Nor is it true that patients put insuperable obstacles in the way of an investigation into their sexual life. After some slight hesitation, adults usually adjust themselves to the situation by saying: 'After all, I'm at the doctor's; I can say anything to him.' A great many women who find it difficult enough to go through life concealing their sexual feelings, are relieved to find that with the doctor no other consideration outweighs that of their recovery, and they are grateful to him that for once they are allowed to behave quite humanly about sexual things. A dim knowledge of the overwhelming importance of sexual factors in the production of neuroses (a knowledge which I am trying to capture afresh for science) seems never to have been lost in the consciousness of laymen. How often do we witness scenes like this: A married couple, one of whom is suffering from a neurosis, comes to us for consultation. After we have made a great many introductory remarks and apologies to the effect that no conventional barriers should exist between them and the doctor who wants to be of use in such cases, and so on, we tell them that we suspect that the cause of the illness lies in the unnatural and detrimental form of sexual intercourse which they must have chosen since the wife's last confinement. We tell them that doctors do not as a rule concern themselves with such matters, but that that is reprehensible of them, even though the patients do not want to be told about things like that, etc. Thereupon one of the couple nudges the other and says: 'You see! I told you all along it would make me ill.' And the other answers: 'Well, I know, I thought so too; but what is one to do?'

[1897b, 457]

Another task is set to the physician by the aetiology of anxiety neurosis. It consists in inducing the patient to give up all detrimental forms of sexual intercourse and to adopt normal sexual relations. This duty, it will be understood, falls primarily on the patient's trusted physician - his family doctor; and he will do his patient a serious injury if he regards himself as too respectable to intervene in this field.

[1897b, 468]
Since in these instances it is most often a question of a married couple, the physician's efforts at once encounter Malthusian plans for limiting the number of conceptions in marriage. There seems to me no doubt that such proposals are gaining ground more and more among our middle classes. I have come across some couples who have already begun practising methods for preventing conception as soon as they have had their first child, and others whose sexual intercourse was from their wedding-night designed to comply with that purpose. The problem of Malthusianism is far-reaching and complicated, and I have no intention of handling it here in the exhaustive manner which would actually be necessary for the treatment of neuroses. I shall only consider what attitude a physician who recognizes the sexual aetiology of the neuroses had best take up towards the problem. [1897b, 468]

I must now explain how my phantasy of telling Professor N. that the patient we had both examined was only suffering from a neurosis made its way into the dream. Shortly before the end of my working year, I began the treatment of a new patient who quite baffled my powers of diagnosis. The presence of a grave organic disease - perhaps some degeneration of the spinal cord - strongly suggested itself but could not be established. It would have been tempting to diagnose a neurosis (which would have solved every difficulty), if only the patient had not repudiated with so much energy the sexual history without which I refuse to recognize the presence of a neurosis. In my embarrassment I sought help from the physician whom I, like many other people, respect more than any as a man and before whose authority I am readiest to bow. He listened to my doubts, told me they were justified, and then gave his opinion: 'Keep the man under observation; it must be a neurosis.' Since I knew he did not share my views on the aetiology of the neuroses, I did not produce my counter-argument, but I made no concealment of my scepticism. A few days later I informed the patient that I could do nothing for him and recommended him to seek other advice. Whereupon, to my intense astonishment, he started apologizing for having lied to me. He had been too much ashamed of himself, he said, and went on to reveal precisely the piece of sexual aetiology which I had been expecting and without which I had been unable to accept his illness as a neurosis. I was relieved but at the same time humiliated. I had to admit that my consultant, not being led astray by considering the anamnesis, had seen more clearly than I had. And I proposed to tell him as much when I next met him - to tell him that he had been right and I wrong. [1900a, 773]
Even if I ignore the ill-will of narrow-minded critics such as these, the presentation of my case histories remains a problem which is hard for me to solve. The difficulties are partly of a technical kind, but are partly due to the nature of the circumstances themselves. If it is true that the causes of hysterical disorders are to be found in the intimacies of the patients’ psychosexual life, and that hysterical symptoms are the expression of their most secret and repressed wishes, then the complete elucidation of a case of hysteria is bound to involve the revelation of those intimacies and the betrayal of those secrets. It is certain that the patients would never have spoken if it had occurred to them that their admissions might possibly be put to scientific uses; and it is equally certain that to ask them themselves for leave to publish their case would be quite availing. In such circumstances persons of delicacy, as well as those who were merely timid, would give first place to the duty of medical discretion and would declare with regret that the matter was one upon which they could offer science no enlightenment. But in my opinion the physician has taken upon himself duties not only towards the individual patient but towards science as well; and his duties towards science mean ultimately nothing else than his duties towards the many other patients who are suffering or will some day suffer from the same disorder. Thus it becomes the physician's duty to publish what he believes he knows of the causes and structure of hysteria, and it becomes a disgraceful piece of cowardice on his part to neglect doing so, as long as he can avoid causing direct personal injury to the single patient concerned. I think I have taken every precaution to prevent my patient from suffering any such injury. I have picked out a person the scenes of whose life were laid not in Vienna but in a remote provincial town, and whose personal circumstances must therefore be practically unknown in Vienna. I have from the very beginning kept the fact of her being under my treatment such a careful secret that only one other physician - and one in whose discretion I have complete confidence - can be aware that the girl was a patient of mine. I have waited for four whole years since the end of the treatment and have postponed publication till hearing that a change has taken place in the patient's life of such a character as allows me to suppose that her own interest in the occurrences and psychological events which are to be related here may now have grown faint. Needless to say, I have allowed no name to stand which could put a non-medical reader upon the scent; and the publication of the case in a purely scientific, and technical periodical should, further, afford a guarantee against unauthorized readers of this sort. I naturally cannot prevent the patient herself from being pained if her own case history should accidentally fall into her hands. But she will learn nothing from it that she does not already know; and she may ask herself who besides her could discover from it that she is the subject of this paper.

Now in this case history - the only one which I have hitherto succeeded in forcing through the limitations imposed by medical discretion and unfavourable circumstances - sexual questions will be discussed with all possible frankness, the organs and functions of sexual life will be called by their proper names, and the pure-minded reader can convince himself from my description that I have not hesitated to converse upon such subjects in such language even with a young woman. Am I then, to defend myself upon this score as well? I will simply claim for myself the rights of the gynaecologist - or rather, much more modest ones - and add that it would be the mark of a singular and perverse prurience to suppose that conversations of this kind are a good means of exciting or of gratifying sexual desire. For the rest, I feel inclined to express my opinion on this subject in a few borrowed words:

[1905e, 1351]

[1905e, 1352]
This short piece of the analysis may perhaps have excited in the medical reader - apart from the scepticism to which he is entitled - feelings of astonishment and horror; and I am prepared at this point to look into these two reactions so as to discover whether they are justifiable. The astonishment is probably caused by my daring to talk about such delicate and unpleasant subjects to a young girl - or, for that matter, to any woman who is sexually active. The horror is aroused, no doubt, by the possibility that an inexperienced girl could know about practices of such a kind and could occupy her imagination with them. I would advise recourse to moderation and reasonableness upon both points. There is no cause for indignation either in the one case or in the other. It is possible for a man to talk to girls and women upon sexual matters of every kind without doing them harm and without bringing suspicion upon himself, so long as, in the first place, he adopts a particular way of doing it, and, in the second place, can make them feel convinced that it is unavoidable. A gynaecologist, after all, under the same conditions, does not hesitate to make them submit to uncovering every possible part of their body. The best way of speaking about such things is to be dry and direct; and that is at the same time the method furthest removed from the prurience with which the same subjects are handled in 'society', and to which girls and women alike are so thoroughly accustomed. I call bodily organs and processes by their technical names, and I tell these to the patient if they - the names, I mean - happen to be unknown to her. J'appelle un chat un chat. I have certainly heard of some people - doctors and laymen - who are scandalized by a therapeutic method in which conversations of this sort occur, and who appear to envy either me or my patients the titillation which, according to their notions, such a method must afford. But I am too well acquainted with the respectability of these gentry to excite myself over them. I shall avoid the temptation of writing a satire upon them. But there is one thing that I will mention: often, after I have for some time treated a patient who had not at first found it easy to be open about sexual matters, I have had the satisfaction of hearing her exclaim: 'Why, after all, your treatment is far more respectable than Mr. X.'s conversation!'

[1905e, 1385]

No one can undertake the treatment of a case of hysteria until he is convinced of the impossibility of avoiding the mention of sexual subjects, or unless he is prepared to allow himself to be convinced by experience. The right attitude is: 'pour faire une omelette il faut casser des œufs.' The patients themselves are easy to convince; and there are only too many opportunities of doing so in the course of the treatment. There is no necessity for feeling any compunction at discussing the facts of normal or abnormal sexual life with them. With the exercise of a little caution all that is done is to translate into conscious ideas what was already known in the unconscious; and, after all, the whole effectiveness of the treatment is based upon our knowledge that the affect attached to an unconscious idea operates more strongly and, since it cannot be inhibited, more injuriously than the affect attached to a conscious one. There is never any danger of corrupting an inexperienced girl. For where there is no knowledge of sexual processes even in the unconscious, no hysterical symptom will arise; and where hysteria is found there can no longer be any question of 'innocence of mind' in the sense in which parents and educators use the phrase. With children of ten, of twelve, or of fourteen, with boys and girls alike, I have satisfied myself that the truth of this statement can invariably be relied upon.

[1905e, 1386]
As regards the second kind of emotional reaction, which is not directed against me this time, but against my patient - supposing that my view of her is correct - and which regards the perverse nature of her phantasies as horrible, I should like to say emphatically that a medical man has no business to indulge in such passionate condemnation. I may also remark in passing that it seems to me superfluous for a physician who is writing upon the aberrations of the sexual instincts to seize every opportunity of inserting into the text expressions of his personal repugnance at such revolting things. We are faced by a fact; and it is to be hoped that we shall grow accustomed to it, when we have put our own tastes on one side. We must learn to speak without indignation of what we call the sexual perversions - instances in which the sexual function has extended its limits in respect either to the part of the body concerned or to the sexual object chosen. The uncertainty in regard to the boundaries of what is to be called normal sexual life, when we take different races and different epochs into account, should in itself be enough to cool the zealot's ardour. We surely ought not to forget that the perversion which is the most repellant to us, the sensual love of a man for a man, was not only tolerated by a people so far our superiors in cultivation as were the Greeks, but was actually entrusted by them with important social functions. The sexual life of each one of us extends to a slight degree - now in this direction, now in that - beyond the narrow lines imposed as the standard of normality. The perversions are neither bestial nor degenerate in the emotional sense of the word. They are a development of germs all of which are contained in the undifferentiated sexual disposition of the child, and which, by being suppressed or by being diverted to higher, asexual aims - by being 'sublimated' - are destined to provide the energy for a great number of our cultural achievements. When, therefore, any one has become a gross and manifest pervert, it would be more correct to say that he has remained one, for he exhibits a certain stage of inhibited development. All psychoneurotics are persons with strongly marked perverse tendencies, which have been repressed in the course of their development and have become unconscious. Consequently their unconscious phantasies show precisely the same content as the documentarily recorded actions of perverts - even though they have not read Krafft-Ebing's *Psychopathia Sexualis*, to which simple-minded people attribute such a large share of the responsibility for the production of perverse tendencies. Psychoneuroses are, so to speak, the negative of perversions. In neurotics their sexual constitution, under which the effects of heredity are included, operates in combination with any accidental influences in their life which may disturb the development of normal sexuality. A stream of water which meets with an obstacle in the river-bed is dammed up and flows back into old channels which had formerly seemed fated to run dry. The motive forces leading to the formation of hysterical symptoms draw their strength not only from repressed normal sexuality but also from unconscious perverse activities.¹

[1905e, 1387]
For this reason it not uncommonly happens that obsessional neurotics, who are troubled with self-reproaches but have connected their affects with the wrong causes, will also tell the physician the true causes, without any suspicion that their self-reproaches have simply become detached from them. In relating such an incident they will sometimes add with astonishment or even with an air of pride: ‘But I think nothing of that.’ This happened in the first case of obsessional neurosis which gave me an insight many years ago into the nature of the malady. The patient, who was a government official, was troubled by innumerable scruples. He was the man whose compulsive act in connection with the branch in the park at Schönbrunn I have already described. I was struck by the fact that the florin notes with which he paid his consultation fees were invariably clean and smooth. (This was before we had a silver coinage in Austria.) I once remarked to him that one could always tell a government official by the brand-new florins that he drew from the State treasury, and he then informed me that his florins were by no means new, but that he had them ironed out at home. It was a matter of conscience with him, he explained, not to hand any one dirty paper florins; for they harboured all sorts of dangerous bacteria and might do some harm to the recipient. At that time I already had a vague suspicion of the connection between neuroses and sexual life, so on another occasion I ventured to ask the patient how he stood in regard to that matter. ‘Oh, that's quite all right,’ he answered airily, ’I'm not at all badly off in that respect. I play the part of a dear old uncle in a number of respectable families, and now and then I make use of my position to invite some young girl to go out with me for a day's excursion in the country. Then I arrange that we shall miss the train home and be obliged to spend the night out of town. I always engage two rooms - I do things most handsomely; but when the girl has gone to bed I go in to her and masturbate her with my fingers.’ - ’But aren't you afraid of doing her some harm, fiddling about in her genitals with your dirty hand?’ - At this he flared up: ’Harm? Why, what harm should it do her? It hasn't done a single one of them any harm yet, and they've all of them enjoyed it. Some of them are married now, and it hasn't done them any harm at all.’ - He took my remonstrance in very bad part, and never appeared again. But I could only account for the contrast between his fastidiousness with the paper florins and his unscrupulousness in abusing the girls entrusted to him by supposing that the self-reproachful affect had become displaced. The aim of this displacement was obvious enough: if his self-reproaches had been allowed to remain where they belonged he would have had to abandon a form of sexual gratification to which he was probably impelled by some powerful infantile determinants. The displacement therefore ensured his deriving a considerable advantage from his illness.

[1909d, 2155]

Few details are known about the sexual behaviour of the great artist and scientist, but we may place confidence in the probability that the assertions of his contemporaries were not grossly erroneous. In the light of these traditions, then, he appears as a man whose sexual need and activity were exceptionally reduced, as if a higher aspiration had raised him above the common animal need of mankind. It may remain open to doubt whether he ever sought direct sexual satisfaction - and if so, in what manner - or whether he was able to dispense with it altogether. We are however justified in looking in him too for the emotional currents which drive other men imperatively on to perform the sexual act; for we cannot imagine the mental life of any human being in the formation of which sexual desire in the broadest sense - libido - did not have its share, even if that desire has departed far from its original aim, or has refrained from putting itself into effect.

[1910c, 2275]
We cannot expect to find in Leonardo anything more than traces of untransformed sexual inclination. But these point in one direction and moreover allow him to be reckoned as a homosexual. It has always been emphasized that he took only strikingly handsome boys and youths as pupils. He treated them with kindness and consideration, looked after them, and when they were ill nursed them himself, just as a mother nurses her children and just as his own mother might have tended him. As he had chosen them for their beauty and not for their talent, none of them - Cesare da Sesto, Boltraffio, Andrea Salaino, Francesco Melzi and others - became a painter of importance. Generally they were unable to make themselves independent of their master, and after his death they disappeared without having left any definite mark on the history of art. The others, whose works entitled them to be called his pupils, like Luini and Bazi, called Sodoma, he probably did not know personally.

Hitherto, this authority, with its enormous weight of suggestion, has been against us. All our therapeutic successes have been achieved in the face of this suggestion: it is surprising that any successes at all could be gained in such circumstances. I must not let myself be led into describing my agreeable experiences during the period when I alone represented psycho-analysis. I can only say that when I assured my patients that I knew how to relieve them permanently of their sufferings they looked round my modest abode, reflected on my lack of fame and title, and regarded me like the possessor of an infallible system at a gambling-resort, of whom people say that if he could do what he professes he would look very different himself. Nor was it really pleasant to carry out a psychical operation while the colleagues whose duty it should have been to assist took particular pleasure in spitting into the field of operation, and while at the first signs of blood or restlessness in the patient his relatives began threatening the operating surgeon. An operation is surely entitled to produce reactions; in surgery we became accustomed to that long ago. People simply did not believe me, just as even to-day people do not much believe any of us. Under such conditions not a few attempts were bound to fail. To estimate the increase in our therapeutic prospects when we have received general recognition, you should think of the position of a gynaecologist in Turkey and in the West. In Turkey, all he may do is to feel the pulse of all arm stretched out to him through a hole in the wall: and his medical achievements are in proportion to the inaccessibility of their object. Our opponents in the West wish to allow us much the same degree of access to our patient's minds. But now that the force of social suggestion drives sick women to the gynaecologist, he has become their helper and saviour. I trust you will not say that the fact of the authority of society coming to our aid and increasing our successes so greatly would do nothing to prove the validity of our hypotheses - arguing as you might that, since suggestion is supposed to be able to do anything, our successes would then be successes of suggestion and not of psycho-analysis. Social suggestion is at present favourable to treating nervous patients by hydropathy, dieting and electro-therapy, but that does not enable such measures to get the better of neuroses. Time will show whether psycho-analytic treatment can accomplish more.

This surprising sexualization of the state of heavenly bliss suggests the possibility that Schreber's concept of the state of bliss is derived from a condensation of the two principal meanings of the German word 'selig' - namely, 'dead' and 'sensually happy'.¹ But this instance of sexualization will also give us occasion to examine the patient's general attitude to the erotic side of life and to questions of sexual indulgence. For we psycho-analysts have hitherto supported the view that the roots of every nervous and mental disorder are chiefly to be found in the patient's sexual life - some of us merely upon empirical grounds, others influenced in addition by theoretical considerations.
And one thing more. Were you not struck by the way in which this unobtrusive obsessional action has led us into the intimacies of the patient's life? A woman cannot have anything much more intimate to tell than the story of her wedding-night. Is it a matter of chance and of no further significance that we have arrived precisely at the intimacies of sexual life? No doubt it might be the result of the choice I have made on this occasion. Do not let us be too hasty in forming our judgement, and let us turn to my second example, which is of quite a different kind - a sample of a very common species, a sleep-ceremonial.

[1916-1917, 3344]

More could be made, too, of the analysis of this ceremonial if it could be properly linked up with the patient's other symptoms. But our path does not lead in that direction. You must be content with a hint that the girl was in the grip of an erotic attachment to her father whose beginnings went back to her childhood. Perhaps that was why she behaved in such an unfriendly way to her mother. Nor can we overlook the fact that the analysis of this symptom has once again taken us back to a patient's sexual life. We shall perhaps be less surprised at this the more often we gain an insight into the sense and intention of neurotic symptoms.

[1916-1917, 3348]

You will recollect that, in the two cases whose symptoms we submitted to a detailed investigation, the analysis initiated us into these patients' most intimate sexual life. In the first case we further recognized with particular clarity the intention or purpose of the symptom we were examining; in the second case this was perhaps somewhat concealed by a factor which will be mentioned later. Well, every other case that we submit to analysis would show us the same thing that we have found in these two examples. In every instance we should be introduced by the analysis into the patient's sexual experiences and wishes; and in every instance we should be bound to see that the symptoms served the same intention. We find that this intention is the satisfaction of sexual wishes; the symptoms serve for the patients' sexual satisfaction; they are a substitute for satisfaction of this kind, which the patients are without in their lives.

[1916-1917, 3371]
But I still owe you further enlightenment, Gentlemen, on my reasons for not starting my account of the theory of the neuroses with the common neurotic state. You may perhaps suppose that it was because in that case I should have had greater difficulty in proving the sexual causation of the neuroses. But you would be wrong there. In the case of the transference neuroses one must work one's way through the interpretation of symptoms before one can arrive at that discovery. In the common forms of what are known as the 'actual neuroses' the aetiological significance of sexual life is a crude fact that springs to the observer's eyes. I came upon it more than twenty years ago when one day I asked myself the question of why in the examination of neurotics their sexual activities were so regularly excluded from consideration. At that time I sacrificed my popularity with my patients for the sake of these enquiries; but after only a brief effort I was able to declare that 'if the vita sexualis is normal, there can be no neurosis' - and by this I meant no 'actual neurosis'. No doubt this statement passes too lightly over people's individual differences; it suffers, too, from the indefiniteness inseparable from the judgement of what is 'normal'. But as a rough guide it retains its value to this day. I had by then reached the point of establishing specific relations between particular forms of neurosis and particular sexual noxae; and I have no doubt that I could repeat the same observations to-day if similar pathological material were still at my disposal. I found often enough that a man who indulged in a certain kind of incomplete sexual satisfaction (for instance, manual masturbation) had fallen ill of a particular form of 'actual neurosis', and that this neurosis promptly gave place to another if he replaced this sexual régime by another equally far from being irreproachable. I was then in a position to infer the change in a patient's sexual mode of life from an alteration in his condition. I also learnt then to stand obstinately by my suspicions till I had overcome the patients' disingenuousness and compelled them to confirm my views. It is true that thereafter they preferred to go to other doctors who did not make such keen enquiries about their sexual life.

[1916-1917, 3438]

'Well, it is generally reported that in analyses the most intimate - and the nastiest - events in sexual life come up for discussion in every detail. If that is so - I have not been able to gather from your psychological discussions that it is necessarily so - it would be a strong argument in favour of restricting these treatments to doctors. How could one dream of allowing such dangerous liberties to people of whose discretion one was not sure and of whose character one had no guarantee?'

[1926e, 4349]

It is true that doctors enjoy certain privileges in the sphere of sex: they are even allowed to inspect people's genitals - though they were not allowed to in the East and though some idealistic reformers (you know whom I have in mind) have disputed this privilege. But you want to know in the first place whether it is so in analysis and why it must be so. - Yes, it is so.

[1926e, 4349]
And it must be so, firstly, because analysis is entirely founded on complete candour. Financial circumstances, for instance, are discussed with equal detail and openness: things are said that are kept back from every fellow-citizen, even if he is not a competitor or a tax-collector. I will not dispute - indeed, I will myself insist with energy - that this obligation to candour puts a grave moral responsibility on the analyst as well. And it must be so, secondly, because factors from sexual life play an extremely important, a dominating, perhaps even a specific part among the causes and precipitating factors of neurotic illnesses. What else can analysis do but keep close to its subject-matter, to the material brought up by the patient? The analyst never entices his patient on to the ground of sex. He does not say to him in advance: 'We shall be dealing with the intimacies of your sexual life!' He allows him to begin what he has to say whenever he pleases, and quietly waits until the patient himself touches on sexual things. I used always to warn my pupils: 'Our opponents have told us that we shall come upon cases in which the factor of sex plays no part. Let us be careful not to introduce it into our analyses and so spoil our chances of finding such a case.' But so far none of us has had that good fortune.

[1926e, 4350]
But she gave me no more definite answer. She smiled in an embarrassed way, as though she
had been found out, like someone who is obliged to admit that a fundamental position has been
reached where there is not much more to be said. I could imagine what the tactile sensation
was which she had later learnt to interpret. Her facial expression seemed to me to be saying
that she supposed that I was right in my conjecture. But I could not penetrate further, and in any
case I owed her a debt of gratitude for having made it so much easier for me to talk to her than
to the prudish ladies of my city practice, who regard whatever is natural as shameful.

[1895d, 118]

In certain other circumstances, such as when one is dealing with young girls, who, after all,
are systematically brought up to conceal their sexual life, one will have to be content with a very
small measure of sincere response on the part of the patient. But an important consideration
comes into play here namely that a doctor who is experienced in these things does not meet his
patients unprepared and as a rule does not have to ask them for information but only for a
confirmation of his surmises. Anyone who will follow my indications as to how to elucidate the
morphology of the neuroses and translate it into aetiological terms, will need the addition of very
few further admissions from his patients; in the very description of their symptoms, which they
are only too ready to give, they have usually acquainted him at the same time with the sexual
factors that are hidden behind.

[1897b, 458]

Originally my theory related only to the clinical pictures comprised under the term
'neurasthenia', among which I was particularly struck by two, which occasionally appear as pure
types and which I described as 'neurasthenia proper' and 'anxiety neurosis'. It had, to be sure,
always been a matter of common knowledge that sexual factors may play a part in the
causation of these forms of illness; but those factors were not regarded as invariably operative,
nor was there any idea of giving them precedence over other aetiological influences. I was
surprised to begin with at the frequency of gross disturbances in the vita sexualis of nervous
patients; the more I set about looking for such disturbances - bearing in mind the fact that
everyone hides the truth in matters of sex - and the more skilful I became at pursuing my
enquiries in the face of a preliminary denial, the more regularly was I able to discover
pathogenic factors in sexual life, till little seemed to stand in the way of my assuming their
universal occurrence. It was necessary, however, to presuppose from the start that sexual
irregularities occurred with similar frequency in our ordinary society under the pressure of social
conditions; and a doubt might remain as to the degree of deviation from normal sexual
functioning which should be regarded as pathogenic. I was therefore obliged to attach less
importance to the inviable evidence of sexual noxae than to a second discovery which
seemed to me less ambiguous. It emerged that the form taken by the illness - neurasthenia or
anxiety neurosis - bore a constant relation to the nature of the sexual noxa involved. In typical
cases of neurasthenia a history of regular masturbation or persistent emissions was found; in
anxiety neurosis factors appeared such as coitus interruptus, 'unconsummated excitation', and
other conditions - in all of which there seemed to be the common element of an insufficient
discharge of the libido that had been produced. It was only after this discovery, which was easy
to make and could be confirmed as often as one liked, that I had the courage to claim a
preferential position for sexual influences in the aetiology of the neuroses. Furthermore, in the
mixed forms of neurasthenia and anxiety neurosis which are so common it was possible to trace
a combination of the aetiologies which I had assumed for the two pure forms. Moreover, this
twofold form assumed by the neurosis seemed to tally with the polar (i.e. the masculine and
feminine) character of sexuality.

[1906a, 1575]
A conviction of the correctness of this thesis was not precisely made easier by the behaviour of patients. Instead of willingly presenting us with information about their sexual life, they try to conceal it by every means in their power. People are in general not candid over sexual matters. They do not show their sexuality freely, but to conceal it they wear a heavy overcoat woven of a tissue of lies, as though the weather were bad in the world of sexuality. Nor are they mistaken. It is a fact that sun and wind are not favourable to sexual activity in this civilized world of ours; none of us can reveal his erotism freely to others. But when your patients discover that they can feel quite easy about it while they are under your treatment, they discard this veil of lies, and only then are you in a position to form a judgement on this debatable question. Unluckily even doctors are not preferred above other human creatures in their personal relation to questions of sexual life, and many of them are under the spell of the combination of prudery and prurience which governs the attitude of most ‘civilized people’ in matters of sexuality.

[1910a, 2227]

People will not reach a proper understanding of the activities of children's sexuality and will probably take refuge in declaring that what has been said here is incredible, so long as they cling to the attitude taken up by our civilization of depreciating the genitals and the sexual functions. To understand the mental life of children we require analogies from primitive times. Through a long series of generations the genitals have been for us the 'pudenda', objects of shame, and even (as a result of further successful sexual repression) of disgust. If one makes a broad survey of the sexual life of our time and in particular of the classes who sustain human civilization, one is tempted to declare that it is only with reluctance that the majority of those alive to-day obey the command to propagate their kind; they feel that their dignity as human beings suffers and is degraded in the process. What is to be found among us in the way of another view of sexual life is confined to the uncultivated lower strata of society; among the higher and more refined classes it is concealed, since it is considered culturally inferior, and it ventures to put itself into practice only in the face of a bad conscience. In the primaeval days of the human race it was a different story. The laborious compilations of the student of civilization provide convincing evidence that originally the genitals were the pride and hope of living beings; they were worshipped as gods and transmitted the divine nature of their functions to all newly learned human activities. As a result of the sublimation of their basic nature there arose innumerable divinities; and at the time when the connection between official religions and sexual activity was already hidden from the general consciousness, secret cults devoted themselves to keeping it alive among a number of initiates. In the course of cultural development so much of the divine and sacred was ultimately extracted from sexuality that the exhausted remnant fell into contempt. But in view of the indelibility that is characteristic of all mental traces, it is surely not surprising that even the most primitive forms of genital-worship can be shown to have existed in very recent times and that the language, customs and superstitions of mankind to-day contain survivals from every phase of this process of development.²

[1910c, 2271]
The critical remarks I referred to are concerned with two points. Firstly, it is a pity that in these reports a more careful distinction is not made between simple rupture of the hymen without intercourse, and intercourse for the purpose of effecting this rupture. There is only one passage in which we are told expressly that the procedure falls into two actions: defloration (carried out by hand or with some instrument) and the act of intercourse which follows it. The material in Ploss and Bartels (1891), in other respects so rich, is almost useless for our purpose, because in their presentation of it the psychological importance of the act of defloration is completely displaced in favour of its anatomical results. Secondly, we should be glad to be informed how the 'ceremonial' (purely formal, ritual, or official) coitus, which takes place on these occasions, differs from ordinary sexual intercourse. The authors to whom I have had access either have been too embarrassed to discuss the matter or have once again underestimated the psychological importance of such sexual details. It is to be hoped that the first-hand accounts of travellers and missionaries may be more complete and less ambiguous, but since this literature, which is for the most part foreign, is for the time being inaccessible I cannot say anything definite on the subject. Besides, we may get round the problem arising over this second point if we bear in mind the fact that a ceremonial mock-coitus would after all only represent a substitute for, and perhaps replace altogether, an act that in earlier times would have been carried out completely.¹

[1918a, 2352]

Since this is the first time I have spoken of the subject-matter of sexual life in one of these lectures, I owe you some account of the way in which I propose to treat the topic. Psychoanalysis finds no occasion for concealments and hints, it does not think it necessary to be ashamed of dealing with this important material, it believes it is right and proper to call everything by its correct name, and it hopes that this will be the best way of keeping irrelevant thoughts of a disturbing kind at a distance. The fact that these lectures are being given before a mixed audience of both sexes can make no difference to this. Just as there can be no science in usum Delphini, there can be none for schoolgirls; and the ladies among you have made it clear by their presence in this lecture-room that they wish to be treated on an equality with men. [1916-1917, 3248]
But I still owe you further enlightenment, Gentlemen, on my reasons for not starting my account of the theory of the neuroses with the common neurotic state. You may perhaps suppose that it was because in that case I should have had greater difficulty in proving the sexual causation of the neuroses. But you would be wrong there. In the case of the transference neuroses one must work one's way through the interpretation of symptoms before one can arrive at that discovery. In the common forms of what are known as the 'actual neuroses' the aetiological significance of sexual life is a crude fact that springs to the observer's eyes. I came upon it more than twenty years ago when one day I asked myself the question of why in the examination of neurotics their sexual activities were so regularly excluded from consideration. At that time I sacrificed my popularity with my patients for the sake of these enquiries; but after only a brief effort I was able to declare that 'if the *vita sexualis* is normal, there can be no neurosis' - and by this I meant no 'actual neurosis'. No doubt this statement passes too lightly over people's individual differences; it suffers, too, from the indefiniteness inseparable from the judgement of what is 'normal'. But as a rough guide it retains its value to this day. I had by then reached the point of establishing specific relations between particular forms of neurosis and particular sexual noxae; and I have no doubt that I could repeat the same observations to-day if similar pathological material were still at my disposal. I found often enough that a man who indulged in a certain kind of incomplete sexual satisfaction (for instance, manual masturbation) had fallen ill of a particular form of 'actual neurosis', and that this neurosis promptly gave place to another if he replaced this sexual régime by another equally far from being irreproachable. I was then in a position to infer the change in a patient's sexual mode of life from an alteration in his condition. I also learnt then to stand obstinately by my suspicions till I had overcome the patients' disingenuousness and compelled them to confirm my views. It is true that thereafter they preferred to go to other doctors who did not make such keen enquiries about their sexual life.

[1916-1917, 3438]
I must also refrain from any detailed analysis of the two remaining episodes of the dream. I will merely pick out the elements leading to the two childhood scenes on whose account alone I embarked upon a discussion of this dream. It will rightly be suspected that what compels me to make this suppression is sexual material; but there is no need to rest content with this explanation. After all, there are many things which one has to keep secret from other people but of which one makes no secret to oneself; and the question here is not as to why I am obliged to conceal the solution but as to the motives for the *internal* censorship which hid the true content of the dream from myself. I must therefore explain that the analysis of these three episodes of the dream showed that they were impertinent boastings, the issue of an absurd megalomania which had long been suppressed in my waking life and a few of whose ramifications had even made their way into the dream's manifest content (e. g. *I felt I was being very cunning*), and which incidentally accounted for my exuberant spirits during the evening before I had the dream. The boasting extended to all spheres; for instance, the mention of Graz went back to the slang phrase 'What's the price of Graz?', which expresses the self-satisfaction of a person who feels extremely well-off. The first episode of the dream may also be included among the boastings by anyone who will bear in mind the great Rabelais' incomparable account of the life and deeds of Gargantua and his son Pantagruel.

[1900a, 696]

The field I have in mind is indeed very different from yours. I am referring to the therapy employed for certain 'nervous diseases' - what are known as the psychoneuroses - of which hysteria and obsessional ideas may be taken as samples. The method is called 'psychoanalysis'; it was evolved by me from the 'cathartic' method of therapy first practised by Josef Breuer in Vienna.¹ To combat your surprise, I must draw an analogy between the criminal and the hysteric. In both we are concerned with a secret, with something hidden. But in order not to be paradoxical I must at once point out the difference. In the case of the criminal it is a secret which he knows and hides from you, whereas in the case of the hysteric it is a secret which he himself does not know either, which is hidden even from himself. How is this possible? Now we know, through laborious research, that all these illnesses are the result of the patient's having succeeded in repressing certain ideas and memories that are strongly cathected with affect, together with the wishes that arise from them, in such a way that they play no part in his thinking - do not enter into his consciousness - and thus remain unknown to him. But from this repressed psychical material (these 'complexes') are generated the somatic and psychical symptoms which plague the patient in just the same way as a guilty conscience does. In this one respect, therefore, the difference between the criminal and the hysteric is fundamental.

[1906c, 1892]
Some preparation must of course be given to him; and there is a simple way of doing it. We call on him to be completely straightforward with his analyst, to keep nothing back intentionally that comes into his head, and then to put aside every reservation that might prevent his reporting certain thoughts or memories. Everyone is aware that there are some things in himself that he would be very unwilling to tell other people or that he considers it altogether out of the question to tell. These are his 'intimacies'. He has a notion too - and this represents a great advance in psychological self-knowledge - that there are other things that one would not care to admit to oneself: things that one likes to conceal from oneself and which for that reason one breaks off short and drives out of one's thoughts if, in spite of everything, they turn up. Perhaps he may himself notice that a very remarkable psychological problem begins to appear in this situation - of a thought of his own being kept secret from his own self. It looks as though his own self were no longer the unity which he had always considered it to be, as though there were something else as well in him that could confront that self. He may become obscurely aware of a contrast between a self and a mental life in the wider sense. If now he accepts the demand made by analysis that he shall say everything, he will easily become accessible to an expectation that to have relations and exchanges of thought with someone under such unusual conditions might also lead to peculiar results.

[1926e, 4331]

We must reply: 'Yes and no!' Confession no doubt plays a part in analysis - as an introduction to it, we might say. But it is very far from constituting the essence of analysis or from explaining its effects. In Confession the sinner tells what he knows; in analysis the neurotic has to tell more. Nor have we heard that Confession has ever developed enough power to get rid of actual pathological symptoms.

[1926e, 4332]

'Then, after all, I do not understand,' comes the rejoinder. 'What can you possibly mean by "telling more than he knows"? But I can well believe that as an analyst you gain a stronger influence over your patients than a Father Confessor over his penitents, since your contacts with him are so much longer, more intensive and also more individual, and since you use this increased influence to divert him from his sick thoughts, to talk him out of his fears, and so on. It would certainly be strange if it were possible by such means to control purely physical phenomena as well, such as vomiting, diarrhoea, convulsions; but I know that influence like that is in fact quite possible if a person is put into a state of hypnosis. By the trouble you take with the patient you probably succeed in bringing about a hypnotic relation of that sort with him - a suggestive attachment to yourself - even though you may not intend to; and in that case the miraculous results of your treatment are the effect of hypnotic suggestion. But, so far as I know, hypnotic treatment works much faster than your analysis, which, as you tell me, lasts for months and years.'

[1926e, 4332]
There is another kind of incompleteness which I myself have intentionally introduced. I have as a rule not reproduced the process of interpretation to which the patient's associations and communications had to be subjected, but only the results of that process. Apart from the dreams, therefore, the technique of the analytic work has been revealed in only a very few places. My object in this case history was to demonstrate the intimate structure of a neurotic disorder and the determination of its symptoms; and it would have led to nothing but hopeless confusion if I had tried to complete the other task at the same time. Before the technical rules, most of which have been arrived at empirically, could be properly laid down, it would be necessary to collect material from the histories of a large number of treatments. Nevertheless, the degree of shortening produced by the omission of the technique is not to be exaggerated in this particular case. Precisely that portion of the technical work which is the most difficult never came into question with the patient; for the factor of 'transference', which is considered at the end of the case history, did not come up for discussion during the short treatment.

¹ At this point his father in his perplexity was trying to practise the classical technique of psycho-analysis. This did not lead to much; but the result, such as it was, can be given a meaning in the light of later disclosures.

Nevertheless, the situation was decidedly obscure. The analysis was making little progress; and I am afraid the reader will soon begin to find this description of it tedious. Every analysis, however, has dark periods of this kind. But Hans was now on the point of leading us into an unexpected region.
Therapeutic success, however, is not our primary aim; we endeavour rather to enable the patient to obtain a conscious grasp of his unconscious wishes. And this we can achieve by working upon the basis of the hints he throws out, and so, with the help of our interpretative technique, presenting the unconscious complex to his consciousness in our own words. There will be a certain degree of similarity between that which he hears from us and that which he is looking for, and which, in spite of all resistances, is trying to force its way through to consciousness; and it is this similarity that will enable him to discover the unconscious material.

The physician is a step in front of him in knowledge; and the patient follows along his own road, until the two meet at the appointed goal. Beginners in psycho-analysis are apt to assimilate these two events, and to suppose that the moment at which one of the patient's unconscious complexes has become known to them is also the moment at which the patient himself recognizes it. They are expecting too much when they think that they will cure the patient by informing him of this piece of knowledge; for he can do no more with the information than make use of it to help himself in discovering the unconscious complex where it is anchored in his unconscious. A first success of this sort had now been achieved with Hans. Having partly mastered his castration complex, he was now able to communicate his wishes in regard to his mother. He did so, in what was still a distorted form, by means of the phantasy of the two giraffes, one of which was calling out in vain because Hans had taken possession of the other. He represented the 'taking possession of' pictorially as 'sitting down on'. His father recognized the phantasy as a reproduction of a bedroom scene which used to take place in the morning between the boy and his parents; and he quickly stripped the underlying wish of the disguise which it still wore. The boy's father and mother were the two giraffes. The reason for the choice of a giraffe-phantasy for the purposes of disguise was fully explained by a visit that the boy had paid to those same large beasts at Schönbrunn a few days earlier, by the giraffe-drawing, belonging to an earlier period, which had been preserved by his father, and also, perhaps, by an unconscious comparison based upon the giraffe's long, stiff neck.¹ It may be remarked that the giraffe, as being a large animal and interesting on account of its widdler, was a possible competitor with the horse for the role of bugbear; moreover, the fact that both his father and his mother appeared as giraffes offered a hint which had not yet been followed up, as regards the interpretation of the anxiety-horses.

¹[1909b, 2103]

I hope you will have formed an impression that, when we know all that we now only suspect and when we have carried out all the improvements in technique to which deeper observation of our patients is bound to lead us, our medical procedure will reach a degree of precision and certainty of success which is not to be found in every specialized field of medicine.

¹[1910d, 2310]

This brings us to the technical errors which are to be seen in the doctor's procedure in this alleged case. It is a long superseded idea, and one derived from superficial appearances, that the patient suffers from a sort of ignorance, and that if one removes this ignorance by giving him information (about the causal connection of his illness with his life, about his experiences in childhood, and so on) he is bound to recover. The pathological factor is not his ignorance in itself, but the root of this ignorance in his inner resistances; it was they that first called this ignorance into being, and they still maintain it now. The task of the treatment lies in combating these resistances. Informing the patient of what he does not know because he has repressed it is only one of the necessary preliminaries to the treatment. If knowledge about the unconscious were as important for the patient as people inexperienced in psycho-analysis imagine, listening to lectures or reading books would be enough to cure him. Such measures, however, have as much influence on the symptoms of nervous illness as a distribution of menu-cards in a time of famine has upon hunger. The analogy goes even further than its immediate application; for informing the patient of his unconscious regularly results in an intensification of the conflict in him and an exacerbation of his troubles.

¹[1910k, 2378]
The question with which I now intend to deal is not that of the technique of dream-interpretation: neither the methods by which dreams should be interpreted nor the use of such interpretations when made will be considered, but only the way in which the analyst should employ the art of interpretation in the psycho-analytic treatment of patients. There are undoubtedly different ways of going to work in the matter, but then the answer to questions of technique in analysis is never a matter of course. Although there may perhaps be more than one good road to follow, still there are very many bad ones, and a comparison of the various methods cannot fail to be illuminating, even if it should not lead to a decision in favour of any particular one.

[1911e, 2450]

It is now time for us to take a survey of the play of forces which is set in motion by the treatment. The primary motive force in the therapy is the patient's suffering and the wish to be cured that arises from it. The strength of this motive force is subtracted from by various factors - which are not discovered till the analysis is in progress - above all, by what we have called the 'secondary gain from illness'; but it must be maintained till the end of the treatment. Every improvement effects a diminution of it. By itself, however, this motive force is not sufficient to get rid of the illness. Two things are lacking in it for this: it does not know what paths to follow to reach this end; and it does not possess the necessary quota of energy with which to oppose the resistances. The analytic treatment helps to remedy both these deficiencies. It supplies the amounts of energy that are needed for overcoming the resistances by making mobile the energies which lie ready for the transference; and, by giving the patient information at the right time, it shows him the paths along which he should direct those energies. Often enough the transference is able to remove the symptoms of the disease by itself, but only for a while - only for as long as it itself lasts. In this case the treatment is a treatment by suggestion, and not a psycho-analysis at all. It only deserves the latter name if the intensity of the transference has been utilized for the overcoming of resistances. Only then has being ill become impossible, even when the transference has once more been dissolved, which is its destined end.

[1913c, 2494]

The main instrument, however, for curbing the patient's compulsion to repeat and for turning it into a motive for remembering lies in the handling of the transference. We render the compulsion harmless, and indeed useful, by giving it the right to assert itself in a definite field. We admit it into the transference as a playground in which it is allowed to expand in almost complete freedom and in which it is expected to display to us everything in the way of pathogenic instincts that is hidden in the patient's mind. Provided only that the patient shows compliance enough to respect the necessary conditions of the analysis, we regularly succeed in giving all the symptoms of the illness a new transference meaning and in replacing his ordinary neurosis by a 'transference-neurosis' of which he can be cured by the therapeutic work. The transference thus creates an intermediate region between illness and real life through which the transition from the one to the other is made. The new condition has taken over all the features of the illness; but it represents an artificial illness which is at every point accessible to our intervention. It is a piece of real experience, but one which has been made possible by especially favourable conditions, and it is of a provisional nature. From the repetitive reactions which are exhibited in the transference we are led along the familiar paths to the awakening of the memories, which appear without difficulty, as it were, after the resistance has been overcome.

[1914g, 2505]
Our plan of cure is based on these discoveries. The ego is weakened by the internal conflict and we must go to its help. The position is like that in a civil war which has to be decided by the assistance of an ally from outside. The analytic physician and the patient's weakened ego, basing themselves on the real external world, have to band themselves together into a party against the enemies, the instinctual demands of the id and the conscientious demands of the super-ego. We form a pact with each other. The sick ego promises us the most complete candour - promises, that is, to put at our disposal all the material which its self-perception yields it; we assure the patient of the strictest discretion and place at his service our experience in interpreting material that has been influenced by the unconscious. Our knowledge is to make up for his ignorance and to give his ego back its mastery over lost provinces of his mental life. This pact constitutes the analytic situation.

[1940a [1938], 4983]

With the neurotics, then, we make our pact: complete candour on one side and strict discretion on the other. This looks as though we were only aiming at the post of a secular father confessor. But there is a great difference, for what we want to hear from our patient is not only what he knows and conceals from other people; he is to tell us too what he does not know. With this end in view we give him a more detailed definition of what we mean by candour. We pledge him to obey the fundamental rule of analysis, which is henceforward to govern his behaviour towards us. He is to tell us not only what he can say intentionally and willingly, what will give him relief like a confession, but everything else as well that his self-observation yields him, everything that comes into his head, even if it is disagreeable for him to say it, even if it seems to him unimportant or actually nonsensical. If he can succeed after this injunction in putting his self-criticism out of action, he will present us with a mass of material - thoughts, ideas, recollections - which are already subject to the influence of the unconscious, which are often its direct derivatives, and which thus put us in a position to conjecture his repressed unconscious material and to extend, by the information we give him, his ego's knowledge of his unconscious.

[1940a [1938], 4984]

The therapeutic successes that occurred under the sway of the positive transference are open to the suspicion of being of a suggestive nature. If the negative transference gains the upper hand, they are blown away like chaff before the wind. We observe with horror that all our trouble and labour hitherto have been in vain. Indeed, what we might have regarded as a permanent intellectual gain by the patient, his understanding of psycho-analysis and his reliance on its efficacy, suddenly vanish. He behaves like a child who has no power of judgement of his own but blindly believes anyone whom he loves and no one who is a stranger to him. The danger of these states of transference evidently lies in the patient's misunderstanding their nature and taking them for fresh real experiences instead of reflections of the past. If he (or she) becomes aware of the strong erotic desire that lies concealed behind the positive transference, he believes that he has fallen passionately in love; if the transference changes over, then he feels insulted and neglected, he hates the analyst as his enemy and is ready to abandon the analysis. In both these extreme cases he has forgotten the pact that he made at the beginning of the treatment and has become useless for continuing the common work. It is the analyst's task constantly to tear the patient out of his menacing illusion and to show him again and again that what he takes to be new real life is a reflection of the past. And lest he should fall into a state in which he is inaccessible to all evidence, the analyst takes care that neither the love nor the hostility reach an extreme height. This is effected by preparing him in good time for these possibilities and by not overlooking the first signs of them. Careful handling of the transference on these lines is as a rule richly rewarded. If we succeed, as we usually can, in enlightening the patient on the true nature of the phenomena of transference, we shall have struck a powerful weapon out of the hand of his resistance and shall have converted dangers into gains. For a patient never forgets again what he has experienced in the form of transference; it carries a greater force of conviction than anything he can acquire in other ways.

[1940a [1938], 4986]
The overcoming of resistances is the part of our work that requires the most time and the greatest trouble. It is worth while, however, for it brings about an advantageous alteration of the ego which will be maintained independently of the outcome of the transference and will hold good in life. We have also worked simultaneously at getting rid of the alteration of the ego which had been brought about under the influence of the unconscious; for whenever we have been able to detect any of its derivatives in the ego we have pointed out their illegitimate origin and have instigated the ego to reject them. It will be remembered that it was one of the necessary preconditions of our pact of assistance that any such alteration of the ego due to the intrusion of unconscious elements should not have gone beyond a certain amount.

[1940a [1938], 4989]

Concerning the third factor, the alteration of the ego, we have as yet said nothing. When we turn our attention to it, the first impression we receive is that there is much to ask and much to answer here, and that what we have to say about it will prove to be very inadequate. This first impression is confirmed when we go further into the problem. As is well known, the analytic situation consists in our allying ourselves with the ego of the person under treatment, in order to subdue portions of his id which are uncontrolled - that is to say to include them in the synthesis of his ego. The fact that a co-operation of this kind habitually fails in the case of psychotics affords us a first solid footing for our judgement. The ego, if we are to be able to make such a pact with it, must be a normal one. But a normal ego of this sort is, like normality in general, an ideal fiction. The abnormal ego, which is unserviceable for our purposes, is unfortunately no fiction. Every normal person, in fact, is only normal on the average. His ego approximates to that of the psychotic in some part or other and to a greater or lesser extent; and the degree of its remoteness from one end of the series and of its proximity to the other will furnish us with a provisional measure of what we have so indefinitely termed an 'alteration of the ego'.

[1937c, 5030]
(a) Advances in our knowledge. We are, of course, still a long way from knowing all that is required for an understanding of the unconscious in our patients. It is clear that every advance in our knowledge means an increase in our therapeutic power. As long as we have understood nothing, we have accomplished nothing; the more we understand, the more we shall achieve. At its beginning psycho-analytic treatment was inexorable and exhausting. The patient had to say everything himself, and the physician's activity consisted of urging him on incessantly. To-day things have a more friendly air. The treatment is made up of two parts - what the physician infers and tells the patient, and the patient's working-over of what he has heard. The mechanism of our assistance is easy to understand: we give the patient the conscious anticipatory idea and he then finds the repressed unconscious idea in himself on the basis of its similarity to the anticipatory one. This is the intellectual help which makes it easier for him to overcome the resistances between conscious and unconscious. Incidentally, I may remark that it is not the only mechanism made use of in analytic treatment; you all know the far more powerful one which lies in the use of the 'transference'. It is my intention in the near future to deal with these various factors, which are so important for an understanding of the treatment, in an Allgemeine Methodik der Psychoanalyse. And further, in speaking to you I need not rebut the objection that the evidential value in support of the correctness of our hypotheses is obscured in our treatment as we practise it to-day; you will not forget that this evidence is to be found elsewhere, and that a therapeutic procedure cannot be carried out in the same way as a theoretical investigation.

[1910d, 2307]

The method by which we strengthen the weakened ego has as a starting-point an extending of its self-knowledge. That is not, of course, the whole story but it is a first step. The loss of such knowledge signifies for the ego a surrender of power and influence; it is the first tangible sign that it is being hemmed in and hampered by the demands of the id and the super-ego. Accordingly, the first part of the help we have to offer is intellectual work on our side and encouragement to the patient to collaborate in it. This first kind of activity, as we know, is intended to pave the way to another, more difficult, task. We shall not lose sight of the dynamic element in this task, even during its preliminary stage. We gather the material for our work from a variety of sources - from what is conveyed to us by the information given us by the patient and by his free associations, from what he shows us in his transferences, from what we arrive at by interpreting his dreams and from what he betrays by his slips or parapraxes. All this material helps us to make constructions about what happened to him and has been forgotten as well as about what is happening in him now without his understanding it. But in all this we never fail to make a strict distinction between our knowledge and his knowledge. We avoid telling him at once things that we have often discovered at an early stage, and we avoid telling him the whole of what we think we have discovered. We reflect carefully over when we shall impart the knowledge of one of our constructions to him and we wait for what seems to us the suitable moment - which it is not always easy to decide. As a rule we put off telling him of a construction or explanation till he himself has so nearly arrived at it that only a single step remains to be taken, though that step is in fact the decisive synthesis. If we proceeded in another way and overwhelmed him with our interpretations before he was prepared for them, our information would either produce no effect or it would provoke a violent outbreak of resistance which would make the progress of our work more difficult or might even threaten to stop it altogether. But if we have prepared everything properly, it often happens that the patient will at once confirm our construction and himself recollect the internal or external event which he had forgotten. The more exactly the construction coincides with the details of what has been forgotten the easier will it be for him to assent. On that particular matter our knowledge will then have become his knowledge as well.

[1940a [1938], 4987]
Let us once more glance over the situation which we have reached in our attempt at bringing help to the patient's neurotic ego. That ego is no longer able to fulfil the task set it by the external world (including human society). Not all of its experiences are at its disposal, a large proportion of its store of memories have escaped it. Its activity is inhibited by strict prohibitions from the super-ego, its energy is consumed in vain attempts at fending off the demands of the id. Beyond this, as a result of continuous irruptions by the id, its organization is impaired, it is no longer capable of any proper synthesis, it is torn by mutually opposed urges, by unsettled conflicts and by unsolved doubts. To start with, we get the patient's thus weakened ego to take part in the purely intellectual work of interpretation, which aims at provisionally filling the gaps in his mental assets, and to transfer to us the authority of his super-ego; we encourage it to take up the struggle over each individual demand made by the id and to conquer the resistances which arise in connection with it. At the same time we restore order in the ego by detecting the material and urges which have forced their way in from the unconscious, and expose them to criticism by tracing them back to their origin. We serve the patient in various functions, as an authority and a substitute for his parents, as a teacher and educator; and we have done the best for him if, as analysts, we raise the mental processes in his ego to a normal level, transform what has become unconscious and repressed into preconscious material and thus return it once more to the possession of his ego. On the patient's side a few rational factors work in our favour, such as the need for recovery which has its motive in his sufferings, and the intellectual interest that we may awaken in him in the theories and revelations of psychoanalysis; but of far greater force is the positive transference with which he meets us. Fighting against us, on the other hand, are the negative transference, the ego's resistance due to repression (that is, its displeasure at having to lay itself open to the hard work imposed on it), the sense of guilt arising from its relation to the super-ego and the need to be ill due to deep-going changes in the economics of his instincts. The share taken by the last two factors decides whether the case is to be regarded as slight or severe. Apart from these, a few other factors may be discerned as having a favourable or unfavourable bearing. A certain psychical inertia, a sluggishness of the libido, which is unwilling to abandon its fixations cannot be welcome to us; the patient's capacity for sublimating his instincts plays a large part and so does his capacity for rising above the crude life of the instincts; so, too, does the relative power of his intellectual functions.

[1940a [1938], 4990]
The phenomenon of hysterical symptoms joining in the conversation during the analysis involves a practical drawback, to which we ought to be able to reconcile the patient. It is quite impossible to effect an analysis of a symptom at a single stretch or to distribute the intervals in our work so that they fit in precisely with pauses in the process of dealing with the symptom. On the contrary, interruptions which are imperatively prescribed by incidental circumstances in the treatment, such as the lateness of the hour, often occur at the most inconvenient points, just as one may be approaching a decision or just as a new topic emerges. Every newspaper reader suffers from the same drawback in reading the daily instalment of his serial story, when, immediately after the heroine's decisive speech or after the shot has rung out, he comes upon the words: 'To be continued.' In our own case the topic that has been raised but not dealt with, the symptom that has become temporarily intensified and has not yet been explained, persists in the patient's mind and may perhaps be more troublesome to him than it has otherwise been. He will simply have to make the best of this; there is no other way of arranging things. There are patients who, in the course of an analysis, simply cannot get free of a topic that has once been raised and who are obsessed by it in the interval between two treatments; since by themselves they cannot take any steps towards getting rid of it, they suffer more, to begin with, than they did before the treatment. But even such patients learn in the end to wait for the doctor and to shift all the interest that they feel in getting rid of the pathogenic material on to the hours of treatment, after which they begin to feel freer in the intervals.

The general condition of patients during an analysis of this kind also deserves notice. For a time it is uninfluenced by the treatment and continues to be an expression of the factors that were operative earlier. But after this there comes a moment when the treatment takes hold of the patient; it grips his interest, and thenceforward his general condition becomes more and more dependent on the state of the work. Every time something new is elucidated or an important stage in the process of the analysis is reached, the patient, too, feels relieved and enjoys a foretaste, as it were, of his approaching liberation. Every time the work halts and confusion threatens, the psychical burden by which he is oppressed increases; his feeling of unhappiness and his incapacity for work grow more intense. But neither of these things happens for more than a short time. For the analysis proceeds, disdaining to boast because the patient feels well for the time being and going on its way regardless of his periods of gloom. We feel glad, in general, when we have replaced the spontaneous oscillations in his condition by oscillations which we ourselves have provoked and which we understand, just as we are glad when we see the spontaneous succession of symptoms replaced by an order of the day which corresponds to the state of the analysis.

To begin with, the work becomes more obscure and difficult, as a rule, the deeper we penetrate into the stratified psychical structure which I have described above. But once we have worked our way as far as the nucleus, light dawns and we need not fear that the patient's general condition will be subject to any severe periods of gloom. But the reward of our labours, the cessation of the symptoms, can only be expected when we have accomplished the complete analysis of every individual symptom; and indeed, if the individual symptoms are interconnected at numerous nodal points, we shall not even be encouraged during the work by partial successes. Thanks to the abundant causal connections, every pathogenic idea which has not yet been got rid of operates as a motive for the whole of the products of the neurosis, and it is only with the last word of the analysis that the whole clinical picture vanishes, just as happens with memories that are reproduced individually.
The ideas which are derived from the greatest depth and which form the nucleus of the pathogenic organization are also those which are acknowledged as memories by the patient with greatest difficulty. Even when everything is finished and the patients have been overborne by the force of logic and have been convinced by the therapeutic effect accompanying the emergence of precisely these ideas - when, I say, the patients themselves accept the fact that they thought this or that, they often add: ‘But I can’t remember having thought it.’ It is easy to come to terms with them by telling them that the thoughts were unconscious. But how is this state of affairs to be fitted into our own psychological views? Are we to disregard this withholding of recognition on the part of patients, when, now that the work is finished, there is no longer any motive for their doing so? Or are we to suppose that we are really dealing with thoughts which never came about, which merely had a possibility of existing, so that the treatment would lie in the accomplishment of a psychical act which did not take place at the time? It is clearly impossible to say anything about this - that is, about the state which the pathogenic material was in before the analysis - until we have arrived at a thorough clarification of our basic psychological views, especially on the nature of consciousness. It remains, I think, a fact deserving serious consideration that in our analyses we can follow a train of thought from the conscious into the unconscious (i.e. into something that is absolutely not recognized as a memory), that we can trace it from there for some distance through consciousness once more and that we can see it terminate in the unconscious again, without this alternation of ‘psychical illumination’ making any change in the train of thought itself, in its logical consistency and in the interconnection between its various parts. Once this train of thought was before me as a whole I should not be able to guess which part of it was recognized by the patient as a memory and which was not. I only, as it were, see the peaks of the train of thought dipping down into the unconscious - the reverse of what has been asserted of our normal psychical processes.

[1895d, 265]
I, too, have made exactly the same observation, without, however, being misled by it. I myself have caused anxiety attacks to disappear by means of psychical treatment, improvement of the patient's general health, and so on; but I have naturally not concluded from this that what had caused the anxiety attack was a lack of treatment. Not that I should like to foist a conclusion of this sort upon Löwenfeld. My joking remark is only intended to show that the state of affairs may easily be complicated enough to render Löwenfeld's objection quite invalid. I have not found it difficult to reconcile the fact brought forward here with my assertion that anxiety neurosis has a specific aetiology. It will readily be granted that there are aetiological factors which, in order to exercise their effect, must operate with a certain intensity (or quantity) and over a certain period of time - which, that is to say, become summated. The effects of alcohol are a standard example of causation like this through summation. It follows that there must be a period of time in which the specific aetiology is at work but in which its effect is not yet manifest. During this time the subject is not ill as yet, but he is predisposed to a particular illness - in our case, to anxiety neurosis - and now the addition of a stock noxa will be able to set the neurosis off, just as would a further intensification of the operation of the specific noxa. The situation may also be expressed as follows: it is not enough for the specific noxa to be present; it must also reach a definite amount; and, in the process of reaching that limit, a quantity of specific noxa can be replaced by a quota of stock noxa. If the latter is removed once more, we find ourselves below a certain threshold and the clinical symptoms depart once more. The whole therapy of the neuroses rests upon the fact that the total load upon the nervous system, to which it has succumbed, can be brought below this threshold by influencing the aetiological mixture in a great variety of ways. From these circumstances we can draw no conclusion as to the existence or non-existence of a specific aetiology. These considerations are surely indisputable and assured. But anyone who does not think them sufficient may be influenced by the following argument. According to the views of Löwenfeld and very many others, the aetiology of anxiety states is to be found in heredity. Now heredity is certainly immune to alteration; thus if anxiety neurosis is curable by treatment, we should have to conclude according to Löwenfeld's argument that its aetiology cannot reside in heredity.

[1895f, 358]
An observation which I have been able to make in the course of preparing this manuscript has shown me that dreams are no more forgotten than other mental acts and can be compared, by no means to their disadvantage, with other mental functions in respect of their retention in the memory. I had kept records of a large number of my own dreams which for one reason or another I had not been able to interpret completely at the time or had left entirely uninterpreted. And now, between one and two years later, I have attempted to interpret some of them for the purpose of obtaining more material in illustration of my views. These attempts have been successful in every instance; indeed the interpretation may be said to have proceeded more easily after this long interval than it did at the time when the dream was a recent experience. A possible explanation of this is that in the meantime I have overcome some of the internal resistances which previously obstructed me. When making these subsequent interpretations I have compared the dream-thoughts that I elicited at the time of the dream with the present, usually far more copious, yield, and I have always found that the old ones are included among the new. My astonishment at this was quickly halted by the reflection that I had long been in the habit of getting my patients, who sometimes tell me dreams dating from earlier years, to interpret them - by the same procedure and with the same success - as though they had dreamt them the night before. When I come to discuss anxiety-dreams I shall give two examples of postponed interpretations like these. I was led into making my first experiment of this kind by the justifiable expectation that in this as in other respects dreams would behave like neurotic symptoms. When I treat a psychoneurotic - a hysteric, let us say - by psycho-analysis, I am obliged to arrive at an explanation for the earliest and long since vanished symptoms of his illness no less than for the contemporary ones which brought him to me for treatment; and I actually find the earlier problem easier to solve than the immediate one. As long ago as in 1895 I was able to give an explanation in *Studies on Hysteria* of the first hysterical attack which a woman of over forty had had in her fifteenth year.¹

[1900a, 956]

In 1913 I wrote a short paper describing another phenomenon that is very similar to 'déjà vu'. This is 'déjà raconté', the illusion of having already reported something of special interest when it comes up in the course of psycho-analytic treatment. On these occasions the patient maintains with every sign of subjective certainty that he has already recounted a particular memory a long time ago. The physician is however sure of the contrary and is as a rule able to convince the patient of his error. The explanation of this interesting parapraxis is probably that the patient has felt an urge to communicate this information and intended to do so, but has failed to carry it into effect, and that he now takes the memory of the former as a substitute for the latter, the carrying out of his intention.

[1901b, 1338]
If I were to begin by giving a full and consistent case history, it would place the reader in a very different situation from that of the medical observer. The reports of the patient's relatives - in the present case I was given one by the eighteen-year-old girl's father - usually afford a very indistinct picture of the course of the illness. I begin the treatment, indeed, by asking the patient to give me the whole story of his life and illness, but even so the information I receive is never enough to let me see my way about the case. This first account may be compared to an unnavigable river whose stream is at one moment choked by masses of rock and at another divided and lost among shallows and sandbanks. I cannot help wondering how it is that the authorities can produce such smooth and precise histories in cases of hysteria. As a matter of fact the patients are incapable of giving such reports about themselves. They can, indeed, give the physician plenty of coherent information about this or that period of their lives; but it is sure to be followed by another period as to which their communications run dry, leaving gaps unfilled, and riddles unanswered; and then again will come yet another period which will remain totally obscure and unilluminated by even a single piece of serviceable information. The connections - even the ostensible ones - are for the most part incoherent, and the sequence of different events is uncertain. Even during the course of their story patients will repeatedly correct a particular or a date, and then perhaps, after wavering for some time, return to their first version. The patients' inability to give an ordered history of their life in so far as it coincides with the history of their illness is not merely characteristic of the neurosis.¹ It also possesses great theoretical significance. For this inability has the following grounds. In the first place, patients consciously and intentionally keep back part of what they ought to tell - things that are perfectly known to them - because they have not got over their feelings of timidity and shame (or discretion, where what they say concerns other people); this is the share taken by conscious disingenuousness. In the second place, part of the anamnestic knowledge, which the patients have at their disposal at other times, disappears while they are actually telling their story, but without their making any deliberate reservations: the share taken by unconscious disingenuousness. In the third place, there are invariably true amnesias - gaps in the memory into which not only old recollections but even quite recent ones have fallen - and paramnesias, formed secondarily so as to fill in those gaps.² When the events themselves have been kept in mind, the purpose underlying the amnesias can be fulfilled just as surely by destroying a connection, and a connection is most surely broken by altering the chronological order of events. The latter always proves to be the most vulnerable element in the store of memory and the one which is most easily subject to repression. Again we meet with many recollections that are in what might be described as the first stage of repression, and these we find surrounded with doubts. At a later period the doubts would be replaced by a loss or a falsification of memory.³

[1905e, 1358]
Nor is the case of whose history and treatment I have published a fragment in these pages well calculated to put the value of psycho-analytic therapy in its true light. Not only the briefness of the treatment (which hardly lasted three months) but another factor inherent in the nature of the case prevented results being brought about such as are attainable in other instances, where the improvement will be admitted by the patient and his relatives and will approximate more or less closely to a complete recovery. Satisfactory results of this kind are reached when the symptoms are maintained solely by the internal conflict between the impulses concerned with sexuality. In such cases the patient's condition will be seen improving in proportion as he is helped towards a solution of his mental problems by the translation of pathogenic into normal material. The course of events is very different when the symptoms have become enlisted in the service of external motives, as had happened with Dora during the two preceding years. It is surprising, and might easily be misleading, to find that the patient's condition shows no noticeable alteration even though considerable progress has been made with the work of analysis. But in reality things are not as bad as they seem. It is true that the symptoms do not disappear while the work is proceeding; but they disappear a little while later, when the relations between patient and physician have been dissolved. The postponement of recovery or improvement is really only caused by the physician's own person.

[1905e, 1449]

I must go back a little, in order to make the matter intelligible. It may be safely said that during psycho-analytic treatment the formation of new symptoms is invariably stopped. But the productive powers of the neurosis are by no means extinguished; they are occupied in the creation of a special class of mental structures, for the most part unconscious, to which the name of 'transferences' may be given.

[1905e, 1450]

The first of these modern dramas is *Hamlet*. It has as its subject the way in which a man who has so far been normal becomes neurotic owing to the peculiar nature of the task by which he is faced, a man, that is, in whom an impulse that has hitherto been successfully suppressed endeavours to make its way into action. *Hamlet* is distinguished by three characteristics which seem important in connection with our present discussion. (1) The hero is not psychopathic, but only becomes psychopathic in the course of the action of the play. (2) The repressed impulse is one of those which are similarly repressed in all of us, and the repression of which is part and parcel of the foundations of our personal evolution. It is this repression which is shaken up by the situation in the play. As a result of these two characteristics it is easy for us to recognize ourselves in the hero: we are susceptible to the same conflict as he is, since 'a person who does not lose his reason under certain conditions can have no reason to lose'. (3) It appears as a necessary precondition of this form of art that the impulse that is struggling into consciousness, however clearly it is recognizable, is never given a definite name; so that in the spectator too the process is carried through with his attention averted, and he is in the grip of his emotions instead of taking stock of what is happening. A certain amount of resistance is no doubt saved in this way, just as, in an analytic treatment, we find derivatives of the repressed material reaching consciousness, owing to a lower resistance, while the repressed material itself is unable to do so. After all, the conflict in *Hamlet* is so effectively concealed that it was left to me to unearth it.

[1942a [1905], 1611]
We ourselves were unprepared for this. Our hero was beginning to cast off his humility and to play an active part. Evidently he was completely cured of his delusion and had risen above it; and he proved this by himself tearing the last threads of the cobweb of his delusion. This, too, is just how patients behave when one has loosened the compulsion of their delusional thoughts by revealing the repressed material lying behind them. Once they have understood, they themselves bring forward the solutions of the final and most important riddles of their strange condition in a number of ideas that suddenly occur to them. We had already guessed that the Greek origin of the imaginary Gradiva was an obscure result of the Greek name 'Zoe'; but we had not ventured to approach the name 'Gradiva' itself, and had let it pass as the untrammelled creation of Norbert Hanold's imagination. But, to and behold! that very name now turns out to have been a derivative - indeed a translation - of the repressed surname of the girl he had loved in the childhood which he was supposed to have forgotten.

It will interest you, from the point of view of your own profession, to hear how we doctors proceed in psycho-analysis. After the patient has given us a first account of his history, we ask him to give himself up to the thoughts that occur to him spontaneously and to say without any critical reserve whatever comes into his head. We start, as you see, on the assumption, which he does not share in the least, that these spontaneous thoughts will not be arbitrarily chosen but will be determined by their relation to his secret - to his 'complex' - and may, as it were, be regarded as derivatives of that complex. You will note that this is the same assumption as the one with the help of which you were able to interpret the association experiments. But although we have instructed the patient to follow the rule of communicating all the thoughts that occur to him, he seems to be unable to do so. He soon begins to hold back first one thought and then another. He gives various reasons to account for this: either the thought was quite unimportant, or it was irrelevant or it was totally meaningless. We thereupon demand that he shall tell us the thought in spite of these objections and shall follow it up; for the very fact of his criticism proves to us that the thought belongs to the 'complex' which we are seeking to uncover. We recognize in this behaviour of the patient's a manifestation of the 'resistance' present in him, which we are never free from through the whole duration of the treatment. I will merely indicate briefly that this concept of resistance has acquired the highest importance for us in understanding the origin of an illness as well as the mechanism of its cure.

We will not follow Hans's father either in his easily comprehensible anxieties or in his first attempts at finding an explanation; we will begin by examining the material before us. It is not in the least our business to 'understand' a case at once: this is only possible at a later stage, when we have received enough impressions of it. For the present we will suspend our judgement and give our impartial attention to everything that there is to observe.

Nevertheless, the situation was decidedly obscure. The analysis was making little progress; and I am afraid the reader will soon begin to find this description of it tedious. Every analysis, however, has dark periods of this kind. But Hans was now on the point of leading us into an unexpected region.
Speaking with the air of superiority which is so easily acquired after the event, we may correct Hans's father, and explain that the boy's wish to 'tease' the horse had two constituents; it was compounded of an obscure sadistic desire for his mother and of a clear impulse for revenge against his father. The latter could not be reproduced until the former's turn had come to emerge in connection with the pregnancy complex. In the process of the formation of a phobia from the unconscious thoughts underlying it, condensation takes place; and for that reason the course of the analysis can never follow that of the development of the neurosis.

[1909b, 2069]

Immediately after the giraffe story Hans produced two minor phantasies: one of his forcing his way into a forbidden space at Schönbrunn, and the other of his smashing a railway-carriage window on the Stadtbahn. In each case the punishable nature of the action was emphasized, and in each his father appeared as an accomplice. Unluckily his father failed to interpret either of these phantasies, so that Hans himself gained nothing from telling them. In an analysis, however, a thing which has not been understood inevitably reappears; like an un laid ghost, it cannot rest until the mystery has been solved and the spell broken.

[1909b, 2104]

While the analysis of a case is in progress it is impossible to obtain any clear impression of the structure and development of the neurosis. That is the business of a synthetic process which must be performed subsequently. In attempting to carry out such a synthesis of little Hans's phobia we shall take as our basis the account of his mental constitution, of his governing sexual wishes, and of his experiences up to the time of his sister's birth, which we have given in an earlier part of this paper.

[1909b, 2112]

The reader must not expect to hear at once what light I have to throw upon the patient's strange and senseless obsessions about the rats. The true technique of psycho-analysis requires the physician to suppress his curiosity and leaves the patient complete freedom in choosing the order in which topics shall succeed each other during the treatment. At the fourth session, accordingly, I received the patient with the question: 'And how do you intend to proceed to-day?'

[1909d, 2142]
In elucidating the effects produced by the captain's rat story we must follow the course of the analysis more closely. The patient began by producing an enormous mass of associative material, which at first, however, threw no light upon the circumstances in which the formation of his obsession had taken place. The idea of the punishment carried out by means of rats had acted as a stimulus to a number of his instincts and had called up a whole quantity of recollections; so that, in the short interval between the captain's story and his request to him to pay back the money, rats had acquired a series of symbolic meanings, to which, during the period which followed, fresh ones were continually being added. I must confess that I can only give a very incomplete account of the whole business. What the rat punishment stirred up more than anything else was his anal erotism, which had played an important part in his childhood and had been kept in activity for many years by a constant irritation due to worms. In this way rats came to have the meaning of 'money'.¹ The patient gave an indication of this connection by reacting to the word 'Ratten' ['rats'] with the association 'Raten' ['instalments']. In his obsessional deliria he had coined himself a regular rat currency. When, for instance, in reply to a question, I told him the amount of my fee for an hour's treatment, he said to himself (as I learned six months later): 'So many florins, so many rats'. Little by little he translated into this language the whole complex of money interests which centred round his father's legacy to him, that is to say, all his ideas connected with that subject were, by way of the verbal bridge 'Raten - Ratten', carried over into his obsessional life and brought under the dominion of his unconscious. Moreover, the captain's request to him to pay back the charges due upon the packet served to strengthen the money significance of rats, by way of another verbal bridge 'Spielratte', which led back to his father's gambling debt.

[1909d, 2166]

The distinction between a primary and a secondary defensive struggle is no doubt well founded, but we find its value unexpectedly diminished when we discover that the patients themselves do not know the wording of their own obsessional ideas. This may sound paradoxical, but it is perfectly good sense. During the progress of a psycho-analysis it is not only the patient who plucks up courage, but his disease as well; it grows bold enough to speak more plainly than before. To drop the metaphor, what happens is that the patient, who his hitherto turned his eyes away in terror from his own pathological productions, begins to attend to them and obtains a clearer and more detailed view of them.¹

[1909d, 2174]

Every one of you will know from his own experience what a very different attitude he has towards a new case of illness when once he has thoroughly grasped the structure of a few typical cases. Imagine that we had arrived at a succinct formula of the factors regularly concerned in constructing the various forms of neuroses, as we have so far succeeded in doing for the construction of hysterical symptoms, and consider how firmly it would establish our prognostic judgement! Just as an obstetrician can tell by examining the placenta whether it has been completely expelled or whether noxious fragments of it still remain, so should we, independently of the outcome and of the patient's condition at the moment, be able to say whether our work had been definitely successful or whether we had to expect relapses and fresh onsets of illness.

