When we set out to form an opinion about the causation of a pathological state such as hysteria, we begin by adopting the method of anamnestic investigation: we question the patient or those about him in order to find out to what harmful influences they themselves attribute his having fallen ill and developed these neurotic symptoms. What we discover in this way is, of course, falsified by all the factors which commonly hide the knowledge of his own state from a patient - by his lack of scientific understanding of aetiological influences, by the fallacy of post hoc, propter hoc, by his reluctance to think about or mention certain noxae and traumas. Thus in making an anamnestic investigation of this sort, we keep to the principle of not adopting the patients' belief without a thorough critical examination, of not allowing them to lay down our scientific opinion for us on the aetiology of the neurosis. Although we do, on the one hand, acknowledge the truth of certain constantly repeated assertions, such as that the hysterical state is a long-persisting after-effect of an emotion experienced in the past, we have, on the other hand, introduced into the aetiology of hysteria a factor which the patient himself never brings forward and whose validity he only reluctantly admits - namely, the hereditary disposition derived from his progenitors. As you know, in the view of the influential school of Charcot heredity alone deserves to be recognized as the true cause of hysteria, while all other noxae of the most various nature and intensity only play the part of incidental causes, of 'agents provocateurs'.

[1896c, 407]
You will readily admit that it would be a good thing to have a second method of arriving at the aetiology of hysteria, one in which we should feel less dependent on the assertions of the patients themselves. A dermatologist, for instance, is able to recognize a sore as luetic from the character of its margins, or the crust on it and of its shape, without being misled by the protestations of his patient, who denies any source of infection for it; and a forensic physician can arrive at the cause of an injury, even if he has to do without any information from the injured person. In hysteria, too, there exists a similar possibility of penetrating from the symptoms to a knowledge of their causes. But in order to explain the relationship between the method which we have to employ for this purpose and the older method of anamnestic enquiry, I should like to bring before you an analogy taken from an advance that has in fact been made in another field of work.

I have now come to the end of what I have to say to-day. Prepared as I am to meet with contradiction and disbelief, I should like to say one thing more in support of my position. Whatever you may think about the conclusions I have come to, I must ask you not to regard them as the fruit of idle speculation. They are based on a laborious individual examination of patients which has in most cases taken up a hundred or more hours of work. What is even more important to me than the value you put on my results is the attention you give to the procedure I have employed. This procedure is new and difficult to handle, but it is nevertheless irreplaceable for scientific and therapeutic purposes. You will realize, I am sure, that one cannot properly deny the findings which follow from this modification of Breuer's procedure so long as one puts it aside and uses only the customary method of questioning patients. To do so would be like trying to refute the findings of histological technique by relying upon macroscopic examination. The new method of research gives wide access to a new element in the psychical field of events, namely, to processes of thought which have remained unconscious - which, to use Breuer's expression, are 'inadmissible to consciousness'. Thus it inspires us with the hope of a new and better understanding of all functional psychical disturbances. I cannot believe that psychiatry will long hold back from making use of this new pathway to knowledge.

This volume contains the carrying-through of the subject raised in the 'Preliminary Communication' (No. XXIV) dealing with the psychical mechanism of hysterical phenomena. Although it proceeds from the joint work of the two authors, it is divided into separate sections, of which four detailed case histories together with discussions and an attempt at a 'Psychotherapy of Hysteria' represent my share. The aetiological part played by the sexual factor is stressed with greater emphasis in this book than in the 'Preliminary Communication', and the concept of 'conversion' is used to throw light on the formation of hysterical symptoms. The essay on psychotherapy seeks to give some insight into the technique of the psycho-analytic procedure, which is alone able to lead to the investigation of the unconscious content of the mind, and the employment of which may also be expected to lead to important psychological discoveries.
The appearance of there nevertheless being 'negative cases' can arise in another way as well. Sometimes an interrogation discloses the presence of a normal sexual life in a patient whose neurosis, on a superficial view, does in fact closely resemble neurasthenia or anxiety neurosis. But a more deep-going investigation regularly reveals the true state of affairs. Behind such cases, which have been taken for neurasthenia, there lies a psychoneurosis - hysteria or obsessional neurosis. Hysteria in especial, which imitates so many organic affections, can easily assume the appearance of one of the 'actual neuroses' by elevating the latter's symptoms into hysterical ones. Such hysterias in the form of neurasthenia are not even very rare. Falling back on psychoneurosis when a case of neurasthenia shows a negative sexual result, is, however, no cheap way out of the difficulty; the proof that we are right is to be obtained by the method which alone unmasks hysteria with certainty - the method of psycho-analysis, to which we shall refer presently.

[1897b, 462]

For such cases it has quite correctly come to be the therapeutic practice to disregard the psychoneurotic components in the clinical picture and to treat the 'actual neurosis' exclusively. In very many cases it is possible to overcome the neurosis as well which it has brought along with it, provided that the neurasthenia is effectively dealt with. But a different view must be taken in those cases of psychoneurosis which either appear spontaneously or remain behind as an independent entity after an illness composed of neurasthenia and psychoneurosis has run its course. When I speak of a 'spontaneous' appearance of a psychoneurosis, I do not mean that anamnestic investigation shows us no aetiological element whatever. It may do so, no doubt; but it may also happen that our attention is directed to some indifferent factor - an emotional state, an enfeeblement owing to physical illness, and so on. It must, however, be born in mind in all these cases that the true aetiology of the psychoneuroses does not lie in such precipitating causes, but remains beyond the reach of ordinary anamnestic examination.

[1897b, 471]

My knowledge of that procedure was reached in the following manner. I have been engaged for many years (with a therapeutic aim in view) in unravelling certain psychopathological structures - hysterical phobias, obsessional ideas, and so on. I have been doing so, in fact, ever since I learnt from an important communication by Josef Breuer that as regards these structures (which are looked on as pathological symptoms) unravelling these coincides with removing them. (Cf. Breuer and Freud, 1895.) If a pathological idea of this sort can be traced back to the elements in the patient's mental life from which it originated, it simultaneously crumbles away and the patient is freed from it. Considering the impotence of our other therapeutic efforts and the puzzling nature of these disorders, I felt tempted to follow the path marked out by Breuer, in spite of every difficulty, till a complete explanation was reached. I shall have on another occasion to report at length upon the form finally taken by this procedure and the results of my labours. It was in the course of these psycho-analytic studies that I came upon dream-interpretation. My patients were pledged to communicate to me every idea or thought that occurred to them in connection with some particular subject; amongst other things they told me their dreams and so taught me that a dream can be inserted into the psychical chain that has to be traced backwards in the memory from a pathological idea. It was then only a short step to treating the dream itself as a symptom and to applying to dreams the method of interpretation that had been worked out for symptoms.

[1900a, 603]
The orthopaedic institute referred back to a remark I had made in which I had compared the treatment, alike in its length and in its nature, to an orthopaedic one. When I started her treatment I had been obliged to tell her that for the time being I had not much time for her, though later I should be able to give her a whole hour daily. This had stirred up her old sensitiveness, which is a principal trait in the character of children inclined to hysteria: they are insatiable for love. My patient had been the youngest of a family of six children (hence: at the same time as five others) and had therefore been her father's favourite; but even so she seems to have felt that her adored father devoted too little of his time and attention to her. -Her waiting for me to say it wasn't true had the following origin. A young tailor's apprentice had brought her a dress and she had given him the money for it. Afterwards she had asked her husband whether if the boy lost the money she would have to pay it over again. Her husband, to tease her, had said that was so. (The teasing in the dream.) She kept on asking over and over again and waited for him to say after all it wasn't true. It was then possible to infer that in the latent content of the dream she had had a thought of whether she would have to pay me twice as much if I gave her twice as much time - a thought which she felt was avaricious or filthy. (Uncleanliness in childhood is often replaced in dreams by avariciousness for money; the link between the two is the word 'filthy'.) If the whole passage about waiting for me to say, etc., was intended in the dream as a circumlocution for the word 'filthy', then her 'standing in the corner' and 'not lying down in the bed' would fit in with it as constituents of a scene from her childhood: a scene in which she had dirtied her bed and been punished by being made to stand in the corner, with a threat that her father would not love her any more and her brothers and sisters would laugh at her, and so on. -The small squares related to her little niece, who had shown her the arithmetical trick of arranging the digits in nine squares (I believe this is correct) so that they add up in all directions to fifteen.

[1900a, 684]

A number of the results of the analysis have been omitted, because at the time when work was broken off they had either not been established with sufficient certainty or they required further study before any general statement could be made about them. At other points, where it seemed to be permissible, I have indicated the direction along which some particular solution would probably have been found to lie. I have in this paper left entirely out of account the technique, which does not at all follow as a matter of course, but by whose means alone the pure metal of valuable unconscious thoughts can be extracted from the raw material of the patient's associations. This brings with it the disadvantage of the reader being given no opportunity of testing the correctness of my procedure in the course of this exposition of the case. I found it quite impracticable, however, to deal simultaneously with the technique of analysis and with the internal structure of a case of hysteria: I could scarcely have accomplished such a task, and if I had, the result would have been almost unreadable. The technique of analysis demands an entirely separate exposition, which would have to be illustrated by numerous examples chosen from a very great variety of cases and which would not have to take the results obtained in each particular case into account. Nor have I attempted in this paper to substantiate the psychological postulates which will be seen to underlie my descriptions of mental phenomena. A cursory attempt to do so would have effected nothing; an exhaustive one would have been a volume in itself. I can only assure the reader that I approached the study of the phenomena revealed by observation of the psychoneuroses without being pledged to any particular psychological system, and that I then proceeded to adjust my views until they seemed adapted for giving an account of the collection of facts which had been observed. I take no pride in having avoided speculation; the material for my hypotheses was collected by the most extensive and laborious series of observations. The decidedness of my attitude on the subject of the unconscious is perhaps specially likely to cause offence, for I handle unconscious ideas, unconscious trains of thought, and unconscious impulses as though they were no less valid and unimpeachable psychological data than conscious ones. But of this I am certain - that any one who sets out to investigate the same region of phenomena and employs the same method will find himself compelled to take up the same position, however much philosophers may expostulate.

[1905e, 1446]
Nevertheless, in publishing this paper, incomplete though it is, I had two objects in view. In the first place, I wished to supplement my book on the interpretation of dreams by showing how an art, which would otherwise be useless, can be turned to account for the discovery of the hidden and repressed parts of mental life. (Incidentally, in the process of analysing the two dreams dealt with in the paper, the technique of dream-interpretation, which is similar to that of psycho-analysis, has come under consideration.) In the second place, I wished to stimulate interest in a whole group of phenomena of which science is still in complete ignorance to-day because they can only be brought to light by the use of this particular method. No one, I believe, can have had any true conception of the complexity of the psychological events in a case of hysteria - the juxtaposition of the most dissimilar tendencies, the mutual dependence of contrary ideas, the repressions and displacements, and so on. The emphasis laid by Janet upon the 'idée fixe' which becomes transformed into a symptom amounts to no more than an extremely meagre attempt at schematization. Moreover, it is impossible to avoid the suspicion that, when the ideas attaching to certain excitations are incapable of becoming conscious, those excitations must act upon one another differently, run a different course, and manifest themselves differently from those other excitations which we describe as 'normal' and which have ideas attaching to them of which we become conscious. When once things have been made clear up to this point, no obstacle can remain in the way of an understanding of a therapeutic method which removes neurotic symptoms by transforming ideas of the former kind into normal ones.

Nevertheless I cannot bring myself to accept the idea that this part of psycho-analytic theory can be very much more distant than the rest from the reality which it is its business to discover. My recollections, as well as a constant re-examination of the material, assure me that this part of the theory is based upon equally careful and impartial observation. There is, moreover, no difficulty in finding an explanation of this discrepancy in the general acceptance of my views. In the first place, the beginnings of human sexual life which are here described can only be confirmed by investigators who have enough patience and technical skill to trace back an analysis to the first years of a patient's childhood. And there is often no possibility of doing this, since medical treatment demands that an illness should, at least in appearance, be dealt with more rapidly. None, however, but physicians who practise psycho-analysis can have any access whatever to this sphere of knowledge or any possibility of forming a judgement that is uninfluenced by their own dislikes and prejudices. If mankind had been able to learn from a direct observation of children, these three essays could have remained unwritten.

An important addition to our knowledge of the sexual instinct in certain people who at least approximate to the normal can be obtained from a source which can only be reached in one particular way. There is only one means of obtaining exhaustive information that will not be misleading about the sexual life of the persons known as 'psychoneurotics' - sufferers from hysteria, from obsessional neurosis, from what is wrongly described as neurasthenia, and, undoubtedly, from dementia praecox and paranoia was well. They must be subjected to psycho-analytic investigation, which is employed in the therapeutic procedure introduced by Josef Breuer and myself in 1893 and known at that time as 'catharsis'.
The removal of the symptoms of hysterical patients by psycho-analysis proceeds on the supposition that those symptoms are substitutes - transcriptions as it were - for a number of emotionally cathected mental processes, wishes and desires, which, by the operation of a special psychical procedure (repression), have been prevented from obtaining discharge in psychical activity that is admissible to consciousness. These mental processes, therefore, being held back in a state of unconsciousness, strive to obtain an expression that shall be appropriate to their emotional importance - to obtain discharge; and in the case of hysteria they find such an expression (by means of the process of 'conversion') in somatic phenomena, that is, in hysterical symptoms. By systematically turning these symptoms back (with the help of a special technique) into emotionally cathected ideas - ideas that will now have become conscious - it is possible to obtain the most accurate knowledge of the nature and origin of these formerly unconscious psychical structures.

From these remarks on the technique of the psycho-analytic method the conclusion might be drawn that its inventor has given himself needless trouble and has made a mistake in abandoning the less complicated hypnotic mode of procedure. However, in the first place, the technique of psycho-analysis is much easier in practice, when once one has learnt it, than any description of it would indicate; and, secondly, there is no other way which leads to the desired goal, so that the hard road is still the shortest one to travel. The objection to hypnosis is that it conceals the resistance and for that reason has obstructed the physician's insight into the play of psychical forces. Hypnosis does not do away with the resistance but only evades it and therefore yields only incomplete information and transitory therapeutic success.

There are many ways and means of practising psychotherapy. All that lead to recovery are good. Our usual word of comfort, which we dispense so liberally to our patients - 'You'll soon be all right again' -, corresponds to one of these psychotherapeutic methods; but now that we have deeper insight into the neuroses, we are no longer obliged to confine ourselves to the word of comfort. We have developed the technique of hypnotic suggestion, and psychotherapy by mental distraction, by exercise, and by eliciting suitable affects. I despise none of these methods and would use them all in appropriate circumstances. If I have actually come to confine myself to one form of treatment, to the method which Breuer called cathartic, but which I myself prefer to call 'analytic', it is because I have allowed myself to be influenced by purely subjective motives. Because of the part I have played in founding this therapy, I feel a personal obligation to devote myself to closer investigation of it and to the development of its technique. And I may say that the analytic method of psychotherapy is the one that penetrates most deeply and carries farthest, the one by means of which the most extensive transformations can be effected in patients. Putting aside for a moment the therapeutic point of view, I may also say of it that it is the most interesting method, the only one which informs us at all about the origin and inter-relation of morbid phenomena. Owing to the insight which we gain into mental illness by this method, it alone should be capable of leading us beyond its own limits and of pointing out the way to other forms of therapeutic influence.
(a) I have observed that this method is very often confused with hypnotic treatment by suggestion; I have noticed this because it happens comparatively often that colleagues who do not ordinarily confide their cases to me send me patients refractory patients, of course - with a request that I should hypnotize them. Now I have not used hypnosis for therapeutic purposes for some eight years (except for a few special experiments) so that I habitually send back these cases with the recommendation that anyone who relies upon hypnosis may employ it himself. There is, actually, the greatest possible antithesis between suggestive and analytic technique - the same antithesis which, in regard to the fine arts, the great Leonardo da Vinci summed up in the formulas: *per via di porre* and *per via di levare*. Painting, says Leonardo, works *per via di porre*, for it applies a substance - particles of colour - where there was no thing before, on the colourless canvas; sculpture, however, proceeds *per via di levare*, since it takes away from the block of stone all that hides the surface of the statue contained in it. In a similar way, the technique of suggestion aims at proceeding *per via di porre*; it is not concerned with the origin, strength and meaning of the morbid symptoms, but instead, it superimposes something - a suggestion - in the expectation that it will be strong enough to restrain the pathogenic idea from coming to expression. Analytic therapy, on the other hand, does not seek to add or to introduce anything new, but to take away something, to bring out something; and to this end concerns itself with the genesis of the morbid symptoms and the psychical context of the pathogenic idea which it seeks to remove. It is by the use of this mode of investigation that analytic therapy has increased our knowledge so notably. I gave up the suggestive technique, and with it hypnosis, so early in my practice because I despaired of making suggestion powerful and enduring enough to effect permanent cures. In every severe case I saw the suggestions which had been applied crumble away again; after which the disease or some substitute for it was back once more. Besides all this I have another reproach to make against this method, namely, that it conceals from us all insight into the play of mental forces; it does not permit us, for example, to recognize the *resistance* with which the patient clings to his disease and thus even fights against his own recovery; yet it is this phenomenon of resistance which alone makes it possible to understand his behaviour in daily life.

[1905a, 1566]
(c) From certain of my remarks you will have gathered that there are many characteristics in the analytic method which prevent it from being an ideal form of therapy. *Tuto, cito, jucunde:* investigation and probing do not indicate speedy results, and the resistance I have mentioned would prepare you to expect unpleasantness of various kinds. Psycho-analytic treatment certainly makes great demands upon the patient as well as upon the physician. From the patient it requires perfect sincerity - a sacrifice in itself; it absorbs time and is therefore also costly; for the physician it is no less time-absorbing, and the technique which he must study and practise is fairly laborious. I consider it quite justifiable to resort to more convenient methods of treatment as long as there is any prospect of achieving anything by their means. That, after all, is the only point at issue. If the more difficult and lengthy method accomplishes considerably more than the short and easy one, then, in spite of everything, the use of the former is justified. Only consider, Gentlemen, how much more inconvenient and costly is the Finsen therapy of lupus than the method of cauterizing and scraping previously employed; and yet the use of the former signifies a great advance, for it performs a radical cure. Although I do not wish to carry this comparison to extremes, the psycho-analytic method may claim a similar privilege. Actually, I have been able to elaborate and to test my therapeutic method only on severe, indeed on the severest cases; at first my material consisted entirely of patients who had tried everything else without success, and had spent long years in sanatoria. I have scarcely been able to bring together sufficient material to enable me to say how my method works with those slighter, episodic cases which we see recovering under all kinds of influences and even spontaneously. Psycho-analytic therapy was created through and for the treatment of patients permanently unfit for existence, and its triumph has been that it has made a satisfactorily large number of these permanently fit for existence. In the face of such an achievement all the effort expended seems trivial. We cannot conceal from ourselves what, as physicians, we are in the habit of denying to our patients, namely, that a severe neurosis is no less serious for the sufferer than any cachexia or any of the dreaded major diseases.

[1905a, 1568]

It is gratifying that precisely the most valuable and most highly developed persons are best suited for this procedure; and one may also safely claim that in cases where analytic psychotherapy has been able to achieve but little, any other therapy would certainly not have been able to effect anything at all.

[1905a, 1570]
I think it is worth emphasizing the fact that, whatever modifications my views on the aetiology of the psychoneuroses have passed through, there are two positions which I have never repudiated or abandoned - the importance of sexuality and of infantilism. Apart from this, accidental influences have been replaced by constitutional factors and 'defence' in the purely psychological sense has been replaced by organic 'sexual repression'. The question may, however, be raised of where convincing evidence is to be found in favour of the alleged aetiological importance of sexual factors in the psychoneuroses, in view of the fact that the onset of these illnesses may be observed in response to the most commonplace emotions or even to somatic precipitating causes, and since I have had to abandon a specific aetiology depending on the particular form of the childhood experiences concerned. To such a question I would reply that the psycho-analytic examination of neurotics is the source from which this disputed conviction of mine is derived. If we make use of that irreplaceable method of research, we discover that the patient's symptoms constitute his sexual activity (whether wholly or in part), which arises from the sources of the normal or perverse component instincts of sexuality. Not only is a large part of the symptomatology of hysteria derived directly from expressions of sexual excitement, not only do a number of erotogenic zones attain the significance of genitals during neuroses owing to an intensification of infantile characteristics, but the most complicated symptoms are themselves revealed as representing, by means of 'conversion', phantasies which have a sexual situation as their subject-matter. Anyone who knows how to interpret the language of hysteria will recognize that the neurosis is concerned only with the patient's repressed sexuality. The sexual function must, however, be understood in its true extent, as it is laid down by disposition in infancy. Wherever some commonplace emotion must be included among the determinants of the onset of the illness, analysis invariably shows that it is the sexual component of the traumatic experience - a component that is never lacking which has produced the pathogenic result.

Psycho-analytic research into the neuroses (the various forms of nervous illness with a mental causation) has endeavoured to trace their connection with instinctual life and the restrictions imposed on it by the claims of civilization, with the activities of the normal individual in phantasies and dreams, and with the creations of the popular mind in religion, myths and fairy tales. The psycho-analytic treatment of neurotic patients, based on this method of research, makes far higher demands on doctor and patient than the methods hitherto in common use, which operate through medicaments, diet, hydropathy and suggestion. But it brings the patients so much more relief and permanent strengthening in the face of life's problems, that there is no cause for surprise at the continual advances made by this therapeutic method in spite of violent opposition.