[1910d, 2309]
To shorten analytic treatment is a justifiable wish, and its fulfilment, as we shall learn, is being attempted along various lines. Unfortunately, it is opposed by a very important factor, namely, the slowness with which deep-going changes in the mind are accomplished - in the last resort, no doubt, the 'timelessness' of our unconscious processes. When patients are faced with the difficulty of the great expenditure of time required for analysis they not infrequently manage to propose a way out of it. They divide up their ailments and describe some as unbearable, and others as secondary, and then say: 'If only you will relieve me from this one (for instance, a headache or a particular fear) I can deal with the other one on my own in my ordinary life.' In doing this, however, they over-estimate the selective power of analysis. The analyst is certainly able to do a great deal, but he cannot determine beforehand exactly what results he will effect. He sets in motion a process, that of the resolving of existing repressions. He can supervise this process, further it, remove obstacles in its way, and he can undoubtedly vitiate much of it. But on the whole, once begun, it goes its own way and does not allow either the direction it takes or the order in which it picks up its points to be prescribed for it. The analyst's power over the symptoms of the disease may thus be compared to male sexual potency. A man can, it is true, beget a whole child, but even the strongest man cannot create in the female organism a head alone or an arm or a leg; he cannot even prescribe the child's sex. He, too, only sets in motion a highly complicated process, determined by events in the remote past, which ends with the severance of the child from its mother. A neurosis as well has the character of an organism. Its component manifestations are not independent of one another; they condition one another and give one another mutual support. A person suffers from one neurosis only, never from several which have accidentally met together in a single individual. The patient freed, according to his wish, from his one unendurable symptom might easily find that a symptom which had previously been negligible had now increased and grown unendurable. The analyst who wishes the treatment to owe its success as little as possible to its elements of suggestion (i.e. to the transference) will do well to refrain from making use of even the trace of selective influence upon the results of the therapy which may perhaps be open to him. The patients who are bound to be most welcome to him are those who ask him to give them complete health, in so far as that is attainable, and who place as much time at his disposal as is necessary for the process of recovery. Such favourable conditions as these are, of course, to be looked for in only a few cases.

[1913c, 2483]

There is another question that I might draw your attention to, which has been dealt with too little in our discussions: that of 'unconscious' masturbation. I mean masturbation during sleep, during abnormal states, or fits. You will recall the many hysterical fits in which masturbatory acts recur in a disguised or unrecognizable way, after the subject has renounced that form of satisfaction, and the many symptoms in obsessional neurosis which seek to replace and repeat this kind of sexual activity, which has formerly been forbidden. We may also speak of a therapeutic return of masturbation. A number of you will have found on occasion, as I have, that it represents a great advance if during the treatment the patient ventures to take up masturbation once more, though he may have no intention of making a permanent stop at that infantile halting-place. In this connection I may remind you that a considerable number of precisely the most severe sufferers from neurosis have avoided all recollection of masturbation during historic times, while psycho-analysis is able to prove that that species of sexual activity had by no means been strange to them during the forgotten earliest period of their lives.

[1912f, 2574]
It not infrequently happens in the course of an analytic treatment that the patient, after reporting some fact that he has remembered, will go on to say: 'But I've told you that already' - while the analyst himself feels sure that this is the first time he has heard the story. If the patient is contradicted upon the point, he will often protest with energy that he is perfectly certain he is right, that he is ready to swear to it, and so on; while the analyst's own conviction that what he has heard is new to him will become correspondingly stronger. To try to decide the dispute by shouting the patient down or by outhing him in protestations would be a most unpsychological proceeding. It is familiar ground that a sense of conviction of the accuracy of one's memory has no objective value; and, since one of the two persons concerned must necessarily be in the wrong, it may just as well be the physician as the patient who has fallen a victim to a paramnesia. The analyst will admit as much to the patient, will break off the argument, and will postpone a settlement of the point until some later occasion.

[1914a, 2836]

Leaving on one side any cases in which there may still be some element of doubt, I will now bring forward a few others which are of special theoretical interest. With certain people it happens, and may even happen repeatedly, that they cling with particular obstinacy to the assertion that they have already told the analyst this or that, when the nature of the circumstances and of the information in question makes it quite impossible that they can be right. For what they claim to have told the analyst already and what they claim to recognize as something old, which must be familiar to the analyst as well, turn out to be memories of the greatest importance to the analysis - confirmatory facts for which the analyst has long been waiting, or solutions which wind up a whole section of the work and which he would certainly have made the basis of an exhaustive discussion. In the face of these considerations the patient himself soon admits that his recollection must have deceived him, though he is unable to account for its definite character.

[1914a, 2837]

There is another kind of fausse reconnaissance which not infrequently makes its appearance at the close of a treatment, much to the physician's satisfaction. After he has succeeded in forcing the repressed event (whether it was of a real or of a psychical nature) upon the patient's acceptance in the teeth of all resistances, and has succeeded, as it were, in rehabilitating it - the patient may say: 'Now I feel as though I had known it all the time.' With this the work of the analysis has been completed.

[1914a, 2842]

I must now mention two secessions which have taken place among the adherents of psychoanalysis; the first occurred between the founding of the Association in 1910 and the Weimar Congress in 1911; the second took place after this and became manifest at Munich in 1913. The disappointment that they caused me might have been averted if I had paid more attention to the reactions of patients under analytic treatment. I knew very well of course that anyone may take to flight at his first approach to the unwelcome truths of analysis; I had always myself maintained that everyone's understanding of it is limited by his own repressions (or rather, by the resistances which sustain them) so that he cannot go beyond a particular point in his relation to analysis. But I had not expected that anyone who had reached a certain depth in his understanding of analysis could renounce that understanding and lose it. And yet daily experience with patients had shown that total rejection of analytic knowledge may result whenever a specially strong resistance arises at any depth in the mind; one may have succeeded in laboriously bringing a patient to grasp some parts of analytic knowledge and to handle them like possessions of his own, and yet one may see him, under the domination of the very next resistance, throw all he has learnt to the winds and stand on the defensive as he did in the days when he was a carefree beginner. I had to learn that the very same thing can happen with psycho-analysts as with patients in analysis.

[1914d, 2911]
There is, however, another symptom in our fellow-citizens of the world which has perhaps astonished and shocked us no less than the descent from their ethical heights which has given us so much pain. What I have in mind is the want of insight shown by the best intellects, their obduracy, their inaccessibility to the most forcible arguments and their uncritical credulity towards the most disputable assertions. This indeed presents a lamentable picture, and I wish to say emphatically that in this I am by no means a blind partisan who finds all the intellectual shortcomings on one side. But this phenomenon is much easier to account for and much less disquieting than the one we have just considered. Students of human nature and philosophers have long taught us that we are mistaken in regarding our intelligence as an independent force and in overlooking its dependence on emotional life. Our intellect, they teach us, can function reliably only when it is removed from the influences of strong emotional impulses; otherwise it behaves merely as an instrument of the will and delivers the inference which the will requires. Thus, in their view, logical arguments are impotent against affective interests, and that is why disputes backed by reasons, which in Falstaff's phrase are 'as plenty as blackberries', are so unfruitful in the world of interests. Psycho-analytic experience has, if possible, further confirmed this statement. It can show every day that the shrewdest people will all of a sudden behave without insight, like imbeciles, as soon as the necessary insight is confronted by an emotional resistance, but that they will completely regain their understanding once that resistance has been overcome. The logical bedazzlement which this war has conjured up in our fellow-citizens, many of them the best of their kind, is therefore a secondary phenomenon, a consequence of emotional excitement, and is bound, we may hope, to disappear with it.

For these reasons I refrained altogether from holding out to the parents any prospect of their wish being fulfilled. I merely said I was prepared to study the girl carefully for a few weeks or months, so as then to be able to pronounce how far a continuation of the analysis would be likely to influence her. In quite a number of cases, indeed, an analysis falls into two clearly distinguishable phases. In the first, the physician procures from the patient the necessary information, makes him familiar with the premises and postulates of psycho-analysis, and unfolds to him the reconstruction of the genesis of his disorder as deduced from the material brought up in the analysis. In the second phase the patient himself gets hold of the material put before him; he works on it, recollects what he can of the apparently repressed memories, and tries to repeat the rest as if he were in some way living it over again. In this way he can confirm, supplement, and correct the inferences made by the physician. It is only during this work that he experiences, through overcoming resistances, the inner change aimed at, and acquires for himself the convictions that make him independent of the physician's authority. These two phases in the course of the analytic treatment are not always sharply divided from each other; this can only happen when the resistance obeys certain conditions. But when this is so, one may bring up as an analogy the two stages of a journey. The first comprises all the necessary preparations, to-day so complicated and hard to effect, before, ticket in hand, one can at last go on to the platform and secure a seat in the train. One then has the right, and the possibility, of travelling into a distant country; but after all these preliminary exertions one is not yet there - indeed, one is not a single mile nearer to one's goal. For this to happen one has to make the journey itself from one station to the other, and this part of the performance may well be compared with the second phase of the analysis.
In the girl’s account of her conscious motives the father did not figure at all; there was not even any mention of fear of his anger. In the motives laid bare by the analysis, on the other hand, he played the principal part. Her relation to her father had the same decisive importance for the course and outcome of the analytic treatment, or rather, analytic exploration. Behind her pretended consideration for her parents, for whose sake she had been willing to make the attempt to be transformed, lay concealed her attitude of defiance and revenge against her father which held her fast to her homosexuality. Secure under this cover, the resistance set a considerable region free to analytic investigation. The analysis went forward almost without any signs of resistance, the patient participating actively with her intellect, though absolutely tranquil emotionally. Once when I expounded to her a specially important part of the theory, one touching her nearly, she replied in an inimitable tone, ‘How very interesting’, as though she were a grande dame being taken over a museum and glancing through her lorgnon at objects to which she was completely indifferent. The impression one had of her analysis was not unlike that of a hypnotic treatment, where the resistance has in the same way withdrawn to a certain boundary line, beyond which it proves to be unconquerable. The resistance very often pursues similar tactics - Russian tactics, as they might be called - in cases of obsessional neurosis. For a time, consequently, these cases yield the clearest results and permit a deep insight into the causation of the symptoms. But presently one begins to wonder how it is that such marked progress in analytic understanding can be unaccompanied by even the slightest change in the patient’s compulsions and inhibitions, until at last one perceives that everything that has been accomplished is subject to a mental reservation of doubt, and that behind this protective barrier the neurosis can feel secure. ‘It would be all very fine’, thinks the patient, often quite consciously, ‘if I were obliged to believe what the man says, but there is no question of that, and so long as this is so I need change nothing.’ Then, when one comes to close quarters with the motives for this doubt, the fight with the resistances breaks out in earnest. [1920a, 3852]

In the further course of psycho-analytic work, however, even these distinctions have proved to be inadequate and, for practical purposes, insufficient. This has become clear in more ways than one; but the decisive instance is as follows. We have formed the idea that in each individual there is a coherent organization of mental processes; and we call this his ego. It is to this ego that consciousness is attached; the ego controls the approaches to motility - that is, to the discharge of excitations into the external world; it is the mental agency which supervises all its own constituent processes, and which goes to sleep at night, though even then it exercises the censorship on dreams. From this ego proceed the repressions, too, by means of which it is sought to exclude certain trends in the mind not merely from consciousness but also from other forms of effectiveness and activity. In analysis these trends which have been shut out stand in opposition to the ego, and the analysis is faced with the task of removing the resistances which the ego displays against concerning itself with the repressed. Now we find during analysis that, when we put certain tasks before the patient, he gets into difficulties; his associations fail when they should be coming near the repressed. We then tell him that he is dominated by a resistance; but he is quite unaware of the fact, and, even if he guesses from his unpleasurable feelings that a resistance is now at work in him, he does not know what it is or how to describe it. Since, however, there can be no question but that this resistance emanates from his ego and belongs to it, we find ourselves in an unforeseen situation. We have come upon something in the ego itself which is also unconscious, which behaves exactly like the repressed - that is, which produces powerful effects without itself being conscious and which requires special work before it can be made conscious. From the point of view of analytic practice, the consequence of this discovery is that we land in endless obscurities and difficulties if we keep to our habitual forms of expression and try, for instance, to derive neuroses from a conflict between the conscious and the unconscious. We shall have to substitute for this antithesis another, taken from our insight into the structural conditions of the mind - the antithesis between the coherent ego and the repressed which is split off from it.¹ [1923b, 3951]
If a dream brings up situations that can be interpreted as referring to scenes from the dreamer's past, it seems especially important to ask whether the physician's influence can also play a part in such contents of the dream as these. And this question is most urgent of all in the case of what are called 'corroborative' dreams, dreams which, as it were, 'tag along behind' the analysis. With some patients these are the only dreams that one obtains. Such patients reproduce the forgotten experiences of their childhood only after one has constructed them from their symptoms, associations and other signs and has propounded these constructions to them. Then follow the corroborative dreams, concerning which, however, the doubt arises whether they may not be entirely without evidential value, since they may have been imagined in compliance with the physician's words instead of having been brought to light from the dreamer's unconscious. This ambiguous position cannot be escaped in the analysis, since with these patients unless one interprets, constructs and propounds, one never obtains access to what is repressed in them.

The situation takes a favourable turn if the analysis of a corroborative dream of this sort, which 'tags along behind', is immediately followed by feelings of remembering what has hitherto been forgotten. But even then the sceptic can fall back upon an assertion that the recollections are illusory. Moreover, such feelings are for the most part absent. The repressed material is only allowed through bit by bit; and every lack of completeness inhibits or delays the forming of a sense of conviction. Furthermore, what we are dealing with may not be the reproduction of a real and forgotten event but the bringing forward of an unconscious phantasy, about which no feeling of memory is ever to be expected, though the possibility may sometimes remain of a sense of subjective conviction.

Is it possible, then, that corroborative dreams are really the result of suggestion, that they are 'obliging' dreams? The patients who produce only corroborative dreams are the same patients in whom doubt plays the principal part in resistance. One makes no attempt at shouting down this doubt by means of one's authority or at reducing it by arguments. It must persist until it is brought to an end in the further course of the analysis. The analyst, too, may himself retain a doubt of the same kind in some particular instances. What makes him certain in the end is precisely the complication of the problem before him, which is like the solution of a jig-saw puzzle. A coloured picture, pasted upon a thin sheet of wood and fitting exactly into a wooden frame, is cut into a large number of pieces of the most irregular and crooked shapes. If one succeeds in arranging the confused heap of fragments, each of which bears upon it an unintelligible piece of drawing, so that the picture acquires a meaning, so that there is no gap anywhere in the design and so that the whole fits into the frame - if all these conditions are fulfilled, then one knows that one has solved the puzzle and that there is no alternative solution.
Critical voices will now be raised. It will be objected that, since it is not possible to interpret every dream that is dealt with, one should cease asserting more than one can establish and should be content to say that some dreams can be shown by interpretation to have a meaning but that as to the rest we are in ignorance. But the very fact that success in interpretation depends upon the resistance absolves the analyst from the necessity for such modesty. He may have the experience of a dream that was at first unintelligible becoming clear during the very same hour after some fortunate remark has got rid of one of the dreamer's resistances. A portion of the dream which the patient had hitherto forgotten may suddenly occur to him and may bring the key to the interpretation; or a new association may emerge which may throw light upon the darkness. It sometimes happens, too, that, after months or years of analytic labour, one returns to a dream which at the beginning of the treatment seemed meaningless and incomprehensible but which is now, in the light of knowledge obtained in the meantime, completely elucidated. And if one further takes into consideration the argument from the theory of dreams that the model dream-products of children invariably have a clear meaning and are easy to interpret, then it will be justifiable to assert that dreams are quite generally mental structures that are capable of interpretation, though the situation may not always allow of an interpretation being reached.

[1925i, 4046]

It may seem surprising that this method of free association, carried out subject to the observation of the fundamental rule of psycho-analysis, should have achieved what was expected of it, namely the bringing into consciousness of the repressed material which was held back by resistances. We must, however, bear in mind that free association is not really free. The patient remains under the influence of the analytic situation even though he is not directing his mental activities on to a particular subject. We shall be justified in assuming that nothing will occur to him that has not some reference to that situation. His resistance against reproducing the repressed material will now be expressed in two ways. Firstly it will be shown by critical objections; and it was to deal with these that the fundamental rule of psycho-analysis was invented. But if the patient observes that rule and so overcomes his reticences, the resistance will find another means of expression. It will so arrange it that the repressed material itself will never occur to the patient but only something which approximates to it in an allusive way; and the greater the resistance, the more remote from the actual idea that the analyst is in search of will be the substitutive association which the patient has to report. The analyst, who listens composedly but without any constrained effort to the stream of associations and who, from his experience, has a general notion of what to expect, can make use of the material brought to light by the patient according to two possibilities. If the resistance is slight he will be able from the patient's allusions to infer the unconscious material itself; or if the resistance is stronger he will be able to recognize its character from the associations, as they seem to become more remote from the topic in hand, and will explain it to the patient. Uncovering the resistance, however, is the first step towards overcoming it. Thus the work of analysis involves an art of interpretation, the successful handling of which may require tact and practice but which is not hard to acquire. But it is not only in the saving of labour that the method of free association has an advantage over the earlier method. It exposes the patient to the least possible amount of compulsion, it never allows of contact being lost with the actual current situation, it guarantees to a great extent that no factor in the structure of the neurosis will be overlooked and that nothing will be introduced into it by the expectations of the analyst. It is left to the patient in all essentials to determine the course of the analysis and the arrangement of the material; any systematic handling of particular symptoms or complexes thus becomes impossible. In complete contrast to what happened with hypnotism and with the urging method, interrelated material makes its appearance at different times and at different points in the treatment. To a spectator, therefore - though in fact there must be none - an analytic treatment would seem completely obscure.

[1925d, 4216]
It is easy now to describe our therapeutic aim. We try to restore the ego, to free it from its restrictions, and to give it back the command over the id which it has lost owing to its early repressions. It is for this one purpose that we carry out analysis, our whole technique is directed to this aim. We have to seek out the repressions which have been set up and to urge the ego to correct them with our help and to deal with conflicts better than by an attempt at flight. Since these repressions belong to the very early years of childhood, the work of analysis leads us, too, back to that period. Our path to these situations of conflict, which have for the most part been forgotten and which we try to revive in the patient's memory, is pointed out to us by his symptoms, dreams and free associations. These must, however, first be interpreted - translated for, under the influence of the psychology of the id, they have assumed forms of expression that are strange to our comprehension. We may assume that whatever associations, thoughts and memories the patient is unable to communicate to us without internal struggles are in some way connected with the repressed material or are its derivatives. By encouraging the patient to disregard his resistances to telling us these things, we are educating his ego to overcome its inclination towards attempts at flight and to tolerate an approach to what is repressed. In the end, if the situation of the repression can be successfully reproduced in his memory, his compliance will be brilliantly rewarded. The whole difference between his age then and now works in his favour; and the thing from which his childish ego fled in terror will often seem to his adult and strengthened ego no more than child's play.

And it must be so, firstly, because analysis is entirely founded on complete candour. Financial circumstances, for instance, are discussed with equal detail and openness: things are said that are kept back from every fellow-citizen, even if he is not a competitor or a tax-collector. I will not dispute - indeed, I will myself insist with energy - that this obligation to candour puts a grave moral responsibility on the analyst as well. And it must be so, secondly, because factors from sexual life play an extremely important, a dominating, perhaps even a specific part among the causes and precipitating factors of neurotic illnesses. What else can analysis do but keep close to its subject-matter, to the material brought up by the patient? The analyst never entices his patient on to the ground of sex. He does not say to him in advance: 'We shall be dealing with the intimacies of your sexual life!' He allows him to begin what he has to say whenever he pleases, and quietly waits until the patient himself touches on sexual things. I used always to warn my pupils: 'Our opponents have told us that we shall come upon cases in which the factor of sex plays no part. Let us be careful not to introduce it into our analyses and so spoil our chance of finding such a case.' But so far none of us has had that good fortune.

Let me return to your question about certainty. We have become quite generally convinced from the direct analytic examination of children that we were right in our interpretation of what adults told us about their childhood. In a number of cases, however, another sort of confirmation has become possible. The material of the analysis of some patients has enabled us to reconstruct certain external happenings, certain impressive events of their childhood years, of which they have preserved no conscious memory. Lucky accidents, information from parents or nurses, have afterwards provided irrefutable evidence that these occurrences which we had inferred really did take place. This, of course, has not happened often, but when it has it has made an overwhelming impression. The correct reconstruction, you must know, of such forgotten experiences of childhood always has a great therapeutic effect, whether they permit of objective confirmation or not. These events owe their importance, of course, to their having occurred at such an early age, at a time when they could still produce a traumatic effect on the feeble ego.
‘I will add that. Thereupon he begins to talk and I listen. And what then? I infer from what he tells me the kind of impressions, experiences and wishes which he has repressed because he came across them at a time when his ego was still feeble and was afraid of them instead of dealing with them. When he has learnt this from me, he puts himself back in the old situations and with my help he manages better. The limitations to which his ego was tied then disappear, and he is cured. Is that right?’

[1926e, 4360]

When one really practises analysis one learns all kinds of things besides. For instance: you would not find it at all such a simple matter to deduce from what the patient tells you the experiences he has forgotten and the instinctual impulses he has repressed. He says something to you which at first means as little to you as it does to him. You will have to make up your mind to look at the material which he delivers to you in obedience to the rule in a quite special way: as though it were ore, perhaps, from which its content of precious metal has to be extracted by a particular process. You will be prepared, too, to work over many tons of ore which may contain but little of the valuable material you are in search of. Here we should have a first reason for the prolonged character of the treatment.

[1926e, 4361]

‘But how does one work over this raw material - to keep to your simile?’

[1926e, 4361]

By assuming that the patient’s remarks and associations are only distortions of what you are looking for - allusions, as it were, from which you have to guess what is hidden behind them. In a word, this material, whether it consists of memories, associations or dreams, has first to be interpreted. You will do this, of course, with an eye to the expectations you have formed as you listened, thanks to your special knowledge.

[1926e, 4361]
Let us once more glance over the situation which we have reached in our attempt at bringing help to the patient’s neurotic ego. That ego is no longer able to fulfil the task set it by the external world (including human society). Not all of its experiences are at its disposal, a large proportion of its store of memories have escaped it. Its activity is inhibited by strict prohibitions from the super-ego, its energy is consumed in vain attempts at fending off the demands of the id. Beyond this, as a result of continuous irruptions by the id, its organization is impaired, it is no longer capable of any proper synthesis, it is torn by mutually opposed urges, by unsettled conflicts and by unsolved doubts. To start with, we get the patient’s thus weakened ego to take part in the purely intellectual work of interpretation, which aims at provisionally filling the gaps in his mental assets, and to transfer to us the authority of his super-ego; we encourage it to take up the struggle over each individual demand made by the id and to conquer the resistances which arise in connection with it. At the same time we restore order in the ego by detecting the material and urges which have forced their way in from the unconscious, and expose them to criticism by tracing them back to their origin. We serve the patient in various functions, as an authority and a substitute for his parents, as a teacher and educator; and we have done the best for him if, as analysts, we raise the mental processes in his ego to a normal level, transform what has become unconscious and repressed into preconscious material and thus return it once more to the possession of his ego. On the patient’s side a few rational factors work in our favour, such as the need for recovery which has its motive in his sufferings, and the intellectual interest that we may awaken in him in the theories and revelations of psycho-analysis; but of far greater force is the positive transference with which he meets us. Fighting against us, on the other hand, are the negative transference, the ego’s resistance due to repression (that is, its unpleasure at having to lay itself open to the hard work imposed on it), the sense of guilt arising from its relation to the super-ego and the need to be ill due to deep-going changes in the economics of his instincts. The share taken by the last two factors decides whether the case is to be regarded as slight or severe. Apart from these, a few other factors may be discerned as having a favourable or unfavourable bearing. A certain psychical inertia, a sluggishness of the libido, which is unwilling to abandon its fixations cannot be welcome to us; the patient’s capacity for sublimating his instincts plays a large part and so does his capacity for rising above the crude life of the instincts; so, too, does the relative power of his intellectual functions.

[1940a [1938], 4990]
However much our therapeutic ambition may be tempted to undertake such tasks, experience flatly rejects the notion. If an instinctual conflict is not a currently active one, is not manifesting itself, we cannot influence it even by analysis. The warning that we should let sleeping dogs lie, which we have so often heard in connection with our efforts to explore the psychical underworld, is peculiarly inapposite when applied to the conditions of mental life. For if the instincts are causing disturbances, it is a proof that the dogs are not sleeping; and if they seem really to be sleeping, it is not in our power to awaken them. This last statement, however, does not seem to be quite accurate and calls for a more detailed discussion. Let us consider what means we have at our disposal for turning an instinctual conflict which is at the moment latent into one which is currently active. Obviously there are only two things that we can do. We can bring about situations in which the conflict does become currently active, or we can content ourselves with discussing it in the analysis and pointing out the possibility of its arising. The first of these two alternatives can be carried out in two ways: in reality, or in the transference - in either case by exposing the patient to a certain amount of real suffering through frustration and the damming up of libido. Now it is true that we already make use of a technique of this kind in our ordinary analytic procedure. What would otherwise be the meaning of the rule that analysis must be carried out 'in a state of frustration'? But this is a technique which we use in treating a conflict which is already currently active. We seek to bring this conflict to a head, to develop it to its highest pitch, in order to increase the instinctual force available for its solution. Analytic experience has taught us that the better is always the enemy of the good and that in every phase of the patient's recovery we have to fight against his inertia, which is ready to be content with an incomplete solution.

If, however, what we are aiming at is a prophylactic treatment of instinctual conflicts that are not currently active but merely potential, it will not be enough to regulate sufferings which are already present in the patient and which he cannot avoid. We should have to make up our minds to provoke fresh sufferings in him; and this we have hitherto quite rightly left to fate. We should receive admonitions from all sides against the presumption of vying with fate in subjecting poor human creatures to such cruel experiments. And what sort of experiments would they be? Could we, for purposes of prophylaxis, take the responsibility of destroying a satisfactory marriage, or causing a patient to give up a post upon which his livelihood depends? Fortunately, we never find ourselves in the position of having to consider whether such interventions in the patient's real life are justified; we do not possess the plenary powers which they would necessitate, and the subject of our therapeutic experiment would certainly refuse to co-operate in it. In practice, then, such a procedure is virtually excluded; but there are, besides, theoretical objections to it. For the work of analysis proceeds best if the patient's pathogenic experiences belong to the past, so that his ego can stand at a distance from them. In states of acute crisis analysis is to all intents and purposes unusable. The ego's whole interest is taken up by the painful reality and it withholds itself from analysis, which is attempting to go below the surface and uncover the influences of the past. To create a fresh conflict would thus only be to make the work of analysis longer and more difficult.
It is not, however, a preliminary labour in the sense that the whole of it must be completed before the next piece of work can be begun, as, for instance, is the case with house-building, where all the walls must be erected and all the windows inserted before the internal decoration of the rooms can be taken in hand. Every analyst knows that things happen differently in an analytic treatment and that there both kinds of work are carried on side by side, the one kind being always a little ahead and the other following upon it. The analyst finishes a piece of construction and communicates it to the subject of the analysis so that it may work upon him; he then constructs a further piece out of the fresh material pouring in upon him, deals with it in the same way and proceeds in this alternating fashion until the end. If, in accounts of analytic technique, so little is said about 'constructions', that is because 'interpretations' and their effects are spoken of instead. But I think that 'construction' is by far the more appropriate description. 'Interpretation' applies to something that one does to some single element of the material, such as an association or a parapraxis. But it is a 'construction' when one lays before the subject of the analysis a piece of his early history that he has forgotten, in some such way as this: 'Up to your nth year you regarded yourself as the sole and unlimited possessor of your mother; then came another baby and brought you grave disillusionment. Your mother left you for some time, and even after her reappearance she was never again devoted to you exclusively. Your feelings towards your mother became ambivalent, your father gained a new importance for you,' . . . and so on.
[1937d, 5052]
I shall not return any further to these examples, for I have to confess that they are not derived from any case in my experience but are inventions of mine. Most probably, too, they are bad inventions. I even regard such solutions of hysterical symptoms as impossible. But I was obliged to make up fictitious examples for several reasons, one of which I can state at once. The real examples are all incomparably more complicated: to relate a single one of them in detail would occupy the whole period of this lecture. The chain of associations always has more than two links; and the traumatic scenes do not form a simple row, like a string of pearls, but ramify and are interconnected like genealogical trees, so that in any new experience two or more earlier ones come into operation as memories. In short, giving an account of the resolution of a single symptom would in fact amount to the task of relating an entire case history.

[1896c, 411]

It seems to me really astonishing that hysterical symptoms can only arise with the cooperation of memories, especially when we reflect that, according to the unanimous accounts of the patients themselves, these memories did not come into their consciousness at the moment when the symptom first made its appearance. Here is much food for thought; but these problems must not distract us at this point from our discussion of the aetiology of hysteria. We must rather ask ourselves: where shall we get to if we follow the chains of associated memories which the analysis has uncovered? How far do they extend! Do they come anywhere to a natural end? Do they perhaps lead to experiences which are in some way alike, either in their content or the time of life at which they occur, so that we may discern in these universally similar factors the aetiology of hysteria of which we are in search?

[1896c, 412]

The knowledge I have so far gained already enables me to answer these questions. If we take a case which presents several symptoms, we arrive by means of the analysis, starting from each symptom, at a series of experiences the memories of which are linked together in association. To begin with, the chains of memories lead backwards separately from one another; but, as I have said, they ramify. From a single scene two or more memories are reached at the same time, and from these again side-chains proceed whose individual links may once more be associatively connected with links belonging to the main chain. Indeed, a comparison with the genealogical tree of a family whose members have also intermarried, is not at all a bad one. Other complications in the linkage of the chains arise from the circumstance that a single scene may be called up several times in the same chain, so that it has multiple relationships to a later scene, and exhibits both a direct connection with it and a connection established through intermediate links. In short, the concatenation is far from being a single one; and the fact that the scenes are uncovered in a reversed chronological order (a fact which justifies our comparison of the work with the excavation of a stratified ruined site) certainly contributes nothing to a more rapid understanding of what has taken place.

[1896c, 413]
It is easy now to describe our therapeutic aim. We try to restore the ego, to free it from its restrictions, and to give it back the command over the id which it has lost owing to its early repressions. It is for this one purpose that we carry out analysis, our whole technique is directed to this aim. We have to seek out the repressions which have been set up and to urge the ego to correct them with our help and to deal with conflicts better than by an attempt at flight. Since these repressions belong to the very early years of childhood, the work of analysis leads us, too, back to that period. Our path to these situations of conflict, which have for the most part been forgotten and which we try to revive in the patient's memory, is pointed out to us by his symptoms, dreams and free associations. These must, however, first be interpreted - translated - for, under the influence of the psychology of the id, they have assumed forms of expression that are strange to our comprehension. We may assume that whatever associations, thoughts and memories the patient is unable to communicate to us without internal struggles are in some way connected with the repressed material or are its derivatives. By encouraging the patient to disregard his resistances to telling us these things, we are educating his ego to overcome its inclination towards attempts at flight and to tolerate an approach to what is repressed. In the end, if the situation of the repression can be successfully reproduced in his memory, his compliance will be brilliantly rewarded. The whole difference between his age then and now works in his favour; and the thing from which his childish ego fled in terror will often seem to his adult and strengthened ego no more than child's play.

And it must be so, firstly, because analysis is entirely founded on complete candour. Financial circumstances, for instance, are discussed with equal detail and openness: things are said that are kept back from every fellow-citizen, even if he is not a competitor or a tax-collector. I will not dispute - indeed, I will myself insist with energy - that this obligation to candour puts a grave moral responsibility on the analyst as well. And it must be so, secondly, because factors from sexual life play an extremely important, a dominating, perhaps even a specific part among the causes and precipitating factors of neurotic illnesses. What else can analysis do but keep close to its subject-matter, to the material brought up by the patient? The analyst never entices his patient on to the ground of sex. He does not say to him in advance: 'We shall be dealing with the intimacies of your sexual life!' He allows him to begin what he has to say whenever he pleases, and quietly waits until the patient himself touches on sexual things. I used always to warn my pupils: 'Our opponents have told us that we shall come upon cases in which the factor of sex plays no part. Let us be careful not to introduce it into our analyses and so spoil our chance of finding such a case.' But so far none of us has had that good fortune.
I have described such groupings of similar memories into collections arranged in linear sequences (like a file of documents, a packet, etc.) as constituting 'themes'. These themes exhibit a second kind of arrangement. Each of them is - I can not express it in any other way - stratified concentrically round the pathogenic nucleus. It is not hard to say what produces this stratification, what diminishing or increasing magnitude is the basis of this arrangement. The contents of each particular stratum are characterized by an equal degree of resistance, and that degree increases in proportion as the strata are nearer to the nucleus. Thus there are zones within which there is all equal degree of modification of consciousness, and the different themes extend across these zones. The most peripheral strata contain the memories (or files), which, belonging to different themes, are easily remembered and have always been clearly conscious. The deeper we go the more difficult it becomes for the emerging memories to be recognized, till near the nucleus we come upon memories which the patient disavows even in reproducing them. [1895d, 254]

I must dwell for a moment longer on this last simile in order to emphasize a point in which it does not do justice to the characteristics of the subject of the comparison. The logical chain corresponds not only to a zig-zag, twisted line, but rather to a ramifying system of lines and more particularly to a converging one. It contains nodal points at which two or more threads meet and thereafter proceed as one; and as a rule several threads which run independently, or which are connected at various points by side-paths, debouch into the nucleus. To put this in other words, it is very remarkable how often a symptom is determined in several ways, is 'overdetermined'. [1895d, 255]

My attempt to demonstrate the organization of the pathogenic psychical material will be complete when I have introduced one more complication. For it can happen that there is more than one nucleus in the pathogenic material - if, for instance, we have to analyse a second outbreak of hysteria which has an aetiology of its own but is nevertheless connected with a first outbreak of acute hysteria which was got over years earlier. It is easy to imagine, if this is so, what additions there must be to the strata and paths of thought in order to establish a connection between the two pathogenic nuclei. [1895d, 255]

I shall now make one or two further remarks on the picture we have just arrived at of the organization of the pathogenic material. We have said that this material behaves like a foreign body, and that the treatment, too, works like the removal of a foreign body from the living tissue. We are now in a position to see where this comparison fails. A foreign body does not enter into any relation with the layers of tissue that surround it, although it modifies them and necessitates a reactive inflammation in them. Our pathogenic psychical group, on the other hand, does not admit of being cleanly extirpated from the ego. Its external strata pass over in every direction into portions of the normal ego; and, indeed, they belong to the latter just as much as to the pathogenic organization. In analysis the boundary between the two is fixed purely conventionally, now at one point, now at another, and in some places it cannot be laid down at all. The interior layers of the pathogenic organization are increasingly alien to the ego, but once more without there being any visible boundary at which the pathogenic material begins. In fact the pathogenic organization does not behave like a foreign body, but far more like an infiltrate. In this simile the resistance must be regarded as what is infiltrating. Nor does the treatment consist in extirpating something - psychotherapy is not able to do this for the present - but in causing the resistance to melt and in thus enabling the circulation to make its way into a region that has hitherto been cut off. [1895d, 255]
If it were possible, after the case had been completely cleared up, to demonstrate the pathogenic material to a third person in what we now know is its complicated and multidimensional organization, we should rightly be asked how a camel like this got through the eye of the needle. For there is some justification for speaking of the 'defile' of consciousness. The term gains meaning and liveliness for a physician who carries out an analysis like this. Only a single memory at a time can enter ego-consciousness. A patient who is occupied in working through such a memory sees nothing of what is pushing after it and forgets what has already pushed its way through. If there are difficulties in the way of mastering this single pathogenic memory - as, for instance, if the patient does not relax his resistance against it, if he tries to repress or mutilate it - then the defile is, so to speak, blocked. The work is at a standstill, nothing more can appear, and the single memory which is in process of breaking through remains in front of the patient until he has taken it up into the breadth of his ego. The whole spatially-extended mass of psychogenic material is in this way drawn through a narrow cleft and thus arrives in consciousness cut up, as it were, into pieces or strips. It is the psychotherapist's business to put these together once more into the organization which he presumes to have existed. Anyone who has a craving for further similes may think at this point of a Chinese puzzle.

If we are faced with starting such an analysis, in which we have reason to expect an organization of pathogenic material like this, we shall be assisted by what experience has taught us, namely that it is quite hopeless to try to penetrate directly to the nucleus of the pathogenic organization. Even if we ourselves could guess it, the patient would not know what to do with the explanation offered to him and would not be psychologically changed by it.

Advances are brought about, as we know, by overcoming resistance in the manner already indicated. But before this, we have as a rule another task to perform. We must get hold of a piece of the logical thread, by whose guidance alone we may hope to penetrate to the interior. We cannot expect that the free communications made by the patient, the material from the most superficial strata, will make it easy for the analyst to recognize at what points the path leads into the depths or where he is to find the starting-points of the connections of thought of which he is in search. On the contrary, this is precisely what is carefully concealed; the account given by the patient sounds as if it were complete and self-contained. It is at first as though we were standing before a wall which shut out every prospect and prevents us from having any idea whether there is anything behind it, and if so, what.

In this way, then, by detecting lacunas in the patient's first description, lacunas which are often covered by 'false connections', we get hold of a piece of the logical thread at the periphery, and from this point on we clear a further path by the pressure technique.
It is easy to imagine how complicated a work of this kind can become. We force our way into the internal strata, overcoming resistances all the time; we get to know the themes accumulated in one of these strata and the threads running through it, and we experiment how far we can advance with our present means and the knowledge we have acquired; we obtain preliminary information about the contents of the next strata by means of the pressure technique; we drop threads and pick them up again; we follow them as far as nodal points; we are constantly making up arrears; and every time that we pursue a file of memories we are led to some side-path, which nevertheless eventually joins up again. By this method we at last reach a point at which we can stop working in strata and can penetrate by a main path straight to the nucleus of the pathogenic organization. With this the struggle is won, though not yet ended. We must go back and take up the other threads and exhaust the material. But now the patient helps us energetically. His resistance is for the most part broken.

[1895d, 260]

Another observation, which is constantly repeated, relates to the patient's spontaneous reproductions. It may be asserted that every single reminiscence which emerges during an analysis of this kind has significance. An intrusion of irrelevant mnemic images (which happen in some way or other to be associated with the important ones) in fact never occurs. An exception which does not contradict this rule may be postulated for memories which, unimportant in themselves, are nevertheless indispensable as a bridge, in the sense that the association between two important memories can only be made through them.

[1895d, 260]

Among the tasks presented by analysis is that of getting rid of symptoms which are capable of increasing in intensity or of returning: pains, symptoms (such as vomiting) which are due to stimuli, sensations or contractures. While we are working at one of these symptoms we come across the interesting and not undesired phenomenon of 'joining in the conversation'. The problematical symptom re-appears, or appears with greater intensity, as soon as we reach the region of the pathogenic organization which contains the symptom's aetiology, and thenceforward it accompanies the work with characteristic oscillations which are instructive to the physician. The intensity of the symptom (let us take for instance a desire to vomit) increases the deeper we penetrate into one of the relevant pathogenic memories; it reaches its climax shortly before the patient gives utterance to that memory; and when he has finished doing so it suddenly diminishes or even vanishes completely for a time. If, owing to resistance, the patient delays his telling for a long time, the tension of the sensation - of the desire to vomit - becomes unbearable, and if we cannot force him to speak he actually begins to vomit. In this way we obtain a plastic impression of the fact that 'vomiting' takes the place of a psychical act (in this instance, the act of utterance), exactly as the conversion theory of hysteria maintains.

[1895d, 261]
The phenomenon of hysterical symptoms joining in the conversation during the analysis involves a practical drawback, to which we ought to be able to reconcile the patient. It is quite impossible to effect an analysis of a symptom at a single stretch or to distribute the intervals in our work so that they fit in precisely with pauses in the process of dealing with the symptom. On the contrary, interruptions which are imperatively prescribed by incidental circumstances in the treatment, such as the lateness of the hour, often occur at the most inconvenient points, just as one may be approaching a decision or just as a new topic emerges. Every newspaper reader suffers from the same drawback in reading the daily instalment of his serial story, when, immediately after the heroine’s decisive speech or after the shot has rung out, he comes upon the words: ‘To be continued.’ In our own case the topic that has been raised but not dealt with, the symptom that has become temporarily intensified and has not yet been explained, persists in the patient’s mind and may perhaps be more troublesome to him than it has otherwise been. He will simply have to make the best of this; there is no other way of arranging things. There are patients who, in the course of an analysis, simply cannot get free of a topic that has once been raised and who are obsessed by it in the interval between two treatments; since by themselves they cannot take any steps towards getting rid of it, they suffer more, to begin with, than they did before the treatment. But even such patients learn in the end to wait for the doctor and to shift all the interest that they feel in getting rid of the pathogenic material on to the hours of treatment, after which they begin to feel freer in the intervals.

The ideas which are derived from the greatest depth and which form the nucleus of the pathogenic organization are also those which are acknowledged as memories by the patient with greatest difficulty. Even when everything is finished and the patients have been overborne by the force of logic and have been convinced by the therapeutic effect accompanying the emergence of precisely these ideas - when, I say, the patients themselves accept the fact that they thought this or that, they often add: ‘But I can’t remember having thought it.’ It is easy to come to terms with them by telling them that the thoughts were unconscious. But how is this state of affairs to be fitted into our own psychological views? Are we to disregard this withholding of recognition on the part of patients, when, now that the work is finished, there is no longer any motive for their doing so? Or are we to suppose that we are really dealing with thoughts which never came about, which merely had a possibility of existing, so that the treatment would lie in the accomplishment of a psychical act which did not take place at the time? It is clearly impossible to say anything about this - that is, about the state which the pathogenic material was in before the analysis - until we have arrived at a thorough clarification of our basic psychological views, especially on the nature of consciousness. It remains, I think, a fact deserving serious consideration that in our analyses we can follow a train of thought from the conscious into the unconscious (i.e. into something that is absolutely not recognized as a memory), that we can trace it from there for some distance through consciousness once more and that we can see it terminate in the unconscious again, without this alternation of ‘psychical illumination’ making any change in the train of thought itself, in its logical consistency and in the interconnection between its various parts. Once this train of thought was before me as a whole I should not be able to guess which part of it was recognized by the patient as a memory and which was not. I only, as it were, see the peaks of the train of thought dipping down into the unconscious - the reverse of what has been asserted of our normal psychical processes.
The first of these modern dramas is *Hamlet*. It has as its subject the way in which a man who has so far been normal becomes neurotic owing to the peculiar nature of the task by which he is faced, a man, that is, in whom an impulse that has hitherto been successfully suppressed endeavours to make its way into action. *Hamlet* is distinguished by three characteristics which seem important in connection with our present discussion. (1) The hero is not psychopathic, but only becomes psychopathic in the course of the action of the play. (2) The repressed impulse is one of those which are similarly repressed in all of us, and the repression of which is part and parcel of the foundations of our personal evolution. It is this repression which is shaken up by the situation in the play. As a result of these two characteristics it is easy for us to recognize ourselves in the hero: we are susceptible to the same conflict as he is, since ‘a person who does not lose his reason under certain conditions can have no reason to lose’. (3) It appears as a necessary precondition of this form of art that the impulse that is struggling into consciousness, however clearly it is recognizable, is never given a definite name; so that in the spectator too the process is carried through with his attention averted, and he is in the grip of his emotions instead of taking stock of what is happening. A certain amount of resistance is no doubt saved in this way, just as, in an analytic treatment, we find derivatives of the repressed material reaching consciousness, owing to a lower resistance, while the repressed material itself is unable to do so. After all, the conflict in *Hamlet* is so effectively concealed that it was left to me to unearth it.

[1942a [1905], 1611]

To shorten analytic treatment is a justifiable wish, and its fulfilment, as we shall learn, is being attempted along various lines. Unfortunately, it is opposed by a very important factor, namely, the slowness with which deep-going changes in the mind are accomplished - in the last resort, no doubt, the ‘timelessness’ of our unconscious processes. When patients are faced with the difficulty of the great expenditure of time required for analysis they not infrequently manage to propose a way out of it. They divide up their ailments and describe some as unbearable, and others as secondary, and then say: ‘If only you will relieve me from this one (for instance, a headache or a particular fear) I can deal with the other one on my own in my ordinary life.’ In doing this, however, they over-estimate the selective power of analysis. The analyst is certainly able to do a great deal, but he cannot determine beforehand exactly what results he will effect. He sets in motion a process, that of the resolving of existing repressions. He can supervise this process, further it, remove obstacles in its way, and he can undoubtedly vitiate much of it. But on the whole, once begun, it goes its own way and does not allow either the direction it takes or the order in which it picks up its points to be prescribed for it. The analyst's power over the symptoms of the disease may thus be compared to male sexual potency. A man can, it is true, beget a whole child, but even the strongest man cannot create in the female organism a head alone or an arm or a leg; he cannot even prescribe the child's sex. He, too, only sets in motion a highly complicated process, determined by events in the remote past, which ends with the severance of the child from its mother. A neurosis as well has the character of an organism. Its component manifestations are not independent of one another; they condition one another and give one another mutual support. A person suffers from one neurosis only, never from several which have accidentally met together in a single individual. The patient freed, according to his wish, from his one unendurable symptom might easily find that a symptom which had previously been negligible had now increased and grown unendurable. The analyst who wishes the treatment to owe its success as little as possible to its elements of suggestion (i.e. to the transference) will do well to refrain from making use of even the trace of selective influence upon the results of the therapy which may perhaps be open to him. The patients who are bound to be most welcome to him are those who ask him to give them complete health, in so far as that is attainable, and who place as much time at his disposal as is necessary for the process of recovery. Such favourable conditions as these are, of course, to be looked for in only a few cases.

[1913c, 2483]
The situation takes a favourable turn if the analysis of a corroborative dream of this sort, which "tags along behind", is immediately followed by feelings of remembering what has hitherto been forgotten. But even then the sceptic can fall back upon an assertion that the recollections are illusory. Moreover, such feelings are for the most part absent. The repressed material is only allowed through bit by bit; and every lack of completeness inhibits or delays the forming of a sense of conviction. Furthermore, what we are dealing with may not be the reproduction of a real and forgotten event but the bringing forward of an unconscious phantasy, about which no feeling of memory is ever to be expected, though the possibility may sometimes remain of a sense of subjective conviction.

[1923c, 4036]
To shorten analytic treatment is a justifiable wish, and its fulfilment, as we shall learn, is being attempted along various lines. Unfortunately, it is opposed by a very important factor, namely, the slowness with which deep-going changes in the mind are accomplished - in the last resort, no doubt, the 'timelessness' of our unconscious processes. When patients are faced with the difficulty of the great expenditure of time required for analysis they not infrequently manage to propose a way out of it. They divide up their ailments and describe some as unbearable, and others as secondary, and then say: 'If only you will relieve me from this one (for instance, a headache or a particular fear) I can deal with the other one on my own in my ordinary life.' Such favourable conditions as these are, of course, to be looked for in only a few cases.

[1913c, 2483]
If a pathogenic memory or a pathogenic connection which had formerly been withdrawn from
the ego-consciousness is uncovered by the work of the analysis and introduced into the ego, we
find that the psychical personality which is thus enriched has various ways of expressing itself
with regard to what it has acquired. It happens particularly often that, after we have laboriously
forced some piece of knowledge on a patient, he will declare: 'I've always known that, I could
have told you that before.' Those with some degree of insight recognize afterwards that this is a
piece of self-deception and blame themselves for being ungrateful. Apart from this, the attitude
adopted by the ego to its new acquisition depends in general on the stratum of analysis from
which that acquisition originates. Things that belong to the external strata are recognized
without difficulty; they had, indeed, always remained in the ego's possession, and the only
novelty to the ego is their connection with the deeper strata of pathological material. Things that
are brought to light from these deeper strata are also recognized and acknowledged, but often
only after considerable hesitations and doubts. Visual memory-images are of course more
difficult to disavow than the memory-traces of mere trains of thought. Not at all infrequently the
patient begins by saying: 'It's possible that I thought this, but I can't remember having done so.'
And it is not until he has been familiar with the hypothesis for some time that he comes to
recognize it as well; he remembers - and confirms the fact, too, by subsidiary links - that he
really did once have the thought. I make it a rule, however, during the analysis to keep my
estimate of the reminiscence that comes up independent of the patient's acknowledgement of it.
I shall never be tired of repeating that we are bound to accept whatever our procedure brings to
light. If there is anything in it that is not genuine or correct, the context will later on tell us to
reject it. But I may say in passing that I have scarcely ever had occasion to disavow
subsequently a reminiscence that has been provisionally accepted. Whatever has emerged has,
in spite of the most deceptive appearance of being a glaring contradiction, nevertheless turned
out to be correct.

[1895d, 264]

The ideas which are derived from the greatest depth and which form the nucleus of the
pathogenic organization are also those which are acknowledged as memories by the patient
with greatest difficulty. Even when everything is finished and the patients have been overborne
by the force of logic and have been convinced by the therapeutic effect accompanying the
emergence of precisely these ideas - when, I say, the patients themselves accept the fact that
they thought this or that, they often add: 'But I can't remember having thought it.' It is easy to
come to terms with them by telling them that the thoughts were
unconscious. But how is this
state of affairs to be fitted into our own psychological views? Are we to disregard this
withholding of recognition on the part of patients, when, now that the work is finished, there is
no longer any motive for their doing so? Or are we to suppose that we are really dealing with
thoughts which never came about, which merely had a possibility of existing, so that the
treatment would lie in the accomplishment of a psychical act which did not take place at the
time? It is clearly impossible to say anything about this - that is, about the state which the
pathogenic material was in before the analysis - until we have arrived at a thorough clarification
of our basic psychological views, especially on the nature of consciousness. It remains, I think,
a fact deserving serious consideration that in our analyses we can follow a train of thought from
the conscious into the unconscious (i.e. into something that is absolutely not recognized as a
memory), that we can trace it from there for some distance through consciousness once more
and that we can see it terminate in the unconscious again, without this alternation of 'psychical
illumination' making any change in the train of thought itself, in its logical consistency and in the
interconnection between its various parts. Once this train of thought was before me as a whole I
should not be able to guess which part of it was recognized by the patient as a memory and
which was not. I only, as it were, see the peaks of the train of thought dipping down into the
unconscious - the reverse of what has been asserted of our normal psychical processes.

[1895d, 265]
We showed on an earlier occasion that the resistance that has to be overcome in analysis proceeds from the ego, which clings to its anticathexes. It is hard for the ego to direct its attention to perceptions and ideas which it has up till now made a rule of avoiding, or to acknowledge as belonging to itself impulses that are the complete opposite of those which it knows as its own. Our fight against resistance in analysis is based upon this view of the facts. If the resistance is itself unconscious, as so often happens owing to its connection with the repressed material, we make it conscious. If it is conscious, or when it has become conscious, we bring forward logical arguments against it; we promise the ego rewards and advantages if it will give up its resistance. There can be no doubt or mistake about the existence of this resistance on the part of the ego. But we have to ask ourselves whether it covers the whole state of affairs in analysis. For we find that even after the ego has decided to relinquish its resistances it still has difficulty in undoing the repressions; and we have called the period of strenuous effort which follows after its praiseworthy decision, the phase of 'working-through'. The dynamic factor which makes a working-through of this kind necessary and comprehensible is not far to seek. It must be that after the ego's resistance has been removed the power of the compulsion to repeat - the attraction exerted by the unconscious prototype upon the repressed instinctual process - has still to be overcome. There is nothing to be said against describing this factor as the *resistance of the unconscious*. There is no need to be discouraged by these emendations. They are to be welcomed if they add something to our knowledge, and they are no disgrace to us so long as they enrich rather than invalidate our earlier views - by limiting some statement, perhaps, that was too general or by enlarging some idea that was too narrowly formulated.

[1926d, 4312]
This brings us to the technical errors which are to be seen in the doctor's procedure in this alleged case. It is a long superseded idea, and one derived from superficial appearances, that the patient suffers from a sort of ignorance, and that if one removes this ignorance by giving him information (about the causal connection of his illness with his life, about his experiences in childhood, and so on) he is bound to recover. The pathological factor is not his ignorance in itself, but the root of this ignorance in his inner resistances; it was they that first called this ignorance into being, and they still maintain it now. The task of the treatment lies in combating these resistances. Informing the patient of what he does not know because he has repressed it is only one of the necessary preliminaries to the treatment. If knowledge about the unconscious were as important for the patient as people inexperienced in psycho-analysis imagine, listening to lectures or reading books would be enough to cure him. Such measures, however, have as much influence on the symptoms of nervous illness as a distribution of menu-cards in a time of famine has upon hunger. The analogy goes even further than its immediate application; for informing the patient of his unconscious regularly results in an intensification of the conflict in him and an exacerbation of his troubles.

Neither I myself nor my friends and co-workers find it agreeable to claim a monopoly in this way in the use of a medical technique. But in face of the dangers to patients and to the cause of psycho-analysis which are inherent in the practice that is to be foreseen of a 'wild' psycho-analysis, we have had no other choice. In the spring of 1910 we founded an International Psycho-Analytical Association, to which its members declare their adherence by the publication of their names, in order to be able to repudiate responsibility for what is done by those who do not belong to us and yet call their medical procedure 'psycho-analysis'. For as a matter of fact 'wild' analysts of this kind do more harm to the cause of psycho-analysis than to individual patients. I have often found that a clumsy procedure like this, even if at first it produced an exacerbation of the patient's condition, led to a recovery in the end. Not always but still often. When he has abused the physician enough and feels far enough away from his influence, his symptoms give way, or he decides to take some step which leads along the path to recovery. The final improvement then comes about 'of itself', or is ascribed to some totally indifferent treatment by some other doctor to whom the patient has later turned. In the case of the lady whose complaint against her physician we have heard, I should say that, despite everything, the 'wild' psycho-analyst did more for her than some highly respected authority who might have told her she was suffering from a 'vasomotor neurosis'. He forced her attention to the real cause of her trouble, or in that direction, and in spite of all her opposition this intervention of his cannot be without some favourable results. But he has done himself harm and helped to intensify the prejudices which patients feel, owing to their natural affective resistances, against the methods of psycho-analysis. And this can be avoided.
I have now led you into the region in which the next advances in the work of analysis are to be expected. Since we have ventured to operate with the concept of ego-libido the narcissistic neuroses have become accessible to us; the task before us is to arrive at a dynamic elucidation of these disorders and at the same time to complete our knowledge of mental life by coming to understand the ego. The ego-psychology after which we are seeking must not be based on the data of our self-perceptions but (as in the case of the libido) on the analysis of disturbances and disruptions of the ego. It is likely that we shall have a low opinion of our present knowledge of the vicissitudes of the libido, which we have gained from a study of the transference neuroses, when we have achieved this greater task. But hitherto we have not made much progress with it. The narcissistic neuroses can scarcely be attacked with the technique that has served us with the transference neuroses. You will soon learn why. What always happens with them is that, after proceeding for a short distance, we come up against a wall which brings us to a stop. Even with the transference neuroses, as you know, we met with barriers of resistance, but we were able to demolish them bit by bit. In the narcissistic neuroses the resistance is unconquerable; at the most, we are able to cast an inquisitive glance over the top of the wall and spy out what is going on on the other side of it. Our technical methods must accordingly be replaced by others; and we do not know yet whether we shall succeed in finding substitute. Nevertheless, we have no lack of material with these patients either. They make a large number of remarks, even if they do not answer our questions, and for the time being it is our business to interpret these remarks with the help of the understanding we have gained from the symptoms of the transference neuroses. The agreement is great enough to guarantee us some initial advantage. It remains to be seen how far this technique will take us.

In the Oedipus complex the libido was seen to be attached to the image of the parental figures. But earlier there was a period in which there were no such objects. There followed from this fact the concept (of fundamental importance for the libido theory) of a state in which the subject's libido filled his own ego and had that for its object. This state could be called narcissism or self-love. A moment's reflection showed that this state never completely ceases. All through the subject's life his ego remains the great reservoir of his libido, from which object-cathexes are sent out and into which the libido can stream back again from the objects. Thus narcissistic libido is constantly being transformed into object-libido, and vice versa. An excellent instance of the length to which this transformation can go is afforded by the state of being in love, whether in a sexual or sublimated manner, which goes so far as involving a sacrifice of the self. Whereas hitherto in considering the process of repression attention had only been paid to what was repressed, these ideas made it possible to form a correct estimate of the repressing forces too. It had been said that repression was set in action by the instincts of self-preservation operating in the ego (the 'ego-instincts') and that it was brought to bear upon the libidinal instincts. But since the instincts of self-preservation were now recognized as also being of a libidinal nature, as being narcissistic libido, the process of repression was seen to be a process occurring within the libido itself; narcissistic libido was opposed to object-libido, the interest of self-preservation was defending itself against the demands of object-love, and therefore against the demands of sexuality in the narrower sense as well.

[1916-1917, 3467]

[1925d, 4231]
At the moment, however, we are not concerned with the pathogenic role of the defensive mechanisms. What we are trying to discover is what influence the alteration of the ego which corresponds to them has upon our therapeutic efforts. The material for an answer to this question is given in the volume by Anna Freud to which I have already referred. The essential point is that the patient repeats these modes of reaction during the work of analysis as well, that he produces them before our eyes, as it were. In fact, it is only in this way that we get to know them. This does not mean that they make analysis impossible. On the contrary, they constitute half of our analytic task. The other half, the one which was first tackled by analysis in its early days, is the uncovering of what is hidden in the id. During the treatment our therapeutic work is constantly swinging backwards and forwards like a pendulum between a piece of id-analysis and a piece of ego-analysis. In the one case we want to make something from the id conscious, in the other we want to correct something in the ego. The crux of the matter is that the defensive mechanisms directed against former danger recur in the treatment as resistances against recovery. It follows from this that the ego treats recovery itself as a new danger.

[1937c, 5034]

The therapeutic effect depends on making conscious what is repressed, in the widest sense of the word, in the id. We prepare the way for this making conscious by interpretations and constructions, but we have interpreted only for ourselves not for the patient so long as the ego holds on to its earlier defences and does not give up its resistances. Now these resistances, although they belong to the ego, are nevertheless unconscious and in some sense separated off within the ego. The analyst recognizes them more easily than he does the hidden material in the id. One might suppose that it would be sufficient to treat them like portions of the id and, by making them conscious, bring them into connection with the rest of the ego. In this way, we should suppose, one half of the task of analysis would be accomplished; we should not reckon on meeting with a resistance against the uncovering of resistances. But what happens is this. During the work on the resistances the ego withdraws - with a greater or less degree of seriousness - from the agreement on which the analytic situation is founded. The ego ceases to support our efforts at uncovering the id; it opposes them, disobeys the fundamental rule of analysis, and allows no further derivatives of the repressed to emerge. We cannot expect the patient to have a strong conviction of the curative power of analysis. He may have brought along with him a certain amount of confidence in his analyst, which will be strengthened to an effective point by the factors of the positive transference which will be aroused in him. Under the influence of the unpleasurable impulses which he feels as a result of the fresh activation of his defensive conflicts, negative transferences may now gain the upper hand and completely annul the analytic situation. The patient now regards the analyst as no more than a stranger who is making disagreeable demands on him, and he behaves towards him exactly like a child who does not like the stranger and does not believe anything he says. If the analyst tries to explain to the patient one of the distortions made by him for the purposes of defence, and to correct it, he finds him incomprehending and inaccessible to sound arguments. Thus we see that there is a resistance against the uncovering of resistances, and the defensive mechanisms really do deserve the name which we gave them originally, before they had been more closely examined. They are resistances not only to the making conscious of contents of the id, but also to the analysis as a whole, and thus to recovery.

[1937c, 5034]
In the psychotherapeutic procedure which I employ for resolving and removing neurotic symptoms I am very often faced with the task of discovering, from the patient's apparently casual utterances and associations, a thought-content which is at pains to remain concealed but which cannot nevertheless avoid unintentionally betraying its existence in a whole variety of ways. Slips of the tongue often perform a most valuable service here, as I could show by some highly convincing and at the same time very singular examples. Thus, for instance, a patient will be speaking of his aunt and, without noticing the slip, will consistently call her 'my mother'; or another will refer to her husband as her 'brother'. In this way they draw my attention to the fact that they have 'identified' these persons with one another - that they have put them into a series which implies a recurrence of the same type in their emotional life. To give another example: a young man of twenty introduced himself to me during my consulting hours in these words: 'I am the father of So-and-so who came to you for treatment. I beg your pardon, I meant to say I am his brother: he is four years older than I am.' I inferred that he intended this slip to express the view that, like his brother, he had fallen ill through the fault of his father; that, like his brother, he wished to be cured; but that his father was the one who most needed to be cured. - At other times an arrangement of words that sounds unusual, or an expression that seems forced, is enough to reveal that a repressed thought is participating in the patient's remarks, which had a different end in view.

If the theory of analytic technique is gone into, it becomes evident that transference is an inevitable necessity. Practical experience, at all events, shows conclusively that there is no means of avoiding it, and that this latest creation of the disease must be combated like all the earlier ones. This happens, however, to be by far the hardest part of the whole task. It is easy to learn how to interpret dreams, to extract from the patient's associations his unconscious thoughts and memories, and to practise similar explanatory arts: for these the patient himself will always provide the text. Transference is the one thing the presence of which has to be detected almost without assistance and with only the slightest clues to go upon, while at the same time the risk of making arbitrary inferences has to be avoided. Nevertheless, transference cannot be evaded, since use is made of it in setting up all the obstacles that make the material inaccessible to treatment, and since it is only after the transference has been resolved that a patient arrives at a sense of conviction of the validity of the connections which have been constructed during the analysis.

Freud has developed on this basis an art of interpretation which takes on the task of, as it were, extracting the pure metal of the repressed thoughts from the ore of the unintentional ideas. This work of interpretation is applied not only to the patient's ideas but also to his dreams, which open up the most direct approach to a knowledge of the unconscious, to his unintentional as well as to his purposeless actions (symptomatic acts) and to the blunders he makes in everyday life (slips of the tongue, bungled actions, and so on). The details of this technique of interpretation or translation have not yet been published by Freud. According to indications he has given, they comprise a number of rules, reached empirically, of how the unconscious material may be reconstructed from the associations, directions on how to know what it means when the patient's ideas cease to flow, and experiences of the most important typical resistances that arise in the course of such treatments. A bulky volume called The Interpretation of Dreams, published by Freud in 1900, may be regarded as the forerunner of an initiation into his technique.
The task of the therapist, however, is the same as that of the examining magistrate. We have to uncover the hidden psychical material; and in order to do this we have invented a number of detective devices, some of which it seems that you gentlemen of the law are now about to copy from us.

[1906c, 1892]

We may justly claim that, in principle, techniques of the kind I have described enable us to make the patient conscious of what is repressed in him - of his secret - and thus to remove the psychological causation of the symptoms from which he is suffering. But before you draw any conclusions from these successful results as to the possibilities of your own work, we will examine some points of difference between the psychological situations in the two cases.

[1906c, 1895]

Working over the ideas that occur to patients when they submit to the main rule of psycho-analysis is not our only technical method of discovering the unconscious. The same purpose is served by two other procedures: the interpretation of patients' dreams and the exploitation of their faulty and haphazard actions.

[1910a, 2220]

If you will now bring together the means we possess for uncovering what is concealed, forgotten and repressed in the mind (the study of the ideas occurring to patients under free association, of their dreams and of their faulty and symptomatic actions), and if you will add to these the exploitation of certain other phenomena which occur during psycho-analytic treatment and on which I shall have a few remarks to make later under the heading of 'transference' - if you bear all these in mind, you will agree with me in concluding that our technique is already efficient enough to fulfil its task, to bring the pathogenic psychical material into consciousness and so to get rid of the ailments that have been brought about by the formation of substitutive symptoms. And if, in the course of our therapeutic endeavours, we extend and deepen our knowledge of the human mind both in health and sickness, that can, of course, only be regarded as a peculiar attraction in our work.

[1910a, 2225]
You may have formed an impression that the technique through whose armoury I have just conducted you is particularly difficult. In my opinion that technique is entirely in conformity with the material with which it has to deal. But this much at least is clear: it is not a self-evident one and it must be learnt just as the techniques of histology or surgery must be learnt. You will perhaps be surprised to hear that in Europe we have heard a large number of judgements on psycho-analysis from people who know nothing of this technique and do not employ it; and who go on to demand with apparent scorn that we shall prove to them the correctness of our findings. Among these adversaries there are no doubt some to whom a scientific mode of thought is not as a rule alien, who, for instance, would not reject the results of a microscopic examination because it could not be confirmed on the anatomical preparation with the naked eye, but who would first form a judgement on the matter themselves with the help of a microscope. But, where psycho-analysis is concerned, the prospects of recognition are in truth less favourable. Psycho-analysis is seeking to bring to conscious recognition the things in mental life which are repressed; and everyone who forms a judgement on it is himself a human being, who possesses similar repressions and may perhaps be maintaining them with difficulty. They are therefore bound to call up the same resistance in him as in our patients; and that resistance finds it easy to disguise itself is an intellectual rejection and to bring up arguments like those which we ward off in our patients by means of the fundamental rule of psycho-analysis. We often become aware in our opponents, just as we do in our patients, that their power of judgement is very noticeably influenced affectively in the sense of being diminished. The arrogance of consciousness (in rejecting dreams with such contempt, for instance) is one of the most powerful of the devices with which we are provided as a universal protection against the incursion of unconscious complexes. That is why it is so hard to convince people of the reality of the unconscious and to teach them to recognize something new which is in contradiction to their conscious knowledge.

LADIES AND GENTLEMEN, - You will want to know now what we have found out about the pathogenic complexes and repressed wishful impulses of neurotics with the help of the technical methods I have described.

If, then, Leonardo's story about the vulture that visited him in his cradle is only a phantasy from a later period, one might suppose it could hardly be worth while spending much time on it. One might be satisfied with explaining it on the basis of his inclination, of which he makes no secret, to regard his preoccupation with the flight of birds as pre-ordained by destiny. Yet in underrating this story one would be committing just as great an injustice as if one were carelessly to reject the body of legends, traditions and interpretations found in a nation's early history. In spite of all the distortions and misunderstandings, they still represent the reality of the past: they are what a people forms out of the experience of its early days and under the dominance of motives that were once powerful and still operate to-day; and if it were only possible, by a knowledge of all the forces at work, to undo these distortions, there would be no difficulty in disclosing the historical truth lying behind the legendary material. The same holds good for the childhood memories or phantasies of an individual. What someone thinks he remembers from his childhood is not a matter of indifference; as a rule the residual memories - which he himself does not understand - cloak priceless pieces of evidence about the most important features in his mental development.¹ As we now possess in the techniques of psycho-analysis excellent methods for helping us to bring this concealed material to light, we may venture to fill in the gap in Leonardo's life story by analysing his childhood phantasy. And if in doing so we remain dissatisfied with the degree of certainty which we achieve, we shall have to console ourselves with the reflection that so many other studies of this great and enigmatic man have met with no better fate.

[1910a, 2226]

[1910a, 2227]

[1910c, 2261]
Psycho-analysis finds as a rule no credence among laymen for assertions such as these. They reject them as calumnies which are confuted by conscious experience, and they adroitly overlook the faint indications by which even the unconscious is apt to betray itself to consciousness. It is therefore relevant to point out that many thinkers who could not have been influenced by psycho-analysis have quite definitely accused our unspoken thoughts of being ready, heedless of the prohibition against murder, to get rid of anything which stands in our way. From many examples of this I will choose one that has become famous:

[1915b, 3090]

From the standpoint of the libido theory, too, we may say a last word on dreams. A neurotic’s dreams help us, like his parapraxes and his free associations to them, to discover the sense of his symptoms and to reveal the way in which his libido is allocated. They show us, in the form of a wish-fulfilment, what wishful impulses have been subjected to repression and to what objects the libido withdrawn from the ego has become attached. For this reason the interpretation of dreams plays a large part in a psycho-analytic treatment, and in some cases it is over long periods the most important instrument of our work. We already know that the state of sleep in itself leads to a certain relaxation of the repressions. A repressed impulse, owing to this reduction in the pressure weighing down upon it, becomes able to express itself far more clearly in a dream than it can be allowed to be expressed by a symptom during the day. The study of dreams therefore becomes the most convenient means of access to a knowledge of the repressed unconscious, of which the libido withdrawn from the ego forms a part.

[1916-1917, 3496]

The method by which we strengthen the weakened ego has as a starting-point an extending of its self-knowledge. That is not, of course, the whole story but it is a first step. The loss of such knowledge signifies for the ego a surrender of power and influence; it is the first tangible sign that it is being hemmed in and hampered by the demands of the id and the super-ego. Accordingly, the first part of the help we have to offer is intellectual work on our side and encouragement to the patient to collaborate in it. This first kind of activity, as we know, is intended to pave the way to another, more difficult, task. We shall not lose sight of the dynamic element in this task, even during its preliminary stage. We gather the material for our work from a variety of sources - from what is conveyed to us by the information given us by the patient and by his free associations, from what he shows us in his transferences, from what we arrive at by interpreting his dreams and from what he betrays by his slips or parapraxes. All this material helps us to make constructions about what happened to him and has been forgotten as well as about what is happening in him now without his understanding it. But in all this we never fail to make a strict distinction between our knowledge and his knowledge. We avoid telling him at once things that we have often discovered at an early stage, and we avoid telling him the whole of what we think we have discovered. We reflect carefully over when we shall impart the knowledge of one of our constructions to him and we wait for what seems to us the suitable moment - which it is not always easy to decide. As a rule we put off telling him of a construction or explanation till he himself has so nearly arrived at it that only a single step remains to be taken, though that step is in fact the decisive synthesis. If we proceeded in another way and overwhelmed him with our interpretations before he was prepared for them, our information would either produce no effect or it would provoke a violent outbreak of resistance which would make the progress of our work more difficult or might even threaten to stop it altogether. But if we have prepared everything properly, it often happens that the patient will at once confirm our construction and himself recollect the internal or external event which he had forgotten. The more exactly the construction coincides with the details of what has been forgotten the easier will it be for him to assent. On that particular matter our knowledge will then have become his knowledge as well.

[1940a [1938], 4987]
Before I resume my account of the case I will add a few words on the patient's behaviour during this second phase of the treatment. Throughout the analysis I made use of the technique of bringing out pictures and ideas by means of pressing on the patient's head, a method, that is, which would be unworkable without the patient's full co-operation and willing attention. Sometimes, indeed, her behaviour fulfilled my highest expectations, and during such periods it was surprising with what promptitude the different scenes relating to a given theme emerged in a strictly chronological order. It was as though she were reading a lengthy book of pictures, whose pages were being turned over before her eyes. At other times there seemed to be impediments of whose nature I had no suspicion then. When I pressed her head she would maintain that nothing occurred to her. I would repeat my pressure and tell her to wait, but still nothing appeared. The first few times when this recalcitrance exhibited itself I allowed myself to be led into breaking off the work: it was an unfavourable day; we would try another time. Two observations, however, decided me to alter my attitude. I noticed, in the first place, that the method failed in this way only when I found Elisabeth in a cheerful state and free from pain, never when she was feeling badly. In the second place, that she often made such assertions as that she saw nothing, after she had allowed a long interval to pass during which her tense and preoccupied expression of face nevertheless betrayed the fact that a mental process was taking place in her. I resolved, therefore, to adopt the hypothesis that the procedure never failed: that on every occasion under the pressure of my hand some idea occurred to Elisabeth or some picture came before her eyes, but that she was not always prepared to communicate it to me, and tried to suppress once more what had been conjured up. I could think of two motives for this concealment. Either she was applying criticism to the idea, which she had no right to do, on the ground of its not being important enough or of its being an irrelevant reply to the question she had been asked; or she hesitated to produce it because she found it too disagreeable to tell. I therefore proceeded as though I was completely convinced of the trustworthiness of my technique. I no longer accepted her declaration that nothing had occurred to her, but assured her that something must have occurred to her. Perhaps, I said, she had not been sufficiently attentive, in which case I should be glad to repeat my pressure. Or perhaps she thought that her idea was not the right one. This, I told her, was not her affair; she was under an obligation to remain completely objective and say what had come into her head, whether it was appropriate or not. Finally I declared that I knew very well that something had occurred to her and that she was concealing it from me; but she would never be free of her pains so long as she concealed anything. By thus insisting, I brought it about that from that time forward my pressure on her head never failed in its effect. I could not but conclude that I had formed a correct opinion of the state of affairs, and I derived from this analysis a literally unqualified reliance on my technique. It often happened that it was not until I had pressed her head three times that she produced a piece of information; but she herself would remark afterwards: 'I could have said it to you the first time.' - 'And why didn't you?' - 'I thought it wasn't what was wanted,' or 'I thought I could avoid it, but it came back each time.' In the course of this difficult work I began to attach a deeper significance to the resistance offered by the patient in the reproduction of her memories and to make a careful collection of the occasions on which it was particularly marked. [1895d, 139]
In these circumstances I make use in the first instance of a small technical device. I inform the patient that, a moment later, I shall apply pressure to his forehead, and I assure him that, all the time the pressure lasts, he will see before him a recollection in the form of a picture or will have it in his thoughts in the form of an idea occurring to him; and I pledge him to communicate this picture or idea to me, whatever it may be. He is not to keep it to himself because he may happen to think it is not, or because it would be too disagreeable for him to say it. There is to be no criticism of it, no reticence, either for emotional reasons or because it is judged unimportant. Only in this manner can we find what we are in search of, but in this manner we shall find it infallibly. Having said this, I press for a few seconds on the forehead of the patient as he lies in front of me; I then leave go and ask quietly, as though there were no question of a disappointment: 'What did you see?' or 'What occurred to you?'

This procedure has taught me much and has also invariably achieved its aim. To-day I can no longer do without it. I am of course aware that a pressure on the forehead like this could be replaced by any other signal or by some other exercise of physical influence on the patient; but since the patient is lying in front of me, pressure on his forehead, or taking his head between my two hands, seems to be the most convenient way of applying suggestion for the purpose I have in view. It would be possible for me to say by way of explaining the efficacy of this device that it corresponded to a 'momentarily intensified hypnosis'; but the mechanism of hypnosis is so puzzling to me that I would rather not make use of it as an explanation. I am rather of opinion that the advantage of the procedure lies in the fact that by means of it I dissociate the patient's attention from his conscious searching and reflecting - from everything, in short, on which he can employ his will - in the same sort of way in which this is effected by staring into a crystal ball, and so on. The conclusion which I draw from the fact that what I am looking for always appears under the pressure of my hand is as follows. The pathogenic idea which has ostensibly been forgotten is always lying ready 'close at hand' and can be reached by associations that are easily accessible. It is merely a question of getting some obstacle out of the way. This obstacle seems once again to be the subject's will, and different people can learn with different degrees of ease to free themselves from their intentional thinking and to adopt an attitude of completely objective observation towards the psychical processes taking place in them.