4 I only produced these arguments so as once more to demonstrate to myself their inefficacy. I cannot understand how other psychotherapists can assert that they successfully combat neuroses with such weapons as these.
If, then, Leonardo's story about the vulture that visited him in his cradle is only a phantasy from a later period, one might suppose it could hardly be worth while spending much time on it. One might be satisfied with explaining it on the basis of his inclination, of which he makes no secret, to regard his preoccupation with the flight of birds as pre-ordained by destiny. Yet in underrating this story one would be committing just as great an injustice as if one were carelessly to reject the body of legends, traditions and interpretations found in a nation's early history. In spite of all the distortions and misunderstandings, they still represent the reality of the past: they are what a people forms out of the experience of its early days and under the dominance of motives that were once powerful and still operate to-day; and if it were only possible, by a knowledge of all the forces at work, to undo these distortions, there would be no difficulty in disclosing the historical truth lying behind the legendary material. The same holds good for the childhood memories or phantasies of an individual. What someone thinks he remembers from his childhood is not a matter of indifference; as a rule the residual memories - which he himself does not understand - cloak priceless pieces of evidence about the most important features in his mental development.¹ As we now possess in the techniques of psycho-analysis excellent methods for helping us to bring this concealed material to light, we may venture to fill in the gap in Leonardo's life story by analysing his childhood phantasy. And if in doing so we remain dissatisfied with the degree of certainty which we achieve, we shall have to console ourselves with the reflection that so many other studies of this great and enigmatic man have met with no better fate.

I should therefore like to let you go with an assurance that in treating your patients psycho-analytically you are doing your duty in more senses than one. You are not merely working in the service of science, by making use of the one and only opportunity for discovering the secrets of the neuroses; you are not only giving your patients the most efficacious remedy for their sufferings that is available to-day; you are contributing your share to the enlightenment of the community from which we expect to achieve the most radical prophylaxis against neurotic disorders along the indirect path of social authority.

It should be taken as an encouraging sign of the awakening interest in psychotherapy that a second edition of this book has been called for so quickly. Unluckily we cannot hail the book itself as an encouraging phenomenon. The author, who is an assistant physician in the Gainfarn hydrothermal institute near Vienna, has borrowed the form of Oppenheim's Psychotherapeutische Briehe and has given that form a psycho-analytic content. This is in a sense ill-judged, since psycho-analysis cannot be satisfactorily combined with Oppenheim's (or, if that is preferred, Dubois') technique of 'persuasion'; it looks for it therapeutic results along quite other paths. What is more important, however, is the fact that the author fails to attain the merits of his model - tact and moral seriousness - and that in his presentation of psycho-analytic theory he often drops into empty rhetoric and is also guilty of some misstatements. Nevertheless much of what he writes is neatly and aptly expressed; and the book may pass muster as a work for popular consumption. In a more serious, scientific exposition of the subject the author would have had to indicate the sources of his views and assertions with greater conscientiousness.
The interest felt by the practical psychiatrist in such delusional formations as these is, as a rule, exhausted when once he has ascertained the character of the products of the delusion and has formed an estimate of their influence on the patient's general behaviour: in his case marvelling is not the beginning of understanding. The psycho-analyst, in the light of his knowledge of the psychoneuroses, approaches the subject with a suspicion that even thought-structures so extraordinary as these and so remote from our common modes of thinking are nevertheless derived from the most general and comprehensible impulses of the human mind; and he would be glad to discover the motives of such a transformation as well as the manner in which it has been accomplished. With this aim in view, he will wish to go more deeply into the details of the delusion and into the history of its development.

[1911c, 2394]

This working-through of the resistances may in practice turn out to be an arduous task for the subject of the analysis and a trial of patience for the analyst. Nevertheless it is a part of the work which effects the greatest changes in the patient and which distinguishes analytic treatment from any kind of treatment by suggestion. From a theoretical point of view one may correlate it with the 'abreacting' of the quotas of affect strangulated by repression - an abreaction without which hypnotic treatment remained ineffective.

[1914g, 2506]

In its time, hypnotic treatment by suggestion very soon passed beyond the sphere of medical application and entered the service of the education of young people. If we are to believe the reports, it proved to be an effective means forgetting rid of childish faults, of inconvenient physical habits and of character traits that were otherwise irreducible. No one at that time objected to, or was surprised at, this extension of its uses, which, incidentally, has only been made fully understandable by the researches of psycho-analysis. For we know to-day that pathological symptoms are often nothing but substitutes for bad (that is, unserviceable) inclinations, and that the determinants of these symptoms are laid down in the years of childhood and youth - during the same period in which human beings are the subject of education - whether the illnesses themselves already emerge in youth or only at a later time of life.

[1913b, 2634]

We may hope, therefore, that the time is not far distant when it will be generally recognized that no sort of nervous disturbance can be understood and treated without the help of the line of approach and often of the technique of psycho-analysis. Such an assertion may sound to-day like a piece of presumptuous exaggeration; but I venture to prophesy that it is destined to become a platitude. It will, however, always be to the credit of the author of the present work that he has not waited for this to happen before admitting psycho-analysis as a treatment of the nervous ailments within his own specialized branch of medicine.

[1913e, 2645]

We may give as instances of disorders that are accessible to psycho-analytic treatment hysterical convulsions and paralyses as well as the various symptoms of obsessional neurosis (obsessive ideas and actions). All of these are conditions which are occasionally subject to spontaneous recovery and are dependent on the personal influence of the physician in a haphazard fashion which has not yet been explained. Psycho-analysis has no therapeutic effect on the severer forms of mental disorder properly so called. But - for the first time in the history of medicine - psycho-analysis has made it possible to get some insight into the origin and mechanism alike of the neuroses and psychoses.

[1913j, 2802]
Let us now leave primaeval man, and turn to the unconscious in our own mental life. Here we depend entirely upon the psycho-analytic method of investigation, the only one which reaches to such depths. What, we ask, is the attitude of our unconscious towards the problem of death? The answer must be: almost exactly the same as that of primaeval man. In this respect, as in many others, the man of prehistoric times survives unchanged in our unconscious. Our unconscious, then, does not believe in its own death; it behaves as if it were immortal. What we call our 'unconscious' - the deepest strata of our minds, made up of instinctual impulses - knows nothing that is negative, and no negation; in it contradictories coincide. For that reason it does not know its own death, for to that we can give only a negative content. Thus there is nothing instinctual in us which responds to a belief in death. This may even be the secret of heroism. The rational grounds for heroism rest on a judgement that the subject's own life cannot be so precious as certain abstract and general goods. But more frequent, in my view, is the instinctive and impulsive heroism which knows no such reasons, and flouts danger in the spirit of Anzengruber's Steinklopfherans: 'Nothing can happen to me'. Or else those reasons only serve to clear away the hesitations which might hold back the heroic reaction that corresponds to the unconscious. The fear of death, which dominates us oftener than we know, is on the other hand something secondary, and is usually the outcome of a sense of guilt.

[1915b, 3088]

Readers of Hebrew and especially young people eager for knowledge are presented in this volume with psycho-analysis clothed in the ancient language which has been awakened to a new life by the will of the Jewish people. The author can well picture the problem which this has set its translator. Nor need he suppress his doubt whether Moses and the Prophets would have found these Hebrew lectures intelligible. But he begs their descendants (among whom he himself is numbered), for whom this book is designed, not to react too quickly to their first impulses of criticism and dislike by rejecting it. Psycho-analysis brings forward so much that is new, and among it so much that contradicts traditional opinions and wounds deeply rooted feelings, that it is bound at first to provoke denial. A reader who suspends his judgement and allows psycho-analysis as a whole to make its impression on him will perhaps become open to a conviction that even this undesired novelty is worth knowing and is indispensable for anyone who wishes to understand the mind and human life.

[1916-1917, 3127]

And now perhaps you understand better why I did not choose to arrange my material differently. If I had promised you an 'Introduction to the Theory of the Neuroses' the correct path would certainly have led from the simple forms of the 'actual' neuroses to the more complicated psychical illnesses due to disturbance of the libido. As regards the former I should have had to collect from various sources what we have learnt or believe we know, and in connection with the psychoneuroses psycho-analysis would have come up for discussion as the most important technical aid in throwing light on those conditions. But what I intended to give and what I announced was an 'Introduction to Psycho-Analysis'. It was more important for me that you should gain an idea of psycho-analysis than that you should obtain some pieces of knowledge about the neuroses; and for that reason the 'actual' neuroses, unproductive so far as psycho-analysis is concerned, could no longer have a place in the foreground. I believe, too, that I have made the better choice for you. For, on account of the profundity of its hypotheses and the comprehensiveness of its connections, psycho-analysis deserves a place in the interest of every educated person, while the theory of the neuroses is a chapter in medicine like any other.

[1916-1917, 3440]
Your second observation, too, raises a justifiable question, but it is aimed in the wrong direction. It is true that a withdrawal of the object-libido into the ego is not directly pathogenic; it takes place, indeed, as we know, every time before we go to sleep, only to be reversed when we wake up. The amoeba withdraws its protrusions only to send them out again at the first opportunity. But it is quite a different thing when a particular, very energetic process forces a withdrawal of libido from objects. Here the libido that has become narcissistic cannot find its way back to objects, and this interference with the libido's mobility certainly becomes pathogenic. It seems that an accumulation of narcissistic libido beyond a certain amount is not tolerated. We may even imagine that it was for that very reason that object-cathexes originally came about, that the ego was obliged to send out its libido so as not to fall ill as a result of its being dammed up. If it lay within our plan to go more deeply into dementia praecox, I would show you that the process which detaches the libido from objects and cuts off its return to them is closely related to the process of repression and is to be looked at as its counterpart. But you would, first and foremost, find yourselves on familiar ground when you learnt that the determinants of this process are almost identical - so far as we know at present - with those of repression. The conflict seems to be the same and to be carried on between the same forces. If the outcome is so different from, for instance, that in hysteria, the reason can only depend on a difference in innate disposition. The weak spot in the libidinal development of these patients lies in a different phase; the determining fixation, which, as you will recollect, permits the irruption that leads to the formation of symptoms, lies elsewhere, probably in the stage of primitive narcissism to which dementia praecox returns in its final outcome. It is very remarkable that in the case of all the narcissistic neuroses we have to assume fixation points for the libido going back to far earlier phases of development than in hysteria or obsessional neurosis. As you heard, however, the concepts which we arrived at during our study of the transference neuroses are adequate in helping us to find our way about in the narcissistic neuroses which are so much more severe in practice. The conformities go very far; at bottom the field of phenomena is the same. And you can imagine how small a prospect anyone has of explaining these disorders (which belong within the sphere of psychiatry) who is not forearmed for his task with an analytic knowledge of the transference neuroses.

[1916-1917, 3466]

There are difficulties in addition which hold up our advance. The narcissistic disorders and the psychoses related to them can only be deciphered by observers who have been trained through the analytic study of the transference neuroses. But our psychiatrists are not students of psycho-analysis and we psycho-analysts see too few psychiatric cases. A race of psychiatrists must first grow up who have passed through the school of psycho-analysis as a preparatory science. A start in that direction is now being made in America, where very many leading psychiatrists lecture to students on the theories of psycho-analysis and where the proprietors of institutions and the directors of insane asylums endeavour to observe their patients in conformity with those theories. Nevertheless we too, over here, have succeeded sometimes in casting a glance over the narcissistic wall and in what follows I shall tell you a little of what we think we have detected. [1916-1917, 3467]
Moreover, I can assure you that you are misinformed if you suppose that advice and guidance in the affairs of life play an integral part in analytic influence. On the contrary, so far as possible we avoid the role of a mentor such as this and there is nothing we would rather bring about than the patient should make his decisions for himself. With this purpose, too, we require him to postpone for the term of his treatment any vital decisions on choice of a profession, business undertakings, marriage or divorce, and only to put them in practice when the treatment is finished. You must admit that all this is different from what you pictured. Only in the case of some very youthful or quite helpless or unstable individuals are we unable to put the desired limitation of our role into effect. With them we have to combine the functions of a doctor and an educator; but when this is so we are quite conscious of our responsibility and behave with the necessary caution.

[1916-1917, 3476]

But you must not conclude from my eagerness in defending myself against the charge that neurotics are encouraged in analytic treatment to live a full life - you must not conclude from this that we influence them in favour of conventional virtue. That is at least as far from being the case. It is true that we are not reformers but merely observers; nevertheless, we cannot help observing with a critical eye and we have found it impossible to side with conventional sexual morality or to form a very high opinion of the manner in which society attempts the practical regulation of the problems of sexual life. We can present society with a blunt calculation that what is described as its morality calls for a bigger sacrifice than it is worth and that its proceedings are not based on honesty and do not display wisdom. We do not keep such criticisms from our patients’ ears, we accustom them to giving unprejudiced consideration to sexual matters no less than to any others; and if, having grown independent after the completion of their treatment, they decide on their own judgement in favour of some midway position between living a full life and absolute asceticism, we feel our conscience clear whatever their choice. We tell ourselves that anyone who has succeeded in educating himself to truth about himself is permanently defended against the danger of immorality, even though his standard of morality may differ in some respect from that which is customary in society. Moreover, we must guard against over-estimating the importance of the part played by the question of abstinence in influencing neuroses. Only in a minority of cases can the pathogenic situation of frustration and the subsequent damming-up of libido be brought to an end by the sort of sexual intercourse that can be procured without much trouble.

[1916-1917, 3477]

I will digress for a moment to ask if you know what is meant by a causal therapy. That is how we describe procedure which does not take the symptoms of an illness as its point of attack but sets about removing its causes. Well, then, is our psycho-analytic method a causal therapy or not? The reply is not a simple one, but it may perhaps give us an opportunity of realizing the worthlessness of a question framed in this way. In so far as analytic therapy does not make it its first task to remove the symptoms, it is behaving like a causal therapy. In another respect, you may say, it is not. For we long ago traced the causal chain back through the repressions to the instinctual dispositions, their relative intensities in the constitution and the deviations in the course of their development. Supposing, now, that it was possible, by some chemical means, perhaps, to interfere in this mechanism, to increase or diminish the quantity of libido present at a given time or to strengthen one instinct at the cost of another - this then would be a causal therapy in the true sense of the word, for which our analysis would have carried out the indispensable preliminary work of reconnaissance. At present, as you know, there is no question of any such method of influencing libidinal processes; with our psychical therapy we attack at a different point in the combination - not exactly at what we know are the roots of the phenomena, but nevertheless far enough away from the symptoms, at a point which has been made accessible to us by some very remarkable circumstances.

[1916-1917, 3478]
But here I will pause, and let you have a word; for I see an objection boiling up in you so fiercely that it would make you incapable of listening if it were not put into words: ‘Ah! so you’ve admitted it at last! You work with the help of suggestion, just like the hypnotists! That is what we’ve thought for a long time. But, if so, why the roundabout road by way of memories of the past, discovering the unconscious, interpreting and translating back distortions - this immense expenditure of labour, time and money - when the one effective thing is after all only suggestion? Why do you not make direct suggestion against the symptoms, as the others do - the honest hypnotists? Moreover, if you try to excuse yourself for your long detour on the ground that you have made a number of important psychological discoveries which are hidden by direct suggestion - what about the certainty of these discoveries now? Are not they a result of suggestion too, of unintentional suggestion? Is it not possible that you are forcing on the patient what you want and what seems to you correct, in this field as well?’

Direct suggestion is suggestion aimed against the manifestation of the symptoms; it is a struggle between your authority and the motives for the illness. In this you do not concern yourself with these motives; you merely request the patient to suppress their manifestation in symptoms. It makes no difference of principle whether you put the patient under hypnosis or not. Once again Bernheim, with his characteristic perspicacity, maintained that suggestion was the essential element in the phenomena of hypnotism, that hypnosis itself was already a result of suggestion, a suggested state; and he preferred to practise suggestion in a waking state, which can achieve the same effects as suggestion under hypnosis.

In the light of the knowledge we have gained from psycho-analysis we can describe the difference between hypnotic and psycho-analytic suggestion as follows. Hypnotic treatment seeks to cover up and gloss over something in mental life; analytic treatment seeks to expose and get rid of something. The former acts like a cosmetic, the latter like surgery. The former makes use of suggestion in order to forbid the symptoms; it strengthens the repressions, but, apart from that, leaves all the processes that have led to the formation of the symptoms unaltered. Analytic treatment makes its impact further back towards the roots, where the conflicts are which gave rise to the symptoms, and uses suggestion in order to alter the outcome of those conflicts. Hypnotic treatment leaves the patient inert and unchanged, and for that reason, too, equally unable to resist any fresh occasion for falling ill. An analytic treatment demands from both doctor and patient the accomplishment of serious work, which is employed in lifting internal resistances. Through the overcoming of these resistances the patient’s mental life is permanently changed, is raised to a high level of development and remains protected against fresh possibilities of falling ill. This work of overcoming resistances is the essential function of analytic treatment; the patient has to accomplish it and the doctor makes this possible for him with the help of suggestion operating in an educative sense. For that reason psycho-analytic treatment has justly been described as a kind of after-education.
I hope I have now made it clear to you in what way our method of employing suggestion therapeutically differs from the only method possible in hypnotic treatment. You will understand too, from the fact that suggestion can be traced back to transference, the capriciousness which struck us in hypnotic therapy, while analytic treatment remains calculable within its limits. In using hypnosis we are dependent on the state of the patient's capacity for transference without being able to influence it itself. The transference of a person who is to be hypnotized may be negative or, as most frequently, ambivalent, or he may have protected himself against his transference by adopting special attitudes; of that we learn nothing. In psycho-analysis we act upon the transference itself, resolve what opposes it, adjust the instrument with which we wish to make our impact. Thus it becomes possible for us to derive an entirely fresh advantage from the power of suggestion; we get it into our hands. The patient does not suggest to himself whatever he pleases: we guide his suggestion so far as he is in any way accessible to its influence.

But you will now tell me that, no matter whether we call the motive force of our analysis transference or suggestion, there is a risk that the influencing of our patient may make the objective certainty of our findings doubtful. What is advantageous to our therapy is damaging to our researches. This is the objection that is most often raised against psycho-analysis, and it must be admitted that, though it is groundless, it cannot be rejected as unreasonable. If it were justified, psycho-analysis would be nothing more than a particularly well-disguised and particularly effective form of suggestive treatment and we should have to attach little weight to all that it tells us about what influences our lives, the dynamics of the mind or the unconscious. That is what our opponents believe; and in especial they think that we have 'talked' the patients into everything relating to the importance of sexual experiences - or even into those experiences themselves - after such notions have grown up in our own depraved imagination. These accusations are contradicted more easily by an appeal to experience than by the help of theory. Anyone who has himself carried out psycho-analyses will have been able to convince himself on countless occasions that it is impossible to make suggestions to a patient in that way. The doctor has no difficulty, of course, in making him a supporter of some particular theory and in thus making him share some possible error of his own. In this respect the patient is behaving like anyone else - like a pupil - but this only affects his intelligence, not his illness. After all, his conflicts will only be successfully solved and his resistances overcome if the anticipatory ideas he is given tally with what is real in him. Whatever in the doctor's conjectures is inaccurate drops out in the course of the analysis; it has to be withdrawn and replaced by something more correct. We endeavour by a careful technique to avoid the occurrence of premature successes due to suggestion; but no harm is done even if they do occur, for we are not satisfied by a first success. We do not regard an analysis as at an end until all the obscurities of the case are cleared up, the gaps in the patient's memory filled in, the precipitating causes of the repressions discovered. We look upon successes that set in too soon as obstacles rather than as a help to the work of analysis; and we put an end to such successes by constantly resolving the transference on which they are based. It is this last characteristic which is the fundamental distinction between analytic and purely suggestive therapy, and which frees the results of analysis from the suspicion of being successes due to suggestion. In every other kind of suggestive treatment the transference is carefully preserved and left untouched; in analysis it is itself subjected to treatment and is dissected in all the shapes in which it appears. At the end of an analytic treatment the transference must itself be cleared away; and if success is then obtained or continues, it rests, not on suggestion, but on the achievement by its means of an overcoming of internal resistances, on the internal change that has been brought about in the patient.
We shall soon have reached the end. You are perhaps disappointed that on the topic of the psycho-analytic method of therapy I have only spoken to you about theory and not about the conditions which determine whether a treatment is to be undertaken or about the results it produces. I shall discuss neither: the former because it is not my intention to give you practical instructions on how to carry out a psycho-analysis, and the latter because several reasons deter me from it. At the beginning of our talks, I emphasized the fact that under favourable conditions we achieve successes which are second to none of the finest in the field of internal medicine; and I can now add something further - namely that they could not have been achieved by any other procedure. If I were to say more than this I should be suspected of trying to drown the loudly raised voices of depreciation by self-advertisement. The threat has repeatedly been made against psycho-analysts by our medical 'colleagues' - even at public congresses - that a collection of the failures and damaging results of analysis would be published which would open the suffering public's eyes to the worthlessness of this method of treatment. But, apart from the malicious, denunciatory character of such a measure, it would not even be calculated to make it possible to form a correct judgement of the therapeutic effectiveness of analysis. Analytic therapy, as you know, is in its youth; it has taken a long time to establish its technique, and that could only be done in the course of working and under the influence of increasing experience. In consequence of the difficulties in giving instruction, the doctor who is a beginner in psycho-analysis is thrown back to a greater extent than other specialists on his own capacity for further development, and the results of his first years will never make it possible to judge the efficacy of analytic therapy. [1916-1917, 3497]

Another characteristic which makes the present analysis noteworthy is connected with the severity of the illness and the duration of the treatment. Analyses which lead to a favourable conclusion in a short time are of value in ministering to the therapeutist's self-esteem and substantiate the medical importance of psycho-analysis; but they remain for the most part insignificant as regards the advancement of scientific knowledge. Nothing new is learnt from them. In fact they only succeed so quickly because everything that was necessary for their accomplishment was already known. Something new can only be gained from analyses that present special difficulties, and to the overcoming of these a great deal of time has to be devoted. Only in such cases do we succeed in descending into the deepest and most primitive strata of mental development and in gaining from there solutions for the problems of the later formations. And we feel afterwards that, strictly speaking, only an analysis which has penetrated so far deserves the name. Naturally a single case does not give us all the information that we should like to have. Or, to put it more correctly, it might teach us everything, if we were only in a position to make everything out, and if we were not compelled by the inexperience of our own perception to content ourselves with a little. [1918b, 3506]

The two other doubts are based on a low estimate of the importance of early infantile impressions and an unwillingness to ascribe such enduring effects to them. The supporters of this view look for the causes of neuroses almost exclusively in the grave conflicts of later life; they assume that the importance of childhood is only held up before our eyes in analysis on account of the inclination of neurotics for expressing their present interests in reminiscences and symbols from the remote past. Such an estimate of the importance of the infantile factor would involve the disappearance of much that has formed part of the most intimate characteristics of analysis, though also, no doubt, of much that raises resistance to it and alienates the confidence of the outsider. [1918b, 3536]
Another of the functions of psycho-analysis should be to afford a preparation for the study of psychiatry. This, in its present shape, is exclusively descriptive in character; it merely teaches the student to recognize a series of pathological entities, enabling him to distinguish which are incurable and which are dangerous to the community. Its sole connection with the other branches of medical science lies in organic aetiology - that is, in its anatomical findings; but it offers not the slightest understanding of the facts observed. Such an understanding can be furnished only by a depth-psychology.

Its further course led it away from the study of the somatic determinants of nervous disease to an extent that was bewildering to physicians. Instead, it was brought into contact with the mental substance of human lives - the lives not only of the sick, but of the healthy, the normal and the supernormal. It had to deal with emotions and passions, and most of all with those which the poets never tire of depicting and celebrating - the emotions of love. It learnt to recognize the power of memories, the unsuspected importance of the years of childhood in shaping the adult, and the strength of wishes, which falsify human judgements and lay down fixed lines for human endeavour.

Psycho-Analysis as a Therapeutic Procedure. - Psycho-analysis has never set itself up as a panacea and has never claimed to perform miracles. In one of the most difficult spheres of medical activity it is the only possible method of treatment for certain illnesses and for others it is the method which yields the best or the most permanent results - though never without a corresponding expenditure of time and trouble. A physician who is not wholly absorbed in the work of giving help will find his labours amply repaid by obtaining an unhoped-for insight into the complications of mental life and the interrelations between the mental and the physical. Where at present it cannot offer help but only theoretical understanding, it may perhaps be preparing the way for some later, more direct means of influencing neurotic disorders. Its province is above all the two transference neuroses, hysteria and obsessional neurosis, in which it has contributed to the discovery of their internal structure and operative mechanisms; and, beyond them, all kinds of phobias, inhibitions, deformities of character, sexual perversions and difficulties in erotic life. Some analysts (Jelliffe, Groddeck, Felix Deutsch) have reported too that the analytic treatment of gross organic diseases is not unpromising, since a mental factor not infrequently contributes to the origin and continuance of such illnesses. Since psycho-analysis demands a certain amount of psychical plasticity from its patients, some kind of age-limit must be laid down in their selection; and since it necessitates the devotion of long and intense attention to the individual patient, it would be uneconomical to squander such expenditure upon completely worthless persons who happen to be neurotic. Experience upon material in clinics can alone show what modifications may be necessary in order to make psycho-analytic treatment accessible to wider strata of the population or to adapt it to weaker intelligences.
Comparison between Psycho-Analysis and Hypnotic and Suggestive Methods. - Psycho-analytic procedure differs from all methods making use of suggestion, persuasion, etc., in that it does not seek to suppress by means of authority any mental phenomenon that may occur in the patient. It endeavours to trace the causation of the phenomenon and to remove it by bringing about a permanent modification in the conditions that led to it. In psycho-analysis the suggestive influence which is inevitably exercised by the physician is diverted on to the task assigned to the patient of overcoming his resistances, that is, of carrying forward the curative process. Any danger of falsifying the products of a patient's memory by suggestion can be avoided by prudent handling of the technique; but in general the arousing of resistances is a guarantee against the misleading effects of suggestive influence. It may be laid down that the aim of the treatment is to remove the patient's resistances and to pass his repressions in review and thus to bring about the most far-reaching unification and strengthening of his ego, to enable him to save the mental energy which he is expending upon internal conflicts, to make the best of him that his inherited capacities will allow and so to make him as efficient and as capable of enjoyment as is possible. The removal of the symptoms of the illness is not specifically aimed at, but is achieved, as it were, as a by-product if the analysis is properly carried through. The analyst respects the patient's individuality and does not seek to remould him in accordance with his own - that is, according to the physician's - personal ideals; he is glad to avoid giving advice and instead to arouse the patient's power of initiative.

Its Relation to Psychiatry. - Psychiatry is at present essentially a descriptive and classificatory science whose orientation is still towards the somatic rather than the psychological and which is without the possibility of giving explanations of the phenomena which it observes. Psycho-analysis does not, however, stand in opposition to it, as the almost unanimous behaviour of the psychiatrists might lead one to believe. On the contrary, as a depth-psychology, a psychology of those processes in mental life which are withdrawn from consciousness, it is called upon to provide psychiatry with an indispensable groundwork and to free it from its present limitations. We can foresee that the future will give birth to a scientific psychiatry, to which psycho-analysis has served as an introduction.

The papers here collected into a single volume, which were written by Putnam between 1909 and the end of his life, give a good picture of his relations to psycho-analysis. They show how he was at first occupied in correcting a provisional judgement which was based on insufficient knowledge; how he then accepted the essence of analysis, recognized its capacity for throwing a clear light upon the origin of human imperfections and failings, and how he was struck by the prospect of contributing towards the improvement of humanity along analytical lines; how he then became convinced by his own activities as a physician as to the truth of most of the psycho-analytical conclusions and postulates, and then in his turn bore witness to the fact that the physician who makes use of analysis understands far more about the sufferings of his patients and can do far more for them than was possible with the earlier methods of treatment; and finally how he began to extend beyond the limits of analysis, demanding that as a science it should be linked on to a particular philosophical system, and that its practice should be openly associated with a particular set of ethical doctrines.
I will not preface my reply with the words, 'to be honest' or 'to be candid', for one must always be able to be these things without any special preliminaries. I will instead say quite simply that I know very well that no reader who does not already believe in the justifiability of the psychoanalytic mode of thought will acquire that belief from the case of the seventeenth-century painter, Christoph Haizmann. Nor is it my intention to make use of this case as evidence of the validity of psycho-analysis. On the contrary, I presuppose its validity and am employing it to throw light on the painter's demonological illness. My justification for doing so lies in the success of our investigations into the nature of the neuroses in general. We may say in all modesty that to-day even the more obtuse among our colleagues and contemporaries are beginning to realize that no understanding of neurotic states can be reached without the help of psycho-analysis.

The noisy rejection of psycho-analysis by the medical world could not deter its supporters from developing it, to begin with, along its original lines into a specialized pathology and treatment of the neuroses - a task which has not been completely accomplished even to-day. Its undeniable therapeutic success, which far exceeded any that had previously been achieved, constantly spurred them on to fresh efforts; while the difficulties which came to light as the material was examined more deeply led to profound alterations in the technique of analysis and to important corrections in its theoretical hypotheses and postulates.

In this way psychiatry became the first field to which psycho-analysis was applied and it has remained so ever since. The same research workers who have done most to deepen analytic knowledge of the neuroses, such as Karl Abraham in Berlin and Sándor Ferenczi in Budapest (to name only the most prominent), have also played a leading part in throwing analytic light on the psychoses. The conviction of the unity and intimate connection of all the disorders that present themselves as neurotic and psychotic phenomena is becoming more and more firmly established despite all the efforts of the psychiatrists. People are beginning to understand - best of all, perhaps, in America - that the psycho-analytic study of the neuroses is the only preparation for an understanding of the psychoses, and that psycho-analysis is destined to make possible a scientific psychiatry of the future which will not need to content itself with describing curious clinical pictures and unintelligible sequences of events and with tracing the influence of gross anatomical and toxic traumas upon a mental apparatus which is inaccessible to our knowledge.

If we may assume that the most general features of unconscious mental life (conflicts between instinctual impulses, repressions and substitutive satisfactions) are present everywhere, and if there is a depth-psychology which leads to a knowledge of those features, then we may reasonably expect that the application of psycho-analysis to the most varied spheres of human mental activity will everywhere bring to light important and hitherto unattainable results. In an exceedingly valuable study, Otto Rank and Hanns Sachs (1913) have tried to bring together what the work of psycho-analysts had been able to achieve up to that time towards fulfilling these expectations. Lack of space prevents me from attempting to complete their enumeration here. I can only select for mention the most important findings with the addition of a few details.
In my own writings and in those of my followers more and more stress is laid on the necessity that the analyses of neurotics shall deal thoroughly with the remotest period of their childhood, the time of the early efflorescence of sexual life. It is only by examining the first manifestations of the patient's innate instinctual constitution and the effects of his earliest experiences that we can accurately gauge the motive forces that have led to his neurosis and can be secure against the errors into which we might be tempted by the degree to which things have become remodelled and overlaid in adult life. This requirement is not only of theoretical but also of practical importance, for it distinguishes our efforts from the work of those physicians whose interests are focused exclusively on therapeutic results and who employ analytic methods, but only up to a certain point. An analysis of early childhood such as we are considering is tedious and laborious and makes demands both upon the physician and upon the patient which cannot always be met. Moreover, it leads us into dark regions where there are as yet no sign posts. Indeed, analysts may feel reassured, I think, that there is no risk of their work becoming mechanical, and so of losing its interest, during the next few decades.

[1925j, 4146]

It is a good thing you have asked me about that. This personal influence is our most powerful dynamic weapon. It is the new element which we introduce into the situation and by means of which we make it fluid. The intellectual content of our explanations cannot do it, for the patient, who shares all the prejudices of the world around him, need believe us as little as our scientific critics do. The neurotic sets to work because he has faith in the analyst, and he believes him because he acquires a special emotional attitude towards the figure of the analyst. Children, too, only believe people they are attached to. I have already told you what use we make of this particularly large 'suggestive' influence. Not for suppressing the symptoms - this distinguishes the analytic method from other psychotherapeutic procedures - but as a motive force to induce the patient to overcome his resistances.

[1926e, 4366]
I come now to a question the discussion of which seems to me more important. Is the practice of psycho-analysis a matter which should in general be subject to official interference, or would it be more expedient to leave it to follow its natural development? I shall certainly not come to any decision on this point here and now, but I shall take the liberty of putting the problem before you for your consideration. In our country from of old a positive *furor prohibendi* has been the rule, a tendency to keep people under tutelage, to interfere and to forbid, which, as we all know, has not borne particularly good fruit. In our new republican Austria, it seems, things have not yet changed very much. I fancy you will have an important word to say in deciding the case of psycho-analysis which we are now considering; I do not know whether you have the wish or the influence with which to oppose these bureaucratic tendencies. At all events, I shall not spare you my unauthoritative thoughts on the subject. In my opinion a superabundance of regulations and prohibitions injures the authority of the law. It can be observed that where only a few prohibitions exist they are carefully observed, but where one is accompanied by prohibitions at every step, one feels definitely tempted to disregard them. Moreover, it does not mean one is quite an anarchist if one is prepared to realize that laws and regulations cannot from their origin claim to possess the attribute of being sacred and untransgressable, that they are often inadequately framed and offend our sense of justice, or will do so after a time, and that, in view of the sluggishness of the authorities, there is often no other means of correcting such inexpedient laws than by boldly violating them. Furthermore, if one desires to maintain respect for laws and regulations it is advisable not to enact any where a watch cannot easily be kept on whether they are obeyed or transgressed. Much of what I have quoted above on the practice of analysis by doctors could be repeated here in regard to genuine analysis by laymen which the law is seeking to suppress. The course of an analysis is most inconspicuous, it employs neither medicines nor instruments and consists only in talking and an exchange of information; it will not be easy to prove that a layman is practising 'analysis', if he asserts that he is merely giving encouragement and explanations and trying to establish a healthy human influence on people who are in search of mental assistance. It would surely not be possible to forbid that merely because doctors sometimes do the same thing. In English-speaking countries the practices of Christian Science have become very widespread: a kind of dialectical denial of the evils in life, based on an appeal to the doctrines of the Christian religion. I do not hesitate to assert that that procedure represents a regrettable aberration of the human spirit; but who in America or England would dream of forbidding it and making it punishable? Are the authorities so certain of the right path to salvation that they venture to prevent each man from trying 'to be saved after his own fashion'. And granted that many people if they are left to themselves run into danger and come to grief, would not the authorities do better carefully to mark the limits of the regions which are to be regarded as not to be trespassed upon, and for the rest, so far as possible, to allow human beings to be educated by experience and mutual influence? Psycho-analysis is something so new in the world, the mass of mankind is so little instructed about it, the attitude of official science to it is still so vacillating, that it seems to me over-hasty to intervene in its development with legislative regulations. Let us allow patients themselves to discover that it is damaging to them to look for mental assistance to people who have not learnt how to give it. If we explain this to them and warn them against it, we shall have spared ourselves the need to forbid it. On the main roads of Italy the pylons that carry high-tension cables bear the brief and impressive inscription: *Chi tocca, muore.* This is perfectly calculated to regulate the behaviour of passers-by to any wires that may be hanging down. The corresponding German notices exhibit an unnecessary and offensive verbosity: *Das Berühren der Leitungsdrähte ist, weil lebensgefährlich, strengstens verboten.* Why the prohibition? Anyone who holds his life dear will make the prohibition for himself; and anyone who wants to kill himself in that way will not ask for permission.

[1926e, 4377]
Psycho-analysis finds a constantly increasing amount of support as a therapeutic procedure, owing to the fact that it can do more for its patients than any other method of treatment. The principle field of its application is in the milder neuroses - hysteria, phobias and obsessional states; and in malformations of character and sexual inhibitions or abnormalities it can also bring about marked improvements or even recoveries. Its influence upon dementia praecox and paranoia is doubtful; on the other hand, in favourable circumstances it can cope with depressive states, even if they are of a severe type.

In every instance the treatment makes heavy claims upon both the physician and the patient: the former requires a special training and must devote a long period of time to exploring the mind of each patient, while the latter must make considerable sacrifices, both material and mental. Nevertheless, all the trouble involved is as a rule rewarded by the results. Psycho-analysis does not act as a convenient panacea ("cito, tute, jucunde") for psychological disorders. On the contrary, its application has been instrumental in making clear for the first time the difficulties and limitations in the treatment of such affections. For the moment it is only in Berlin and Vienna that there are voluntary institutions which make psycho-analytic treatment accessible to the wage-earning classes.

When psycho-analysis puts itself at the service of biography, it naturally has the right to be treated no more harshly than the latter itself. Psycho-analysis can supply some information which cannot be arrived at by other means, and can thus demonstrate new connecting threads in the 'weaver's masterpiece' spread between the instinctual endowments, the experiences and the works of an artist. Since it is one of the principal functions of our thinking to master the material of the external world psychically, it seems to me that thanks are due to psycho-analysis if, when it is applied to a great man, it contributes to the understanding of his great achievement. But, I admit, in the case of Goethe we have not yet succeeded very far. This is because Goethe was not only, as a poet, a great self-revealer, but also, in spite of the abundance of autobiographical records, a careful concealer. We cannot help thinking here of the words of Mephistopheles:
You are perhaps aware that I have never been a therapeutic enthusiast; there is no danger of my misusing this lecture by indulging in eulogies. I would rather say too little than too much. During the period at which I was the only analyst, people who were ostensibly friendly to my ideas used to say to me: 'That's all very nice and clever; but show me a case that you have cured by analysis.' This was one of the many formulas which in the course of time have succeeded one another in performing the function of pushing the uncomfortable novelty aside. To-day it is as out of date as many others: the analyst, too, has a heap of letters in his files from grateful patients who have been cured. The analogy does not stop at that. Psycho-analysis is really a method of treatment like others. It has its triumphs and its defeats, its difficulties, its limitations, its indications. At one time a complaint was made against analysis that it was not to be taken seriously as a treatment since it did not dare to issue any statistics of its successes. Since then, the Psycho-Analytic Institute in Berlin, which was founded by Dr. Max Eitingon, has published a statement of its results during its first ten years. Its therapeutic successes give grounds neither for boasting nor for being ashamed. But statistics of that kind are in general uninformative; the material worked upon is so heterogeneous that only very large numbers would show anything. It is wiser to examine one's individual experiences. And here I should like to add that I do not think our cures can compete with those of Lourdes. There are so many more people who believe in the miracles of the Blessed Virgin than in the existence of the unconscious. If we turn to mundane competitors, we must compare psycho-analytic treatment with other kinds of psychotherapy. To-day organic physical methods of treating neurotic states need scarcely be mentioned. Analysis as a psycho-therapeutic procedure does not stand in opposition to other methods used in this specialized branch of medicine; it does not diminish their value nor exclude them. There is no theoretical inconsistency in a doctor who likes to call himself a psychotherapist using analysis on his patients alongside of any other method of treatment according to the peculiarities of the case and the favourable or unfavourable external circumstances. It is in fact technique that necessitates the specialization in medical practice. Thus in the same way surgery and orthopaedics were obliged to separate. Psycho-analytic activity is arduous and exacting; it cannot well be handled like a pair of glasses that one puts on for reading and takes off when one goes for a walk. As a rule psycho-analysis possesses a doctor either entirely or not at all. Those psychotherapists who make use of analysis among other methods, occasionally, do not to my knowledge stand on firm analytic ground; they have not accepted the whole of analysis but have watered it down - have drawn its fangs, perhaps; they cannot be counted as analysts. This is, I think, to be regretted. But co-operation in medical practice between an analyst and a psychotherapist who restricts himself to other techniques would serve quite a useful purpose. [1933a, 4751]
Compared with the other psychotherapeutic procedures psycho-analysis is beyond any doubt the most powerful. It is just and fair, too, that this should be so for it is also the most laborious and time-consuming; it would not be used on slight cases. In suitable cases it is possible by its means to get rid of disturbances and bring about changes for which in pre-analytic times one would not have ventured to hope. But it has its very appreciable limits. The therapeutic ambition of some of my adherents has made the greatest efforts to overcome these obstacles so that every sort of neurotic disorder might be curable by psycho-analysis. They have endeavoured to compress the work of analysis into a shorter duration, to intensify transference so that it may be able to overcome any resistance, to unite other forms of influence with it so as to compel a cure. These efforts are certainly praiseworthy, but, in my opinion, they are vain. They bring with them, too, a danger of being oneself forced away from analysis and drawn into a boundless course of experimentation. The expectation that every neurotic phenomenon can be cured may, I suspect, be derived from the layman's belief that the neuroses are something quite unnecessary which have no right whatever to exist. Whereas in fact they are severe, constitutionally fixed illnesses, which rarely restrict themselves to only a few attacks but persist as a rule over long periods or throughout life. Our analytic experience that they can be extensively influenced, if the historical precipitating causes and accidental auxiliary factors of the illness can be dealt with, has led us to neglect the constitutional factor in our therapeutic practice, and in any case we can do nothing about it; but in theory we ought always to bear it in mind. The radical inaccessibility of the psychoses to analytic treatment should, in view of their close relationship to the neuroses, restrict our pretensions in regard to these latter. The therapeutic effectiveness of psycho-analysis remains cramped by a number of weighty and scarcely assailable factors. In the case of children, where one might count on the greatest successes, the difficulties are the external ones connected with their relation to their parents, though these difficulties are after all a necessary part of being a child. In the case of adults the difficulties arise in the first instance from two factors: the amount of psychical rigidity present and the form of the illness with all that that covers in the way of deeper determinants.

[1933a, 4752]

I have told you that psycho-analysis began as a method of treatment; but I did not want to commend it to your interest as a method of treatment but on account of the truths it contains, on account of the information it gives us about what concerns human beings most of all - their own nature - and on account of the connections it discloses between the most different of their activities. As a method of treatment it is one among many, though, to be sure, primus inter pares. If it was without therapeutic value it would not have been discovered, as it was, in connection with sick people and would not have gone on developing for more than thirty years.

[1933a, 4756]

With the neurotics, then, we make our pact: complete candour on one side and strict discretion on the other. This looks as though we were only aiming at the post of a secular father confessor. But there is a great difference, for what we want to hear from our patient is not only what he knows and conceals from other people; he is to tell us too what he does not know. With this end in view we give him a more detailed definition of what we mean by candour. We pledge him to obey the fundamental rule of analysis, which is henceforward to govern his behaviour towards us. He is to tell us not only what he can say intentionally and willingly, what will give him relief like a confession, but everything else as well that his self-observation yields him, everything that comes into his head, even if it is disagreeable for him to say it, even if it seems to him unimportant or actually nonsensical. If he can succeed after this injunction in putting his self-criticism out of action, he will present us with a mass of material - thoughts, ideas, recollections - which are already subject to the influence of the unconscious, which are often its direct derivatives, and which thus put us in a position to conjecture his repressed unconscious material and to extend, by the information we give him, his ego's knowledge of his unconscious.

[1940a [1938], 4984]
The study of a mental disorder occurring during sleep, which is transient and harmless and which, indeed, performs a useful function, has given us a key to the understanding of the mental diseases which are permanent and injurious to life. And we may now venture on the assertion that the psychology of consciousness was no better capable of understanding the normal functioning of the mind than of understanding dreams. The data of conscious self-perception, which alone were at its disposal, have proved in every respect inadequate to fathom the profusion and complexity of the processes of the mind, to reveal their interconnections and so to recognize the determinants of their disturbances.

[1940a [1938], 5002]
In the first instance, therefore, I was able to do without hypnosis, with the reservation, however, that I could make use of it later if in the course of her confession material arose to the elucidation of which her memory was unequal. Thus it came about that in this, the first full-length analysis of a hysteria undertaken by me, I arrived at a procedure which I later developed into a regular method and employed deliberately. This procedure was one of clearing away the pathogenic psychical material layer by layer, and we liked to compare it with the technique of excavating a buried city. I would begin by getting the patient to tell me what was known to her and I would carefully note the points at which some train of thought remained obscure or some link in the causal chain seemed to be missing. And afterwards I would penetrate into deeper layers of her memories at these points by carrying out an investigation under hypnosis or by the use of some similar technique. The whole work was, of course, based on the expectation that it would be possible to establish a completely adequate set of determinants for the events concerned. I shall discuss presently the methods used for the deep investigation.