What emerges under the pressure of my hand is not always a 'forgotten' recollection; it is only in the rarest cases that the actual pathogenic recollections lie so easily to hand on the surface. It is much more frequent for an idea to emerge which is an intermediate link in the chain of associations between the idea from which we start and the pathogenic idea which we are in search of; or it may be an idea which forms the starting point of a new series of thoughts and recollections at the end of which the pathogenic idea will be found. It is true that where this happens my pressure has not revealed the pathogenic idea - which would in any case be incomprehensible, torn from its context and without being led up to - but it has pointed the way to it and has shown the direction in which further investigation is to be made. The idea that is first provoked by the pressure may in such cases be a familiar recollection which has never been repressed. If on our way to the pathogenic idea the thread is broken off once more, it only needs a repetition of the procedure, of the pressure, to give us fresh bearings and a fresh starting-point.
I must mention the different forms in which this resistance appears. One is that, as a rule, the pressure procedure fails on the first or second occasion. The patient then declares, very disappointedly: 'I expected something would occur to me, but all I thought was how tensely I was expecting it. Nothing came.' The fact of the patient putting himself on his guard like this does not yet amount to an obstacle. We can say in reply: 'It's precisely because you were too curious; it will work next time.' And in fact it does work. It is remarkable how often patients, even the most docile and intelligent, can completely forget their undertaking, though they had agreed to it beforehand. They promised to say whatever occurred to them under the pressure of my hand, irrespectively of whether it seemed to them relevant or not, and of whether it was agreeable to them to say it or not - to say it, that is, without selecting and without being influenced by criticism or affect. But they do not keep this promise; it is evidently beyond their strength to do so. The work keeps on coming to a stop and they keep on maintaining that this time nothing has occurred to them. We must not believe what they say, we must always assume, and tell them, too, that they have kept something back because they thought it unimportant or found it distressing. We must insist on this, we must repeat the pressure and represent ourselves as infallible, till at last we are really told something. The patient then adds: 'I could have told you that the first time.' 'Why didn't you say it?' 'I couldn't believe it could be that. It was only when it came back every time that I made up my mind to say it.' Or else: 'I hoped it wouldn't be that of all things. I could well do without saying that. It was only when it refused to be repressed that I saw I shouldn't be let off.' Thus after the event the patient betrays the motives for a resistance which he refused to admit to begin with. He is evidently quite unable to do anything but put up resistance.

[1895d, 246]

This resistance often conceals itself behind some remarkable excuses. 'My mind is distracted to-day; the clock (or the piano in the next room) is disturbing me.' I have learned to answer such remarks: 'Not at all. You have at this moment come up against something that you had rather not say. It won't do any good. Go on thinking about it.' The longer the pause between my hand-pressure and the patient's beginning to speak, the more suspicious I become and the more it is to be feared that the patient is re-arranging what has occurred to him and is mutilating it in his reproduction of it. A most important piece of information is often announced as being a redundant accessory, like an opera prince disguised as a beggar. 'Something has occurred to me now, but it has nothing to do with the subject. I'm only saying it because you want to know every thing.' Accompanying words such as these usually introduce the long-sought solution. I always prick up my ears when I hear a patient speak so disparagingly of something that has occurred to him. For it is an indication that defence has been successful if the pathogenic ideas seem, when they re-emerge, to have so little importance. From this we can infer in what the process of defence consisted: it consisted in turning a strong idea into a weak one, in robbing it of its affect.

[1895d, 247]

Another observation, which is constantly repeated, relates to the patient's spontaneous reproductions. It may be asserted that every single reminiscence which emerges during an analysis of this kind has significance. An intrusion of irrelevant mnemonic images (which happen in some way or other to be associated with the important ones) in fact never occurs. An exception which does not contradict this rule may be postulated for memories which, unimportant in themselves, are nevertheless indispensable as a bridge, in the sense that the association between two important memories can only be made through them.

[1895d, 260]
If a pathogenic memory or a pathogenic connection which had formerly been withdrawn from the ego-consciousness is uncovered by the work of the analysis and introduced into the ego, we find that the psychical personality which is thus enriched has various ways of expressing itself with regard to what it has acquired. It happens particularly often that, after we have laboriously forced some piece of knowledge on a patient, he will declare: 'I've always known that, I could have told you that before.' Those with some degree of insight recognize afterwards that this is a piece of self-deception and blame themselves for being ungrateful. Apart from this, the attitude adopted by the ego to its new acquisition depends in general on the stratum of analysis from which that acquisition originates. Things that belong to the external strata are recognized without difficulty; they had, indeed, always remained in the ego's possession, and the only novelty to the ego is their connection with the deeper strata of pathological material. Things that are brought to light from these deeper strata are also recognized and acknowledged, but often only after considerable hesitations and doubts. Visual memory-images are of course more difficult to disavow than the memory-traces of mere trains of thought. Not at all infrequently the patient begins by saying: 'It's possible that I thought this, but I can't remember having done so.' And it is not until he has been familiar with the hypothesis for some time that he comes to recognize it as well; he remembers - and confirms the fact, too, by subsidiary links - that he really did once have the thought. I make it a rule, however, during the analysis to keep my estimate of the reminiscence that comes up independent of the patient's acknowledgement of it. I shall never be tired of repeating that we are bound to accept whatever our procedure brings to light. If there is anything in it that is not genuine or correct, the context will later on tell us to reject it. But I may say in passing that I have scarcely ever had occasion to disavow subsequently a reminiscence that has been provisionally accepted. Whatever has emerged has, in spite of the most deceptive appearance of being a glaring contradiction, nevertheless turned out to be correct.

[1895d, 264]

You will readily admit that it would be a good thing to have a second method of arriving at the aetiology of hysteria, one in which we should feel less dependent on the assertions of the patients themselves. A dermatologist, for instance, is able to recognize a sore as luetic from the character of its margins, or the crust on it and of its shape, without being misled by the protestations of his patient, who denies any source of infection for it; and a forensic physician can arrive at the cause of an injury, even if he has to do without any information from the injured person. In hysteria, too, there exists a similar possibility of penetrating from the symptoms to a knowledge of their causes. But in order to explain the relationship between the method which we have to employ for this purpose and the older method of anamnestic enquiry, I should like to bring before you an analogy taken from an advance that has in fact been made in another field of work.

[1896c, 408]

¹ I purposely leave out of this discussion the question of what the category is to which the association between the two memories belong, (whether it is an association by simultaneity, or by causal connections or by similarity of content), and of what psychological character is to be attributed to the various 'memories' (conscious or unconscious).

[1896c, 411]
For this topic to have been able to produce such effects it is not enough that I should have suppressed it once in conversation - an event brought about by chance motives. We must assume rather that the topic itself was also intimately bound up with trains of thought which were in a state of repression in me - that is, with trains of thought which, in spite of the intensity of the interest taken in them, were meeting with a resistance that was keeping them from being worked over by a particular psychical agency and thus from becoming conscious. That this was really true at that time of the topic of 'death and sexuality' I have plenty of evidence, which I need not bring up here, derived from my own self-investigation. But I may draw attention to one consequence of these repressed thoughts. Experience has taught me to require that every psychical product shall be fully elucidated and even overdetermined. Accordingly, it seemed to me that the second substitutive name, 'Boltraffio', called for a further determination; for so far only its initial letters had been accounted for, by their assonance with 'Bosnia'. I now recollected that these repressed thoughts had never engrossed me more than they had a few weeks before after I had received a certain piece of news. The place where the news reached me was called 'Trafoi' and this name is too much like the second half of the name 'Boltraffio' not to have had a determining effect on my choice of the latter. In the following small schematic diagram, I have attempted to reproduce the relations which have now been brought to light.

My knowledge of that procedure was reached in the following manner. I have been engaged for many years (with a therapeutic aim in view) in unravelling certain psychopathological structures - hysterical phobias, obsessional ideas, and so on. I have been doing so, in fact, ever since I learnt from an important communication by Josef Breuer that as regards these structures (which are looked on as pathological symptoms) unravelling these coincides with removing them. (Cf. Breuer and Freud, 1895.) If a pathological idea of this sort can be traced back to the elements in the patient's mental life from which it originated, it simultaneously crumbles away and the patient is freed from it. Considering the impotence of our other therapeutic efforts and the puzzling nature of these disorders, I felt tempted to follow the path marked out by Breuer, in spite of every difficulty, till a complete explanation was reached. I shall have on another occasion to report at length upon the form finally taken by this procedure and the results of my labours. It was in the course of these psycho-analytic studies that I came upon dream-interpretation. My patients were pledged to communicate to me every idea or thought that occurred to them in connection with some particular subject; amongst other things they told me their dreams and so taught me that a dream can be inserted into the psychical chain that has to be traced backwards in the memory from a pathological idea. It was then only a short step to treating the dream itself as a symptom and to applying to dreams the method of interpretation that had now been worked out for symptoms.

This involves some psychological preparation of the patient. In the attention he pays to his own psychical perceptions and the elimination of the criticism by which he normally sifts the thoughts that occur to him. In order that he may be able to concentrate his attention on his self-observation it is an advantage for him to lie in a restful attitude and shut his eyes. It is necessary to insist explicitly on his renouncing all criticism of the thoughts that he perceives. We therefore tell him that the success of the psycho-analysis depends on his noticing and reporting whatever comes into his head and not being misled, for instance, into suppressing an idea because it strikes him as unimportant or irrelevant or because it seems to him meaningless. He must adopt a completely impartial attitude to what occurs to him, since it is precisely his critical attitude which is responsible for his being unable, in the ordinary course of things, to achieve the desired unravelling of his dream or obsessional idea or whatever it may be.
I have noticed in my psycho-analytical work that the whole frame of mind of a man who is reflecting is totally different from that of a man who is observing his own psychical processes. In reflection there is one more psychical activity at work than in the most attentive self-observation, and this is shown amongst other things by the tense looks and wrinkled forehead of a person pursuing his reflections as compared with the restful expression of a self-observer. In both cases attention must be concentrated, but the man who is reflecting is also exercising his critical faculty; this leads him to reject some of the ideas that occur to him after perceiving them, to cut short others without following the trains of thought which they would open up to him, and to behave in such a way towards still others that they never become conscious at all and are accordingly suppressed before being perceived. The self-observer on the other hand need only take the trouble to suppress his critical faculty. If he succeeds in doing that, innumerable ideas come into his consciousness of which he could otherwise never have got hold. The material which is in this way freshly obtained for his self-perception makes it possible to interpret both his pathological ideas and his dream-structures. What is in question, evidently, is the establishment of a psychical state which, in its distribution of psychical energy (that is, of mobile attention), bears some analogy to the state before falling asleep - and no doubt also to hypnosis. As we fall asleep, 'involuntary ideas' emerge, owing to the relaxation of a certain deliberate (and no doubt also critical) activity which we allow to influence the course of our ideas while we are awake. (We usually attribute this relaxation to 'fatigue'.) As the involuntary ideas emerge they change into visual and acoustic images. (Cf. the remarks by Schleiermacher and others quoted above on p. 559 f.¹) In the state used for the analysis of dreams and pathological ideas, the patient purposely and deliberately abandons this activity and employs the psychical energy thus saved (or a portion of it) in attentively following the involuntary thoughts which now emerge, and which - and here the situation differs from that of falling asleep - retain the character of ideas. In this way the 'involuntary' ideas are transformed into voluntary ones.

¹[1900a, 604]

The adoption of the required attitude of mind towards ideas that seem to emerge 'of their own free will' and the abandonment of the critical function that is normally in operation against them seem to be hard of achievement for some people. The 'involuntary thoughts' are liable to release a most violent resistance, which seeks to prevent their emergence. If we may trust that great poet and philosopher Friedrich Schiller, however, poetic creation must demand an exactly similar attitude. In a passage in his correspondence with Körner - we have to thank Otto Rank for unearthing it - Schiller (writing on December 1, 1788) replies to his friend's complaint of insufficient productivity: 'The ground for your complaint seems to me to lie in the constraint imposed by your reason upon your imagination. I will make my idea more concrete by a simile. It seems a bad thing and detrimental to the creative work of the mind if Reason makes too close an examination of the ideas as they come pouring in - at the very gateway, as it were. Looked at in isolation, a thought may seem very trivial or very fantastic; but it may be made important by another thought that comes after it, and, in conjunction with other thoughts that may seem equally absurd, it may turn out to form a most effective link. Reason cannot form any opinion upon all this unless it retains the thought long enough to look at it in connection with the others. On the other hand, where there is a creative mind, Reason - so it seems to me - relaxes its watch upon the gates, and the ideas rush in pell-mell, and only then does it look them through and examine them in a mass. - You critics, or whatever else you may call yourselves, are ashamed or frightened of the momentary and transient extravagances which are to be found in all truly creative minds and whose longer or shorter duration distinguishes the thinking artist from the dreamer. You complain of your unfruitfulness because you reject too soon and discriminate too severely.'

¹[1900a, 605]
Nevertheless, what Schiller describes as a relaxation of the watch upon the gates of Reason, the adoption of an attitude of uncritical self-observation, is by no means difficult. Most of my patients achieve it after their first instructions. I myself can do so very completely, by the help of writing down my ideas as they occur to me. The amount of psychical energy by which it is possible to reduce critical activity and increase the intensity of self-observation varies considerably according to the subject on which one is trying to fix one's attention. [1900a, 605]

My own dream (recorded on p. 717) of running upstairs and of soon afterwards finding myself glued to the steps was equally a dream of exhibiting, since it bears the essential marks of being one. It should be possible, therefore, to trace it back to experiences during my childhood, and if these could be discovered they should enable us to judge how far the maid-servant's behaviour to me - her accusing me of dirtying the carpet - helped to give her her place in my dream. I can, as it happens, provide the necessary particulars. In a psycho-analysis one learns to interpret propinquity in time as representing connection in subject-matter. Two thoughts which occur in immediate sequence without any apparent connection are in fact part of a single unity which has to be discovered; in just the same way, if I write an 'a' and a 'b' in succession, they have to be pronounced as a single syllable 'ab'. The same is true of dreams. The staircase dream to which I have referred was one of a series of dreams; and I understood the interpretation of the other members of the series. Since this particular dream was surrounded by the others it must have dealt with the same subject. Now these other dreams were based on a recollection of a nurse in whose charge I had been from some date during my earliest infancy till I was two and a half. I even retain an obscure conscious memory of her. According to what I was told not long ago by my mother, she was old and ugly, but very sharp and efficient. From what I can infer from my own dreams her treatment of me was not always excessive in its amiability and her words could be harsh if I failed to reach the required standard of cleanliness. And thus the maid servant, since she had undertaken the job of carrying on this educational work, acquired the right to be treated in my dream as a reincarnation of the prehistoric old nurse. It is reasonable to suppose that the child loved the old woman who taught him these lessons, in spite of her rough treatment of him.¹ [1900a, 726]

No one should expect that an interpretation of his dreams will fall into his lap like manna from the skies. Practice is needed even for perceiving endoptic phenomena or other sensations from which our attention is normally withhold; and this is so even though there is no psychical motive fighting against such perceptions. It is decidedly more difficult to get hold of 'involuntary ideas.' Anyone who seeks to do so must familiarize himself with the expectations raised in the present volume and must, in accordance with the rules laid down in it, endeavour during the work to refrain from any criticism, any parti pris, and any emotional or intellectual bias. He must bear in mind Claude Bernard's advice to experimenters in a physiological laboratory: 'travailler comme une bête' - he must work, that is, with as much persistence as an animal and with as much disregard of the result. If this advice is followed, the task will no longer be a hard one. [1900a, 957]
For it is demonstrably untrue that we are being carried along a purposeless stream of ideas when, in the process of interpreting a dream, we abandon reflection and allow involuntary ideas to emerge. It can be shown that all that we can ever get rid of are purposive ideas that are known to us; as soon as we have done this, unknown - or, as we inaccurately say, 'unconscious' - purposive ideas take charge and thereafter determine the course of the involuntary ideas. No influence that we can bring to bear upon our mental processes can ever enable us to think without purposive ideas; nor am I aware of any states of psychical confusion which can do so.¹ Psychiatrists have been far too ready in this respect to abandon their belief in the connectedness of psychical processes. I know for a fact that trains of thought without purposive ideas no more occur in hysteria and paranoia than they do in the formation or resolution of dreams. It may be that they do not occur in any of the endogenous psychical disorders. Even the deliria of confusional states may have a meaning, if we are to accept Leuret's brilliant suggestion that they are only unintelligible to us owing to the gaps in them. I myself have formed the same opinion when I have had the opportunity of observing them. Deliria are the work of a censorship which no longer takes the trouble to conceal its operation; instead of collaborating in producing a new version that shall be unobjectionable, it ruthlessly deletes whatever it disapproves of, so that what remains becomes quite disconnected. This censorship acts exactly like the censorship of newspapers at the Russian frontier, which allows foreign journals to fall into the hands of the readers whom it is its business to protect only after a quantity of passages have been blacked out. [1900a, 962]

It may be that free play of ideas with a fortuitous chain of associations is to be found in destructive organic cerebral processes; what is regarded as such in the psychoneuroses can always be explained as an effect of the censorship's influence upon a train of thought which has been pushed into the foreground by purposive ideas that have remained hidden.⁷ It has been regarded as an unfailing sign of an association being uninfluenced by purposive ideas if the associations (or images) in question seem to be interrelated in what is described as a 'superficial' manner - by assonance, verbal ambiguity, temporal coincidence without connection in meaning, or by any association of the kind that we allow in jokes or in play upon words. This characteristic is present in the chains of thought which lead from the elements of a dream to the intermediate thoughts and from these to the dream-thoughts proper; we have seen instances of this - not without astonishment - in many dream-analyses. No connection was too loose, no joke too bad, to serve as a bridge from one thought to another. But the true explanation of this easy-going state of things is soon found. Whenever one psychical element is linked with another by an objectionable or superficial association, there is also a legitimate and deeper link between them which is subjected to the resistance of the censorship. [1900a, 963]

The real reason for the prevalence of superficial associations is not the abandonment of purposive ideas but the pressure of the censorship. Superficial associations replace deep ones if the censorship makes the normal connecting paths impassable. We may picture, by way of analogy, a mountain region, where some general interruption of traffic (owing to floods, for instance) has blocked the main, major roads, but where communications are still maintained over inconvenient and steep footpaths normally used only by the hunter. [1900a, 963]
Two cases may here be distinguished, though in essence they are the same. In the first of these, the censorship is directed only against the connection between two thoughts, which are unobjectionable separately. If so, the two thoughts will enter consciousness in succession; the connection between them will remain concealed, but, instead, a superficial link between them will occur to us, of which we should otherwise never have thought. This link is usually attached to some part of the complex of ideas quite other than that on which the suppressed and essential connection is based. The second case is where the two thoughts are in themselves subject to censorship on account of their content. If so, neither of them appears in its true shape but only in a modified one which replaces it; and the two replacing thoughts are chosen in such a way that they have a superficial association that repeats the essential connection which relates the two thoughts that have been replaced. In both these cases the pressure of the censorship has resulted in a displacement from a normal and serious association to a superficial and apparently absurd one.

Since we are aware that displacements of this kind occur, we have no hesitation when we are interpreting dreams in relying upon superficial associations as much as upon others.¹

In the psycho-analysis of neuroses the fullest use is made of these two theorems - that, when conscious purposive ideas are abandoned, concealed purposive ideas assume control of the current of ideas, and that superficial associations are only substitutes by displacement for suppressed deeper ones. Indeed, these theorems have become basic pillars of psycho-analytic technique. When I instruct a patient to abandon reflection of any kind and to tell me whatever comes into his head, I am relying firmly on the presumption that he will not be able to abandon the purposive ideas inherent in the treatment and I feel justified in inferring that what seem to be the most innocent and arbitrary things which he tells me are in fact related to his illness. There is another purposive idea of which the patient has no suspicion - one relating to myself. The full estimate of the importance of these two theorems, as well as more detailed information about them, fall within the province of an account of the technique of psycho-analysis. Here, then, we have reached one of the frontier posts at which, in accordance with our programme, we must drop the subject of dream-interpretation.²

¹ [1900a, 964]
² [1900a, 964]
Here is another example. A fourteen-year-old boy came to me for psycho-analytic treatment suffering from tic convulsif, hysterical vomiting, headaches, etc. I began the treatment by assuring him that if he shut his eyes he would see pictures or have ideas, which he was then to communicate to me. He replied in pictures. His last impression before coming to me was revived visually in his memory. He had been playing at draughts with his uncle and saw the board in front of him. He thought of various positions, favourable or unfavourable, and of moves that one must not make. He then saw a dagger lying on the board - an object that belonged to his father but which his imagination placed on the board. Then there was a sickle lying on the board and next a scythe. And there now appeared a picture of an old peasant mowing the grass in front of the patient's distant home with a scythe. After a few days I discovered the meaning of this series of pictures. The boy had been upset by an unhappy family situation. He had a father who was a hard man, liable to fits of rage, who had been unhappily married to the patient's mother, and whose educational methods had consisted of threats. His father had been divorced from his mother, a tender and affectionate woman, had married again and had one day brought a young woman home with him who was to be the boy's new mother. It was during the first few days after this that the fourteen-year-old boy's illness had come on. His suppressed rage against his father was what had constructed this series of pictures with their understandable allusions. The material for them was provided by a recollection from mythology. The sickle was the one with which Zeus castrated his father; the scythe and the picture of the old peasant represented Kronos, the violent old man who devoured his children and on whom Zeus took such un filial vengeance. His father's marriage gave the boy an opportunity of repaying the reproaches and threats which he had heard from his father long before because he had played with his genitals. (Cf. the playing at draughts; the forbidden moves; the dagger which could be used to kill.) In this case long-repressed memories and derivatives from them which had remained unconscious slipped into consciousness by a roundabout path in the form of apparently meaningless pictures.

If we make use of it on someone else, let us say on a patient with a phobia, we require him to direct his attention on to the idea in question, not, however, to reflect upon it as he has done so often already, but to take notice of whatever occurs to his mind without any exception and report it to the physician. If he should then assert that his attention is unable to grasp anything at all, we dismiss this with an energetic assurance that a complete absence of any ideational subject-matter is quite impossible. And in fact very soon numerous ideas will occur to him and will lead on to others; but they will invariably be prefaced by a judgement on the part of the self-observer to the effect that they are senseless or unimportant, that they are irrelevant, and that they occurred to him by chance and without any connection with the topic under consideration. We perceive at once that it was this critical attitude which prevented the subject from reporting any of these ideas, and which indeed had previously prevented them from becoming conscious. If we can induce him to abandon his criticism of the ideas that occur to him, and to continue pursuing the trains of thought which will emerge so long as he keeps his attention turned upon them, we find ourselves in possession of a quantity of psychical material, which we soon find is clearly connected with the pathological idea which was our starting-point; this material will soon reveal connections between the pathological idea and other ideas, and will eventually enable us to replace the pathological idea by a new one which fits into the nexus of thought in an intelligible fashion.

[1900a, 1043]

[1901a, 1054]
This is not the place in which to give a detailed account of the premises upon which this experiment was based, or the consequences which follow from its invariable success. It will therefore be enough to say that we obtain material that enables us to resolve any pathological idea if we turn our attention precisely to those associations which are 'involuntary', which 'interfere with our reflection', and which are normally dismissed by our critical faculty as worthless rubbish.

[1901a, 1054]

I took up this challenge most readily, for I was hoping for a contribution to my collection. So I said: 'That should not take us long. I must only ask you to tell me, candidly and uncritically, whatever comes into your mind if you direct your attention to the forgotten word without any definite aim.'¹

[1901b, 1107]

¹ This is the general method of introducing concealed ideational elements to consciousness. Cf. my Interpretation of Dreams, p. 604.

[1901b, 1107]

¹ [Footnote added 1920:] Herr Rudolf Schneider (1920) of Munich has raised an interesting objection to the conclusiveness of such analyses of numbers. He experimented with numbers that were presented to him - for example, with the number that first caught his eye when he opened a history book - or he presented someone else with a number he had chosen; and he then noticed whether associations emerged to the imposed number which had the appearance of having determined it. This was in fact what did happen. In one instance which he relates that concerned himself, the associations provided determinants just as abundant and full of meaning as in our analyses of numbers that have arisen spontaneously, whereas the number in Schneider's experiments, having been presented from outside, called for no determinant. In a second experiment carried out on someone else, he clearly made the problem too easy, for the number he set him was 2, and everybody has some material which would enable him to find a determinant for that number. - From his experiments Schneider then draws two conclusions: first, that 'the mind possesses the same potentialities for finding associations to numbers as to concepts'; and secondly, that the emergence of determining associations to numbers that occur to the mind spontaneously does not in any way prove that these numbers originated from the thoughts discovered in the 'analysis' of them. The former conclusion is undoubtedly correct. It is just as easy to find an appropriate association to a number which is presented as it is to a word which is called out - indeed it is perhaps easier, since the ability of the few digits to form connections is particularly great. The situation in which one finds oneself is then simply that of what are called 'association experiments', which have been studied from the greatest variety of angles by the school of Bleuler and Jung. In this situation the association (reaction) is determined by the word presented (stimulus-word). This reaction could however still be of very diverse kinds, and Jung's experiments have shown that even these further distinctions are not left to 'chance', but that unconscious 'complexes' participate in the determination if they have been touched on by the stimulus-word. - Schneider's second conclusion goes too far. The fact that appropriate associations arise to numbers (or words) which are presented tells us nothing more about the origin of numbers (or words) which emerge spontaneously than could already be taken into consideration before that fact was known. These spontaneous ideas (words or numbers) may be undetermined, or may have been determined by the thoughts that come out in the analysis, or by other thoughts not disclosed in the analysis - in which last case the analysis will have led us astray. The important thing is to get rid of the impression that this problem is different for numbers from what it is for verbal associations. A critical examination of the problem and with it a justification of the psycho-analytic technique of association lie outside the scope of this book. In analytic practice we proceed on the presupposition that the second of the possibilities mentioned above meets the facts and that in the majority of instances use can be made of it. The investigations of an experimental psychologist (Poppelreuter [1914]) have demonstrated that it is by far the most probable one. See further in this connection the valuable findings in Section 9 of Bleuler's book on autistic thinking (1919).

[1901b, 1322]
I will begin by bringing together some material for answering the last question. In discussing the examples of slips of the tongue we found it necessary to go beyond the content of what was intended to be said, and were obliged to look for the cause of the speech-disturbance in something outside the intention. What this was was obvious in a number of cases, and was known to the speaker's consciousness. In the examples that seemed simplest and most transparent it was another version of the same thought - one which sounded as if it had an equal right, and which disturbed the expression of the thought without its being possible to explain why the one version had succumbed and the other had won the day. (These are Meringer and Mayer's 'contaminations'.) In a second group of cases the motive for the defeat of one version was a consideration which, however, did not prove strong enough to withhold it completely ("zum Vorschwein gekommen"). The version which was withheld was perfectly conscious too. Only of the third group can it be asserted unreservedly that the disturbing thought differed from the one intended, and only in their case can a distinction which is apparently essential be established. The disturbing thought is either connected with the disturbed thought by thought associations (disturbance as a result of internal contradiction), or it is unrelated to it in its nature and the disturbed word happens to be connected with the disturbing thought - which is often unconscious - by an unexpected external association. In the examples I have given from my psycho-analyses the entire speech is under the influence of thoughts which have become active but have at the same time remained entirely unconscious; either these are betrayed by the disturbance itself ("Klapperschlange" - "Kleopatra") or they exercise an indirect influence by making it possible for the different parts of the consciously intended speech to disturb each other ("Ase natmen", where 'Hasenauer Street' and reminiscences of a Frenchwoman are in the background). The withheld or unconscious thoughts from which the disturbance in speech derives are of the most varied origin. This survey therefore does not enable us to generalize in any direction.

[1901b, 1341]

Now in this case history - the only one which I have hitherto succeeded in forcing through the limitations imposed by medical discretion and unfavourable circumstances - sexual questions will be discussed with all possible frankness, the organs and functions of sexual life will be called by their proper names, and the pure-minded reader can convince himself from my description that I have not hesitated to converse upon such subjects in such language even with a young woman. Am I then, to defend myself upon this score as well? I will simply claim for myself the rights of the gynaecologist - or rather, much more modest ones - and add that it would be the mark of a singular and perverse prurience to suppose that conversations of this kind are a good means of exciting or of gratifying sexual desire. For the rest, I feel inclined to express my opinion on this subject in a few borrowed words:

[1905e, 1352]

Readers who are familiar with the technique of analysis as it was expounded in the Studies on Hysteria will perhaps be surprised that it should not have been possible in three months to find a complete solution at least for those of the symptoms which were taken in hand. This will become intelligible when I explain that since the date of the Studies psycho-analytic technique has been completely revolutionized. At that time the work of analysis started out from the symptoms, and aimed at clearing them up one after the other. Since then I have abandoned that technique, because I found it totally inadequate for dealing with the finer structure of a neurosis. I now let the patient himself choose the subject of the day's work, and in that way I start out from whatever surface his unconscious happens to be presenting to his notice at the moment. But on this plan everything that has to do with the clearing-up of a particular symptom emerges piecemeal, woven into various contexts, and distributed over widely separated periods of time. In spite of this apparent disadvantage, the new technique is far superior to the old, and indeed there can be no doubt that it is the only possible one.

[1905e, 1355]
This short piece of the analysis may perhaps have excited in the medical reader - apart from the scepticism to which he is entitled - feelings of astonishment and horror; and I am prepared at this point to look into these two reactions so as to discover whether they are justifiable. The astonishment is probably caused by my daring to talk about such delicate and unpleasant subjects to a young girl - or, for that matter, to any woman who is sexually active. The horror is aroused, no doubt, by the possibility that an inexperienced girl could know about practices of such a kind and could occupy her imagination with them. I would advise recourse to moderation and reasonableness upon both points. There is no cause for indignation either in the one case or in the other. It is possible for a man to talk to girls and women upon sexual matters of every kind without doing them harm and without bringing suspicion upon himself, so long as, in the first place, he adopts a particular way of doing it, and, in the second place, can make them feel convinced that it is unavoidable. A gynaecologist, after all, under the same conditions, does not hesitate to make them submit to uncovering every possible part of their body. The best way of speaking about such things is to be dry and direct; and that is at the same time the method furthest removed from the prurience with which the same subjects are handled in 'society', and to which girls and women alike are so thoroughly accustomed. I call bodily organs and processes by their technical names, and I tell these to the patient if they - the names, I mean - happen to be unknown to her. J'appelle un chat un chat. I have certainly heard of some people - doctors and laymen - who are scandalized by a therapeutic method in which conversations of this sort occur, and who appear to envy either me or my patients the titillation which, according to their notions, such a method must afford. But I am too well acquainted with the respectability of these gentry to excite myself over them. I shall avoid the temptation of writing a satire upon them. But there is one thing that I will mention: often, after I have for some time treated a patient who had not at first found it easy to be open about sexual matters, I have had the satisfaction of hearing her exclaim: 'Why, after all, your treatment is far more respectable than Mr. X.'s conversation!' [1905e, 1385]
A number of the results of the analysis have been omitted, because at the time when work was broken off they had either not been established with sufficient certainty or they required further study before any general statement could be made about them. At other points, where it seemed to be permissible, I have indicated the direction along which some particular solution would probably have been found to lie. I have in this paper left entirely out of account the technique, which does not at all follow as a matter of course, but by whose means alone the pure metal of valuable unconscious thoughts can be extracted from the raw material of the patient's associations. This brings with it the disadvantage of the reader being given no opportunity of testing the correctness of my procedure in the course of this exposition of the case. I found it quite impracticable, however, to deal simultaneously with the technique of analysis and with the internal structure of a case of hysteria: I could scarcely have accomplished such a task, and if I had, the result would have been almost unreadable. The technique of analysis demands an entirely separate exposition, which would have to be illustrated by numerous examples chosen from a very great variety of cases and which would not have to take the results obtained in each particular case into account. Nor have I attempted in this paper to substantiate the psychological postulates which will be seen to underlie my descriptions of mental phenomena. A cursory attempt to do so would have effected nothing; an exhaustive one would have been a volume in itself. I can only assure the reader that I approached the study of the phenomena revealed by observation of the psychoneuroses without being pledged to any particular psychological system, and that I then proceeded to adjust my views until they seemed adapted for giving an account of the collection of facts which had been observed. I take no pride in having avoided speculation; the material for my hypotheses was collected by the most extensive and laborious series of observations. The decidedness of my attitude on the subject of the unconscious is perhaps specially likely to cause offence, for I handle unconscious ideas, unconscious trains of thought, and unconscious impulses as though they were no less valid and unimpeachable psychological data than conscious ones. But of this I am certain - that any one who sets out to investigate the same region of phenomena and employs the same method will find himself compelled to take up the same position, however much philosophers may expostulate.

If the theory of analytic technique is gone into, it become, evident that transference is an inevitable necessity. Practical experience, at all events, shows conclusively that there is no means of avoiding it, and that this latest creation of the disease must be combated like all the earlier ones. This happens, however, to be by far the hardest part of the whole task. It is easy to learn how to interpret dreams, to extract from the patient's associations his unconscious thoughts and memories, and to practise similar explanatory arts: for these the patient himself will always provide the text. Transference is the one thing the presence of which has to be detected almost without assistance and with only the slightest clues to go upon, while at the same time the risk of making arbitrary inferences has to be avoided. Nevertheless, transference cannot be evaded, since use is made of it in setting up all the obstacles that make the material inaccessible to treatment, and since it is only after the transference has been resolved that a patient arrives at a sense of conviction of the validity of the connections which have been constructed during the analysis.

Freud found such a substitute - and a completely satisfactory one - in the 'associations' of his patients; that is, in the involuntary thoughts (most frequently regarded as disturbing elements and therefore ordinarily pushed aside) which so often break across the continuity of a consecutive narrative.
In order to secure these ideas and associations he asks the patient to ‘let himself go’ in what he says, ‘as you would do in a conversation in which you were rambling on quite disconnectedly and at random’. Before he asks them for a detailed account of their case history he insists that they must include in it whatever comes into their heads, even if they think it unimportant or irrelevant or nonsensical; he lays special stress on their not omitting any thought or idea from their story because to relate it would be embarrassing or distressing to them. In the course of collecting this material of otherwise neglected ideas Freud made the observations which became the determining factor of his entire theory. Gaps appear in the patient's memory even while he narrates his case: actual occurrences are forgotten, the chronological order is confused, or causal connections are broken, with unintelligible results. No neurotic case history is without amnesia of some kind or other. If the patient is urged to fill these gaps in his memory by an increased application of attention, it is noticed that all the ideas which occur to him are pushed back by every possible critical expedient, until at last he feels positive discomfort when the memory really returns. From this experience Freud concludes that the amnesias are the result of a process which he calls 'repression' and the motive for which he finds in feelings of unpleasure. The psychical forces which have brought about this repression can also be detected, according to him, in the ‘resistance’ which operates against the recovery of the lost memories.

[1904a, 1557]

The factor of resistance has become one of the corner-stones of his theory. The ideas which are normally pushed aside on every sort of excuse - such as those mentioned above - are regarded by him as derivatives of the repressed psychical phenomena (thoughts and impulses), distorted owing to the resistance against their reproduction. Ideas which are normally pushed aside on every sort of excuse - such as those mentioned above - are regarded by him as derivatives of the repressed psychical phenomena (thoughts and impulses), distorted owing to the resistance against their reproduction.

[1904a, 1557]

The greater the resistance, the greater is the distortion. The value of these unintentional thoughts for the purposes of therapeutic technique lies in this relation of theirs to the repressed psychical material. If one possesses a procedure which makes it possible to arrive at the repressed material from the associations, at the distorted material from the distortions, then what was formerly unconscious in mental life can be made accessible to consciousness even without hypnosis.

[1904a, 1558]

Freud has developed on this basis an art of interpretation which takes on the task of, as it were, extracting the pure metal of the repressed thoughts from the ore of the unintentional ideas. This work of interpretation is applied not only to the patient's ideas but also to his dreams, which open up the most direct approach to a knowledge of the unconscious, to his unintentional as well as to his purposeless actions (symptomatic acts) and to the blunders he makes in everyday life (slips of the tongue, bungled actions, and so on). The details of this technique of interpretation or translation have not yet been published by Freud. According to indications he has given, they comprise a number of rules, reached empirically, of how the unconscious material may be reconstructed from the associations, directions on how to know what it means when the patient's ideas cease to flow, and experiences of the most important typical resistances that arise in the course of such treatments. A bulky volume called The Interpretation of Dreams, published by Freud in 1900, may be regarded as the forerunner of an initiation into his technique.

[1904a, 1558]
From these remarks on the technique of the psycho-analytic method the conclusion might be drawn that its inventor has given himself needless trouble and has made a mistake in abandoning the less complicated hypnotic mode of procedure. However, in the first place, the technique of psycho-analysis is much easier in practice, when once one has learnt it, than any description of it would indicate; and, secondly, there is no other way which leads to the desired goal, so that the hard road is still the shortest one to travel. The objection to hypnosis is that it conceals the resistance and for that reason has obstructed the physician's insight into the play of psychical forces. Hypnosis does not do away with the resistance but only evades it and therefore yields only incomplete information and transitory therapeutic success.

[1904a, 1558]

(c) From certain of my remarks you will have gathered that there are many characteristics in the analytic method which prevent it from being an ideal form of therapy. *Tuto, cito, jucunde:* investigation and probing do not indicate speedy results, and the resistance I have mentioned would prepare you to expect unpleasantness of various kinds. Psycho-analytic treatment certainly makes great demands upon the patient as well as upon the physician. From the patient it requires perfect sincerity - a sacrifice in itself; it absorbs time and is therefore also costly; for the physician it is no less time-absorbing, and the technique which he must study and practise is fairly laborious. I consider it quite justifiable to resort to more convenient methods of treatment as long as there is any prospect of achieving anything by their means. That, after all, is the only point at issue. If the more difficult and lengthy method accomplishes considerably more than the short and easy one, then, in spite of everything, the use of the former is justified. Only consider, Gentlemen, how much more inconvenient and costly is the Finsen therapy of lupus than the method of cauterizing and scraping previously employed; and yet the use of the former signifies a great advance, for it performs a radical cure. Although I do not wish to carry this comparison to extremes, the psycho-analytic method may claim a similar privilege. Actually, I have been able to elaborate and to test my therapeutic method only on severe, indeed on the severest cases; at first my material consisted entirely of patients who had tried everything else without success, and had spent long years in sanatoria. I have scarcely been able to bring together sufficient material to enable me to say how my method works with those slighter, episodic cases which we see recovering under all kinds of influences and even spontaneously. Psycho-analytic therapy was created through and for the treatment of patients permanently unfit for existence, and its triumph has been that it has made a satisfactorily large number of these permanently fit for existence. In the face of such an achievement all the effort expended seems trivial. We cannot conceal from ourselves what, as physicians, we are in the habit of denying to our patients, namely, that a severe neurosis is no less serious for the sufferer than any cachexia or any of the dreaded major diseases.

[1905a, 1568]
The first of these modern dramas is *Hamlet*. It has as its subject the way in which a man who has so far been normal becomes neurotic owing to the peculiar nature of the task by which he is faced, a man, that is, in whom an impulse that has hitherto been successfully suppressed endeavours to make its way into action. *Hamlet* is distinguished by three characteristics which seem important in connection with our present discussion. (1) The hero is not psychopathic, but only becomes psychopathic in the course of the action of the play. (2) The repressed impulse is one of those which are similarly repressed in all of us, and the repression of which is part and parcel of the foundations of our personal evolution. It is this repression which is shaken up by the situation in the play. As a result of these two characteristics it is easy for us to recognize ourselves in the hero: we are susceptible to the same conflict as he is, since 'a person who does not lose his reason under certain conditions can have no reason to lose'. (3) It appears as a necessary precondition of this form of art that the impulse that is struggling into consciousness, however clearly it is recognizable, is never given a definite name; so that in the spectator too the process is carried through with his attention averted, and he is in the grip of his emotions instead of taking stock of what is happening. A certain amount of resistance is no doubt saved in this way, just as, in an analytic treatment, we find derivatives of the repressed material reaching consciousness, owing to a lower resistance, while the repressed material itself is unable to do so. After all, the conflict in *Hamlet* is so effectively concealed that it was left to me to unearth it.

The procedure which the author makes his Zoe adopt for curing her childhood friend's delusion shows a far-reaching similarity - no, a complete agreement in its essence - with a therapeutic method which was introduced into medical practice in 1895 by Dr. Josef Breuer and myself, and to the perfecting of which I have since then devoted myself. This method of treatment, to which Breuer first gave the name of 'cathartic' but which I prefer to describe as 'analytic', consists, as applied to patients suffering from disorders analogous to Hanold's delusion, in bringing to their consciousness, to some extent forcibly, the unconscious whose repression led to their falling ill - exactly as Gradiva did with the repressed memories of their childhood relations. Gradiva, it is true, could carry out this task more easily than a doctor: in several respects she was in what may be described as an ideal position for it. The doctor, who has no pre-existing knowledge of his patient and possesses no conscious memory of what is unconsciously at work in him, must call a complicated technique to his help in order to make up for this disadvantage. He must learn how to infer with great certainty from the conscious associations and communications of the patient what is repressed in him, how to discover his unconscious as it betrays itself behind his conscious words and acts. He then brings about something like what Norbert Hanold grasped at the end of the story when he translated back the name 'Gradiva' into 'Bertgang'. The disorder vanishes while being traced back to its origin; analysis, too, brings simultaneous cure.

I know that you are at the moment concerned with the potentialities and difficulties of this procedure, whose aim is to lead the accused into an objective self-betrayal. I should therefore like to bring to your notice the fact that an exactly similar method of disclosing psychical material which is buried away or kept secret has been practised for more than a decade in another field. My purpose is to lay before you the resemblances and differences between conditions in the two fields.
It will interest you, from the point of view of your own profession, to hear how we doctors proceed in psycho-analysis. After the patient has given us a first account of his history, we ask him to give himself up to the thoughts that occur to him spontaneously and to say without any critical reserve whatever comes into his head. We start, as you see, on the assumption, which he does not share in the least, that these spontaneous thoughts will not be arbitrarily chosen but will be determined by their relation to his secret - to his 'complex' - and may, as it were, be regarded as derivatives of that complex. You will note that this is the same assumption as the one with the help of which you were able to interpret the association experiments. But although we have instructed the patient to follow the rule of communicating all the thoughts that occur to him, he seems to be unable to do so. He soon begins to hold back first one thought and then another. He gives various reasons to account for this: either the thought was quite unimportant, or it was irrelevant or it was totally meaningless. We thereupon demand that he shall tell us the thought in spite of these objections and shall follow it up; for the very fact of his criticism proves to us that the thought belongs to the 'complex' which we are seeking to uncover. We recognize in this behaviour of the patient's a manifestation of the 'resistance' present in him, which we are never free from through the whole duration of the treatment. I will merely indicate briefly that this concept of resistance has acquired the highest importance for us in understanding the origin of an illness as well as the mechanism of its cure.

In your experiments you do not directly observe criticisms like these of his spontaneous ideas by the subject; while we, on the other hand, are able in our psycho-analyses to observe all the indications of a complex which come to your notice. When the patient no longer ventures to evade the rule which has been laid down for him, we nevertheless note that he stops or hesitates from time to time or pauses in the reproduction of his ideas. Every hesitation of this kind is, as we see it, an expression of his resistance and serves as an indication of a connection with the 'complex'. Indeed, we regard it as the most important sign of such a connection, just as is in your case the analogous prolongation of the reaction-time. We are accustomed to interpret hesitation in this sense even when the content of the idea that is being held back does not seem to be at all objectionable and when the patient assures us he cannot imagine why he should hesitate to tell it to us. The pauses which occur in psycho-analysis are as a rule many times longer than the delays that you observe in the reaction experiments.

Another of your indications of a complex - the change in the content of the reaction - also plays its part in the technique of psycho-analysis. We quite generally regard even slight deviations in our patients from the ordinary forms of expression as a sign of some hidden meaning, and we are quite willing to expose ourselves for a while to the patient's ridicule by making interpretations in that sense, all that we require in order to uncover the complex.

The third of your indications of a complex (mistakes - that is, changes - in the reproduction) is also employed, though in a more restricted field, in the technique of psycho-analysis. One task which often faces us is the interpretation of dreams - that is, the translation of the remembered content of a dream into its hidden meaning. It sometimes happens that we are uncertain at which point to set about the task, and in that case we may make use of a rule, discovered empirically, which recommends us to get the dreamer to tell us his dream once more. In doing so, he usually alters his modes of expression in some parts of it while repeating the rest accurately. The points at which his reproduction is defective owing to changes, and often owing to omissions as well, are the points which we fasten upon, because the inaccuracy guarantees a connection with the complex and promises the best approach to the secret meaning of the dream.¹

[1906c, 1893]

[1906c, 1894]
You must not get the impression that we have come to an end of the points of agreement which I have been following up, if I admit to you that no phenomenon similar to *perseveration* is manifested in psycho-analysis. This apparent difference only arises from the special conditions of your experiments. For you do not allow the effect of the complex time to develop. Scarcely has it begun to act than you distract the subject’s attention by a new and probably innocent stimulus word; and then you may observe that he sometimes continues to be occupied with the complex in spite of your interference. In psycho-analysis, on the other hand, we avoid such interferences and keep the patient occupied with the complex. Since in our procedure *everything*, so to speak, is perseveration, we cannot observe that phenomenon as an isolated occurrence.

[1906c, 1895]

Psycho-analytic research into the neuroses (the various forms of nervous illness with a mental causation) has endeavoured to trace their connection with instinctual life and the restrictions imposed on it by the claims of civilization, with the activities of the normal individual in phantasies and dreams, and with the creations of the popular mind in religion, myths and fairy tales. The psycho-analytic treatment of neurotic patients, based on this method of research, makes far higher demands on doctor and patient than the methods hitherto in common use, which operate through medicaments, diet, hydropathy and suggestion. But it brings the patients so much more relief and permanent strengthening in the face of life’s problems, that there is no cause for surprise at the continual advances made by this therapeutic method in spite of violent opposition.

[1910b, 1995]

The next day I made him pledge himself to submit to the one and only condition of the treatment - namely, to say everything that came into his head, even if it was *unpleasant* to him, or seemed *unimportant* or *irrelevant* or *senseless*. I then gave him leave to start his communications with any subject he pleased, and he began thus:¹

[1909d, 2130]

The reader must not expect to hear at once what light I have to throw upon the patient’s strange and senseless obsessions about the rats. The true technique of psycho-analysis requires the physician to suppress his curiosity and leaves the patient complete freedom in choosing the order in which topics shall succeed each other during the treatment. At the fourth session, accordingly, I received the patient with the question: ‘And how do you intend to proceed to-day?’

[1909d, 2142]
A discussion of this childhood scene will be found in the footnote, and here I will only remark that its emergence shook the patient for the first time in his refusal to believe that at some prehistoric period in his childhood he had been seized with fury (which had subsequently become latent) against the father whom he loved so much. I must confess that I had expected it to have a greater effect, for the incident had been described to him so often - even by his father himself - that there could be no doubt of its objective reality. But, with that capacity for being illogical which never fails to bewilder one in such highly intelligent people as obsessional neurotics, he kept urging against the evidential value of the story the fact that he himself could not remember the scene. And so it was only along the painful road of transference that he was able to reach a conviction that his relation to his father really necessitated the postulation of this unconscious complement. Things soon reached a point at which, in his dreams, his waking phantasies, and his associations, he began heaping the grossest and filthiest abuse upon me and my family, though in his deliberate actions he never treated me with anything but the greatest respect. His demeanour as he repeated these insults to me was that of a man in despair. 'How can a gentleman like you, sir,' he used to ask, 'let yourself be abused in this way by a low, good-for-nothing fellow like me? You ought to turn me out: that's all I deserve.' While he talked like this, he would get up from the sofa and roam about the room, - a habit which he explained at first as being due to delicacy of feeling: he could not bring himself, he said, to utter such horrible things while he was lying there so comfortably. But soon he himself found a more cogent explanation, namely, that he was avoiding my proximity for fear of my giving him a beating. If he stayed on the sofa he behaved like some one in desperate terror trying to save himself from castigations of terrific violence; he would bury his head in his hands, cover his face with his arm, jump up suddenly and rush away, his features distorted with pain, and so on. He recalled that his father had had a passionate temper, and sometimes in his violence had not known where to stop. Thus, little by little, in this school of suffering, the patient won the sense of conviction which he had lacked - though to any disinterested mind the truth would have been almost self-evident.

In elucidating the effects produced by the captain's rat story we must follow the course of the analysis more closely. The patient began by producing an enormous mass of associative material, which at first, however, threw no light upon the circumstances in which the formation of his obsession had taken place. The idea of the punishment carried out by means of rats had acted as a stimulus to a number of his instincts and had called up a whole quantity of recollections; so that, in the short interval between the captain's story and his request to him to pay back the money, rats had acquired a series of symbolic meanings, to which, during the period which followed, fresh ones were continually being added. I must confess that I can only give a very incomplete account of the whole business. What the rat punishment stirred up more than anything else was his anal erotism, which had played an important part in his childhood and had been kept in activity for many years by a constant irritation due to worms. In this way rats came to have the meaning of 'money'.¹ The patient gave an indication of this connection by reacting to the word 'Ratten' ['rats'] with the association 'Raten' ['instalments']. In his obsessional deliria he had coined himself a regular rat currency. When, for instance, in reply to a question, I told him the amount of my fee for an hour's treatment, he said to himself (as I learned six months later): 'So many florins, so many rats'. Little by little he translated into this language the whole complex of money interests which centred round his father's legacy to him, that is to say, all his ideas connected with that subject were, by way of the verbal bridge 'Raten - Ratten', carried over into his obsessional life and brought under the dominion of his unconscious. Moreover, the captain's request to him to pay back the charges due upon the packet served to strengthen the money significance of rats, by way of another verbal bridge 'Spielratte', which led back to his father's gambling debt.

¹ [1909d, 2166]
I did not abandon it, however, before the observations I made during my use of it afforded me
decisive evidence. I found confirmation of the fact that the forgotten memories were not lost.
They were in the patient's possession and were ready to emerge in association to what was still
known by him; but there was some force that prevented them from becoming conscious and
compelled them to remain unconscious. The existence of this force could be assumed with
certainty, since one became aware of an effort corresponding to it if, in opposition to it, one tried
to introduce the unconscious memories into the patient's consciousness. The force which was
maintaining the pathological condition became apparent in the form of *resistance* on the part of
the patient.
[1910a, 2212]

While I was thus at a loss, I clung to a prejudice the scientific justification for which was
proved years later by my friend C. G. Jung and his pupils in Zurich. I am bound to say that it is
sometimes most useful to have prejudices. I cherished a high opinion of the strictness with
which mental processes are determined, and I found it impossible to believe that an idea
produced by a patient while his attention was on the stretch could be an arbitrary one and
unrelated to the idea we were in search of. The fact that the two ideas were not identical could
be satisfactorily explained from the postulated psychological state of affairs. In the patient under
treatment two forces were in operation against each other: on the one hand, his conscious
endeavour to bring into consciousness the forgotten idea in his unconscious, and on the other
hand, the resistance we already know about, which was striving to prevent what was repressed
or its derivatives from thus becoming conscious. If this resistance amounted to little or nothing,
what had been forgotten became conscious without distortion. It was accordingly plausible to
suppose that the greater the resistance against what we were in search of becoming conscious,
the greater would be its distortion. The idea which occurred to the patient in place of what we
were in search of had thus itself originated like a symptom: it was a new, artificial and
ephemeral substitute for what had been repressed, and was dissimilar to it in proportion to the
degree of distortion it had undergone under the influence of the resistance. But, owing to its
nature as a symptom, it must nevertheless have a certain similarity to what we were in search
of; and if the resistance were not too great, we ought to be able to guess the latter from the
former. The idea occurring to the patient must be in the nature of an *allusion* to the repressed
element, like a representation of it in indirect speech.
[1910a, 2217]
This is the anecdote.¹ Two not particularly scrupulous business men had succeeded, by dint of a series of highly risky enterprises, in amassing a large fortune, and they were now making efforts to push their way into good society. One method, which struck them as a likely one, was to have their portraits painted by the most celebrated and highly-paid artist in the city, whose pictures had an immense reputation. The precious canvases were shown for the first time at a large evening party, and the two hosts themselves led the most influential connoisseur and art critic up to the wall on which the portraits were hanging side by side. He studied the works for a long time, and then, shaking his head, as though there was something he had missed, pointed to the gap between the pictures and asked quietly: 'But where's the Saviour?'² I see you are all much amused at this joke. Let us now proceed to examine it. Clearly what the connoisseur meant to say was: 'You are a couple of rogues, like the two thieves between whom the Saviour was crucified.' But he did not say this. Instead he made a remark which seems at first sight strangely inappropriate and irrelevant, but which we recognize a moment later as an allusion to the insult that he had in mind and as a perfect substitute for it. We cannot expect to find in jokes all the characteristics that we have attributed to the ideas occurring to our patients, but we must stress the identity of the motive for the joke and for the idea. Why did the critic not tell the rogues straight out what he wanted to say? Because he had excellent counter-motives working against his desire to say it to their faces. There are risks attendant upon insulting people who are one's hosts and who have at their command the fists of a large domestic staff. One might easily meet with the fate which I suggested in my last lecture as an analogy for repression. That was the reason why the critic did not express the insult he had in mind directly but in the form of an 'allusion accompanied by omission'; and the same state of things is responsible for our patients' producing a more or less distorted substitute instead of the forgotten idea we are in search of.

[1910a, 2218]

It is highly convenient, Ladies and Gentlemen, to follow the Zurich school (Bleuler, Jung, etc.) in describing a group of interdependent ideational elements cathected with affect as a 'complex'. We see, then, that if in our search for a repressed complex in one of our patients we start out from the last thing he remembers, we shall have every prospect of discovering the complex, provided that the patient puts a sufficient number of his free associations at our disposal. Accordingly, we allow the patient to say whatever he likes, and hold fast to the postulate that nothing can occur to him which is not in an indirect fashion dependent on the complex we are in search of. If this method of discovering what is repressed strikes you as unduly circumstantial, I can at least assure you that it is the only practicable one.

[1910a, 2219]

When we come to putting this procedure into effect, we are subject to yet another interference. For the patient will often pause and come to a stop, and assert that he can think of nothing to say, and that nothing whatever occurs to his mind. If this were so and if the patient were right, then our procedure would once again have proved ineffective. But closer observation shows that such a stoppage of the flow of ideas never in fact occurs. It appears to happen only because the patient holds back or gets rid of the idea that he has become aware of, under the influence of the resistances which disguise themselves as various critical judgements about the value of the idea that has occurred to him. We can protect ourselves against this by warning him beforehand of this behaviour and requiring him to take no notice of such criticisms. He must, we tell him, entirely renounce any critical selection of this kind and say whatever comes into his head, even if he considers it incorrect or irrelevant or nonsensical, and above all if he finds it disagreeable to let himself think about what has occurred to him. So long as this ordinance is carried out we are certain of obtaining the material which will put us on the track of the repressed complexes.

[1910a, 2219]
Working over the ideas that occur to patients when they submit to the main rule of psychoanalysis is not our only technical method of discovering the unconscious. The same purpose is served by two other procedures: the interpretation of patients' dreams and the exploitation of their faulty and haphazard actions.

[1910a, 2220]

I invite you now to follow me on a brief excursion through the region of dream-problems. When we are awake we are in the habit of treating dreams with the same contempt with which patients regard the associations that are demanded of them by the psycho-analyst. We dismiss them, too, by forgetting them as a rule, quickly and completely. Our low opinion of them is based on the strange character even of those dreams that are not confused and meaningless, and on the obvious absurdity and nonsensicalness of other dreams. Our dismissal of them is related to the uninhibited shamelessness and immorality of the tendencies openly exhibited in some dreams. It is well known that the ancient world did not share this low opinion of dreams. Nor are the lower strata of our own society to-day in any doubt about the value of dreams; like the peoples of antiquity, they expect them to reveal the future. I confess that I feel no necessity for making any mystical assumptions in order to fill the gaps in our present knowledge, and accordingly I have never been able to find anything to confirm the prophetic nature of dreams. There are plenty of other things - sufficiently wonderful too - to be said about them.

[1910a, 2221]

You can convince yourself that there are such things as latent dream-thoughts and that the relation between them and the manifest content of the dream is really as I have described it, if you carry out an analysis of dreams, the technique of which is the same as that of psycho-analysis. You entirely disregard the apparent connections between the elements in the manifest dream and collect the ideas that occur to you in connection with each separate element of the dream by free association according to the psycho-analytic rule of procedure. From this material you arrive at the latent dream-thoughts, just as you arrived at the patient's hidden complexes from his associations to his symptoms and memories. The latent dream-thoughts which have been reached in this way will at once show you how completely justified we have been in tracing back adults' dreams to children's dreams. The true meaning of the dream, which has now taken the place of its manifest content, is always clearly intelligible; it has its starting-point in experiences of the previous day, and proves to be a fulfilment of unsatisfied wishes. The manifest dream, which you know from your memory when you wake up, can therefore only be described as a disguised fulfilment of repressed wishes.

[1910a, 2222]

If you will now bring together the means we possess for uncovering what is concealed, forgotten and repressed in the mind (the study of the ideas occurring to patients under free association, of their dreams and of their faulty and symptomatic actions), and if you will add to these the exploitation of certain other phenomena which occur during psycho-analytic treatment and on which I shall have a few remarks to make later under the heading of 'transference' - if you bear all these in mind, you will agree with me in concluding that our technique is already efficient enough to fulfil its task, to bring the pathogenic psychical material into consciousness and so to get rid of the ailments that have been brought about by the formation of substitutive symptoms. And if, in the course of our therapeutic endeavours, we extend and deepen our knowledge of the human mind both in health and sickness, that can, of course, only be regarded as a peculiar attraction in our work.

[1910a, 2225]
You may have formed an impression that the technique through whose armoury I have just conducted you is particularly difficult. In my opinion that technique is entirely in conformity with the material with which it has to deal. But this much at least is clear: it is not a self-evident one and it must be learnt just as the techniques of histology or surgery must be learnt. You will perhaps be surprised to hear that in Europe we have heard a large number of judgements on psycho-analysis from people who know nothing of this technique and do not employ it; and who go on to demand with apparent scorn that we shall prove to them the correctness of our findings. Among these adversaries there are no doubt some to whom a scientific mode of thought is not as a rule alien, who, for instance, would not reject the results of a microscopic examination because it could not be confirmed on the anatomical preparation with the naked eye, but who would first form a judgement on the matter themselves with the help of a microscope. But, where psycho-analysis is concerned, the prospects of recognition are in truth less favourable. Psycho-analysis is seeking to bring to conscious recognition the things in mental life which are repressed; and everyone who forms a judgement on it is himself a human being, who possesses similar repressions and may perhaps be maintaining them with difficulty. They are therefore bound to call up the same resistance in him as in our patients; and that resistance finds it easy to disguise itself is an intellectual rejection and to bring up arguments like those which we ward off in our patients by means of the fundamental rule of psycho-analysis. We often become aware in our opponents, just as we do in our patients, that their power of judgement is very noticeably influenced affectively in the sense of being diminished. The arrogance of consciousness (in rejecting dreams with such contempt, for instance) is one of the most powerful of the devices with which we are provided as a universal protection against the incursion of unconscious complexes. That is why it is so hard to convince people of the reality of the unconscious and to teach them to recognize something new which is in contradiction to their conscious knowledge.

More than ten years ago, at a time when the findings and hypotheses of psycho-analysis were known to only a few people, the following events were reported to me from a trustworthy source. A girl, who was the daughter of a medical man, fell ill of hysteria with local symptoms. Her father denied that it was hysteria and arranged for various somatic treatments to be initiated, which brought little improvement. One day a woman friend of the patient's said to her: 'Have you never thought of consulting Dr. F.?' To which the patient replied: 'What good would that be? I know he'd say to me: "Have you ever had the idea of having sexual intercourse with your father?"' - It seems unnecessary for me to say explicitly that it has never been my practice and is not my practice to-day to ask such questions. But it is worth remarking that much of what patients report of the words and actions of their physicians may be understood as revelations of their own pathogenic phantasies.

In conclusion, I will mention a particular type of dream which, in the nature of the case, occurs only in the course of psycho-analytic treatment, and may bewilder or mislead beginners. These are the corroborative dreams which, as it were 'tag along behind'; they are easily accessible to analysis, and their translation merely presents what the treatment has inferred during the last new days from the material of the daily associations. When this happens, it looks as though the patient has been amiable enough to bring us in dream-form exactly what we had been 'suggesting' to him immediately before. The more experienced analyst will no doubt have some difficulty in attributing any such amiability to the patient; he accepts such dreams as hoped-for confirmations, and recognizes that they are only observed under certain conditions brought about by the influence of the treatment. The great majority of dreams forge ahead of the analysis; so that, after subtraction of everything in them which is already known and understood, there still remains a more or less clear hint at something which has hitherto been hidden.
In all these reflections, however, we have hitherto dealt only with one side of the phenomenon of transference; we must turn our attention to another aspect of the same subject. Anyone who forms a correct appreciation of the way in which a person in analysis, as soon as he comes under the dominance of any considerable transference-resistance, is flung out of his real relation to the doctor, how he feels at liberty then to disregard the fundamental rule of psycho-analysis which lays it down that whatever comes into one's head must be reported without criticizing it, how he forgets the intentions with which he started the treatment, and how he regards with indifference logical arguments and conclusions which only a short time before had made a great impression on him - anyone who has observed all this will feel it necessary to look for an explanation of his impression in other factors besides those that have already been adduced. Nor are such factors far to seek: they arise once again from the psychological situation in which the treatment places the patient.

It will be seen that the rule of giving equal notice to everything is the necessary counterpart to the demand made on the patient that he should communicate everything that occurs to him without criticism or selection. If the doctor behaves otherwise, he is throwing away most of the advantage which results from the patient's obeying the 'fundamental rule of psycho-analysis'. The rule for the doctor may be expressed: 'He should withhold all conscious influences from his capacity to attend, and give himself over completely to his "unconscious memory".' Or, to put it purely in terms of technique: 'He should simply listen, and not bother about whether he is keeping anything in mind.'

It is easy to see upon what aim the different rules I have brought forward converge. They are all intended to create for the doctor a counterpart to the 'fundamental rule of psycho-analysis' which is laid down for the patient. Just as the patient must relate everything that his self-observation can detect, and keep back all the logical and affective objections that seek to induce him to make a selection from among them, so the doctor must put himself in a position to make use of everything he is told for the purposes of interpretation and of recognizing the concealed unconscious material without substituting a censorship of his own for the selection that the patient has forgoned. To put it in a formula: he must turn his own unconscious like a receptive organ towards the transmitting unconscious of the patient. He must adjust himself to the patient as a telephone receiver is adjusted to the transmitting microphone. Just as the receiver converts back into sound waves the electric oscillations in the telephone line which were set up by sound waves, so the doctor's unconscious is able, from the derivatives of the unconscious which are communicated to him, to reconstruct that unconscious, which has determined the patient's free associations.
(1) To what extent should the patient's intellectual co-operation be sought for in the treatment? It is difficult to say anything of general applicability on this point: the patient's personality is the determining factor. But in any case caution and self-restraint must be observed in this connection. It is wrong to set a patient tasks, such as collecting his memories or thinking over some particular period of his life. On the contrary, he has to learn above all - what never comes easily to anyone - that mental activities such as thinking something over or concentrating the attention solve none of the riddles of a neurosis; that can only be done by patiently obeying the psycho-analytic rule, which enjoins the exclusion of all criticism of the unconscious or of its derivatives. One must be especially unyielding about obedience to that rule with patients who practise the art of sheering off into intellectual discussion during their treatment, who speculate a great deal and often very wisely about their condition and in that way avoid doing anything to overcome it. For this reason I dislike making use of analytic writings as an assistance to my patients; I require them to learn by personal experience, and I assure them that they will acquire wider and more valuable knowledge than the whole literature of psycho-analysis could teach them. I recognize, however, that under institutional conditions it may be of great advantage to employ reading as a preparation for patients in analysis and as a means of creating an atmosphere of influence.

[1912e, 2474]

Both lay public and doctors - still ready to confuse psycho-analysis with treatment by suggestion - are inclined to attribute great importance to the expectations which the patient brings to the new treatment. They often believe in the case of one patient that he will not give much trouble, because he has great confidence in psycho-analysis and is fully convinced of its truth and efficacy; whereas in the case of another, they think that he will undoubtedly prove more difficult, because he has a sceptical outlook and will not believe anything until he has experienced its successful results on his own person. Actually, however, this attitude on the part of the patient has very little importance. His initial trust or distrust is almost negligible compared with the internal resistances which hold the neurosis firmly in place. It is true that the patient's happy trustfulness makes our earliest relationship with him a very pleasant one; we are grateful to him for that, but we warn him that his favourable prepossession will be shattered by the first difficulty that arises in the analysis. To the sceptic we say that the analysis requires no faith, that he may be as critical and suspicious as he pleases and that we do not regard his attitude as the effect of his judgement at all, for he is not in a position to form a reliable judgement on these matters; his distrust is only a symptom like his other symptoms and it will not be an interference, provided he conscientiously carries out what the rule of the treatment requires of him.

[1913c, 2479]

Before I wind up these remarks on beginning analytic treatment, I must say a word about a certain ceremonial which concerns the position in which the treatment is carried out. I hold to the plan of getting the patient to lie on a sofa while I sit behind him out of his sight. This arrangement has a historical basis; it is the remnant of the hypnotic method out of which psycho-analysis was evolved. But it deserves to be maintained for many reasons. The first is a personal motive, but one which others may share with me. I cannot put up with being stared at by other people for eight hours a day (or more). Since, while I am listening to the patient, I, too, give myself over to the current of my unconscious thoughts, I do not wish my expressions of face to give the patient material for interpretations or to influence him in what he tells me. The patient usually regards being made to adopt this position as a hardship and rebels against it, especially if the instinct for looking (scopophilia) plays an important part in his neurosis. I insist on this procedure, however, for its purpose and result are to prevent the transference from mingling with the patient's associations imperceptibly, to isolate the transference and to allow it to come forward in due course sharply defined as a resistance. I know that many analysts work in a different way, but I do not know whether this deviation is due more to a craving for doing things differently or to some advantage which they find they gain by it.

[1913c, 2487]
The only exception to this is in regard to the fundamental rule of psycho-analytic technique which the patient has to observe. This must be imparted to him at the very beginning: 'One more thing before you start. What you tell me must differ in one respect from an ordinary conversation. Ordinarily you rightly try to keep a connecting thread running through your remarks and you exclude any intrusive ideas that may occur to you and any side-issues, so as not to wander too far from the point. But in this case you must proceed differently. You will notice that as you relate things various thoughts will occur to you which you would like to put aside on the ground of certain criticisms and objections. You will be tempted to say to yourself that this or that is irrelevant here, or is quite up important, or nonsensical, so that there is no need to say it. You must never give in to these criticisms, but must say it in spite of them - indeed, you must say it precisely because you feel an aversion to doing so. Later on you will find out and learn to understand the reason for this injunction, which is really the only one you have to follow. So say whatever goes through your mind. Act as though, for instance, you were a traveller sitting next to the window of a railway carriage and describing to someone inside the carriage the changing views which you see outside. Finally, never forget that you have promised to be absolutely honest, and never leave anything out because, for some reason or other, it is unpleasant to tell it.'¹

¹ Much might be said about our experiences with the fundamental rule of psycho-analysis. One occasionally comes across people who behave as if they had made this rule for themselves. Others offend against it from the very beginning. It is indispensable, and also advantageous, to lay down the rule in the first stages of the treatment. Later, under the dominance of the resistances, obedience to it weakens, and there comes a time in every analysis when the patient disregards it. We must remember from our own self-analysis how irresistible the temptation is to yield to these pretexts put forward by critical judgement for rejecting certain ideas. How small is the effect of such agreements as one makes with the patient in laying down the fundamental rule is regularly demonstrated when something intimate about a third person comes up in his mind for the first time. He knows that he is supposed to say everything, but he turns discretion about other people into a new obstacle! 'Must I really say everything? I thought that only applied to things that concern myself.' It is naturally impossible to carry out analysis if the patient's relations with other people and his thoughts about them are excluded. Pour faire une omelette il faut casser des œufs. An honourable man readily forgets such of the private affairs of strangers as do not seem to him important to know. Nor can an exception be made in the case of names. Otherwise the patient's narratives became a little shadowy, like the scenes in Goethe's play Die natürliche Tochter [The Natural Daughter], and do not lodge in the doctor's memory. Moreover, the names that are withheld screen the approach to all sorts of important connections. But one may perhaps allow names to be left on one side until the patient has become more familiar with the doctor and the procedure of analysis. It is very remarkable how the whole task becomes impossible if a reservation is allowed at any single point. But we have only to reflect what would happen if the right of asylum existed at any one point in a town; how long would it be before all the riff-raff of the town had collected there? I once treated a high official who was bound by his oath of office not to communicate certain things because they were state secrets, and the analysis came to grief as a consequence of this restriction. Psycho-analytic treatment must have no regard for any consideration, because the neurosis and its resistances are themselves without any such regard.

[1913c, 2488]
To return to the beginning of the treatment. Patients are occasionally met with who start the treatment by assuring us that they cannot think of anything to say, although the whole field of their life-history and the story of their illness is open to them to choose from. Their request that we should tell them what to talk about must not be granted on this first occasion any more than on any later one. We must bear in mind what is involved here. A strong resistance has come to the front in order to defend the neurosis; we must take up the challenge then and there and come to grips with it. Energetic and repeated assurances to the patient that it is impossible for no ideas at all to occur to him at the beginning, and that what is in question is a resistance against the analysis, soon oblige him to make the expected admissions or to uncover a first piece of his complexes. It is a bad sign if he has to confess that while he was listening to the fundamental rule of analysis he made a mental reservation that he would nevertheless keep this or that to himself; it is not so serious if all he has to tell us is how mistrustful he is of analysis or the horrifying things he has heard about it. If he denies these and similar possibilities when they are put before him, he can be driven by our insistence to acknowledge that he has nevertheless overlooked certain thoughts which were occupying his mind. He had thought of the treatment itself, though nothing definite about it, or he had been occupied with the picture of the room in which he was, or he could not help thinking of the objects in the consulting room and of the fact that he was lying here on a sofa - all of which he has replaced by the word 'nothing'. These indications are intelligible enough: everything connected with the present situation represents a transference to the doctor, which proves suitable to serve as a first resistance. We are thus obliged to begin by uncovering this transference; and a path from it will give rapid access to the patient's pathogenic material. Women who are prepared by events in their past history to be subjected to sexual aggression and men with over-strong repressed homosexuality are the most apt thus to withhold the ideas that occur to them at the outset of their analysis.

It seems to me not unnecessary to keep on reminding students of the far-reaching changes which psycho-analytic technique has undergone since its first beginnings. In its first phase - that of Breuer's catharsis - it consisted in bringing directly into focus the moment at which the symptom was formed, and in persistently endeavouring to reproduce the mental processes involved in that situation, in order to direct their discharge along the path of conscious activity. Remembering and abreacting, with the help of the hypnotic state, were what was at that time aimed at. Next, where hypnosis had been given up, the task became one of discovering from the patient's free associations what he failed to remember. The resistance was to be circumvented by the work of interpretation and by making its results known to the patient. The situations which had given rise to the formation of the symptom and the other situations which lay behind the moment at which the illness broke out retained their place as the focus of interest; but the element of abreaction receded into the background and seemed to be replaced by the expenditure of work which the patient had to make in being obliged to overcome his criticism of his free associations, in accordance with the fundamental rule of psycho-analysis. Finally, there was evolved the consistent technique used to-day, in which the analyst gives up the attempt to bring a particular moment or problem into focus. He contents himself with studying whatever is present for the time being on the surface of the patient's mind, and he employs the art of interpretation mainly for the purpose of recognizing the resistances which appear there, and making them conscious to the patient. From this there results a new sort of division of labour: the doctor uncovers the resistances which are unknown to the patient; when these have been got the better of, the patient often relates the forgotten situations and connections without any difficulty. The aim of these different techniques has, of course, remained the same. Descriptively speaking, it is to fill in gaps in memory; dynamically speaking, it is to overcome resistances due to repression.
Above all, the patient will begin his treatment with a repetition of this kind. When one has announced the fundamental rule of psycho-analysis to a patient with an eventful life-history and a long story of illness and has then asked him to say what occurs to his mind, one expects him to pour out a flood of information; but often the first thing that happens is that he has nothing to say. He is silent and declares that nothing occurs to him. This, of course, is merely a repetition of a homosexual attitude which comes to the fore as a resistance against remembering anything. As long as the patient is in the treatment he cannot escape from this compulsion to repeat; and in the end we understand that this is his way of remembering.

[1914g, 2501]

I might break off at this point but for the title of this paper, which obliges me to discuss a further point in analytic technique. The first step in overcoming the resistances is made, as we know, by the analyst's uncovering the resistance, which is never recognized by the patient, and acquainting him with it. Now it seems that beginners in analytic practice are inclined to look on this introductory step as constituting the whole of their work. I have often been asked to advise upon cases in which the doctor complained that he had pointed out his resistance to the patient and that nevertheless no change had set in; indeed, the resistance had become all the stronger, and the whole situation was more obscure than ever. The treatment seemed to make no headway. This gloomy foreboding always proved mistaken. The treatment was as a rule progressing most satisfactorily. The analyst had merely forgotten that giving the resistance a name could not result in its immediate cessation. One must allow the patient time to become more conversant with this resistance with which he has now become acquainted, to work through it, to overcome it, by continuing, in defiance of it, the analytic work according to the fundamental rule of analysis. Only where the resistance is at its height can the analyst, working in common with his patient, discover the repressed instinctual impulses which are feeding the resistance; and it is this kind of experience which convinces the patient of the existence and power of such impulses. The doctor has nothing else to do than to wait and let things take their course, a course which cannot be avoided nor always hastened. If he holds fast to this conviction he will often be spared the illusion of having failed when in fact he is conducting the treatment on the right lines.

[1914g, 2506]

Just as little can I advocate a middle course, which would recommend itself to some people as being specially ingenious. This would consist in declaring that one returns the patient's fond feelings but at the same time in avoiding any physical implementation of this fondness until one is able to guide the relationship into calmer channels and raise it to a highest level. My objection to this expedient is that psycho-analytic treatment is founded on truthfulness. In this fact lies a great part of its educative effect and its ethical value. It is dangerous to depart from this foundation. Anyone who has become saturated in the analytic technique will no longer be able to make use of the lies and pretences which a doctor normally finds unavoidable; and if, with the best intentions, he does attempt to do so, he is very likely to betray himself. Since we demand strict truthfulness from our patients, we jeopardize our whole authority if we let ourselves be caught out by them in a departure from the truth. Besides, the experiment of letting oneself go a little way in tender feelings for the patient is not altogether without danger. Our control over ourselves is not so complete that we may not suddenly one day go further than we had intended. In my opinion, therefore, we ought not to give up the neutrality towards the patient, which we have acquired through keeping the counter-transference in check.