[1895d, 125]

You will readily admit that it would be a good thing to have a second method of arriving at the aetiology of hysteria, one in which we should feel less dependent on the assertions of the patients themselves. A dermatologist, for instance, is able to recognize a sore as luetic from the character of its margins, or the crust on it and of its shape, without being misled by the protestations of his patient, who denies any source of infection for it; and a forensic physician can arrive at the cause of an injury, even if he has to do without any information from the injured person. In hysteria, too, there exists a similar possibility of penetrating from the symptoms to a knowledge of their causes. But in order to explain the relationship between the method which we have to employ for this purpose and the older method of anamnestic enquiry, I should like to bring before you an analogy taken from an advance that has in fact been made in another field of work.

[1896c, 408]

The knowledge I have so far gained already enables me to answer these questions. If we take a case which presents several symptoms, we arrive by means of the analysis, starting from each symptom, at a series of experiences the memories of which are linked together in association. To begin with, the chains of memories lead backwards separately from one another; but, as I have said, they ramify. From a single scene two or more memories are reached at the same time, and from these again side-chains proceed whose individual links may once more be associatively connected with links belonging to the main chain. Indeed, a comparison with the genealogical tree of a family whose members have also intermarried, is not at all a bad one. Other complications in the linkage of the chains arise from the circumstance that a single scene may be called up several times in the same chain, so that it has multiple relationships to a later scene, and exhibits both a direct connection with it and a connection established through intermediate links. In short, the concatenation is far from being a simple one; and the fact that the scenes are uncovered in a reversed chronological order (a fact which justifies our comparison of the work with the excavation of a stratified ruined site) certainly contributes nothing to a more rapid understanding of what has taken place.

[1896c, 413]
His work of construction, or, if it is preferred, of reconstruction, resembles to a great extent an archaeologist's excavation of some dwelling-place that has been destroyed and buried or of some ancient edifice. The two processes are in fact identical, except that the analyst works under better conditions and has more material at his command to assist him, since what he is dealing with is not something destroyed but something that is still alive - and perhaps for another reason as well. But just as the archaeologist builds up the walls of the building from the foundations that have remained standing, determines the number and position of the columns from depressions in the floor and reconstructs the mural decorations and paintings from the remains found in the debris, so does the analyst proceed when he draws his inferences from the fragments of memories, from the associations and from the behaviour of the subject of the analysis. Both of them have an undisputed right to reconstruct by means of supplementing and combining the surviving remains. Both of them, moreover, are subject to many of the same difficulties and sources of error. One of the most ticklish problems that confronts the archaeologist is notoriously the determination of the relative age of his finds; and if an object makes its appearance in some particular level, it often remains to be decided whether it belongs to that level or whether it was carried down to that level owing to some subsequent disturbance. It is easy to imagine the corresponding doubts that arise in the case of analytic constructions.

The analyst, as we have said, works under more favourable conditions than the archaeologist since he has at his disposal material which can have no counterpart in excavations, such as the repetitions of reactions dating from infancy and all that is indicated by the transference in connection with these repetitions. But in addition to this it must be borne in mind that the excavator is dealing with destroyed objects of which large and important portions have quite certainly been lost, by mechanical violence, by fire and by plundering. No amount of effort can result in their discovery and lead to their being united with the surviving remains. The one and only course open is that of reconstruction, which for this reason can often reach only a certain degree of probability. But it is different with the psychical object whose early history the analyst is seeking to recover. Here we are regularly met by a situation which with the archaeological object occurs only in such rare circumstances as those of Pompeii or of the tomb of Tut'ankhamun. All of the essentials are preserved; even things that seem completely forgotten are present somehow and somewhere, and have merely been buried and made inaccessible to the subject. Indeed, it may, as we know, be doubted whether any psychical structure can really be the victim of total destruction. It depends only upon analytic technique whether we shall succeed in bringing what is concealed completely to light. There are only two other facts that weigh against the extraordinary advantage which is thus enjoyed by the work of analysis: namely, that psychical objects are incomparably more complicated than the excavator's material ones and that we have insufficient knowledge of what we may expect to find, since their finer structure contains so much that is still mysterious. But our comparison between the two forms of work can go no further than this; for the main difference between them lies in the fact that for the archaeologist the reconstruction is the aim and end of his endeavours while for analysis the construction is only a preliminary labour.
I must now consider the difficulties and disadvantages of our therapeutic procedure, so far as they do not become obvious to everyone from the case histories reported above or from the remarks on the technique of the method which follow later. I will enumerate and indicate these difficulties rather that elaborate them.

[1895d, 235]

The procedure is laborious and time-consuming for the physician. It presupposes great interest in psychological happenings, but personal concern for the patients as well. I cannot imagine bringing myself to delve into the psychical mechanism of a hysteria in anyone who struck me as low-minded and repellent, and who, on closer acquaintance, would not be capable of arousing human sympathy; whereas I can keep the treatment of a tabetic or rheumatic patient apart from personal approval of this kind. The demands made on the patient are not less. The procedure is not applicable at all below a certain level of intelligence, and it is made very much more difficult by any trace of feebleness of mind. The complete consent and complete attention of the patients are needed, but above all their confidence, since the analysis invariably leads to the disclosure of the most intimate and secret psychical events. A good number of the patients who would be suitable for this form of treatment abandon the doctor as soon as the suspicion begins to dawn on them of the direction in which the investigation is leading. For patients such as these the doctor has remained a stranger. With others, who have decided to put themselves in his hands and place their confidence in him - a step which in other such situations is only taken voluntarily and never at the doctor's request - with these other patients, I say, it is almost inevitable that their personal relation to him will force itself, for a time at least, unduly into the foreground. It seems, indeed, as though an influence of this kind on the part of the doctor is a \textit{sine qua non} to a solution of the problem. I do not think any essential difference is made in this respect whether hypnosis can be used or whether it has to be bypassed and replaced by something else. But reason demands that we should emphasize the fact that these drawbacks, though they are inseparable from our procedure, cannot be laid at its door. On the contrary, it is quite clear that they are based on the predetermining conditions of the neuroses that are to be cured and that they must attach to any medical activity which involves intense preoccupation with the patient and leads to a psychical change in him. I have not been able to attribute any deleterious effects or danger to the employment of hypnosis, though I made copious use of it in some of my cases. Where I caused damage, the reasons lay elsewhere and deeper. If I survey my therapeutic efforts during the last few years since the communications made by my honoured teacher and friend Josef Breuer showed me the use of the cathartic method, I believe that in spite of everything, I have done much more, and more frequent, good than harm and have accomplished some things which no other therapeutic procedure could have achieved. It has on the whole, as the 'Preliminary Communication' put it, brought 'considerable therapeutic advantages'.

[1895d, 235]
(c) From certain of my remarks you will have gathered that there are many characteristics in the analytic method which prevent it from being an ideal form of therapy. Tuto, cito, jucunde: investigation and probing do not indicate speedy results, and the resistance I have mentioned would prepare you to expect unpleasantness of various kinds. Psycho-analytic treatment certainly makes great demands upon the patient as well as upon the physician. From the patient it requires perfect sincerity - a sacrifice in itself; it absorbs time and is therefore also costly; for the physician it is no less time-absorbing, and the technique which he must study and practise is fairly laborious. I consider it quite justifiable to resort to more convenient methods of treatment as long as there is any prospect of achieving anything by their means. That, after all, is the only point at issue. If the more difficult and lengthy method accomplishes considerably more than the short and easy one, then, in spite of everything, the use of the former is justified. Only consider, Gentlemen, how much more inconvenient and costly is the Finsen therapy of lupus than the method of cautering and scraping previously employed; and yet the use of the former signifies a great advance, for it performs a radical cure. Although I do not wish to carry this comparison to extremes, the psycho-analytic method may claim a similar privilege. Actually, I have been able to elaborate and to test my therapeutic method only on severe, indeed on the severest cases; at first my material consisted entirely of patients who had tried everything else without success, and had spent long years in sanatoria. I have scarcely been able to bring together sufficient material to enable me to say how my method works with those slighter, episodic cases which we see recovering under all kinds of influences and even spontaneously. Psycho-analytic therapy was created through and for the treatment of patients permanently unfit for existence, and its triumph has been that it has made a satisfactorily large number of these permanently fit for existence. In the face of such an achievement all the effort expended seems trivial. We cannot conceal from ourselves what, as physicians, we are in the habit of denying to our patients, namely, that a severe neurosis is no less serious for the sufferer than any cachexia or any of the dreaded major diseases. [1905a, 1568]

(a) Advances in our knowledge. We are, of course, still a long way from knowing all that is required for an understanding of the unconscious in our patients. It is clear that every advance in our knowledge means an increase in our therapeutic power. As long as we have understood nothing, we have accomplished nothing; the more we understand, the more we shall achieve. At its beginning psycho-analytic treatment was inexorable and exhausting. The patient had to say everything himself, and the physician's activity consisted of urging him on incessantly. To-day things have a more friendly air. The treatment is made up of two parts - what the physician infers and tells the patient, and the patient's working-over of what he has heard. The mechanism of our assistance is easy to understand: we give the patient the conscious anticipatory idea and he then finds the repressed unconscious idea in himself on the basis of its similarity to the anticipatory one. This is the intellectual help which makes it easier for him to overcome the resistances between conscious and unconscious. Incidentally, I may remark that it is not the only mechanism made use of in analytic treatment; you all know the far more powerful one which lies in the use of the 'transference'. It is my intention in the near future to deal with these various factors, which are so important for an understanding of the treatment, in an Allgemeine Methodik der Psychoanalyse. And further, in speaking to you I need not rebut the objection that the evidential value in support of the correctness of our hypotheses is obscured in our treatment as we practise it to-day; you will not forget that this evidence is to be found elsewhere, and that a therapeutic procedure cannot be carried out in the same way as a theoretical investigation. [1910d, 2307]
And now in conclusion I will cast a glance at a situation which belongs to the future - one that will seem fantastic to many of you, but which I think, nevertheless, deserves that we should be prepared for it in our minds. You know that our therapeutic activities are not very far-reaching. There are only a handful of us, and even by working very hard each one can devote himself in a year to only a small number of patients. Compared to the vast amount of neurotic misery which there is in the world, and perhaps need not be, the quantity we can do away with is almost negligible. Besides this, the necessities of our existence limit our work to the well-to-do classes, who are accustomed to choose their own physicians and whose choice is diverted away from psycho-analysis by all kinds of prejudices. At present we can do nothing for the wider social strata, who suffer extremely seriously from neuroses. [1919a, 3635]
The procedure is laborious and time-consuming for the physician. It presupposes great interest in psychological happenings, but personal concern for the patients as well. I cannot imagine bringing myself to delve into the psychical mechanism of a hysteria in anyone who struck me as low-minded and repellent, and who, on closer acquaintance, would not be capable of arousing human sympathy; whereas I can keep the treatment of a tabetic or rheumatic patient apart from personal approval of this kind. The demands made on the patient are not less. The procedure is not applicable at all below a certain level of intelligence, and it is made very much more difficult by any trace of feebleness of mind. The complete consent and complete attention of the patients are needed, but above all their confidence, since the analysis invariably leads to the disclosure of the most intimate and secret psychical events. A good number of the patients who would be suitable for this form of treatment abandon the doctor as soon as the suspicion begins to dawn on them of the direction in which the investigation is leading. For patients such as these the doctor has remained a stranger. With others, who have decided to put themselves in his hands and place their confidence in him - a step which in other such situations is only taken voluntarily and never at the doctor's request - with these other patients, I say, it is almost inevitable that their personal relation to him will force itself, for a time at least, unduly into the foreground. It seems, indeed, as though an influence of this kind on the part of the doctor is a *sine qua non* to a solution of the problem. I do not think any essential difference is made in this respect whether hypnosis can be used or whether it has to be bypassed and replaced by something else. But reason demands that we should emphasize the fact that these drawbacks, though they are inseparable from our procedure, cannot be laid at its door. On the contrary, it is quite clear that they are based on the predetermining conditions of the neuroses that are to be cured and that they must attach to any medical activity which involves intense preoccupation with the patient and leads to a psychical change in him. I have not been able to attribute any deleterious effects or danger to the employment of hypnosis, though I made copious use of it in some of my cases. Where I caused damage, the reasons lay elsewhere and deeper. If I survey my therapeutic efforts during the last few years since the communications made by my honoured teacher and friend Josef Breuer showed me the use of the cathartic method, I believe that in spite of everything, I have done much more, and more frequent, good than harm and have accomplished some things which no other therapeutic procedure could have achieved. It has on the whole, as the 'Preliminary Communication' put it, brought 'considerable therapeutic advantages'.

[1895d, 235]

I have now come to the end of what I have to say to-day. Prepared as I am to meet with contradiction and disbelief, I should like to say one thing more in support of my position. Whatever you may think about the conclusions I have come to, I must ask you not to regard them as the fruit of idle speculation. They are based on a laborious individual examination of patients which has in most cases taken up a hundred or more hours of work. What is even more important to me than the value you put on my results is the attention you give to the procedure I have employed. This procedure is new and difficult to handle, but it is nevertheless irreplaceable for scientific and therapeutic purposes. You will realize, I am sure, that one cannot properly deny the findings which follow from this modification of Breuer's procedure so long as one puts it aside and uses only the customary method of questioning patients. To do so would be like trying to refute the findings of histological technique by relying upon macroscopic examination. The new method of research gives wide access to a new element in the psychical field of events, namely, to processes of thought which have remained unconscious - which, to use Breuer's expression, are 'inadmissible to consciousness'. Thus it inspires us with the hope of a new and better understanding of all functional psychical disturbances. I cannot believe that psychiatry will long hold back from making use of this new pathway to knowledge.

[1896c, 433]
That the method is confined within these limits is to a large extent explained by the circumstances in which I had to work it out. My material does in fact consist of chronic nervous cases derived from the more educated classes. I think it very probable that supplementary methods may be devised for treating children and the public who go for assistance to hospitals. I ought also to say that up to the present I have tried my treatment exclusively on severe cases of hysteria and obsessional neurosis; I cannot tell how it would turn out with those mild cases which, to all appearance at least, are cured by some unspecific kind of treatment lasting for a few months. It will readily be understood that a new therapy which calls for many sacrifices can only reckon on obtaining patients who have already tried the generally accepted methods without success, or whose condition has justified the inference that they could expect nothing from these supposedly more convenient and shorter therapeutic procedures. Thus it happened that I was obliged to tackle the hardest tasks straightaway with an imperfect instrument. The test has proved all the more convincing.

[1897b, 474]

It would be more dignified as well as more helpful to the patient - who, after all, has to come to terms with his ailments - for the doctor to tell the truth, as he knows it from his daily practice. The psychoneuroses as a genus are by no means mild illnesses. When hysteria sets in, no one can foretell when it will come to an end. We mostly comfort ourselves with the vain prophecy that 'one day it will suddenly disappear'. Recovery often enough turns out to be merely an agreement to mutual toleration between the sick part of the patient and the healthy part; or it is the result of the transformation of a symptom into a phobia. A girl's hysteria, calmed down with difficulty, revives in her as a wife after the short interruption of young married happiness. The only difference is that another person, the husband, is now driven by his own interests to keep silence about her condition. Even if an illness of this kind leads to no manifest incapacity on the patients' part to carry on their life, it nearly always prevents free unfolding of their mental powers. Obsessions recur throughout their lives; and phobias and other restrictions upon the will have hitherto been unamenable to treatment of any kind. All this is kept from the knowledge of the layman. The father of a hysterical girl is consequently horrified if, for instance, he is asked to agree to her being given a year's treatment, when she has perhaps only been ill for a few months. The layman is, as it were, deeply convinced in himself that all these psychoneuroses are unnecessary; so he has no patience with the processes of the illness and no readiness to make sacrifices for its treatment. If, in face of a case of typhus which lasts three weeks, or of a broken leg which takes six months to mend, he adopts a more understanding attitude, and if, as soon as his child shows the first signs of a curvature of the spine, he finds it reasonable that orthopaedic treatment should be carried on over several years, the difference in his behaviour is due to the better knowledge on the part of the physicians who pass on their knowledge honestly to the layman. Honesty on the part of the physician and willing acquiescence on the part of the layman will be established for the neuroses too, as soon as an insight into the nature of those affections becomes common property in the medical world. Radical treatment of these disorders will no doubt always require special training and will be incompatible with other kinds of medical activity. On the other hand, this class of physicians, which will, I believe, be a large one in the future, has the prospect of achieving noteworthy results and of obtaining a satisfying insight into the mental life of mankind.

[1897b, 475]
The treatment described in this paper was broken off on December 31st, 1899. My account of it was written during the two weeks immediately following, but was not published until 1905. It is not to be expected that after more than twenty years of uninterrupted work I should see nothing to alter in my view of such a case and in my presentment of it; but it would obviously be absurd to bring the case history 'up to date' by means of emendations and additions. In all essentials, therefore, I have left it as it was, and in the text I have merely corrected a few oversights and inaccuracies to which my excellent English translators, Mr. and Mrs. James Strachey, have directed my attention. Such critical remarks as I have thought it permissible to add I have incorporated in these additional notes: so that the reader will be justified in assuming that I still hold to the opinions expressed in the text unless he finds them contradicted in the footnotes. The problem of medical discretion which I have discussed in this preface does not touch the remaining case histories contained in this volume; for three of them were published with the express assent of the patients (or rather, as regards little Hans, with that of his father), while in the fourth case (that of Schreber) the subject of the analysis was not actually a person but a book produced by him. In Dora's case the secret was kept until this year. I had long been out of touch with her, but a short while ago I heard that she had recently fallen ill again from other causes, and had confided to her physician that she had been analysed by me when she was a girl. This disclosure made it easy for my well-informed colleague to recognize her as the Dora of 1899. No fair judge of analytic therapy will make it a reproach that the three months' treatment she received at that time effected no more than the relief of her current conflict and was unable to give her protection against subsequent illnesses.

Nor is the case of whose history and treatment I have published a fragment in these pages well calculated to put the value of psycho-analytic therapy in its true light. Not only the briefness of the treatment (which hardly lasted three months) but another factor inherent in the nature of the case prevented results being brought about such as are attainable in other instances, where the improvement will be admitted by the patient and his relatives and will approximate more or less closely to a complete recovery. Satisfactory results of this kind are reached when the symptoms are maintained solely by the internal conflict between the impulses concerned with sexuality. In such cases the patient's condition will be seen improving in proportion as he is helped towards a solution of his mental problems by the translation of pathogenic into normal material. The course of events is very different when the symptoms have become enlisted in the service of external motives, as had happened with Dora during the two preceding years. It is surprising, and might easily be misleading, to find that the patient's condition shows no noticeable alteration even though considerable progress has been made with the work of analysis. But in reality things are not as bad as they seem. It is true that the symptoms do not disappear while the work is proceeding; but they disappear a little while later, when the relations between patient and physician have been dissolved. The postponement of recovery or improvement is really only caused by the physician's own person.

In Dora's second dream there are several clear allusions to transference. At the time she was telling me the dream I was still unaware (and did not learn until two days later) that we had only two hours more work before us. This was the same length of time which she had spent in front of the Sistine Madonna, and which (by making a correction and putting 'two hours' instead of 'two and a half hours') she had taken as the length of the walk which she had not made round the lake. The striving and waiting in the dream, which related to the young man in Germany, and had their origin in her waiting till Herr K. could marry her, had been expressed in the transference a few days before. The treatment, she had thought, was too long for her; she would never have the patience to wait so long. And yet in the first few weeks she had had discernment enough to listen without making any such objections when I informed her that her complete recovery would require perhaps a year. Her refusing in the dream to be accompanied, and preferring to go alone, also originated from her visit to the gallery at Dresden, and I was myself to experience them on the appointed day. What they meant was, no doubt: 'Men are all so detestable that I would rather not marry. This is my revenge.'
Nevertheless I cannot bring myself to accept the idea that this part of psycho-analytic theory can be very much more distant than the rest from the reality which it is its business to discover. My recollections, as well as a constant re-examination of the material, assure me that this part of the theory is based upon equally careful and impartial observation. There is, moreover, no difficulty in finding an explanation of this discrepancy in the general acceptance of my views. In the first place, the beginnings of human sexual life which are here described can only be confirmed by investigators who have enough patience and technical skill to trace back an analysis to the first years of a patient's childhood. And there is often no possibility of doing this, since medical treatment demands that an illness should, at least in appearance, be dealt with more rapidly. None, however, but physicians who practise psycho-analysis can have any access whatever to this sphere of knowledge or any possibility of forming a judgement that is uninfluenced by their own dislikes and prejudices. If mankind had been able to learn from a direct observation of children, these three essays could have remained unwritten.

[1905d, 1462]

The therapeutic procedure remains the same, apart from insignificant modifications, for all the various clinical pictures that may be presented in hysteria, and all forms of obsessional neurosis. This does not imply, however, that it can have an unlimited application. The nature of the psycho-analytic method involves indications and contra-indications with respect to the person to be treated as well as with respect to the clinical picture. Chronic cases of psychoneuroses without any very violent or dangerous symptoms are the most favourable ones for psycho-analysis: thus in the first place every species of obsessional neurosis, obsessive thinking and acting, and cases of hysteria in which phobias and aboulias play the most important part; further, all somatic expressions of hysteria whenever they do not, as in anorexia, require the physician to attend promptly to the speedy removal of symptoms. In acute cases of hysteria it will be necessary to wait for a calmer stage; in all cases where nervous exhaustion dominates the clinical picture a treatment which in itself demands effort, brings only slow improvement and for a time cannot take the persistence of the symptoms into account, will have to be avoided.

[1904a, 1559]

In spite of all these limitations, the number of persons suitable for psycho-analytic treatment is extraordinarily large and the extension which has come to our therapeutic powers from this method is, according to Freud, very considerable. Freud requires long periods, six months to three years, for an effective treatment; yet he informs us that up to the present, owing to various circumstances which can easily be guessed, he has for the most part been in a position to try his treatment only on very severe cases: patients have come to him after many years of illness, completely incapacitated for life, and, after being disappointed by all kinds of treatments, have had recourse as a last resort to a method which is novel and has been greeted with many doubts. In cases of less severe illness the duration of the treatment might well be much shorter, and very great advantage in the direction of future prevention might be achieved.

[1904a, 1560]
(c) From certain of my remarks you will have gathered that there are many characteristics in the analytic method which prevent it from being an ideal form of therapy. *Tuto, cito, jucunde*: investigation and probing do not indicate speedy results, and the resistance I have mentioned would prepare you to expect unpleasantness of various kinds. Psycho-analytic treatment certainly makes great demands upon the patient as well as upon the physician. From the patient it requires perfect sincerity - a sacrifice in itself; it absorbs time and is therefore also costly; for the physician it is no less time-absorbing, and the technique which he must study and practise is fairly laborious. I consider it quite justifiable to resort to more convenient methods of treatment as long as there is any prospect of achieving anything by their means. That, after all, is the only point at issue. If the more difficult and lengthy method accomplishes considerably more than the short and easy one, then, in spite of everything, the use of the former is justified. Only consider, Gentlemen, how much more inconvenient and costly is the Finsen therapy of lupus than the method of cauterizing and scraping previously employed; and yet the use of the former signifies a great advance, for it performs a radical cure. Although I do not wish to carry this comparison to extremes, the psycho-analytic method may claim a similar privilege. Actually, I have been able to elaborate and to test my therapeutic method only on severe, indeed on the severest cases; at first my material consisted entirely of patients who had tried everything else without success, and had spent long years in sanatoria. I have scarcely been able to bring together sufficient material to enable me to say how my method works with those slighter, episodic cases which we see recovering under all kinds of influences and even spontaneously. Psycho-analytic therapy was created through and for the treatment of patients permanently unfit for existence, and its triumph has been that it has made a satisfactorily large number of these permanently fit for existence. In the face of such an achievement all the effort expended seems trivial. We cannot conceal from ourselves what, as physicians, we are in the habit of denying to our patients, namely, that a severe neurosis is no less serious for the sufferer than any cachexia or any of the dreaded major diseases.

[1905a, 1568]

Only when these conditions have been fulfilled is it possible to recognize and to master the resistances which have led to the repression and the ignorance. Psycho-analytic intervention, therefore, absolutely requires a fairly long period of contact with the patient. Attempts to 'rush' him at first consultation, by brusquely telling him the secrets which have been discovered by the physician, are technically objectionable. And they mostly bring their own punishment by inspiring a hearty enmity towards the physician on the patient's part and cutting him off from having any further influence.

[1910k, 2379]
It will now be asked whether we shall not be giving up too much valuable material which might throw light on the unconscious if dream-interpretation is only to be carried out subject to such restrictions of method. The answer to this is that the loss is by no means so great as might appear from a superficial view of the matter. To begin with, it must be recognized that in cases of severe neurosis any elaborate dream-productions must from the nature of things be regarded as incapable of complete solution. A dream of this kind is often based on the entire pathogenic material of the case, as yet unknown to both doctor and patient (so called 'programme-dreams' and biographical dreams), and is sometimes equivalent to a translation into dream-language of the whole content of the neurosis. In the attempt to interpret such a dream all the latent, as yet untouched, resistances will be roused to activity and soon set a limit to its understanding. The full interpretation of such a dream will coincide with the completion of the whole analysis; if a note is made of it at the beginning, it may be possible to understand it at the end, many months later. It is the same as with the elucidation of a single symptom (the main symptom, perhaps). The whole analysis is needed to explain it; in the course of the treatment one must endeavour to lay hold first of this, then of that, fragment of the symptom's meaning, one after another, until they can all be pieced together. Similarly, no more can be expected of a dream occurring in the early stages of the analysis; one must be content if the attempt at interpretation brings a single pathogenic wishful impulse to light.

[1911e, 2451]

An unwelcome question which the patient asks the doctor at the outset is: 'How long will the treatment take? How much time will you need to relieve me of my trouble?' If one has proposed a trial treatment of a few weeks one can avoid giving a direct answer to this question by promising to make a more reliable pronouncement at the end of the trial period. Our answer is like the answer given by the Philosopher to the Wayfarer in Aesop's fable. When the Wayfarer asked how long a journey lay ahead, the Philosopher merely answered 'Walk!' and afterwards explained his apparently unhelpful reply on the ground that he must know the length of the Wayfarer's stride before he could tell how long his journey would take. This expedient helps one over the first difficulties; but the comparison is not a good one, for the neurotic can easily alter his pace and may at times make only very slow progress. In point of fact, the question as to the probable duration of a treatment is almost unanswerable.

[1913c, 2481]

As the combined result of lack of insight on the part of patients and disingenuousness on the part of doctors, analysis finds itself expected to fulfil the most boundless demands, and that in the shortest time. Let me, as an example, give some details from a letter which I received a few days ago from a lady in Russia. She is 53 years old, her illness began twenty-three years ago and for the last ten years she has no longer been able to do any continuous work. 'Treatment in a number of institutions for nervous cases' have not succeeded in making an 'active life' possible for her. She hopes to be completely cured by psycho-analysis, which she has read about, but her illness has already cost her family so much money that she cannot manage to come to Vienna for longer than six weeks or two months. Another added difficulty is that she wishes from the very start to 'explain' herself in writing only, since any discussion of her complexes would cause an explosion of feeling in her or 'render her temporarily unable to speak'. - No one would expect a man to lift a heavy table with two fingers as if it were a light stool, or to build a large house in the time it would take to put up a wooden hut; but as soon as it becomes a question of the neuroses - which do not seem so far to have found a proper place in human thought - even intelligent people forget that a necessary proportion must be observed between time, work and success. This, incidentally, is an understandable result of the deep ignorance which prevails about the aetiology of the neuroses. Thanks to this ignorance, neurosis is looked or as a kind of 'maiden from afar'. 'None knew whence she came'; so they expected that one day she would vanish.

[1913c, 2481]
Doctors lend support to these fond hopes. Even the informed among them often fail to estimate properly the severity of nervous disorders. A friend and colleague of mine, to whose great credit I account it that after several decades of scientific work on other principles he became converted to the merits of psycho-analysis, once wrote to me: ‘What we need is a short, convenient, out-patient treatment for obsessional neurosis.’ I could not supply him with it and felt ashamed; so I tried to excuse myself with the remark that specialists in internal diseases, too, would probably be very glad of a treatment for tuberculosis or carcinoma which combined these advantages.
[1913c, 2482]

To speak more plainly, psycho-analysis is always a matter of long periods of time, of half a year or whole years - of longer periods than the patient expects. It is therefore our duty to tell the patient this before he finally decides upon the treatment. I consider it altogether more honourable, and also more expedient, to draw his attention - without trying to frighten him off, but at the very beginning - to the difficulties and sacrifices which analytic treatment involves, and in this way to deprive him of any right to say later on that he has been inveigled into a treatment whose extent and implications he did not realize. A patient who lets himself be dissuaded by this information would in any case have shown himself unsuitable later on. It is a good thing to institute a selection of this kind before the beginning of the treatment. With the progress of understanding among patients the number of those who successfully meet this first test increases.
[1913c, 2482]

I do not bind patients to continue the treatment for a certain length of time; I allow each one to break off whenever he likes. But I do not hide it from him that if the treatment is stopped after only a small amount of work has been done it will not be successful and may easily, like an unfinished operation, leave him in an unsatisfactory state. In the early years of my psycho-analytic practice I used to have the greatest difficulty in prevailing on my patients to continue their analysis. This difficulty has long since been shifted, and I now have to take the greatest pains to induce them to give it up.
[1913c, 2482]
To shorten analytic treatment is a justifiable wish, and its fulfilment, as we shall learn, is being attempted along various lines. Unfortunately, it is opposed by a very important factor, namely, the slowness with which deep-going changes in the mind are accomplished - in the last resort, no doubt, the 'timelessness' of our unconscious processes. When patients are faced with the difficulty of the great expenditure of time required for analysis they not infrequently manage to propose a way out of it. They divide up their ailments and describe some as unbearable, and others as secondary, and then say: 'If only you will relieve me from this one (for instance, a headache or a particular fear) I can deal with the other one on my own in my ordinary life.' In doing this, however, they over-estimate the selective power of analysis. The analyst is certainly able to do a great deal, but he cannot determine beforehand exactly what results he will effect. He sets in motion a process, that of the resolving of existing repressions. He can supervise this process, further it, remove obstacles in its way, and he can undoubtedly vitiate much of it. But on the whole, once begun, it goes its own way and does not allow either the direction it takes or the order in which it picks up its points to be prescribed for it. The analyst's power over the symptoms of the disease may thus be compared to male sexual potency. A man can, it is true, beget a whole child, but even the strongest man cannot create in the female organism a head alone or an arm or a leg; he cannot even prescribe the child's sex. He, too, only sets in motion a highly complicated process, determined by events in the remote past, which ends with the severance of the child from its mother. A neurosis as well has the character of an organism. Its component manifestations are not independent of one another; they condition one another and give one another mutual support. A person suffers from one neurosis only, never from several which have accidentally met together in a single individual. The patient freed, according to his wish, from his one unendurable symptom might easily find that a symptom which had previously been negligible had now increased and grown unendurable. The analyst who wishes the treatment to owe its success as little as possible to its elements of suggestion (i.e. to the transference) will do well to refrain from making use of even the trace of selective influence upon the results of the therapy which may perhaps be open to him. The patients who are bound to be most welcome to him are those who ask him to give them complete health, in so far as that is attainable, and who place as much time at his disposal as is necessary for the process of recovery. Such favourable conditions as these are, of course, to be looked for in only a few cases.

[1913c, 2483]

The question then arises whether the advantage gained by the patient would not to some extent counterbalance the sacrifice made by the physician. I may venture to form a judgement about this, since for ten years or so I set aside one hour a day, and sometimes two, for gratuitous treatments, because I wanted, in order to find my way about in the neuroses, to work in the face of as little resistance as possible. The advantages I sought by this means were not forthcoming. Free treatment enormously increases some of a neurotic's resistances - in young women, for instance, the temptation which is inherent in their transference-relation, and in young men, their opposition to an obligation to feel grateful, an opposition which arises from their father-complex and which presents one of the most troublesome hindrances to the acceptance of medical help. The absence of the regulating effect offered by the payment of a fee to the doctor makes itself very painfully felt; the whole relationship is removed from the real world, and the patient is deprived of a strong motive for endeavouring to bring the treatment to an end.

[1913c, 2485]
As far as the middle classes are concerned, the expense involved in psycho-analysis is excessive only in appearance. Quite apart from the fact that no comparison is possible between restored health and efficiency on the one hand and a moderate financial outlay on the other, when we add up the unceasing costs of nursing-homes and medical treatment and contrast them with the increase of efficiency and earning capacity which results from a successfully completed analysis, we are entitled to say that the patients have made a good bargain. Nothing in life is so expensive as illness - and stupidity.

I can, however, assume this much - that you know that psycho-analysis is a procedure for the medical treatment of neurotic patients. And here I can at once give you an instance of how in this field a number of things take place in a different way - often, indeed, in an opposite way - from what they do elsewhere in medical practice. When elsewhere we introduce a patient to a medical technique which is new to him, we usually minimize its inconveniences and give him confident assurances of the success of the treatment. I think we are justified in this, since by doing so we are increasing the probability of success. But when we take a neurotic patient into psycho-analytic treatment, we act differently. We point out the difficulties of the method to him, its long duration, the efforts and sacrifices it calls for; and as regards its success, we tell him we cannot promise it with certainty, that it depends on his own conduct, his understanding, his adaptability and his perseverance. We have good reasons, of course, for such apparently wrong-headed behaviour, as you will perhaps come to appreciate later on.

Think it over! You have learnt all that is essential about the determinants of falling ill as well as all the factors that come into effect after the patient has fallen ill. Where do these leave room for any therapeutic influence? In the first place there is hereditary disposition. We have not talked about it very often because it is emphatically stressed from other directions and we have nothing new to say about it. But do not suppose that we underestimate it; precisely as therapists we come to realize its power clearly enough. In any case we can do nothing to alter it; we too must take it as something given, which sets a limit to our efforts. Next there is the influence of early experiences in childhood, to which we are in the habit of giving prominence in analysis: they belong to the past and we cannot undo them. Then comes everything that we have summarized as 'real frustration' - the misfortunes of life from which arise deprivation of love, poverty, family quarrels, ill-judged choice of a partner in marriage, unfavourable social circumstances, and the strictness of the ethical standards to whose pressure the individual is subject. Here, to be sure, there would be handles enough for a very effective therapy, but it would have to be of the kind which Viennese folklore attributes to the Emperor Joseph - the benevolent interference of a powerful personage before whose will people bow and difficulties vanish. But who are we, that we should be able to adopt benevolence of this kind as an instrument of our therapy? Poor ourselves and socially powerless, and compelled to earn our livelihood from our medical activity, we are not even in a position to extend our efforts to people without means, as other doctors with other methods of treatment are after all able to do. Our therapy is too time-consuming and too laborious for that to be possible. Perhaps, however, you are clutching at one of the factors I have mentioned and believe that there you have found the point at which our influence can make its attack. If the ethical restrictions demanded by society play a part in the deprivation imposed on the patient, treatment can, after all, give him the courage, or perhaps a direct injunction, to disregard those barriers and achieve satisfaction and recovery while forgoing the fulfilment of an ideal that is exalted, but so often not adhered to, by society. The patient will thus become healthy by 'living a full life' sexually. This, it is true, casts a shadow on analytic treatment for not serving general morality. What it has given to the individual it will have taken from the community.

[1916-1917, 3475]
We can express the aim of our efforts in a variety of formulas: making conscious what is unconscious, lifting repressions, filling gaps in the memory - all these amount to the same thing. But perhaps you will be dissatisfied by this admission. You had formed a different picture of the return to health of a neurotic patient - that, after submitting to the tedious hours of a psycho-analysis, he would become another man; but the total result, so it seems, is that he has rather less that is unconscious and rather more that is conscious in him than he had before. The fact is that you are probably under-estimating the importance of an internal change of this kind. The neurotic who is cured has really become another man, though a bottom, of course, he has remained the same; that is to say, he has become what he might have become at best under the most favourable conditions. But that is a very great deal. If you now hear all that has to be done and what efforts it needs to bring about this apparently trivial change in a man's mental life, you will no doubt begin to realize the importance of this difference in psychical levels.

[1916-1917, 3477]

Another characteristic which makes the present analysis noteworthy is connected with the severity of the illness and the duration of the treatment. Analyses which lead to a favourable conclusion in a short time are of value in ministering to the therapeutist's self-esteem and substantiate the medical importance of psycho-analysis; but they remain for the most part insignificant as regards the advancement of scientific knowledge. Nothing new is learnt from them. In fact they only succeed so quickly because everything that was necessary for their accomplishment was already known. Something new can only be gained from analyses that present special difficulties, and to the overcoming of these a great deal of time has to be devoted. Only in such cases do we succeed in descending into the deepest and most primitive strata of mental development and in gaining from there solutions for the problems of the later formations. And we feel afterwards that, strictly speaking, only an analysis which has penetrated so far deserves the name. Naturally a single case does not give us all the information that we should like to have. Or, to put it more correctly, it might teach us everything, if we were only in a position to make everything out, and if we were not compelled by the inexperience of our own perception to content ourselves with a little.

[1918b, 3506]

As regards these fertile difficulties the case I am about to discuss left nothing to be desired. The first years of the treatment produced scarcely any change. Owing to a fortunate concatenation, all the external circumstances nevertheless combined to make it possible to proceed with the therapeutic experiment. I can easily believe that in less favourable circumstances the treatment would have been given up after a short time. Of the physician's point of view I can only declare that in a case of this kind he must behave as 'timelessly' as the unconscious itself, if he wishes to learn anything or to achieve anything. And in the end he will succeed in doing so, if he has the strength to renounce any short-sighted therapeutic ambition. It is not to be expected that the amount of patience, adaptability, insight, and confidence demanded of the patient and his relatives will be forthcoming in many other cases. But the analyst has a right to feel that the results which he has attained from such lengthy work in one case will help substantially to reduce the length of the treatment in a subsequent case of equal severity, and that by submitting on a single occasion

[1918b, 3506]
Leaving on one side everything in this quotation that anticipates the dream's remoter implications, let us return to its immediate interpretation. I may remark that this interpretation was a task that dragged on over several years. The patient related the dream at a very early stage of the analysis and very soon came to share my conviction that the causes of his infantile neurosis lay concealed behind it. In the course of the treatment we often came back to the dream, but it was only during the last months of the analysis that it became possible to understand it completely, and only then thanks to spontaneous work on the patient's part. He had always emphasized the fact that two factors in the dream had made the greatest impression on him: first, the perfect stillness and immobility of the wolves, and secondly, the strained attention with which they all looked at him. The lasting sense of reality, too, which the dream left behind it, seemed to him to deserve notice.

[1918b, 3524]

The diffuseness and elaboration of this commentary have been forced on me by the effort to present the reader with some sort of equivalent for the convincing power of an analysis carried through by oneself; perhaps they may also serve to discourage him from asking for the publication of analyses which have stretched over several years.

[1918b, 3532]

Many months later, in quite another connection, the patient remarked that the opening and shutting of the butterfly's wings while it was settled on the flower had given him an uncanny feeling. It had looked, so he said, like a woman opening her legs, and the legs then made the shape of a Roman V, which, as we know, was the hour at which, in his boyhood, and even up to the time of the treatment, he used to fall into a depressed state of mind.

[1918b, 3572]

It is obvious that a case such as that which is described in these pages might be made an excuse for dragging into the discussion every one of the findings and problems of psycho-analysis. But this would be an endless and unjustifiable labour. It must be recognized that everything cannot be learnt from a single case and that everything cannot be decided by it; we must content ourselves with exploiting whatever it may happen to show most clearly. There are in any case narrow limits to what a psycho-analysis is called upon to explain. For, while it is its business to explain the striking symptoms by revealing their genesis, it is not its business to explain but merely to describe the psychical mechanisms and instinctual processes to which one is led by that means. In order to derive fresh generalizations from what has thus been established with regard to the mechanisms and instincts, it would be essential to have at one's disposal numerous cases as thoroughly and deeply analysed as the present one. But they are not easily to be had, and each one of them requires years of labour. So that advances in these spheres of knowledge must necessarily be slow. There is no doubt a great temptation to content oneself with 'scratching' the mental surface of a number of people and of replacing what is left undone by speculation - the latter being put under the patronage of some school or other of philosophy. Practical requirements may also be adduced in favour of this procedure; but no substitute can satisfy the requirements of science.

[1918b, 3583]
And now in conclusion I will cast a glance at a situation which belongs to the future - one that will seem fantastic to many of you, but which I think, nevertheless, deserves that we should be prepared for it in our minds. You know that our therapeutic activities are not very far-reaching. There are only a handful of us, and even by working very hard each one can devote himself in a year to only a small number of patients. Compared to the vast amount of neurotic misery which there is in the world, and perhaps need not be, the quantity we can do away with is almost negligible. Besides this, the necessities of our existence limit our work to the well-to-do classes, who are accustomed to choose their own physicians and whose choice is diverted away from psycho-analysis by all kinds of prejudices. At present we can do nothing for the wider social strata, who suffer extremely seriously from neuroses.

[1919a, 3635]

I am in a position to bring forward conclusive evidence of the final break-down of the electrical treatment of the war neuroses. In 1918 Dr. Ernst Simmel, head of a hospital for war neuroses at Posen, published a pamphlet in which he reported the extraordinarily favourable results achieved in severe cases of war neurosis by the psychotherapeutic method introduced by me. As a result of this publication, the next Psycho-Analytical Congress, held in Budapest in September 1918, was attended by official delegates of the German, Austrian and Hungarian Army Command, who promised that Centres should be set up for the purely psychological treatment of war neuroses. This promise was made although the delegates can have been left in no doubt that with this considerate, laborious and tedious kind of treatment it was impossible to count on the quickest restoration of these patients to fitness for service. Preparations for the establishment of Centres of this kind were actually under way, when the revolution broke out and put an end to the war and to the influence of the administrative offices which had hitherto been all-powerful. But with the end of the war the war neurotics, too, disappeared - a final but impressive proof of the psychical causation of their illnesses.

[1919d, 3672]

The uncanny effect of epilepsy and of madness has the same origin. The layman sees in them the working of forces hitherto unsuspected in his fellow-men, but at the same time he is dimly aware of them in remote corners of his own being. The Middle Ages quite consistently ascribed all such maladies to the influence of demons, and in this their psychology was almost correct. Indeed, I should not be surprised to hear that psycho-analysis, which is concerned with laying bare these hidden forces, has itself become uncanny to many people for that very reason. In one case, after I had succeeded - though none too rapidly - in effecting a cure in a girl who had been an invalid for many years, I myself heard this view expressed by the patient's mother long after her recovery.

[1919h, 3693]

Another fact certainly seems to me of more significance, namely, that during some twenty-seven years of work as an analyst I have never been in a position to observe a truly telepathic dream in any of my patients. And yet those patients made up a fair collection of severely neuropathic and 'highly sensitive' natures. Many of them have related to me most remarkable incidents in their earlier life on which they based a belief in mysterious occult influences. Events such as accidents or illnesses of near relatives, in particular the death of a parent, have often enough happened during the treatment and interrupted it; but not on one single occasion did these occurrences, eminently suitable as they were in character, afford me the opportunity of registering a single telepathic dream, although treatment extended over several months or even years. Anyone who cares to may look for an explanation of this fact, which still further restricts the material at my disposal. In any case it will be seen that such an explanation would not affect the subject of this paper.