[1915a, 2514]
The first psycho-analytic examinations and attempts at treatment were made with the help of hypnotism. Afterwards this was abandoned and the work was carried out by the method of 'free association', with the patient remaining in his normal state. This modification had the advantage of enabling the procedure to be applied to a far larger number of cases of hysteria, as well as to other neuroses and also to healthy people. The development of a special technique of interpretation became necessary, however, in order to draw conclusions from the expressed ideas of the person under investigation. These interpretations established with complete certainty the fact that psychical dissociations are maintained entirely by 'internal resistances'. The conclusion seems justified, therefore, that the dissociations have originated owing to internal conflict, which has led to the 'repression' of the underlying impulse. To overcome this conflict and in that way to cure the neurosis, the guiding hand of a doctor trained in psycho-analysis is required.

[1913m, 2546]

The mind of the hysterical patient is full of active yet unconscious ideas; all her symptoms proceed from such ideas. It is in fact the most striking character of the hysterical mind to be ruled by them. If the hysterical woman vomits, she may do so from the idea of being pregnant. She has, however, no knowledge of this idea, although it can easily be detected in her mind, and made conscious to her, by one of the technical procedures of psycho-analysis. If she is executing the jerks and movements constituting her 'fit', she does not even consciously represent to herself the intended actions, and she may perceive those actions with the detached feelings of an onlooker. Nevertheless analysis will show that she was acting her part in the dramatic reproduction of some incident in her life, the memory of which was unconsciously active during the attack. The same preponderance of active unconscious ideas is revealed by analysis as the essential fact in the psychology of all other forms of neurosis.

[1912g, 2579]

Reverting once more, however, to the opposite aspect of repression, let us make it clear that it is not even correct to suppose that repression withholds from the conscious all the derivatives of what was primally repressed. If these derivatives have become sufficiently far removed from the repressed representative, whether owing to the adoption of distortions or by reason of the number of intermediate links inserted, they have free access to the conscious. It is as though the resistance of the conscious against them was a function of their distance from what was originally repressed. In carrying out the technique of psycho-analysis, we continually require the patient to produce such derivatives of the repressed as, in consequence either of their remoteness or of their distortion, can pass the censorship of the conscious. Indeed, the associations which we require him to give without being influenced by any conscious purposive idea and without any criticism, and from which we reconstitute a conscious translation of the repressed representative - these associations are nothing else than remote and distorted derivatives of this kind. During this process we observe that the patient can go on spinning a thread of such associations, till he is brought up against some thought, the relation of which to what is repressed becomes so obvious that he is compelled to repeat his attempt at repression. Neurotic symptoms, too, must have fulfilled this same condition, for they are derivatives of the repressed, which has, by their means, finally won the access to consciousness which was previously denied to it.

[1915d, 2980]
In psycho-analytic treatment the existence of the second censorship, located between the systems *Pcs.* and *Cs.*, is proved beyond question. We require the patient to form numerous derivatives of the *Ucs.*, we make him pledge himself to overcome the objections of the censorship to these preconscious formations becoming conscious, and by overthrowing this censorship, we open up the way to abrogating the repression accomplished by the *earlier* one. To this let us add that the existence of the censorship between the *Pcs.* and the *Cs.* teaches us that becoming conscious is no mere act of perception, but is probably also a *hypercathectic*, a further advance in the psychical organization.

The content of the system *Pcs.* (or *Cs.*) is derived partly from instinctual life (through the medium of the *Ucs.*), and partly from perception. It is doubtful how far the processes of this system can exert a direct influence on the *Ucs.*; examination of pathological cases often reveals an almost incredible independence and lack of susceptibility to influence on the part of the *Ucs.*. A complete divergence of their trends, a total severance of the two systems, is what above all characterizes a condition of illness. Nevertheless, psycho-analytic treatment is based upon an influencing of the *Ucs.* from the direction of the *Cs.*, and at any rate shows that this, though a laborious task, is not impossible. The derivatives of the *Ucs.* which act as intermediaries between the two systems open the way, as we have already said, towards accomplishing this. But we may safely assume that a spontaneously effected alteration in the *Ucs.* from the direction of the *Cs.* is a difficult and slow process.

But on your main point you are wrong. If you think it is arbitrary to assume that the first thing that occurs to the dreamer is bound to bring what we are looking for or to lead us to it, if you think that what occurs to him might be anything in the world and might have no connection with what we are looking for, and that it is only exhibiting my trust in Providence if I expect something different - then you are making a great mistake. Once before I ventured to tell you that you nourish a deeply rooted faith in undetermined psychical events and in free will, but that this is quite unscientific and must yield to the demand of a determinism whose rule extends over mental life. I beg you to respect it as a fact that *that* is what occurred to the man when he was questioned and nothing else. But I am not opposing one faith with another. It can be proved that the idea produced by the man was not arbitrary nor indeterminable nor unconnected with what we were looking for. Indeed, not long ago I learnt - without, I may say, attaching too much importance to the fact - that experimental psychology too had brought up evidence to that effect. In view of the importance of the matter, I will ask for your special attention. If I ask someone to tell me what occurs to him in response to a particular element of a dream, I am asking him to surrender himself to free association *while keeping an idea in mind as a starting point*. This calls for a special attitude of the attention which is quite different from reflection and which excludes reflection. Some people achieve this attitude with ease; others show an incredibly high degree of clumsiness when they attempt it. There is, however, a higher degree of freedom of association: that is to say, I may drop the insistence on keeping an initial idea in mind and only lay down the sort or kind of association I want - I may, for instance, require the experimenter to allow a proper name or a number to occur to him freely. What then occurs to him would presumably be even more arbitrary and more indeterminable than with our own technique. It can be shown, however, that it is always strictly determined by important internal attitudes of mind which are not known to us at the moment at which they operate - which are as little known to us as the disturbing purposes of paraprases and the provoking ones of chance actions.
I and many others after me have repeatedly made such experiments with names and numbers thought of at random, and a few of these have been published. Here the procedure is to produce a series of associations to the name which has emerged; these latter associations are accordingly no longer completely free but have a link, like the associations to the elements of dreams. One continues doing this until one finds the impulse exhausted. But by then light will have been thrown both on the motive and the meaning of the random choice of the name. These experiments always lead to the same result; reports on them often cover a wealth of material and call for extensive expositions. The associations to numbers chosen at random are perhaps the most convincing; they run off so quickly and proceed with such incredible certainty to a hidden goal that the effect is really staggering. I will give you only one example of an analysis like this of a name, since dealing with it calls for a conveniently small amount of material.

[1916-1917, 3205]

Having learnt thus much, you will be able to say: 'We acknowledge now that thoughts that occur to one freely are determined and not arbitrary as we supposed. We admit that this is also true of thoughts occurring in response to the elements of dreams. But that is not what we are concerned with. You assert that what occurs to the dreamer in response to the dream-element will be determined by the psychical background (unknown to us) of that particular element. This does not seem to us to be proved. We quite expect that what occurs to the dreamer in response to the dream-element will turn out to be determined by one of the dreamer's complexes, but what good does that do us? This does not lead us to an understanding of dreams but, like the association-experiment, to a knowledge of these so-called complexes. But what have they got to do with dreams?'

[1916-1917, 3206]

These objections are obviously a threat to the success of our work. We must guard against them, and in our own case we do so by firmly resolving not to give way to them. If we are analysing someone else's dream, we do so by laying it down as an inviolable rule that he must not hold back any idea from us, even if it gives rise to one of the four objections - of being too unimportant or too senseless or of being irrelevant or too distressing to be reported. The dreamer promises to obey the rule, and we may be annoyed afterwards to find how badly he keeps his promise when the occasion arises. We may explain this to ourselves to begin with by supposing that, in spite of our authoritative assurance, he has not yet realized the justification for free association, and we may perhaps have the notion of first convincing him theoretically by giving him books to read or by sending him to lectures which may convert him into a supporter of our views on free association. But we shall be held back from blunders like this when we consider that in the case of ourselves, as to the strength of whose convictions we can, after all, hardly be in doubt, the same objections arise to certain ideas and are only set aside subsequently - by a court of appeal, as it were.

[1916-1917, 3211]

Instead of being annoyed by the dreamer's disobedience, we may take advantage of these experiences by learning something new from them - something which is all the more important the less we are expecting it. We perceive that the work of interpreting dreams is carried out in the face of a resistance, which opposes it and of which the critical objections are manifestations. This resistance is independent of the dreamer's theoretical conviction. We learn still more, indeed. We discover that a critical objection of this kind never turns out to be justified. On the contrary, the ideas which people try to suppress in this way turn out invariably to be the most important ones and those which are decisive in our search for the unconscious material. It amounts, in fact, to a special distinguishing mark, if an idea is accompanied by an objection like this.

[1916-1917, 3211]
For that is in fact the case. You will recall that when we began to make use of our technique of free association we made a surprising discovery. We became aware that our efforts at proceeding from the dream-element to the unconscious element for which it is a substitute were being met by a resistance. This resistance, we said, could be of different magnitudes, sometimes enormous and sometimes quite insignificant. In the latter case we need to pass through only a small number of intermediate links in our work of interpretation; but when the resistance is large we have to traverse long chains of associations from the dream-element, we are led far away from it and on our path we have to overcome all the difficulties which represent themselves as critical objections to the ideas that occur. What we met with as resistance in our work of interpretation must now be introduced into the dream-work in the form of the dream-censorship. The resistance to interpretation is only a putting into effect of the dream-censorship. It also proves to us that the force of the censorship is not exhausted in bringing about the distortion of dreams and thereafter extinguished, but that the censorship persists as a permanent institution which has as its aim the maintenance of the distortion. Moreover, just as the strength of the resistance varies in the interpretation of each element in a dream, so too the magnitude of the distortion introduced by the censorship varies for each element in the same dream. If we compare the manifest and the latent dream, we shall find that some particular latent elements have been completely eliminated, others modified to a greater or less extent, while yet others have been carried over into the manifest content of the dream unaltered or even perhaps strengthened.

Furthermore, we have not got nearly far enough yet to be able to feel indignant at this result of our work of interpretation. We do not yet, I think, understand it properly; but our first duty is to defend it against certain aspersions. There is no difficulty in finding a weak point in it. Our dream-interpretations are made on the basis of the premisses which we have already accepted - that dreams in general have a sense, that it is legitimate to carry across from hypnotic to normal sleep the fact of the existence of mental processes which are at the time unconscious, and that everything that occurs to the mind is determined. If on the basis of these premisses we had arrived at plausible findings from dream-interpretation, we should have been justified in concluding that the premisses were valid. But how about it if these findings seem to be as I have pictured them? We should then be tempted to say: 'These are impossible, senseless or at the least most improbable findings; so there was something wrong about the premisses. Either dreams are not psychical phenomena, or there is nothing unconscious in the normal state, or our technique has a flaw in it. Is it not simpler and more satisfactory to suppose this rather than accept all the abominations which we are supposed to have discovered on the basis of our premisses?'

In psycho-analytic therapy we make use of the same technique that is familiar to you from dream-interpretation. We instruct the patient to put himself into a state of quiet, unreflecting self-observation, and to report to us whatever internal perceptions he is able to make - feelings, thoughts, memories in the order in which they occur to him. At the same time we warn him expressly against giving way to any motive which would lead him to make a selection among these associations or to exclude any of them, whether on the ground that it is too disagreeable or too indiscreet to say, or that it is too unimportant or irrelevant, or that it is nonsensical and need not be said. We urge him always to follow only the surface of his consciousness and to leave aside any criticism of what he finds, whatever shape that criticism may take; and we assure him that the success of the treatment, and above all its duration, depends on the conscientiousness with which he obeys this fundamental technical rule of analysis. We already know from the technique of dream-interpretation that the associations giving rise to the doubts and objections I have just enumerated are precisely the ones that invariably contain the material which leads to the uncovering of the unconscious.

[1916-1917, 3236]
The first thing we achieve by setting up this fundamental technical rule is that it becomes the target for the attacks of the resistance. The patient endeavours in every sort of way to extricate himself from its provisions. At one moment he declares that nothing occurs to him, at the next that so many things are crowding in on him that he cannot get hold of anything. Presently we observe with pained astonishment that he has given way first to one and then to another critical objection: he betrays this to us by the long pauses that he introduces into his remarks. He then admits that there is something he really cannot say - he would be ashamed to; and he allows this reason to prevail against his promise. Or he says that something has occurred to him, but it concerns another person and not himself and is therefore exempt from being reported. Or, what has now occurred to him is really too unimportant, too silly and senseless: I cannot possibly have meant him to enter into thoughts like that. So it goes on in innumerable variations, and one can only reply that 'to say everything' really does mean 'to say everything'.

[1916-1917, 3363]

One hardly comes across a single patient who does not make an attempt at reserving some region or other for himself so as to prevent the treatment from having access to it. A man, whom I can only describe as of the highest intelligence, kept silence in this way for weeks on end about an intimate love-affair, and, when he was called to account for having broken the sacred rule, defended himself with the argument that he thought this particular story was his private business. Analytic treatment does not, of course, recognize any such right of asylum. Suppose that in a town like Vienna the experiment was made of treating a square such as the Hohe Markt, or a church like St. Stephen's, as places where no arrests might be made, and suppose we then wanted to catch a particular criminal. We could be quite sure of finding him in the sanctuary. I once decided to allow a man, on whose efficiency much depended in the external world, the right to make an exception of this kind because he was bound under his oath of office not to make communications about certain things to another person. He, it is true, was satisfied with the outcome; but I was not. I determined not to repeat an attempt under such conditions.

[1916-1917, 3363]

Obsessional neurotics understand perfectly how to make the technical rule almost useless by applying their over-conscientiousness and doubts to it. Patients suffering from anxiety hysteria occasionally succeed in carrying the rule *ad absurdum* by producing only associations which are so remote from what we are in search of that they contribute nothing to the analysis. But it is not my intention to induct you into the handling of these technical difficulties. It is enough to say that in the end, through resolution and perseverance, we succeed in extorting a certain amount of obedience to the fundamental technical rule from the resistance - which thereupon jumps over to another sphere.

[1916-1917, 3364]
It now appears as an intellectual resistance, it fights by means of arguments and exploits all the difficulties and improbabilities which normal but uninstructed thinking finds in the theories of analysis. It is now our fate to hear from this single voice all the criticisms and objections which assail our ears in a chorus in the scientific literature of the subject. And for this reason none of the shouts that reach us from outside sound unfamiliar. It is a regular storm in a tea-cup. But the patient is willing to be argued with; he is anxious to get us to instruct him, teach him, contradict him, introduce him to the literature, so that he can find further instruction. He is quite ready to become an adherent of psycho-analysis - on condition that analysis spares him personally. But we recognize this curiosity as a resistance, as a diversion from our particular tasks, and we repel it. In the case of an obsessional neurotic we have to expect special tactics of resistance. He will often allow the analysis to proceed on its way uninhibited, so that it is able to shed an ever-increasing light upon the riddle of his illness. We begin to wonder in the end, however, why this enlightenment is accompanied by no practical advance, no diminution of the symptoms. We are then able to realize that resistance has withdrawn on to the doubt belonging to the obsessional neurosis and from that position is successfully defying us. It is as though the patient were saying: 'Yes, that's all very nice and interesting, and I'll be very glad to go on with it further. It would change my illness a lot if it were true. But I don't in the least believe that it is true; and, so long as I don't believe it, it makes no difference to my illness.' Things can proceed like this for a long time, till finally one comes up against this uncommitted attitude itself, and the decisive struggle then breaks out.

[1916-1917, 3364]

But such fine weather cannot last for ever. One day it clouds over. Difficulties arise in the treatment; the patient declares that nothing more occurs to him. He gives the clearest impression of his interest being no longer in the work and of his cheerfully disregarding the instructions given him to say everything that comes into his head and not to give way to any critical obstacle to doing so. He behaves as though he were outside the treatment and as though he had not made this agreement with the doctor. He is evidently occupied with something, but intends to keep it to himself. This is a situation that is dangerous for the treatment. We are unmistakably confronted by a formidable resistance. But what has happened to account for it?

[1916-1917, 3482]

From the standpoint of the libido theory, too, we may say a last word on dreams. A neurotic's dreams help us, like his parapraxes and his free associations to them, to discover the sense of his symptoms and to reveal the way in which his libido is allocated. They show us, in the form of a wish-fulfilment, what wishful impulses have been subjected to repression and to what objects the libido withdrawn from the ego has become attached. For this reason the interpretation of dreams plays a large part in a psycho-analytic treatment, and in some cases it is over long periods the most important instrument of our work. We already know that the state of sleep in itself leads to a certain relaxation of the repressions. A repressed impulse, owing to this reduction in the pressure weighing down upon it, becomes able to express itself far more clearly in a dream than it can be allowed to be expressed by a symptom during the day. The study of dreams therefore becomes the most convenient means of access to a knowledge of the repressed unconscious, of which the libido withdrawn from the ego forms a part.

[1916-1917, 3496]
The missing elements could easily be supplied from other directions. During the first months of the treatment he had told me of how he had suddenly fallen in love in a compulsive manner with a peasant girl from whom, in his eighteenth year, he had contracted the precipitating cause of his later illness. When he told me this he had displayed a most extraordinary unwillingness to give me the girl's name. It was an entirely isolated instance of resistance, for apart from it he obeyed the fundamental rule of analysis unreservedly. He asserted, however, that the reason for his being so much ashamed of mentioning the name was that it was a purely peasant name and that no girl of gentle birth could possibly be called by it. When eventually the name was produced, it turned out to be Matrona, which has a motherly ring about it. The shame was evidently displaced. He was not ashamed of the fact that these love-affairs were invariably concerned with girls of the humblest origin; he was ashamed only of the name. If it should turn out that the affair with Matrona had something in common with the Grusha scene, then the shame would have to be transferred back to that early episode.

[1918b, 3573]

¹ This situation, in which the subject's attitude is unconsciously directed towards the hypnotist, while he is consciously occupied with monotonous and uninteresting perceptions, finds a parallel among the events of psycho-analytic treatment, which deserves to be mentioned here. At least once in the course of every analysis a moment comes when the patient obstinately maintains that just now positively nothing whatever occurs to his mind. His free associations come to a stop and the usual incentives for putting them in motion fail in their effect. If the analyst insists, the patient is at last induced to admit that he is thinking of the view from the consulting-room window, of the wall-paper that he sees before him, or of the gas-lamp hanging from the ceiling. Then one knows at once that he has gone off into the transference and that he is engaged upon what are still unconscious thoughts relating to the physician; and one sees the stoppage in the patient's associations disappear, as soon as he has been given this explanation.

[1921c, 3818]
The little series of reminiscences must engage our attention for a while longer. I have stated elsewhere that such scenes of childhood are 'screen memories' selected at a later period, put together, and not infrequently falsified in the process. This subsequent remodelling serves a purpose that is sometimes easy to guess. In our case one can almost hear the writer's ego glorifying or soothing itself by means of this series of recollections. 'I was from infancy a particularly noble and compassionate creature. I learnt quite early that animals have souls as we have, and could not endure cruelty to animals. The sins of the flesh were far from me and I preserved my chastity till late in life.' With declarations such as these she was loudly contradicting the inferences that we have to make about her early childhood on the basis of our analytical experience, namely, that she had an abundance of premature sexual impulses and violent feelings of hatred for her mother and her younger brothers and sisters. (Besides the genital significance I have just assigned to it, the little bird may also be a symbol of a child, like all small animals; her recollection thus accentuated very insistently the fact that this small creature had the same right to exist as she herself.) Hence the short series of recollections furnishes a very nice example of a mental structure with a twofold aspect. Viewed superficially, we may find in it the expression of an abstract idea, here, as usually, with an ethical reference. In Silberer's nomenclature the structure has an anagogic content. On deeper investigation it reveals itself as a chain of phenomena belonging to the region of the repressed life of the instincts - it displays its psycho-analytic content. As you know, Silberer, who was among the first to issue a warning to us not to lose sight of the nobler side of the human soul, has put forward the view that all or nearly all dreams permit such a twofold interpretation, a purer, anagogic one beside the ignoble, psycho-analytic one. This is, however, unfortunately not so. On the contrary, an over-interpretation of this kind is rarely possible. To my knowledge no valid example of such a dream-analysis with a double meaning has been published up to the present time. But observations of this kind can often be made upon the series of associations that our patients produce during analytic treatment. On the one hand the successive ideas are linked by a line of association which is plain to the eye, while on the other hand you become aware of an underlying theme which is kept secret but which at the same time plays a part in all these ideas. The contrast between the two themes that dominate the same series of ideas is not always one between the lofty anagogic and the low psycho-analytic, but one rather between offensive and respectable or indifferent ideas - a fact that easily explains why such a chain of associations with a twofold determination arises. In our present example it is of course not accidental that the anagogic and the psycho-analytic interpretations stood in such a sharp contrast to each other; both related to the same material, and the later trend was no other than that of the reaction-formations which had been erected against the disowned instinctual impulses. [1922a, 3894]
Free Association. - The effect of the hypnotic condition upon the patient had been so greatly to increase his ability to make associations that he was able straight away to find the path - inaccessible to his conscious reflection - which led from the symptom to the thoughts and memories connected with it. The abandonment of hypnosis seemed to make the situation hopeless, until the writer recalled a remark of Bernheim's to the effect that things that had been experienced in a state of somnambulism were only apparently forgotten and that they could be brought into recollection at any time if the physician insisted forcibly enough that the patient knew them. The writer therefore endeavoured to insist on his unhypnotized patients giving him their associations, so that from the material thus provided he might find the path leading to what had been forgotten or fended off. He noticed later that the insistence was unnecessary and that copious ideas almost always arose in the patient's mind, but that they were held back from being communicated and even from becoming conscious by certain objections put by the patient in his own way. It was to be expected - though this was still unproved and not until later confirmed by wide experience - that everything that occurred to a patient setting out from a particular starting-point must also stand in an internal connection with that starting-point; hence arose the technique of educating the patient to give up the whole of his critical attitude and of making use of the material which was thus brought to light for the purpose of uncovering the connections that were being sought. A strong belief in the strict determination of mental events certainly played a part in the choice of this technique as a substitute for hypnosis.
[1923a, 3915]

The 'Fundamental Technical Rule' of this procedure of 'free association' has from that time on been maintained in psycho-analytic work. The treatment is begun by the patient being required to put himself in the position of an attentive and dispassionate self-observer, merely to read off all the time the surface of his consciousness, and on the one hand to make a duty of the most complete honesty while on the other not to hold back any idea from communication, even if (1) he feels that it is too disagreeable or if (2) he judges that it is nonsensical or (3) too unimportant or (4) irrelevant to what is being looked for. It is uniformly found that precisely those ideas which provoke these last-mentioned reactions are of particular value in discovering the forgotten material.
[1923a, 3915]
Psycho-analysis as an Interpretive Art. - The new technique altered the picture of the treatment so greatly, brought the physician into such a new relation to the patient and produced so many surprising results that it seemed justifiable to distinguish the procedure from the cathartic method by giving it a new name. The present writer gave this method of treatment, which could now be extended to many other forms of neurotic disorder, the name of psycho-analysis. Now, in the first resort, this psycho-analysis was an art of interpretation and it set itself the task of carrying deeper the first of Breuer's great discoveries - namely, that neurotic symptoms are significant substitutes for other mental acts which have been omitted. It was now a question of regarding the material produced by the patients' associations as though it hinted at a hidden meaning and of discovering that meaning from it. Experience soon showed that the attitude which the analytic physician could most advantageously adopt was to surrender himself to his own unconscious mental activity, in a state of evenly suspended attention, to avoid so far as possible reflection and the construction of conscious expectations, not to try to fix anything that he heard particularly in his memory, and by these means to catch the drift of the patient's unconscious with his own unconscious. It was then found that, except under conditions that were too unfavourable, the patient's associations emerged like allusions, as it were, to one particular theme and that it was only necessary for the physician to go a step further in order to guess the material which was concealed from the patient himself and to be able to communicate it to him. It is true that this work of interpretation was not to be brought under strict rules and left a great deal of play to the physician's tact and skill; but, with impartiality and practice, it was usually possible to obtain trustworthy results - that is to say, results which were confirmed by being repeated in similar cases. At a time when so little was as yet known of the unconscious, the structure of the neuroses and the pathological processes underlying them, it was a matter for satisfaction that a technique of this kind should be available, even if it had no better theoretical basis. Moreover it is still employed in analyses at the present day in the same manner, though with a sense of greater assurance and with a better understanding of its limitations.

[1923a, 3916]

The Interpretation of Parapraxes and Haphazard Acts. - It was a triumph for the interpretative art of psycho-analysis when it succeeded in demonstrating that certain common mental acts of normal people, for which no one had hitherto attempted to put forward a psychological explanation, were to be regarded in the same light as the symptoms of neurotics: that is to say, they had a meaning, which was unknown to the subject but which could easily be discovered by analytic means. The phenomena in question were such events as the temporary forgetting of familiar words and names, forgetting to carry out prescribed tasks, everyday slips of the tongue and of the pen, misreadings, losses and mislayings of objects, certain errors, instances of apparently accidental self-injury, and finally habitual movements carried out seemingly without intention or in play, tunes hummed 'thoughtlessly', and so on. All of these were shorn of their physiological explanation, if any such had ever been attempted, were shown to be strictly determined and were revealed as an expression of the subject's suppressed intentions or as a result of a clash between two intentions one of which was permanently or temporarily unconscious. The importance of this contribution to psychology was of many kinds. The range of mental determinism was extended by it in an unforeseen manner; the supposed gulf between normal and pathological mental events was narrowed; in many cases a useful insight was afforded into the play of mental forces that must be suspected to lie behind the phenomena. Finally, a class of material was brought to light which is calculated better than any other to stimulate a belief in the existence of unconscious mental acts even in people to whom the hypothesis of something at once mental and unconscious seems strange and even absurd. The study of one's own parapraxes and haphazard acts, for which most people have ample opportunities, is even to-day the best preparation for an approach to psycho-analysis. In analytic treatment, the interpretation of parapraxes retains a place as a means of uncovering the unconscious, alongside the immeasurably more important interpretation of associations.

[1923a, 3917]
In the further course of psycho-analytic work, however, even these distinctions have proved to be inadequate and, for practical purposes, insufficient. This has become clear in more ways than one; but the decisive instance is as follows. We have formed the idea that in each individual there is a coherent organization of mental processes; and we call this his ego. It is to this ego that consciousness is attached; the ego controls the approaches to motility - that is, to the discharge of excitations into the external world; it is the mental agency which supervises all its own constituent processes, and which goes to sleep at night, though even then it exercises the censorship on dreams. From this ego proceed the repressions, too, by means of which it is sought to exclude certain trends in the mind not merely from consciousness but also from other forms of effectiveness and activity. In analysis these trends which have been shut out stand in opposition to the ego, and the analysis is faced with the task of removing the resistances which the ego displays against concerning itself with the repressed. Now we find during analysis that, when we put certain tasks before the patient, he gets into difficulties; his associations fail when they should be coming near the repressed. We then tell him that he is dominated by a resistance; but he is quite unaware of the fact, and, even if he guesses from his unpleasurable feelings that a resistance is now at work in him, he does not know what it is or how to describe it. Since, however, there can be no question but that this resistance emanates from his ego and belongs to it, we find ourselves in an unforeseen situation. We have come upon something in the ego itself which is also unconscious, which behaves exactly like the repressed - that is, which produces powerful effects without itself being conscious and which requires special work before it can be made conscious. From the point of view of analytic practice, the consequence of this discovery is that we land in endless obscurities and difficulties if we keep to our habitual forms of expression and try, for instance, to derive neuroses from a conflict between the conscious and the unconscious. We shall have to substitute for this antithesis another, taken from our insight into the structural conditions of the mind - the antithesis between the coherent ego and the repressed which is split off from it.¹

If a dream brings up situations that can be interpreted as referring to scenes from the dreamer's past, it seems especially important to ask whether the physician's influence can also play a part in such contents of the dream as these. And this question is most urgent of all in the case of what are called 'corroborative' dreams, dreams which, as it were, 'tag along behind' the analysis. With some patients these are the only dreams that one obtains. Such patients reproduce the forgotten experiences of their childhood only after one has constructed them from their symptoms, associations and other signs and has propounded these constructions to them. Then follow the corroborative dreams, concerning which, however, the doubt arises whether they may not be entirely without evidential value, since they may have been imagined in compliance with the physician's words instead of having been brought to light from the dreamer's unconscious. This ambiguous position cannot be escaped in the analysis, since with these patients unless one interprets, constructs and propounds, one never obtains access to what is repressed in them.²

¹ [1923b, 3951]
² [1923c, 4036]
Hypnosis had, however, performed the service of restoring to the patient's memory what he had forgotten. It was necessary to find some other technique to replace it; and the idea occurred to Freud of substituting for it the method of 'free association'. That is to say, he pledged his patients to refrain from any conscious reflection and to abandon themselves, in a state of quiet concentration, to following the ideas which occurred to them spontaneously (involuntarily) - 'to skim off the surface of their consciousness'. They were to communicate these ideas to the physician even if they felt objections to doing so, if, for instance, the thoughts seemed too disagreeable, too senseless, too unimportant or irrelevant. The choice of free association as a means of investigating the forgotten unconscious material seems so strange that a word in justification of it will not be out of place. Freud was led to it by an expectation that the so-called 'free' association would prove in fact to be unfree, since, when all conscious intellectual purposes had been suppressed, the ideas that emerged would be seen to be determined by the unconscious material. This expectation was justified by experience. When the 'fundamental rule of psycho-analysis' which has just been stated was obeyed, the course of free association produced a plentiful store of ideas which could put one on the track of what the patient had forgotten. To be sure, this material did not bring up what had actually been forgotten, but it brought up such plain and numerous hints at it that, with the help of a certain amount of supplementing and interpreting, the doctor was able to guess (to reconstruct) the forgotten material from it. Thus free association together with the art of interpretation performed the same function as had previously been performed by hypnotism.

[1924f, 4105]

It looked as though our work had been made much more difficult and complicated; but the inestimable gain was that an insight was now obtained into an interplay of forces which had been concealed from the observer by the hypnotic state. It became evident that the work of uncovering what had pathogenically forgotten had to struggle against a constant and very intense resistance. The critical objections which the patient raised in order to avoid communicating the ideas which occurred to him, and against which the fundamental rule of psycho-analysis was directed, had themselves already been manifestations of this resistance. A consideration of the phenomena of resistance led to one of the corner-stones of the psycho-analytic theory of the neuroses - the theory of repression. It was plausible to suppose that the same forces which were now struggling against the pathogenic material being made conscious had at an earlier time made the same efforts with success. A gap in the aetiology of neurotic symptoms was thus filled. The impressions and mental impulses, for which the symptoms were now serving as substitutes, had not been forgotten without reason or on account of a constitutional incapacity for synthesis (as Janet supposed); they had, though the influence of other mental forces, met with a repression the success and evidence of which was precisely their being debarred from consciousness and excluded from memory. It was only in consequence of this repression that they had become pathogenic - that is, had succeeded in manifesting themselves along unusual paths as symptoms.

[1924f, 4106]
The analysis of dreams led further: it was brought to public notice by the present writer as early as in 1900 in *The Interpretation of Dreams*. This showed that dreams are constructed in just the same way as neurotic symptoms. Like them, they may appear strange and senseless; but, if we examine them by a technique which differs little from the free association used in psycho-analysis, we are led from their manifest content to a secret meaning, to the latent dream-thoughts. This latent meaning is always a wishful impulse which is represented as fulfilled at the moment of the dream. But, except in young children and under the pressure of imperative physical needs, this secret wish can never be expressed recognizably. It has first to submit to a distortion, which is the work of restrictive, censoring forces in the dreamer's ego. In this way the manifest dream, as it is remembered in waking life, comes about. It is distorted, to the pitch of being unrecognizable, by concessions made to the dream-censorship; but it can be revealed once more by analysis as an expression of a situation of satisfaction or as the fulfilment of a wish. It is a compromise between two conflicting groups of mental trends, just as we have found to be the case with hysterical symptoms. The formula which, at bottom, best meets the essence of the dream is this: a dream is a (disguised) fulfilment of a (repressed) wish. The study of the process which transforms the latent dream-wish into the manifest content of the dream - a process known as the 'dream-work' - has taught us the best part of what we know of unconscious mental life. [1924f, 4109]

The means which I first adopted for overcoming the patient's resistance, by insistence and encouragement, had been indispensable for the purpose of giving me a first general survey of what was to be expected. But in the long run it proved to be too much of a strain on both sides, and further, it seemed open to certain obvious criticisms. It therefore gave place to another method which was in one sense its opposite. Instead of urging the patient to say something upon some particular subject, I now asked him to abandon himself to a process of free association - that is, to say whatever came into his head, while ceasing to give any conscious direction to his thoughts. It was essential, however, that he should bind himself to report literally everything that occurred to his self-perception and not to give way to critical objections which sought to put certain associations on one side on the ground that they were not sufficiently important or that they were irrelevant or that they were altogether meaningless. There was no necessity to repeat explicitly the demand for candour on the patient's part in reporting his thoughts, for it was the precondition of the whole analytic treatment. [1925d, 4215]
It may seem surprising that this method of free association, carried out subject to the observation of the fundamental rule of psycho-analysis, should have achieved what was expected of it, namely the bringing into consciousness of the repressed material which was held back by resistances. We must, however, bear in mind that free association is not really free. The patient remains under the influence of the analytic situation even though he is not directing his mental activities on to a particular subject. We shall be justified in assuming that nothing will occur to him that has not some reference to that situation. His resistance against reproducing the repressed material will now be expressed in two ways. Firstly it will be shown by critical objections; and it was to deal with these that the fundamental rule of psycho-analysis was invented. But if the patient observes that rule and so overcomes his reticences, the resistance will find another means of expression. It will so arrange it that the repressed material itself will never occur to the patient but only something which approximates to it in an allusive way; and the greater the resistance, the more remote from the actual idea that the analyst is in search of will be the substitutive association which the patient has to report. The analyst, who listens composedly but without any constrained effort to the stream of associations and who, from his experience, has a general notion of what to expect, can make use of the material brought to light by the patient according to two possibilities. If the resistance is slight he will be able from the patient's allusions to infer the unconscious material itself; or if the resistance is stronger he will be able to recognize its character from the associations, as they seem to become more remote from the topic in hand, and will explain it to the patient. Uncovering the resistance, however, is the first step towards overcoming it. Thus the work of analysis involves an art of interpretation, the successful handling of which may require tact and practice but which is not hard to acquire. But it is not only in the saving of labour that the method of free association has an advantage over the earlier method. It exposes the patient to the least possible amount of compulsion, it never allows of contact being lost with the actual current situation, it guarantees to a great extent that no factor in the structure of the neurosis will be overlooked and that nothing will be introduced into it by the expectations of the analyst. It is left to the patient in all essentials to determine the course of the analysis and the arrangement of the material; any systematic handling of particular symptoms or complexes thus becomes impossible. In complete contrast to what happened with hypnosis and with the urging method, interrelated material makes its appearance at different times and at different points in the treatment. To a spectator, therefore - though in fact there must be none - an analytic treatment would seem completely obscure. [1925d, 4216]

Another advantage of the method is that it need never break down. It must theoretically always be possible to have an association, provided that no conditions are made as to its character. Yet there is one case in which in fact a breakdown occurs with absolute regularity; from its very uniqueness, however, this case too can be interpreted. [1925d, 4217]
The second of these techniques which we are setting out to describe for the first time, that of isolation, is peculiar to obsessional neurosis. It, too, takes place in the motor sphere. When something unpleasant has happened to the subject or when he himself has done something which has a significance for his neurosis, he interpolates an interval during which nothing further must happen - during which he must perceive nothing and do nothing. This behaviour, which seems strange at first sight, is soon seen to have a relation to repression. We know that in hysteria it is possible to cause a traumatic experience to be overtaken by amnesia. In obsessional neurosis this can often not be achieved: the experience is not forgotten, but, instead, it is deprived of its affect, and its associative connections are suppressed or interrupted so that it remains as though isolated and is not reproduced in the ordinary processes of thought. The effect of this isolation is the same as the effect of repression with amnesia. This technique, then, is reproduced in the isolations of obsessional neurosis; and it is at the same time given motor reinforcement for magical purposes. The elements that are held apart in this way are precisely those which belong together associatively. The motor isolation is meant to ensure an interruption of the connection in thought. The normal phenomenon of concentration provides a pretext for this kind of neurotic procedure: what seems to us important in the way of an impression or a piece of work must not be interfered with by the simultaneous claims of any other mental processes or activities. But even a normal person uses concentration to keep away not only what is irrelevant or unimportant, but, above all, what is unsuitable because it is contradictory. He is most disturbed by those elements which once belonged together but which have been torn apart in the course of his development - as, for instance, by manifestations of the ambivalence of his father-complex in his relation to God, or by impulses attached to his excretory organs in his emotions of love. Thus, in the normal course of things, the ego has a great deal of isolating work to do in its function of directing the current of thought. And, as we know, we are obliged, in carrying out our analytic technique, to train it to relinquish that function for the time being, eminently justified as it usually is.

We have all found by experience that it is especially difficult for an obsessional neurotic to carry out the fundamental rule of psycho-analysis. His ego is more watchful and makes sharper isolations, probably because of the high degree of tension due to conflict that exists between his super-ego and his id. While he is engaged in thinking, his ego has to keep off too much - the intrusion of unconscious phantasies and the manifestation of ambivalent trends. It must not relax, but is constantly prepared for a struggle. It fortifies this compulsion to concentrate and to isolate by the help of the magical acts of isolation which, in the form of symptoms, grow to be so noticeable and to have so much practical importance for the patient, but which are, of course, useless in themselves and are in the nature of ceremonials.
Some preparation must of course be given to him; and there is a simple way of doing it. We call on him to be completely straightforward with his analyst, to keep nothing back intentionally that comes into his head, and then to put aside every reservation that might prevent his reporting certain thoughts or memories. Everyone is aware that there are some things in himself that he would be very unwilling to tell other people or that he considers it altogether out of the question to tell. These are his 'intimacies'. He has a notion too - and this represents a great advance in psychological self-knowledge - that there are other things that one would not care to admit to oneself: things that one likes to conceal from oneself and which for that reason one breaks off short and drives out of one's thoughts if, in spite of everything, they turn up. Perhaps he may himself notice that a very remarkable psychological problem begins to appear in this situation - of a thought of his own being kept secret from his own self. It looks as though his own self were no longer the unity which he had always considered it to be, as though there were something else as well in him that could confront that self. He may become obscurely aware of a contrast between a self and a mental life in the wider sense. If now he accepts the demand made by analysis that he shall say everything, he will easily become accessible to an expectation that to have relations and exchanges of thought with someone under such unusual conditions might also lead to peculiar results.

[1926e, 4331]

It is easy now to describe our therapeutic aim. We try to restore the ego, to free it from its restrictions, and to give it back the command over the id which it has lost owing to its early repressions. It is for this one purpose that we carry out analysis, our whole technique is directed to this aim. We have to seek out the repressions which have been set up and to urge the ego to correct them with our help and to deal with conflicts better than by an attempt at flight. Since these repressions belong to the very early years of childhood, the work of analysis leads us, too, back to that period. Our path to these situations of conflict, which have for the most part been forgotten and which we try to revive in the patient's memory, is pointed out to us by his symptoms, dreams and free associations. These must, however, first be interpreted - translated - for, under the influence of the psychology of the id, they have assumed forms of expression that are strange to our comprehension. We may assume that whatever associations, thoughts and memories the patient is unable to communicate to us without internal struggles are in some way connected with the repressed material or are its derivatives. By encouraging the patient to disregard his resistances to telling us these things, we are educating his ego to overcome its inclination towards attempts at flight and to tolerate an approach to what is repressed. In the end, if the situation of the repression can be successfully reproduced in his memory, his compliance will be brilliantly rewarded. The whole difference between his age then and now works in his favour; and the thing from which his childish ego fled in terror will often seem to his adult and strengthened ego no more than child's play.

[1926e, 4348]
And it must be so, firstly, because analysis is entirely founded on complete candour. Financial circumstances, for instance, are discussed with equal detail and openness: things are said that are kept back from every fellow-citizen, even if he is not a competitor or a tax-collector. I will not dispute - indeed, I will myself insist with energy - that this obligation to candour puts a grave moral responsibility on the analyst as well. And it must be so, secondly, because factors from sexual life play an extremely important, a dominating, perhaps even a specific part among the causes and precipitating factors of neurotic illnesses. What else can analysis do but keep close to its subject-matter, to the material brought up by the patient? The analyst never entices his patient on to the ground of sex. He does not say to him in advance: 'We shall be dealing with the intimacies of your sexual life!' He allows him to begin what he has to say whenever he pleases, and quietly waits until the patient himself touches on sexual things. I used always to warn my pupils: 'Our opponents have told us that we shall come upon cases in which the factor of sex plays no part. Let us be careful not to introduce it into our analyses and so spoil our chance of finding such a case.' But so far none of us has had that good fortune.

[1926e, 4350]

'A fine idea, to be sure! No, I have not the least intention of settling our controversy by an experiment of that sort. But just to oblige, I will do what you ask - the responsibility will be yours. Very well. I will suppose that the patient comes to me and complains of his troubles. I promise him recovery or improvement if he will follow my directions. I call on him to tell me with perfect candour everything that he knows and that occurs to him, and not to be deterred from that intention even if some things are disagreeable to say. Have I taken in the rule properly?'

[1926e, 4360]

'Yes. You should add: 'even if what occurs to him seems unimportant or senseless.'

[1926e, 4360]

'I will add that. Thereupon he begins to talk and I listen. And what then? I infer from what he tells me the kind of impressions, experiences and wishes which he has repressed because he came across them at a time when his ego was still feeble and was afraid of them instead of dealing with them. When he has learnt this from me, he puts himself back in the old situations and with my help he manages better. The limitations to which his ego was tied then disappear, and he is cured. Is that right?'

[1926e, 4360]

When one really practises analysis one learns all kinds of things besides. For instance: you would not find it at all such a simple matter to deduce from what the patient tells you the experiences he has forgotten and the instinctual impulses he has repressed. He says something to you which at first means as little to you as it does to him. You will have to make up your mind to look at the material which he delivers to you in obedience to the rule in a quite special way: as though it were ore, perhaps, from which its content of precious metal has to be extracted by a particular process. You will be prepared, too, to work over many tons of ore which may contain but little of the valuable material you are in search of. Here we should have a first reason for the prolonged character of the treatment.

[1926e, 4361]

'But how does one work over this raw material - to keep to your simile?'

[1926e, 4361]
By assuming that the patient's remarks and associations are only distortions of what you are looking for—allusions, as it were, from which you have to guess what is hidden behind them. In a word, this material, whether it consists of memories, associations or dreams, has first to be _interpreted_. You will do this, of course, with an eye to the expectations you have formed as you listened, thanks to your special knowledge.

[1926e, 4361]

Let us suppose, then, that someone—a patient in analysis, for instance—tells us one of his dreams. We shall assume that in this way he is making us one of the communications to which he has pledged himself by the fact of having started an analytic treatment. It is, to be sure, a communication made by inappropriate means, for dreams are not in themselves social utterances, not a means of giving information. Nor, indeed, do we understand what the dreamer was trying to say to us, and he himself is equally in the dark. And now we have to make a quick decision. On the one hand, the dream may be, as non-analytic doctors assure us, a sign that the dreamer has slept badly, that not every part of his brain has come to rest equally, that some areas of it, under the influence of unknown stimuli, endeavoured to go on working but were only able to do so in a very incomplete fashion. If that is the case, we shall be right to concern ourselves no further with the product of a nocturnal disturbance which has no psychical value: for what could we expect to derive from investigating it that would be of use for our purposes? Or on the other hand—but it is plain that we have from the first decided otherwise. We have—quite arbitrarily, it must be admitted—made the assumption, adopted as a postulate, that even this unintelligible dream must be a fully valid psychical act, with sense and worth, which we can use in analysis like any other communication. Only the outcome of our experiment can show whether we are right. If we succeed in turning the dream into an utterance of value of that kind, we shall evidently have a prospect of learning something new and of receiving communications of a sort which would otherwise be inaccessible to us.

[1933a, 4623]
Now, however, another problem awaits us - at the opposite end of the ego, as we might put it. It is presented to us by an observation during the work of analysis, an observation which is actually a very old one. As not infrequently happens, it has taken a long time to come to the point of appreciating its importance. The whole theory of psycho-analysis is, as you know, in fact built up on the perception of the resistance offered to us by the patient when we attempt to make his unconscious conscious to him. The objective sign of this resistance is that his associations fail or depart widely from the topic that is being dealt with. He may also recognize the resistance subjectively by the fact that he has distressing feelings when he approaches the topic. But this last sign may also be absent. We then say to the patient that we infer from his behaviour that he is now in a state of resistance; and he replies that he knows nothing of that, and is only aware that his associations have become more difficult. It turns out that we were right; but in that case his resistance was unconscious too, just as unconscious as the repressed, at the lifting of which we were working. We should long ago have asked the question: from what part of his mind does an unconscious resistance like this arise? The beginner in psycho-analysis will be ready at once with the answer: it is, of course, the resistance of the unconscious. An ambiguous and unserviceable answer! If it means that the resistance arises from the repressed, we must rejoin: certainly not! We must rather attribute to the repressed a strong upward drive, an impulsion to break through into consciousness. The resistance can only be a manifestation of the ego, which originally put the repression into force and now wishes to maintain it. That, moreover, is the view we always took. Since we have come to assume a special agency in the ego, the super-ego, which represents demands of a restrictive and rejecting character, we may say that repression is the work of this super-ego and that it is carried out either by itself or by the ego in obedience to its orders. If then we are met by the case of the resistance in analysis not being conscious to the patient, this means either that in quite important situations the super-ego and the ego can operate unconsciously, or - and this would be still more important - that portions of both of them, the ego and the super-ego themselves, are unconscious. In both cases we have to reckon with the disagreeable discovery that on the one hand (super-) ego and conscious and on the other hand repressed and unconscious are far from coinciding.

[1933a, 4677]

For these new experiments made it a certainty that the patients whom we described as neurotic were in some sense suffering from mental disturbances and ought therefore to be treated by psychological methods. Our interest therefore necessarily turned to psychology. The psychology which ruled at that time in the academic schools of philosophy had very little to offer and nothing at all for our purposes: we had to discover from the start both our methods and the theoretical hypotheses behind them. So I worked in this direction, first in collaboration with Breuer and afterwards independently of him. In the end I made it a part of my technique to require my patients to tell me without criticism whatever occurred to their minds, even if they were ideas which did not seem to make sense or which it was distressing to report.

[1932c, 4807]

Our plan of cure is based on these discoveries. The ego is weakened by the internal conflict and we must go to its help. The position is like that in a civil war which has to be decided by the assistance of an ally from outside. The analytic physician and the patient's weakened ego, basing themselves on the real external world, have to band themselves together into a party against the enemies, the instinctual demands of the id and the conscientious demands of the super-ego. We form a pact with each other. The sick ego promises us the most complete candour - promises, that is, to put at our disposal all the material which its self-perception yields it; we assure the patient of the strictest discretion and place at his service our experience in interpreting material that has been influenced by the unconscious. Our knowledge is to make up for his ignorance and to give his ego back its mastery over lost provinces of his mental life. This pact constitutes the analytic situation.

[1940a [1938], 4983]
With the neurotics, then, we make our pact: complete candour on one side and strict discretion on the other. This looks as though we were only aiming at the post of a secular father confessor. But there is a great difference, for what we want to hear from our patient is not only what he knows and conceals from other people; he is to tell us too what he does not know. With this end in view we give him a more detailed definition of what we mean by candour. We pledge him to obey the fundamental rule of analysis, which is henceforward to govern his behaviour towards us. He is to tell us not only what he can say intentionally and willingly, what will give him relief like a confession, but everything else as well that his self-observation yields him, everything that comes into his head, even if it is disagreeable for him to say it, even if it seems to him unimportant or actually nonsensical. If he can succeed after this injunction in putting his self-criticism out of action, he will present us with a mass of material - thoughts, ideas, recollections - which are already subject to the influence of the unconscious, which are often its direct derivatives, and which thus put us in a position to conjecture his repressed unconscious material and to extend, by the information we give him, his ego's knowledge of his unconscious.

But it is far from being the case that his ego is content to play the part of passively and obediently bringing us the material we require and of believing and accepting our translation of it. A number of other things happen, a few of which we might have foreseen but others of which are bound to surprise us. The most remarkable thing is this. The patient is not satisfied with regarding the analyst in the light of reality as a helper and adviser who, moreover, is remunerated for the trouble he takes and who would himself be content with some such role as that of a guide on a difficult mountain climb. On the contrary, the patient sees in him the return, the reincarnation, of some important figure out of his childhood or past, and consequently transfers on to him feelings and reactions which undoubtedly applied to this prototype. This fact of transference soon proves to be a factor of undreamt-of importance, on the one hand an instrument of irreplaceable value and on the other hand a source of serious dangers. This transference is ambivalent: it comprises positive (affectionate) as well as negative (hostile) attitudes towards the analyst, who as a rule is put in the place of one or other of the patient's parents, his father or mother. So long as it is positive it serves us admirably. It alters the whole analytic situation; it pushes to one side the patient's rational aim of becoming healthy and free from his ailments. Instead of it there emerges the aim of pleasing the analyst and of winning his applause and love. It becomes the true motive force of the patient's collaboration; his weak ego becomes strong; under its influence he achieves things that would ordinarily be beyond his power; he leaves off his symptoms and seems apparently to have recovered - merely for the sake of the analyst. The analyst may shamefacedly admit to himself that he set out on a difficult undertaking without any suspicion of the extraordinary powers that would be at his command.

[1940a [1938], 4984]
The method by which we strengthen the weakened ego has as a starting-point an extending of its self-knowledge. That is not, of course, the whole story but it is a first step. The loss of such knowledge signifies for the ego a surrender of power and influence; it is the first tangible sign that it is being hemmed in and hampered by the demands of the id and the super-ego. Accordingly, the first part of the help we have to offer is intellectual work on our side and encouragement to the patient to collaborate in it. This first kind of activity, as we know, is intended to pave the way to another, more difficult, task. We shall not lose sight of the dynamic element in this task, even during its preliminary stage. We gather the material for our work from a variety of sources - from what is conveyed to us by the information given us by the patient and by his free associations, from what he shows us in his transferences, from what we arrive at by interpreting his dreams and from what he betrays by his slips or parapraxes. All this material helps us to make constructions about what happened to him and has been forgotten as well as about what is happening in him now without his understanding it. But in all this we never fail to make a strict distinction between our knowledge and his knowledge. We avoid telling him at once things that we have often discovered at an early stage, and we avoid telling him the whole of what we think we have discovered. We reflect carefully over when we shall impart the knowledge of one of our constructions to him and we wait for what seems to us the suitable moment - which it is not always easy to decide. As a rule we put off telling him of a construction or explanation till he himself has so nearly arrived at it that only a single step remains to be taken, though that step is in fact the decisive synthesis. If we proceeded in another way and overwhelmed him with our interpretations before he was prepared for them, our information would either produce no effect or it would provoke a violent outbreak of resistance which would make the progress of our work more difficult or might even threaten to stop it altogether. But if we have prepared everything properly, it often happens that the patient will at once confirm our construction and himself recollect the internal or external event which he had forgotten. The more exactly the construction coincides with the details of what has been forgotten the easier will it be for him to assent. On that particular matter our knowledge will then have become his knowledge as well.

[1940a [1938], 4987]
The therapeutic effect depends on making conscious what is repressed, in the widest sense of the word, in the id. We prepare the way for this making conscious by interpretations and constructions, but we have interpreted only for ourselves not for the patient so long as the ego holds on to its earlier defences and does not give up its resistances. Now these resistances, although they belong to the ego, are nevertheless unconscious and in some sense separated off within the ego. The analyst recognizes them more easily than he does the hidden material in the id. One might suppose that it would be sufficient to treat them like portions of the id and, by making them conscious, bring them into connection with the rest of the ego. In this way, we should suppose, one half of the task of analysis would be accomplished; we should not reckon on meeting with a resistance against the uncovering of resistances. But what happens is this. During the work on the resistances the ego withdraws - with a greater or less degree of seriousness - from the agreement on which the analytic situation is founded. The ego ceases to support our efforts at uncovering the id; it opposes them, disobeys the fundamental rule of analysis, and allows no further derivatives of the repressed to emerge. We cannot expect the patient to have a strong conviction of the curative power of analysis. He may have brought along with him a certain amount of confidence in his analyst, which will be strengthened to an effective point by the factors of the positive transference which will be aroused in him. Under the influence of the unpleasurable impulses which he feels as a result of the fresh activation of his defensive conflicts, negative transferences may now gain the upper hand and completely annul the analytic situation. The patient now regards the analyst as no more than a stranger who is making disagreeable demands on him, and he behaves towards him exactly like a child who does not like the stranger and does not believe anything he says. If the analyst tries to explain to the patient one of the distortions made by him for the purposes of defence, and to correct it, he finds him uncomprehending and inaccessible to sound arguments. Thus we see that there is a resistance against the uncovering of resistances, and the defensive mechanisms really do deserve the name which we gave them originally, before they had been more closely examined. They are resistances not only to the making conscious of contents of the id, but also to the analysis as a whole, and thus to recovery.

[1937c, 5034]

It cannot be disputed that analysts in their own personalities have not invariably come up to the standard of psychical normality to which they wish to educate their patients. Opponents of analysis often point to this fact with scorn and use it as an argument to show the uselessness of analytic exertions. We might reject this criticism as making unjustifiable demands. Analysts are people who have learned to practise a particular art; alongside of this, they may be allowed to be human beings like anyone else. After all, nobody maintains that a physician is incapable of treating internal diseases if his own internal organs are not sound; on the contrary, it may be argued that there are certain advantages in a man who is himself threatened with tuberculosis specializing in the treatment of persons suffering from that disease. But the cases are not on all fours. So long as he is capable of practising at all, a doctor suffering from disease of the lungs or heart is not handicapped either in diagnosing or treating internal complaints; whereas the special conditions of analytic work do actually cause the analyst's own defects to interfere with his making a correct assessment of the state of things in his patient and reacting to them in a useful way. It is therefore reasonable to expect of an analyst, as a part of his qualifications, a considerable degree of mental normality and correctness. In addition, he must possess some kind of superiority, so that in certain analytic situations he can act as a model for his patient and in others as a teacher. And finally we must not forget that the analytic relationship is based on a love of truth - that is, on a recognition of reality - and that it precludes any kind of sham or deceit.

[1937c, 5041]
It is familiar ground that the work of analysis aims at inducing the patient to give up the repressions (using the word in the widest sense) belonging to his early development and to replace them by reactions of a sort that would correspond to a psychically mature condition. With this purpose in view he must be brought to recollect certain experiences and the affective impulses called up by them which he has for the time being forgotten. We know that his present symptoms and inhibitions are the consequences of repressions of this kind: thus that they are a substitute for these things that he has forgotten. What sort of material does he put at our disposal which we can make use of to put him on the way to recovering the lost memories? All kinds of things. He gives us fragments of these memories in his dreams, invaluable in themselves but seriously distorted as a rule by all the factors concerned in the formation of dreams. Again, he produces ideas, if he gives himself up to ‘free association’, in which we can discover allusions to the repressed experiences and derivatives of the suppressed affective impulses as well as of the reactions against them. And, finally, there are hints of repetitions of the affects belonging to the repressed material to be found in actions performed by the patient, some fairly important, some trivial, both inside and outside the analytic situation. Our experience has shown that the relation of transference, which becomes established towards the analyst, is particularly calculated to favour the return of these emotional connections. It is out of such raw material - if we may so describe it - that we have to put together what we are in search of.

[1937d, 5050]

His work of construction, or, if it is preferred, of reconstruction, resembles to a great extent an archaeologist's excavation of some dwelling-place that has been destroyed and buried or of some ancient edifice. The two processes are in fact identical, except that the analyst works under better conditions and has more material at his command to assist him, since what he is dealing with is not something destroyed but something that is still alive - and perhaps for another reason as well. But just as the archaeologist builds up the walls of the building from the foundations that have remained standing, determines the number and position of the columns from depressions in the floor and reconstructs the mural decorations and paintings from the remains found in the debris, so does the analyst proceed when he draws his inferences from the fragments of memories, from the associations and from the behaviour of the subject of the analysis. Both of them have an undisputed right to reconstruct by means of supplementing and combining the surviving remains. Both of them, moreover, are subject to many of the same difficulties and sources of error. One of the most ticklish problems that confronts the archaeologist is notoriously the determination of the relative age of his finds; and if an object makes its appearance in some particular level, it often remains to be decided whether it belongs to that level or whether it was carried down to that level owing to some subsequent disturbance. It is easy to imagine the corresponding doubts that arise in the case of analytic constructions.

[1937d, 5061]
Psycho-analytic research into the neuroses (the various forms of nervous illness with a mental causation) has endeavoured to trace their connection with instinctual life and the restrictions imposed on it by the claims of civilization, with the activities of the normal individual in phantasies and dreams, and with the creations of the popular mind in religion, myths and fairy tales. The psycho-analytic treatment of neurotic patients, based on this method of research, makes far higher demands on doctor and patient than the methods hitherto in common use, which operate through medicaments, diet, hydropathy and suggestion. But it brings the patients so much more relief and permanent strengthening in the face of life's problems, that there is no cause for surprise at the continual advances made by this therapeutic method in spite of violent opposition. [1910b, 1995]

(a) Advances in our knowledge. We are, of course, still a long way from knowing all that is required for an understanding of the unconscious in our patients. It is clear that every advance in our knowledge means an increase in our therapeutic power. As long as we have understood nothing, we have accomplished nothing; the more we understand, the more we shall achieve. At its beginning psycho-analytic treatment was inexorable and exhausting. The patient had to say everything himself, and the physician's activity consisted of urging him on incessantly. To-day things have a more friendly air. The treatment is made up of two parts - what the physician infers and tells the patient, and the patient's working-over of what he has heard. The mechanism of our assistance is easy to understand: we give the patient the conscious anticipatory idea and he then finds the repressed unconscious idea in himself on the basis of its similarity to the anticipatory one. This is the intellectual help which makes it easier for him to overcome the resistances between conscious and unconscious. Incidentally, I may remark that it is not the only mechanism made use of in analytic treatment; you all know the far more powerful one which lies in the use of the 'transference'. It is my intention in the near future to deal with these various factors, which are so important for an understanding of the treatment, in an Allgemeine Methodik der Psychoanalyse. And further, in speaking to you I need not rebut the objection that the evidential value in support of the correctness of our hypotheses is obscured in our treatment as we practise it to-day; you will not forget that this evidence is to be found elsewhere, and that a therapeutic procedure cannot be carried out in the same way as a theoretical investigation. [1910d, 2307]

The analytic psychotherapist thus has a threefold battle to wage - in his own mind against the forces which seek to drag him down from the analytic level; outside the analysis, against opponents who dispute the importance he attaches to the sexual instinctual forces and hinder him from making use of them in his scientific technique; and inside the analysis, against his patients, who at first behave like opponents but later on reveal the overvaluation of sexual life which dominates them, and who try to make him captive to their socially untamed passion. [1915a, 2520]
To my surprise, after this suggestion of mine, she began without any transition speaking of Prince L., whose escape from an asylum was being talked about a great deal at the time. She brought out new fears about asylums - that people in them were treated with douches of ice-cold water on the head and put into an apparatus which turned them round and round till they were quiet. When, three days ago, she had first complained about her fear of asylums, I had interrupted her after her first story, that the patients were tied on to chairs. I now saw that I had gained nothing by this interruption and that I cannot evade listening to her stories in every detail to the very end. After these arrears had been made up, I took this fresh crop of fears from her as well, I appealed to her good sense and told her she really ought to believe me more than the silly girl from whom she had had the gruesome stories about the way in which asylums are run. As I noticed that she still stammered occasionally in telling me these further things, I asked her once more what the stammer came from. No reply. 'Don't you know?' 'No.' 'Why not?' 'Why not? Because I mayn't!' (She pronounced these words violently and angrily.) This declaration seemed to me to be evidence of the success of my suggestion, but she expressed a desire for me to wake her up from her hypnosis, and I did so.¹

¹ It was not until the next day that I understood this little scene. Her unruly nature, which rebelled, both in her waking state and in artificial sleep, against any constraint, had made her angry with me because I had assumed that her narrative was finished and had interrupted it by my concluding suggestion. I have come across many other proofs that she kept a critical eye upon my work in her hypnotic consciousness. She had probably wanted to reproach me with interrupting her story to-day just as I had previously interrupted her accounts of the horrors in the asylum; but she had not ventured to do so. Instead of this, she had produced these further stories, apparently without any transition and without revealing the connecting thoughts. My blunder was made plain to me the next day by a depreciatory comment on her part.

Hypnosis. - She had had some fearful dreams. The legs and arms of the chairs were all turned into snakes; a monster with a vulture's beak was tearing and eating at her all over her body; other wild animals leapt upon her, etc. She then passed on to other animal-deliria, which, however, she qualified with the addition 'That was real' (not a dream): how (on an earlier occasion) she had been going to pick up a ball of wool, and it was a mouse and ran away; how she had been on a walk, and a big toad suddenly jumped out at her, and so on. I saw that my general prohibition had been ineffective and that I should have to take her frightening impressions away from her one by one.¹ I took an opportunity of asking her, too, why she had gastric pains and what they came from. (I believe that all her attacks of zoöpsia are accompanied by gastric pains.) Her answer, which she gave rather grudgingly, was that she did not know. I requested her to remember by tomorrow. She then said in a definitely grumbling tone that I was not to keep on asking her where this and that came from. After this, she said, she had hated her child for three years, because she always told herself that she might have been able to nurse her husband back to health if she had not been in bed on account of the child. And then after her husband's death there had been nothing but insults and agitations. His relatives, who had always been against the marriage and had then been angry because they had been so happy together, had spread a rumour that she had poisoned him, so that she had wanted to demand an enquiry. Her relatives had involved her in all kinds of legal proceedings with the help of a shady journalist. The wretch had sent round agents to stir people up against her. He got the local papers to print libellous articles about her, and then sent her the cuttings. This had been the origin of her unsociability and her hatred of all strangers. After I had spoken some calming words about what she had told me, she said she felt easier.
(e) I cannot advise my colleagues too urgently to model themselves during psycho-analytic treatment on the surgeon, who puts aside all his feelings, even his human sympathy, and concentrates his mental forces on the simple aim of performing the operation as skilfully as possible. Under present-day conditions the feeling that is most dangerous to a psycho-analyst is the therapeutic ambition to achieve by this novel and much disputed method something that will produce a convincing effect upon other people. This will not only put him into a state of mind which is unfavourable for his work, but will make him helpless against certain resistances of the patient, whose recovery, as we know, primarily depends on the interplay of forces in him. The justification for requiring this emotional coldness in the analyst is that it creates the most advantageous conditions for both parties: for the doctor a desirable protection for his own emotional life and for the patient the largest amount of help that we can give him to-day. A surgeon of earlier times took as his motto the words: 'Je le pansai, Dieu le guérit.'¹ The analyst should be content with something similar.

[1912e, 2470]

(f) It is easy to see upon what aim the different rules I have brought forward converge. They are all intended to create for the doctor a counterpart to the ‘fundamental rule of psycho-analysis’ which is laid down for the patient. Just as the patient must relate everything that his self-observation can detect, and keep back all the logical and affective objections that seek to induce him to make a selection from among them, so the doctor must put himself in a position to make use of everything he is told for the purposes of interpretation and of recognizing the concealed unconscious material without substituting a censorship of his own for the selection that the patient has forgone. To put it in a formula: he must turn his own unconscious like a receptive organ towards the transmitting unconscious of the patient. He must adjust himself to the patient as a telephone receiver is adjusted to the transmitting microphone. Just as the receiver converts back into sound waves the electric oscillations in the telephone line which were set up by sound waves, so the doctor's unconscious is able, from the derivatives of the unconscious which are communicated to him, to reconstruct that unconscious, which has determined the patient's free associations.

[1912e, 2470]

But if the doctor is to be in a position to use his unconscious in this way as an instrument in the analysis, he must himself fulfil one psychological condition to a high degree. He may not tolerate any resistances in himself which hold back from his consciousness what has been perceived by his unconscious; otherwise he would introduce into the analysis a new species of selection and distortion which would be far more detrimental than that resulting from concentration of conscious attention. It is not enough for this that he himself should be an approximately normal person. It may be insisted, rather, that he should have undergone a psycho-analytic purification and have become aware of those complexes of his own which would be apt to interfere with his grasp of what the patient tells him. There can be no reasonable doubt about the disqualifying effect of such defects in the doctor; every unresolved repression in him constitutes what has been aptly described by Stekel as a 'blind spot' in his analytic perception.

[1912e, 2471]
Psycho-analysis as an Interpretive Art. - The new technique altered the picture of the treatment so greatly, brought the physician into such a new relation to the patient and produced so many surprising results that it seemed justifiable to distinguish the procedure from the cathartic method by giving it a new name. The present writer gave this method of treatment, which could now be extended to many other forms of neurotic disorder, the name of psycho-analysis. Now, in the first resort, this psycho-analysis was an art of interpretation and it set itself the task of carrying deeper the first of Breuer's great discoveries - namely, that neurotic symptoms are significant substitutes for other mental acts which have been omitted. It was now a question of regarding the material produced by the patients' associations as though it hinted at a hidden meaning and of discovering that meaning from it. Experience soon showed that the attitude which the analytic physician could most advantageously adopt was to surrender himself to his own unconscious mental activity, in a state of evenly suspended attention, to avoid so far as possible reflection and the construction of conscious expectations, not to try to fix anything that he heard particularly in his memory, and by these means to catch the drift of the patient's unconscious with his own unconscious. It was then found that, except under conditions that were too unfavourable, the patient's associations emerged like allusions, as it were, to one particular theme and that it was only necessary for the physician to go a step further in order to guess the material which was concealed from the patient himself and to be able to communicate it to him. It is true that this work of interpretation was not to be brought under strict rules and left a great deal of play to the physician's tact and skill; but, with impartiality and practice, it was usually possible to obtain trustworthy results - that is to say, results which were confirmed by being repeated in similar cases. At a time when so little was as yet known of the unconscious, the structure of the neuroses and the pathological processes underlying them, it was a matter for satisfaction that a technique of this kind should be available, even if it had no better theoretical basis. Moreover it is still employed in analyses at the present day in the same manner, though with a sense of greater assurance and with a better understanding of its limitations.

[1923a, 3916]
It may seem surprising that this method of free association, carried out subject to the observation of the *fundamental rule of psycho-analysis*, should have achieved what was expected of it, namely the bringing into consciousness of the repressed material which was held back by resistances. We must, however, bear in mind that free association is not really free. The patient remains under the influence of the analytic situation even though he is not directing his mental activities on to a particular subject. We shall be justified in assuming that nothing will occur to him that has not some reference to that situation. His resistance against reproducing the repressed material will now be expressed in two ways. Firstly it will be shown by critical objections; and it was to deal with these that the fundamental rule of psycho-analysis was invented. But if the patient observes that rule and so overcomes his reticences, the resistance will find another means of expression. It will so arrange it that the repressed material itself will never occur to the patient but only something which approximates to it in an allusive way; and the greater the resistance, the more remote from the actual idea that the analyst is in search of will be the substitutive association which the patient has to report. The analyst, who listens composedly but without any constrained effort to the stream of associations and who, from his experience, has a general notion of what to expect, can make use of the material brought to light by the patient according to two possibilities. If the resistance is slight he will be able from the patient's allusions to infer the unconscious material itself; or if the resistance is stronger he will be able to recognize its character from the associations, as they seem to become more remote from the topic in hand, and will explain it to the patient. Uncovering the resistance, however, is the first step towards overcoming it. Thus the work of analysis involves an *art of interpretation*, the successful handling of which may require tact and practice but which is not hard to acquire. But it is not only in the saving of labour that the method of free association has an advantage over the earlier method. It exposes the patient to the least possible amount of compulsion, it never allows of contact being lost with the actual current situation, it guarantees to a great extent that no factor in the structure of the neurosis will be overlooked and that nothing will be introduced into it by the expectations of the analyst. It is left to the patient in all essentials to determine the course of the analysis and the arrangement of the material; any systematic handling of particular symptoms or complexes thus becomes impossible. In complete contrast to what happened with hypnosis and with the urging method, interrelated material makes its appearance at different times and at different points in the treatment. To a spectator, therefore - though in fact there must be none - an analytic treatment would seem completely obscure.

[1925d, 4216]
The Interpretation of Parapraxes and Haphazard Acts. - It was a triumph for the interpretative art of psycho-analysis when it succeeded in demonstrating that certain common mental acts of normal people, for which no one had hitherto attempted to put forward a psychological explanation, were to be regarded in the same light as the symptoms of neurotics: that is to say, they had a meaning, which was unknown to the subject but which could easily be discovered by analytic means. The phenomena in question were such events as the temporary forgetting of familiar words and names, forgetting to carry out prescribed tasks, everyday slips of the tongue and of the pen, misreadings, losses and mislayings of objects, certain errors, instances of apparently accidental self-injury, and finally habitual movements carried out seemingly without intention or in play, tunes hummed 'thoughtlessly', and so on. All of these were shorn of their physiological explanation, if any such had ever been attempted, were shown to be strictly determined and were revealed as an expression of the subject's suppressed intentions or as a result of a clash between two intentions one of which was permanently or temporarily unconscious. The importance of this contribution to psychology was of many kinds. The range of mental determinism was extended by it in an unforeseen manner; the supposed gulf between normal and pathological mental events was narrowed; in many cases a useful insight was afforded into the play of mental forces that must be suspected to lie behind the phenomena. Finally, a class of material was brought to light which is calculated better than any other to stimulate a belief in the existence of unconscious mental acts even in people to whom the hypothesis of something at once mental and unconscious seems strange and even absurd. The study of one's own parapraxes and haphazard acts, for which most people have ample opportunities, is even to-day the best preparation for an approach to psycho-analysis. In analytic treatment, the interpretation of parapraxes retains a place as a means of uncovering the unconscious, alongside the immeasurably more important interpretation of associations. [1923a, 3917]
If within ten years of the publication of this book (which is very far from being an easy one to read) a second edition is called for, this is not due to the interest taken in it by the professional circles to whom my original preface was addressed. My psychiatric colleagues seem to have taken no trouble to overcome the initial bewilderment created by my new approach to dreams. The professional philosophers have become accustomed to polishing off the problems of dream-life (which they treat as a mere appendix to conscious states) in a few sentences - and usually in the same ones; and they have evidently failed to notice that we have something here from which a number of inferences can be drawn that are bound to transform our psychological theories. The attitude adopted by reviewers in the scientific periodicals could only lead one to suppose that my work was doomed to be sunk into complete silence; while the small group of gallant supporters, who practise medical psycho-analysis under my guidance and who follow my example in interpreting dreams and make use of their interpretations in treating neurotics, would never have exhausted the first edition of the book. Thus it is that I feel indebted to a wider circle of educated and curious-minded readers, whose interest has led me to take up once more after nine years this difficult, but in many respects fundamental, work.

[1900a, 509]

As I have already explained, when I undertake the analytic treatment of a psycho-neurotic patient his dreams are invariably discussed between us. In the course of these discussions I am obliged to give him all the psychological explanations which have enabled me myself to reach an understanding of his symptoms. I am thereupon subjected to a remorseless criticism, certainly no less severe than I have to expect from the members of my own profession. And my patients invariably contradict my assertion that all dreams are fulfilments of wishes. Here, then, are some instances from the material of dreams that have been brought up against me as evidence to the contrary.

[1900a, 641]

The same point is illustrated by one last dream of the kind which I will quote from a patient under treatment. This was the dream of a girl who had succeeded in her struggle to continue her treatment with me against the will of her relatives and of the authorities whose opinions had been consulted. She dreamt that her people forbade her to go on coming to me. She then reminded me of a promise I had given her that if necessary I would continue the treatment without a fee. To this I replied: ‘I cannot make any allowances in money matters.’ It must be admitted that it was not easy to point to the wish-fulfilment in this instance. But in all such cases one discovers a second riddle, the solution of which helps one to solve the original one. What was the origin of the words she put into my mouth? Of course I had said nothing of the kind to her; but one of her brothers, and the one by whom she was most influenced, had been good enough to attribute this sentiment to me. The dream was thus intended to prove her brother right. And it was not only in her dreams that she insisted on his being right; the same idea dominated her whole life and it was the motive of her illness.

[1900a, 652]

Though observations of this kind on small children fit in perfectly with the interpretation I have proposed, they do not carry such complete conviction as is forced upon the physician by psycho-analyses of adult neurotics. In the latter case dreams of the sort we are considering are introduced into the analysis in such a context that it is impossible to avoid interpreting them as wishful dreams.

[1900a, 737]
One day one of my women patients was in a distressed and tearful mood. 'I don't want ever to see my relations again', she said, 'they must think me horrible.' She then went on, with almost no transition, to say that she remembered a dream, though of course she had no idea what it meant. When she was four years old she had a dream that a lynx or a fox was walking on the roof; then something had fallen down or she had fallen down; and then her mother was carried out of the house dead - and then she wept bitterly. I told her that this dream must mean that when she was a child she had wished she could see her mother dead, and that it must be on account of the dream that she felt her relations must think her horrible. I had scarcely said this when she produced some material which threw light on the dream. 'Lynx eye' was a term of abuse that had been thrown at her by a street-urchin when she was a very small child. When she was three years old, a tile off the roof had fallen on her mother's head and made it bleed violently.

I once had an opportunity of making a detailed study of a young woman who passed through a variety of psychical conditions. Her illness began with a state of confusional excitement during which she displayed a quite special aversion to her mother, hitting and abusing her whenever she came near her bed, while at the same period she was docile and affectionate towards a sister who was many years her senior. This was followed by a state in which she was lucid but somewhat apathetic and suffered from badly disturbed sleep. It was during this phase that I began treating her and analysing her dreams. An immense number of these dreams were concerned, with a greater or less degree of disguise, with the death of her mother: at one time she would be attending an old woman's funeral, at another she and her sister would be sitting at table dressed in mourning. There could be no question as to the meaning of these dreams. As her condition improved still further, hysterical phobias developed. The most tormenting of these was a fear that something might have happened to her mother. She was obliged to hurry home, wherever she might be, to convince herself that her mother was still alive. This case, taken in conjunction with what I had learnt from other sources, was highly instructive: it exhibited, translated as it were into different languages, the various ways in which the psychical apparatus reacted to one and the same exciting idea. In the confusional state, in which, as I believe, the second psychical agency was overwhelmed by the normally suppressed first one, her unconscious hostility to her mother found a powerful motor expression. When the calmer condition set in, when the rebellion was suppressed and the domination of the censorship re-established, the only region left open in which her hostility could realize the wish for her mother's death was that of dreaming. When a normal state was still more firmly established, it led to the production of her exaggerated worry about her mother as a hysterical counter-reaction and defensive phenomenon. In view of this it is no longer hard to understand why hysterical girls are so often attached to their mothers with such exaggerated affection.