[1922a, 3880]
And now an explanation, given in writing by a doctor who was a stranger to her, was expected to effect what all the most important experiences of her later life had failed to do! Probably a regular analysis continued for a considerable time would have succeeded in this. As things were, I was obliged to content myself with writing to her that I was convinced she was suffering from the after-effects of a strong emotional tie binding her to her father and from a corresponding identification with her mother, but that I did not myself expect that this explanation would help her. Spontaneous cures of neurosis usually leave scars behind, and these become painful again from time to time. We are very proud of our art if we achieve a cure through psycho-analysis, yet here too we cannot always prevent the formation of a painful scar as an outcome.

[1922a, 3893]

_Psycho-Analysis as a Therapeutic Procedure._ - Psycho-analysis has never set itself up as a panacea and has never claimed to perform miracles. In one of the most difficult spheres of medical activity it is the only possible method of treatment for certain illnesses and for others it is the method which yields the best or the most permanent results - though never without a corresponding expenditure of time and trouble. A physician who is not wholly absorbed in the work of giving help will find his labours amply repaid by obtaining an unhoped-for insight into the complications of mental life and the interrelations between the mental and the physical. Where at present it cannot offer help but only theoretical understanding, it may perhaps be preparing the way for some later, more direct means of influencing neurotic disorders. Its province is above all the two transference neuroses, hysteria and obsessional neurosis, in which it has contributed to the discovery of their internal structure and operative mechanisms; and, beyond them, all kinds of phobias, inhibitions, deformities of character, sexual perversions and difficulties in erotic life. Some analysts (Jelliffe, Groddeck, Felix Deutsch) have reported too that the analytic treatment of gross organic diseases is not unpromising, since a mental factor not infrequently contributes to the origin and continuance of such illnesses. Since psycho-analysis demands a certain amount of psychical plasticity from its patients, some kind of age-limit must be laid down in their selection; and since it necessitates the devotion of long and intense attention to the individual patient, it would be uneconomical to squander such expenditure upon completely worthless persons who happen to be neurotic. Experience upon material in clinics can alone show what modifications may be necessary in order to make psycho-analytic treatment accessible to wider strata of the population or to adapt it to weaker intelligences.

[1923a, 3926]

In my own writings and in those of my followers more and more stress is laid on the necessity that the analyses of neurotics shall deal thoroughly with the remotest period of their childhood, the time of the early efflorescence of sexual life. It is only by examining the first manifestations of the patient's innate instinctual constitution and the effects of his earliest experiences that we can accurately gauge the motive forces that have led to his neurosis and can be secure against the errors into which we might be tempted by the degree to which things have become remodelled and overlaid in adult life. This requirement is not only of theoretical but also of practical importance, for it distinguishes our efforts from the work of those physicians whose interests are focused exclusively on therapeutic results and who employ analytic methods, but only up to a certain point. An analysis of early childhood such as we are considering is tedious and laborious and makes demands both upon the physician and upon the patient which cannot always be met. Moreover, it leads us into dark regions where there are as yet no sign posts. Indeed, analysts may feel reassured, I think, that there is no risk of their work becoming mechanical, and so of losing its interest, during the next few decades.

[1925j, 4146]
We psycho-analysts, who have long been familiar with the idea of devoting hundreds of sessions to a single patient, can form no conception of how novel such a procedure must have seemed forty-five years ago. It must have called for a large amount of personal interest and, if the phrase can be allowed, of medical libido, but also for a considerable degree of freedom of thought and certainty of judgement. At the date of the publication of our *Studies* we were able to appeal to Charcot's writings and to Pierre Janet's investigations, which had by that time deprived Breuer's discoveries of some of their priority. But when Breuer was treating his first case (in 1881-2) none of this was as yet available. Janet's *Automatisme psychologique* appeared in 1889 and his second work, *L'état mental des hysteriques*, not until 1892. It seems that Breuer's researches were wholly original, and were directed only by the hints offered to him by the material of his case.

Dr. de Saussure has not only conscientiously studied my writings, but in addition he has made the sacrifice of coming to me to undergo an analysis lasting several months. This has put him in a position to form his own judgement on the majority of those questions in psycho-analysis which are still undecided, and to avoid the many distortions and errors which one is accustomed to finding in French as well as in German expositions of psycho-analysis. Nor has he failed to contradict certain false or negligent statements which commentators pass on from one to another: such as, for instance, that all dreams have a sexual meaning or that, according to me, the only motive force in our mental life is that of sexual libido.

Quite true. It *would* be magic if it worked rather quicker. An essential attribute of a magician is speed - one might say suddenness - of success. But analytic treatments take months and even years: magic that is so slow loses its miraculous character. And incidentally do not let us despise the word. After all it is a powerful instrument; it is the means by which we convey our feelings to one another, our method of influencing other people. Words can do unspeakable good and cause terrible wounds. No doubt 'in the beginning was the deed' and the word came later; in some circumstances it meant an advance in civilization when deeds were softened into words. But originally the word was magic - a magical act; and it has retained much of its ancient power.

'Then, after all, I do not understand,' comes the rejoinder. 'What can you possibly mean by "telling more than he knows"? But I can well believe that as an analyst you gain a stronger influence over your patients than a Father Confessor over his penitents, since your contacts with him are so much longer, more intensive and also more individual, and since you use this increased influence to divert him from his sick thoughts, to talk him out of his fears, and so on. It would certainly be strange if it were possible by such means to control purely physical phenomena as well, such as vomiting, diarrhoea, convulsions; but I know that influence like that is in fact quite possible if a person is put into a state of hypnosis. By the trouble you take with the patient you probably succeed in bringing about a hypnotic relation of that sort with him - a suggestive attachment to yourself - even though you may not intend to; and in that case the miraculous results of your treatment are the effect of hypnotic suggestion. But, so far as I know, hypnotic treatment works much faster than your analysis, which, as you tell me, lasts for months and years.'
'I have done no more than repeat what I have heard from you - as though it was something I had learnt by heart. All the same, I cannot form any picture of how I should do it, and I am quite at a loss to understand why a job like that should take an hour a day for so many months. After all, an ordinary person has not as a rule experienced such a lot, and what was repressed in childhood is probably in every case the same.'
[1926e, 4360]

When one really practises analysis one learns all kinds of things besides. For instance: you would not find it at all such a simple matter to deduce from what the patient tells you the experiences he has forgotten and the instinctual impulses he has repressed. He says something to you which at first means as little to you as it does to him. You will have to make up your mind to look at the material which he delivers to you in obedience to the rule in a quite special way: as though it were ore, perhaps, from which its content of precious metal has to be extracted by a particular process. You will be prepared, too, to work over many tons of ore which may contain but little of the valuable material you are in search of. Here we should have a first reason for the prolonged character of the treatment.
[1926e, 4361]

Yes, we are only beginning to appreciate the significance of all these important circumstances. That is why my description was bound to turn out so obscure. But now I can proceed. We describe all the forces that oppose the work of recovery as the patient's 'resistances'. The gain from illness is one such resistance. The 'unconscious sense of guilt' represents the super-ego's resistance; it is the most powerful factor, and the one most dreaded by us. We meet with still other resistances during the treatment. If the ego during the early period has set up a repression out of fear, then the fear still persists and manifests itself as a resistance if the ego approaches the repressed material. And finally, as you can imagine, there are likely to be difficulties if an instinctual process which has been going along a particular path for whole decades is suddenly expected to take a new path that has just been made open for it. That might be called the id's resistance. The struggle against all these resistances is our main work during an analytic treatment; the task of making interpretations is nothing compared to it. But as a result of this struggle and of the overcoming of the resistances, the patient's ego is so much altered and strengthened that we can look forward calmly to his future behaviour when the treatment is over. On the other hand, you can understand now why we need such long treatments. The length of the path of development and the wealth of the material are not the decisive factors. It is more a question of whether the path is clear. An army can be held up for weeks on a stretch of country which in peace time an express train crosses in a couple of hours - if the army has to overcome the enemy's resistance there. Such battles call for time in mental life too. I am unfortunately obliged to tell you that every effort to hasten analytic treatment appreciably has hitherto failed. The best way of shortening it seems to be to carry it out according to the rules.
[1926e, 4366]

In every instance the treatment makes heavy claims upon both the physician and the patient: the former requires a special training and must devote a long period of time to exploring the mind of each patient, while the latter must make considerable sacrifices, both material and mental. Nevertheless, all the trouble involved is as a rule rewarded by the results. Psychoanalysis does not act as a convenient panacea ('cito, tute, jucunde') for psychological disorders. On the contrary, its application has been instrumental in making clear for the first time the difficulties and limitations in the treatment of such affections. For the moment it is only in Berlin and Vienna that there are voluntary institutions which make psycho-analytic treatment accessible to the wage-earning classes.
[1926f, 4402]
You are perhaps aware that I have never been a therapeutic enthusiast; there is no danger of my misusing this lecture by indulging in eulogies. I would rather say too little than too much. During the period at which I was the only analyst, people who were ostensibly friendly to my ideas used to say to me: 'That's all very nice and clever; but show me a case that you have cured by analysis.' This was one of the many formulas which in the course of time have succeeded one another in performing the function of pushing the uncomfortable novelty aside. To-day it is as out of date as many others: the analyst, too, has a heap of letters in his files from grateful patients who have been cured. The analogy does not stop at that. Psycho-analysis is really a method of treatment like others. It has its triumphs and its defeats, its difficulties, its limitations, its indications. At one time a complaint was made against analysis that it was not to be taken seriously as a treatment since it did not dare to issue any statistics of its successes. Since then, the Psycho-Analytic Institute in Berlin, which was founded by Dr. Max Eitingon, has published a statement of its results during its first ten years. Its therapeutic successes give grounds neither for boasting nor for being ashamed. But statistics of that kind are in general uninstructive; the material worked upon is so heterogeneous that only very large numbers would show anything. It is wiser to examine one's individual experiences. And here I should like to add that I do not think our cures can compete with those of Lourdes. There are so many more people who believe in the miracles of the Blessed Virgin than in the existence of the unconscious. If we turn to mundane competitors, we must compare psycho-analytic treatment with other kinds of psychotherapy. To-day organic physical methods of treating neurotic states need scarcely be mentioned. Analysis as a psycho-therapeutic procedure does not stand in opposition to other methods used in this specialized branch of medicine; it does not diminish their value nor exclude them. There is no theoretical inconsistency in a doctor who likes to call himself a psychotherapist using analysis on his patients alongside of any other method of treatment according to the peculiarities of the case and the favourable or unfavourable external circumstances. It is in fact technique that necessitates the specialization in medical practice. Thus in the same way surgery and orthopaedics were obliged to separate. Psycho-analytic activity is arduous and exacting; it cannot well be handled like a pair of glasses that one puts on for reading and takes off when one goes for a walk. As a rule psycho-analysis possesses a doctor either entirely or not at all. Those psychotherapists who make use of analysis among other methods, occasionally, do not to my knowledge stand on firm analytic ground; they have not accepted the whole of analysis but have watered it down - have drawn its fangs, perhaps; they cannot be counted as analysts. This is, I think, to be regretted. But co-operation in medical practice between an analyst and a psychotherapist who restricts himself to other techniques would serve quite a useful purpose.

[1933a, 4751]
Compared with the other psychotherapeutic procedures psycho-analysis is beyond any doubt the most powerful. It is just and fair, too, that this should be so for it is also the most laborious and time-consuming; it would not be used on slight cases. In suitable cases it is possible by its means to get rid of disturbances and bring about changes for which in pre-analytic times one would not have ventured to hope. But it has its very appreciable limits. The therapeutic ambition of some of my adherents has made the greatest efforts to overcome these obstacles so that every sort of neurotic disorder might be curable by psycho-analysis. They have endeavoured to compress the work of analysis into a shorter duration, to intensify transference so that it may be able to overcome any resistance, to unite other forms of influence with it so as to compel a cure. These efforts are certainly praiseworthy, but, in my opinion, they are vain. They bring with them, too, a danger of being oneself forced away from analysis and drawn into a boundless course of experimentation. The expectation that every neurotic phenomenon can be cured may, I suspect, be derived from the layman's belief that the neuroses are something quite unnecessary which have no right whatever to exist. Whereas in fact they are severe, constitutionally fixed illnesses, which rarely restrict themselves to only a few attacks but persist as a rule over long periods or throughout life. Our analytic experience that they can be extensively influenced, if the historical precipitating causes and accidental auxiliary factors of the illness can be dealt with, has led us to neglect the constitutional factor in our therapeutic practice, and in any case we can do nothing about it; but in theory we ought always to bear it in mind. The radical inaccessibility of the psychoses to analytic treatment should, in view of their close relationship to the neuroses, restrict our pretensions in regard to these latter. The therapeutic effectiveness of psycho-analysis remains cramped by a number of weighty and scarcely assailable factors. In the case of children, where one might count on the greatest successes, the difficulties are the external ones connected with their relation to their parents, though these difficulties are after all a necessary part of being a child. In the case of adults the difficulties arise in the first instance from two factors: the amount of psychical rigidity present and the form of the illness with all that covers in the way of deeper determinants.

I am afraid these detailed discussions are exhausting your interest. But I should be still more sorry if you were to think it is my intention to lower your opinion of psycho-analysis as a therapy. Perhaps I really made a clumsy start. For I wanted to do the opposite: to excuse the therapeutic limitations of analysis by pointing out their inevitability. With the same aim in view I turn to another point: the reproach against analytic treatment that it takes a disproportionately long time. On this it must be said that psychical changes do in fact only take place slowly; if they occur rapidly, suddenly, that is a bad sign. It is true that the treatment of a fairly severe neurosis may easily extend over several years; but consider, in case of success, how long the illness would have lasted. A decade, probably, for every year of treatment: the illness, that is to say (as we see so often in untreated cases), would not have ended at all. In some cases we have reasons for resuming an analysis many years afterwards. Life had developed fresh pathological reactions to fresh precipitating causes; but in the meantime our patient had been well. The first analysis had not in fact brought to light all his pathological dispositions, and it was natural for the analysis to have been stopped when success was achieved. There are also severely handicapped people who are kept under analytic supervision all through their lives and are taken back into analysis from time to time. But these people would otherwise have been altogether incapable of existence and we must feel glad that they can be kept on their feet by this piecemeal and recurrent treatment. The analysis of character disorders also calls for long periods of treatment; but it is often successful; and do you know of any other therapy with which such a task could even be approached? Therapeutic ambition may feel unsatisfied by such results; but we have learnt from the example of tuberculosis and lupus that success can only be obtained when the treatment has been adapted to the characteristics of the illness.
Experience has taught us that psycho-analytic therapy - the freeing of someone from his neurotic symptoms, inhibitions and abnormalities of character - is a time-consuming business. Hence, from the very first, attempts have been made to shorten the duration of analyses. Such endeavours required no justification; they could claim to be based on the strongest considerations of reason and expediency. But there was probably still at work in them as well some trace of the impatient contempt with which the medical science of an earlier day regarded the neuroses as being uncalled-for consequences of invisible injuries. If it had now become necessary to attend to them, they should at least be disposed of as quickly as possible.

I myself had adopted another way of speeding up an analytic treatment even before the war. At that time I had taken on the case of a young Russian, a man spoilt by wealth, who had come to Vienna in a state of complete helplessness, accompanied by a private doctor and an attendant.¹ In the course of a few years it was possible to give him back a large amount of his independence, to awaken his interest in life and to adjust his relations to the people most important to him. But there progress came to a stop. We advanced no further in clearing up the neurosis of his childhood, on which his later illness was based, and it was obvious that the patient found his present position highly comfortable and had no wish to take any step forward which would bring him nearer to the end of his treatment. It was a case of the treatment inhibiting itself: it was in danger of failing as a result of its - partial - success. In this predicament I resorted to the heroic measure of fixing a time limit for the analysis. At the beginning of a year's work I informed the patient that the coming year was to be the last one of his treatment, no matter what he achieved in the time still left to him. At first he did not believe me, but once he was convinced that I was in deadly earnest, the desired change set in. His resistances shrank up, and in these last months of his treatment he was able to reproduce all the memories and to discover all the connections which seemed necessary for understanding his early neurosis and mastering his present one. When he left me in the midsummer of 1914, with as little suspicion as the rest of us of what lay so shortly ahead, I believed that his cure was radical and permanent.

We started from the question of how we can shorten the inconveniently long duration of analytic treatment, and, still with this question of time in mind, we went on to consider whether it is possible to achieve a permanent cure or even to prevent future illness by prophylactic treatment. In doing so, we found that the factors which were decisive for the success of our therapeutic efforts were the influence of traumatic aetiology, the relative strength of the instincts which have to be controlled, and something which we have called an alteration of the ego. Only the second of these factors has been discussed by us in any detail, and in connection with it we have had occasion to recognize the paramount importance of the quantitative factor and to stress the claim of the metapsychological line of approach to be taken into account in any attempt at explanation.

---

¹ In this case, the patient's time limit was extended to two years.
That the method is confined within these limits is to a large extent explained by the circumstances in which I had to work it out. My material does in fact consist of chronic nervous cases derived from the more educated classes. I think it very probable that supplementary methods may be devised for treating children and the public who go for assistance to hospitals. I ought also to say that up to the present I have tried my treatment exclusively on severe cases of hysteria and obsessional neurosis; I cannot tell how it would turn out with those mild cases which, to all appearance at least, are cured by some unspecific kind of treatment lasting for a few months. It will readily be understood that a new therapy which calls for many sacrifices can only reckon on obtaining patients who have already tried the generally accepted methods without success, or whose condition has justified the inference that they could expect nothing from these supposedly more convenient and shorter therapeutic procedures. Thus it happened that I was obliged to tackle the hardest tasks straightaway with an imperfect instrument. The test has proved all the more convincing. [1897b, 474]

One may be very far from the ascetic view of money as a curse and yet regret that analytic therapy is almost inaccessible to poor people, both for external and internal reasons. Little can be done to remedy this. Perhaps there is truth in the widespread belief that those who are forced by necessity to a life of hard toil are less easily overtaken by neurosis. But on the other hand experience shows without a doubt that when once a poor man has produced a neurosis it is only with difficulty that he lets it be taken from him. It renders him too good a service in the struggle for existence; the secondary gain from illness which it brings him is much too important. He now claims by right of his neurosis the pity which the world has refused to his material distress, and he can now absolve himself from the obligation of combating his poverty by working. Anyone therefore who tries to deal with the neurosis of a poor person by psychotherapy usually discovers that what is here required of him is a practical therapy of a very different kind - the kind which, according to our local tradition, used to be dispensed by the Emperor Joseph II. Naturally, one does occasionally come across deserving people who are helpless from no fault of their own, in whom unpaid treatment does not meet with any of the obstacles that I have mentioned and in whom it leads to excellent results. [1913c, 2486]
Think it over! You have learnt all that is essential about the determinants of falling ill as well as all the factors that come into effect after the patient has fallen ill. Where do these leave room for any therapeutic influence? In the first place there is hereditary disposition. We have not talked about it very often because it is emphatically stressed from other directions and we have nothing new to say about it. But do not suppose that we underestimate it; precisely as therapists we come to realize its power clearly enough. In any case we can do nothing to alter it; we too must take it as something given, which sets a limit to our efforts. Next there is the influence of early experiences in childhood, to which we are in the habit of giving prominence in analysis: they belong to the past and we cannot undo them. Then comes everything that we have summarized as 'real frustration' - the misfortunes of life from which arise deprivation of love, poverty, family quarrels, ill-judged choice of a partner in marriage, unfavourable social circumstances, and the strictness of the ethical standards to whose pressure the individual is subject. Here, to be sure, there would be handles enough for a very effective therapy, but it would have to be of the kind which Viennese folklore attributes to the Emperor Joseph - the benevolent interference of a powerful personage before whose will people bow and difficulties vanish. But who are we, that we should be able to adopt benevolence of this kind as an instrument of our therapy? Poor ourselves and socially powerless, and compelled to earn our livelihood from our medical activity, we are not even in a position to extend our efforts to people without means, as other doctors with other methods of treatment are after all able to do. Our therapy is too time-consuming and too laborious for that to be possible. Perhaps, however, you are clutching at one of the factors I have mentioned and believe that there you have found the point at which our influence can make its attack. If the ethical restrictions demanded by society play a part in the deprivation imposed on the patient, treatment can, after all, give him the courage, or perhaps a direct injunction, to disregard those barriers and achieve satisfaction and recovery while forgoing the fulfilment of an ideal that is exalted, but so often not adhered to, by society. The patient will thus become healthy by 'living a full life' sexually. This, it is true, casts a shadow on analytic treatment for not serving general morality. What it has given to the individual it will have taken from the community.

[1916-1917, 3475]

I shall begin, then, by giving a picture of the child's world, and by telling as much of the story of his childhood as could be learnt without any exertion; it was not, indeed, for several years that the story became any less incomplete and obscure.

[1918b, 3508]

And now in conclusion I will cast a glance at a situation which belongs to the future - one that will seem fantastic to many of you, but which I think, nevertheless, deserves that we should be prepared for it in our minds. You know that our therapeutic activities are not very far-reaching. There are only a handful of us, and even by working very hard each one can devote himself in a year to only a small number of patients. Compared to the vast amount of neurotic misery which there is in the world, and perhaps need not be, the quantity we can do away with is almost negligible. Besides this, the necessities of our existence limit our work to the well-to-do classes, who are accustomed to choose their own physicians and whose choice is diverted away from psycho-analysis by all kinds of prejudices. At present we can do nothing for the wider social strata, who suffer extremely seriously from neuroses.

[1919a, 3635]
Now let us assume that by some kind of organization we succeeded in increasing our numbers to an extent sufficient for treating a considerable mass of the population. On the other hand, it is possible to foresee that at some time or other the conscience of society will awake and remind it that the poor man should have just as much right to assistance for his mind as he now has to the life-saving help offered by surgery; and that the neuroses threaten public health no less than tuberculosis, and can be left as little as the latter to the impotent care of individual members of the community. When this happens, institutions or out-patient clinics will be started, to which analytically-trained physicians will be appointed, so that men who would otherwise give way to drink, women who have nearly succumbed under their burden of privations, children for whom there is no choice but between running wild or neurosis, may be made capable, by analysis, of resistance and of efficient work. Such treatments will be free. It may be a long time before the State comes to see these duties as urgent. Present conditions may delay its arrival even longer. Probably these institutions will first be started by private charity. Some time or other, however, it must come to this.