² [Footnote added 1909:] If in the actual course of a dream dreamt during psycho-analytic treatment the dreamer says to himself: 'I must tell the doctor that', it invariably implies the presence of a strong resistance against confessing the dream - which is not infrequently thereupon forgotten.
An observation which I have been able to make in the course of preparing this manuscript has shown me that dreams are no more forgotten than other mental acts and can be compared, by no means to their disadvantage, with other mental functions in respect of their retention in the memory. I had kept records of a large number of my own dreams which for one reason or another I had not been able to interpret completely at the time or had left entirely uninterpreted. And now, between one and two years later, I have attempted to interpret some of them for the purpose of obtaining more material in illustration of my views. These attempts have been successful in every instance; indeed the interpretation may be said to have proceeded more easily after this long interval than it did at the time when the dream was a recent experience. A possible explanation of this is that in the meantime I have overcome some of the internal resistances which previously obstructed me. When making these subsequent interpretations I have compared the dream-thoughts that I elicited at the time of the dream with the present, usually far more copious, yield, and I have always found that the old ones are included among the new. My astonishment at this was quickly halted by the reflection that I had long been in the habit of getting my patients, who sometimes tell me dreams dating from earlier years, to interpret them - by the same procedure and with the same success - as though they had dreamt them the night before. When I come to discuss anxiety-dreams I shall give two examples of postponed interpretations like these. I was led into making my first experiment of this kind by the justifiable expectation that in this as in other respects dreams would behave like neurotic symptoms. When I treat a psychoneurotic - a hysterical, let us say - by psycho-analysis, I am obliged to arrive at an explanation for the earliest and long since vanished symptoms of his illness no less than for the contemporary ones which brought him to me for treatment; and I actually find the earlier problem easier to solve than the immediate one. As long ago as in 1895 I was able to give an explanation in *Studies on Hysteria* of the first hysterical attack which a woman of over forty had had in her fifteenth year.¹

I will now describe the way in which I have overcome the technical difficulties of drawing up the report of this case history. The difficulties are very considerable when the physician has to conduct six or eight psychotherapeutic treatments of the sort in a day, and cannot make notes during the actual session with the patient for fear of shaking the patient's confidence and of disturbing his own view of the material under observation. Indeed, I have not yet succeeded in solving the problem of how to record for publication the history of a treatment of long duration. As regards the present case, two circumstances have come to my assistance. In the first place the treatment did not last for more than three months; and in the second place the material which elucidated the case was grouped around two dreams (one related in the middle of the treatment and one at the end). The wording of these dreams was recorded immediately after the session, and they thus afforded a secure point of attachment for the chain of interpretations and recollections which proceeded from them. The case history itself was only committed to writing from memory after the treatment was at an end, but while my recollection of the case was still fresh and was heightened by my interest in its publication. Thus the record is not absolutely - phonographically - exact, but it can claim to possess a high degree of trustworthiness. Nothing of any importance has been altered in it except in some places the order in which the explanations are given; and this has been done for the sake of presenting the case in a more connected form.

[1900a, 956]

¹ [1905e, 1352]
I next proceed to mention more particularly what is to be found in this paper and what is not to be found in it. The title of the work was originally 'Dreams and Hysteria', for it seemed to me peculiarly well-adapted for showing how dream-interpretation is woven into the history of a treatment and how it can become the means of filling in amnesias and elucidating symptoms. It was not without good reasons that in the year 1900 I gave precedence to a laborious and exhaustive study of dreams (The Interpretation of Dreams) over the publications upon the psychology of the neuroses which I had in view. And incidentally I was able to judge from its reception with what an inadequate degree of comprehension such efforts are met by other specialists at the present time. In this instance there was no validity in the objection that the material upon which had based my assertions had been withheld and that it was therefore impossible to become convinced of their truth by testing and checking them. For every one can submit his own dreams to analytic examination, and the technique of interpreting dreams may be easily learnt from the instructions and examples which I have given. I must once more insist, just as I did at that time, that a thorough investigation of the problems of dreams is an indispensable prerequisite for any comprehension of the mental processes in hysteria and the other psychoneuroses, and that no one who wishes to shirk that preparatory labour has the smallest prospect of advancing even a few steps into this region of knowledge. Since, therefore, this case history presupposes a knowledge of the interpretation of dreams, it will seem highly unsatisfactory to any reader to whom this presupposition does not apply. Such a reader will find only bewilderment in these pages instead of the enlightenment he is in search of, and he will certainly be inclined to project the cause of his bewilderment on to the author and to pronounce his views fantastic. But in reality this bewildering character attaches to the phenomena of the neurosis itself; its presence there is only concealed by the physician's familiarity with the facts, and it comes to light again with every attempt a explaining them. It could only be completely banished if we could succeed in tracing back every single element of a neurosis to factors with which we were already familiar. But everything tends to show that, on the contrary, we shall be driven by the study of neuroses to assume the existence of many new thing which will later on gradually become the subject of more certain knowledge. What is new has always aroused bewilderment and resistance.

Nevertheless, it would be wrong to suppose that dreams and their interpretation occupy such a prominent position in all psycho-analyses as they do in this example.

While the case history before us seems particularly favoured as regards the utilization of dreams, in other respects it has turned out poorer than I could have wished. But its shortcomings are connected with the very circumstances which have made its publication possible. As I have already said, I should not have known how to deal with the material involved in the history of a treatment which had lasted, perhaps, for a whole year. The present history, which covers only three months could be recollected and reviewed; but its results remain incomplete in more than one respect. The treatment was not carried through to its appointed end, but was broken off at the patient's own wish when it had reached a certain point. At that time some of the problems of the case had not even been attacked and others had only been imperfectly elucidated; whereas, if the work had been continued, we should no doubt have obtained the fullest possible enlightenment upon every particular of the case. In the following pages, therefore, I can present only a fragment of an analysis.
In my *Interpretation of Dreams*, published in 1900, I showed that dreams in general can be interpreted, and that after the work of interpretation has been completed they can be replaced by perfectly correctly constructed thoughts which can be assigned a recognizable position in the chain of mental events. I wish to give an example in the following pages of the only practical application of which the art of interpreting dreams seems to admit. I have already mentioned in my book¹ how it was that I came upon the problem of dreams. The problem crossed my path as I was endeavouring to cure psychoneuroses by means of a particular psychotherapeutic method. For, among their other mental experiences, my patients told me their dreams, and these dreams seemed to call for insertion in the long thread of connections which spun itself out between a symptom of the disease and a pathogenic idea. At that time I learnt how to translate the language of dreams into the forms of expression of our own thought-language, which can be understood without further help. And I may add that this knowledge is essential for the psycho-analyst; for the dream is one of the roads along which consciousness can be reached by the psychical material which, on account of the opposition aroused by its content, has been cut off from consciousness and repressed, and has thus become pathogenic. The dream, in short, is one of the détours by which repression can be evaded; it is one of the principal means employed by what is known as the indirect method of representation in the mind. The following fragment from the history of the treatment of a hysterical girl is intended to show the way in which the interpretation of dreams plays a part in the work of analysis. It will at the same time give me a first opportunity of publishing at sufficient length to prevent further misunderstanding some of my views upon the psychical processes of hysteria and upon its organic determinants. I need no longer apologize on the score of length, since it is now agreed that the exacting demands which hysteria makes upon physician and investigator can be met only by the most sympathetic spirit of inquiry and not by an attitude of superiority and contempt. For,

[1905e, 1357]

Just at a moment when there was a prospect that the material that was coming up for analysis would throw light upon an obscure point in Dora's childhood, she reported that a few nights earlier she had once again had a dream which she had already dreamt in exactly the same way on many previous occasions. A periodically recurrent dream was by its very nature particularly well calculated to arouse my curiosity; and in any case it was justifiable in the interests of the treatment to consider the way in which the dream worked into the analysis as a whole. I therefore determined to make an especially careful investigation of it.

[1905e, 1401]

I should like, further, to draw special attention to the fact that the analysis of this dream has given us access to certain details of the pathogenically operative events which had otherwise been inaccessible to memory, or at all events to reproduction. The recollection of the bed-wetting in childhood had, as we have seen, already been repressed. And Dora had never mentioned the details of her persecution by Herr K.; they had never occurred to her mind.

[1905e, 1424]
If the theory of analytic technique is gone into, it becomes evident that transference is an inevitable necessity. Practical experience, at all events, shows conclusively that there is no means of avoiding it, and that this latest creation of the disease must be combated like all the earlier ones. This happens, however, to be by far the hardest part of the whole task. It is easy to learn how to interpret dreams, to extract from the patient's associations his unconscious thoughts and memories, and to practise similar explanatory arts: for these the patient himself will always provide the text. Transference is the one thing the presence of which has to be detected almost without assistance and with only the slightest clues to go upon, while at the same time the risk of making arbitrary inferences has to be avoided. Nevertheless, transference cannot be evaded, since use is made of it in setting up all the obstacles that make the material inaccessible to treatment, and since it is only after the transference has been resolved that a patient arrives at a sense of conviction of the validity of the connections which have been constructed during the analysis.

Freud has developed on this basis an art of interpretation which takes on the task of, as it were, extracting the pure metal of the repressed thoughts from the ore of the unintentional ideas. This work of interpretation is applied not only to the patient's ideas but also to his dreams, which open up the most direct approach to a knowledge of the unconscious, to his unintentional as well as to his purposeless actions (symptomatic acts) and to the blunders he makes in everyday life (slips of the tongue, bungled actions, and so on). The details of this technique of interpretation or translation have not yet been published by Freud. According to indications he has given, they comprise a number of rules, reached empirically, of how the unconscious material may be reconstructed from the associations, directions on how to know what it means when the patient's ideas cease to flow, and experiences of the most important typical resistances that arise in the course of such treatments. A bulky volume called *The Interpretation of Dreams*, published by Freud in 1900, may be regarded as the forerunner of an initiation into his technique.

The third of your indications of a complex (mistakes - that is, changes - in the reproduction) is also employed, though in a more restricted field, in the technique of psycho-analysis. One task which often faces us is the interpretation of dreams - that is, the translation of the remembered content of a dream into its hidden meaning. It sometimes happens that we are uncertain at which point to set about the task, and in that case we may make use of a rule, discovered empirically, which recommends us to get the dreamer to tell us his dream once more. In doing so, he usually alters his modes of expression in some parts of it while repeating the rest accurately. The points at which his reproduction is defective owing to changes, and often owing to omissions as well, are the points which we fasten upon, because the inaccuracy guarantees a connection with the complex and promises the best approach to the secret meaning of the dream.
A discussion of this childhood scene will be found in the footnote, and here I will only remark that its emergence shook the patient for the first time in his refusal to believe that at some prehistoric period in his childhood he had been seized with fury (which had subsequently become latent) against the father whom he loved so much. I must confess that I had expected it to have a greater effect, for the incident had been described to him so often - even by his father himself - that there could be no doubt of its objective reality. But, with that capacity for being illogical which never fails to bewilder one in such highly intelligent people as obsessional neurotics, he kept urging against the evidential value of the story the fact that he himself could not remember the scene. And so it was only along the painful road of transference that he was able to reach a conviction that his relation to his father really necessitated the postulation of this unconscious complement. Things soon reached a point at which, in his dreams, his waking phantasies, and his associations, he began heaping the grossest and filthiest abuse upon me and my family, though in his deliberate actions he never treated me with anything but the greatest respect. His demeanour as he repeated these insults to me was that of a man in despair. ‘How can a gentleman like you, sir,’ he used to ask, ‘let yourself be abused in this way by a low, good-for-nothing fellow like me? You ought to turn me out: that’s all I deserve.’ While he talked like this, he would get up from the sofa and roam about the room, - a habit which he explained at first as being due to delicacy of feeling: he could not bring himself, he said, to utter such horrible things while he was lying there so comfortably. But soon he himself found a more cogent explanation, namely, that he was avoiding my proximity for fear of my giving him a beating. If he stayed on the sofa he behaved like some one in desperate terror trying to save himself from castigations of terrific violence; he would bury his head in his hands, cover his face with his arm, jump up suddenly and rush away, his features distorted with pain, and so on. He recalled that his father had had a passionate temper, and sometimes in his violence had not known where to stop. Thus, little by little, in this school of suffering, the patient won the sense of conviction which he had lacked - though to any disinterested mind the truth would have been almost self-evident.

There are, besides this, two special ways in which a more precise knowledge of obsessional structures can be gained. In the first place, experience shows that an obsessional command (or whatever it may be), which in waking life is known only in a truncated and distorted form, like a mutilated telegraph message, may have its actual text brought to light in a dream. Such texts appear in dreams in the shape of speeches, and are thus an exception to the rule that speeches in dreams are derived from speeches in real life.² Secondly, in the course of the analytic examination of a case history, one becomes convinced that if a number of obsessions succeed one another they are often - even though their wording is not identical - ultimately one and the same. The obsession may have been successfully shaken off on its first appearance, but it comes back a second time in a distorted form and without being recognized, and may then perhaps be able to hold its own in the defensive struggle more effectively, precisely because of its distortion. But the original form is the correct one, and often displays its meaning quite openly. When we have at great pains elucidated an unintelligible obsessional idea, it often happens that the patient informs us that just such a notion, wish, or temptation as the one we have constructed did in fact make its appearance on one occasion before the obsessional idea had arisen, but that it did not persist. It would unfortunately involve us in too lengthy a digression if we were to give instances of this from the history of our present patient.

Working over the ideas that occur to patients when they submit to the main rule of psycho-analysis is not our only technical method of discovering the unconscious. The same purpose is served by two other procedures: the interpretation of patients’ dreams and the exploitation of their faulty and haphazard actions.
As you see, research into dreams would be justified for its own sake merely by the information it
gives us on matters that can with difficulty be discovered in other ways. But we were in fact led to
the subject in connection with the psycho-analytic treatment of neurotics. You will easily
understand from what I have already said how it is that dream-interpretation, if it is not made too
difficult by the patient's resistances, leads to a knowledge of his hidden and repressed wishes
and of the complexes nourished by them; and I can now pass on to the third group of mental
phenomena whose study has become one of the technical instruments of psycho-analysis.
[1910a, 2224]

If you will now bring together the means we possess for uncovering what is concealed,
forgotten and repressed in the mind (the study of the ideas occurring to patients under free
association, of their dreams and of their faulty and symptomatic actions), and if you will add to
these the exploitation of certain other phenomena which occur during psycho-analytic treatment
and on which I shall have a few remarks to make later under the heading of 'transference' - if you
bear all these in mind, you will agree with me in concluding that our technique is already efficient
even to fulfil its task, to bring the pathogenic psychical material into consciousness and so to
get rid of the ailments that have been brought about by the formation of substitutive symptoms.
And if, in the course of our therapeutic endeavours, we extend and deepen our knowledge of the
human mind both in health and sickness, that can, of course, only be regarded as a peculiar
attraction in our work.
[1910a, 2225]

Some time ago I chanced to have an opportunity of obtaining insight into a dream of a newly-
married woman which was recognizable as a reaction to the loss of her virginity. It betrayed
spontaneously the woman's wish to castrate her young husband and to keep his penis for herself.
Certainly there was also room for the more innocent interpretation that what she wished for was
the prolongation and repetition of the act, but several details of the dream did not fit into this
meaning and the character as well as the subsequent behaviour of the woman who had the
dream gave evidence in favour of the more serious view. Behind this envy for the penis, there
comes to light the woman's hostile bitterness against the man, which never completely
disappears in the relations between the sexes, and which is clearly indicated in the strivings and
in the literary productions of 'emancipated' women. In a palaeo-biological speculation, Ferenczi
has traced back this hostility of women - I do not know if he is the first to do so - to the period in
time when the sexes became differentiated. At first, in his opinion, copulation took place between
two similar individuals, one of which, however, developed into the stronger and forced the weaker
one to submit to sexual union. The feelings of bitterness arising from this subjection still persist in
the present-day disposition of women. I do not think there is any harm in employing such
speculations, so long as one avoids setting too much value on them.
[1918a, 2360]

The question with which I now intend to deal is not that of the technique of dream-interpretation:
neither the methods by which dreams should be interpreted nor the use of such interpretations
when made will be considered, but only the way in which the analyst should employ the art of
interpretation in the psycho-analytic treatment of patients. There are undoubtedly different ways
of going to work in the matter, but then the answer to questions of technique in analysis is never a
matter of course. Although there may perhaps be more than one good road to follow, still there
are very many bad ones, and a comparison of the various methods cannot fail to be illuminating,
even if it should not lead to a decision in favour of any particular one.
[1911e, 2450]
Anyone coming from dream-interpretation to analytic practice will retain his interest in the content of dreams, and his inclination will be to interpret as fully as possible every dream related by the patient. But he will soon remark that he is now working under quite different conditions, and that if he attempts to carry out his intention he will come into collision with the most immediate tasks of the treatment. Even if a patient's first dream proves to be admirably suited for the introduction of the first explanations to be given, other dreams will promptly appear, so long and so obscure that the full meaning cannot be extracted from them in the limited session of one day's work. If the doctor continues the work of interpretation during the following days, fresh dreams will be produced in the meantime and these will have to be put aside until he can regard the first dream as finally resolved. The production of dreams is at times so copious, and the patient's progress towards comprehension of them so hesitant, that a suspicion will force itself on the analyst that the appearance of the material in this manner may be simply a manifestation of the patient's resistance taking advantage of the discovery that the method is unable to master what is so presented. Moreover, the treatment will meanwhile have fallen quite a distance behind the present and have lost touch with actuality. In opposition to such a technique stands the rule that it is of the greatest importance for the treatment that the analyst should always be aware of the surface of the patient's mind at any given moment, that he should know what complexes and resistances are active in him at the time and what conscious reaction to them will govern his behaviour. It is scarcely ever right to sacrifice this therapeutic aim to an interest in dream-interpretation.

What then, if we bear this rule in mind, is to be our attitude to interpreting dreams in analysis? More or less as follows: The amount of interpretation which can be achieved in one session should be taken as sufficient and it is not to be regarded as a loss if the content of the dream is not fully discovered. On the following day, the interpretation of the dream is not to be taken up again as a matter of course, until it has become evident that nothing else has meanwhile forced its way into the foreground of the patient's thoughts. Thus no exception in favour of an interrupted dream-interpretation is to be made to the rule that the first thing that comes into the patient's head is the first thing to be dealt with. If fresh dreams occur before the earlier ones have been disposed of, the more recent productions are to be attended to, and no uneasiness need be felt about neglecting the older ones. If the dreams become altogether too diffuse and voluminous, all hope of completely unravelling them should tacitly be given up from the start. One must in general guard against displaying very special interest in the interpretation of dreams, or arousing an idea in the patient that the work would come to a standstill if he were to bring up no dreams; otherwise there is a danger of the resistance being directed to the production of dreams, with a consequent cessation of them. The patient must be brought to believe, on the contrary, that the analysis invariably finds material for its continuation, regardless of whether or no he brings up dreams or what amount of attention is devoted to them.
It will now be asked whether we shall not be giving up too much valuable material which might throw light on the unconscious if dream-interpretation is only to be carried out subject to such restrictions of method. The answer to this is that the loss is by no means so great as might appear from a superficial view of the matter. To begin with, it must be recognized that in cases of severe neurosis any elaborate dream-productions must from the nature of things be regarded as incapable of complete solution. A dream of this kind is often based on the entire pathogenic material of the case, as yet unknown to both doctor and patient (so called 'programme-dreams' and biographical dreams), and is sometimes equivalent to a translation into dream-language of the whole content of the neurosis. In the attempt to interpret such a dream all the latent, as yet untouched, resistances will be roused to activity and soon set a limit to its understanding. The full interpretation of such a dream will coincide with the completion of the whole analysis; if a note is made of it at the beginning, it may be possible to understand it at the end, many months later. It is the same as with the elucidation of a single symptom (the main symptom, perhaps). The whole analysis is needed to explain it; in the course of the treatment one must endeavour to lay hold first of this, then of that, fragment of the symptom's meaning, one after another, until they can all be pieced together. Similarly, no more can be expected of a dream occurring in the early stages of the analysis; one must be content if the attempt at interpretation brings a single pathogenic wishful impulse to light.

Thus nothing attainable is renounced if one gives up the idea of a complete dream-interpretation; nor is anything lost as a rule if one breaks off the interpretation of a comparatively old dream and turns to a more recent one. We have found from fine examples of fully analysed dreams that several successive scenes of one dream may have the same content, which may find expression in them with increasing clarity; and we have learnt, too, that several dreams occurring in the same night need be nothing more than attempts, expressed in various forms, to represent one meaning. In general, we may rest assured that every wishful impulse which creates a dream to-day will re-appear in other dreams as long as it has not been understood and withdrawn from the domination of the unconscious. It often happens, therefore, that the best way to complete the interpretation of a dream is to leave it and to devote one's attention to a new dream, which may contain the same material in a possibly more accessible form. I know that it is asking a great deal, not only of the patient but also of the doctor, to expect them to give up their conscious purposive aims during the treatment, and to abandon themselves to a guidance which, in spite of everything, still seems to us 'accidental'. But I can answer for it that one is rewarded every time one resolves to have faith in one's own theoretical principles, and prevails upon oneself not to dispute the guidance of the unconscious in establishing connecting links.

I submit, therefore, that dream-interpretation should not be pursued in analytic treatment as an art for its own sake, but that its handling should be subject to those technical rules that govern the conduct of the treatment as a whole. Occasionally, of course, one can act otherwise and allow a little free play to one's theoretical interest; but one should always be aware of what one is doing. Another situation to be considered is one which has arisen since we have acquired more confidence in our understanding of dream-symbolism, and know ourselves to be more independent of the patient's associations. An unusually skilful dream-interpreter will sometimes find himself in the position of being able to see through every one of a patient's dreams without requiring him to go through the tedious and time-absorbing process of working over them. Such an analyst is thus exempt from any conflict between the demands of dream-interpretation and those of the treatment. Moreover he will be tempted to make full use of dream-interpretation on every occasion, by telling the patient everything he has detected in his dreams. In doing so, however, he will have adopted a method of treatment which departs considerably from the established one, as I shall point out in another connection. Beginners in psycho-analytic practice, at any rate, are advised not to take this exceptional case as a model.
Every analyst is in the position of the superior dream-interpreter, whom we have been imagining, in regard to the very first dreams that his patients bring, before they have learnt anything of the technique of translating dreams. These initial dreams may be described as unsophisticated: they betray a great deal to the listener, like the dreams of so-called healthy people. The question then arises whether the analyst is at once to translate to the patient all that he himself reads from them. This, however, is not the place for answering this question, for it evidently forms part of a wider one: at what stage in the treatment and how rapidly should the analyst introduce the patient to the knowledge of what lies veiled in his mind? The more the patient has learnt of the practice of dream-interpretation, the more obscure do his later dreams as a rule become. All the knowledge acquired about dreams serves also to put the dream-constructing process on its guard.

[1911e, 2453]

In the 'scientific' works about dreams, which in spite of their repudiation of dream-interpretation have received a new stimulus from psycho-analysis, one constantly finds that scrupulous care is most unnecessarily attached to the accurate preservation of the text of the dream. This is supposed to need protection from distortions and attritions in the hours immediately after waking. Some psycho-analysts, even, in giving the patient instructions to write down every dream immediately upon waking, seem not to rely consistently enough upon their knowledge of the conditions of dream-formation. In therapeutic work this rule is superfluous; and patients are glad to make use of it to disturb their sleep and to display great zeal where it can serve no useful purpose. For even if the text of a dream is in this way laboriously rescued from oblivion, it is easy enough to convince oneself that nothing has been achieved for the patient. Associations will not come to the text, and the result is the same as if the dream had not been preserved. No doubt the doctor has acquired some knowledge which he would not have done otherwise. But it is not the same thing whether the analyst knows something or the patient knows it; the importance of this distinction for the technique of psycho-analysis will be more fully considered elsewhere.

[1911e, 2453]

In conclusion, I will mention a particular type of dream which, in the nature of the case, occurs only in the course of psycho-analytic treatment, and may bewilder or mislead beginners. These are the corroborative dreams which, as it were 'tag along behind'; they are easily accessible to analysis, and their translation merely presents what the treatment has inferred during the last new days from the material of the daily associations. When this happens, it looks as though the patient has been amiable enough to bring us in dream-form exactly what we had been 'suggesting' to him immediately before. The more experienced analyst will no doubt have some difficulty in attributing any such amiability to the patient; he accepts such dreams as hoped-for confirmations, and recognizes that they are only observed under certain conditions brought about by the influence of the treatment. The great majority of dreams forge ahead of the analysis; so that, after subtraction of everything in them which is already known and understood, there still remains a more or less clear hint at something which has hitherto been hidden.

[1911e, 2454]

There is one special class of experiences of the utmost importance for which no memory can as a rule be recovered. These are experiences which occurred in very early childhood and were not understood at the time but which were subsequently understood and interpreted. One gains a knowledge of them through dreams and one is obliged to believe in them on the most compelling evidence provided by the fabric of the neurosis. Moreover, we can ascertain for ourselves that the patient, after his resistances have been overcome, no longer invokes the absence of any memory of them (any sense of familiarity with them) as a ground for refusing to accept them. This matter, however, calls for so much critical caution and introduces so much that is novel and startling that I shall reserve it for a separate discussion in connection with suitable material.

[1914g, 2500]
Recognition of the simultaneous presence of the three factors of ‘infantilism’, ‘sexuality’ and ‘repression' constitutes the main characteristic of the psycho-analytic theory, and marks its distinction from other views of pathological mental life. At the same time, psycho-analysis has demonstrated that there is no fundamental difference, but only one of degree, between the mental life of normal people, of neurotics and of psychotics. A normal person has to pass through the same repressions and has to struggle with the same substitutive structures; the only difference is that he deals with these events with less trouble and better success. The psycho-analytic method of investigation can accordingly be applied equally to the explanation of normal psychical phenomena, and has made it possible to discover the close relationship between pathological psychical products and normal structures such as dreams, the small blunders of everyday life, and such valuable phenomena as jokes, myths and imaginative works. The explanation of these has been carried furthest in the case of dreams, and has resulted here in the following general formula: ‘A dream is a disguised fulfilment of a repressed wish.’ The interpretation of dreams has as its object the removal of the disguise to which the dreamer's thoughts have been subjected. It is, moreover, a highly valuable aid to psycho-analytic technique, for it constitutes the most convenient method of obtaining insight into unconscious psychical life. [1913m, 2548]

We have recently received a piece of advice, purporting to represent one of the latest developments of psycho-analysis, to the effect that the current conflict and the exciting cause of illness are to be brought into the foreground in analysis. Now this is exactly what Breuer and I used to do at the beginning of our work with the cathartic method. We led the patient's attention directly to the traumatic scene in which the symptom had arisen, and we endeavoured to discover the mental conflict in that scene and to release the suppressed affection in it. In the course of this we discovered the mental process, characteristic of the neuroses, which I later named ‘regression’. The patient's associations moved back from the scene which we were trying to elucidate to earlier experiences, and compelled the analysis, which was supposed to correct the present, to occupy itself with the past. This regression led constantly further backwards; at first it seemed regularly to bring us to puberty; later on, failures and points which still eluded explanation drew the analytic work still further back into years of childhood which had hitherto been inaccessible to any kind of exploration. This regressive direction became an important characteristic of analysis. It appeared that psycho-analysis could explain nothing belonging to the present without referring back to something past; indeed, that every pathogenic experience implied a previous experience which, though not in itself pathogenic, had yet endowed the later one with its pathogenic quality. The temptation to confine one's attention to the known present exciting cause was so strong, however, that even in later analyses I gave way to it. In the analysis of the patient I named 'Dora', carried out in 1899, I had knowledge of the scene which occasioned the outbreak of the current illness. I tried innumerable times to submit this experience to analysis, but even direct demands always failed to produce from her anything more than the same meagre and incomplete description of it. Not until a long détour, leading back over her earliest childhood, had been made, did a dream present itself which on analysis brought to her mind the hitherto forgotten details of this scene, so that a comprehension and a solution of the current conflict became possible. [1914d, 2880]

Among the other new factors which were added to the cathartic procedure as a result of my work and which transformed it into psycho-analysis, I may mention in particular the theory of repression and resistance, the recognition of infantile sexuality, and the interpreting and exploiting of dreams as a source of knowledge of the unconscious. [1914d, 2884]
I need say little about the interpretation of dreams. It came as the first fruits of the technical innovation I had adopted when, following a dim presentiment, I decided to replace hypnosis by free association. My desire for knowledge had not at the start been directed towards understanding dreams. I do not know of any outside influence which drew my interest to them or inspired me with any helpful expectations. Before Breuer and I ceased to meet I only just had time to tell him in a single sentence that I now understood how to translate dreams. Since this was how the discovery came about, it followed that the symbolism in the language of dreams was almost the last thing to become accessible to me, for the dreamer's associations help very little towards understanding symbols. I have held fast to the habit of always studying things themselves before looking for information about them in books, and therefore I was able to establish the symbolism of dreams for myself before I was led to it by Scherner's work on the subject. It was only later that I came to appreciate to its full extent this mode of expression of dreams. This was partly through the influence of the works of Stekel, who at first did such very creditable work but afterwards went totally astray. The close connection between psycho-analytic dream-interpretation and the art of interpreting dreams as practised and held in such high esteem in antiquity only became clear to me much later. Later on I found the essential characteristic and most important part of my dream theory - the derivation of dream-distortion from an internal conflict, a kind of inner dishonesty - in a writer who was ignorant, it is true, of medicine, though not of philosophy, the famous engineer J. Popper, who published his Phantasien eines Realisten under the name of Lynkeus.
[1914d, 2888]

The interpretation of dreams became a solace and a support to me in those arduous first years of analysis, when I had to master the technique, clinical phenomena and therapy of the neuroses all at the same time. At that period I was completely isolated and in the network of problems and accumulation of difficulties I often dreaded losing my bearings and also my confidence. There were often patients with whom an unaccountably long time elapsed before my hypothesis, that a neurosis was bound to become intelligible through analysis, proved true; but these patients' dreams, which might be regarded as analogues of their symptoms, almost always confirmed the hypothesis.
[1914d, 2889]

LADIES AND GENTLEMEN, - It was discovered one day that the pathological symptoms of certain neurotic patients have a sense.¹ On this discovery the psycho-analytic method of treatment was founded. It happened in the course of this treatment that patients, instead of bringing forward their symptoms, brought forward dreams. A suspicion thus arose that the dreams too had a sense.
[1916-1917, 3185]

In the first place I must admit that no one carries on the interpretation of dreams as his main occupation. How does it come about, then, that people do interpret them? Occasionally, with no particular end in view, one may interest oneself in the dreams of an acquaintance, or one may work through one's own dreams for a time in order to train oneself in psycho-analytic work; but for the most part what one has to deal with are the dreams of neurotic patients who are under psycho-analytic treatment. These latter dreams are excellent material and are in no way inferior to those of healthy people; but the technique of the treatment necessitates our subordinating dream-interpretation to therapeutic aims, and we have to allow a whole number of dreams to drop after we have extracted something from them that is of service to the treatment. Some dreams that occur during treatment entirely escape any full analysis: since they have arisen out of the great mass of psychical material which is still unknown to us, it is impossible to understand them before the treatment is finished. If I were to report dreams of this kind, it would oblige me to uncover all the secrets of a neurosis as well; and that will not do for us, since it is precisely to prepare us for the study of the neuroses that we have attacked the problem of dreams.
[1916-1917, 3275]
From the standpoint of the libido theory, too, we may say a last word on dreams. A neurotic's dreams help us, like his parapraxes and his free associations to them, to discover the sense of his symptoms and to reveal the way in which his libido is allocated. They show us, in the form of a wish-fulfilment, what wishful impulses have been subjected to repression and to what objects the libido withdrawn from the ego has become attached. For this reason the interpretation of dreams plays a large part in a psycho-analytic treatment, and in some cases it is over long periods the most important instrument of our work. We already know that the state of sleep in itself leads to a certain relaxation of the repressions. A repressed impulse, owing to this reduction in the pressure weighing down upon it, becomes able to express itself far more clearly in a dream than it can be allowed to be expressed by a symptom during the day. The study of dreams therefore becomes the most convenient means of access to a knowledge of the repressed unconscious, of which the libido withdrawn from the ego forms a part.

[1916-1917, 3496]

The identity of the dreams of healthy and neurotic people enables us to infer thus much in regard to defining the characteristics of health. But in regard to dreams themselves we can make a further inference: we must not detach them from their connection with neurotic symptoms, we must not suppose that their essential nature is exhausted by the formula that describes them as a translation of thoughts into an archaic form of expression, but we must suppose that they exhibit to us allocations of the libido and object-cathexes that are really present.

[1916-1917, 3496]

It is easy to understand that the first suspicion fell upon the English governess, for the change in the boy made its appearance while she was there. Two screen memories had persisted, which were incomprehensible in themselves, and which related to her. On one occasion, as she was walking along in front of them, she said: 'Do look at my little tail!' Another time, when they were on a drive, her hat flew away, to the two children's great satisfaction. This pointed to the castration complex, and might permit of a construction being made to the effect that a threat uttered by her against the boy had been largely responsible for originating his abnormal conduct. There is no danger at all in communicating constructions of this kind to the person under analysis; they never do any damage to the analysis if they are mistaken; but at the same time they are not put forward unless there is some prospect of reaching a nearer approximation to the truth by means of them. The first effect of this supposition was the appearance of some dreams, which it was not possible to interpret completely, but all of which seemed to centre around the same material. As far as they could be understood, they were concerned with aggressive actions on the boy's part against his sister or against the governess and with energetic reproofs and punishments on account of them. It was as though . . . after her bath . . . he had tried . . . to undress his sister . . . to tear off her coverings . . . or veils - and so on. But it was not possible to get at any firm content from the interpretation; and since these dreams gave an impression of always working over the same material in various different ways, the correct reading of these ostensible reminiscences became assured: it could only be a question of phantasies, which the dreamer had made on the subject of his childhood at some time or other, probably at the age of puberty, and which had now come to the surface again in this unrecognizable form.

[1918b, 3512]
We owe the further explanation of the case to a recollection which emerged with great
distinctness. This was to the effect that the signs of an alteration in the patient's character were
not accompanied by any symptoms of anxiety until after the occurrence of a particular event.
Previously, it seems, there was no anxiety, while directly after the event the anxiety expressed
itself in the most tormenting shape. The date of this transformation can be stated with certainty; it
was immediately before his fourth birthday. Taking this as a fixed point, we are able to divide the
period of his childhood with which we are concerned into two phases: a first phase of naughtiness
and perversity from his seduction at the age of three and a quarter up to his fourth birthday, and a
longer subsequent phase in which the signs of neurosis predominated. But the event which
makes this division possible was not an external trauma, but a dream, from which he awoke in a
state of anxiety.
[1918b, 3519]

Leaving on one side everything in this quotation that anticipates the dream's remoter
implications, let us return to its immediate interpretation. I may remark that this interpretation was
a task that dragged on over several years. The patient related the dream at a very early stage of
the analysis and very soon came to share my conviction that the causes of his infantile neurosis
lay concealed behind it. In the course of the treatment we often came back to the dream, but it
was only during the last months of the analysis that it became possible to understand it
completely, and only then thanks to spontaneous work on the patient's part. He had always
emphasized the fact that two factors in the dream had made the greatest impression on him: first,
the perfect stillness and immobility of the wolves, and secondly, the strained attention with which
they all looked at him. The lasting sense of reality, too, which the dream left behind it, seemed to
him to deserve notice.
[1918b, 3524]

One day the patient began to continue with the interpretation of the dream. He thought that the
part of the dream which said that 'suddenly the window opened of its own accord' was not
completely explained by its connection with the window at which the tailor was sitting and through
which the wolf came into the room. 'It must mean: "My eyes suddenly opened." I was asleep,
therefore, and suddenly woke up, and as I woke I saw something: the tree with the wolves.' No
objection could be made to this; but the point could be developed further. He had woken up and
had seen something. The attentive looking, which in the dream was ascribed to the wolves,
should rather be shifted on to him. At a decisive point, therefore, a transposition has taken place;
and moreover this is indicated by another transposition in the manifest content of the dream. For
the fact that the wolves were sitting on the tree was also a transposition, since in his grandfather's
story they were underneath, and were unable to climb on to the tree.
[1918b, 3525]

I am not of opinion, however, that such scenes must necessarily be phantasies because they
do not reappear in the shape of recollections. It seems to me absolutely equivalent to a
recollection, if the memories are replaced (as in the present case) by dreams the analysis of
which invariably leads back to the same scene and which reproduce every portion of its content in
an inexhaustible variety of new shapes. Indeed, dreaming is another kind of remembering, though
one that is subject to the conditions that rule at night and to the laws of dream-formation. It is this
recurrence in dreams that I regard as the explanation of the fact that the patients themselves
gradually acquire a profound conviction of the reality of these primal scenes, a conviction which is
in no respect inferior to one based on recollection.¹
[1918b, 3538]
A passage in the first edition of my Interpretation of Dreams (1900a) will show at what an early stage I was occupied with this problem. On p. 670 of that work there is an analysis of a remark occurring in a dream: "That's not obtainable any longer." It is explained that the phrase originated from myself. "A few days earlier I had explained to the patient that the earliest experiences of childhood were "not obtainable any longer as such" but were replaced in analysis by "transferences" and dreams.' [1918b, 3538]

Eventually, in connection with a dream, the analysis elicited the information that the breathing out at the sight of pitiable-looking people had begun only after his sixth year and was related to his father. He had not seen his father for many months, when one day his mother said she was going to take the children with her to the town and show them something that would very much please them. She then took them to a sanatorium, where they saw their father again; he looked ill, and the boy felt very sorry for him. His father was thus the prototype of all the cripples, beggars, and poor people in whose presence he was obliged to breathe out; just as a father is the prototype of the bogies that people see in anxiety states, and of the caricatures that are drawn to bring derision upon some one. We shall learn elsewhere that this attitude of compassion was derived from a particular detail of the primal scene, a detail which only became operative in the obsessional neurosis at this late moment. [1918b, 3550]

At this point we must consider an objection, the discussion of which may contribute much to the elucidation of the apparent confusion of the circumstances. We have been driven to assume that during the process of the dream he understood that women are castrated, that instead of a male organ they have a wound which serves for sexual intercourse, and that castration is the necessary condition of femininity; we have been driven to assume that the threat of this loss induced him to repress his feminine attitude towards men, and that he awoke from his homosexual enthusiasm in anxiety. Now how can this comprehension of sexual intercourse, this recognition of the vagina, be brought into harmony with the selection of the bowel for the purpose of identification with women? Are not the intestinal symptoms based on what is probably an older notion, and one which in any case completely contradicts the dread of castration - the notion, namely, that sexual intercourse takes place at the anus? [1918b, 3560]

Even his final choice of object, which played such an important part in his life, is shown by its details (though they cannot be adduced here) to have been dependent upon the same condition and to have been an offshoot of the compulsion which, starting from the primal scene and going on to the scene with Grusha, had dominated his love-choice. I have remarked on an earlier page that I recognize in the patient an endeavour to debase his love-object. This is to be explained as a reaction against pressure from the sister who was so much his superior. But I promised at the same time (see p. 3515) to show that this self-assertive motive was not the only determinant, but that it concealed another and deeper one based on purely erotic motives. These were brought to light by the patient's memory of the nursery-maid scrubbing the floor - physically debased too, by the by. All his later love-objects were surrogates for this one person, who through the accident of her attitude had herself become his first mother-surrogate. The patient's first association in connection with the problem of his fear of the butterfly can now easily be explained retrospectively as a distant allusion to the primal scene (the hour of five). He confirmed the connection between the Grusha scene and the threat of castration by a particularly ingenious dream, which he himself succeeded in deciphering. 'I had a dream,' he said, 'of a man tearing off the wings of an Espe.' 'Espe?' I asked; 'what do you mean by that?' "You know; that insect with yellow stripes on its body, that stings." I could now put him right: 'So what you mean is a Wespe [wasp].' 'Is it called a Wespe? I really thought it was called an Espe.' (Like so many other people, he used his difficulties with a foreign language as a screen for symptomatic acts.) 'But Espe, why, that's myself: S. P.' (which were his initials). The Espe was of course a mutilated Wespe. The dream said clearly that he was avenging himself on Grusha for her threat of castration. [1918b, 3575]
The analysis of the anxiety-dream shows us that the repression was connected with his recognition of the existence of castration. The new element was rejected because its acceptance would have cost him his penis. Closer consideration leads us to some such conclusion as the following. What was repressed was the homosexual attitude understood in the genital sense, an attitude which had been formed under the influence of this recognition of castration. But that attitude was retained as regards the unconscious and set up as a dissociated and deeper stratum. The motive force of the repression seems to have been the narcissistic masculinity which attached to the boy's genitals, and which had come into a long-prepared conflict with the passivity of his homosexual sexual aim. The repression was thus a result of his masculinity.

[1918b, 3586]

There was a single piece of material in the course of this analysis which I could regard as a positive transference, as a greatly weakened revival of the girl's original passionate love for her father. Even this manifestation was not quite free from other motives, but I mention it because it brings up, in another direction, an interesting problem of analytic technique. At a certain period, not long after the treatment had begun, the girl brought a series of dreams which, distorted according to rule and couched in the usual dream-language, could nevertheless be easily translated with certainty. Their content, when interpreted, was, however, remarkable. They anticipated the cure of the inversion through the treatment, expressed her joy over the prospects in life that would then be opened before her, confessed her longing for a man's love and for children, and so might have been welcomed as a gratifying preparation for the desired change. The contradiction between them and the girl's utterances in waking life at the time was very great. She did not conceal from me that she meant to marry, but only in order to escape from her father's tyranny and to follow her true inclinations undisturbed. As for the husband, she remarked rather contemptuously, she would easily deal with him, and besides, one could have sexual relations with a man and a woman at one and the same time, as the example of the adored lady showed. Warned through some slight impression or other, I told her one day that I did not believe these dreams, that I regarded them as false or hypocritical, and that she intended to deceive me just as she habitually deceived her father. I was right; after I had made this clear, this kind of dream ceased. But I still believe that, beside the intention to mislead me, the dreams partly expressed the wish to win my favour; they were also an attempt to gain my interest and my good opinion - perhaps in order to disappoint me all the more thoroughly later on.

[1920a, 3853]
I can imagine that to point out the existence of lying dreams of this kind, 'obliging' dreams, will arouse a positive storm of helpless indignation in some readers who call themselves analysts. 'What!' they will exclaim, 'the unconscious, the real centre of our mental life, the part of us that is so much nearer the divine than our poor consciousness - it too can lie! Then how can we still build on the interpretations of analysis and the accuracy of our findings?' To which one must reply that the recognition of these lying dreams does not constitute any shattering novelty. I know, indeed, that the craving of mankind for mysticism is ineradicable, and that it makes ceaseless efforts to win back for mysticism the territory it has been deprived of by The Interpretation of Dreams, but surely in the case under consideration everything is simple enough. A dream is not the 'unconscious'; it is the form into which a thought left over from preconscious, or even from conscious, waking life, can, thanks to the favouring state of sleep, be recast. In the state of sleep this thought has been reinforced by unconscious wishful impulses and has thus experienced distortion through the dream-work, which is determined by the mechanisms prevailing in the unconscious. With our dreamer, the intention to mislead me, just as she did her father, certainly emanated from the preconscious, and may indeed have been conscious; it could come to expression by entering into connection with the unconscious wishful impulse to please her father (or father-substitute), and in this way it created a lying dream. The two intentions, to betray and to please her father, originated in the same complex; the former resulted from the repression of the latter, and the later one was brought back by the dream-work to the earlier one. There can therefore be no question of any devaluation of the unconscious, nor of a shattering of our confidence in the results of analysis.

[1920a, 3854]

The dreams of my jealous patient presented me with a great surprise. They were not simultaneous with the outbreaks of the attacks, it is true, but they occurred within the period which was under the dominance of the delusion; yet they were completely free from delusion and they revealed the underlying homosexual impulses with no more than the usual degree of disguise. Since I had had little experience of the dreams of paranoics, it seemed plausible at the time to suppose that it was true in general that paranoia does not penetrate into dreams.

[1922b, 3904]

My two cases of paranoia showed an instructive contrast in the behaviour of their dreams. Whereas those of the first case were free from delusion, as has already been said, the other patient produced great numbers of persecutory dreams, which may be regarded as forerunners of or substitutes for the delusional ideas. The pursuer, whom he only managed to escape with great fear, was usually a powerful bull or some other male symbol which even in the dream itself he sometimes recognized as representing his father. One day he produced a very characteristic paranoid transference-dream. He saw me shaving in front of him, and from the scent he realized that I was using the same soap as his father had used. I was doing this in order to oblige him to make a father-transference on to me. The choice of this incident for his dream quite unmistakably betrays the patient's depreciatory attitude to his paranoid phantasies and his disbelief in them; for his own eyes could tell him every day that I was never in a position to make use of shaving-soap and that therefore there was in this respect nothing to which a father-transference could attach itself.

[1922b, 3906]
A comparison of the dreams of the two patients shows, however, that the question whether or not paranoia (or any other psychoneurosis) can penetrate into dreams is based on a false conception of dreams. Dreams are distinguished from waking thought by the fact that they can include material (belonging to the region of the repressed) which must not emerge in waking thought. Apart from this, dreams are merely a form of thinking, a transformation of preconscious material of thought by the dream-work and its conditions. Our terminology of the neuroses is not applicable to repressed material; this cannot be called hysterical, nor obsessional, nor paranoic. As against this, the other part of the material which is subjected to the process of dream-formation - the preconscious thoughts - may be normal or may bear the character of any neurosis; they may be the products of any of the pathogenic processes in which the essence of a neurosis lies. There seems to be no reason why any such pathological idea should not be transformed into a dream. A dream may therefore quite simply represent a hysterical phantasy, an obsessional idea, or a delusion - that is, may reveal one or other of these upon interpretation. Observation of the two paranoics shows that the dreams of the one were quite normal while he was subject to his delusion, and that those of the other were paranoic in content while he was treating his delusional ideas with contempt. In both cases, therefore, the dream took up the material that was at the time forced into the background in waking life. This too, however, need not necessarily be an invariable rule.

[1922b, 3906]

The Interpretation of Dreams. - A new approach to the depths of mental life was opened when the technique of free association was applied to dreams, whether one's own or those of patients in analysis. In fact, the greater and better part of what we know of the processes in the unconscious levels of the mind is derived from the interpretation of dreams. Psycho-analysis has restored to dreams the importance which was generally ascribed to them in ancient times, but it treats them differently. It does not rely upon the cleverness of the dream-interpreter but for the most part hands the task over to the dreamer himself by asking him for his associations to the separate elements of the dream. By pursuing these associations further we obtain knowledge of thoughts which coincide entirely with the dream but which can be recognized - up to a certain point - as genuine and completely intelligible portions of waking mental activity. Thus the recollected dream emerges as the manifest dream content, in contrast to the latent dream-thoughts discovered by interpretation. The process which has transformed the latter into the former, that is to say into 'the dream', and which is undone by the work of interpretation, may be called the 'dream-work'.

[1923a, 3917]

The majority of dreams in a difficult analysis are of this kind; so that one cannot learn much from them about the nature and mechanism of dream-formation. Least of all can one learn anything from them upon the recurring question of where the dream's wish-fulfilment may lie hidden. When the pressure of resistance is quite extremely high, one meets with the phenomenon of the dreamer's associations broadening instead of deepening. In place of the desired associations to the dream that has already been narrated, there appear a constant succession of new fragments of dream, which in their turn remain without associations.

[1923c, 4031]

It is only when the resistance is kept within moderate limits that the familiar picture of the work of interpretation comes into view: the dreamer's associations begin by diverging widely from the manifest elements, so that a great number of subjects and ranges of ideas are touched on, after which, a second series of associations quickly converge from these on to the dream-thoughts that are being looked for. When this is so, collaboration between the analyst and the dreamer becomes possible; whereas under a high pressure of resistance it would not even be of any advantage.

[1923c, 4031]
A number of dreams which occur during analyses are untranslatable even though they do not actually make much show of the resistance that is there. They represent free renderings of the latent dream-thoughts behind them and are comparable to successful creative writings which have been artistically worked over and in which the basic themes are still recognizable though they have been subjected to any amount of re-arrangement and transformation. Dreams of this kind serve in the treatment as an introduction to thoughts and memories of the dreamer without their own actual content coming into account.

Let us take as an example the so-called dreams of recovery. If a patient has had a dream of this kind, in which he seems to abandon the restrictions of his neurosis - if, for instance, he overcomes some phobia or gives up some emotional attachment - we are inclined to think that he has made a great step forward, that he is ready to take his place in a new state of life, that he has begun to reckon on his recovery, etc. This may often be true, but quite as often such dreams of recovery only have the value of dreams of convenience: they signify a wish to be well at last, in order to avoid another portion of the work of analysis which is felt to lie ahead. In this sense, dreams of recovery very frequently occur, for instance, when the patient is about to enter upon a new and disagreeable phase of the transference. He is behaving in this just like some neurotics who after a few hours of analysis declare they have been cured - because they want to escape all the unpleasantness that is bound to come up for discussion in the analysis. Sufferers from war neuroses, too, who gave up their symptoms because the therapy adopted by the army doctors succeeded in making being ill even more uncomfortable than serving at the front - these sufferers, too, were following the same economic laws and in both cases alike the cures have proved to be only temporary.

It is by no means easy to arrive at general conclusions upon the value of correctly translated dreams. If a conflict due to ambivalence is taking place in a patient, then the emergence in him of a hostile thought certainly does not imply a permanent overcoming of his affectionate impulse - that is to say, a resolution of the conflict: neither does any such implication follow from a dream with a similarly hostile content. During a conflict such as this arising from ambivalence, there are often two dreams every night, each of them representing an opposite attitude. In that case the progress lies in the fact that a complete isolation of the two contrasted impulses has been achieved and that each of them, with the help of its unconscious reinforcements, can be followed and understood to its extreme limits. And if it sometimes happens that one of the two ambivalent dreams has been forgotten, one must not be deceived into assuming that a decision has been made in favour of the one side. The fact that one of the dreams has been forgotten shows, it is true, that for the moment one tendency is in the ascendant, but that is true only of the one day, and may be changed. The next night may perhaps bring the opposite expression into the foreground. The true state of the conflict can only be determined by taking into account all the other indications, including those of waking life.

The question of the value to be assigned to dreams is intimately related to the other question of their susceptibility to influence from 'suggestion' by the physician. Analysts may at first be alarmed at the mention of this possibility. But on further reflection this alarm will give place to the realization that the influencing of the patient's dreams is no more a blunder on the part of the analyst or disgrace to him than the guiding of the patient's conscious thoughts.
The fact that the manifest content of dreams is influenced by the analytic treatment stands in no need of proof. It follows from our knowledge that dreams take their start from waking life and work over material derived from it. Occurrences during analytic treatment are of course among the impressions of waking life and soon become some of the most powerful of these. So it is not to be wondered at that patients should dream of things which the analyst has discussed with them and of which he has aroused expectations in them. At least it is no more to be wondered at than what is implied in the familiar fact of 'experimental' dreams.

[1923c, 4035]

But from here our interest proceeds to the question whether the latent dream-thoughts that have to be arrived at by interpretation can also be influenced or suggested by the analyst. And to this the answer must once more be that they obviously can be. For a portion of these latent dream-thoughts correspond to preconscious thought-formations, perfectly capable of being conscious, with which the dreamer might quite well have reacted to the physician's remarks in his waking state too - whether the patient's reactions were in harmony with those remarks or in opposition to them. In fact, if we replace the dream by the dream-thoughts which it contains, the question of how far one can suggest dreams coincides with the more general question of how far a patient in analysis is accessible to suggestion.

[1923c, 4035]

If a dream brings up situations that can be interpreted as referring to scenes from the dreamer's past, it seems especially important to ask whether the physician's influence can also play a part in such contents of the dream as these. And this question is most urgent of all in the case of what are called 'corroborative' dreams, dreams which, as it were, 'tag along behind' the analysis. With some patients these are the only dreams that one obtains. Such patients reproduce the forgotten experiences of their childhood only after one has constructed them from their symptoms, associations and other signs and has propounded these constructions to them. Then follow the corroborative dreams, concerning which, however, the doubt arises whether they may not be entirely without evidential value, since they may have been imagined in compliance with the physician's words instead of having been brought to light from the dreamer's unconscious. This ambiguous position cannot be escaped in the analysis, since with these patients unless one interprets, constructs and propounds, one never obtains access to what is repressed in them.

[1923c, 4036]

The situation takes a favourable turn if the analysis of a corroborative dream of this sort, which 'tags along behind', is immediately followed by feelings of remembering what has hitherto been forgotten. But even then the sceptic can fall back upon an assertion that the recollections are illusory. Moreover, such feelings are for the most part absent. The repressed material is only allowed through bit by bit; and every lack of completeness inhibits or delays the forming of a sense of conviction. Furthermore, what we are dealing with may not be the reproduction of a real and forgotten event but the bringing forward of an unconscious phantasy, about which no feeling of memory is ever to be expected, though the possibility may sometimes remain of a sense of subjective conviction.

[1923c, 4036]
An analogy of this kind can of course have no meaning for a patient while the work of analysis is still uncompleted. At this point I recall a discussion which I was led into with a patient whose exceptionally ambivalent attitude was expressed in the most intense compulsive doubt. He did not dispute my interpretations of his dreams and was very much struck by their agreement with the hypotheses which I put forward. But he asked whether these corroborative dreams might not be an expression of his compliance towards me. I pointed out that the dreams had also brought up a quantity of details of which I could have had no suspicion and that his behaviour in the treatment apart from this had not been precisely characterized by compliance. Whereupon he switched over to another theory and asked whether his narcissistic wish to be cured might not have caused him to produce these dreams, since, after all, I had held out to him a prospect of recovery if he were able to accept my constructions. I could only reply that I had not yet come across any such mechanism of dream-formation. But a decision was reached by another road. He recollected some dreams which he had had before starting analysis and indeed before he had known anything about it; and the analysis of these dreams, which were free from all suspicion of suggestion, led to the same interpretations as the later ones. It is true that his obsession for contradiction once more found a way out in the idea that the earlier dreams had been less clear than those that occurred during the treatment; but I was satisfied with their similarity. I think that in general it is a good plan occasionally to bear in mind the fact that people were in the habit of dreaming before there was such a thing as psycho-analysis.

[1923c, 4037]

It may well be that dreams during psycho-analysis succeed in bringing to light what is repressed to a greater extent than dreams outside that situation. But it cannot be proved, since the two situations are not comparable; the employment of dreams in analysis is something very remote from their original purpose. On the other hand, it cannot be doubted that within an analysis far more of the repressed is brought to light in connection with dreams than by any other method. In order to account for this, there must be some motive power, some unconscious force, which is better able to lend support to the purposes of analysis during the state of sleep than at other times. What is here in question cannot well be any factor other than the patient's compliance towards the analyst which is derived from his parental complex - in other words, the positive portion of what we call the transference; and in fact, in many dreams which recall what has been forgotten and repressed, it is impossible to discover any other unconscious wish to which the motive force for the formation of the dream can be attributed. So that if anyone wishes to maintain that most of the dreams that can be made use of in analysis are obliging dreams and owe their origin to suggestion, nothing can be said against that opinion from the point of view of analytic theory. In that case I need only add a reference to what I have said in my Introductory Lectures, where I have dealt with the relation between transference and suggestion and shown how little the trustworthiness of our results is affected by a recognition of the operation of suggestion in our sense.

[1923c, 4038]

It follows from this that it is on the whole a matter of indifference to the sleeping ego what may be dreamt during the night so long as the dream performs its task, and that those dreams best fulfil their function about which one knows nothing after waking. If it so often happens otherwise, if we remember dreams - even after years and decades - it always means that there has been an irruption of the repressed unconscious into the normal ego. Without this concession to it the repressed would not have consented to lend its help to the removal of the threat of disturbance to sleep. We know that it is the fact of this irruption that gives dreams their importance for psychopathology. If we can uncover a dream's motivating force, we shall obtain unsuspected information about the repressed impulses in the unconscious; and on the other hand, if we can undo its distortions, we shall overhear preconscious thought taking place in states of internal reflection which would not have attracted consciousness to themselves during the day-time.

[1925i, 4045]
No one can practise the interpretation of dreams as an isolated activity: it remains a part of the
work of analysis. In analysis we direct our interest according to necessity, now to the
preconscious content of the dream and now to the unconscious contribution to its formation; and
we often neglect the one element in favour of the other. Nor would it be of any avail for anyone to
endeavour to interpret dreams outside analysis. He would not succeed in escaping the conditions
of the analytic situation; and if he worked at his own dreams, he would be undertaking a self-
analysis. This comment would not apply to someone who did without the dreamer's collaboration
and sought to interpret dreams by intuitive insight. But dream-interpretation of such a kind,
without reference to the dreamer's associations, would in the most favourable case remain a
piece of unscientific virtuosity of very doubtful value.
[1925i, 4045]

If one practises dream-interpretation according to the sole justifiable technical procedure, one
soon notices that success depends entirely upon the tension of resistance between the
awakened ego and the repressed unconscious. Work under a 'high pressure of resistance'
demands (as I have explained elsewhere) a different attitude on the part of the analyst from work
under a low pressure. In analysis one has for long periods at a time to deal with strong
resistances which are still unknown to one and which it will in any case be impossible to
overcome so long as they remain unknown. It is therefore not to he wondered at that only a
certain portion of a patient's dream-products can be translated and made use of, and, even at
that, most often incompletely. Even if, owing to one's own experience, one is in a position to
understand many dreams to the interpretation of which the dreamer has contributed little, one
must always remember that the certainty of such interpretations remains in doubt and one
hesitates to press one's conjectures upon the patient.
[1925i, 4045]

Critical voices will now be raised. It will be objected that, since it is not possible to interpret
every dream that is dealt with, one should cease asserting more than one can establish and
should be content to say that some dreams can be shown by interpretation to have a meaning but
that as to the rest we are in ignorance. But the very fact that success in interpretation depends
upon the resistance absolves the analyst from the necessity for such modesty. He may have the
experience of a dream that was at first unintelligible becoming clear during the very same hour
after some fortunate remark has got rid of one of the dreamer's resistances. A portion of the
dream which the patient had hitherto forgotten may suddenly occur to him and may bring the key
to the interpretation; or a new association may emerge which may throw light upon the darkness.
It sometimes happens, too, that, after months or years of analytic labour, one returns to a dream
which at the beginning of the treatment seemed meaningless and incomprehensible but which is
now, in the light of knowledge obtained in the meantime, completely elucidated. And if one further
takes into consideration the argument from the theory of dreams that the model dream-products
of children invariably have a clear meaning and are easy to interpret, then it will be justifiable to
assert that dreams are quite generally mental structures that are capable of interpretation, though
the situation may not always allow of an interpretation being reached.
[1925i, 4046]

The excellent dream which Dr. Odier has put at the author's disposal may give even the
uninitiated an idea of the wealth of dream-associations and of the relation between the manifest
dream-image and the latent thoughts concealed behind it. It demonstrates too the significance
that the analysis of a dream can have in the treatment of a patient.
[1922e, 4174]
We have explained that the unconscious instinctual impulse of the dream connects itself with a residue of the day, with some interest of waking life which has not been disposed of; it thus gives the dream which it constructs a double value for the work of analysis. For on the one hand a dream that has been analysed reveals itself as the fulfilment of a repressed wish; but on the other hand it may be a continuation of some preconscious activity of the day before and may contain every kind of subject-matter and give expression to an intention, a warning, a reflection, or once more to the fulfilment of a wish. Analysis exploits the dream in both directions, as a means of obtaining knowledge alike of the patient's conscious and of his unconscious processes. It also profits from the fact that dreams have access to the forgotten material of childhood, and so it happens that infantile amnesia is for the most part overcome in connection with the interpretation of dreams. In this respect dreams achieve a part of what was previously the task of hypnotism. On the other hand, I have never maintained the assertion which has so often been ascribed to me that dream-interpretation shows that all dreams have a sexual content or are derived from sexual motive forces. It is easy to see that hunger, thirst, or the need to excrete, can produce dreams of satisfaction just as well as any repressed sexual or egoistic impulse. The case of young children affords us a convenient test of the validity of our theory of dreams. In them the various psychical systems are not yet sharply divided and the repressions have not yet grown deep, so that we often come upon dreams which are nothing more than undisguised fulfilments of wishful impulses left over from waking life. Under the influence of imperative needs, adults may also produce dreams of this infantile type.¹

In the same way that psycho-analysis makes use of dream-interpretation, it also profits by the study of the numerous little slips and mistakes which people make - symptomatic actions, as they are called. I investigated this subject in a series of papers which were published for the first time in book form in 1904 under the title of *The Psychopathology of Everyday Life*. In this widely circulated work I have pointed out that these phenomena are not accidental, that they require more than physiological explanations, that they have a meaning and can be interpreted, and that one is justified in inferring from them the presence of restrained or repressed impulses and intentions. But what constitutes the enormous importance of dream-interpretation, as well as of this latter study, is not the assistance they give to the work of analysis but another of their attributes. Previously psycho-analysis had only been concerned with solving pathological phenomena and in order to explain them it had often been driven into making assumptions whose comprehensiveness was out of all proportion to the importance of the actual material under consideration. But when it came to dreams, it was no longer dealing with a pathological symptom, but with a phenomenon of normal mental life which might occur in any healthy person. If dreams turned out to be constructed like symptoms, if their explanation required the same assumptions - the repression of impulses, substitutive formation, compromise-formation, the dividing of the conscious and the unconscious into various psychical systems - then psycho-analysis was no longer an auxiliary science in the field of psychopathology, it was rather the starting-point of a new and deeper science of the mind which would be equally indispensable for the understanding of the normal. Its postulates and findings could be carried over to other regions of mental happening; a path lay open to it that led far afield, into spheres of universal interest.  

¹You are becoming aggressive; so you have evidently got on to a sensitive spot. I have heard, it is true, that in analysis great value is attached to dreams, that they are interpreted, and that memories of real events are looked for behind them, and so on. But I have heard as well that the interpretation of dreams is left to the caprice of analysts, and that they themselves have never ceased disputing over the way of interpreting dreams and the justification for drawing conclusions from them. If that is so, you ought not to underline so heavily the advantage that analysis has won over academic psychology.’

¹You are becoming aggressive; so you have evidently got on to a sensitive spot. I have heard, it is true, that in analysis great value is attached to dreams, that they are interpreted, and that memories of real events are looked for behind them, and so on. But I have heard as well that the interpretation of dreams is left to the caprice of analysts, and that they themselves have never ceased disputing over the way of interpreting dreams and the justification for drawing conclusions from them. If that is so, you ought not to underline so heavily the advantage that analysis has won over academic psychology.’
There is really a great deal of truth in what you say. It is true that the interpretation of dreams has come to have unequalled importance both for the theory and the practice of analysis. If I seem to be aggressive, that is only a way of defending myself. And when I think of all the mischief some analysts have done with the interpretation of dreams I might lose heart and echo the pessimistic pronouncement of our great satirist Nestroy when he says that every step forward is only half as big as it looks at first. But have you ever found that men do anything but confuse and distort what they get hold of? By the help of a little foresight and self-discipline most of the dangers of dream-interpretation can be avoided with certainty. But you will agree that I shall never come to my exposition if we let ourselves be led aside like this.

[1926e, 4336]

It is easy now to describe our therapeutic aim. We try to restore the ego, to free it from its restrictions, and to give it back the command over the id which it has lost owing to its early repressions. It is for this one purpose that we carry out analysis, our whole technique is directed to this aim. We have to seek out the repressions which have been set up and to urge the ego to correct them with our help and to deal with conflicts better than by an attempt at flight. Since these repressions belong to the very early years of childhood, the work of analysis leads us, too, back to that period. Our path to these situations of conflict, which have for the most part been forgotten and which we try to revive in the patient's memory, is pointed out to us by his symptoms, dreams and free associations. These must, however, first be interpreted - translated - for, under the influence of the psychology of the id, they have assumed forms of expression that are strange to our comprehension. We may assume that whatever associations, thoughts and memories the patient is unable to communicate to us without internal struggles are in some way connected with the repressed material or are its derivatives. By encouraging the patient to disregard his resistances to telling us these things, we are educating his ego to overcome its inclination towards attempts at flight and to tolerate an approach to what is repressed. In the end, if the situation of the repression can be successfully reproduced in his memory, his compliance will be brilliantly rewarded. The whole difference between his age then and now works in his favour; and the thing from which his childish ego fled in terror will often seem to his adult and strengthened ego no more than child's play.

[1926e, 4348]

By assuming that the patient's remarks and associations are only distortions of what you are looking for - allusions, as it were, from which you have to guess what is hidden behind them. In a word, this material, whether it consists of memories, associations or dreams, has first to be interpreted. You will do this, of course, with an eye to the expectations you have formed as you listened, thanks to your special knowledge.

[1926e, 4361]
Let us suppose, then, that someone - a patient in analysis, for instance - tells us one of his dreams. We shall assume that in this way he is making us one of the communications to which he has pledged himself by the fact of having started an analytic treatment. It is, to be sure, a communication made by inappropriate means, for dreams are not in themselves social utterances, not a means of giving information. Nor, indeed, do we understand what the dreamer was trying to say to us, and he himself is equally in the dark. And now we have to make a quick decision. On the one hand, the dream may be, as non-analytic doctors assure us, a sign that the dreamer has slept badly, that not every part of his brain has come to rest equally, that some areas of it, under the influence of unknown stimuli, endeavoured to go on working but were only able to do so in a very incomplete fashion. If that is the case, we shall be right to concern ourselves no further with the product of a nocturnal disturbance which has no psychical value: for what could we expect to derive from investigating it that would be of use for our purposes? Or on the other hand - but it is plain that we have from the first decided otherwise. We have - quite arbitrarily, it must be admitted - made the assumption, adopted as a postulate, that even this unintelligible dream must be a fully valid psychical act, with sense and worth, which we can use in analysis like any other communication. Only the outcome of our experiment can show whether we are right. If we succeed in turning the dream into an utterance of value of that kind, we shall evidently have a prospect of learning something new and of receiving communications of a sort which would otherwise be inaccessible to us.

Well then, the patient has told us a dream, which we are to interpret. We have listened passively, without putting our powers of reflection into action. What do we do next? We decide to concern ourselves as little as possible with what we have heard, with the manifest dream. Of course this manifest dream exhibits all sorts of characteristics which are not entirely a matter of indifference to us. It may be coherent, smoothly constructed like a literary composition, or it may be confused to the point of unintelligibility, almost like a delirium; it may contain absurd elements or jokes and apparently witty conclusions; it may seem to the dreamer clear and sharp or obscure and hazy; its pictures may exhibit the complete sensory strength of perceptions or may be shadowy like an indistinct mist; the most diverse characteristics may be present in the same dream, distributed over various portions of it; the dream, finally, may show an indifferent emotional tone or be accompanied by feelings of the strongest joy or distress. You must not suppose that we think nothing of this endless diversity in manifest dreams. We shall come back to it later and we shall find a great deal in it that we can make use of in our interpretations. But for the moment we will disregard it and follow the main road that leads to the interpretation of dreams. That is to say, we ask the dreamer, too, to free himself from the impression of the manifest dream, to divert his attention from the dream as a whole on to the separate portions of its content and to report to us in succession everything that occurs to him in relation to each of these portions - what associations present themselves to him if he focuses on each of them separately.

This was what I wanted to say to you, Ladies and Gentlemen, about dream-interpretation, whose task it is to lead the way from the manifest dream to the latent dream-thoughts. When this has been achieved, interest in a dream, so far as practical analysis is concerned, is for the most part at an end. We add the communication we have received in the form of a dream to the rest of the patient's communications and proceed with the analysis. We, however, have an interest in dwelling a little longer on the dream. We are tempted to study the process by which the latent dream-thoughts were transformed into the manifest dream. We call this the 'dream-work'. As you will recall, I described it in such detail in my earlier lectures that I can restrict my present survey to the most concise summary.
For I think my hypothesis - that, in order to gain control over fire, men had to renounce the homosexually-tinged desire to put it out with a stream of urine - can be confirmed by an interpretation of the Greek myth of Prometheus, provided that we bear in mind the distortions which must be expected to occur in the transition from facts to the contents of a myth. These distortions are of the same sort as, and no worse than, those which we acknowledge every day, when we reconstruct from patients' dreams the repressed but extremely important experiences of their childhood. The mechanisms employed in the distortions I have in mind are symbolic representation and turning into the opposite. I should not venture to explain all the features of our myth in this fashion; apart from the original set of facts, other and later occurrences may have contributed to its content. But the elements which admit of analytic interpretation are, after all, the most striking and important - viz. the manner in which Prometheus transported the fire, the character of his act (an outrage, a theft, a defrauding of the gods) and the meaning of his punishment.

When they fell in with my instructions they told me their dreams, amongst other things, as though they were of the same kind as their other thoughts. This was a plain hint that I should assign as much importance to these dreams as to other, intelligible, phenomena. They, however, were not intelligible, but strange, confused, absurd: like dreams, in fact - which for that very reason, were condemned by science as random and senseless twitchings of the organ of the mind. If my patients were right - and they seemed only to be repeating the ancient beliefs held by unscientific men for thousands of years - I was faced by the task of 'interpreting dreams' in a way that could stand up against scientific criticism.

To begin with, I naturally understood no more about my patients' dreams than the dreamers did themselves. But by applying to these dreams, and more particularly to my own dreams, the procedure which I had already used for the study of other abnormal psychological structures, I succeeded in answering most of the questions which could be raised by an interpretation of dreams. There were many such questions: What do we dream about? Why do we dream at all? What is the origin of all the strange characteristics which distinguish dreams from waking life? - and many more such questions besides. Some of the answers were easily given and turned out to confirm views that had already been put forward; but others involved completely new hypotheses with regard to the structure and functioning of the apparatus of the mind. People dream about the things that have engaged their minds during the waking day. People dream in order to allay impulses that seek to disturb sleep, and in order to be able to sleep on. But why was it possible for dreams to present such a strange appearance, so confusedly senseless, so obviously contrasted with the content of waking thought, in spite of being concerned with the same material? There could be no doubt that dreams were only a substitute for a rational process of thought and could be interpreted - that is to say, translated into a rational process. But what needed explaining was the fact of the distortion which the dream-work had carried out upon the rational and intelligible material.
The evidence of the share taken by the unconscious id in the formation of dreams is abundant and convincing. (a) Memory is far more comprehensive in dreams than in waking life. Dreams bring up recollections which the dreamer has forgotten, which are inaccessible to him when he is awake. (b) Dreams make an unrestricted use of linguistic symbols, the meaning of which is for the most part unknown to the dreamer. Our experience, however, enables us to confirm their sense. They probably originate from earlier phases in the development of speech. (c) Memory very often reproduces in dreams impressions from the dreamer's early childhood of which we can definitely assert not only that they had been forgotten but that they had become unconscious owing to repression. That explains the help - usually indispensable - given us by dreams in the attempts we make during the analytic treatment of neuroses to reconstruct the dreamer's early life. (d) Furthermore, dreams bring to light material which cannot have originated either from the dreamer's adult life or from his forgotten childhood. We are obliged to regard it as part of the archaic heritage which a child brings with him into the world, before any experience of his own, influenced by the experiences of his ancestors. We find the counterpart of this phylogenetic material in the earliest human legends and in surviving customs. Thus dreams constitute a source of human prehistory which is not to be despised.

[1940a [1938], 4976]

The method by which we strengthen the weakened ego has as a starting-point an extending of its self-knowledge. That is not, of course, the whole story but it is a first step. The loss of such knowledge signifies for the ego a surrender of power and influence; it is the first tangible sign that it is being hemmed in and hampered by the demands of the id and the super-ego. Accordingly, the first part of the help we have to offer is intellectual work on our side and encouragement to the patient to collaborate in it. This first kind of activity, as we know, is intended to pave the way to another, more difficult, task. We shall not lose sight of the dynamic element in this task, even during its preliminary stage. We gather the material for our work from a variety of sources - from what is conveyed to us by the information given us by the patient and by his free associations, from what he shows us in his transferences, from what we arrive at by interpreting his dreams and from what he betrays by his slips or parapraxes. All this material helps us to make constructions about what happened to him and has been forgotten as well as about what is happening in him now without his understanding it. But in all this we never fail to make a strict distinction between our knowledge and his knowledge. We avoid telling him at once things that we have often discovered at an early stage, and we avoid telling him the whole of what we think we have discovered. We reflect carefully over when we shall impart the knowledge of one of our constructions to him and we wait for what seems to us the suitable moment - which it is not always easy to decide. As a rule we put off telling him of a construction or explanation till he himself has so nearly arrived at it that only a single step remains to be taken, though that step is in fact the decisive synthesis. If we proceeded in another way and overwhelmed him with our interpretations before he was prepared for them, our information would either produce no effect or it would provoke a violent outbreak of resistance which would make the progress of our work more difficult or might even threaten to stop it altogether. But if we have prepared everything properly, it often happens that the patient will at once confirm our construction and himself recollect the internal or external event which he had forgotten. The more exactly the construction coincides with the details of what has been forgotten the easier will it be for him to assent. On that particular matter our knowledge will then have become his knowledge as well.

[1940a [1938], 4987]
We have repeatedly had to insist on the fact that the ego owes its origin as well as the most important of its acquired characteristics to its relation to the real external world. We are thus prepared to assume that the ego's pathological states, in which it most approximates once again to the id, are founded on a cessation or slackening of that relation to the external world. This tallies very well with what we learn from clinical experience - namely, that the precipitating cause of the outbreak of a psychosis is either that reality has become intolerably painful or that the instincts have become extraordinarily intensified - both of which, in view of the rival claims made on the ego by the id and the external world, must lead to the same result. The problem of psychoses would be simple and perspicuous if the ego's detachment from reality could be carried through completely. But that seems to happen only rarely or perhaps never. Even in a state so far removed from the reality of the external world as one of hallucinatory confusion, one learns from patients after their recovery that at the time in some corner of their mind (as they put it) there was a normal person hidden, who, like a detached spectator, watched the hubbub of illness go past him. I do not know if we may assume that this is so in general, but I can report the same of other psychoses with a less tempestuous course. I call to mind a case of chronic paranoia in which after each attack of jealousy a dream conveyed to the analyst a correct picture of the precipitating cause, free from any delusion. An interesting contrast was thus brought to light: while we are accustomed to discover from the dreams of neurotics jealousies which are alien to their waking lives, in this psychotic case the delusion which dominated the patient in the day-time was corrected by his dream. We may probably take it as being generally true that what occurs in all these cases is a psychical \textit{split}. Two psychical attitudes have been formed instead of a single one - one, the normal one, which takes account of reality, and another which under the influence of the instincts detaches the ego from reality. The two exist alongside of each other. The issue depends on their relative strength. If the second is or becomes the stronger, the necessary precondition for a psychosis is present. If the relation is reversed, then there is an apparent cure of the delusional disorder. Actually it has only retreated into the unconscious - just as numerous observations lead us to believe that the delusion existed ready-made for a long time before its manifest irruption.

[1940a [1938], 5007]

It is familiar ground that the work of analysis aims at inducing the patient to give up the repressions (using the word in the widest sense) belonging to his early development and to replace them by reactions of a sort that would correspond to a psychically mature condition. With this purpose in view he must be brought to recollect certain experiences and the affective impulses called up by them which he has for the time being forgotten. We know that his present symptoms and inhibitions are the consequences of repressions of this kind: thus that they are a substitute for these things that he has forgotten. What sort of material does he put at our disposal which we can make use of to put him on the way to recovering the lost memories? All kinds of things. He gives us fragments of these memories in his dreams, invaluable in themselves but seriously distorted as a rule by all the factors concerned in the formation of dreams. Again, he produces ideas, if he gives himself up to 'free association', in which we can discover allusions to the repressed experiences and derivatives of the suppressed affective impulses as well as of the reactions against them. And, finally, there are hints of repetitions of the affects belonging to the repressed material to be found in actions performed by the patient, some fairly important, some trivial, both inside and outside the analytic situation. Our experience has shown that the relation of transference, which becomes established towards the analyst, is particularly calculated to favour the return of these emotional connections. It is out of such raw material - if we may so describe it - that we have to put together what we are in search of.

[1937d, 5050]
I shall conclude this brief paper with a few remarks which open up a wider perspective. I have been struck by the manner in which, in certain analyses, the communication of an obviously apt construction has evoked in the patients a surprising and at first incomprehensible phenomenon. They have had lively recollections called up in them - which they themselves have described as 'ultra-clear' - but what they have recollected has not been the event that was the subject of the construction but details relating to that subject. For instance, they have recollected with abnormal sharpness the faces of the people involved in the construction or the rooms in which something of the sort might have happened, or, a step further away, the furniture in such rooms - on the subject of which the construction had naturally no possibility of any knowledge. This has occurred both in dreams immediately after the construction had been put forward and in waking states resembling phantasies. These recollections have themselves led to nothing further and it has seemed plausible to regard them as the product of a compromise. The 'upward drive' of the repressed, stirred into activity by the putting forward of the construction, has striven to carry the important memory-traces into consciousness; but a resistance has succeeded, not, it is true, in stopping that movement, but in displacing it on to adjacent objects of minor significance. [1937d, 5057]
Once again this was a repetition of a real event of the previous day. Her husband had asked this question and she had made some such reply. But what was the explanation of her dreaming it? She told me that the piano was a disgusting old box, that it made an ugly noise, that it had been in her husband's possession before their marriage,¹ and so on. But the key to the solution was only given by her words: 'It's not worth while.' These were derived from a visit she had paid the day before to a woman friend. She had been invited to take off her jacket, but had refused with the words: 'Thank you, but its not worth while; I can only stop a minute.' As she was telling me this, I recollected that during the previous day's analysis she had suddenly caught hold of her jacket, one of the buttons having come undone. Thus it was as though she were saying: 'Please don't look; its not worth while.' In the same way the 'box' ['Kasten'] was a substitute for a 'chest' ['Bruskasten']; and the interpretation of the dream led us back at once to the time of her physical development at puberty, when she had begun to be dissatisfied by her figure. We can hardly doubt that it led back to still earlier times, if we take the word 'disgusting' into account and the 'ugly noise', and if we remember how often - both in double entendres and in dreams - the lesser hemispheres of a woman's body are used, whether as contrasts or as substitutes, for the larger ones.

¹ [1900a, 672]

(5) A slip of the tongue had a similar mechanism in the case of another woman patient, whose memory failed her in the middle of reproducing a long-lost recollection of childhood. Her memory would not tell her what part of her body had been grasped by a prying and lascivious hand. Immediately afterwards she called on a friend with whom she discussed summer residences. When she was asked where her cottage at M. was situated she answered: 'on the Berglende [hill-thigh]' instead of Berglehne [hill-side].

[1901b, 1154]

(6) When I asked another woman patient at the end of the session how her uncle was, she answered: 'I don't know, nowadays I only see him in flagranti.' Next day she began: 'I am really ashamed of myself for having given you such a stupid answer. You must of course have thought me a very uneducated person who is always getting foreign words mixed up. I meant to say: *en passant.*' We did not as yet know the source of the foreign phrase which she had wrongly applied. In the same session, however, while continuing the previous day's topic, she brought up a reminiscence in which the chief role was played by being caught in flagranti. The slip of the tongue of the day before had therefore anticipated the memory which at the time had not yet become conscious.

[1901b, 1154]

(7) At a certain point in the analysis of another woman patient I had to tell her that I suspected her of having been ashamed of her family during the period we were just then concerned with, and of having reproached her father with something we did not yet know about. She remembered nothing of the kind and moreover declared it was unlikely. However, she continued the conversation with some remarks about her family: 'One thing must be granted them: they are certainly unusual people, they all possess Geiz - I meant to say "Geist".' And this was in fact the reproach which she had repressed from her memory. It is a frequent occurrence for the idea one wants to withhold to be precisely the one which forces its way through in the form of a slip of the tongue. We may compare Meringer's case of 'zum Vorschwein gekommen'. The only difference is that Meringer's speaker wanted to keep back something that was in his consciousness, whereas my patient did not know what was being kept back, or, to put it in another way, did not know she was keeping something back and what that something was.

[1901b, 1155]
In the psychotherapeutic procedure which I employ for resolving and removing neurotic symptoms I am very often faced with the task of discovering, from the patient's apparently casual utterances and associations, a thought-content which is at pains to remain concealed but which nevertheless avoid unintentionally betraying its existence in a whole variety of ways. Slips of the tongue often perform a most valuable service here, as I could show by some highly convincing and at the same time very singular examples. Thus, for instance, a patient will be speaking of his aunt and, without noticing the slip, will consistently call her 'my mother'; or another will refer to her husband as her 'brother'. In this way they draw my attention to the fact that they have 'identified' these persons with one another - that they have put them into a series which implies a recurrence of the same type in their emotional life. To give another example: a young man of twenty introduced himself to me during my consulting hours in these words: 'I am the father of So-and-so who came to you for treatment. I beg your pardon, I meant to say I am his brother: he is four years older than I am.' I inferred that he intended this slip to express the view that, like his brother, he had fallen ill through the fault of his father; that, like his brother, he wished to be cured; but that his father was the one who most needed to be cured. - At other times an arrangement of words that sounds unusual, or an expression that seems forced, is enough to reveal that a repressed thought is participating in the patient's remarks, which had a different end in view.

[1901b, 1171]

Making slips of the tongue was a symptom of a woman patient of mine which persisted until it was traced back to the childhood joke of replacing 'ruinieren' [ruin] by 'urinieren' [urinate]. - [Added 1924:] The temptation to employ the artifice of a slip of the tongue for enabling improper and forbidden words to be freely used forms the basis of Abraham's observations on paraphrasies 'with an overcompensating purpose' (Abraham, 1922a). A woman patient was very liable to duplicate the first syllable of proper names by stammering. She changed the name 'Protagoras' to 'Protragoras', shortly after having said 'A-alexander' instead of 'Alexander'. Inquiry revealed that in childhood she had been especially fond of the vulgar joke of repeating the syllables 'a' and 'po' when they occurred at the beginnings of words, a form of amusement which quite commonly leads to stammering in children. ['A-a' and 'Popo' are the German nursery words for 'faeces' and 'buttocks'.] On approaching the name 'Protagoras' she became aware of the risk that she might omit the 'r' in the first syllable and say 'Po-potagoras'. As a protection against this danger she held on firmly to this 'r', and inserted another 'r' in the second syllable. She acted in the same way on other occasions, distorting the words 'Parterre' [ground floor] and 'Kondolenz' [condolence] so as to avoid 'Pater' (father) and 'Kondom' [condom] which were closely linked to them in her associations. Another of Abraham's patients confessed to an inclination to say 'Angora' every time for 'angina' - very probably because of a fear of being tempted to replace 'angina' by 'vagina'. These slips of the tongue owed their existence therefore to the fact that a defensive trend had retained the upper hand instead of the distorting one; and Abraham justly draws attention to the analogy between this process and the formation of symptoms in obsessional neurosis.

[1901b, 1173]

A slip of the tongue has a more cheering effect during psycho-analytic work, when it serves as a means of providing the doctor with a confirmation that may be very welcome to him if he is engaged in a dispute with the patient. I once had to interpret a patient's dream in which the name 'Jauner' occurred. The dreamer knew someone of that name, but it was impossible to discover the reason for his appearing in the context of the dream; I therefore ventured to suggest that it might be merely because of his name, which sounds like the term of abuse 'Gauner'. My patient hastily and vigorously contested this; but in doing so he made a slip of the tongue which confirmed my guess, since he confused the same letters once more. His answer was: 'That seems to me too jëwagt.'¹ When I had drawn his attention to his slip, he accepted my interpretation.

[1901b, 1183]
If a furious raging against one's own integrity and one's own life can be hidden in this way behind apparently accidental clumsiness and motor inefficiency, it is not a very large step to find it possible to transfer the same view to mistakes that seriously endanger the lives and health of other people. What evidence I have to show that this view is a valid one is drawn from my experience with neurotics, and thus does not wholly meet the demands of the situation. I will give an account of a case in which something that was not strictly a faulty action but that rather deserves the name of a symptomatic or chance action gave me the clue which subsequently made it possible to resolve the patient's conflict. I once undertook the task of bringing an improvement to the marriage of a very intelligent man, whose disagreements with his fondly attached young wife could undoubtedly be shown to have a real basis, but could not, as he himself admitted, be completely accounted for in that way. He was continually occupied with the thought of a divorce, which he then dismissed once more because of his warm love for his two small children. In spite of this he constantly returned to his intention and made no attempt to find a way of making the situation tolerable to himself. Such inability to deal with a conflict is taken by me as proof that unconscious and repressed motives have lent a hand in strengthening the conscious ones which are struggling against each other, and I undertake in such cases to end the conflict by psychical analysis. One day the man told me of a small incident which had frightened him extremely. He was romping with his elder child, who was by far his favourite; he was swinging him high in the air and down again, and once he swung him so high while he was standing at a particular spot that the top of the child's head almost struck the heavy gas chandelier that was hanging there. Almost, but not quite - or perhaps just! No harm came to the child, but it was made giddy with fright. The father stood horrified with the child in his arms, and the mother had a hysterical attack. The peculiar adroitness of this imprudent movement and the violence of the parents' reaction prompted me to look for a symptomatic act in this accident - one which aimed at expressing an evil intention directed against the beloved child. I was able to remove the contradiction between this and the father's contemporary affection for his child by shifting the impulse to injure it back to the time when this child had been the only one and had been so small that its father had not yet had any reason to take an affectionate interest in it. It was then easy for me to suppose that, as he was getting little satisfaction from his wife, he may at that time have had a thought or formed a decision of this kind: 'If this little creature that means nothing at all to me dies, I shall be free and able to get a divorce.' A wish for the death of the creature that he now loved so dearly must therefore have persisted unconsciously. From this point it was easy to find the path by which this wish had become unconsciously fixated. A powerful determinant was in fact provided by a memory from the patient's childhood: namely that the death of a small brother, for which his mother blamed his father's negligence, had led to violent quarrels between the parents and threats of a divorce. The subsequent course of my patient's marriage, as well as my therapeutic success, confirmed my conjecture.

[1901b, 1266]
These extremely frequent chance and symptomatic acts might be arranged in three groups, according to whether they occur habitually, regularly under certain conditions, or sporadically. Actions of the first group (such as playing with one's watch-chain, fingering one's beard and so on), which can almost be taken as characteristics of the person concerned, trench upon the multifarious movements known as tics and no doubt deserve to be dealt with in connection with them. In the second group I include playing with a stick or scribbling with a pencil that one happens to be holding, jingling coins in one's pocket, kneading bread-crumbs and other plastic materials, fiddling with one's clothing in all kinds of ways and so forth. During psychical treatment idle play of this sort regularly conceals a sense and meaning which are denied any other form of expression. Generally the person concerned is quite unaware that he is doing anything of the kind or that he has modified his usual play in certain ways; and he fails to see and hear the effects of these actions. He does not, for example, hear the noise made by the jingling of coins, and, if his attention is drawn to it, he behaves as though he were astonished and incredulous. All the things that a person does with his clothing, often without realizing it, are no less important and deserve the doctor's attention. Every change in the clothing usually worn, every small sign of carelessness - such as an unfastened button - every trace of exposure, is intended to express something which the wearer of the clothes does not want to say straight out and which for the most part he is unaware of. The interpretations of these small chance actions, and the evidence for these interpretations, emerge each time with sufficient certainty from the material which accompanies them during the session, from the topic that is under discussion and from the associations that occur when attention is drawn to the apparently chance action. Because of this I shall not proceed to support my assertions with examples accompanied by analyses; but I mention these actions because I believe that they have the same meaning in the case of normal people as they have in my patients. [1901b, 1272]
I can quote a further instance from my psychotherapeutic experience in which eloquent testimony was borne by a hand playing with a lump of bread-crumbs. My patient was a boy of not yet thirteen; for almost two years he had been severely hysterical and I finally took him for psycho-analytic treatment after a lengthy stay in a hydropathic institution had brought no success. I was going on the assumption that he must have had sexual experiences and be tormented by sexual questions, which was likely enough at his age; but I refrained from helping him with explanations as I wished to put my hypotheses once again to the test. I was therefore naturally curious as to the way in which he would bring out what I was looking for. One day it struck me that he was rolling something between the fingers of his right hand; he would thrust it in his pocket and continue playing with it there, and then take it out again, and so on. I did not ask what he had in his hand; but he suddenly opened his hand and showed me. It was bread-crumbs kneaded into a lump. At the next session he again brought along a similar lump and this time, while we were talking, he modelled figures out of it which excited my interest; he did this with incredible rapidity, with his eyes closed. They were undoubtedly little men, with a head, two arms and two legs, like the crudest prehistoric idols, and with an appendage between the legs which he drew out into a long point. He had hardly completed this when he kneaded the figure together again; later he allowed it to remain, but drew out a similar appendage from the surface of the back and other parts of the body in order to disguise the meaning of the first one. I wanted to show him I had understood him, but at the same time I wanted to prevent him from pretending that he had not thought of anything while he was engaged in making these figures. With this in mind I suddenly asked him if he remembered the story of the Roman king who gave his son's envoy an answer in dumb-show in his garden. The boy failed to recall it, although he must have learnt it so much more recently than I. He asked whether it was the story of the slave and the answer that was written on his shaven head. No, I answered, that is from Greek history, and I told him the story. King Tarquinius Superbus had made his son Sextus find his way secretly into a hostile Latin city. The son, who had meanwhile collected a following in the city, sent a messenger to the king asking what steps he should take next. The king did not answer, but went into his garden, had the question repeated to him there, and then silently struck off the heads of the tallest and finest poppies. All that the messenger could do was to report this to Sextus, who understood his father and arranged for the most distinguished citizens in the city to be removed by assassination.

[1901b, 1276]

While I was speaking, the boy stopped kneading and, as I was on the point of describing what the king did in his garden and had reached the words 'silently struck', he made a lightning movement and tore the head off his little man. He had therefore understood me and had seen that he had been understood by me. I could now question him directly, I gave him the information he needed, and in a short time we had brought the neurosis to an end.

[1901b, 1277]
The symptomatic acts that can be observed in almost inexhaustible abundance in healthy people no less than in sick ones have more than one claim to our interest. To the doctor they often serve as valuable clues which enable him to get his bearings in new or unfamiliar situations; to the observer of human nature they often betray everything - and at times even more than he cares to know. A person who is familiar with their significance may at times feel like King Solomon who, according to oriental legend, understood the language of animals. One day I was to examine a young man, whom I did not know, at his mother's house. As he came towards me I was struck by a large stain on his trousers - made by albumen, as I could tell from its peculiar stiff edges. After a moment's embarrassment the young man apologized and said that he had felt hoarse and so had swallowed a raw egg; some of the slippery white of egg had probably fallen on his clothes. He was able to confirm this by pointing to the egg-shell, which was still visible in the room on a small plate. In this way the suspicious stain was given an innocent explanation; but when his mother had left us alone I thanked him for making my diagnosis so very much easier, and without more ado took as the basis of our discussion his confession that he was suffering from the troubles arising from masturbation. Another time I was paying a visit to a lady who was as rich as she was miserly and foolish, and who was in the habit of giving the doctor the task of working through a host of complaints before the simple cause of her condition could he reached. When I entered she was sitting at a small table and was busy arranging silver florins in little piles. On rising she knocked some of the coins on to the floor. I helped her to pick them up, and soon cut short her account of her sufferings by asking: 'Has your noble son-in-law robbed you of so much money then?' She denied this angrily, only to go on very soon afterwards to tell the sad story of the agitation which her son-in-law's extravagance had caused her. She has not however sent for me since. I cannot claim that one always makes friends of those to whom one shows the meaning of their symptomatic acts.

[1901b, 1277]

(4) Here is another instructive error that put me to shame, an example of what might be called temporary ignorance. One day a patient reminded me to give him the two books on Venice that I had promised him, as he needed them in preparing for a journey at Easter. 'I have them ready,' I replied, and went to the library to fetch them. The truth, however, was that I had forgotten to look them out, for I did not entirely approve of my patient's journey, which I saw as an unnecessary interruption of the treatment and a material loss to the physician. I therefore took a hasty look round the library for two books I had had my eye on. One was 'Venice, City of Art'; but besides this I thought I must own a historical work in a similar series. Quite right, there it was: 'The Medici'. I took it and brought it to my waiting patient, only ashamedly to acknowledge the error. In reality I of course knew that the Medici have nothing to do with Venice, but for a short time it did not strike me as in any way incorrect. I now had to be fair; as I had so frequently confronted my patient with his own symptomatic acts I could only vindicate my authority in his eyes by being honest and showing him the motives (which I had kept secret) for my disapproval of his journey.

[1901b, 1295]
I then understood that behind the train of thought in which she brought these open accusations against her father there lay concealed as usual a self-accusation. I met her half-way by assuring her that in my view the occurrence of leucorrhoea in young girls pointed primarily to masturbation, and I considered that all the other causes which were commonly assigned to that complaint were put in the background by masturbation.¹ I added that she was now on the way to finding an answer to her own question of why it was that precisely she had fallen ill - by confessing that she had masturbated, probably in childhood. Dora denied flatly that she could remember any such thing. But a few days later she did something which I could not help regarding as a further step towards the confession. For on that day she wore at her waist - a thing she never did on any other occasion before or after - a small reticule of a shape which had just come into fashion; and, as she lay on the sofa and talked, she kept playing with it - opening it, putting a finger into it, shutting it again, and so on. I looked on for some time, and then explained to her the nature of a 'symptomatic act'.² I give the name of symptomatic acts to those acts which people perform, as we say, automatically, unconsciously, without attending to them, or as if in a moment of distraction. They are actions to which people would like to deny any significance, and which, if questioned about them, they would explain as being indifferent and accidental. Closer observation, however, will show that these actions, about which consciousness knows nothing or wishes to know nothing, in fact give expression to unconscious thoughts and impulses, and are therefore most valuable and instructive as being manifestations of the unconscious which have been able to come to the surface. There are two sorts of conscious attitudes possible towards these symptomatic acts. If we can ascribe inconspicuous motives to them we recognize their existence; but if no such pretext can be found for conscious use we usually fail altogether to notice that we have performed them. Dora found no difficulty in producing a motive: 'Why should I not wear a reticule like this, as it is now the fashion to do?' But a justification of this kind does not dismiss the possibility of the action in question having an unconscious origin. Though on the other hand the existence of such an origin and the meaning attributed to the act cannot be conclusively established. We must content ourselves with recording the fact that such a meaning fits in quite extraordinarily well with the situation as a whole and with the programme laid down by the unconscious.

[1905e, 1413]
I should like to be able to add some definite information as to when and under what particular influence Dora gave up masturbating; but owing to the incompleteness of the analysis I have only fragmentary material to present. We have heard that the bed-wetting lasted until shortly before she first fell ill with dyspnoea. Now the only light she was able to throw upon this first attack was that at the time of its occurrence her father was away from home for the first time since his health had improved. In this small recollection there must be a trace of an allusion to the aetiology of the dyspnoea. Dora's symptomatic acts and certain other signs gave me good reasons for supposing that the child, whose bedroom had been next door to her parents', had overheard her father in his wife's room at night and had heard him (for he was always short of breath) breathing hard while they had intercourse. Children, in such circumstances, divine something sexual in the uncanny sounds that reach their ears. Indeed, the movements expressive of sexual excitement lie within them ready to hand, as innate pieces of mechanism. I maintained years ago that the dyspnoea and palpitations that occur in hysteria and anxiety neurosis are only detached fragments of the act of copulation; and in many cases, as in Dora's, I have been able to trace back the symptom of dyspnoea or nervous asthma to the same exciting cause - to the patient's having overheard sexual intercourse taking place between adults. The sympatetic excitement which may be supposed to have occurred in Dora on such an occasion may very easily have made the child's sexuality veer round and have replaced her inclination to masturbation by an inclination to anxiety. A little while later, when her father was away and the child, devotedly in love with him, was wishing him back, she must have reproduced in the form of an attack of asthma the impression she had received. She had preserved in her memory the event which had occasioned the first onset of the symptom, and we can conjecture from it the nature of the train of thought, charged with anxiety, which had accompanied the attack. The first attack had come on after she had over-exerted herself on an expedition in the mountains, so that she had probably been really a little out of breath. To this was added the thought that her father was forbidden to climb mountains and was not allowed to over-exert himself, because he suffered from shortness of breath; then came the recollection of how much he had exerted himself with her mother that night, and the question whether it might not have done him harm; next came concern whether she might not have over-exerted herself in masturbating - an act which, like the other, led to a sexual orgasm accompanied by slight dyspnoea - and finally came a return of the dyspnoea in an intensified form as a symptom. Part of this material I was able to obtain directly from the analysis, but the rest required supplementing. But the way in which the occurrence of masturbation in Dora's case was verified has already shown us that material belonging to a single subject can only be collected piece by piece at various times and in different connections.¹

It was not until fifteen months after the case was over and this paper composed that I had news of my patient's condition and the effects of my treatment. On a date which is not a matter of complete indifference, on the first of April (times and dates, as we know, were never without significance for her), Dora came to see me again: to finish her story and to ask for help once more. One glance at her face, however, was enough to tell me that she was not in earnest over her request. For four or five weeks after stopping the treatment she had been 'all in a muddle', as she said. A great improvement had then set in; her attacks had become less frequent and her spirits had risen. In the May of that year one of the K.'s two children (it had always been delicate) had died. She took the opportunity of their loss to pay them a visit of condolence, and they received her as though nothing had happened in the last three years. She made it up with them, she took her revenge on them and she brought her own business to a satisfactory conclusion. To the wife she said: 'I know you have an affair with my father'; and the other did not deny it. From the husband she drew an admission of the scene by the lake which he had disputed, and brought the news of her vindication home to her father. Since then she had not resumed her relations with the family.

¹[1905e, 1416]

[1905e, 1454]
Freud has developed on this basis an art of interpretation which takes on the task of, as it were, extracting the pure metal of the repressed thoughts from the ore of the unintentional ideas. This work of interpretation is applied not only to the patient's ideas but also to his dreams, which open up the most direct approach to a knowledge of the unconscious, to his unintentional as well as to his purposeless actions (symptomatic acts) and to the blunders he makes in everyday life (slips of the tongue, bungled actions, and so on). The details of this technique of interpretation or translation have not yet been published by Freud. According to indications he has given, they comprise a number of rules, reached empirically, of how the unconscious material may be reconstructed from the associations, directions on how to know what it means when the patient's ideas cease to flow, and experiences of the most important typical resistances that arise in the course of such treatments. A bulky volume called *The Interpretation of Dreams*, published by Freud in 1900, may be regarded as the forerunner of an initiation into his technique.

In the course of the psychotherapeutic treatment of a delusion or of an analogous disorder, ambiguous speeches of this kind are often produced by the patient, as new symptoms of the briefest duration; and it can happen that the doctor finds himself too in the position of making use of them. In that way it not infrequently happens that with the meaning that is intended for the patient's conscious he stirs up an understanding of the meaning that applies to his unconscious. I know from experience that the part thus played by ambiguity is apt to raise the greatest objection in the uninitiated and to give rise to the greatest misunderstandings. But in any case our author was right in giving a place in his creation to a picture of this characteristic feature of what takes place in the formation of dreams and delusions.

The procedure which the author makes his Zoe adopt for curing her childhood friend's delusion shows a far-reaching similarity - no, a complete agreement in its essence - with a therapeutic method which was introduced into medical practice in 1895 by Dr. Josef Breuer and myself, and to the perfecting of which I have since then devoted myself. This method of treatment, to which Breuer first gave the name of 'cathartic' but which I prefer to describe as 'analytic', consists, as applied to patients suffering from disorders analogous to Hanold's delusion, in bringing to their consciousness, to some extent forcibly, the unconscious whose repression led to their falling ill - exactly as Gradiva did with the repressed memories of their childhood relations. Gradiva, it is true, could carry out this task more easily than a doctor: in several respects she was in what may be described as an ideal position for it. The doctor, who has no pre-existing knowledge of his patient and possesses no conscious memory of what is unconsciously at work in him, must call a complicated technique to his help in order to make up for this disadvantage. He must learn how to infer with great certainty from the conscious associations and communications of the patient what is repressed in him, how to discover his unconscious as it betrays itself behind his conscious words and acts. He then brings about something like what Norbert Hanold grasped at the end of the story when he translated back the name 'Gradiva' into 'Bertgang'. The disorder vanishes while being traced back to its origin; analysis, too, brings simultaneous cure.
You ask me to name ‘ten good books’ for you, and refrain from adding to this any word of explanation. Thus you leave to me not only the choice of the books but also the interpretation of your request. Accustomed to paying attention to small signs, I must then trust the wording in which you couch your enigmatical demand. You did not say: ‘the ten most magnificent works (of world literature)’, in which case I should have been obliged to reply, with so many others: Homer, the tragedies of Sophocles, Goethe’s Faust, Shakespeare’s Hamlet, Macbeth, etc. Nor did you say the ‘ten most significant books’, among which scientific achievements like those of Copernicus, of the old physician Johann Weier on the belief in witches, Darwin’s Descent of Man, and others, would then have found a place. You did not even ask for ‘favourite books’, among which I should not have forgotten Milton’s Paradise Lost and Heine’s Lazarus. I think, therefore, that a particular stress falls on the ‘good’ in your phrase, and that with this predicate you intend to designate books to which one stands in rather the same relationship as to ‘good’ friends, to whom one owes a part of one’s knowledge of life and view of the world - books which one has enjoyed oneself and gladly commends to others, but in connection with which the element of timid reverence, the feeling of one’s own smallness in the face of their greatness, is not particularly prominent.

[1906f, 1991]

As his parents still hesitated to give him the information which was already long overdue, little Hans had by a bold stroke taken the conduct of the analysis into his own hands. By means of a brilliant symptomatic act, ‘Look!’ he had said to them, ‘this is how I imagine that a birth takes place.’ What he had told the maid-servant about the meaning of his game with the doll had been insincere; to his father he explicitly denied that he had only wanted to see its widdler. After his father had told him, as a kind of payment on account, how chickens come out of eggs, Hans gave a combined expression to his dissatisfaction, his mistrust, and his superior knowledge in a charming piece of persiflage, which culminated with his last words in an unmistakable allusion to his sister’s birth.

[1909b, 2072]

‘I: “Are you fond of Daddy?”

[1909b, 2074]

¹ Hans, having good reason to mistrust information given him by grown-up people, was considering whether the landlord might not be more trustworthy than his father.

[1909b, 2076]
Therapeutic success, however, is not our primary aim; we endeavour rather to enable the patient to obtain a conscious grasp of his unconscious wishes. And this we can achieve by working upon the basis of the hints he throws out, and so, with the help of our interpretative technique, presenting the unconscious complex to his consciousness in our own words. There will be a certain degree of similarity between that which he hears from us and that which he is looking for, and which, in spite of all resistances, is trying to force its way through to consciousness; and it is this similarity that will enable him to discover the unconscious material. The physician is a step in front of him in knowledge; and the patient follows along his own road, until the two meet at the appointed goal. Beginners in psycho-analysis are apt to assimilate these two events, and to suppose that the moment at which one of the patient's unconscious complexes has become known to them is also the moment at which the patient himself recognizes it. They are expecting too much when they think that they will cure the patient by informing him of this piece of knowledge; for he can do no more with the information than make use of it to help himself in discovering the unconscious complex where it is anchored in his unconscious. A first success of this sort had now been achieved with Hans. Having partly mastered his castration complex, he was now able to communicate his wishes in regard to his mother. He did so, in what was still a distorted form, by means of the phantasy of the two giraffes, one of which was calling out in vain because Hans had taken possession of the other. He represented the 'taking possession of' pictorially as 'sitting down on'. His father recognized the phantasy as a reproduction of a bedroom scene which used to take place in the morning between the boy and his parents; and he quickly stripped the underlying wish of the disguise which it still wore. The boy's father and mother were the two giraffes. The reason for the choice of a giraffe-phony for the purposes of disguise was fully explained by a visit that the boy had paid to those same large beasts at Schönbrunn a few days earlier, by the giraffe-drawing, belonging to an earlier period, which had been preserved by his father, and also, perhaps, by an unconscious comparison based upon the giraffe's long, stiff neck.¹ It may be remarked that the giraffe, as being a large animal and interesting on account of its widdler, was a possible competitor with the horse for the role of bugbear; moreover, the fact that both his father and his mother appeared as giraffes offered a hint which had not yet been followed up, as regards the interpretation of the anxiety-horses.

[1909b, 2103]

What remains are just such confirmations on Hans's part of analytical conclusions which our interpretations had already established. In an entirely unequivocal symptomatic act, which he disguised slightly from the maid but not at all from his father, he showed how he imagined a birth took place; but if we look into it more closely we can see that he showed something else, that he was hinting at something which was not alluded to again in the analysis. He pushed a small penknife which belonged to his mother in through a round hole in the body of an india-rubber doll, and then let it drop out again by tearing apart the doll's legs. The enlightenment which he received from his parents soon afterwards, to the effect that children do in fact grow inside their mother's body and are pushed out of it like a lumf, came too late; it could tell him nothing new. Another symptomatic act, happening as though by accident, involved a confession that he had wished his father dead; for, just at the moment his father was talking of this death-wish, Hans let a horse that he was playing with fall down - knocked it over in fact. Further, he confirmed in so many words the hypothesis that heavily loaded carts represented his mother's pregnancy to him, and the horse's falling down was like having a baby. The most delightful piece of confirmation in this connection - a proof that, in his view, children were 'lumfs' - was his inventing the name of 'Lodi' for his favourite child. There was some delay in reporting this fact, for it then appeared that he had been playing with this sausage child of his for a long time past.¹

[1909b, 2111]
Working over the ideas that occur to patients when they submit to the main rule of psychoanalysis is not our only technical method of discovering the unconscious. The same purpose is served by two other procedures: the interpretation of patients' dreams and the exploitation of their faulty and haphazard actions.

[1910a, 2220]

As you see, research into dreams would be justified for its own sake merely by the information it gives us on matters that can with difficulty be discovered in other ways. But we were in fact led to the subject in connection with the psycho-analytic treatment of neurotics. You will easily understand from what I have already said how it is that dream-interpretation, if it is not made too difficult by the patient's resistances, leads to a knowledge of his hidden and repressed wishes and of the complexes nourished by them; and I can now pass on to the third group of mental phenomena whose study has become one of the technical instruments of psycho-analysis.

[1910a, 2224]

The phenomena in question are the small faulty actions performed by both normal and neurotic people, to which as a rule no importance is attached: forgetting things that might be known and sometimes in fact are known (e.g. the occasional difficulty in recalling proper names), slips of the tongue in talking, by which we ourselves are so often affected, analogous slips of the pen and misreadings, bungling the performance of actions, losing objects or breaking them. All of these are things for which as a rule no psychological determinants are sought and which are allowed to pass without criticism as consequences of distraction or inattention or similar causes. Besides these there are the actions and gestures which people carry out without noticing them at all, to say nothing of attributing any psychological importance to them: playing about and fiddling with things, humming tunes, fingering parts of one's own body or one's clothing and so on.¹ These small things, faulty actions and symptomatic or haphazard actions alike, are not so insignificant as people, by a sort of conspiracy of silence, are ready to suppose. They always have a meaning, which can usually be interpreted with ease and certainty from the situation in which they occur. And it turns out that once again they give expression to impulses and intentions which have to be kept back and hidden from one's own consciousness, or that they are actually derived from the same repressed wishful impulses and complexes which we have already come to know as the creators of symptoms and the constructors of dreams. They therefore deserve to be rated as symptoms, and if they are examined they may lead, just as dreams do, to the uncovering of the hidden part of the mind. A man's most intimate secrets are as a rule betrayed by their help. If they occur particularly easily and frequently even in healthy people in whom the repression of unconscious impulses has on the whole been quite successful, they have their triviality and inconspicuousness to thank for it. But they can claim a high theoretical value, since they prove that repression and the formation of substitutes occur even under healthy conditions.

[1910a, 2224]

If you will now bring together the means we possess for uncovering what is concealed, forgotten and repressed in the mind (the study of the ideas occurring to patients under free association, of their dreams and of their faulty and symptomatic actions), and if you will add to these the exploitation of certain other phenomena which occur during psycho-analytic treatment and on which I shall have a few remarks to make later under the heading of 'transference' - if you bear all these in mind, you will agree with me in concluding that our technique is already efficient enough to fulfil its task, to bring the pathogenic psychical material into consciousness and so to get rid of the ailments that have been brought about by the formation of substitutive symptoms. And if, in the course of our therapeutic endeavours, we extend and deepen our knowledge of the human mind both in health and sickness, that can, of course, only be regarded as a peculiar attraction in our work.

[1910a, 2225]
The psycho-analyst thinks differently. To him nothing is too small to be a manifestation of hidden mental processes. He has learnt long ago that such cases of forgetting or repetition are significant, and that it is the ‘distraction’ which allows impulses that are otherwise hidden to be revealed.

[1910c, 2290]

The patient's first symptoms or chance actions, like his first resistance, may possess a special interest and may betray a complex which governs his neurosis. A clever young philosopher with exquisite aesthetic sensibilities will hasten to put the creases of his trousers straight before lying down for his first hour; he is revealing himself as a former coprophilic of the highest refinement - which was to be expected from the later aesthete. A young girl will at the same juncture hurriedly pull the hem of her skirt over her exposed ankles; in doing this she is giving away the gist of what her analysis will uncover later: her narcissistic pride in her physical beauty and her inclinations to exhibitionism.

[1913c, 2490]

I am to put before you, then, the psycho-analytic view of the phenomena of neurosis. In doing so, the best plan would seem to be to make a start in connection with the phenomena we have already dealt with, for the sake both of analogy and contrast; and I will begin with a symptomatic action which I have seen many people perform during my consulting hours. We analysts cannot do much for the people who come to us in our consulting-room to lay before us in a quarter of an hour the miseries of a long lifetime. Our deeper knowledge makes it difficult for us to give the kind of opinion another doctor would - 'There's nothing wrong with you' - with the added advice: 'You should arrange for a mild hydropathic treatment.' One of my colleagues who was asked what he did with his consultation patients shrugged his shoulders and replied: 'I fine them so-and-so many Kronen for a frivolous waste of time.' So you will not be surprised to hear that even in the case of busy psycho-analysts their consulting hours are not apt to be very lively. I have had the ordinary door between my waiting-room and my consulting- and treatment-room doubled and given a baize lining. There can be no doubt about the purpose of this arrangement. Now it constantly happens that a person whom I have brought in from the waiting-room omits to shut the door behind him and almost always he leaves both doors open. As soon as I notice this I insist in a rather unfriendly tone on his or her going back and making good the omission even if the person concerned is a well-dressed gentleman or a fashionable lady. This makes an impression of uncalled-for pedantry. Occasionally, too, I have put myself in a foolish position by making this request when it has turned out to be a person who cannot touch a door-handle himself and is glad if someone with him spares him the necessity. But in the majority of cases I have been right; for anyone who behaves like this and leaves the door open between a doctor's waiting-room and consulting-room is ill-mannered and deserves an unfriendly reception. But do not take sides over this till you have heard the sequel. For this carelessness on the part of the patient only occurs when he has been alone in the waiting-room and has therefore left an empty room behind him; it never happens if other people, strangers to him, have been waiting with him. In this latter case he knows quite well that it is in his interest not to be overheard while he is talking to the doctor, and he never fails to shut both the doors carefully.

[1916-1917, 3329]
Thus the patient's omission is neither accidentally nor senselessly determined; and indeed it is not unimportant, for, as we shall see, it throws light on the newcomer's attitude to the doctor. The patient is one of the great multitude who have a craving for mundane authority, who wish to be dazzled and intimidated. He may have enquired on the telephone as to the hour at which he could most easily get an appointment; he had formed a picture of a crowd of people seeking for help, like the crowd outside one of Julius Meinl's branches. He now comes into an empty, and moreover extremely modestly furnished, waiting-room, and is shocked. He has to make the doctor pay for the superfluous respect which he had intended to offer him: so - he omits to shut the door between the waiting-room and the consulting-room. What he means to say to the doctor by his conduct is: 'Ah, so there's no one here and no one's likely to come while I'm here.' He would behave equally impolitely and disrespectfully during the consultation if his arrogance were not given a sharp reprimand at the very beginning.

The analysis of this small symptomatic action tells you no thing you did not know before: the thesis that it was not a matter of chance but had a motive, a sense and an intention, that it had a place in an assignable mental context and that it provided information, by a small indication, of a more important mental process. But, more than anything else, it tells you that the process thus indicated was unknown to the consciousness of the person who carried out the action, since none of the patients who left the two doors open would have been able to admit- that by this omission he wanted to give evidence of his contempt. Some of them would probably have been aware of a sense of disappointment when they entered the empty waiting room; but the connection between this impression and the symptomatic action which followed certainly remained unknown to their consciousness.

What attitude, then, will a psychiatrist adopt in a case of illness like this? We know already how he would behave to the symptomatic action of the patient who fails to shut the consulting-room door. He pronounces it to be a chance event of no psychological interest with which he has no further concern. But this procedure cannot be carried over to the illness of the jealous woman. The symptomatic action seems to be a matter of indifference; but the symptom forces itself on our attention as a matter of importance. It is accompanied by intense subjective suffering and, as an objective fact, it threatens the communal life of a family; it is thus an undeniable subject of psychiatric interest. The psychiatrist will start by endeavouring to characterize the symptom by some essential feature. The idea with which the woman torments herself cannot in itself be called absurd; it does, indeed, happen that elderly gentlemen have love affairs with young girls. But there is something else about it which is absurd and hard to understand. The patient had no other reason at all for believing that her affectionate and loyal husband belonged to this otherwise not so rare class of husbands except what was asserted in the anonymous letter. She knew that this document had no evidential value and she was able to give a satisfying explanation of its origin. She ought therefore to have been able to tell herself that she had no ground whatever for her jealousy, and she did tell herself so. But in spite of this she suffered as much as if she regarded this jealousy as completely justified. Ideas of this kind, which are inaccessible to logical arguments based on reality, are by general agreement described as delusions. The good lady, then, was suffering from delusions of jealousy. This is no doubt the essential feature of this case of illness.
From the standpoint of the libido theory, too, we may say a last word on dreams. A neurotic's dreams help us, like his parapraxes and his free associations to them, to discover the sense of his symptoms and to reveal the way in which his libido is allocated. They show us, in the form of a wish-fulfilment, what wishful impulses have been subjected to repression and to what objects the libido withdrawn from the ego has become attached. For this reason the interpretation of dreams plays a large part in a psycho-analytic treatment, and in some cases it is over long periods the most important instrument of our work. We already know that the state of sleep in itself leads to a certain relaxation of the repressions. A repressed impulse, owing to this reduction in the pressure weighing down upon it, becomes able to express itself far more clearly in a dream than it can be allowed to be expressed by a symptom during the day. The study of dreams therefore becomes the most convenient means of access to a knowledge of the repressed unconscious, of which the libido withdrawn from the ego forms a part.

When the news of his sister's death arrived, so the patient told me, he felt hardly a trace of grief. He had to force himself to show signs of sorrow, and was able quite coolly to rejoice at having now become the sole heir to the property. He had already been suffering from his recent illness for several years when this occurred. But I must confess that this one piece of information made me for a long time uncertain in my diagnostic judgement of the case. It was to be assumed, no doubt, that his grief over the loss of the most dearly loved member of his family would meet with an inhibition in its expression, as a result of the continued operation of his jealousy of her and of the added presence of his incestuous love for her which had now become unconscious. But I could not do without some substitute for the missing outbursts of grief. And this was at last found in another expression of feeling which had remained inexplicable to the patient. A few months after his sister's death he himself made a journey in the neighbourhood in which she had died. There he sought out the burial-place of a great poet, who was at that time his ideal, and shed bitter tears upon his grave. This reaction seemed strange to him himself, for he knew that more than two generations had passed by since the death of the poet he admired. He only understood it when he remembered that his father had been in the habit of comparing his dead sister's works with the great poet's. He gave me another indication of the correct way of interpreting the homage which he ostensibly paid to the poet, by a mistake in his story which I was able to detect at this point. He had repeatedly specified before that his sister had shot herself; but he was now obliged to make a correction and say that she had taken poison. The poet, however, had been shot in a duel.

While he was at his secondary school the Fates provided him with a remarkable opportunity of reviving his wolf phobia, and of using the relation which lay behind it as an occasion for severe inhibitions. The master who taught his form Latin was called Wolf. From the very first he felt cowed by him, and he was once taken severely to task by him for having made a stupid mistake in a piece of Latin translation. From that time on he could not get free from a paralysing fear of this master, and it was soon extended to other masters besides. But the occasion on which he made his blunder in the translation was also to the purpose. He had to translate the Latin word 'filius', and he did it with the French word 'fils' instead of with the corresponding word from his own language. The wolf, in fact, was still his father.
Even his final choice of object, which played such an important part in his life, is shown by its
details (though they cannot be adduced here) to have been dependent upon the same condition
and to have been an offshoot of the compulsion which, starting from the primal scene and going
on to the scene with Grusha, had dominated his love-choice. I have remarked on an earlier
page that I recognize in the patient an endeavour to debase his love-object. This is to be
explained as a reaction against pressure from the sister who was so much his superior. But I
promised at the same time (see p. 3515) to show that this self-assertive motive was not the only
determinant, but that it concealed another and deeper one based on purely erotic motives.
These were brought to light by the patient's memory of the nursery-maid scrubbing the floor -
physically debased too, by the by. All his later love-objects were surrogates for this one person,
who through the accident of her attitude had herself become his first mother-surrogate. The
patient's first association in connection with the problem of his fear of the butterfly can now
easily be explained retrospectively as a distant allusion to the primal scene (the hour of five). He
confirmed the connection between the Grusha scene and the threat of castration by a
particularly ingenious dream, which he himself succeeded in deciphering. 'I had a dream,' he
said, 'of a man tearing off the wings of an Espe.' 'Espe?' I asked; 'what do you mean by that?'
'You know; that insect with yellow stripes on its body, that stings.' I could now put him right: 'So
what you mean is a Wespe [wasp].' 'Is it called a Wespe? I really thought it was called an Espe.'
(like so many other people, he used his difficulties with a foreign language as a screen for
symptomatic acts.) 'But Espe, why, that's myself: S. P.' (which were his initials). The Espe was
of course a mutilated Wespe. The dream said clearly that he was avenging himself on Grusha
for her threat of castration.
[1918b, 3575]

When he came to me for treatment - by no means the least reason for his coming was that his
mother, a religious bigot, had a horror of psycho-analysis - his jealousy of the younger brother
(which had once actually been manifested as a murderous attack on the infant in its cradle) had
long been forgotten. He now treated his brother with great consideration; but certain curious
fortuitous actions of his (which involved sudden and severe injuries to favourite animals, like his
sporting dog or birds which he had carefully reared,) were probably to be understood as echoes
of these hostile impulses against the little brother.
[1917b, 3620]
The Interpretation of Parapraxes and Haphazard Acts. - It was a triumph for the interpretative art of psycho-analysis when it succeeded in demonstrating that certain common mental acts of normal people, for which no one had hitherto attempted to put forward a psychological explanation, were to be regarded in the same light as the symptoms of neurotics: that is to say, they had a meaning, which was unknown to the subject but which could easily be discovered by analytic means. The phenomena in question were such events as the temporary forgetting of familiar words and names, forgetting to carry out prescribed tasks, everyday slips of the tongue and of the pen, misreadings, losses and mislayings of objects, certain errors, instances of apparently accidental self-injury, and finally habitual movements carried out seemingly without intention or in play, tunes hummed 'thoughtlessly', and so on. All of these were shorn of their physiological explanation, if any such had ever been attempted, were shown to be strictly determined and were revealed as an expression of the subject's suppressed intentions or as a result of a clash between two intentions one of which was permanently or temporarily unconscious. The importance of this contribution to psychology was of many kinds. The range of mental determinism was extended by it in an unforeseen manner; the supposed gulf between normal and pathological mental events was narrowed; in many cases a useful insight was afforded into the play of mental forces that must be suspected to lie behind the phenomena. Finally, a class of material was brought to light which is calculated better than any other to stimulate a belief in the existence of unconscious mental acts even in people to whom the hypothesis of something at once mental and unconscious seems strange and even absurd. The study of one's own parapraxes and haphazard acts, for which most people have ample opportunities, is even to-day the best preparation for an approach to psycho-analysis. In analytic treatment, the interpretation of parapraxes retains a place as a means of uncovering the unconscious, alongside the immeasurably more important interpretation of associations. [1923a, 3917]

All this sounds convincing and reasonable. Psycho-analysis has once more to meet the reproach that it makes hair-splitting complications in the simplest things and sees mysteries and problems where none exist, and that it does this by laying undue stress on insignificant and irrelevant details, such as occur every where, and making them the basis of the most far-reaching and strangest conclusions. It would be useless for us to point out that this rejection of our interpretation would do away with many striking analogies and break a number of subtle connections which we are able to demonstrate in this case. Our opponents will say that those analogies and connections do not in fact exist, but have been imported into the case by us with quite uncalled-for ingenuity. [1923d, 4008]

If we are right in regarding our painter's bond with the Devil as a neurotic phantasy, there is no need for any further apology for considering it psycho-analytically. Even small indications have a meaning and importance, and quite specially when they are related to the conditions under which a neurosis originates. To be sure, it is as possible to overvalue as to undervalue them, and it is a matter of judgement how far one should go in exploiting them. But anyone who does not believe in psycho-analysis - or, for the matter of that, even in the Devil - must be left to make what he can of the painter's case, whether he is able to furnish an explanation of his own or whether he sees nothing in it that needs explaining. [1923d, 4008]
If a dream brings up situations that can be interpreted as referring to scenes from the dreamer's past, it seems especially important to ask whether the physician's influence can also play a part in such contents of the dream as these. And this question is most urgent of all in the case of what are called 'corroborative' dreams, dreams which, as it were, 'tag along behind' the analysis. With some patients these are the only dreams that one obtains. Such patients reproduce the forgotten experiences of their childhood only after one has constructed them from their symptoms, associations and other signs and has propounded these constructions to them. Then follow the corroborative dreams, concerning which, however, the doubt arises whether they may not be entirely without evidential value, since they may have been imagined in compliance with the physician's words instead of having been brought to light from the dreamer's unconscious. This ambiguous position cannot be escaped in the analysis, since with these patients unless one interprets, constructs and propounds, one never obtains access to what is repressed in them.

[1923c, 4036]

In the same way that psycho-analysis makes use of dream-interpretation, it also profits by the study of the numerous little slips and mistakes which people make - symptomatic actions, as they are called. I investigated this subject in a series of papers which were published for the first time in book form in 1904 under the title of *The Psychopathology of Everyday Life*. In this widely circulated work I have pointed out that these phenomena are not accidental, that they require more than physiological explanations, that they have a meaning and can be interpreted, and that one is justified in inferring from them the presence of restrained or repressed impulses and intentions. But what constitutes the enormous importance of dream-interpretation, as well as of this latter study, is not the assistance they give to the work of analysis but another of their attributes. Previously psycho-analysis had only been concerned with solving pathological phenomena and in order to explain them it had often been driven into making assumptions whose comprehensiveness was out of all proportion to the importance of the actual material under consideration. But when it came to dreams, it was no longer dealing with a pathological symptom, but with a phenomenon of normal mental life which might occur in any healthy person. If dreams turned out to be constructed like symptoms, if their explanation required the same assumptions - the repression of impulses, substitutive formation, compromise-formation, the dividing of the conscious and the unconscious into various psychical systems - then psycho-analysis was no longer an auxiliary science in the field of psychopathology, it was rather the starting-point of a new and deeper science of the mind which would be equally indispensable for the understanding of the normal. Its postulates and findings could be carried over to other regions of mental happening; a path lay open to it that led far afield, into spheres of universal interest.

[1925d, 4222]

For anyone who is accustomed to regard men's internal experiences and actions analytically the explanation is very obvious - so obvious that it actually crept into my recollections of the facts themselves. Once, when I was referring to my pious colleague's letter in the course of a discussion, I spoke of his having written that the dead woman's face had reminded him of his own mother. In fact these words were not in his letter, and a moment's reflection will show that they could not possibly have been. But that is the explanation irresistibly forced on us by his affectionately phrased description of the 'sweet-faced dear old woman'. Thus the weakness of judgement displayed by the young doctor is to be accounted for by the emotion roused in him by the memory of his mother. It is difficult to escape from the bad psycho-analytic habit of bringing forward as evidence details which also allow of more superficial explanations - and I am tempted to recall the fact that my colleague addressed me later as a 'brother physician'.

[1928a, 4549]
The method by which we strengthen the weakened ego has as a starting-point an extending of its self-knowledge. That is not, of course, the whole story but it is a first step. The loss of such knowledge signifies for the ego a surrender of power and influence; it is the first tangible sign that it is being hemmed in and hampered by the demands of the id and the super-ego. Accordingly, the first part of the help we have to offer is intellectual work on our side and encouragement to the patient to collaborate in it. This first kind of activity, as we know, is intended to pave the way to another, more difficult, task. We shall not lose sight of the dynamic element in this task, even during its preliminary stage. We gather the material for our work from a variety of sources - from what is conveyed to us by the information given us by the patient and by his free associations, from what he shows us in his transferences, from what we arrive at by interpreting his dreams and from what he betrays by his slips or parapraxes. All this material helps us to make constructions about what happened to him and has been forgotten as well as about what is happening in him now without his understanding it. But in all this we never fail to make a strict distinction between our knowledge and his knowledge. We avoid telling him at once things that we have often discovered at an early stage, and we avoid telling him the whole of what we think we have discovered. We reflect carefully over when we shall impart the knowledge of one of our constructions to him and we wait for what seems to us the suitable moment - which it is not always easy to decide. As a rule we put off telling him of a construction or explanation till he himself has so nearly arrived at it that only a single step remains to be taken, though that step is in fact the decisive synthesis. If we proceed in another way and overwhelmed him with our interpretations before he was prepared for them, our information would either produce no effect or it would provoke a violent outbreak of resistance which would make the progress of our work more difficult or might even threaten to stop it altogether. But if we have prepared everything properly, it often happens that the patient will at once confirm our construction and himself recollect the internal or external event which he had forgotten. The more exactly the construction coincides with the details of what has been forgotten the easier will it be for him to assent. On that particular matter our knowledge will then have become his knowledge as well.

[1940a [1938], 4987]

It is familiar ground that the work of analysis aims at inducing the patient to give up the repressions (using the word in the widest sense) belonging to his early development and to replace them by reactions of a sort that would correspond to a psychically mature condition. With this purpose in view he must be brought to recollect certain experiences and the affective impulses called up by them which he has for the time being forgotten. We know that his present symptoms and inhibitions are the consequences of repressions of this kind: thus that they are a substitute for these things that he has forgotten. What sort of material does he put at our disposal which we can make use of to put him on the way to recovering the lost memories? All kinds of things. He gives us fragments of these memories in his dreams, invaluable in themselves but seriously distorted as a rule by all the factors concerned in the formation of dreams. Again, he produces ideas, if he gives himself up to 'free association', in which we can discover allusions to the repressed experiences and derivatives of the suppressed affective impulses as well as of the reactions against them. And, finally, there are hints of repetitions of the affects belonging to the repressed material to be found in actions performed by the patient, some fairly important, some trivial, both inside and outside the analytic situation. Our experience has shown that the relation of transference, which becomes established towards the analyst, is particularly calculated to favour the return of these emotional connections. It is out of such raw material - if we may so describe it - that we have to put together what we are in search of.

[1937d, 5050]
His work of construction, or, if it is preferred, of reconstruction, resembles to a great extent an archaeologist's excavation of some dwelling-place that has been destroyed and buried or of some ancient edifice. The two processes are in fact identical, except that the analyst works under better conditions and has more material at his command to assist him, since what he is dealing with is not something destroyed but something that is still alive - and perhaps for another reason as well. But just as the archaeologist builds up the walls of the building from the foundations that have remained standing, determines the number and position of the columns from depressions in the floor and reconstructs the mural decorations and paintings from the remains found in the debris, so does the analyst proceed when he draws his inferences from the fragments of memories, from the associations and from the behaviour of the subject of the analysis. Both of them have an undisputed right to reconstruct by means of supplementing and combining the surviving remains. Both of them, moreover, are subject to many of the same difficulties and sources of error. One of the most ticklish problems that confronts the archaeologist is notoriously the determination of the relative age of his finds; and if an object makes its appearance in some particular level, it often remains to be decided whether it belongs to that level or whether it was carried down to that level owing to some subsequent disturbance. It is easy to imagine the corresponding doubts that arise in the case of analytic constructions.

Indirect confirmation from associations that fit in with the content of a construction - that give us a 'too' like the one in my story - provides a valuable basis for judging whether the construction is likely to be confirmed in the course of the analysis. It is particularly striking when, by means of a parapraxis, a confirmation of this kind insinuates itself into a direct denial. I once published elsewhere a nice example of this. The name 'Jauner' (a familiar one in Vienna) came up repeatedly in one of my patient's dreams without a sufficient explanation appearing in his associations. I finally put forward the interpretation that when he said 'Jauner' he probably meant 'Gauner', whereupon he promptly replied: 'That seems to me too "jewagt".' Or there was the other instance, in which, when I suggested to a patient that he considered a particular fee too high, he meant to deny the suggestion with the words 'Ten dollars mean nothing to me' but instead of dollars put in a coin of lower value and said 'ten shillings'.
In these later stages of the work it is of use if we can guess the way in which things are connected up and tell the patient before we have uncovered it. If we have guessed right, the course of the analysis will be accelerated; but even a wrong hypothesis helps us on, by compelling the patient to take sides and by enticing him into energetic denials which betray his undoubted better knowledge.

I reproached Irma for not having accepted my solution. I said: 'If you still get pains, it's your own fault.' I might have said this to her in waking life, and I may actually have done so. It was my view at that time (though I have since recognized it as a wrong one) that my task was fulfilled when I had informed a patient of the hidden meaning of his symptoms: I considered that I was not responsible for whether he accepted the solution or not - though this was what success depended on. I owe it to this mistake, which I have now fortunately corrected, that my life was made easier at a time when, in spite of all my inevitable ignorance, I was expected to produce therapeutic successes. - I noticed, however, that the words which I spoke to Irma in the dream showed that I was specially anxious not to be responsible for the pains which she still had. If they were her fault they could not be mine. Could it be that the purpose of the dream lay in this direction?

As I have already explained, when I undertake the analytic treatment of a psycho-neurotic patient his dreams are invariably discussed between us. In the course of these discussions I am obliged to give him all the psychological explanations which have enabled me myself to reach an understanding of his symptoms. I am thereupon subjected to a remorseless criticism, certainly no less severe than I have to expect from the members of my own profession. And my patients invariably contradict my assertion that all dreams are fulfillments of wishes. Here, then, are some instances from the material of dreams that have been brought up against me as evidence to the contrary.

There is another kind of incompleteness which I myself have intentionally introduced. I have as a rule not reproduced the process of interpretation to which the patient's associations and communications had to be subjected, but only the results of that process. Apart from the dreams, therefore, the technique of the analytic work has been revealed in only a very few places. My object in this case history was to demonstrate the intimate structure of a neurotic disorder and the determination of its symptoms; and it would have led to nothing but hopeless confusion if I had tried to complete the other task at the same time. Before the technical rules, most of which have been arrived at empirically, could be properly laid down, it would be necessary to collect material from the histories of a large number of treatments. Nevertheless, the degree of shortening produced by the omission of the technique is not to be exaggerated in this particular case. Precisely that portion of the technical work which is the most difficult never came into question with the patient; for the factor of 'transference', which is considered at the end of the case history, did not come up for discussion during the short treatment.
I now return to the reproach of malingering which Dora brought against her father. It soon became evident that this reproach corresponded to self-reproaches not only concerning her earlier states of ill-health but also concerning the present time. At such points the physician is usually faced by the task of guessing and filling in what the analysis offers him in the shape only of hints and allusions. I was obliged to point out to the patient that her present ill-health was just as much actuated by motives and was just as tendentious as had been Frau K.'s illness, which she had understood so well. There could be no doubt, I said, that she had an aim in view which she hoped to gain by her illness. That aim could be none other than to detach her father from Frau K. She had been unable to achieve this by prayers or arguments; perhaps she hoped to succeed by frightening her father (there was her farewell letter), or by awakening his pity (there were her fainting-fits), or if all this was in vain, at least she would be taking her revenge on him. She knew very well, I went on, how much he was attached to her, and that tears used to come into his eyes whenever he was asked after his daughter's health. I felt quite convinced that she would recover at once if only her father were to tell her that he had sacrificed Frau K, for the sake of her health. But, I added, I hoped he would not let himself be persuaded to do this, for then she would have learned what a powerful weapon she had in her hands, and she would certainly not fail on every future occasion to make use once more of her liability to ill health. Yet if her father refused to give way to her, I was quite sure she would not let herself be deprived of her illness so easily. [1905e, 1379]

Freud has developed on this basis an art of interpretation which takes on the task of, as it were, extracting the pure metal of the repressed thoughts from the ore of the unintentional ideas. This work of interpretation is applied not only to the patient's ideas but also to his dreams, which open up the most direct approach to a knowledge of the unconscious, to his unintentional as well as to his purposeless actions (symptomatic acts) and to the blunders he makes in everyday life (slips of the tongue, bungled actions, and so on). The details of this technique of interpretation or translation have not yet been published by Freud. According to indications he has given, they comprise a number of rules, reached empirically, of how the unconscious material may be reconstructed from the associations, directions on how to know what it means when the patient's ideas cease to flow, and experiences of the most important typical resistances that arise in the course of such treatments. A bulky volume called The Interpretation of Dreams, published by Freud in 1900, may be regarded as the forerunner of an initiation into his technique. [1904a, 1558]
The procedure which the author makes his Zoe adopt for curing her childhood friend's delusion shows a far-reaching similarity - no, a complete agreement in its essence - with a therapeutic method which was introduced into medical practice in 1895 by Dr. Josef Breuer and myself, and to the perfecting of which I have since then devoted myself. This method of treatment, to which Breuer first gave the name of 'cathartic' but which I prefer to describe as 'analytic', consists, as applied to patients suffering from disorders analogous to Hanold's delusion, in bringing to their consciousness, to some extent forcibly, the unconscious whose repression led to their falling ill - exactly as Gradiva did with the repressed memories of their childhood relations. Gradiva, it is true, could carry out this task more easily than a doctor: in several respects she was in what may be described as an ideal position for it. The doctor, who has no pre-existing knowledge of his patient and possesses no conscious memory of what is unconsciously at work in him, must call a complicated technique to his help in order to make up for this disadvantage. He must learn how to infer with great certainty from the conscious associations and communications of the patient what is repressed in him, how to discover his unconscious as it betrays itself behind his conscious words and acts. He then brings about something like what Norbert Hanold grasped at the end of the story when he translated back the name 'Gradiva' into 'Bertgang'. The disorder vanishes while being traced back to its origin; analysis, too, brings simultaneous cure.

The chief difference has already been named. In the neurotic the secret is hidden from his own consciousness; in the criminal it is hidden only from you. In the former there is a genuine ignorance, though not an ignorance in every sense, while in the latter there is nothing but a pretence of ignorance. Connected with this is another difference, which is in practice of importance. In psycho-analysis the patient assists with his conscious efforts to combat his resistance, because he expects to gain something from the investigation, namely, his recovery. The criminal, on the other hand, does not work with you; if he did, he would be working against his whole ego. As though to make up for this, however, all you are endeavouring to arrive at in your investigation is an objective certainty on your part, whereas our therapy demands that the patient himself should also arrive at the same certainty. But it remains to be seen how far your procedure will be rendered more difficult or be altered by the lack of co-operation on the part of the subject of your examination. This is a situation which you can never create in your experiments in seminars, since the colleague who is playing the part of the accused man remains a fellow-worker after all, and assists you in spite of his conscious determination not to betray himself.

The material on which the following synthesis is based is derived from several sources. Firstly, from the direct observation of what children say and do; secondly, from what adult neurotics consciously remember from their childhood and relate during psycho-analytic treatment; and thirdly, from the inferences and constructions, and from the unconscious memories translated into conscious material, which result from the psycho-analysis of neurotics.
But the peculiar value of this observation lies in the considerations which follow. When a physician treats an adult neurotic by psycho-analysis, the process he goes through of uncovering the psychical formations, layer by layer, eventually enables him to frame certain hypotheses as to the patient's infantile sexuality; and it is in the components of the latter that he believes he has discovered the motive forces of all the neurotic symptoms of later life. I have set out these hypotheses in my *Three Essays on the Theory of Sexuality* (1905d), and I am aware that they seem as strange to an outside reader as they seem incontrovertible to a psycho-analyst. But even a psycho-analyst may confess to the wish for a more direct and less roundabout proof of these fundamental theorems. Surely there must be a possibility of observing in children at first hand and in all the freshness of life the sexual impulses and wishes which we dig out so laboriously in adults from among their own débris - especially as it is also our belief that they are the common property of all men, a part of the human constitution, and merely exaggerated or distorted in the case of neurotics.

[1909b, 2002]

That afternoon the father and son visited me during my consulting hours. I already knew the funny little fellow, and with all his self-assurance he was yet so amiable that I had always been glad to see him. I do not know whether he remembered me, but he behaved irreproachably and like a perfectly reasonable member of human society. The consultation was a short one. His father opened it by remarking that, in spite of all the pieces of enlightenment we had given Hans, his fear of horses had not yet diminished. We were also forced to confess that the connections between the horses he was afraid of and the affectionate feelings towards his mother which had been revealed were by no means abundant. Certain details which I now learnt - to the effect that he was particularly bothered by what horses wear in front of their eyes and by the black round their mouths - were certainly not to be explained from what we knew. But as I saw the two of them sitting in front of me and at the same time heard Hans's description of his anxiety-horses, a further piece of the solution shot through my mind, and a piece which I could well understand might escape his father. I asked Hans jokingly whether his horses wore eyeglasses, to which he replied that they did not. I then asked him whether his father wore eyeglasses, to which, against all the evidence, he once more said no. Finally I asked him whether by 'the black round the mouth' he meant a moustache; and I then disclosed to him that he was afraid of his father, precisely because he was so fond of his mother. It must be, I told him, that he thought his father was angry with him on that account; but this was not so, his father was fond of him in spite of it, and he might admit everything to him without any fear. Long before he was in the world, I went on, I had known that a little Hans would come who would be so fond of his mother that he would be bound to feel afraid of his father because of it; and I had told his father this. 'But why do you think I'm angry with you?' his father interrupted me at this point; 'have I ever scolded you or hit you?' Hans corrected him: 'Oh yes! You have hit me.' 'That's not true. When was it, anyhow?' 'This morning,' answered the little boy; and his father recollected that Hans had quite unexpectedly butted his head into his stomach, so that he had given him as it were a reflex blow with his hand. It was remarkable that he had not brought this detail into connection with the neurosis; but he now recognized it as an expression of the little boy's hostile disposition towards him, and perhaps also as a manifestation of a need for getting punished for it.

[1909b, 2031]
Therapeutic success, however, is not our primary aim; we endeavour rather to enable the patient to obtain a conscious grasp of his unconscious wishes. And this we can achieve by working upon the basis of the hints he throws out, and so, with the help of our interpretative technique, presenting the unconscious complex to his consciousness in our own words. There will be a certain degree of similarity between that which he hears from us and that which he is looking for, and which, in spite of all resistances, is trying to force its way through to consciousness; and it is this similarity that will enable him to discover the unconscious material. The physician is a step in front of him in knowledge; and the patient follows along his own road, until the two meet at the appointed goal. Beginners in psycho-analysis are apt to assimilate these two events, and to suppose that the moment at which one of the patient's unconscious complexes has become known to them is also the moment at which the patient himself recognizes it. They are expecting too much when they think that they will cure the patient by informing him of this piece of knowledge; for he can do no more with the information than make use of it to help himself in discovering the unconscious complex where it is anchored in his unconscious. A first success of this sort had now been achieved with Hans. Having partly mastered his castration complex, he was now able to communicate his wishes in regard to his mother. He did so, in what was still a distorted form, by means of the phantasy of the two giraffes, one of which was calling out in vain because Hans had taken possession of the other. He represented the 'taking possession of' pictorially as 'sitting down on'. His father recognized the phantasy as a reproduction of a bedroom scene which used to take place in the morning between the boy and his parents; and he quickly stripped the underlying wish of the disguise which it still wore. The boy's father and mother were the two giraffes. The reason for the choice of a giraffe-phantasy for the purposes of disguise was fully explained by a visit that the boy had paid to those same large beasts at Schönbrunn a few days earlier, by the giraffe-drawing, belonging to an earlier period, which had been preserved by his father, and also, perhaps, by an unconscious comparison based upon the giraffe's long, stiff neck.¹ It may be remarked that the giraffe, as being a large animal and interesting on account of its widdler, was a possible competitor with the horse for the role of bugbear; moreover, the fact that both his father and his mother appeared as giraffes offered a hint which had not yet been followed up, as regards the interpretation of the anxiety-horses.

[1909b, 2103]

The giraffe phantasy strengthened a conviction which had already begun to form in my mind when Hans expressed his fear that 'the horse'll come into the room'; and I thought the right moment had now arrived for informing him that he was afraid of his father because he himself nourished jealous and hostile wishes against him - for it was essential to postulate this much with regard to his unconscious impulses. In telling him this, I had partly interpreted his fear of horses for him: the horse must be his father - whom he had good internal reasons for fearing. Certain details of which Hans had shown he was afraid, the black on horses' mouths and the things in front of their eyes (the moustaches and eyeglasses which are the privilege of a grown-up man), seemed to me to have been directly transposed from his father on to the horses.

[1909b, 2105]

By enlightening Hans on this subject I had cleared away his most powerful resistance against allowing his unconscious thoughts to be made conscious; for his father was himself acting as his physician. The worst of the attack was now over; there was a plentiful flow of material; the little patient summoned up courage to describe the details of his phobia, and soon began to take an active share in the conduct of the analysis.¹

[1909b, 2105]
This is how, basing my conclusions upon the findings of the analysis, I am obliged to reconstruct the unconscious complexes and wishes, the repression and reawakening of which produced little Hans's phobia. I am aware that in so doing I am attributing a great deal to the mental capacity of a child between four and five years of age; but I have let myself be guided by what we have recently learned, and I do not consider myself bound by the prejudices of our ignorance. It might perhaps have been possible to make use of Hans's fear of the 'making a row with the legs' for filling up a few more gaps in our adjudication upon the evidence. Hans, it is true, declared that it reminded him of his kicking about with his legs when he was compelled to leave off playing so as to do lumf; so that this element of the neurosis becomes connected with the problem whether his mother liked having children or was compelled to have them. But I have an impression that this is not the whole explanation of the 'making a row with the legs'. Hans's father was unable to confirm my suspicion that there was some recollection stirring in the child's mind of having observed a scene of sexual intercourse between his parents in their bedroom. So let us be content with what we have discovered.

If we apply knowledge gained elsewhere to this case of childhood neurosis, we shall not be able to avoid a suspicion that in this instance as in others (that is to say, before the child had reached his sixth year) there had been conflicts and repressions, which had themselves been overtaken by amnesia, but had left behind them as a residuum the particular content of this obsessive fear. Later on we shall learn how far it is possible for us to rediscover those forgotten experiences or to reconstruct them with some degree of certainty. In the meantime stress may be laid on the fact, which is probably more than a mere coincidence, that the patient's infantile amnesia ended precisely with his sixth year.

Here the patient broke off, got up from the sofa, and begged me to spare him the recital of the details. I assured him that I myself had no taste whatever for cruelty, and certainly had no desire to torment him, but that naturally I could not grant him something which was beyond my power. He might just as well ask me to give him the moon. The overcoming of resistances was a law of the treatment, and on no consideration could it be dispensed with. (I had explained the idea of 'resistance' to him at the beginning of the hour, when he told me there was much in himself which he would have to overcome if he was to relate this experience of his.) I went on to say that I would do all I could, nevertheless, to guess the full meaning of any hints he gave me. Was he perhaps thinking of impalement? - 'No, not that; . . . the criminal was tied up . . .' - he expressed himself so indistinctly that I could not immediately guess in what position - 'a pot was turned upside down on his buttocks . . . some rats were put into it . . . and they . . .' - he had again got up, and was showing every sign of horror and resistance - ' . . . bored their way in . . .' - into his anus, I helped him out.

¹ It is never the aim of discussions like this to create conviction. They are only intended to bring the repressed complexes into consciousness, to set the conflict going in the field of conscious mental activity, and to facilitate the emergence of fresh material from the unconscious. A sense of conviction is only attained after the patient has himself worked over the reclaimed material, and so long as he is not fully convinced the material must be considered as unexhausted.
Starting from these indications and from other data of a similar kind, I ventured to put forward a construction to the effect that when he was a child of under six he had been guilty of some sexual misdemeanour connected with masturbation and had been soundly castigated for it by his father. This punishment, according to my hypothesis, had, it was true, put an end to his masturbations, but on the other hand it had left behind it an ineradicable grudge against his father and had established him for all time in his role of an interferer with the patient's sexual enjoyment.¹ To my great astonishment the patient then informed me that his mother had repeatedly described to him an occurrence of this kind which dated from his earliest childhood and had evidently escaped being forgotten by her on account of its remarkable consequences. He himself, however, had no recollection of it whatever. The tale was as follows. When he was very small - it became possible to establish the date more exactly owing to its having coincided with the fatal illness of an elder sister - he had done something naughty, for which his father had given him a beating. The little boy had flown into a terrible rage and had hurled abuse at his father even while he was under his blows. But as he knew no bad language, he had called him all the names of common objects that he could think of, and had screamed: 'You lamp! You towel! You plate!' and so on. His father, shaken by such an outburst of elemental fury, had stopped beating him, and had declared: 'The child will be either a great man or a great criminal!'² The patient believed that the scene made a permanent impression upon himself as well as upon his father. His father, he said, never beat him again; and he also attributed to this experience a part of the change which came over his own character. From that time forward he was a coward - out of fear of the violence of his own rage. His whole life long, moreover, he was terribly afraid of blows, and used to creep away and hide, filled with terror and indignation, when one of his brothers or sisters was beaten.

[1909d, 2161]

And now the path was clear to the solution of his rat idea. The treatment had reached its turning-point, and a quantity of material information which had hitherto been withheld became available, and so made possible a reconstruction of the whole concatenation of events.

[1909d, 2164]

(a) Advances in our knowledge. We are, of course, still a long way from knowing all that is required for an understanding of the unconscious in our patients. It is clear that every advance in our knowledge means an increase in our therapeutic power. As long as we have understood nothing, we have accomplished nothing; the more we understand, the more we shall achieve. At its beginning psycho-analytic treatment was inexorable and exhausting. The patient had to say everything himself, and the physician's activity consisted of urging him on incessantly. To-day things have a more friendly air. The treatment is made up of two parts - what the physician infers and tells the patient, and the patient's working-over of what he has heard. The mechanism of our assistance is easy to understand: we give the patient the conscious anticipatory idea and he then finds the repressed unconscious idea in himself on the basis of its similarity to the anticipatory one. This is the intellectual help which makes it easier for him to overcome the resistances between conscious and unconscious. Incidentally, I may remark that it is not the only mechanism made use of in analytic treatment; you all know the far more powerful one which lies in the use of the 'transference'. It is my intention in the near future to deal with these various factors, which are so important for an understanding of the treatment, in an Allgemeine Methodik der Psychoanalyse. And further, in speaking to you I need not rebut the objection that the evidential value in support of the correctness of our hypotheses is obscured in our treatment as we practise it to-day; you will not forget that this evidence is to be found elsewhere, and that a therapeutic procedure cannot be carried out in the same way as a theoretical investigation.