[1919a, 3635]

Later History of Psycho-Analysis. - Psycho-analysis was carried approximately thus far by the work of the writer of this article, who for more than ten years was its sole representative. In 1906 the Swiss psychiatrists Bleuler and C. G. Jung began to play a lively part in analysis; in 1907 a first conference of its supporters took place at Salzburg; and the young science soon found itself the centre of interest both among psychiatrists and laymen. Its reception in Germany, with her morbid craving for authority, was not precisely to the credit of German science and moved even so cool a partisan as Bleuler to an energetic protest. Yet no condemnation or dismissal at official congresses served to hold up the internal growth or external expansion of psycho-analysis. In the course of the next ten years it extended far beyond the frontiers of Europe and became especially popular in the United States of America, and this was due in no small degree to the advocacy and collaboration of Putnam (Boston), Ernest Jones (Toronto; later London), Flournoy (Geneva), Ferenczi (Budapest), Abraham (Berlin), and many others besides. The anathema which was imposed upon psycho-analysis led its supporters to combine in an international organization which in the present year (1922) is holding its eighth private Congress in Berlin and now includes local groups in Vienna, Budapest, Berlin, Holland, Zurich, London, New York, Calcutta and Moscow. This development was not interrupted even by the World War. In 1918-19 Dr. Anton von Freund of Budapest founded the Internationaler Psychoanalytischer Verlag, which publishes journals and books concerned with psycho-analysis, and in 1920 Dr. M. Eitingon opened in Berlin the first psycho-analytic clinic for the treatment of neurotics without private means. Translations of the writer's principal works, which are now in preparation, into French, Italian and Spanish, testify to a growing interest in psycho-analysis in the Latin world as well.

[1923a, 3924]
Psycho-Analysis as a Therapeutic Procedure. - Psycho-analysis has never set itself up as a panacea and has never claimed to perform miracles. In one of the most difficult spheres of medical activity it is the only possible method of treatment for certain illnesses and for others it is the method which yields the best or the most permanent results - though never without a corresponding expenditure of time and trouble. A physician who is not wholly absorbed in the work of giving help will find his labours amply repaid by obtaining an unhoped-for insight into the complications of mental life and the interrelations between the mental and the physical. Where at present it cannot offer help but only theoretical understanding, it may perhaps be preparing the way for some later, more direct means of influencing neurotic disorders. Its province is above all the two transference neuroses, hysteria and obsessional neurosis, in which it has contributed to the discovery of their internal structure and operative mechanisms; and, beyond them, all kinds of phobias, inhibitions, deformities of character, sexual perversions and difficulties in erotic life. Some analysts (Jelliffe, Groddeck, Felix Deutsch) have reported too that the analytic treatment of gross organic diseases is not unpromising, since a mental factor not infrequently contributes to the origin and continuance of such illnesses. Since psycho-analysis demands a certain amount of psychical plasticity from its patients, some kind of age-limit must be laid down in their selection; and since it necessitates the devotion of long and intense attention to the individual patient, it would be uneconomical to squander such expenditure upon completely worthless persons who happen to be neurotic. Experience upon material in clinics can alone show what modifications may be necessary in order to make psycho-analytic treatment accessible to wider strata of the population or to adapt it to weaker intelligences. [1923a, 3926]

When, during his last years, he came to know psycho-analysis, it seemed to him to promise the fulfilment of his two great wishes. He set himself the task of helping the masses by psycho-analysis and of making use of the therapeutic effects of that medical technique, which had hitherto only been at the service of the rich, in order to mitigate the neurotic suffering of the poor. Since the State took no heed of the neuroses of the common people, since hospital clinics for the most part rejected psycho-analytic therapy without being able to offer any substitute for it, and since the few psycho-analytic physicians, tied by the necessity for maintaining themselves, were unequal to such a gigantic task, Anton von Freund sought, by his private initiative, to open a path for every one towards the fulfilment of this important social duty. During the years of the war he had collected what was then the very considerable sum of one and a half million kronen for humanitarian purposes in the city of Budapest. With the concurrence of Dr Stephan von Bárczy, the then Burgomaster, he assigned this sum for the foundation of a psycho-analytic Institute in Budapest, in which analysis was to be practised, taught and made accessible to the people. It was intended to train a considerable number of physicians in this Institute who would then receive an honorarium from it for the treatment of poor neurotics in an out-patient clinic. The Institute, furthermore, was to be a centre for further scientific research in analysis. Dr. Ferenczi was to be the scientific head of the Institute; von Freund himself was to undertake its organization and finances. The founder handed over a relatively smaller sum to Professor Freud for the foundation of an international psycho-analytic publishing house. But, [1920c, 3939]

None the less, the example which von Freund sought to set has already had its effect. A few weeks after his death, thanks to the energy and liberality of Dr. Max Eitingon, the first psycho-analytical out-patients' clinic has been opened in Berlin. Thus von Freund's work is carried on, though he himself can never be replaced or forgotten. [1920c, 3939]
In the course of this development, the technique of psycho-analysis has become as definite and as delicate as that of any other specialized branch of medicine. A failure to understand this fact has led to many abuses (particularly in England and America) because people who have acquired only a literary knowledge of psycho-analysis from reading consider themselves capable of undertaking analytic treatments without having received any special training. The consequences of such behaviour are damaging both to the science and to the patients and have brought much discredit upon psycho-analysis. The foundation of a first psycho-analytic out-patient clinic (by Max Eitingon in Berlin in 1920) has therefore become a step of high practical importance. This institute seeks on the one hand to make analytic treatment accessible to wide circles of the population and on the other hand undertakes the education of doctors to be practical analysts by a course of training which includes as a condition that the learner shall agree to be analysed himself.

[1924f, 4113]

My friend Max Eitingon, who created the Berlin Psycho-Analytical Policlinic and has hitherto supported it out of his own resources, has in the following pages made public his reasons for founding it and has also given an account of the Institute's organization and functions. I can only add to what he has written my wish that individuals or societies may be found elsewhere to follow Eitingon's example and bring similar institutions into existence. If psycho-analysis, alongside of its scientific significance, has a value as a therapeutic procedure, if it is capable of giving help to sufferers in their struggle to fulfil the demands of civilization, this help should be accessible as well to the great multitude who are too poor themselves to repay an analyst for his laborious work. This seems to be a social necessity particularly in our times, when the intellectual strata of the population, which are especially prone to neurosis, are sinking irresistibly into poverty. Institutes such as the Berlin Policlinic are also alone in a position to overcome the difficulties which otherwise stand in the way of thorough instruction in psycho-analysis. They make possible the education of a considerable number of trained analysts, whose activity must be regarded as the sole possible protection against injury to patients by ignorant and unqualified persons, whether they are laymen or doctors.

[1923g, 4175]
I must add a few more words on the history of psycho-analysis during the last decade. There can no longer be any doubt that it will continue; it has proved its capacity to survive and to develop both as a branch of knowledge and as a therapeutic method. The number of its supporters (organized into the International Psycho-Analytical Association) has considerably increased. In addition to the older local groups (in Vienna, Berlin, Budapest, London, Holland, Switzerland, and Russia), societies have since been formed in Paris and Calcutta, two in Japan, several in the United States, and quite recently one each in Jerusalem and South Africa and two in Scandinavia. Out of their own funds these local societies support (or are in process of forming) training institutes, in which instruction in the practice of psycho-analysis is given according to a uniform plan, and out-patient clinics in which experienced analysts as well as students give free treatment to patients of limited means. Every other year the members of the International Psycho-Analytical Association hold a Congress at which scientific papers are read and questions of organization decided. The thirteenth of these congresses (which I myself can no longer attend) took place at Lucerne in 1934. From a core of interests that are common to all members of the Association, their work radiates in many different directions. Some lay most stress upon clarifying and deepening our knowledge of psychology, while others are concerned with keeping in contact with medicine and psychiatry. From the practical point of view, some analysts have set themselves the task of bringing about the recognition of psycho-analysis at the universities and its inclusion in the medical curriculum, whereas others are content to remain outside these institutions and will not allow that psycho-analysis is less important in the field of education than in that of medicine. It happens from time to time that an analytic worker may find himself isolated in an attempt to emphasize some single one of the findings or views of psycho-analysis at the expense of all the rest. Nevertheless, the whole impression is a satisfactory one - of serious scientific work carried on at a high level. [1925d, 4245]

In every instance the treatment makes heavy claims upon both the physician and the patient: the former requires a special training and must devote a long period of time to exploring the mind of each patient, while the latter must make considerable sacrifices, both material and mental. Nevertheless, all the trouble involved is as a rule rewarded by the results. Psycho-analysis does not act as a convenient panacea ('cito, tute, jucunde') for psychological disorders. On the contrary, its application has been instrumental in making clear for the first time the difficulties and limitations in the treatment of such affections. For the moment it is only in Berlin and Vienna that there are voluntary institutions which make psycho-analytic treatment accessible to the wage-earning classes. [1926f, 4402]

During the years 1911-13 two former adherents, Alfred Adler, of Vienna, and C. G. Jung, of Zurich, seceded from the psycho-analytic movement and founded schools of thought of their own, which, in view of the general hostility to psycho-analysis, could be certain of a favourable reception, but which remained scientifically sterile. In 1921 Dr. M. Eitingon founded in Berlin the first public psycho-analytic clinic and training-school, and this was soon followed by a second in Vienna. [1926f, 4407]

The following pages describe the founding and achievements of the Berlin Psycho-Analytic Institute, to which are allotted three important functions within the psycho-analytic movement. First, it endeavours to make our therapy accessible to the great multitude who suffer under their neuroses no less than the wealthy, but who are not in a position to meet the cost of their treatment. Secondly, it seeks to provide a centre at which analysis can be taught theoretically and at which the experience of older analysts can be handed on to pupils who are anxious to learn. And lastly, it aims at perfecting our knowledge of neurotic illnesses and our therapeutic technique by applying them and testing them under fresh conditions. [1930b, 4614]
An Institute of this kind was indispensable; but we should have waited in vain for assistance from the State or interest from the University in its foundation. Here the energy and self-sacrifice of an individual analyst took the initiative. Ten years ago, Dr. Max Eitingon, now President of the International Psycho-Analytical Association, created an Institute such as this from his own resources, and has since then maintained and directed it by his own efforts. This Report on the first decade of the Berlin Institute is a tribute to its creator and director - an attempt to render him public thanks. Everyone who, in whatever sense, has a share in psycho-analysis will unite in thus thanking him.

[1930b, 4614]
A doctor can always do harm if he is unskilful or unscrupulous, and this is no more and no less true where it is a question of investigating his patients' sexual life than it is in other things. Naturally, if someone, after an honest self-examination, feels that he does not possess the tact, seriousness and discretion which are necessary for questioning neurotic patients, and if he is aware that revelations of a sexual character would provoke lascivious thrills in him rather than scientific interest, then he will be right to avoid the topic of the aetiology of the neuroses. All we ask, in addition, is that he should also refrain from treating nervous patients.

[1897b, 457]

Since the manifestations of the psychoneuroses arise from the deferred action of unconscious psychical traces, they are accessible to psychotherapy. But in this case the therapy must pursue paths other than the only one so far followed of suggestion with or without hypnosis. Basing myself on the 'cathartic' method introduced by Josef Breuer, I have in recent years almost completely worked out a therapeutic procedure which I propose to describe as 'psycho-analytic'. I owe a great number of successes to it, and I hope I may be able further to increase it effectiveness considerably. The first accounts of the technique and scope of this method were given in Studies on Hysteria, written jointly with Breuer and published in 1895. Since then a good deal, as I think I may say, has been altered for the better. Whereas at that time we modestly declared that we could undertake to only to remove the symptoms of hysteria, not to cure hysteria itself, this distinction has since come to seem to me without substance, so that there is a prospect of a genuine cure of hysteria and obsessions. It is therefore with very lively interest that I have read in the publications of colleagues that 'in this case the ingenious procedure devised by Breuer and Freud has failed', or that 'the method has not performed what it seemed to promise'. This gave me something of the feelings of a man who reads his own obituary in the paper, but who is able to reassure himself by his better knowledge of the facts. For the method is so difficult that it has quite definitely to be learned; and I cannot recall that a single one of my critics has expressed a wish to learn it from me. Nor do I believe that, like me, they have occupied themselves with it intensely enough to have been able to discover it for themselves. The remarks in the Studies on Hysteria are totally inadequate to enable a reader to master the technique, nor are they in any way intended to give any such complete instruction.

[1897b, 473]
It would be more dignified as well as more helpful to the patient - who, after all, has to come to terms with his ailments - for the doctor to tell the truth, as he knows it from his daily practice. The psychoneuroses as a genus are by no means mild illnesses. When hysteria sets in, no one can foretell when it will come to an end. We mostly comfort ourselves with the vain prophecy that 'one day it will suddenly disappear'. Recovery often enough turns out to be merely an agreement to mutual toleration between the sick part of the patient and the healthy part; or it is the result of the transformation of a symptom into a phobia. A girl's hysteria, calmed down with difficulty, revives in her as a wife after the short interruption of young married happiness. The only difference is that another person, the husband, is now driven by his own interests to keep silence about her condition. Even if an illness of this kind leads to no manifest incapacity on the patients' part to carry on their life, it nearly always prevents free unfolding of their mental powers. Obsessions recur throughout their lives; and phobias and other restrictions upon the will have hitherto been unamenable to treatment of any kind. All this is kept from the knowledge of the layman. The father of a hysterical girl is consequently horrified if, for instance, he is asked to agree to her being given a year's treatment, when she has perhaps only been ill for a few months. The layman is, as it were, deeply convinced in himself that all these psychoneuroses are unnecessary; so he has no patience with the processes of the illness and no readiness to make sacrifices for its treatment. If, in face of a case of typhus which lasts three weeks, or of a broken leg which takes six months to mend, he adopts a more understanding attitude, and if, as soon as his child shows the first signs of a curvature of the spine, he finds it reasonable that orthopaedic treatment should be carried on over several years, the difference in his behaviour is due to the better knowledge on the part of the physicians who pass on their knowledge honestly to the layman. Honesty on the part of the physician and willing acquiescence on the part of the layman will be established for the neuroses too, as soon as an insight into the nature of those affections becomes common property in the medical world. Radical treatment of these disorders will no doubt always require special training and will be incompatible with other kinds of medical activity. On the other hand, this class of physicians, which will, I believe, be a large one in the future, has the prospect of achieving noteworthy results and of obtaining a satisfying insight into the mental life of mankind.

[1897b, 475]
(b) It seems to me that there is a widespread and erroneous impression among my colleagues that this technique of searching for the origins of an illness and removing its manifestations by that means is an easy one which can be practised off-hand, as it were. I conclude this from the fact that not one of all the people who have shown an interest in my therapy and passed definite judgements upon it has ever asked me how I actually go about it. There can be only one reason for this: that they think there is nothing to enquire about, that the thing is perfectly self-evident. Again, I am now and then astonished to hear that in this or that department of a hospital a young assistant has received an order from his chief to undertake a 'psycho-analysis' of a hysterical patient. I am sure he would not be allowed to examine an extirpated tumour unless he had convinced his chiefs that he was conversant with histological technique. Similarly, reports reach my ears that this or that colleague has arranged appointments with a patient in order to undertake a mental treatment of the case, though I am certain he knows nothing of the technique of any such therapy. His expectation must be therefore that the patient will make him a present of his secrets, or perhaps that he is looking for salvation in some sort of confession or confidence. I should not be surprised if a patient were injured rather than benefited by being treated in such a fashion. For it is not so easy to play upon the instrument of the mind. I am reminded on such occasions of the words of a world-famous neurotic - though it is true that he was never treated by a physician but existed only in a poet's imagination - Hamlet, Prince of Denmark. The King has ordered two courtiers, Rosenkranz and Guildenstern, to follow him, to question him and drag the secret of his depression out of him. He wards them off. Then some recorders are brought on the stage and Hamlet, taking one of them, begs one of his tormentors to play upon it, telling him that it is as easy as lying. The courtier excuses himself, for he knows no touch of the instrument, and when he cannot be persuaded to try it, Hamlet finally breaks out with these words: 'Why, look you now, how unworthy a thing you make of me! You would play upon me;...you would pluck out the heart of my mystery; you would sound me from my lowest note to the top of my compass; and there is much music, excellent voice, in this little organ; yet you cannot make it speak. 'Sblood, do you think I am easier to be played on than a pipe? Call me what instrument you will, though you can fret me, you cannot play upon me.' (Act III, Scene 2.)

[1905a, 1567]
You may have formed an impression that the technique through whose armoury I have just conducted you is particularly difficult. In my opinion that technique is entirely in conformity with the material with which it has to deal. But this much at least is clear: it is not a self-evident one and it must be learnt just as the techniques of histology or surgery must be learnt. You will perhaps be surprised to hear that in Europe we have heard a large number of judgements on psycho-analysis from people who know nothing of this technique and do not employ it; and who go on to demand with apparent scorn that we shall prove to them the correctness of our findings. Among these adversaries there are no doubt some to whom a scientific mode of thought is not as a rule alien, who, for instance, would not reject the results of a microscopic examination because it could not be confirmed on the anatomical preparation with the naked eye, but who would first form a judgement on the matter themselves with the help of a microscope. But, where psycho-analysis is concerned, the prospects of recognition are in truth less favourable. Psycho-analysis is seeking to bring to conscious recognition the things in mental life which are repressed; and everyone who forms a judgement on it is himself a human being, who possesses similar repressions and may perhaps be maintaining them with difficulty. They are therefore bound to call up the same resistance in him as in our patients; and that resistance finds it easy to disguise itself is an intellectual rejection and to bring up arguments like those which we ward off in our patients by means of the fundamental rule of psycho-analysis. We often become aware in our opponents, just as we do in our patients, that their power of judgement is very noticeably influenced affectively in the sense of being diminished. The arrogance of consciousness (in rejecting dreams with such contempt, for instance) is one of the most powerful of the devices with which we are provided as a universal protection against the incursion of unconscious complexes. That is why it is so hard to convince people of the reality of the unconscious and to teach them to recognize something new which is in contradiction to their conscious knowledge.

Other innovations in technique relate to the physician himself. We have become aware of the 'counter-transference', which arises in him as a result of the patient's influence on his unconscious feelings, and we are almost inclined to insist that he shall recognize this counter-transference in himself and overcome it. Now that a considerable number of people are practising psycho-analysis and exchanging their observations with one another, we have noticed that no psycho-analyst goes further than his own complexes and internal resistances permit; and we consequently require that he shall begin his activity with a self-analysis and continually carry it deeper while he is making his observations on his patients. Anyone who fails to produce results in a self-analysis of this kind may at once give up any idea of being able to treat patients by analysis.

It is not enough, therefore, for a physician to know a few of the findings of psycho-analysis; he must also have familiarized himself with its technique if he wishes his medical procedure to be guided by a psycho-analytic point of view. This technique cannot yet be learnt from books, and it certainly cannot be discovered independently without great sacrifices of time, labour and success. Like other medical techniques, it is to be learnt from those who are already proficient in it. It is a matter of some significance, therefore, in forming a judgement on the incident which I took as a starting-point for these remarks, that I am not acquainted with the physician who is said to have given the lady such advice and have never heard his name.
Neither I myself nor my friends and co-workers find it agreeable to claim a monopoly in this way in the use of a medical technique. But in face of the dangers to patients and to the cause of psycho-analysis which are inherent in the practice that is to be foreseen of a 'wild' psycho-analysis, we have had no other choice. In the spring of 1910 we founded an International Psycho-Analytical Association, to which its members declare their adherence by the publication of their names, in order to be able to repudiate responsibility for what is done by those who do not belong to us and yet call their medical procedure 'psycho-analysis'. For as a matter of fact 'wild' analysts of this kind do more harm to the cause of psycho-analysis than to individual patients. I have often found that a clumsy procedure like this, even if at first it produced an exacerbation of the patient's condition, led to a recovery in the end. Not always but still often. When he has abused the physician enough and feels far enough away from his influence, his symptoms give way, or he decides to take some step which leads along the path to recovery. The final improvement then comes about 'of itself', or is ascribed to some totally indifferent treatment by some other doctor to whom the patient has later turned. In the case of the lady whose complaint against her physician we have heard, I should say that, despite everything, the 'wild' psycho-analyst did more for her than some highly respected authority who might have told her she was suffering from a 'vasomotor neurosis'. He forced her attention to the real cause of her trouble, or in that direction, and in spite of all her opposition this intervention of his cannot be without some favourable results. But he has done himself harm and helped to intensify the prejudices which patients feel, owing to their natural affective resistances, against the methods of psycho-analysis. And this can be avoided.

[1910k, 2380]

But if the doctor is to be in a position to use his unconscious in this way as an instrument in the analysis, he must himself fulfil one psychological condition to a high degree. He may not tolerate any resistances in himself which hold back from his consciousness what has been perceived by his unconscious; otherwise he would introduce into the analysis a new species of selection and distortion which would be far more detrimental than that resulting from concentration of conscious attention. It is not enough for this that he himself should be an approximately normal person. It may be insisted, rather, that he should have undergone a psycho-analytic purification and have become aware of those complexes of his own which would be apt to interfere with his grasp of what the patient tells him. There can be no reasonable doubt about the disqualifying effect of such defects in the doctor; every unresolved repression in him constitutes what has been aptly described by Stekel as a 'blind spot' in his analytic perception.