[1910d, 2307]
We are also now coming to the opinion that analytic technique must be modified in certain ways according to the nature of the disease and the dominant instinctual trends in the patient. We started out from the treatment of conversion hysteria; in anxiety hysteria (phobias) we must to some extent alter our procedure. For these patients cannot bring out the material necessary for resolving their phobia so long as they feel protected by obeying the condition which it lays down. One cannot, of course, succeed in getting them to give up their protective measures and work under the influence of anxiety from the beginning of the treatment. One must therefore help them by interpreting their unconscious to them until they can make up their minds to do without the protection of their phobia and expose themselves to a now greatly mitigated anxiety. Only after they have done so does the material become accessible, which, when it has been mastered, leads to a solution of the phobia. Other modifications of technique, which seem to me not yet ripe for discussion, will be required in the treatment of obsessional neurosis. In this connection very important questions arise, which have not hitherto been elucidated: how far the instincts which the patient is combating are to be allowed some satisfaction during the treatment, and what difference it makes whether these impulses are active (sadistic) or passive (masochistic) in their nature.

[1910d, 2310]

This brings us to the technical errors which are to be seen in the doctor's procedure in this alleged case. It is a long superseded idea, and one derived from superficial appearances, that the patient suffers from a sort of ignorance, and that if one removes this ignorance by giving him information (about the causal connection of his illness with his life, about his experiences in childhood, and so on) he is bound to recover. The pathological factor is not his ignorance in itself, but the root of this ignorance in his inner resistances; it was they that first called this ignorance into being, and they still maintain it now. The task of the treatment lies in combating these resistances. Informing the patient of what he does not know because he has repressed it is only one of the necessary preliminaries to the treatment. If knowledge about the unconscious were as important for the patient as people inexperienced in psycho-analysis imagine, listening to lectures or reading books would be enough to cure him. Such measures, however, have as much influence on the symptoms of nervous illness as a distribution of menu-cards in a time of famine has upon hunger. The analogy goes even further than its immediate application; for informing the patient of his unconscious regularly results in an intensification of the conflict in him and an exacerbation of his troubles.

[1910k, 2378]

Since, however, psycho-analysis cannot dispense with giving this information, it lays down that this shall not be done before two conditions have been fulfilled. First, the patient must, through preparation, himself have reached the neighbourhood of what he has repressed, and secondly, he must have formed a sufficient attachment (transference) to the physician for his emotional relationship to him to make a fresh flight impossible.

[1910k, 2379]

Any one who was more daring than I am in making interpretations, or who was in touch with Schreber's family and consequently better acquainted with the society in which he moved and the small events of his life, would find it an easy matter to trace back innumerable details of his delusions to their sources and so discover their meaning, and this in spite of the censorship to which the Denkwürdigkeiten have been subjected. But as it is, we must necessarily content ourselves with this shadowy sketch of the infantile material which was used by the paranoic disorder in portraying the current conflict.

[1911c, 2428]
Anyone coming from dream-interpretation to analytic practice will retain his interest in the content of dreams, and his inclination will be to interpret as fully as possible every dream related by the patient. But he will soon remark that he is now working under quite different conditions, and that if he attempts to carry out his intention he will come into collision with the most immediate tasks of the treatment. Even if a patient's first dream proves to be admirably suited for the introduction of the first explanations to be given, other dreams will promptly appear, so long and so obscure that the full meaning cannot be extracted from them in the limited session of one day's work. If the doctor continues the work of interpretation during the following days, fresh dreams will be produced in the meantime and these will have to be put aside until he can regard the first dream as finally resolved. The production of dreams is at times so copious, and the patient's progress towards comprehension of them so hesitant, that a suspicion will force itself on the analyst that the appearance of the material in this manner may be simply a manifestation of the patient's resistance taking advantage of the discovery that the method is unable to master what is so presented. Moreover, the treatment will meanwhile have fallen quite a distance behind the present and have lost touch with actuality. In opposition to such a technique stands the rule that it is of the greatest importance for the treatment that the analyst should always be aware of the surface of the patient's mind at any given moment, that he should know what complexes and resistances are active in him at the time and what conscious reaction to them will govern his behaviour. It is scarcely ever right to sacrifice this therapeutic aim to an interest in dream-interpretation.

I submit, therefore, that dream-interpretation should not be pursued in analytic treatment as an art for its own sake, but that its handling should be subject to those technical rules that govern the conduct of the treatment as a whole. Occasionally, of course, one can act otherwise and allow a little free play to one's theoretical interest; but one should always be aware of what one is doing. Another situation to be considered is one which has arisen since we have acquired more confidence in our understanding of dream-symbolism, and know ourselves to be more independent of the patient's associations. An unusually skilful dream-interpreter will sometimes find himself in the position of being able to see through every one of a patient's dreams without requiring him to go through the tedious and time-absorbing process of working over them. Such an analyst is thus exempt from any conflict between the demands of dream-interpretation and those of the treatment. Moreover he will be tempted to make full use of dream-interpretation on every occasion, by telling the patient everything he has detected in his dreams. In doing so, however, he will have adopted a method of treatment which departs considerably from the established one, as I shall point out in another connection. Beginners in psycho-analytic practice, at any rate, are advised not to take this exceptional case as a model.

Every analyst is in the position of the superior dream-interpreter, whom we have been imagining, in regard to the very first dreams that his patients bring, before they have learnt anything of the technique of translating dreams. These initial dreams may be described as unsophisticated: they betray a great deal to the listener, like the dreams of so-called healthy people. The question then arises whether the analyst is at once to translate to the patient all that he himself reads from them. This, however, is not the place for answering this question, for it evidently forms part of a wider one: at what stage in the treatment and how rapidly should the analyst introduce the patient to the knowledge of what lies veiled in his mind? The more the patient has learnt of the practice of dream-interpretation, the more obscure do his later dreams as a rule become. All the knowledge acquired about dreams serves also to put the dream-constructing process on its guard.
In the 'scientific' works about dreams, which in spite of their repudiation of dream-interpretation have received a new stimulus from psycho-analysis, one constantly finds that scrupulous care is most unnecessarily attached to the accurate preservation of the text of the dream. This is supposed to need protection from distortions and attritions in the hours immediately after waking. Some psycho-analysts, even, in giving the patient instructions to write down every dream immediately upon waking, seem not to rely consistently enough upon their knowledge of the conditions of dream-formation. In therapeutic work this rule is superfluous; and patients are glad to make use of it to disturb their sleep and to display great zeal where it can serve no useful purpose. For even if the text of a dream is in this way laboriously rescued from oblivion, it is easy enough to convince oneself that nothing has been achieved for the patient. Associations will not come to the text, and the result is the same as if the dream had not been preserved. No doubt the doctor has acquired some knowledge which he would not have done otherwise. But it is not the same thing whether the analyst knows something or the patient knows it; the importance of this distinction for the technique of psycho-analysis will be more fully considered elsewhere.

[1911e, 2453]

(f) It is easy to see upon what aim the different rules I have brought forward converge. They are all intended to create for the doctor a counterpart to the 'fundamental rule of psycho-analysis' which is laid down for the patient. Just as the patient must relate everything that his self-observation can detect, and keep back all the logical and affective objections that seek to induce him to make a selection from among them, so the doctor must put himself in a position to make use of everything he is told for the purposes of interpretation and of recognizing the concealed unconscious material without substituting a censorship of his own for the selection that the patient has forgone. To put it in a formula: he must turn his own unconscious like a receptive organ towards the transmitting unconscious of the patient. He must adjust himself to the patient as a telephone receiver is adjusted to the transmitting microphone. Just as the receiver converts back into sound waves the electric oscillations in the telephone line which were set up by sound waves, so the doctor's unconscious is able, from the derivatives of the unconscious which are communicated to him, to reconstruct that unconscious, which has determined the patient's free associations.

[1912e, 2470]

The next question with which we are faced raises a matter of principle. It is this: When are we to begin making our communications to the patient? When is the moment for disclosing to him the hidden meaning of the ideas that occur to him, and for initiating him into the postulates and technical procedures of analysis?

[1913c, 2491]
This answer of course involves a condemnation of any line of behaviour which would lead us to give the patient a translation of his symptoms as soon as we have guessed it ourselves, or would even lead us to regard it as a special triumph to fling these ‘solutions’ in his face at the first interview. It is not difficult for a skilled analyst to read the patient’s secret wishes plainly between the lines of his complaints and the story of his illness; but what a measure of self-complacency and thoughtlessness must be possessed by anyone who can, on the shortest acquaintance, inform a stranger who is entirely ignorant of all the tenets of analysis that he is attached to his mother by incestuous ties, that he harbours wishes for the death of his wife whom he appears to love, that he conceals an intention of betraying his superior, and so on! I have heard that there are analysts who plume themselves upon these kinds of lightning diagnoses and ‘express’ treatments, but I must warn everyone against following such examples. Behaviour of this sort will completely discredit oneself and the treatment in the patient’s eyes and will arouse the most violent opposition in him, whether one’s guess has been true or not; indeed, the truer the guess the more violent will be the resistance. As a rule the therapeutic effect will be nil; but the deterring of the patient from analysis will be final. Even in the later stages of analysis one must be careful not to give a patient the solution of a symptom or the translation of a wish until he is already so close to it that he has only one short step more to make in order to get hold of the explanation for himself. In former years I often had occasion to find that the premature communication of a solution brought the treatment to an untimely end, on account not only of the resistances which it thus suddenly awakened but also of the relief which the solution brought with it.

[1913c, 2492]

It is true that in the earliest days of analytic technique we took an intellectualist view of the situation. We set a high value on the patient’s knowledge of what he had forgotten, and in this we made hardly any distinction between our knowledge of it and his. We thought it a special piece of good luck if we were able to obtain information about the forgotten childhood trauma from other sources - for instance, from parents or nurses or the seducer himself - as in some cases it was possible to do; and we hastened to convey the information and the proofs of its correctness to the patient, in the certain expectation of thus bringing the neurosis and the treatment to a rapid end. It was a severe disappointment when the expected success was not forthcoming. How could it be that the patient, who now knew about his traumatic experience, nevertheless still behaved as if he knew no more about it than before? Indeed, telling and describing his repressed trauma to him did not even result in any recollection of it coming into his mind.

[1913c, 2493]
It seems to me not unnecessary to keep on reminding students of the far-reaching changes which psycho-analytic technique has undergone since its first beginnings. In its first phase - that of Breuer's catharsis - it consisted in bringing directly into focus the moment at which the symptom was formed, and in persistently endeavouring to reproduce the mental processes involved in that situation, in order to direct their discharge along the path of conscious activity. Remembering and abreacting, with the help of the hypnotic state, were what was at that time aimed at. Next, where hypnosis had been given up, the task became one of discovering from the patient's free associations what he failed to remember. The resistance was to be circumvented by the work of interpretation and by making its results known to the patient. The situations which had given rise to the formation of the symptom and the other situations which lay behind the moment at which the illness broke out retained their place as the focus of interest; but the element of abreaction receded into the background and seemed to be replaced by the expenditure of work which the patient had to make in being obliged to overcome his criticism of his free associations, in accordance with the fundamental rule of psycho-analysis. Finally, there was evolved the consistent technique used to-day, in which the analyst gives up the attempt to bring a particular moment or problem into focus. He contents himself with studying whatever is present for the time being on the surface of the patient's mind, and he employs the art of interpretation mainly for the purpose of recognizing the resistances which appear there, and making them conscious to the patient. From this there results a new sort of division of labour: the doctor uncovers the resistances which are unknown to the patient; when these have been got the better of, the patient often relates the forgotten situations and connections without any difficulty. The aim of these different techniques has, of course, remained the same. Descriptively speaking, it is to fill in gaps in memory; dynamically speaking, it is to overcome resistances due to repression.

I might break off at this point but for the title of this paper, which obliges me to discuss a further point in analytic technique. The first step in overcoming the resistances is made, as we know, by the analyst's uncovering the resistance, which is never recognized by the patient, and acquainting him with it. Now it seems that beginners in analytic practice are inclined to look on this introductory step as constituting the whole of their work. I have often been asked to advise upon cases in which the doctor complained that he had pointed out his resistance to the patient and that nevertheless no change had set in; indeed, the resistance had become all the stronger, and the whole situation was more obscure than ever. The treatment seemed to make no headway. This gloomy foreboding always proved mistaken. The treatment was as a rule progressing most satisfactorily. The analyst had merely forgotten that giving the resistance a name could not result in its immediate cessation. One must allow the patient time to become more conversant with this resistance with which he has now become acquainted, to work through it, to overcome it, by continuing, in defiance of it, the analytic work according to the fundamental rule of analysis. Only where the resistance is at its height can the analyst, working in common with his patient, discover the repressed instinctual impulses which are feeding the resistance; and it is this kind of experience which convinces the patient of the existence and power of such impulses. The doctor has nothing else to do than to wait and let things take their course, a course which cannot be avoided nor always hastened. If he holds fast to this conviction he will often be spared the illusion of having failed when in fact he is conducting the treatment on the right lines.

Every beginner in psycho-analysis probably feels alarmed at first at the difficulties in store for him when he comes to interpret the patient's associations and to deal with the reproduction of the repressed. When the time comes, however, he soon learns to look upon these difficulties as insignificant, and instead becomes convinced that the only really serious difficulties he has to meet lie in the management of the transference.
The first psycho-analytic examinations and attempts at treatment were made with the help of hypnotism. Afterwards this was abandoned and the work was carried out by the method of 'free association', with the patient remaining in his normal state. This modification had the advantage of enabling the procedure to be applied to a far larger number of cases of hysteria, as well as to other neuroses and also to healthy people. The development of a special technique of interpretation became necessary, however, in order to draw conclusions from the expressed ideas of the person under investigation. These interpretations established with complete certainty the fact that psychical dissociations are maintained entirely by 'internal resistances'. The conclusion seems justified, therefore, that the dissociations have originated owing to internal conflict, which has led to the 'repression' of the underlying impulse. To overcome this conflict and in that way to cure the neurosis, the guiding hand of a doctor trained in psycho-analysis is required.

This view may seem odd, but it can be supported by observations from psycho-analytic practice. If we communicate to a patient some idea which he has at one time repressed but which we have discovered in him, our telling him makes at first no change in his mental condition. Above all, it does not remove the repression nor undo its effects, as might perhaps be expected from the fact that the previously unconscious idea has now become conscious. On the contrary, all that we shall achieve at first will be a fresh rejection of the repressed idea. But now the patient has in actual fact the same idea in two forms indifferent places in his mental apparatus: first, he has the conscious memory of the auditory trace of the idea, conveyed in what we told him; and secondly, he also has - as we know for certain - the unconscious memory of his experience as it was in its earlier form. Actually there is no lifting of the repression until the conscious idea, after the resistances have been overcome, has entered into connection with the unconscious memory-trace. It is only through the making conscious of the latter itself that success is achieved. On superficial consideration this would seem to show that conscious and unconscious ideas are distinct registrations, topographically separated, of the same content. But a moment's reflection shows that the identity of the information given to the patient with his repressed memory is only apparent. To have heard something and to have experienced something are in their psychological nature two quite different things, even though the content of both is the same.

The analysis of these torments did not proceed so simply as that of our earlier patient's obsessional action. I was obliged to give the girl hints and propose interpretations, which were always rejected with a decided 'no' or accepted with contemptuous doubt. But after this first reaction of rejection there followed a time during which she occupied herself with the possibilities put before her, collected associations to them, produced recollections and made connections, until by her own work she had accepted all the interpretations. In proportion as this happened, she relaxed the performance of her obsessional measures, and even before the end of the treatment she had given up the whole ceremonial. You must understand, too, that the work of analysis as we carry it out to-day quite excludes the systematic treatment of any individual symptom till it has been entirely cleared up. We are, on the contrary, obliged to keep on leaving any particular topic, in the certain expectation of coming back to it again in other connections. The interpretation of her symptoms which I am about to give you is accordingly a synthesis of findings which were arrived at, interrupted by other work, over a period of weeks and months.
If only that was how things happened! We came upon discoveries in this connection for which we were at first unprepared. Knowledge is not always the same as knowledge; there are different sorts of knowledge, which are far from equivalent psychologically. ‘Il y a fagots et fagots’, as Molière has said. The doctor’s knowledge is not the same as the patient’s and cannot produce the same effects. If the doctor transfers his knowledge to the patient as a piece of information, it has no result. No, it would be wrong to say that. It does not have the result of removing the symptoms, but it has another one - of setting the analysis in motion, of which the first signs are often expressions of denial. The patient knows after this what he did not know before - the sense of his symptom; yet he knows it just as little as he did. Thus we learn that there is more than one kind of ignorance. We shall need to have a somewhat deeper understanding of psychology to show us in what these differences consist. But our thesis that the symptoms vanish when their sense is known remains true in spite of this. All we have to add is that the knowledge must rest on an internal change in the patient such as can only be brought about by a piece of psychical work with a particular aim. We are faced here by problems which will presently be brought together into the dynamics of the construction of symptoms.

[1916-1917, 3358]

I have warned you that we still have something new to learn; it is indeed something surprising and perplexing. By means of analysis, as you know, starting from the symptoms, we arrive at a knowledge of the infantile experiences to which the libido is fixated and out of which the symptoms are made. Well, the surprise lies in the fact that these scenes from infancy are not always true. Indeed, they are not true in the majority of cases, and in a few of them they are the direct opposite of the historical truth. As you will see, this discovery is calculated more than any other to discredit either analysis, which has led to this result, or the patients, on whose statements the analysis and our whole understanding of the neuroses are founded. But there is something else remarkably perplexing about it. If the infantile experiences brought to light by analysis were invariably real, we should feel that we were standing on firm ground; if they were regularly falsified and revealed as inventions, as phantasies of the patient, we should be obliged to abandon this shaky ground and look for salvation elsewhere. But neither of these things is the case: the position can be shown to be that the childhood experiences constructed or remembered in analysis are sometimes indisputably false and sometimes equally certainly correct, and in most cases compounded of truth and falsehood. Sometimes, then, symptoms represent events which really took place and to which we may attribute an influence on the fixation of the libido, and sometimes they represent phantasies of the patient's which are not, of course, suited to playing an aetiological role. It is difficult to find one’s way about in this. We can make a first start, perhaps, with a similar discovery - namely, that the isolated childhood memories that people have possessed consciously from time immemorial and before there was any such thing as analysis may equally be falsified or at least may combine truth and falsehood in plenty. In their case there is seldom any difficulty in showing their incorrectness; so we at least have the reassurance of knowing that the responsibility for this unexpected disappointment lies, not with analysis, but in some way with the patients.

[1916-1917, 3424]
But I still owe you further enlightenment, Gentlemen, on my reasons for not starting my account of the theory of the neuroses with the common neurotic state. You may perhaps suppose that it was because in that case I should have had greater difficulty in proving the sexual causation of the neuroses. But you would be wrong there. In the case of the transference neuroses one must work one's way through the interpretation of symptoms before one can arrive at that discovery. In the common forms of what are known as the 'actual neuroses' the aetiological significance of sexual life is a crude fact that springs to the observer's eyes. I came upon it more than twenty years ago when one day I asked myself the question of why in the examination of neurotics their sexual activities were so regularly excluded from consideration. At that time I sacrificed my popularity with my patients for the sake of these enquiries; but after only a brief effort I was able to declare that 'if the vita sexualis is normal, there can be no neurosis' - and by this I meant no 'actual neurosis'. No doubt this statement passes too lightly over people's individual differences; it suffers, too, from the indefiniteness inseparable from the judgement of what is 'normal'. But as a rough guide it retains its value to this day. I had by then reached the point of establishing specific relations between particular forms of neurosis and particular sexual noxae; and I have no doubt that I could repeat the same observations to-day if similar pathological material were still at my disposal. I found often enough that a man who indulged in a certain kind of incomplete sexual satisfaction (for instance, manual masturbation) had fallen ill of a particular form of 'actual neurosis', and that this neurosis promptly gave place to another if he replaced this sexual régime by another equally far from being irreproachable. I was then in a position to infer the change in a patient's sexual mode of life from an alteration in his condition. I also learnt then to stand obstinately by my suspicions till I had overcome the patients' disingenuousness and compelled them to confirm my views. It is true that thereafter they preferred to go to other doctors who did not make such keen enquiries about their sexual life.

[1916-1917, 3438]

(b) A second pointer is to be found in the analysis of the psychoneuroses, and especially of hysteria. We have seen that in this illness anxiety often appears in company with the symptoms, but that unbound anxiety appears, too, manifested as an attack or as a chronic condition. The patients cannot say what it is they are afraid of, and, by the help of an unmistakable secondary revision, link it to the first phobias that come to hand - such as dying, going mad, or having a stroke. If the situation out of which the anxiety (or the symptoms accompanied by anxiety) arose is subjected to analysis, we can as a rule discover what normal course of psychical events has failed to occur and has been replaced by phenomena of anxiety. To express it in another way: we construct the unconscious process as it would have been if it had not experienced any repression and had proceeded unhindered into consciousness. This process would have been accompanied by a particular affect, and we now learn to our surprise that this affect accompanying the normal course of events is invariably replaced by anxiety after repression has occurred, no matter what its own quality may be. Thus, when we have a hysterical anxiety-state before us, its unconscious correlate may be an impulse of a similar character - anxiety, shame, embarrassment - or, just as easily, a positive libidinal excitation or a hostile aggressive one, such as rage or anger. Anxiety is therefore the universally current coinage for which any affective impulse is or can be exchanged if the ideational content attached to it is subjected to repression.

[1916-1917, 3450]
What, then, must we do in order to replace what is unconscious in our patients by what is conscious? There was a time when we thought this was a very simple matter: all that was necessary was for us to discover this unconscious material and communicate it to the patient. But we know already that this was a short-sighted error. Our knowledge about the unconscious material is not equivalent to his knowledge; if we communicate our knowledge to him, he does not receive it instead of his unconscious material but beside it; and that makes very little change in it. We must rather picture this unconscious material topographically, we must look for it in his memory at the place where it became unconscious owing to a repression. The repression must be got rid of – after which the substitution of the conscious material for the unconscious can proceed smoothly. How, then, do we lift a repression of this kind? Here our task enters a second phase. First, the search for the repression and then the removal of the resistance which maintains the repression.

[1916-1917, 3478]

How do we remove the resistance? In the same way: by discovering it and showing it to the patient. Indeed, the resistance too is derived from a repression - from the same one that we are endeavouring to resolve, or from one that took place earlier. It was set up by the anticathexis which arose in order to repress the objectionable impulse. Thus we now do the same thing that we tried to do to begin with: interpret, discover and communicate; but now we are doing it at the right place. The anticathexis or the resistance does not form part of the unconscious but of the ego, which is our collaborator, and is so even if it is not conscious. As we know, the word 'unconscious' is being used here in two senses: on the one hand as a phenomenon and on the other as a system. This sounds very difficult and obscure; but is it not only repeating what we have already said in earlier passages? We have long been prepared for it. We expect that this resistance will be given up and the anticathexis withdrawn when our interpretation has made it possible for the ego to recognize it. What are the motive forces that we work with in such a case? First with the patient's desire for recovery, which has induced him to take part with us in our joint work, and secondly with the help of his intelligence, to which we give support by our interpretation. There is no doubt that it is easier for the patient's intelligence to recognize the resistance and to find the translation corresponding to what is repressed if we have previously given him the appropriate anticipatory ideas. If I say to you: 'Look up at the sky! There's a balloon there!' you will discover it much more easily than if I simply tell you to look up and see if you can see anything. In the same way, a student who is looking through a microscope for the first time is instructed by his teacher as to what he will see; otherwise he does not see it at all, though it is there and visible.

[1916-1917, 3479]

Let us hope that the doctor is modest enough to attribute his patient's high opinion of him to the hopes he can rouse in him and to the widening of his intellectual horizon by the surprising and liberating enlightenment that the treatment brings with it. Under these conditions the analysis makes fine progress too. The patient understands what is interpreted to him and becomes engrossed in the tasks set him by the treatment; the material of memories and associations floods in upon him in plenty, the certainty and appositeness of his interpretations are a surprise to the doctor, and the latter can only take note with satisfaction that here is a patient who readily accepts all the psychological novelties which are apt to provoke the most bitter contradiction among healthy people in the outside world. Moreover the cordial relations that prevail during the work of analysis are accompanied by an objective improvement, which is recognized on all sides, in the patient's illness.

[1916-1917, 3482]
But here I will pause, and let you have a word; for I see an objection boiling up in you so fiercely that it would make you incapable of listening if it were not put into words: 'Ah! so you've admitted it at last! You work with the help of suggestion, just like the hypnotists! That is what we've thought for a long time. But, if so, why the roundabout road by way of memories of the past, discovering the unconscious, interpreting and translating back distortions - this immense expenditure of labour, time and money - when the one effective thing is after all only suggestion? Why do you not make direct suggestion against the symptoms, as the others do - the honest hypnotists? Moreover, if you try to excuse yourself for your long detour on the ground that you have made a number of important psychological discoveries which are hidden by direct suggestion - what about the certainty of these discoveries now? Are not they a result of suggestion too, of unintentional suggestion? Is it not possible that you are forcing on the patient what you want and what seems to you correct, in this field as well?'

But you will now tell me that, no matter whether we call the motive force of our analysis transference or suggestion, there is a risk that the influencing of our patient may make the objective certainty of our findings doubtful. What is advantageous to our therapy is damaging to our researches. This is the objection that is most often raised against psycho-analysis, and it must be admitted that, though it is groundless, it cannot be rejected as unreasonable. If it were justified, psycho-analysis would be nothing more than a particularly well-disguised and particularly effective form of suggestive treatment and we should have to attach little weight to all that it tells us about what influences our lives, the dynamics of the mind or the unconscious. That is what our opponents believe; and in especial they think that we have 'talked' the patients into everything relating to the importance of sexual experiences - or even into those experiences themselves - after such notions have grown up in our own depraved imagination. These accusations are contradicted more easily by an appeal to experience than by the help of theory. Anyone who has himself carried out psycho-analyses will have been able to convince himself on countless occasions that it is impossible to make suggestions to a patient in that way. The doctor has no difficulty, of course, in making him a supporter of some particular theory and in thus making him share some possible error of his own. In this respect the patient is behaving like anyone else - like a pupil - but this only affects his intelligence, not his illness. After all, his conflicts will only be successfully solved and his resistances overcome if the anticipatory ideas he is given tally with what is real in him. Whatever in the doctor's conjectures is inaccurate drops out in the course of the analysis; it has to be withdrawn and replaced by something more correct. We endeavour by a careful technique to avoid the occurrence of premature successes due to suggestion; but no harm is done even if they do occur, for we are not satisfied by a first success. We do not regard an analysis as at an end until all the obscurities of the case are cleared up, the gaps in the patient's memory filled in, the precipitating causes of the repressions discovered. We look upon successes that set in too soon as obstacles rather than as a help to the work of analysis; and we put an end to such successes by constantly resolving the transference on which they are based. It is this last characteristic which is the fundamental distinction between analytic and purely suggestive therapy, and which frees the results of analysis from the suspicion of being successes due to suggestion. In every other kind of suggestive treatment the transference is carefully preserved and left untouched; in analysis it is itself subjected to treatment and is dissected in all the shapes in which it appears. At the end of an analytic treatment the transference must itself be cleared away; and if success is then obtained or continues, it rests, not on suggestion, but on the achievement by its means of an overcoming of internal resistances, on the internal change that has been brought about in the patient.
Thus our therapeutic work falls into two phases. In the first, all the libido is forced from the symptoms into the transference and concentrated there; in the second, the struggle is waged around this new object and the libido is liberated from it. The change which is decisive for a favourable outcome is the elimination of repression in this renewed conflict so that the libido cannot withdraw once more from the ego by flight into the unconscious. This is made possible by the alteration of the ego which is accomplished under the influence of the doctor's suggestion. By means of the work of interpretation, which transforms what is unconscious into what is conscious, the ego is enlarged at the cost of this unconscious; by means of instruction, it is made conciliatory towards the libido and inclined to grant it some satisfaction, and its repugnance to the claims of the libido is diminished by the possibility of disposing of a portion of it by sublimation. The more closely events in the treatment coincide with this ideal description, the greater will be the success of the psycho-analytic therapy. It finds its limits in the lack of mobility of the libido, which may refuse to leave its objects, and the rigidity of narcissism, which will not allow transference on to objects to increase beyond certain bounds. Further light may perhaps be thrown on the dynamics of the process of cure if I say that we get hold of the whole of the libido which has been withdrawn from the dominance of the ego by attracting a portion of it on to ourselves by means of the transference.

[1916-1917, 3495]

It is easy to understand that the first suspicion fell upon the English governess, for the change in the boy made its appearance while she was there. Two screen memories had persisted, which were incomprehensible in themselves, and which related to her. On one occasion, as she was walking along in front of them, she said: 'Do look at my little tail!' Another time, when they were on a drive, her hat flew away, to the two children's great satisfaction. This pointed to the castration complex, and might permit of a construction being made to the effect that a threat uttered by her against the boy had been largely responsible for originating his abnormal conduct. There is no danger at all in communicating constructions of this kind to the person under analysis; they never do any damage to the analysis if they are mistaken; but at the same time they are not put forward unless there is some prospect of reaching a nearer approximation to the truth by means of them. The first effect of this supposition was the appearance of some dreams, which it was not possible to interpret completely, but all of which seemed to centre around the same material. As far as they could be understood, they were concerned with aggressive actions on the boy's part against his sister or against the governess and with energetic reproofs and punishments on account of them. It was as though . . . after her bath . . . he had tried . . . to undress his sister . . . to tear off her coverings . . . or veils - and so on. But it was not possible to get at any firm content from the interpretation; and since these dreams gave an impression of always working over the same material in various different ways, the correct reading of these ostensible reminiscences became assured: it could only be a question of phantasies, which the dreamer had made on the subject of his childhood at some time or other, probably at the age of puberty, and which had now come to the surface again in this unrecognizable form.

[1918b, 3512]
When the news of his sister's death arrived, so the patient told me, he felt hardly a trace of grief. He had to force himself to show signs of sorrow, and was able quite coolly to rejoice at having now become the sole heir to the property. He had already been suffering from his recent illness for several years when this occurred. But I must confess that this one piece of information made me for a long time uncertain in my diagnostic judgement of the case. It was to be assumed, no doubt, that his grief over the loss of the most dearly loved member of his family would meet with an inhibition in its expression, as a result of the continued operation of his jealousy of her and of the added presence of his incestuous love for her which had now become unconscious. But I could not do without some substitute for the missing outbursts of grief. And this was at last found in another expression of feeling which had remained inexplicable to the patient. A few months after his sister's death he himself made a journey in the neighbourhood in which she had died. There he sought out the burial-place of a great poet, who was at that time his ideal, and shed bitter tears upon his grave. This reaction seemed strange to him himself, for he knew that more than two generations had passed by since the death of the poet he admired. He only understood it when he remembered that his father had been in the habit of comparing his dead sister's works with the great poet's. He gave me another indication of the correct way of interpreting the homage which he ostensibly paid to the poet, by a mistake in his story which I was able to detect at this point. He had repeatedly specified before that his sister had shot herself; but he was now obliged to make a correction and say that she had taken poison. The poet, however, had been shot in a duel.

[1918b, 3515]

By the latter I mean the postures which he saw his parents adopt - the man upright, and the woman bent down like an animal. We have already heard that during his anxiety period his sister used to terrify him with a picture from the fairy-book, in which the wolf was shown standing upright, with one foot forward, with its claws stretched out and its ears pricked. He devoted himself with tireless perseverance during the treatment to the task of hunting in the second-hand book shops till he had found the illustrated fairy-book of his childhood, and had recognized his bogy in an illustration to the story of 'The Wolf and the Seven Little Goats'. He thought that the posture of the wolf in this picture might have reminded him of that of his father during the constructed primal scene. At all events the picture became the point of departure for further manifestations of anxiety. Once when he was in his seventh or eighth year he was informed that next day a new tutor was coming for him. That night he dreamt of this tutor in the shape of a lion that came towards his bed roaring loudly and in the posture of the wolf in the picture; and once again he awoke in a state of anxiety. The wolf phobia had been overcome by that time, so he was free to choose himself a new anxiety-animal, and in this late dream he was recognizing the tutor as a father-surrogate. In the later years of his childhood each of his tutors and masters played the part of his father, and was endowed with his father's influence both for good and for evil.

[1918b, 3529]
I am anxious not to be misunderstood. Every analyst knows - and he has met with the experience on countless occasions - that in the course of a successful treatment the patient brings up a large number of spontaneous recollections from his childhood, for the appearance of which (a first appearance, perhaps) the physician feels himself entirely blameless, since he has not made any attempt at a construction which could have put any material of the sort into the patient's head. It does not necessarily follow that these previously unconscious recollections are always true. They may be; but they are often distorted from the truth, and interspersed with imaginary elements, just like the so-called screen memories which are preserved spontaneously. All that I mean to say is this: scenes, like this one in my present patient's case, which date from such an early period and exhibit a similar content, and which further lay claim to such an extraordinary significance for the history of the case, are as a rule not reproduced as recollections, but have to be divined - constructed - gradually and laboriously from an aggregate of indications. Moreover, it would be sufficient for the purposes of the argument if my admission that scenes of this kind do not become conscious in the shape of recollections applied only to cases of obsessional neurosis, or even if I were to limit my assertion to the case which we are studying here.

Let it be clearly understood that this last attempt at an explanation on the part of those who take the view opposed to mine results in the scenes from infancy being disposed of far more fundamentally than was announced to begin with. What was argued at first was that they were not realities but phantasies. But what is argued now is evidently that they are phantasies not of the patient but of the analyst himself, who forces them upon the person under analysis on account of some complexes of his own. An analyst, indeed, who hears this reproach, will comfort himself by recalling how gradually the construction of this phantasy which he is supposed to have originated came about, and, when all is said and done, how independently of the physician's incentive many points in its development proceeded; how, after a certain phase of the treatment, everything seemed to converge upon it, and how later, in the synthesis, the most various and remarkable results radiated out from it; how not only the large problems but the smallest peculiarities in the history of the case were cleared up by this single assumption. And he will disclaim the possession of the amount of ingenuity necessary for the concoction of an occurrence which can fulfil all these demands. But even this plea will be without an effect on an adversary who has not experienced the analysis himself. On the one side there will be a charge of subtle self-deception, and on the other of obtuseness of judgement; it will be impossible to arrive at a decision.

There was another dream, which belongs to the period before his emancipation by the tutor, and which I mention because it was forgotten until its appearance during the treatment. He saw himself riding on a horse and pursued by a gigantic caterpillar. He recognized in this dream an allusion to an earlier one from the period before the tutor, which we had interpreted long before. In this earlier dream he saw the Devil dressed in black and in the upright posture with which the wolf and the lion had terrified him so much in their day. He was pointing with his out-stretched finger at a gigantic snail. The patient had soon guessed that this Devil was the Demon out of a well-known poem, and that the dream itself was a version of a very popular picture representing the Demon in a love-scene with a girl. The snail was in the woman's place, as being a perfect female sexual symbol. Guided by the Demon's pointing gesture, we were soon able to give as the dream's meaning that the patient was longing for some one who should give him the last pieces of information that were still missing upon the riddle of sexual intercourse, just as his father had given him the first in the primal scene long before.
When we were studying the genesis of the wolf phobia, we followed the effect of his new insight into the sexual act; but now that we are investigating the disturbances of the intestinal function, we find ourselves working on the basis of the old cloacal theory. The two points of view remained separated from each other by a stage of repression. His feminine attitude towards men, which had been repudiated by the act of repression, drew back, as it were, into the intestinal symptoms, and expressed itself in the attacks of diarrhoea, constipation, and intestinal pain, which were so frequent during the patient's childhood. His later sexual phantasies, which were based on a correct sexual knowledge, were thus able to express themselves regressively as intestinal troubles. But we cannot understand them until we have explained the modifications which take place in the significance of faeces from the first years of childhood onward.¹

[1918b, 3562]

This memory recurred occasionally during the analysis, and called for an explanation; but for a long time none was to be found. Nevertheless it was to be assumed as a matter of course that a detail like this had not kept its place in his recollection on its own account, but that it was a screen-memory, representing something of more importance with which it was in some way connected. One day he told me that in his language a butterfly was called 'babushka', 'granny'. He added that in general butterflies had seemed to him like women and girls, and beetles and caterpillars like boys. So there could be little doubt that in this anxiety scene a recollection of some female person had been aroused. I will not hide the fact that at that time I put forward the possibility that the yellow stripes on the butterfly had reminded him of similar stripes on a piece of clothing worn by some woman. I only mention this as an illustration to show how inadequate the physician's constructive efforts usually are for clearing up questions that arise, and how unjust it is to attribute the results of analysis to the physician's imagination and suggestion.¹

[1918b, 3571]

I repeat, however, that as a rule the phantasy remains unconscious, and can only be reconstructed in the course of the analysis. This fact perhaps vindicates patients who say they remember that with them masturbation made its appearance before the third phase of the beating-phantasy (shortly to be discussed), and that this phase was only a later addition, made perhaps under the impression of scenes at school. Every time I have given credit to these statements I have felt inclined to assume that the masturbation was at first under the dominance of unconscious phantasies and that conscious ones were substituted for them later.

[1919e, 3652]

Twenty five years of intense work have had as their result that the immediate aims of psychoanalytic technique are quite other to-day than they were at the outset. At first the analysing physician could do no more than discover the unconscious material that was concealed from the patient, put it together, and, at the right moment, communicate it to him. Psychoanalysis was then first and foremost an art of interpreting. Since this did not solve the therapeutic problem, a further aim quickly came in view: to oblige the patient to confirm the analyst's construction from his own memory. In that endeavour the chief emphasis lay upon the patient's resistances: the art consisted now in uncovering these as quickly as possible, in pointing them out to the patient and in inducing him by human influence - this was where suggestion operating as 'transference' played its part - to abandon his resistances.

[1920g, 3723]
For these reasons I refrained altogether from holding out to the parents any prospect of their wish being fulfilled. I merely said I was prepared to study the girl carefully for a few weeks or months, so as then to be able to pronounce how far a continuation of the analysis would be likely to influence her. In quite a number of cases, indeed, an analysis falls into two clearly distinguishable phases. In the first, the physician procures from the patient the necessary information, makes him familiar with the premises and postulates of psycho-analysis, and unfolds to him the reconstruction of the genesis of his disorder as deduced from the material brought up in the analysis. In the second phase the patient himself gets hold of the material put before him; he works on it, recollects what he can of the apparently repressed memories, and tries to repeat the rest as if he were in some way living it over again. In this way he can confirm, supplement, and correct the inferences made by the physician. It is only during this work that he experiences, through overcoming resistances, the inner change aimed at, and acquires for himself the convictions that make him independent of the physician's authority. These two phases in the course of the analytic treatment are not always sharply divided from each other; this can only happen when the resistance obeys certain conditions. But when this is so, one may bring up as an analogy the two stages of a journey. The first comprises all the necessary preparations, to-day so complicated and hard to effect, before, ticket in hand, one can at last go on to the platform and secure a seat in the train. One then has the right, and the possibility, of travelling into a distant country; but after all these preliminary exertions one is not yet there - indeed, one is not a single mile nearer to one's goal. For this to happen one has to make the journey itself from one station to the other, and this part of the performance may well be compared with the second phase of the analysis.

[1920a, 3842]

_Psycho-analysis as an Interpretive Art._ - The new technique altered the picture of the treatment so greatly, brought the physician into such a new relation to the patient and produced so many surprising results that it seemed justifiable to distinguish the procedure from the cathartic method by giving it a new name. The present writer gave this method of treatment, which could now be extended to many other forms of neurotic disorder, the name of _psycho-analysis_. Now, in the first resort, this psycho-analysis was an art of _interpretation_ and it set itself the task of carrying deeper the first of Breuer's great discoveries - namely, that neurotic symptoms are significant substitutes for other mental acts which have been omitted. It was now a question of regarding the material produced by the patients' associations as though it hinted at a hidden meaning and of discovering that meaning from it. Experience soon showed that the attitude which the analytic physician could most advantageously adopt was to surrender himself to his own unconscious mental activity, in a state of _evenly suspended attention_, to avoid so far as possible reflection and the construction of conscious expectations, not to try to fix anything that he heard particularly in his memory, and by these means to catch the drift of the patient's unconscious with his own unconscious. It was then found that, except under conditions that were too unfavourable, the patient's associations emerged like allusions, as it were, to one particular theme and that it was only necessary for the physician to go a step further in order to guess the material which was concealed from the patient himself and to be able to communicate it to him. It is true that this work of interpretation was not to be brought under strict rules and left a great deal of play to the physician's tact and skill; but, with impartiality and practice, it was usually possible to obtain trustworthy results - that is to say, results which were confirmed by being repeated in similar cases. At a time when so little was as yet known of the unconscious, the structure of the neuroses and the pathological processes underlying them, it was a matter for satisfaction that a technique of this kind should be available, even if it had no better theoretical basis. Moreover it is still employed in analyses at the present day in the same manner, though with a sense of greater assurance and with a better understanding of its limitations.

[1923a, 3916]
The Interpretation of Parapraxes and Haphazard Acts. - It was a triumph for the interpretative art of psycho-analysis when it succeeded in demonstrating that certain common mental acts of normal people, for which no one had hitherto attempted to put forward a psychological explanation, were to be regarded in the same light as the symptoms of neurotics: that is to say, they had a meaning, which was unknown to the subject but which could easily be discovered by analytic means. The phenomena in question were such events as the temporary forgetting of familiar words and names, forgetting to carry out prescribed tasks, everyday slips of the tongue and of the pen, misreadings, losses and mislayings of objects, certain errors, instances of apparently accidental self-injury, and finally habitual movements carried out seemingly without intention or in play, tunes hummed 'thoughtlessly', and so on. All of these were shorn of their physiological explanation, if any such had ever been attempted, were shown to be strictly determined and were revealed as an expression of the subject's suppressed intentions or as a result of a clash between two intentions one of which was permanently or temporarily unconscious. The importance of this contribution to psychology was of many kinds. The range of mental determinism was extended by it in an unforeseen manner; the supposed gulf between normal and pathological mental events was narrowed; in many cases a useful insight was afforded into the play of mental forces that must be suspected to lie behind the phenomena. Finally, a class of material was brought to light which is calculated better than any other to stimulate a belief in the existence of unconscious mental acts even in people to whom the hypothesis of something at once mental and unconscious seems strange and even absurd. The study of one's own parapraxes and haphazard acts, for which most people have ample opportunities, is even to-day the best preparation for an approach to psycho-analysis. In analytic treatment, the interpretation of parapraxes retains a place as a means of uncovering the unconscious, alongside the immeasurably more important interpretation of associations. [1923a, 3917]

Development of Technique. - After the analyst's curiosity had, as it were, been gratified by the elaboration of the technique of interpretation, it was inevitable that interest should turn to the problem of discovering the most effective way of influencing the patient. It soon became evident that the physician's immediate task was to assist the patient in getting to know, and afterwards in overcoming, the resistances which emerged in him during treatment and of which, to begin with, he himself was unaware. And it was found at the same time that the essential part of the process of cure lay in the overcoming of these resistances and that unless this was achieved no permanent mental change could be brought about in the patient. Since the analyst's efforts have in this way been directed upon the patient's resistance, analytic technique has attained a certainty and delicacy rivalling that of surgery. Consequently, everyone is strongly advised against undertaking psycho-analytic treatments without a strict training, and a physician who ventures upon them on the strength of his medical qualification is in no respect better than a layman. [1923a, 3925]
If a dream brings up situations that can be interpreted as referring to scenes from the dreamer's past, it seems especially important to ask whether the physician's influence can also play a part in such contents of the dream as these. And this question is most urgent of all in the case of what are called 'corroborative' dreams, dreams which, as it were, 'tag along behind' the analysis. With some patients these are the only dreams that one obtains. Such patients reproduce the forgotten experiences of their childhood only after one has constructed them from their symptoms, associations and other signs and has propounded these constructions to them. Then follow the corroborative dreams, concerning which, however, the doubt arises whether they may not be entirely without evidential value, since they may have been imagined in compliance with the physician's words instead of having been brought to light from the dreamer's unconscious. This ambiguous position cannot be escaped in the analysis, since with these patients unless one interprets, constructs and propounds, one never obtains access to what is repressed in them.

An analogy of this kind can of course have no meaning for a patient while the work of analysis is still uncompleted. At this point I recall a discussion which I was led into with a patient whose exceptionally ambivalent attitude was expressed in the most intense compulsive doubt. He did not dispute my interpretations of his dreams and was very much struck by their agreement with the hypotheses which I put forward. But he asked whether these corroborative dreams might not be an expression of his compliance towards me. I pointed out that the dreams had also brought up a quantity of details of which I could have had no suspicion and that his behaviour in the treatment apart from this had not been precisely characterized by compliance. Whereupon he switched over to another theory and asked whether his narcissistic wish to be cured might not have caused him to produce these dreams, since, after all, I had held out to him a prospect of recovery if he were able to accept my constructions. I could only reply that I had not yet come across any such mechanism of dream-formation. But a decision was reached by another road. He recollected some dreams which he had had before starting analysis and indeed before he had known anything about it; and the analysis of these dreams, which were free from all suspicion of suggestion, led to the same interpretations as the later ones. It is true that his obsession for contradiction once more found a way out in the idea that the earlier dreams had been less clear than those that occurred during the treatment; but I was satisfied with their similarity. I think that in general it is a good plan occasionally to bear in mind the fact that people were in the habit of dreaming before there was such a thing as psycho-analysis.

[1923c, 4036]

[1923c, 4037]
Hypnosis had, however, performed the service of restoring to the patient's memory what he had forgotten. It was necessary to find some other technique to replace it; and the idea occurred to Freud of substituting for it the method of 'free association'. That is to say, he pledged his patients to refrain from any conscious reflection and to abandon themselves, in a state of quiet concentration, to following the ideas which occurred to them spontaneously (involuntarily) - 'to skim off the surface of their consciousness'. They were to communicate these ideas to the physician even if they felt objections to doing so, if, for instance, the thoughts seemed too disagreeable, too senseless, too unimportant or irrelevant. The choice of free association as a means of investigating the forgotten unconscious material seems so strange that a word in justification of it will not be out of place. Freud was led to it by an expectation that the so-called 'free' association would prove in fact to be unfree, since, when all conscious intellectual purposes had been suppressed, the ideas that emerged would be seen to be determined by the unconscious material. This expectation was justified by experience. When the 'fundamental rule of psycho-analysis' which has just been stated was obeyed, the course of free association produced a plentiful store of ideas which could put one on the track of what the patient had forgotten. To be sure, this material did not bring up what had actually been forgotten, but it brought up such plain and numerous hints at it that, with the help of a certain amount of supplementing and interpreting, the doctor was able to guess (to reconstruct) the forgotten material from it. Thus free association together with the art of interpretation performed the same function as had previously been performed by hypnotism.

[1924f, 4105]

Thus the strongest resistances to psycho-analysis were not of an intellectual kind but arose from emotional sources. This explained their passionate character as well as their poverty in logic. The situation obeyed a simple formula: men in the mass behaved to psycho-analysis in precisely the same way as individual neurotics under treatment for their disorders. It is possible, however, by patient work to convince these latter individuals that everything happened as we maintained it did: we had not invented it ourselves but had arrived at it from a study of other neurotics covering a period of twenty or thirty years. The position was at once alarming and consoling: alarming because it was no small thing to have the whole human race as one's patient, and consoling because after all everything was taking place as the hypotheses of psycho-analysis declared that it was bound to.

[1925e, 4129]
It may seem surprising that this method of free association, carried out subject to the observation of the fundamental rule of psycho-analysis, should have achieved what was expected of it, namely the bringing into consciousness of the repressed material which was held back by resistances. We must, however, bear in mind that free association is not really free. The patient remains under the influence of the analytic situation even though he is not directing his mental activities on to a particular subject. We shall be justified in assuming that nothing will occur to him that has not some reference to that situation. His resistance against reproducing the repressed material will now be expressed in two ways. Firstly it will be shown by critical objections; and it was to deal with these that the fundamental rule of psycho-analysis was invented. But if the patient observes that rule and so overcomes his reticences, the resistance will find another means of expression. It will so arrange it that the repressed material itself will never occur to the patient but only something which approximates to it in an allusive way; and the greater the resistance, the more remote from the actual idea that the analyst is in search of will be the substitutive association which the patient has to report. The analyst, who listens composedly but without any constrained effort to the stream of associations and who, from his experience, has a general notion of what to expect, can make use of the material brought to light by the patient according to two possibilities. If the resistance is slight he will be able from the patient's allusions to infer the unconscious material itself; or if the resistance is stronger he will be able to recognize its character from the associations, as they seem to become more remote from the topic in hand, and will explain it to the patient. Uncovering the resistance, however, is the first step towards overcoming it. Thus the work of analysis involves an art of interpretation, the successful handling of which may require tact and practice but which is not hard to acquire. But it is not only in the saving of labour that the method of free association has an advantage over the earlier method. It exposes the patient to the least possible amount of compulsion, it never allows of contact being lost with the actual current situation, it guarantees to a great extent that no factor in the structure of the neurosis will be overlooked and that nothing will be introduced into it by the expectations of the analyst. It is left to the patient in all essentials to determine the course of the analysis and the arrangement of the material; any systematic handling of particular symptoms or complexes thus becomes impossible. In complete contrast to what happened with hypnosis and with the urging method, interrelated material makes its appearance at different times and at different points in the treatment. To a spectator, therefore - though in fact there must be none - an analytic treatment would seem completely obscure.
[1925d, 4216]
It is easy now to describe our therapeutic aim. We try to restore the ego, to free it from its restrictions, and to give it back the command over the id which it has lost owing to its early repressions. It is for this one purpose that we carry out analysis, our whole technique is directed to this aim. We have to seek out the repressions which have been set up and to urge the ego to correct them with our help and to deal with conflicts better than by an attempt at flight. Since these repressions belong to the very early years of childhood, the work of analysis leads us, too, back to that period. Our path to these situations of conflict, which have for the most part been forgotten and which we try to revive in the patient's memory, is pointed out to us by his symptoms, dreams and free associations. These must, however, first be interpreted - translated - for, under the influence of the psychology of the id, they have assumed forms of expression that are strange to our comprehension. We may assume that whatever associations, thoughts and memories the patient is unable to communicate to us without internal struggles are in some way connected with the repressed material or are its derivatives. By encouraging the patient to disregard his resistances to telling us these things, we are educating his ego to overcome its inclination towards attempts at flight and to tolerate an approach to what is repressed. In the end, if the situation of the repression can be successfully reproduced in his memory, his compliance will be brilliantly rewarded. The whole difference between his age then and now works in his favour; and the thing from which his childish ego fled in terror will often seem to his adult and strengthened ego no more than child's play.

Let me return to your question about certainty. We have become quite generally convinced from the direct analytic examination of children that we were right in our interpretation of what adults told us about their childhood. In a number of cases, however, another sort of confirmation has become possible. The material of the analysis of some patients has enabled us to reconstruct certain external happenings, certain impressive events of their childhood years, of which they have preserved no conscious memory. Lucky accidents, information from parents or nurses, have afterwards provided irrefutable evidence that these occurrences which we had inferred really did take place. This, of course, has not happened often, but when it has it has made an overwhelming impression. The correct reconstruction, you must know, of such forgotten experiences of childhood always has a great therapeutic effect, whether they permit of objective confirmation or not. These events owe their importance, of course, to their having occurred at such an early age, at a time when they could still produce a traumatic effect on the feeble ego.

'I will add that. Thereupon he begins to talk and I listen. And what then? I infer from what he tells me the kind of impressions, experiences and wishes which he has repressed because he came across them at a time when his ego was still feeble and was afraid of them instead of dealing with them. When he has learnt this from me, he puts himself back in the old situations and with my help he manages better. The limitations to which his ego was tied then disappear, and he is cured. Is that right?'

When one really practises analysis one learns all kinds of things besides. For instance: you would not find it at all such a simple matter to deduce from what the patient tells you the experiences he has forgotten and the instinctual impulses he has repressed. He says something to you which at first means as little to you as it does to him. You will have to make up your mind to look at the material which he delivers to you in obedience to the rule in a quite special way: as though it were ore, perhaps, from which its content of precious metal has to be extracted by a particular process. You will be prepared, too, to work over many tons of ore which may contain but little of the valuable material you are in search of. Here we should have a first reason for the prolonged character of the treatment.
By assuming that the patient's remarks and associations are only distortions of what you are looking for - allusions, as it were, from which you have to guess what is hidden behind them. In a word, this material, whether it consists of memories, associations or dreams, has first to be \textit{interpreted}. You will do this, of course, with an eye to the expectations you have formed as you listened, thanks to your special knowledge.

[1926e, 4361]

"Interpret!" A nasty word! I dislike the sound of it; it robs me of all certainty. If everything depends on my interpretation who can guarantee that I interpret right? So after all everything \textit{is} left to my caprice.¹

[1926e, 4361]

Just a moment! Things are not quite as bad as that. Why do you choose to except your own mental processes from the rule of law which you recognize in other people's? When you have attained some degree of self-discipline and have certain knowledge at your disposal, your interpretations will be independent of your personal characteristics and will hit the mark. I am not saying that the analyst's personality is a matter of indifference for this portion of his task. A kind of sharpness of hearing for what is unconscious and repressed, which is not possessed equally by everyone, has a part to play. And here, above all, we are brought to the analyst's obligation to make himself capable, by a deep-going analysis of his own, of the unprejudiced reception of the analytic material. Something, it is true, still remains over: something comparable to the 'personal equation' in astronomical observations. This individual factor will always play a larger part in psycho-analysis than elsewhere. An abnormal person can become an accurate physicist; as an analyst he will be hampered by his own abnormality from seeing the pictures of mental life undistorted. Since it is impossible to demonstrate to anyone his own abnormality, general agreement in matters of depth-psychology will be particularly hard to reach. Some psychologists, indeed, think it is quite impossible and that every fool has an equal right to give out his folly as wisdom. I confess that I am more of an optimist about this. After all, our experiences show that fairly satisfactory agreements can be reached even in psychology. Every field of research has its particular difficulty which we must try to eliminate. And, moreover, even in the interpretative art of analysis there is much that can be learnt like any other material of study: for instance, in connection with the peculiar method of indirect representation through symbols.

[1926e, 4362]

You are quite right to give up the notion. You see how much more training and practice would be needed. When you have found the right interpretation, another task lies ahead. You must wait for the right moment at which you can communicate your interpretation to the patient with some prospect of success.

[1926e, 4362]

"How can one always tell the right moment?"

[1926e, 4362]

That is a question of tact, which can become more refined with experience. You will be making a bad mistake if, in an effort, perhaps, at shortening the analysis, you throw your interpretations at the patient's head as soon as you have found them. In that way you will draw expressions of resistance, rejection and indignation from him; but you will not enable his ego to master his repressed material. The formula is: to wait till he has come so near to the repressed material that he has only a few more steps to take under the lead of the interpretation you propose.

[1926e, 4362]
Yes, we are only beginning to appreciate the significance of all these important circumstances. That is why my description was bound to turn out so obscure. But now I can proceed. We describe all the forces that oppose the work of recovery as the patient's 'resistances'. The gain from illness is one such resistance. The 'unconscious sense of guilt' represents the super-ego's resistance; it is the most powerful factor, and the one most dreaded by us. We meet with still other resistances during the treatment. If the ego during the early period has set up a repression out of fear, then the fear still persists and manifests itself as a resistance if the ego approaches the repressed material. And finally, as you can imagine, there are likely to be difficulties if an instinctual process which has been going along a particular path for whole decades is suddenly expected to take a new path that has just been made open for it. That might be called the id's resistance. The struggle against all these resistances is our main work during an analytic treatment; the task of making interpretations is nothing compared to it. But as a result of this struggle and of the overcoming of the resistances, the patient's ego is so much altered and strengthened that we can look forward calmly to his future behaviour when the treatment is over. On the other hand, you can understand now why we need such long treatments. The length of the path of development and the wealth of the material are not the decisive factors. It is more a question of whether the path is clear. An army can be held up for weeks on a stretch of country which in peace time an express train crosses in a couple of hours - if the army has to overcome the enemy's resistance there. Such battles call for time in mental life too. I am unfortunately obliged to tell you that every effort to hasten analytic treatment appreciably has hitherto failed. The best way of shortening it seems to be to carry it out according to the rules.

There are at the moment two Institutes at which instruction in psycho-analysis is given. The first has been founded in Berlin by Dr. Max Eitingon, who is a member of the Society there. The second is maintained by the Vienna Psycho-Analytical Society at its own expense and at considerable sacrifice. The part played by the authorities is at present limited to the many difficulties which they put in the way of the young undertaking. A third training Institute is at this moment being opened in London by the Society there, under the direction of Dr. Ernest Jones. At these Institutes the candidates themselves are taken into analysis, receive theoretical instruction by lectures on all the subjects that are important for them, and enjoy the supervision of older and more experienced analysts when they are allowed to make their first trials with comparatively slight cases. A period of some two years is calculated for this training. Even after this period, of course, the candidate is only a beginner and not yet a master. What is still needed must be acquired by practice and by an exchange of ideas in the psycho-analytical societies in which young and old members meet together. Preparation for analytic activity is by no means so easy and simple. The work is hard, the responsibility great. But anyone who has passed through such a course of instruction, who has been analysed himself, who has mastered what can be taught to-day of the psychology of the unconscious, who is at home in the science of sexual life, who has learnt the delicate technique of psycho-analysis, the art of interpretation, of fighting resistances and of handling the transference - anyone who has accomplished all this is no longer a layman in the field of psycho-analysis. He is capable of undertaking the treatment of neurotic disorders, and will be able in time to achieve in that field whatever can be required from this form of therapy.

[1926e, 4366]
Thus we have attributed three qualities to psychical processes: they are either conscious, preconscious or unconscious. The division between the three classes of material which possess these qualities is neither absolute nor permanent. What is preconscious becomes conscious, as we have seen, without any assistance from us; what is unconscious can, through our efforts, be made conscious, and in the process we may have a feeling that we are often overcoming very strong resistances. When we attempt to do this with someone else, we should not forget that the conscious filling-in of the gaps in his perceptions - the construction we are presenting him with - does not mean as yet that we have made the unconscious material in question conscious to him. All that is true so far is that the material is present in him in two records, once in the conscious reconstruction he has been given, and besides this in its original unconscious state. Our continued efforts usually succeed eventually in making this unconscious material conscious to him himself, as a result of which the two records are brought to coincide. The amount of effort we have to use, by which we estimate the resistance against the material becoming conscious, varies in magnitude in individual cases. For instance, what comes about in an analytic treatment as a result of our efforts can also occur spontaneously: material which is ordinarily unconscious can transform itself into preconscious material and then becomes conscious - a thing that happens to a large extent in psychotic states. From this we infer that the maintenance of certain internal resistances is a *sine qua non* of normality. A relaxation of resistances such as this, with a consequent pushing forward of unconscious material, takes place regularly in the state of sleep, and thus brings about a necessary precondition for the construction of dreams. Conversely, preconscious material can become temporarily inaccessible and cut off by resistances, as happens when something is temporarily forgotten or escapes the memory; or a preconscious thought can even be temporarily put back into the unconscious state, as seems to be a precondition in the case of jokes. We shall see that a similar transformation back of preconscious material or processes into the unconscious state plays a great part in the causation of neurotic disorders.

[1940a [1938], 4970]

The evidence of the share taken by the unconscious id in the formation of dreams is abundant and convincing. (a) Memory is far more comprehensive in dreams than in waking life. Dreams bring up recollections which the dreamer has forgotten, which are inaccessible to him when he is awake. (b) Dreams make an unrestricted use of linguistic symbols, the meaning of which is for the most part unknown to the dreamer. Our experience, however, enables us to confirm their sense. They probably originate from earlier phases in the development of speech. (c) Memory very often reproduces in dreams impressions from the dreamer's early childhood of which we can definitely assert not only that they had been forgotten but that they had become unconscious owing to repression. That explains the help - usually indispensable - given us by dreams in the attempts we make during the analytic treatment of neuroses to reconstruct the dreamer's early life. (d) Furthermore, dreams bring to light material which cannot have originated either from the dreamer's adult life or from his forgotten childhood. We are obliged to regard it as part of the *archaic heritage* which a child brings with him into the world, before any experience of his own, influenced by the experiences of his ancestors. We find the counterpart of this phylogenetic material in the earliest human legends and in surviving customs. Thus dreams constitute a source of human prehistory which is not to be despised.

[1940a [1938], 4976]
Our plan of cure is based on these discoveries. The ego is weakened by the internal conflict and we must go to its help. The position is like that in a civil war which has to be decided by the assistance of an ally from outside. The analytic physician and the patient's weakened ego, basing themselves on the real external world, have to band themselves together into a party against the enemies, the instinctual demands of the id and the conscientious demands of the super-ego. We form a pact with each other. The sick ego promises us the most complete candour - promises, that is, to put at our disposal all the material which its self-perception yields it; we assure the patient of the strictest discretion and place at his service our experience in interpreting material that has been influenced by the unconscious. Our knowledge is to make up for his ignorance and to give his ego back its mastery over lost provinces of his mental life. This pact constitutes the analytic situation.

[1940a [1938], 4983]

With the neurotics, then, we make our pact: complete candour on one side and strict discretion on the other. This looks as though we were only aiming at the post of a secular father confessor. But there is a great difference, for what we want to hear from our patient is not only what he knows and conceals from other people; he is to tell us too what he does not know. With this end in view we give him a more detailed definition of what we mean by candour. We pledge him to obey the fundamental rule of analysis, which is henceforward to govern his behaviour towards us. He is to tell us not only what he can say intentionally and willingly, what will give him relief like a confession, but everything else as well that his self-observation yields him, everything that comes into his head, even if it is disagreeable for him to say it, even if it seems to him unimportant or actually nonsensical. If he can succeed after this injunction in putting his self-criticism out of action, he will present us with a mass of material - thoughts, ideas, recollections - which are already subject to the influence of the unconscious, which are often its direct derivatives, and which thus put us in a position to conjecture his repressed unconscious material and to extend, by the information we give him, his ego's knowledge of his unconscious.

[1940a [1938], 4984]
The method by which we strengthen the weakened ego has as a starting-point an extending of its self-knowledge. That is not, of course, the whole story but it is a first step. The loss of such knowledge signifies for the ego a surrender of power and influence; it is the first tangible sign that it is being hemmed in and hampered by the demands of the id and the super-ego. Accordingly, the first part of the help we have to offer is intellectual work on our side and encouragement to the patient to collaborate in it. This first kind of activity, as we know, is intended to pave the way to another, more difficult, task. We shall not lose sight of the dynamic element in this task, even during its preliminary stage. We gather the material for our work from a variety of sources - from what is conveyed to us by the information given us by the patient and by his free associations, from what he shows us in his transferences, from what we arrive at by interpreting his dreams and from what he betrays by his slips or *parapraxes*. All this material helps us to make constructions about what happened to him and has been forgotten as well as about what is happening in him now without his understanding it. But in all this we never fail to make a strict distinction between *our* knowledge and *his* knowledge. We avoid telling him at once things that we have often discovered at an early stage, and we avoid telling him the whole of what we think we have discovered. We reflect carefully over when we shall impart the knowledge of one of our constructions to him and we wait for what seems to us the suitable moment - which it is not always easy to decide. As a rule we put off telling him of a construction or explanation till he himself has so nearly arrived at it that only a single step remains to be taken, though that step is in fact the decisive synthesis. If we proceeded in another way and overwhelmed him with our interpretations before he was prepared for them, our information would either produce no effect or it would provoke a violent outbreak of *resistance* which would make the progress of our work more difficult or might even threaten to stop it altogether. But if we have prepared everything properly, it often happens that the patient will at once confirm our construction and himself recollect the internal or external event which he had forgotten. The more exactly the construction coincides with the details of what has been forgotten the easier will it be for him to assent. On that particular matter *our* knowledge will then have become *his* knowledge as well.

[1940a [1938], 4987]
Let us once more glance over the situation which we have reached in our attempt at bringing help to the patient's neurotic ego. That ego is no longer able to fulfil the task set it by the external world (including human society). Not all of its experiences are at its disposal, a large proportion of its store of memories have escaped it. Its activity is inhibited by strict prohibitions from the super-ego, its energy is consumed in vain attempts at fending off the demands of the id. Beyond this, as a result of continuous irruptions by the id, its organization is impaired, it is no longer capable of any proper synthesis, it is torn by mutually opposed urges, by unsettled conflicts and by unsolved doubts. To start with, we get the patient's thus weakened ego to take part in the purely intellectual work of interpretation, which aims at provisionally filling the gaps in his mental assets, and to transfer to us the authority of his super-ego; we encourage it to take up the struggle over each individual demand made by the id and to conquer the resistances which arise in connection with it. At the same time we restore order in the ego by detecting the material and urges which have forced their way in from the unconscious, and expose them to criticism by tracing them back to their origin. We serve the patient in various functions, as an authority and a substitute for his parents, as a teacher and educator; and we have done the best for him if, as analysts, we raise the mental processes in his ego to a normal level, transform what has become unconscious and repressed into preconscious material and thus return it once more to the possession of his ego. On the patient's side a few rational factors work in our favour, such as the need for recovery which has its motive in his sufferings, and the intellectual interest that we may awaken in him in the theories and revelations of psycho-analysis; but of far greater force is the positive transference with which he meets us. Fighting against us, on the other hand, are the negative transference, the ego's resistance due to repression (that is, its unpleasure at having to lay itself open to the hard work imposed on it), the sense of guilt arising from its relation to the super-ego and the need to be ill due to deep-going changes in the economics of his instincts. The share taken by the last two factors decides whether the case is to be regarded as slight or severe. Apart from these, a few other factors may be discerned as having a favourable or unfavourable bearing. A certain psychical inertia, a sluggishness of the libido, which is unwilling to abandon its fixations cannot be welcome to us; the patient's capacity for sublimating his instincts plays a large part and so does his capacity for rising above the crude life of the instincts; so, too, does the relative power of his intellectual functions.

[1940a [1938], 4990]
It is no doubt true that the impact of the threat of castration upon a boy's budding sexual life does not always have these dreaded consequences. It will depend once again on quantitative relations how much damage is done and how much avoided. The whole occurrence, which may probably be regarded as the central experience of the years of childhood, the greatest problem of early life and the strongest source of later inadequacy, is so completely forgotten that its reconstruction during the work of analysis is met in adults by the most decided disbelief. Indeed, aversion to it is so great that people try to silence any mention of the proscribed subject and the most obvious reminders of it are overlooked by a strange intellectual blindness. One may hear it objected, for instance, that the legend of King Oedipus has in fact no connection with the construction made by analysis: the cases are quite different, since Oedipus did not know that it was his father that he killed and his mother that he married. What is overlooked in this is that a distortion of this kind is inevitable if an attempt is made at a poetic handling of the material, and that there is no introduction of extraneous material but only a skilful employment of the factors presented by the theme. The ignorance of Oedipus is a legitimate representation of the unconscious state into which, for adults, the whole experience has fallen; and the coercive power of the oracle, which makes or should make the hero innocent, is a recognition of the inevitability of the fate which has condemned every son to live through the Oedipus complex. Again it was pointed out from psycho-analytic quarters how easily the riddle of another dramatic hero, Shakespeare's procrastinator, Hamlet, can be solved by reference to the Oedipus complex, since the prince came to grief over the task of punishing someone else for what coincided with the substance of his own Oedipus wish - whereupon the general lack of understanding on the part of the literary world showed how ready is the mass of mankind to hold fast to its infantile repressions.¹

The therapeutic effect depends on making conscious what is repressed, in the widest sense of the word, in the id. We prepare the way for this making conscious by interpretations and constructions, but we have interpreted only for ourselves not for the patient so long as the ego holds on to its earlier defences and does not give up its resistances. Now these resistances, although they belong to the ego, are nevertheless unconscious and in some sense separated off within the ego. The analyst recognizes them more easily than he does the hidden material in the id. One might suppose that it would be sufficient to treat them like portions of the id and, by making them conscious, bring them into connection with the rest of the ego. In this way, we should suppose, one half of the task of analysis would be accomplished; we should not reckon on meeting with a resistance against the uncovering of resistances. But what happens is this. During the work on the resistances the ego withdraws - with a greater or less degree of seriousness - from the agreement on which the analytic situation is founded. The ego ceases to support our efforts at uncovering the id; it opposes them, disobeys the fundamental rule of analysis, and allows no further derivatives of the repressed to emerge. We cannot expect the patient to have a strong conviction of the curative power of analysis. He may have brought along with him a certain amount of confidence in his analyst, which will be strengthened to an effective point by the factors of the positive transference which will be aroused in him. Under the influence of the displeasurable impulses which he feels as a result of the fresh activation of his defensive conflicts, negative transferences may now gain the upper hand and completely annul the analytic situation. The patient now regards the analyst as no more than a stranger who is making disagreeable demands on him, and he behaves towards him exactly like a child who does not like the stranger and does not believe anything he says. If the analyst tries to explain to the patient one of the distortions made by him for the purposes of defence, and to correct it, he finds him uncomprehending and inaccessible to sound arguments. Thus we see that there is a resistance against the uncovering of resistances, and the defensive mechanisms really do deserve the name which we gave them originally, before they had been more closely examined. They are resistances not only to the making conscious of contents of the id, but also to the analysis as a whole, and thus to recovery.
It has always seemed to me to be greatly to the credit of a certain well-known man of science that he treated psycho-analysis fairly at a time when most other people felt themselves under no such obligation. On one occasion, nevertheless, he gave expression to an opinion upon analytic technique which was at once derogatory and unjust. He said that in giving interpretations to a patient we treat him upon the famous principle of 'Heads I win, tails you lose'.¹ That is to say, if the patient agrees with us, then the interpretation is right; but if he contradicts us, that is only a sign of his resistance, which again shows that we are right. In this way we are always in the right against the poor helpless wretch whom we are analysing, no matter how he may respond to what we put forward. Now, since it is in fact true that a 'No' from one of our patients is not as a rule enough to make us abandon an interpretation as incorrect, a revelation such as this of the nature of our technique has been most welcome to the opponents of analysis. It is therefore worth while to give a detailed account of how we are accustomed to arrive at an assessment of the 'Yes' or 'No' of our patients during analytic treatment - of their expression of agreement or of denial. The practising analyst will naturally learn nothing in the course of this apologia that he does not know already.

What we are in search of is a picture of the patient's forgotten years that shall be alike trustworthy and in all essential respects complete. But at this point we are reminded that the work of analysis consists of two quite different portions, that it is carried on in two separate localities, that it involves two people, to each of whom a distinct task is assigned. It may for a moment seem strange that such a fundamental fact should not have been pointed out long ago; but it will immediately be perceived that there was nothing being kept back in this, that it is a fact which is universally known and, as it were, self-evident and is merely being brought into relief here and separately examined for a particular purpose. We all know that the person who is being analysed has to be induced to remember something that has been experienced by him and repressed; and the dynamic determinants of this process are so interesting that the other portion of the work, the task performed by the analyst, has been pushed into the background. The analyst has neither experienced nor repressed any of the material under consideration; his task cannot be to remember anything. What then is his task? His task is to make out what has been forgotten from the traces which it has left behind or, more correctly, to construct it. The time and manner in which he conveys his constructions to the person who is being analysed, as well as the explanations with which he accompanies them, constitute the link between the two portions of the work of analysis, between his own part and that of the patient.

His work of construction, or, if it is preferred, of reconstruction, resembles to a great extent an archaeologist's excavation of some dwelling-place that has been destroyed and buried or of some ancient edifice. The two processes are in fact identical, except that the analyst works under better conditions and has more material at his command to assist him, since what he is dealing with is not something destroyed but something that is still alive - and perhaps for another reason as well. But just as the archaeologist builds up the walls of the building from the foundations that have remained standing, determines the number and position of the columns from depressions in the floor and reconstructs the mural decorations and paintings from the remains found in the debris, so does the analyst proceed when he draws his inferences from the fragments of memories, from the associations and from the behaviour of the subject of the analysis. Both of them have an undisputed right to reconstruct by means of supplementing and combining the surviving remains. Both of them, moreover, are subject to many of the same difficulties and sources of error. One of the most ticklish problems that confronts the archaeologist is notoriously the determination of the relative age of his finds; and if an object makes its appearance in some particular level, it often remains to be decided whether it belongs to that level or whether it was carried down to that level owing to some subsequent disturbance. It is easy to imagine the corresponding doubts that arise in the case of analytic constructions.
The analyst, as we have said, works under more favourable conditions than the archaeologist since he has at his disposal material which can have no counterpart in excavations, such as the repetitions of reactions dating from infancy and all that is indicated by the transference in connection with these repetitions. But in addition to this it must be borne in mind that the excavator is dealing with destroyed objects of which large and important portions have quite certainly been lost, by mechanical violence, by fire and by plundering. No amount of effort can result in their discovery and lead to their being united with the surviving remains. The one and only course open is that of reconstruction, which for this reason can often reach only a certain degree of probability. But it is different with the psychical object whose early history the analyst is seeking to recover. Here we are regularly met by a situation which with the archaeological object occurs only in such rare circumstances as those of Pompeii or of the tomb of Tut'ankhamun. All of the essentials are preserved; even things that seem completely forgotten are present somehow and somewhere, and have merely been buried and made inaccessible to the subject. Indeed, it may, as we know, be doubted whether any psychical structure can really be the victim of total destruction. It depends only upon analytic technique whether we shall succeed in bringing what is concealed completely to light. There are only two other facts that weigh against the extraordinary advantage which is thus enjoyed by the work of analysis: namely, that psychical objects are incomparably more complicated than the excavator's material ones and that we have insufficient knowledge of what we may expect to find, since their finer structure contains so much that is still mysterious. But our comparison between the two forms of work can go no further than this; for the main difference between them lies in the fact that for the archaeologist the reconstruction is the aim and end of his endeavours while for analysis the construction is only a preliminary labour.