[1912e, 2471]

Some years ago I gave as an answer to the question of how one can become an analyst: 'By analysing one's own dreams.' This preparation is no doubt enough for many people, but not for everyone who wishes to learn analysis. Nor can everyone succeed in interpreting his own dreams without outside help. I count it as one of the many merits of the Zurich school of analysis that they have laid increased emphasis on this requirement, and have embodied it in the demand that everyone who wishes to carry out analyses on other people shall first himself undergo an analysis by someone with expert knowledge. Anyone who takes up the work seriously should choose this course, which offers more than one advantage; the sacrifice involved in laying oneself open to another person without being driven to it by illness is amply rewarded. Not only is one's aim of learning to know what is hidden in one's own mind far more rapidly attained and with less expense of affect, but impressions and convictions will be gained in relation to oneself which will be sought in vain from studying books and attending lectures. And lastly, we must not under-estimate the advantage to be derived from the lasting mental contact that is as a rule established between the student and his guide.

[1912e, 2471]
An analysis such as this of someone who is practically healthy will, as may be imagined, remain incomplete. Anyone who can appreciate the high value of the self-knowledge and increase in self-control thus acquired will, when it is over, continue the analytic examination of his personality in the form of a self-analysis, and be content to realize that, within himself as well as in the external world, he must always expect to find something new. But anyone who has scorned to take the precaution of being analysed himself will not merely be punished by being incapable of learning more than a certain amount from his patients, he will risk a more serious danger and one which may become a danger to others. He will easily fall into the temptation of projecting outwards some of the peculiarities of his own personality, which he has dimly perceived, into the field of science, as a theory having universal validity; he will bring the psycho-analytic method into discredit, and lead the inexperienced astray.

No one who is familiar with the nature of neurosis will be astonished to hear that even a man who is very well able to carry out an analysis on other people can behave like any other mortal and be capable of producing the most intense resistances as soon as he himself becomes the object of analytic investigation. When this happens we are once again reminded of the dimension of depth in the mind, and it does not surprise us to find that the neurosis has its roots in psychical strata to which an intellectual knowledge of analysis has not penetrated.

The only question is whether the practice of psycho-analysis may not have as its prerequisite a medical training, from which the educator and the pastoral worker must remain debarred, or whether there may be other considerations which are opposed to the suggestion that the technique of psycho-analysis should be confided to any but a doctor's hands. I confess that I can see no ground for any such reservations. The practice of psycho-analysis calls much less for medical training than for psychological instruction and a free human outlook. The majority of doctors are not equipped to practise psycho-analysis and have completely failed to grasp the value of that therapeutic procedure. The educator and the pastoral worker are bound by the standards of their profession to exercise the same consideration, care and restraint as are usually practised by the doctor, and apart from this their association with young people perhaps makes them better fitted to understand these young people's mental life. But in both cases the only guarantee of the harmless application of the analytic procedure must depend on the personality of the analyst.

Where a case borders upon mental abnormality, the analytic educator will be bound to make himself familiar with the most necessary psychiatric knowledge, and furthermore to call a doctor into consultation when the diagnosis and prognosis of the disturbance appear doubtful. In a number of cases it will only be possible to achieve success if there is collaboration between the educator and the doctor.

In one single respect an educator's responsibility may perhaps exceed that of a doctor. The doctor has as a rule to deal with psychical structures which have already become rigid and he will find in the patient's established individuality a limit to his own achievement but at the same time a guarantee of the patient's capacity to stand alone. The educator, however, works upon material which is plastic and open to every impression, and he must keep before himself an obligation not to mould the young mind in accordance with his own personal ideals but rather according to his subject's dispositions and possibilities.
The small circle soon expanded, and in the course of the next few years often changed its composition. On the whole I could tell myself that it was hardly inferior, in wealth and variety of talent, to the staff of any clinical teacher one could think of. It included from the beginning the men who were later to play such a considerable, if not always a welcome, part in the history of the psycho-analytic movement. At that time, however, one could not yet guess at these developments. I had every reason to be satisfied, and I think I did everything possible to impart my own knowledge and experience to the others. There were only two inauspicious circumstances which at last estranged me inwardly from the group. I could not succeed in establishing among its members the friendly relations that ought to obtain between men who are all engaged upon the same difficult work; nor was I able to stifle the disputes about priority for which there were so many opportunities under these conditions of work in common. The difficulties in the way of giving instruction in the practice of psycho-analysis, which are quite particularly great and are responsible for much in the present dissensions, were evident already in this private Vienna Psycho-Analytical Society. I myself did not venture to put forward a still unfinished technique and a theory still in the making with an authority which would probably have enabled the others to avoid some wrong turnings and ultimate disasters. The self-reliance of intellectual workers, their early independence of their teacher, is always gratifying from a psychological point of view; but it is only of advantage to science if those workers fulfill certain personal conditions which are none too common. For psycho-analysis in particular a long and severe discipline and training in self-discipline would have been required. In view of the courage displayed by their devotion to a subject so much frowned upon and so poor in prospects, I was disposed to tolerate much among the members to which I should otherwise have made objection. Besides doctors, the circle included others - men of education who had recognized something important in psycho-analysis: writers, painters and so on. My Interpretation of Dreams and my book on jokes, among others, had shown from the beginning that the theories of psycho-analysis cannot be restricted to the medical field, but are capable of application to a variety of other mental sciences.

[1914d, 2892]

I considered it necessary to form an official association because I feared the abuses to which psycho-analysis would be subjected as soon as it became popular. There should be some headquarters whose business it would be to declare: 'All this nonsense is nothing to do with analysis; this is not psycho-analysis.' At the sessions of the local groups (which together would constitute the international association) instruction should be given as to how psycho-analysis was to be conducted and doctors should be trained, whose activities would then receive a kind of guarantee. Moreover, it seemed to me desirable, since official science had pronounced its solemn ban upon psycho-analysis and had declared a boycott against doctors and institutions practising it, that the adherents of psycho-analysis should come together for friendly communication with one another and mutual support.

[1914d, 2907]

(1) The inclusion of psycho-analysis in the University curriculum would no doubt be regarded with satisfaction by every psycho-analyst. At the same time it is clear that the psycho-analyst can dispense entirely with the University without any loss to himself. For what he needs in the matter of theory can be obtained from the literature of the subject and, going more deeply, at the scientific meetings of the psycho-analytic societies as well as by personal contact with their more experienced members. As regards practical experience, apart from what he gains from his own personal analysis, he can acquire it by carrying out treatments, provided that he can get supervision and guidance from recognized psycho-analysts.

[1919j, 3638]
The fact that an organization of this kind exists is actually due to the exclusion of psycho-
analysis from Universities. And it is therefore evident that these arrangements will continue to
perform an effective function so long as this exclusion persists.
[1919j, 3638]

*Development of Technique.* - After the analyst's curiosity had, as it were, been gratified by the
elaboration of the technique of interpretation, it was inevitable that interest should turn to the
problem of discovering the most effective way of influencing the patient. It soon became evident
that the physician's immediate task was to assist the patient in getting to know, and afterwards
in overcoming, the resistances which emerged in him during treatment and of which, to begin
with, he himself was unaware. And it was found at the same time that the essential part of the
process of cure lay in the overcoming of these resistances and that unless this was achieved no
permanent mental change could be brought about in the patient. Since the analyst's efforts
have in this way been directed upon the patient's resistance, analytic technique has attained a
certainty and delicacy rivalling that of surgery. Consequently, everyone is strongly advised
against undertaking psycho-analytic treatments without a strict training, and a physician who
ventures upon them on the strength of his medical qualification is in no respect better than a
layman.
[1923a, 3925]

In the course of this development, the technique of psycho-analysis has become as definite
and as delicate as that of any other specialized branch of medicine. A failure to understand this
fact has led to many abuses (particularly in England and America) because people who have
acquired only a literary knowledge of psycho-analysis from reading consider themselves
capable of undertaking analytic treatments without having received any special training. The
consequences of such behaviour are damaging both to the science and to the patients and
have brought much discredit upon psycho-analysis. The foundation of a first psycho-analytic
out-patient clinic (by Max Eitingon in Berlin in 1920) has therefore become a step of high
practical importance. This institute seeks on the one hand to make analytic treatment accessible
to wide circles of the population and on the other hand undertakes the education of doctors to
be practical analysts by a course of training which includes as a condition that the learner shall
agree to be analysed himself.
[1924f, 4113]

Purely external difficulties have also contributed to strengthen the resistance to psycho-
analysis. It is not easy to arrive at an independent judgement upon matters to do with analysis
without having experienced it oneself or practised it on someone else. Nor can one do the latter
without having acquired a specific and decidedly delicate technique, while until recently there
was no easily accessible means of learning psycho-analysis and its technique. This position has
now been improved by the foundation (in 1920) of the Berlin Psycho-Analytic Clinic and Training
Institute, and soon afterwards (in 1922) of an exactly similar institute in Vienna.
[1925e, 4130]

It must not be assumed that this gift of intuitive understanding will be found in everyone
concerned with the bringing-up of children. Two lessons may be derived, it seems to me, from
the experience and the success of August Aichhorn. One is that every such person should
receive a psycho-analytic training, since without it children, the object of his endeavours, must
remain an inaccessible problem to him. A training of this kind is best carried out if such a person
himself undergoes an analysis and experiences it on himself: theoretical instruction in analysis
fails to penetrate deep enough and carries no conviction.
[1925f, 4167]
I will end with a further inference, and this time one which is important not for the theory of education but for the status of those who are engaged in education. If one of these has learnt analysis by experiencing it on his own person and is in a position of being able to employ it in borderline and mixed cases to assist him in his work, he should obviously be given the right to practise analysis, and narrow-minded motives should not be allowed to try to put obstacles in his way.

Finally, the remarks which the author makes in conclusion on the technique of psycho-analysis are quite excellent. They are entirely correct and, in spite of their conciseness, leave aside nothing essential. They are convincing evidence of the author's subtle understanding. The reader should not, of course, conclude that knowledge of these rules of technique alone will make him capable of undertaking an analysis.

My friend Max Eitingon, who created the Berlin Psycho-Analytical Policlinic and has hitherto supported it out of his own resources, has in the following pages made public his reasons for founding it and has also given an account of the Institute's organization and functions. I can only add to what he has written my wish that individuals or societies may be found elsewhere to follow Eitingon's example and bring similar institutions into existence. If psycho-analysis, alongside of its scientific significance, has a value as a therapeutic procedure, if it is capable of giving help to sufferers in their struggle to fulfil the demands of civilization, this help should be accessible as well to the great multitude who are too poor themselves to repay an analyst for his laborious work. This seems to be a social necessity particularly in our times, when the intellectual strata of the population, which are especially prone to neurosis, are sinking irresistibly into poverty. Institutes such as the Berlin Policlinic are also alone in a position to overcome the difficulties which otherwise stand in the way of thorough instruction in psycho-analysis. They make possible the education of a considerable number of trained analysts, whose activity must be regarded as the sole possible protection against injury to patients by ignorant and unqualified persons, whether they are laymen or doctors.

I myself have contributed nothing to the application of analysis to education. It was natural, however, that the analytic discoveries about the sexual life and mental development of children should attract the attention of educators and make them see their problems in a new light. Dr. Oskar Pfister, a protestant pastor at Zurich, led the way as a tireless pioneer along these lines, nor did he find the practice of analysis incompatible with the retention of his religion, though it is true that this was of a sublimated kind. Among the many others who worked alongside of him I may mention Frau Dr. Hug-Hellmuth and Dr. S. Bernfeld, both of Vienna. The application of analysis to the prophylactic upbringing of healthy children and to the correcting of those who, though not actually neurotic, have deviated from the normal course of development has led to one consequence which is of practical importance. It is no longer possible to restrict the practice of psycho-analysis to doctors and to exclude laymen from it. In fact, a doctor who has not been through a special training is, in spite of his diploma, a layman in analysis, and a non-doctor who has been suitably trained can, with occasional reference to a doctor, carry out the analytic treatment not only of children but also of neurotics.
The title of this small work is not immediately intelligible. I will therefore explain it. 'Layman' = 'Non-doctor'; and the question is whether non-doctors as well as doctors are to be allowed to practise analysis. This question has its limitations both in time and place. In time, because up to now no one has been concerned as to who practises analysis. Indeed, people have been much too little concerned about it - the one thing they were agreed on was a wish that no one should practise it. Various reasons were given for this, but they were based on the same underlying distaste. Thus the demand that only doctors should analyse corresponds to a new and apparently more friendly attitude to analysis - if, that is, it can escape the suspicion of being after all only a slightly modified derivative of the earlier attitude. It is conceded that in some circumstances an analytic treatment shall be undertaken; but, if so, only doctors are to undertake it. The reason for this restriction then becomes a matter for enquiry.

[1926e, 4327]

The question is limited in place because it does not arise in all countries with equal significance. In Germany and America it would be no more than an academic discussion; for in those countries every patient can have himself treated how and by whom he chooses, and anyone who chooses can, as a 'quack', handle any patients, provided only that he undertakes the responsibility for his actions. The law does not intervene until it is called in to expiate some injury done to the patient. But in Austria, in which and for which I am writing, there is a preventive law, which forbids non-doctors from undertaking the treatment of patients, without waiting for its outcome.¹ So here the question whether laymen (= non-doctors) may treat patients by psycho-analysis has a practical sense. As soon as it is raised, however, it appears to be settled by the wording of the law. Neurotics are patients, laymen are non-doctors, psycho-analysis is a procedure for curing or improving nervous disorders, and all such treatments are reserved to doctors. It follows that laymen are not permitted to practise analysis on neurotics, and are punishable if they nevertheless do so. The position being so simple, one hardly ventures to take up the question of lay analysis. It may perhaps turn out that in this instance the patients are not like other patients, that the laymen are not really laymen, and that the doctors have not exactly the qualities which one has a right to expect of doctors and on which their claims should be based. If this can be proved, there will be justifiable grounds for demanding that the law shall not be applied without modification to the instance before us.

[1926e, 4327]

Whether this happens will depend on people who are not obliged to be familiar with the peculiarities of an analytic treatment. It is our task to give information on the subject to these impartial persons, whom we shall assume to be, at the moment, still in ignorance. It is to be regretted that we cannot let them be present as an audience at a treatment of this kind. But the 'analytic situation' allows of the presence of no third person. Moreover the different sessions are of very unequal value. An unauthorized listener who hit upon a chance one of them would as a rule form no useful impression; he would be in danger of not understanding what was passing between the analyst and the patient, or he would be bored. For good or ill, therefore, he must be content with our information, which we shall try to make as trustworthy as possible.

[1926e, 4328]
I know I cannot convince you. That is beyond any possibility and for that reason beyond my purpose. When we give our pupils theoretical instruction in psycho-analysis, we can see how little impression we are making on them to begin with. They take in the theories of analysis as coolly as other abstractions with which they are nourished. A few of them may perhaps wish to be convinced, but there is not a trace of their being so. But we also require that everyone who wants to practise analysis on other people shall first himself submit to an analysis. It is only in the course of this 'self-analysis' (as it is misleadingly termed), when they actually experience as affecting their own person - or rather, their own mind - the processes asserted by analysis, that they acquire the convictions by which they are later guided as analysts. How then could I expect to convince you, the Impartial Person, of the correctness of our theories, when I can only put before you an abbreviated and therefore unintelligible account of them, without confirming them from your own experiences?
[1926e, 4342]

'Well, it is generally reported that in analyses the most intimate - and the nastiest - events in sexual life come up for discussion in every detail. If that is so - I have not been able to gather from your psychological discussions that it is necessarily so - it would be a strong argument in favour of restricting these treatments to doctors. How could one dream of allowing such dangerous liberties to people of whose discretion one was not sure and of whose character one had no guarantee?'
[1926e, 4349]

'It is true that doctors enjoy certain privileges in the sphere of sex: they are even allowed to inspect people's genitals - though they were not allowed to in the East and though some idealistic reformers (you know whom I have in mind) have disputed this privilege. But you want to know in the first place whether it is so in analysis and why it must be so. - Yes, it is so.
[1926e, 4349]

'I believe I understand your purpose. You want to show me what kind of knowledge is needed in order to practise analysis, so that I may be able to judge whether only doctors should have a right to do so. Well, so far very little to do with medicine has turned up: a great deal of psychology and a little biology or sexual science. But perhaps we have not got to the end?'
[1926e, 4360]
Just a moment! Things are not quite as bad as that. Why do you choose to except your own mental processes from the rule of law which you recognize in other people's? When you have attained some degree of self-discipline and have certain knowledge at your disposal, your interpretations will be independent of your personal characteristics and will hit the mark. I am not saying that the analyst's personality is a matter of indifference for this portion of his task. A kind of sharpness of hearing for what is unconscious and repressed, which is not possessed equally by everyone, has a part to play. And here, above all, we are brought to the analyst's obligation to make himself capable, by a deep-going analysis of his own, of the unprejudiced reception of the analytic material. Something, it is true, still remains over: something comparable to the 'personal equation' in astronomical observations. This individual factor will always play a larger part in psycho-analysis than elsewhere. An abnormal person can become an accurate physicist; as an analyst he will be hampered by his own abnormality from seeing the pictures of mental life undistorted. Since it is impossible to demonstrate to anyone his own abnormality, general agreement in matters of depth-psychology will be particularly hard to reach. Some psychologists, indeed, think it is quite impossible and that every fool has an equal right to give out his folly as wisdom. I confess that I am more of an optimist about this. After all, our experiences show that fairly satisfactory agreements can be reached even in psychology. Every field of research has its particular difficulty which we must try to eliminate. And, moreover, even in the interpretative art of analysis there is much that can be learnt like any other material of study: for instance, in connection with the peculiar method of indirect representation through symbols.

[1926e, 4362]

"Have you finished at last? I am feeling just a little bewildered with all I have heard from you. Only tell me one thing more: how and where can one learn what is necessary for practising analysis?"

[1926e, 4370]

There are at the moment two Institutes at which instruction in psycho-analysis is given. The first has been founded in Berlin by Dr. Max Eitingon, who is a member of the Society there. The second is maintained by the Vienna Psycho-Analytical Society at its own expense and at considerable sacrifice. The part played by the authorities is at present limited to the many difficulties which they put in the way of the young undertaking. A third training Institute is at this moment being opened in London by the Society there, under the direction of Dr. Ernest Jones. At these Institutes the candidates themselves are taken into analysis, receive theoretical instruction by lectures on all the subjects that are important for them, and enjoy the supervision of older and more experienced analysts when they are allowed to make their first trials with comparatively slight cases. A period of some two years is calculated for this training. Even after this period, of course, the candidate is only a beginner and not yet a master. What is still needed must be acquired by practice and by an exchange of ideas in the psycho-analytical societies in which young and old members meet together. Preparation for analytic activity is by no means so easy and simple. The work is hard, the responsibility great. But anyone who has passed through such a course of instruction, who has been analysed himself, who has mastered what can be taught to-day of the psychology of the unconscious, who is at home in the science of sexual life, who has learnt the delicate technique of psycho-analysis, the art of interpretation, of fighting resistances and of handling the transference - anyone who has accomplished all this is no longer a layman in the field of psycho-analysis. He is capable of undertaking the treatment of neurotic disorders, and will be able in time to achieve in that field whatever can be required from this form of therapy.

[1926e, 4370]
'You have expended a great deal of effort on showing me what psycho-analysis is and what sort of knowledge is needed in order to practise it with some prospect of success. Very well. Listening to you can have done me no harm. But I do not know what influence on my judgement you expect your explanations to have. I see before me a case which has nothing unusual about it. The neuroses are a particular kind of illness and analysis is a particular method of treating them - a specialized branch of medicine. It is the rule in other cases as well for a doctor who has chosen a special branch of medicine not to be satisfied with the education that is confirmed by his diploma: particularly if he intends to set up in a fairly large town, such as can alone offer a livelihood to specialists. Anyone who wants to be a surgeon tries to work for a few years at a surgical clinic, and similarly with oculists, laryngologists and so on - to say nothing of psychiatrists, who are perhaps never able to get away from a state institution or a sanatorium. And the same will happen in the case of psycho-analysts: anyone who decides in favour of this new specialized branch of medicine will, when his studies are completed, take on the two years' training you spoke of in a training institute, if it really requires so much time. He will realize afterwards, too, that it is to his advantage to keep up his contact with his colleagues in a psycho-analytical society, and everything will go along swimmingly. I cannot see where there is a place in this for the question of lay analysis.'

[1926e, 4371]

A doctor who does what you have promised on his behalf will be welcome to all of us. Four-fifths of those whom I recognize as my pupils are in any case doctors. But allow me to point out to you how the relations of doctors to analysis have really developed and how they will probably continue to develop. Doctors have no historical claim to the sole possession of analysis. On the contrary, until recently they have met it with everything possible that could damage it, from the shallowest ridicule to the gravest calumny. You will justly reply that that belongs to the past and need not affect the future. I agree, but I fear the future will be different from what you have foretold.

[1926e, 4371]

Permit me to give the word 'quack' the meaning it ought to have instead of the legal one. According to the law a quack is anyone who treats patients without possessing a state diploma to prove he is a doctor. I should prefer another definition: a quack is anyone who undertakes a treatment without possessing the knowledge and capacities necessary for it. Taking my stand on this definition, I venture to assert that - not only in European countries - doctors form a preponderating contingent of quacks in analysis. They very frequently practise analytic treatment without having learnt it and without understanding it.

[1926e, 4372]

The first consideration is that in his medical school a doctor receives a training which is more or less the opposite of what he would need as a preparation for psycho-analysis. His attention has been directed to objectively ascertainable facts of anatomy, physics and chemistry, on the correct appreciation and suitable influencing of which the success of medical treatment depends. The problem of life is brought into his field of vision so far as it has hitherto been explained to us by the play of forces which can also be observed in inanimate nature. His interest is not aroused in the mental side of vital phenomena; medicine is not concerned with the study of the higher intellectual functions, which lies in the sphere of another faculty. Only psychiatry is supposed to deal with the disturbances of mental functions; but we know in what manner and with what aims it does so. It looks for the somatic determinants of mental disorders and treats them like other causes of illness.