It is not, however, a preliminary labour in the sense that the whole of it must be completed before the next piece of work can be begun, as, for instance, is the case with house-building, where all the walls must be erected and all the windows inserted before the internal decoration of the rooms can be taken in hand. Every analyst knows that things happen differently in an analytic treatment and that there both kinds of work are carried on side by side, the one kind being always a little ahead and the other following upon it. The analyst finishes a piece of construction and communicates it to the subject of the analysis so that it may work upon him; he then constructs a further piece out of the fresh material pouring in upon him, deals with it in the same way and proceeds in this alternating fashion until the end. If, in accounts of analytic technique, so little is said about 'constructions', that is because 'interpretations' and their effects are spoken of instead. But I think that 'construction' is by far the more appropriate description. 'Interpretation' applies to something that one does to some single element of the material, such as an association or a parapraxis. But it is a 'construction' when one lays before the subject of the analysis a piece of his early history that he has forgotten, in some such way as this: 'Up to your nth year you regarded yourself as the sole and unlimited possessor of your mother; then came another baby and brought you grave disillusionment. Your mother left you for some time, and even after her reappearance she was never again devoted to you exclusively. Your feelings towards your mother became ambivalent, your father gained a new importance for you,' . . . and so on.
In the present paper our attention will be turned exclusively to this preliminary labour performed by constructions. And here, at the very start, the question arises of what guarantee we have while we are working on these constructions that we are not making mistakes and risking the success of the treatment by putting forward some construction that is incorrect. It may seem that no general reply can in any event be given to this question; but even before discussing it we may lend our ear to some comforting information that is afforded by analytic experience. For we learn from it that no damage is done if, for once in a way, we make a mistake and offer the patient a wrong construction as the probable historical truth. A waste of time is, of course, involved, and anyone who does nothing but present the patient with false combinations will neither create a very good impression on him nor carry the treatment very far; but a single mistake of the sort can do no harm. What in fact occurs in such an event is rather that the patient remains as though he were untouched by what has been said and reacts to it with neither a 'Yes' nor a 'No'. This may possibly mean no more than that his reaction is postponed; but if nothing further develops we may conclude that we have made a mistake and we shall admit as much to the patient at some suitable opportunity without sacrificing any of our authority. Such an opportunity will arise when some new material has come to light which allows us to make a better construction and so to correct our error. In this way the false construction drops out, as if it had never been made; and, indeed, we often get an impression as though, to borrow the words of Polonius, our bait of falsehood had taken a carp of truth. The danger of our leading a patient astray by suggestion, by persuading him to accept things which we ourselves believe but which he ought not to, has certainly been enormously exaggerated. An analyst would have had to behave very incorrectly before such a misfortune could overtake him; above all, he would have to blame himself with not allowing his patients to have their say. I can assert without boasting that such an abuse of 'suggestion' has never occurred in my practice. [1937d, 5053]

It already follows from what has been said that we are not at all inclined to neglect the indications that can be inferred from the patient's reaction when we have offered him one of our constructions. The point must be gone into in detail. It is true that we do not accept the 'No' of a person under analysis at its face value; but neither do we allow his 'Yes' to pass. There is no justification for accusing us of invariably twisting his remarks into a confirmation. In reality things are not so simple and we do not make it so easy for ourselves to come to a conclusion. [1937d, 5054]

A plain 'Yes' from a patient is by no means unambiguous. It can indeed signify that he recognizes the correctness of the construction that has been presented to him; but it can also be meaningless, or can even deserve to be described as 'hypocritical', since it may be convenient for his resistance to make use of an assent in such circumstances in order to prolong the concealment of a truth that has not been discovered. The 'Yes' has no value unless it is followed by indirect confirmations, unless the patient, immediately after his 'Yes', produces new memories which complete and extend the construction. Only in such an event do we consider that the 'Yes' has dealt completely with the subject under discussion. [1937d, 5054]
A 'No' from a person in analysis is quite as ambiguous as a 'Yes', and is indeed of even less value. In some rare cases it turns out to be the expression of a legitimate dissent. Far more frequently it expresses a resistance which may have been evoked by the subject-matter of the construction that has been put forward but which may just as easily have arisen from some other factor in the complex analytic situation. Thus, a patient's 'No' is no evidence of the correctness of a construction, though it is perfectly compatible with it. Since every such construction is an incomplete one, since it covers only a small fragment of the forgotten events, we are free to suppose that the patient is not in fact disputing what has been said to him but is basing his contradiction upon the part that has not yet been uncovered. As a rule he will not give his assent until he has learnt the whole truth - which often covers a very great deal of ground. So that the only safe interpretation of his 'No' is that it points to incompleteness; there can be no doubt that the construction has not told him everything.

[1937d, 5054]

It appears, therefore, that the direct utterances of the patient after he has been offered a construction afford very little evidence upon the question whether we have been right or wrong. It is of all the greater interest that there are indirect forms of confirmation which are in every respect trustworthy. One of these is a form of words that is used (as though by general agreement) with very little variation by the most different people: 'I didn't ever think' (or 'I shouldn't ever have thought') 'that' (or 'of that'). This can be translated without any hesitation into: 'Yes, you're right this time - about my unconscious.' Unfortunately this formula, which is so welcome to the analyst, reaches his ears more often after single interpretations than after he has produced an extensive construction. An equally valuable confirmation is implied (expressed this time positively) when the patient answers with an association which contains something similar or analogous to the content of the construction. Instead of taking an example of this from an analysis (which would be easy to find but lengthy to describe) I prefer to give an account of a small extra-analytical experience which presents a similar situation so strikingly that it produces an almost comic effect. It concerned one of my colleagues who - it was long ago - had chosen me as a consultant in his medical practice. One day, however, he brought his young wife to see me, as she was causing him trouble. She refused on all sorts of pretexts to have sexual relations with him, and what he expected of me was evidently that I should lay before her the consequences of her ill-advised behaviour. I went into the matter and explained to her that her refusal would probably have unfortunate results for her husband's health or would lay him open to temptations that might lead to a break-up of their marriage. At this point he suddenly interrupted me with the remark: 'The Englishman you diagnosed as suffering from a cerebral tumour has died too.' At first the remark seemed incomprehensible; the 'too' in his sentence was a mystery, for we had not been speaking of anyone else who had died. But a short time afterwards I understood. The man was evidently intending to confirm what I had been saying; he was meaning to say: 'Yes, you're certainly quite right. Your diagnosis was confirmed in the case of the other patient too.' It was an exact parallel to the indirect confirmations that we obtain in analysis from associations. I will not attempt to deny that there were other thoughts as well, put on one side by my colleague, which had a share in determining his remark.

[1937d, 5055]
Indirect confirmation from associations that fit in with the content of a construction - that give us a 'too' like the one in my story - provides a valuable basis for judging whether the construction is likely to be confirmed in the course of the analysis. It is particularly striking when, by means of a parapraxis, a confirmation of this kind insinuates itself into a direct denial. I once published elsewhere a nice example of this. The name 'Jauner' (a familiar one in Vienna) came up repeatedly in one of my patient's dreams without a sufficient explanation appearing in his associations. I finally put forward the interpretation that when he said 'Jauner' he probably meant 'Gauner', whereupon he promptly replied: 'That seems to me too "jewagt".' Or there was the other instance, in which, when I suggested to a patient that he considered a particular fee too high, he meant to deny the suggestion with the words 'Ten dollars mean nothing to me' but instead of dollars put in a coin of lower value and said 'ten shillings'.

If an analysis is dominated by powerful factors that impose a negative therapeutic reaction, such as a sense of guilt, a masochistic need for suffering or repugnance to receiving help from the analyst, the patient's behaviour after he has been offered a construction often makes it very easy for us to arrive at the decision that we are in search of. If the construction is wrong, there is no change in the patient; but if it is right or gives an approximation to the truth, he reacts to it with an unmistakable aggravation of his symptoms and of his general condition.

We may sum the matter up by asserting that there is no justification for the reproach that we neglect or underestimate the importance of the attitude taken up by those under analysis towards our constructions. We pay attention to them and often derive valuable information from them. But these reactions on the part of the patient are rarely unambiguous and give no opportunity for a final judgement. Only the further course of the analysis enables us to decide whether our constructions are correct or unserviceable. We do not pretend that an individual construction is anything more than a conjecture which awaits examination, confirmation or rejection. We claim no authority for it, we require no direct agreement from the patient, nor do we argue with him if at first he denies it. In short, we conduct ourselves on the model of a familiar figure in one of Nestroy's farces - the manservant who has a single answer on his lips to every question or objection: 'It will all become clear in the course of future developments.'

How this occurs in the process of the analysis - the way in which a conjecture of ours is transformed into the patient's conviction - this is hardly worth describing. All of it is familiar to every analyst from his daily experience and is intelligible without difficulty. Only one point requires investigation and explanation. The path that starts from the analyst's construction ought to end in the patient's recollection; but it does not always lead so far. Quite often we do not succeed in bringing the patient to recollect what has been repressed. Instead of that, if the analysis is carried out correctly, we produce in him an assured conviction of the truth of the construction which achieves the same therapeutic result as a recaptured memory. The problem of what the circumstances are in which this occurs and of how it is possible that what appears to be an incomplete substitute should nevertheless produce a complete result - all of this is matter for a later enquiry.
I shall conclude this brief paper with a few remarks which open up a wider perspective. I have been struck by the manner in which, in certain analyses, the communication of an obviously apt construction has evoked in the patients a surprising and at first incomprehensible phenomenon. They have had lively recollections called up in them - which they themselves have described as 'ultra-clear' - but what they have recollected has not been the event that was the subject of the construction but details relating to that subject. For instance, they have recollected with abnormal sharpness the faces of the people involved in the construction or the rooms in which something of the sort might have happened, or, a step further away, the furniture in such rooms - on the subject of which the construction had naturally no possibility of any knowledge. This has occurred both in dreams immediately after the construction had been put forward and in waking states resembling phantasies. These recollections have themselves led to nothing further and it has seemed plausible to regard them as the product of a compromise. The 'upward drive' of the repressed, stirred into activity by the putting forward of the construction, has striven to carry the important memory-traces into consciousness; but a resistance has succeeded, not, it is true, in stopping that movement, but in displacing it on to adjacent objects of minor significance.

[1937d, 5057]

These recollections might have been described as hallucinations if a belief in their actual presence had been added to their clearness. The importance of this analogy seemed greater when I noticed that true hallucinations occasionally occurred in the case of other patients who were certainly not psychotic. My line of thought proceeded as follows. Perhaps it may be a general characteristic of hallucinations to which sufficient attention has not hitherto been paid that in them something that has been experienced in infancy and then forgotten returns - something that the child has seen or heard at a time when he could still hardly speak and that now forces its way into consciousness, probably distorted and displaced owing to the operation of forces that are opposed to this return. And, in view of the close relation between hallucinations and particular forms of psychosis, our line of thought may be carried still further. It may be that the delusions into which these hallucinations are so constantly incorporated may themselves be less independent of the upward drive of the unconscious and the return of the repressed than we usually assume. In the mechanism of a delusion we stress as a rule only two factors: the turning away from the real world and its motive forces on the one hand, and the influence exercised by wish-fulfilment on the content of the delusion on the other. But may it not be that the dynamic process is rather that the turning away from reality is exploited by the upward drive of the repressed in order to force its content into consciousness, while the resistances stirred up by this process and the trend to wish-fulfilment share the responsibility for the distortion and displacement of what is recollected? This is after all the familiar mechanism of dreams, which intuition has equated with madness from time immemorial.

[1937d, 5058]
I am aware that it is of small service to handle so important a subject in the cursory fashion that I have here employed. But none the less I have not been able to resist the seduction of an analogy. The delusions of patients appear to me to be the equivalents of the constructions which we build up in the course of an analytic treatment - attempts at explanation and cure, though it is true that these, under the conditions of a psychosis, can do no more than replace the fragment of reality that is being disavowed in the present by another fragment that had already been disavowed in the remote past. It will be the task of each individual investigation to reveal the intimate connections between the material of the present disavowal and that of the original repression. Just as our construction is only effective because it recovers a fragment of lost experience, so the delusion owes its convincing power to the element of historical truth which it inserts in the place of the rejected reality. In this way a proposition which I originally asserted only of hysteria would apply also to delusions - namely, that those who are subject to them are suffering from their own reminiscences. I never intended by this short formula to dispute the complexity of the causation of the illness or to exclude the operation of many other factors.

[1937d, 5059]
The procedure is laborious and time-consuming for the physician. It presupposes great interest in psychological happenings, but personal concern for the patients as well. I cannot imagine bringing myself to delve into the psychical mechanism of a hysteria in anyone who struck me as low-minded and repellent, and who, on closer acquaintance, would not be capable of arousing human sympathy; whereas I can keep the treatment of a tabetic or rheumatic patient apart from personal approval of this kind. The demands made on the patient are not less. The procedure is not applicable at all below a certain level of intelligence, and it is made very much more difficult by any trace of feebleness of mind. The complete consent and complete attention of the patients are needed, but above all their confidence, since the analysis invariably leads to the disclosure of the most intimate and secret psychical events. A good number of the patients who would be suitable for this form of treatment abandon the doctor as soon as the suspicion begins to dawn on them of the direction in which the investigation is leading. For patients such as these the doctor has remained a stranger. With others, who have decided to put themselves in his hands and place their confidence in him - a step which in other such situations is only taken voluntarily and never at the doctor's request - with these other patients, I say, it is almost inevitable that their personal relation to him will force itself, for a time at least, unduly into the foreground. It seems, indeed, as though an influence of this kind on the part of the doctor is a *sine qua non* to a solution of the problem. I do not think any essential difference is made in this respect whether hypnosis can be used or whether it has to be bypassed and replaced by something else. But reason demands that we should emphasize the fact that these drawbacks, though they are inseparable from our procedure, cannot be laid at its door. On the contrary, it is quite clear that they are based on the predetermining conditions of the neuroses that are to be cured and that they must attach to any medical activity which involves intense preoccupation with the patient and leads to a psychical change in him. I have not been able to attribute any deleterious effects or danger to the employment of hypnosis, though I made copious use of it in some of my cases. Where I caused damage, the reasons lay elsewhere and deeper. If I survey my therapeutic efforts during the last few years since the communications made by my honoured teacher and friend Josef Breuer showed me the use of the cathartic method, I believe that in spite of everything, I have done much more, and more frequent, good than harm and have accomplished some things which no other therapeutic procedure could have achieved. It has on the whole, as the 'Preliminary Communication' put it, brought 'considerable therapeutic advantages'.

[1895d, 235]

Besides the intellectual motives which we mobilize to overcome the resistance, there is an affective factor, the personal influence of the physician, which we can seldom do without, and in a number of cases the latter alone is in a position to remove the resistance. The situation here is no different from what it is elsewhere in medicine and there is no therapeutic procedure of which one may say that it can do entirely without the co-operation of this personal factor.

[1895d, 249]

I have already indicated the important part played by the figure of the physician in creating motives to defeat the psychical force of resistance. In not a few cases, especially with women and where it is a question of elucidating erotic trains of thought, the patient's co-operation becomes a personal sacrifice, which must be compensated by some substitute for love. The trouble taken by the physician and his friendliness have to suffice for such a substitute. If, now, this relation of the patient to the physician is disturbed, her co-operativeness fails, too; when the physician tries to investigate the next pathological idea, the patient is held up by an intervening consciousness of the complaints against the physician that have been accumulating in her. In my experience this obstacle arises in three principal cases.

[1895d, 266]
When anything in a dream has the character of direct speech, that is to say, when it is said or heard and not merely thought (and it is easy as a rule to make the distinction with certainty), then it is derived from something actually spoken in waking life - though, to be sure, this something is merely treated as raw material and may be cut up and slightly altered and, more especially, divorced from its context.¹ In carrying out an interpretation, one method is to start from spoken phrases of this kind. What, then, was the origin of the butcher's remark 'That's not obtainable any longer'? The answer was that it came from me myself. A few days earlier I had explained to the patient that the earliest experiences of childhood were 'not obtainable any longer as such', but were replaced in analysis by 'transferences' and dreams. So I was the butcher and she was rejecting these transferences into the present of old habits of thinking and feeling. -What, again, was the origin of her own remark in the dream 'I don't recognize that; I won't take it'? For the purposes of the analysis this had to be divided up. 'I don't recognize that' was something she had said the day before to her cook, with whom she had had a dispute; but at the time she had gone on: 'Behave yourself properly!' At this point there had clearly been a displacement. Of the two phrases that she had used in the dispute with her cook, she had chosen the insignificant one for inclusion in the dream. But it was only the suppressed one, 'Behave yourself properly!' that fitted in with the rest of the content of the dream: those would have been the appropriate words to use if someone had ventured to make improper suggestions and had forgotten 'to close his meat-shop'. The allusions underlying the incident with the vegetable-seller were a further confirmation that our interpretation was on the right track. A vegetable that is sold tied up in bundles (lengthways, as the patient added afterwards) and is also black, could only be a dream-combination of asparagus and black (Spanish) radishes. No knowledgeable person of either sex will ask for an interpretation of asparagus. But the other vegetable - 'Schwarzer Retting' - can be taken as an exclamation - 'Schwarzer rett' dich!' -, and accordingly it too seems to hint at the same sexual topic which we suspected at the very beginning, when we felt inclined to introduce the phrase about the meat-shop being closed into the original account of the dream. We need not enquire now into the full meaning of the dream. So much is quite clear: it had a meaning and that meaning was far from innocent.²

I believe I can trace my enthusiasm for the Carthaginian general a step further back into my childhood; so that once more it would only have been a question of a transference of an already formed emotional relation on to a new object. One of the first books that I got hold of when I had learnt to read was Thiers' history of the Consulate and Empire. I can still remember sticking labels on the flat backs of my wooden soldiers with the names of Napoleon's marshals written on them. And at that time my declared favourite was already Massena (or to give the name its Jewish form, Manasseh).² (No doubt this preference was also partly to be explained by the fact that my birthday fell on the same day as his, exactly a hundred years later.) Napoleon himself lines up with Hannibal owing to their both having crossed the Alps. It may even be that the development of this martial ideal is traceable still further back into my childhood: to the times when, at the age of three, I was in a close relation, sometimes friendly but some times warlike, with a boy a year older than myself, and to the wishes which that relation must have stirred up in the weaker of us.

[1900a, 671]

[1900a, 681]
ANALYSIS. - It is no easy matter to give a complete interpretation of the dream. It formed part of a cycle of dreams and can only be fully understood if it is taken in connection with the others. There is difficulty in obtaining in sufficient isolation the material necessary for establishing the symbolism. - In the first place, the patient declared that the train journey was to be interpreted historically, as an allusion to a journey she had taken when she was leaving a sanatorium for nervous diseases, with whose director, needless to say, she had been in love. Her mother had fetched her away, and the doctor had appeared at the station and handed her a bouquet of flowers as a parting present. It had been very awkward that her mother should have witnessed this tribute. At this point, then, her mother figured as interfering with her attempts at a love affair; and this had in fact been the part played by that severe lady during the patient's girlhood. - Her next association related to the sentence: 'she looked round to see whether the parts could not be seen from behind.' The façade of the dream would of course lead one to think of the parts of her little daughter who had been run over and mangled. But her association led in quite another direction. She recollected having once seen her father naked in the bath room from behind; she went on to talk of the distinctions between the sexes, and laid stress on the fact that a man's genitals can be seen even from behind but a woman's cannot. In this connection she herself interpreted 'the little one' as meaning the genitals and 'her little one' - she had a four-year-old daughter - as her own genitals. She reproached her mother with having expected her to live as though she had no genitals, and pointed out that the same reproach was expressed in the opening sentence of the dream: 'her mother sent her little one away, so that she had to go by herself.' In her imagination 'going by herself in the streets' meant not having a man, not having any sexual relations ('coire' in Latin means literally 'to go with') - and she disliked that. Her accounts all went to show that when she was a girl she had in fact suffered from her mother's jealousy owing to the preference shown her by her father.

Dora had listened to me without any of her usual contradictions. She seemed to be moved; she said good-bye to me very warmly, with the heartiest wishes for the New Year, and - came no more. Her father, who called on me two or three times afterwards, assured me that she would come back again, and said it was easy to see that she was eager for the treatment to continue. But it must be confessed that Dora's father was never entirely straightforward. He had given his support to the treatment so long as he could hope that I should 'talk' Dora out of her belief that there was something more than a friendship between him and Frau K. His interest faded when he observed that it was not my intention to bring about that result. I knew Dora would not come back again. Her breaking off so unexpectedly, just when my hopes of a successful termination of the treatment were at their highest, and her thus bringing those hopes to nothing - this was an unmistakable act of vengeance on her part. Her purpose of self-injury also profited by this action. No one who, like me, conjures up the most evil of those half-tamed demons that inhabit the human breast, and seeks to wrestle with them, can expect to come through the struggle unscathed. Might I perhaps have kept the girl under my treatment if I myself had acted a part, if I had exaggerated the importance to me of her staying on, and had shown a warm personal interest in her - a course which, even after allowing for my position as her physician, would have been tantamount to providing her with a substitute for the affection she longed for? I do not know. Since in every case a portion of the factors that are encountered under the form of resistance remains unknown, I have always avoided acting a part, and have contented myself with practising the humbler arts of psychology. In spite of every theoretical interest and of every endeavour to be of assistance as a physician, I keep the fact in mind that there must be some limits set to the extent to which psychological influence may be used, and I respect as one of these limits the patient's own will and understanding.
Nor is the case of whose history and treatment I have published a fragment in these pages well calculated to put the value of psycho-analytic therapy in its true light. Not only the briefness of the treatment (which hardly lasted three months) but another factor inherent in the nature of the case prevented results being brought about such as are attainable in other instances, where the improvement will be admitted by the patient and his relatives and will approximate more or less closely to a complete recovery. Satisfactory results of this kind are reached when the symptoms are maintained solely by the internal conflict between the impulses concerned with sexuality. In such cases the patient's condition will be seen improving in proportion as he is helped towards a solution of his mental problems by the translation of pathogenic into normal material. The course of events is very different when the symptoms have become enlisted in the service of external motives, as had happened with Dora during the two preceding years. It is surprising, and might easily be misleading, to find that the patient's condition shows no noticeable alteration even though considerable progress has been made with the work of analysis. But in reality things are not as bad as they seem. It is true that the symptoms do not disappear while the work is proceeding; but they disappear a little while later, when the relations between patient and physician have been dissolved. The postponement of recovery or improvement is really only caused by the physician's own person.

[1905e, 1449]

I must go back a little, in order to make the matter intelligible. It may be safely said that during psycho-analytic treatment the formation of new symptoms is invariably stopped. But the productive powers of the neurosis are by no means extinguished; they are occupied in the creation of a special class of mental structures, for the most part unconscious, to which the name of 'transferences' may be given.

[1905e, 1450]

What are transferences? They are new editions or facsimiles of the impulses and phantasies which are aroused and made conscious during the progress of the analysis; but they have this peculiarity, which is characteristic for their species, that they replace some earlier person by the person of the physician. To put it another way: a whole series of psychological experiences are revived, not as belonging to the past, but as applying to the person of the physician at the present moment. Some of these transferences have a content which differs from that of their model in no respect whatever except for the substitution. These then - to keep to the same metaphor - are merely new impressions or reprints. Others are more ingeniously constructed; their content has been subjected to a moderating influence - to sublimation, as I call it - and they may even become conscious, by cleverly taking advantage of some real peculiarity in the physician's person or circumstances and attaching themselves to that. These, then, will no longer be new impressions, but revised editions.

[1905e, 1450]

If the theory of analytic technique is gone into, it become, evident that transference is an inevitable necessity. Practical experience, at all events, shows conclusively that there is no means of avoiding it, and that this latest creation of the disease must be combated like all the earlier ones. This happens, however, to be by far the hardest part of the whole task. It is easy to learn how to interpret dreams, to extract from the patient's associations his unconscious thoughts and memories, and to practise similar explanatory arts: for these the patient himself will always provide the text. Transference is the one thing the presence of which has to be detected almost without assistance and with only the slightest clues to go upon, while at the same time the risk of making arbitrary inferences has to be avoided. Nevertheless, transference cannot be evaded, since use is made of it in setting up all the obstacles that make the material inaccessible to treatment, and since it is only after the transference has been resolved that a patient arrives at a sense of conviction of the validity of the connections which have been constructed during the analysis.

[1905e, 1450]
Some people may feel inclined to look upon it as a serious objection to a method which is in any case troublesome enough that it itself should multiply the labours of the physician by creating a new species of pathological mental products. They may even be tempted to infer from the existence of transferences that the patient will be injured by analytic treatment. Both these suppositions would be mistaken. The physician's labours are not multiplied by transference; it need make no difference to him whether he has to overcome any particular impulse of the patient's in connection with himself or with some one else. Nor does the treatment force upon the patient, in the shape of transference, any new task which he would not other wise have performed. It is true that neuroses may be cured in institutions from which psycho-analytic treatment is excluded, that hysteria may be said to be cured not by the method but by the physician, and that there is usually a sort of blind dependence and a permanent bond between a patient and the physician who has removed his symptoms by hypnotic suggestion; but the scientific explanation of all these facts is to be found in the existence of 'transferences' such as are regularly directed by patients on to their physicians. Psycho-analytic treatment does not create transferences, it merely brings them to light, like so many other hidden psychical factors. The only difference is this - that spontaneously a patient will only call up affectionate and friendly transferences to help towards his recovery; if they cannot be called up, he feels the physician is 'antipathetic' to him, and breaks away from him as fast as possible and without having been influenced by him. In psycho-analysis, on the other hand, since the play of motives is different, all the patient's tendencies, including hostile ones, are aroused; they are then turned to account for the purposes of the analysis by being made conscious, and in this way the transference is constantly being destroyed. Transference, which seems ordained to be the greatest obstacle to psycho-analysis, becomes its most powerful ally, if its presence can be detected each time and explained to the patient.¹

[1905e, 1451]
I have been obliged to speak of transference, for it is only by means of this factor that I can elucidate the peculiarities of Dora's analysis. Its great merit, namely, the unusual clarity which makes it seem so suitable as a first introductory publication, is closely bound up with its great defect, which led to its being broken off prematurely. I did not succeed in mastering the transference in good time. Owing to the readiness with which Dora put one part of the pathogenic material at my disposal during the treatment, I neglected the precaution of looking out for the first signs of transference, which was being prepared in connection with another part of the same material a part of which I was in ignorance. At the beginning it was clear that I was replacing her father in her imagination, which was not unlikely, in view of the difference between our ages. She was even constantly comparing me with him consciously, and kept anxiously trying to make sure whether I was being quite straightforward with her, for her father 'always preferred secrecy and roundabout ways'. But when the first dream came, in which she gave herself the warning that she had better leave my treatment just as she had formerly left Herr K.'s house, I ought to have listened to the warning myself. 'Now,' I ought to have said to her, 'it is from Herr K. that you have made a transference on to me. Have you noticed anything that leads you to suspect me of evil intentions similar (whether openly or in some sublimated form) to Herr K.'s? Or have you been struck by anything about me or got to know anything about me which has caught your fancy, as happened previously with Herr K.' Her attention would then have been turned to some detail in our relations, or in my person or circumstances, behind which there lay concealed something analogous but immeasurably more important concerning Herr K. And when this transference had been cleared up, the analysis would have obtained access to new memories, dealing, probably, with actual events. But I was deaf to this first note of warning, thinking I had ample time before me, since no further stages of transference developed and the material for the analysis had not yet run dry. In this way the transference took me unawares, and, because of the unknown quantity in me which reminded Dora of Herr K., she took her revenge on me as she wanted to take her revenge on him, and deserted me as she believed herself to have been deceived and deserted by him. Thus she acted out an essential part of her recollections and phantasies instead of reproducing it in the treatment. What this unknown quantity was I naturally cannot tell. I suspect that it had to do with money, or with jealousy of another patient who had kept up relations with my family after her recovery. When it is possible to work transferences into the analysis at an early stage, the course of the analysis is retarded and obscured, but its existence is better guaranteed against sudden and overwhelming resistances.

[1905e, 1452]

In Dora's second dream there are several clear allusions to transference. At the time she was telling me the dream I was still unaware (and did not learn until two days later) that we had only two hours more work before us. This was the same length of time which she had spent in front of the Sistine Madonna, and which (by making a correction and putting 'two hours' instead of 'two and a half hours') she had taken as the length of the walk which she had not made round the lake. The striving and waiting in the dream, which related to the young man in Germany, and had their origin in her waiting till Herr K. could marry her, had been expressed in the transference a few days before. The treatment, she had thought, was too long for her; she would never have the patience to wait so long. And yet in the first few weeks she had had discernment enough to listen without making any such objections when I informed her that her complete recovery would require perhaps a year. Her refusing in the dream to be accompanied, and preferring to go alone, also originated from her visit to the gallery at Dresden, and I was myself to experience them on the appointed day. What they meant was, no doubt: 'Men are all so detestable that I would rather not marry. This is my revenge.'

[1905e, 1453]
If cruel impulses and revengeful motives, which have already been used in the patient's ordinary life for maintaining her symptoms, become transferred on to the physician during treatment, before he has had time to detach them from himself by tracing them back to their sources, then it is not to be wondered at if the patient's condition is unaffected by his therapeutic efforts. For how could the patient take a more effective revenge than by demonstrating upon her own person the helplessness and incapacity of the physician? Nevertheless, I am not inclined to put too low a value on the therapeutic results even of such a fragmentary treatment as Dora's. [1905e, 1454]

There are many very effective mental procedures which the physician is obliged to renounce. He either has not the power or has not the right to invoke them. This applies in particular to the provocation of strong affects - the most powerful of all the means by which the mind affects the body. The vicissitudes of life often cure illnesses through the experience of great joy, through the satisfaction of needs or the fulfilment of wishes. The physician, who is often impotent outside his profession, cannot compete along these lines. It might be more within his power to employ fear and fright for therapeutic ends; but, except in the case of children, he must have the gravest doubts about the use of such double-edged tools. On the other hand, the physician must rule out any relations with his patient that are bound up with tender feelings, owing to their implications in practical life. Thus from the first his power to bring about mental changes in his patients seems so restricted that mental treatment conducted on a deliberate plan would seem to offer no advantages over the earlier haphazard method. [1890a, 1595]

But the similarity between Gradiva's procedure and the analytic method of psychotherapy is not limited to these two points - the making conscious of what has been repressed and the coinciding of explanation with cure. It also extends to what turns out to be the essence of the whole change - to the awakening of feelings. Every disorder analogous to Hanold's delusion, what in scientific terms we are in the habit of calling 'psychoneuroses', has as its precondition the repression of a portion of instinctual life, or, as we can safely say, of the sexual instinct. At every attempt to introduce the unconscious and repressed causes of the illness into consciousness, the instinctual component concerned is necessarily aroused to a renewed struggle with the repressing powers, only to come to terms with them in the final outcome, often to the accompaniment of violent manifestations of reaction. The process of cure is accomplished in a relapse into love, if we combine all the many components of the sexual instinct under the term 'love'; and such a relapse is indispensable, for the symptoms on account of which the treatment has been undertaken are nothing other than precipitates of earlier struggles connected with repression or the return of the repressed, and they can only be resolved and washed away by a fresh high tide of the same passions. Every psycho-analytic treatment is an attempt at liberating repressed love which has found a meagre outlet in the compromise of a symptom. Indeed, the agreement between such treatments and the process of cure described by the author of Gradiva reaches its climax in the further fact that in analytic psychotherapy too the re-awakened passion, whether it is love or hate, invariably chooses as its object the figure of the doctor. [1907a, 1881]
It is here that the differences begin, which made the case of Gradiva an ideal one which medical technique cannot attain. Gradiva was able to return the love which was making its way from the unconscious into consciousness, but the doctor cannot. Gradiva had herself been the object of the earlier, repressed love; her figure at once offered the liberated current of love a desirable aim. The doctor has been a stranger, and must endeavour to become a stranger once more after the cure; he is often at a loss what advice to give the patients he has cured as to how in real life they can use their recovered capacity to love. To indicate the expediency and substitutes of which the doctor therefore makes use to help him to approximate with more or less success to the model of a cure by love which has been shown us by our author - all this would take us much too far away from the task before us.

[1907a, 1882]

He once brought me a dream which represented the same conflict in relation to his transference on to the physician. He dreamt that my mother was dead; he was anxious to offer me his condolences, but was afraid that in doing so he might break into an impertinent laugh, as he had repeatedly done on similar occasions in the past. He preferred, therefore, to leave a card on me with 'p. c.' written on it; but as he was writing them the letters turned into 'p. f.'²

[1909d, 2152]

As was to be expected, the patient did not, to begin with, accept my elucidation of the matter. He could not imagine, he said, that the plan of marriage could have had any such effects: it had not made the slightest impression on him at the time. But in the further course of treatment he was forcibly brought to believe in the truth of my suspicion, and in a most singular manner. With the help of a transference phantasy, he experienced, as though it were new and belonged to the present, the very episode from the past which he had forgotten, or which had only passed though his mind unconsciously. There came an obscure and difficult period in the treatment; eventually it turned out that he had once met a young girl on the stairs in my house and had on the spot promoted her into being my daughter. She had pleased him, and he pictured to himself that the only reason I was so kind and incredibly patient with him was that I wanted to have him for a son-in-law. At the same time he raised the wealth and position of my family to a level which agreed with the model he had in mind. But his undying love for his lady fought against the temptation. After we had gone though a series of the severest resistances and bitterest vituperations on his part, he could no longer remain blind to the overwhelming effect of the perfect analogy between the transference phantasy and the actual state of affairs in the past. I will repeat one of the dreams which he had at this period, so as to give an example of his manner of treating the subject. He dreamt that he saw my daughter in front of him; she had two patches of dung instead of eyes. No one who understands the language of dreams will find much difficulty in translating this one: it declared that he was marrying my daughter not for her 'beaux yeux' but for her money.

[1909d, 2157]
A discussion of this childhood scene will be found in the footnote, and here I will only remark that its emergence shook the patient for the first time in his refusal to believe that at some prehistoric period in his childhood he had been seized with fury (which had subsequently become latent) against the father whom he loved so much. I must confess that I had expected it to have a greater effect, for the incident had been described to him so often - even by his father himself - that there could be no doubt of its objective reality. But, with that capacity for being illogical which never fails to bewilder one in such highly intelligent people as obsessional neurotics, he kept urging against the evidential value of the story the fact that he himself could not remember the scene. And so it was only along the painful road of transference that he was able to reach a conviction that his relation to his father really necessitated the postulation of this unconscious complement. Things soon reached a point at which, in his dreams, his waking phantasies, and his associations, he began heaping the grossest and filthiest abuse upon me and my family, though in his deliberate actions he never treated me with anything but the greatest respect. His demeanour as he repeated these insults to me was that of a man in despair. 'How can a gentleman like you, sir,' he used to ask, 'let yourself be abused in this way by a low, good-for-nothing fellow like me? You ought to turn me out: that's all I deserve.' While he talked like this, he would get up from the sofa and roam about the room, - a habit which he explained at first as being due to delicacy of feeling: he could not bring himself, he said, to utter such horrible things while he was lying there so comfortably. But soon he himself found a more cogent explanation, namely, that he was avoiding my proximity for fear of my giving him a beating. If he stayed on the sofa he behaved like some one in desperate terror trying to save himself from castigations of terrific violence; he would bury his head in his hands, cover his face with his arm, jump up suddenly and rush away, his features distorted with pain, and so on. He recalled that his father had had a passionate temper, and sometimes in his violence had not known where to stop. Thus, little by little, in this school of suffering, the patient won the sense of conviction which he had lacked - though to any disinterested mind the truth would have been almost self-evident.

If you will now bring together the means we possess for uncovering what is concealed, forgotten and repressed in the mind (the study of the ideas occurring to patients under free association, of their dreams and of their faulty and symptomatic actions), and if you will add to these the exploitation of certain other phenomena which occur during psycho-analytic treatment and on which I shall have a few remarks to make later under the heading of 'transference' - if you bear all these in mind, you will agree with me in concluding that our technique is already efficient enough to fulfil its task, to bring the pathogenic psychical material into consciousness and so to get rid of the ailments that have been brought about by the formation of substitutive symptoms. And if, in the course of our therapeutic endeavours, we extend and deepen our knowledge of the human mind both in health and sickness, that can, of course, only be regarded as a peculiar attraction in our work.
I have not yet told you, Ladies and Gentlemen, of the most important of the observations which confirm our hypothesis of the sexual instinctual forces operating in neuroses. In every psycho-analytic treatment of a neurotic patient the strange phenomenon that is known as 'transference' makes its appearance. The patient, that is to say, directs towards the physician a degree of affectionate feeling (mingled, often enough, with hostility) which is based on no real relation between them and which - as is shown by every detail of its emergence - can only be traced back to old wishful phantasies of the patient's which have become unconscious. Thus the part of the patient's emotional life which he can no longer recall to memory is re-experienced by him in his relation to the physician; and it is only this re-experiencing in the 'transference' that convinces him of the existence and of the power of these unconscious sexual impulses. His symptoms, to take an analogy from chemistry, are precipitates of earlier experiences in the sphere of love (in the widest sense of the word), and it is only in the raised temperature of his experience of the transference that they can be resolved and reduced to other psychical products. In this reaction the physician, if I may borrow an apt phrase from Ferenczi (1909), plays the part of a catalytic ferment, which temporarily attracts to itself the affects liberated in the process. A study of transference, too, can give you the key to an understanding of hypnotic suggestion, which we employed to begin with as a technical method for investigating the unconscious in our patients. At that time hypnosis was found to be a help therapeutically, but a hindrance to the scientific understanding of the facts; for it cleared away the psychical resistances in a certain area while building them up into an unscalable wall at its frontiers. You must not suppose, moreover, that the phenomenon of transference (of which, unfortunately, I can tell you all too little to-day) is created by psycho-analytic influence. Transference arises spontaneously in all human relationships just as it does between the patient and the physician. It is everywhere the true vehicle of therapeutic influence; and the less its presence is suspected, the more powerfully it operates. So psycho-analysis does not create it, but merely reveals it to consciousness and gains control of it in order to guide psychical processes towards the desired goal. I cannot, however, leave the topic of transference without stressing the fact that this phenomenon plays a decisive part in bringing conviction not only to the patient but also to the physician. I know it to be true of all my followers that they were only convinced of the correctness of my assertions on the pathogenesis of the neuroses by their experiences with transference; and I can very well understand that such certainty of judgement cannot be attained before one has carried out psycho-analyses and has oneself observed the workings of transference.

[1910a, 2236]
(a) Advances in our knowledge. We are, of course, still a long way from knowing all that is required for an understanding of the unconscious in our patients. It is clear that every advance in our knowledge means an increase in our therapeutic power. As long as we have understood nothing, we have accomplished nothing; the more we understand, the more we shall achieve. At its beginning psycho-analytic treatment was inexorable and exhausting. The patient had to say everything himself, and the physician's activity consisted of urging him on incessantly. To-day things have a more friendly air. The treatment is made up of two parts - what the physician infers and tells the patient, and the patient's working-over of what he has heard. The mechanism of our assistance is easy to understand: we give the patient the conscious anticipatory idea and he then finds the repressed unconscious idea in himself on the basis of its similarity to the anticipatory one. This is the intellectual help which makes it easier for him to overcome the resistances between conscious and unconscious. Incidentally, I may remark that it is not the only mechanism made use of in analytic treatment; you all know the far more powerful one which lies in the use of the 'transference'. It is my intention in the near future to deal with these various factors, which are so important for an understanding of the treatment, in an Allgemeine Methodik der Psychoanalyse. And further, in speaking to you I need not rebut the objection that the evidential value in support of the correctness of our hypotheses is obscured in our treatment as we practise it to-day; you will not forget that this evidence is to be found elsewhere, and that a therapeutic procedure cannot be carried out in the same way as a theoretical investigation.

[1910d, 2307]

I will not dwell on the awkward predicament in which I was placed by this visit, but instead will consider the conduct of the practitioner who sent this lady to me. First, however, let us bear a reservation in mind which may possibly not be superfluous - indeed we will hope so. Long years of experience have taught me - as they could teach everyone else - not to accept straight away as true what patients, especially nervous patients, relate about their physician. Not only does a nerve-specialist easily become the object of many of his patients' hostile feelings, whatever method of treatment he employs; he must also sometimes resign himself to accepting responsibility, by a kind of projection, for the buried repressed wishes of his nervous patients. It is a melancholy but significant fact that such accusations nowhere find credence more readily than among other physicians.

[1910k, 2374]

Since, however, psycho-analysis cannot dispense with giving this information, it lays down that this shall not be done before two conditions have been fulfilled. First, the patient must, through preparation, himself have reached the neighbourhood of what he has repressed, and secondly, he must have formed a sufficient attachment (transference) to the physician for his emotional relationship to him to make a fresh flight impossible.

[1910k, 2379]
I can well imagine what a dubious hypothesis it must appear to be to suppose that a man's friendly feeling towards his doctor can suddenly break out in an intensified form after a lapse of eight years¹ and become the occasion of such a severe mental disorder. But I do not think we should be justified in dismissing such a hypothesis merely on account of its inherent improbability, if it recommends itself to us on other grounds; we ought rather to inquire how far we shall get if we follow it up. For the improbability may be of a passing kind and may be due to the fact that the doubtful hypothesis has not as yet been brought into relation with any other pieces of knowledge and that it is the first hypothesis with which the problem has been approached. But for the benefit of those who are unable to hold their judgement in suspense and who regard our hypothesis as altogether untenable, it is easy to suggest a possibility which would rob it of its bewildering character. The patient's friendly feeling towards his doctor may very well have been due to a process of 'transference', by means of which an emotional cathexis became transposed from some person who was important to him on to the doctor who was in reality indifferent to him; so that the doctor will have been chosen as a deputy or surrogate for some one much closer to him. To put the matter in a more concrete form: the patient was reminded of his brother or father by the figure of the doctor, he rediscovered them in him; there will then be nothing to wonder at if, in certain circumstances, a longing for the surrogate figure reappeared in him and operated with a violence that is only to be explained in the light of its origin and primary significance.

[1911c, 2419]

If we pursue this train of thought, which seems to be a legitimate one, we shall be driven to the conclusion that the other person must have been his father; this makes it all the clearer that Flechsig must have stood for his brother - who, let us hope, may have been older than himself.¹ The feminine phantasy, which aroused such violent opposition in the patient, thus had its root in a longing, intensified to an erotic pitch, for his father and brother. This feeling, so far as it referred to his brother, passed, by a process of transference, on to his doctor, Flechsig; and when it was carried back on to his father a settlement of the conflict was reached.

[1911c, 2422]

The almost inexhaustible topic of transference has recently been dealt with by Wilhelm Stekel in this journal on descriptive lines. I should like in the following pages to add a few remarks to explain how it is that transference is necessarily brought about during a psycho-analytic treatment, and how it comes to play its familiar part in it.

[1912b, 2457]
It must be understood that each individual, through the combined operation of his innate disposition and the influences brought to bear on him during his early years, has acquired a specific method of his own in his conduct of his erotic life - that is, in the preconditions to falling in love which he lays down, in the instincts he satisfies and the aims he sets himself in the course of it.¹ This produces what might be described as a stereotype plate (or several such), which is constantly repeated - constantly reprinted afresh - in the course of the person's life, so far as external circumstances and the nature of the love objects accessible to him permit, and which is certainly not entirely insusceptible to change in the face of recent experiences. Now, our observations have shown that only a portion of these impulses which determine the course of erotic life have passed through the full process of psychical development. That portion is directed towards reality, is at the disposal of the conscious personality, and forms a part of it. Another portion of the libidinal impulses has been held up in the course of development; it has been kept away from the conscious personality and from reality, and has either been prevented from further expansion except in phantasy or has remained wholly in the unconscious so that it is unknown to the personality's consciousness. If someone's need for love is not entirely satisfied by reality, he is bound to approach every new person whom he meets with libidinal anticipatory ideas; and it is highly probable that both portions of his libido, the portion that is capable of becoming conscious as well as the unconscious one, have a share in forming that attitude.

Thus it is a perfectly normal and intelligible thing that the libidinal cathexis of someone who is partly unsatisfied, a cathexis which is held ready in anticipation, should be directed as well to the figure of the doctor. It follows from our earlier hypothesis that this cathexis will have recourse to prototypes, will attach itself to one of the stereotype plates which are present in the subject; or, to put the position in another way, the cathexis will introduce the doctor into one of the psychical 'series' which the patient has already formed. If the 'father-imago', to use the apt term introduced by Jung (1911, 164) is the decisive factor in bringing this about, the outcome will tally with the real relations of the subject to his doctor. But the transference is not tied to this particular prototype: it may also come about on the lines of the mother-imago or brother-imago. The peculiarities of the transference to the doctor, thanks to which it exceeds, both in amount and nature, anything that could be justified on sensible or rational grounds, are made intelligible if we bear in mind that this transference has precisely been set up not only by the conscious anticipatory ideas but also by those that have been held back or are unconscious.

[1912b, 2457]

[1912b, 2458]
There would be nothing more to discuss or worry about in this behaviour of transference, if it were not that two points remain unexplained about it which are of particular interest to psycho-analysis. Firstly, we do not understand why transference is so much more intense with neurotic subjects in analysis than it is with other such people who are not being analysed; and secondly, it remains a puzzle why in analysis transference emerges as the most powerful resistance to the treatment, whereas outside analysis it must be regarded as the vehicle of cure and the condition of success. For our experience has shown us - and the fact can be confirmed as often as we please - that if a patient's free associations fail¹ the stoppage can invariably be removed by an assurance that he is being dominated at the moment by an association which is concerned with the doctor himself or with something connected with him. As soon as this explanation is given, the stoppage is removed, or the situation is changed from one in which the associations fail into one in which they are being kept back. At first sight it appears to be an immense disadvantage in psycho-analysis as a method that what is elsewhere the strongest factor towards success is changed in it into the most powerful medium of resistance. If, however, we examine the situation more closely, we can at least clear away the first of our two problems. It is not a fact that transference emerges with greater intensity and lack of restraint during psycho-analysis than outside it. In institutions in which nerve patients are treated non-analytically, we can observe transference occurring with the greatest intensity and in the most unworthy forms, extending to nothing less than mental bondage, and moreover showing the plainest erotic colouring. Gabriele Reuter, with her sharp powers of observation, described this at a time when there was no such thing as psycho-analysis, in a remarkable book which betrays in every respect the clearest insight into the nature and genesis of neuroses.² These characteristics of transference are therefore to be attributed not to psycho-analysis but to neurosis itself.

[1912b, 2458]
Our second problem - the problem of why transference appears in psycho-analysis as resistance - has been left for the moment untouched; and we must now approach it more closely. Let us picture the psychological situation during the treatment. An invariable and indispensable precondition of every onset of a psychoneurosis is the process to which Jung has given the appropriate name of 'introversion'.¹ That is to say: the portion of libido which is capable of becoming conscious and is directed towards reality is diminished, and the portion which is directed away from reality and is unconscious, and which, though it may still feed the subject's phantasies, nevertheless belongs to the unconscious, is proportionately increased. The libido (whether wholly or in part) has entered on a regressive course and has revived the subject's infantile imagos.² The analytic treatment now proceeds to follow it; it seeks to track down the libido, to make it accessible to consciousness and, in the end, serviceable for reality. Where the investigations of analysis come upon the libido withdrawn into its hiding-place, a struggle is bound to break out; all the forces which have caused the libido to regress will rise up as 'resistances' against the work of analysis, in order to conserve the new state of things. For if the libido's introversion or regression had not been justified by a particular relation between the subject and the external world - stated in the most general terms, by the frustration of satisfaction - and if it had not for the moment even become expedient, it could never have taken place at all. But the resistances from this source are not the only ones or indeed the most powerful. The libido at the disposal of the subject's personality had always been under the influence of the attraction of his unconscious complexes (or more correctly, of the portions of those complexes belonging to the unconscious), and it entered on a regressive course because the attraction of reality had diminished. In order to liberate it, this attraction of the unconscious has to be overcome; that is, the repression of the unconscious instincts and of their productions, which has meanwhile been set up in the subject, must be removed. This is responsible for by far the largest part of the resistance, which so often causes the illness to persist even after the turning away from reality has lost its temporary justification. The analysis has to struggle against the resistances from both these sources. The resistance accompanies the treatment step by step. Every single association, every act of the person under treatment must reckon with the resistance and represents a compromise between the forces that are striving towards recovery and the opposing ones which I have described.

If now we follow a pathogenic complex from its representation in the conscious (whether this is an obvious one in the form of a symptom or something quite inconspicuous) to its root in the unconscious, we shall soon enter a region in which the resistance makes itself felt so clearly that the next association must take account of it and appear as a compromise between its demands and those of the work of investigation. It is at this point, on the evidence of our experience, that transference enters on the scene. When anything in the complexive material (in the subject-matter of the complex) is suitable for being transferred on to the figure of the doctor, that transference is carried out; it produces the next association, and announces itself by indications of a resistance - by a stoppage, for instance. We infer from this experience that the transference-idea has penetrated into consciousness in front of any other possible associations because it satisfies the resistance. An event of this sort is repeated on countless occasions in the course of an analysis. Over and over again, when we come near to a pathogenic complex, the portion of that complex which is capable of transference is first pushed forward into consciousness and defended with the greatest obstinacy.¹

[1912b, 2459]

[1912b, 2460]
Thus transference in the analytic treatment invariably appears to us in the first instance as the strongest weapon of the resistance, and we may conclude that the intensity and persistence of the transference are an effect and an expression of the resistance. The mechanism of transference is, it is true, dealt with when we have traced it back to the state of readiness of the libido, which has remained in possession of infantile imago; but the part transference plays in the treatment can only be explained if we enter into its relations with resistance.

[1912b, 2461]

How does it come about that transference is so admirably suited to be a means of resistance? It might be thought that the answer can be given without difficulty. For it is evident that it becomes particularly hard to admit to any proscribed wishful impulse if it has to be revealed in front of the very person to whom the impulse relates. Such a necessity gives rise to situations which in the real world seem scarcely possible. But it is precisely this that the patient is aiming at when he makes the object of his emotional impulses coincide with the doctor. Further consideration, however, shows that this apparent gain cannot provide the solution of the problem. Indeed, a relation of affectionate and devoted dependence can, on the contrary help a person over all the difficulties of making an admission. In analogous real situations people will usually say: 'I feel no shame in front of you: I can say anything to you.' Thus the transference to the doctor might just as easily serve to facilitate admissions, and it is not clear why it should make things more difficult.

[1912b, 2461]

In all these reflections, however, we have hitherto dealt only with one side of the phenomenon of transference; we must turn our attention to another aspect of the same subject. Anyone who forms a correct appreciation of the way in which a person in analysis, as soon as he comes under the dominance of any considerable transference-resistance, is flung out of his real relation to the doctor, how he feels at liberty then to disregard the fundamental rule of psycho-analysis which lays it down that whatever comes into one's head must be reported without criticizing it, how he forgets the intentions with which he started the treatment, and how he regards with indifference logical arguments and conclusions which only a short time before had made a great impression on him - anyone who has observed all this will feel it necessary to look for an explanation of his impression in other factors besides those that have already been adduced. Nor are such factors far to seek: they arise once again from the psychological situation in which the treatment places the patient.

[1912b, 2464]
In the process of seeking out the libido which has escaped from the patient's conscious, we have penetrated into the realm of the unconscious. The reactions which we bring about reveal at the same time some of the characteristics which we have come to know from the study of dreams. The unconscious impulses do not want to be remembered in the way the treatment desires them to be, but endeavour to reproduce themselves in accordance with the timelessness of the unconscious and its capacity for hallucination. Just as happens in dreams, the patient regards the products of the awakening of his unconscious impulses as contemporaneous and real; he seeks to put his passions into action without taking any account of the real situation. The doctor tries to compel him to fit these emotional impulses into the nexus of the treatment and of his life-history, to submit them to intellectual consideration and to understand them in the light of their psychical value. This struggle between the doctor and the patient, between intellect and instinctual life, between understanding and seeking to act, is played out almost exclusively in the phenomena of transference. It is on that field that the victory must be won - the victory whose expression is the permanent cure of the neurosis. It cannot be disputed that controlling the phenomena of transference presents the psycho-analyst with the greatest difficulties. But it should not be forgotten that it is precisely they that do us the inestimable service of making the patient's hidden and forgotten erotic impulses immediate and manifest. For when all is said and done, it is impossible to destroy anyone in absentia or in effigie.

But in psycho-analytic relations things often happen differently from what the psychology of consciousness might lead us to expect. Experience does not speak in favour of an affective technique of this kind. Nor is it hard to see that it involves a departure from psycho-analytic principles and verges upon treatment by suggestion. It may induce the patient to bring forward sooner and with less difficulty things he already knows but would otherwise have kept back for a time through conventional resistances. But this technique achieves nothing towards the uncovering of what is unconscious to the patient. It makes him even more incapable of overcoming his deeper resistances, and in severer cases it invariably fails by encouraging the patient to be insatiable: he would like to reverse the situation, and finds the analysis of the doctor more interesting than his own. The resolution of the transference, too - one of the main tasks of the treatment - is made more difficult by an intimate attitude on the doctor's part, so that any gain there may be at the beginning is more than outweighed at the end. I have no hesitation, therefore, in condemning this kind of technique as incorrect. The doctor should be opaque to his patients and, like a mirror, should show them nothing but what is shown to him. In practice, it is true, there is nothing to be said against a psychotherapist combining a certain amount of analysis with some suggestive influence in order to achieve a perceptible result in a shorter time - as is necessary, for instance, in institutions. But one has a right to insist that he himself should be in no doubt about what he is doing and should know that his method is not that of true psycho-analysis.

Lengthy preliminary discussions before the beginning of the analytic treatment, previous treatment by another method and also previous acquaintance between the doctor and the patient who is to be analysed, have special disadvantageous consequences for which one must be prepared. They result in the patient's meeting the doctor with a transference attitude which is already established and which the doctor must first slowly uncover instead of having the opportunity to observe the growth and development of the transference from the outset. In this way the patient gains a temporary start upon us which we do not willingly grant him in the treatment.
To shorten analytic treatment is a justifiable wish, and its fulfilment, as we shall learn, is being attempted along various lines. Unfortunately, it is opposed by a very important factor, namely, the slowness with which deep-going changes in the mind are accomplished - in the last resort, no doubt, the 'timelessness' of our unconscious processes. When patients are faced with the difficulty of the great expenditure of time required for analysis they not infrequently manage to propose a way out of it. They divide up their ailments and describe some as unbearable, and others as secondary, and then say: 'If only you will relieve me from this one (for instance, a headache or a particular fear) I can deal with the other one on my own in my ordinary life.' In doing this, however, they over-estimate the selective power of analysis. The analyst is certainly able to do a great deal, but he cannot determine beforehand exactly what results he will effect. He sets in motion a process, that of the resolving of existing repressions. He can supervise this process, further it, remove obstacles in its way, and he can undoubtedly vitiate much of it. But on the whole, once begun, it goes its own way and does not allow either the direction it takes or the order in which it picks up its points to be prescribed for it. The analyst's power over the symptoms of the disease may thus be compared to male sexual potency. A man can, it is true, beget a whole child, but even the strongest man cannot create in the female organism a head alone or an arm or a leg; he cannot even prescribe the child's sex. He, too, only sets in motion a highly complicated process, determined by events in the remote past, which ends with the severance of the child from its mother. A neurosis as well has the character of an organism. Its component manifestations are not independent of one another; they condition one another and give one another mutual support. A person suffers from one neurosis only, never from several which have accidentally met together in a single individual. The patient freed, according to his wish, from his one unendurable symptom might easily find that a symptom which had previously been negligible had now increased and grown unendurable. The analyst who wishes the treatment to owe its success as little as possible to its elements of suggestion (i.e. to the transference) will do well to refrain from making use of even the trace of selective influence upon the results of the therapy which may perhaps be open to him. The patients who are bound to be most welcome to him are those who ask him to give them complete health, in so far as that is attainable, and who place as much time at his disposal as is necessary for the process of recovery. Such favourable conditions as these are, of course, to be looked for in only a few cases.

For the same reason he should also refrain from giving treatment free, and make no exceptions to this in favour of his colleagues or their families. This last recommendation will seem to offend against professional amenities. It must be remembered, however, that a gratuitous treatment means much more to a psycho-analyst than to any other medical man; it means the sacrifice of a considerable portion - an eighth or a seventh part, perhaps - of the working time available to him for earning his living, over a period of many months. A second free treatment carried on at the same time would already deprive him of a quarter or a third of his earning capacity, and this would be comparable to the damage inflicted by a severe accident.
Before I wind up these remarks on beginning analytic treatment, I must say a word about a certain ceremoni which concerns the position in which the treatment is carried out. I hold to the plan of getting the patient to lie on a sofa while I sit behind him out of his sight. This arrangement has a historical basis; it is the remnant of the hypnotic method out of which psycho-analysis was evolved. But it deserves to be maintained for many reasons. The first is a personal motive, but one which others may share with me. I cannot put up with being stared at by other people for eight hours a day (or more). Since, while I am listening to the patient, I, too, give myself over to the current of my unconscious thoughts, I do not wish my expressions of face to give the patient material for interpretations or to influence him in what he tells me. The patient usually regards being made to adopt this position as a hardship and rebels against it, especially if the instinct for looking (scopophilia) plays an important part in his neurosis. I insist on this procedure, however, for its purpose and result are to prevent the transference from mingling with the patient's associations imperceptibly, to isolate the transference and to allow it to come forward in due course sharply defined as a resistance. I know that many analysts work in a different way, but I do not know whether this deviation is due more to a craving for doing things differently or to some advantage which they find they gain by it.

To return to the beginning of the treatment. Patients are occasionally met with who start the treatment by assuring us that they cannot think of anything to say, although the whole field of their life-history and the story of their illness is open to them to choose from. Their request that we should tell them what to talk about must not be granted on this first occasion any more than on any later one. We must bear in mind what is involved here. A strong resistance has come to the front in order to defend the neurosis; we must take up the challenge then and there and come to grips with it. Energetic and repeated assurances to the patient that it is impossible for no ideas at all to occur to him at the beginning, and that what is in question is a resistance against the analysis, soon oblige him to make the expected admissions or to uncover a first piece of his complexes. It is a bad sign if he has to confess that while he was listening to the fundamental rule of analysis he made a mental reservation that he would nevertheless keep this or that to himself; it is not so serious if all he has to tell us is how mistrustful he is of analysis or the horrifying things he has heard about it. If he denies these and similar possibilities when they are put before him, he can be driven by our insistence to acknowledge that he has nevertheless overlooked certain thoughts which were occupying his mind. He had thought of the treatment itself, though nothing definite about it, or he had been occupied with the picture of the room in which he was, or he could not help thinking of the objects in the consulting room and of the fact that he was lying here on a sofa - all of which he has replaced by the word 'nothing'. These indications are intelligible enough: everything connected with the present situation represents a transference to the doctor, which proves suitable to serve as a first resistance. We are thus obliged to begin by uncovering this transference; and a path from it will give rapid access to the patient's pathogenic material. Women who are prepared by events in their past history to be subjected to sexual aggression and men with over-strong repressed homosexuality are the most apt thus to withhold the ideas that occur to them at the outset of their analysis.

So long as the patient's communications and ideas run on without any obstruction, the theme of transference should be left untouched. One must wait until the transference, which is the most delicate of all procedures, has become a resistance.
The answer to this can only be: Not until an effective transference has been established in the patient, a proper rapport with him. It remains the first aim of the treatment to attach him to it and to the person of the doctor. To ensure this, nothing need be done but to give him time. If one exhibits a serious interest in him, carefully clears away the resistances that crop up at the beginning and avoids making certain mistakes, he will of himself form such an attachment and link the doctor up with one of the imagos of the people by whom he was accustomed to be treated with affection. It is certainly possible to forfeit this first success if from the start one takes up any standpoint other than one of sympathetic understanding, such as a moralizing one, or if one behaves like a representative or contending party - of the other member of a married couple, for instance.

What interests us most of all is naturally the relation of this compulsion to repeat to the transference and to resistance. We soon perceive that the transference is itself only a piece of repetition, and that the repetition is a transference of the forgotten past not only on to the doctor but also on to all the other aspects of the current situation. We must be prepared to find, therefore, that the patient yields to the compulsion to repeat, which now replaces the impulsion to remember, not only in his personal attitude to his doctor but also in every other activity and relationship which may occupy his life at the time - if, for instance, he falls in love or undertakes a task or starts an enterprise during the treatment. The part played by resistance, too, is easily recognized. The greater the resistance, the more extensively will acting out (repetition) replace remembering. For the ideal remembering of what has been forgotten which occurs in hypnosis corresponds to a state in which resistance has been put completely on one side. If the patient starts his treatment under the auspices of a mild and unpronounced positive transference it makes it possible at first for him to unearth his memories just as he would under hypnosis, and during this time his pathological symptoms themselves are quiescent. But if, as the analysis proceeds, the transference becomes hostile or unduly intense and therefore in need of repression, remembering at once gives way to acting out. From then onwards the resistances determine the sequence of the material which is to be repeated. The patient brings out of the armoury of the past the weapons with which he defends himself against the progress of the treatment - weapons which we must wrest from him one by one.

The tactics to be adopted by the physician in this situation are easily justified. For him, remembering in the old manner - reproduction in the psychical field - is the aim to which he adheres, even though he knows that such an aim cannot be achieved in the new technique. He is prepared for a perpetual struggle with his patient to keep in the psychical sphere all the impulses which the patient would like to direct into the motor sphere; and he celebrates it as a triumph for the treatment if he can bring it about that something that the patient wishes to discharge in action is disposed of through the work of remembering. If the attachment through transference has grown into something at all serviceable, the treatment is able to prevent the patient from executing any of the more important repetitive actions and to utilize his intention to do so in statu nascendi as material for the therapeutic work. One best protects the patient from injuries brought about through carrying out one of his impulses by making him promise not to take any important decisions affecting his life during the time of his treatment - for instance, not to choose any profession or definitive love-object - but to postpone all such plans until after his recovery.
Among the situations which arise in this connection I shall select one which is very sharply circumscribed; and I shall select it, partly because it occurs so often and is so important in its real aspects and partly because of its theoretical interest. What I have in mind is the case in which a woman patient shows by unmistakable indications, or openly declares, that she has fallen in love, as any other mortal woman might, with the doctor who is analysing her. This situation has its distressing and comical aspects, as well as its serious ones. It is also determined by so many and such complicated factors, it is so unavoidable and so difficult to clear up, that a discussion of it to meet a vital need of analytic technique has long been overdue. But since we who laugh at other people's failings are not always free from them ourselves, we have not so far been precisely in a hurry to fulfil this task. We are constantly coming up against the obligation to professional discretion - a discretion which cannot be dispensed with in real life, but which is of no service in our science. In so far as psycho-analytic publications are a part of real life, too, we have here an insoluble contradiction. I have recently disregarded this matter of discretion at one point,¹ and shown how this same transference situation held back the development of psycho-analytic therapy during its first decade.

[1915a, 2509]

To a well-educated layman (for that is what the ideal civilized person is in regard to psycho-analysis) things that have to do with love are incommensurable with everything else; they are, as it were, written on a special page on which no other writing is tolerated. If a woman patient has fallen in love with her doctor it seems to such a layman that only two outcomes are possible. One, which happens comparatively rarely, is that all the circumstances allow of a permanent legal union between them; the other, which is more frequent, is that the doctor and the patient part and give up the work they have begun which was to have led to her recovery, as though it had been interrupted by some elemental phenomenon. There is, to be sure, a third conceivable outcome, which even seems compatible with a continuation of the treatment. This is that they should enter into a love-relationship which is illicit and which is not intended to last for ever. But such a course is made impossible by conventional morality and professional standards. Nevertheless, our layman will beg the analyst to reassure him as unambiguously as possible that this third alternative is excluded.

[1915a, 2510]

Let us take the case of the second outcome of the situation we are considering. After the patient has fallen in love with her doctor, they part; the treatment is given up. But soon the patient's condition necessitates her making a second attempt at analysis, with another doctor. The next thing that happens is that she feels she has fallen in love with this second doctor too; and if she breaks off with him and begins yet again, the same thing will happen with the third doctor, and so on. This phenomenon, which occurs without fail and which is, as we know, one of the foundations of the psycho-analytic theory, may be evaluated from two points of view, that of the doctor who is carrying out the analysis and that of the patient who is in need of it.

[1915a, 2510]
I have no doubt that the patient's relatives and friends will decide as emphatically for the first of these two alternatives as the analyst will for the second. But I think that here is a case in which the decision cannot be left to the tender - or rather, the egoistic and jealous - concern of her relatives. The welfare of the patient alone should be the touchstone; her relatives' love cannot cure her neurosis. The analyst need not push himself forward, but he may insist that he is indispensable for the achievement of certain ends. Any relative who adopts Tolstoy's attitude to this problem can remain in undisturbed possession of his wife or daughter; but he will have to try to put up with the fact that she, for her part, retains her neurosis and the interference with her capacity for love which it involves. The situation, after all, is similar to that in a gynaecological treatment. Moreover, the jealous father or husband is greatly mistaken if he thinks that the patient will escape falling in love with her doctor if he hands her over to some kind of treatment other than analysis for combating her neurosis. The difference, on the contrary, will only be that a love of this kind, which is bound to remain unexpressed and unanalysed, can never make the contribution to the patient's recovery which analysis would have extracted from it.

At a first glance it certainly does not look as if the patient's falling in love in the transference could result in any advantage to the treatment. No matter how amenable she has been up till then, she suddenly loses all understanding of the treatment and all interest in it, and will not speak or hear about anything but her love, which she demands to have returned. She gives up her symptoms or pays no attention to them; indeed, she declares that she is well. There is a complete change of scene; it is as though some piece of make-believe had been stopped by the sudden irruption of reality - as when, for instance, a cry of fire is raised during a theatrical performance. No doctor who experiences this for the first time will find it easy to retain his grasp on the analytic situation and to keep clear of the illusion that the treatment is really at an end.

Even more decidedly, however, do I decline to fulfil the second of the expectations I have mentioned. To urge the patient to suppress, renounce or sublimate her instincts the moment she has admitted her erotic transference would be, not an analytic way of dealing with them, but a senseless one. It would be just as though, after summoning up a spirit from the underworld by cunning spells, one were to send him down again without having asked him a single question. One would have brought the repressed into consciousness, only to repress it once more in a fright. Nor should we deceive ourselves about the success of any such proceeding. As we know, the passions are little affected by sublime speeches. The patient will feel only the humiliation, and she will not fail to take her revenge for it.

As a second argument against the genuineness of this love we advance the fact that it exhibits not a single new feature arising from the present situation, but is entirely composed of repetitions and copies of earlier reactions, including infantile ones. We undertake to prove this by a detailed analysis of the patient's behaviour in love.

I should now like, however, to examine these arguments with a critical eye and to raise the question whether, in putting them forward to the patient, we are really telling the truth, of whether we are not resorting in our desperation to concealments and misrepresentations. In other words: can we truly say that the state of being in love which becomes manifest in analytic treatment is not a real one?
I think we have told the patient the truth, but not the whole truth regardless of the consequences. Of our two arguments the first is the stronger. The part played by resistance in transference-love is unquestionable and very considerable. Nevertheless the resistance did not, after all, create this love; it finds it ready to hand, makes use of it and aggravates its manifestations. Nor is the genuineness of the phenomenon disproved by the resistance. The second argument is far weaker. It is true that the love consists of new editions of old traits and that it repeats infantile reactions. But this is the essential character of every state of being in love. There is no such state which does not reproduce infantile prototypes. It is precisely from this infantile determination that it receives its compulsive character, verging as it does on the pathological. Transference-love has perhaps a degree less of freedom than the love which appears in ordinary life and is called normal; it displays its dependence on the infantile pattern more clearly and is less adaptable and capable of modification; but that is all, and not what is essential.

[1915a, 2518]

By what other signs can the genuineness of a love be recognized? By its efficacy, its serviceability in achieving the aim of love? In this respect transference-love seems to be second to none; one has the impression that one could obtain anything from it.

[1915a, 2518]

Let us sum up, therefore. We have no right to dispute that the state of being in love which makes its appearance in the course of analytic treatment has the character of a 'genuine' love. If it seems so lacking in normality, this is sufficiently explained by the fact that being in love in ordinary life, outside analysis, is also more similar to abnormal than to normal mental phenomena. Nevertheless, transference-love is characterized by certain features which ensure it a special position. In the first place, it is provoked by the analytic situation; secondly, it is greatly intensified by the resistance, which dominates the situation; and thirdly, it is lacking to a high degree in a regard for reality, is less sensible, less concerned about consequences and more blind in its valuation of the loved person than we are prepared to admit in the case of normal love. We should not forget, however, that these departures from the norm constitute precisely what is essential about being in love.

[1915a, 2518]

The analytic psychotherapist thus has a threefold battle to wage - in his own mind against the forces which seek to drag him down from the analytic level; outside the analysis, against opponents who dispute the importance he attaches to the sexual instinctual forces and hinder him from making use of them in his scientific technique; and inside the analysis, against his patients, who at first behave like opponents but later on reveal the overvaluation of sexual life which dominates them, and who try to make him captive to their socially untamed passion.

[1915a, 2520]
I am quite sure, however, that this opposition between our views had nothing to do with the breach in our relations which followed shortly after. This had deeper causes, but it came about in such a way that at first I did not understand it; it was only later that I learnt from many clear indications how to interpret it. It will be remembered that Breuer said of his famous first patient that the element of sexuality was astonishingly undeveloped in her and had contributed nothing to the very rich clinical picture of the case. I have always wondered why the critics did not more often cite this assertion of Breuer's as an argument against my contention of a sexual aetiology in the neuroses, and even to-day I do not know whether I ought to regard the omission as evidence of tact or of carelessness on their part. Anyone who reads the history of Breuer's case now in the light of the knowledge gained in the last twenty years will at once perceive the symbolism in it - the snakes, the stiffening, the paralysis of the arm - and, on taking into account the situation at the bedside of the young woman's sick father, will easily guess the real interpretation of her symptoms; his opinion of the part played by sexuality in her mental life will therefore be very different from that of her doctor. In his treatment of her case, Breuer was able to make use of a very intense suggestive rapport with the patient, which may serve us as a complete prototype of what we call 'transference' to-day. Now I have strong reasons for suspecting that after all her symptoms had been relieved Breuer must have discovered from further indications the sexual motivation of this transference, but that the universal nature of this unexpected phenomenon escaped him, with the result that, as though confronted by an 'untoward event',¹ he broke off all further investigation. He never said this to me in so many words, but he told me enough at different times to justify this reconstruction of what happened. When I later began more and more resolutely to put forward the significance of sexuality in the aetiology of neuroses, he was the first to show the reaction of distaste and repudiation which was later to become so familiar to me, but which at that time I had not yet learnt to recognize as my inevitable fate.

[1914d, 2881]

The fact of the emergence of the transference in its crudely sexual form, whether affectionate or hostile, in every treatment of a neurosis, although this is neither desired nor induced by either doctor or patient, has always seemed to me the most irrefragable proof that the source of the driving forces of neurosis lies in sexual life. This argument has never received anything approaching the degree of attention that it merits, for if it had, investigations in this field would leave no other conclusion open. As far as I am concerned, this argument has remained the decisive one, over and above the more specific findings of analytic work.

[1914d, 2881]
The theory of repression is the corner-stone on which the whole structure of psycho-analysis rests. It is the most essential part of it; and yet it is nothing but a theoretical formulation of a phenomenon which may be observed as often as one pleases if one undertakes an analysis of a neurotic without resorting to hypnosis. In such cases one comes across a resistance which opposes the work of analysis and in order to frustrate it pleads a failure of memory. The use of hypnosis was bound to hide this resistance; the history of psycho-analysis proper, therefore, only begins with the new technique that dispenses with hypnosis. The theoretical consideration of the fact that this resistance coincides with an amnesia leads inevitably to the view of unconscious mental activity which is peculiar to psycho-analysis and which, too, distinguishes it quite clearly from philosophical speculations about the unconscious. It may thus be said that the theory of psycho-analysis is an attempt to account for two striking and unexpected facts of observation which emerge whenever an attempt is made to trace the symptoms of a neurotic back to their sources in his past life: the facts of transference and of resistance. Any line of investigation which recognizes these two facts and takes them as the starting-point of its work has a right to call itself psycho-analysis, even though it arrives at results other than my own. But anyone who takes up other sides of the problem while avoiding these two hypotheses will hardly escape a charge of misappropriation of property by attempted impersonation, if he persists in calling himself a psycho-analyst.

[1914d, 2885]
The first task confronting psycho-analysis was to explain the neuroses; it used the two facts of resistance and transference as starting-points, and, taking into consideration the third fact of amnesia, accounted for them with its theories of repression, of the sexual motive forces in neurosis and of the unconscious. Psycho-analysis has never claimed to provide a complete theory of human mentality in general, but only expected that what it offered should be applied to supplement and correct the knowledge acquired by other means. Adler's theory, however, goes far beyond this point; it seeks at one stroke to explain the behaviour and character of human beings as well as their neurotic and psychotic illnesses. It is actually more suited to any other field than that of neurosis, although for reasons connected with the history of its development it still places this in the foreground. For many years I had opportunities of studying Dr. Adler and have never refused to recognize his unusual ability, combined with a particularly speculative disposition. As an instance of the 'persecution' to which he asserts he has been subjected by me, I can point to the fact that after the Association was founded I made over to him the leadership of the Vienna group. It was not until urgent demands were put forward by all the members of the society that I let myself be persuaded to take the chair again at its scientific meetings. When I perceived how little gift Adler had precisely for judging unconscious material, my view changed to an expectation that he would succeed in discovering the connections of psycho-analysis with psychology and with the biological foundations of instinctual processes - an expectation which was in some sense justified by the valuable work he had done on 'organ-inferiority'. And he did in fact effect something of the kind; but his work conveys an impression 'as if' - to speak in his own 'jargon' - it was intended to prove that psycho-analysis was wrong in everything and that it had only attributed so much importance to sexual motive forces because of its credulity in accepting the assertions of neurotics. I may even speak publicly of the personal motive for his work, since he himself announced it in the presence of a small circle of members of the Vienna group: '- Do you think it gives me such great pleasure to stand in your shadow my whole life long?' To be sure, I see nothing reprehensible in a younger man freely admitting his ambition, which one would in any case guess was among the incentives for his work. But even though a man is dominated by a motive of this kind he should know how to avoid being what the English, with their fine social tact, call 'unfair' - which in German can only be expressed by a much cruder word. How little Adler has succeeded in this is shown by the profusion of petty outbursts of malice which disfigure his writings and by the indications they contain of an uncontrolled craving for priority. At the Vienna Psycho-Analytical Society we once actually heard him claim priority for the conception of the 'unity of the neuroses' and for the 'dynamic view' of them. This came as a great surprise to me, for I had always believed that these two principles were stated by me before I ever made Adler's acquaintance. [1914d, 2913]

Since the publication of a work by Abraham (1908) - which that conscientious author has attributed to my instigation - we have tried to base our characterization of Kraepelin's 'dementia praecox' (Bleuler's 'schizophrenia') on its position with reference to the antithesis between ego and object. In the transference neuroses (anxiety hysteria, conversion hysteria and obsessional neurosis) there was nothing to give special prominence to this antithesis. We knew, indeed, that frustration in regard to the object brings on the outbreak of the neurosis and that the neurosis involves a renunciation of the real object; we knew too that the libido that is withdrawn from the real object reverts first to a phantasied object and then to one that had been repressed (introversion). But in these disorders object-cathexis in general is retained with great energy, and more detailed examination of the process of repression has obliged us to assume that object-cathexis persists in the system Ucs. in spite of - or rather in consequence of - repression. Indeed, the capacity for transference, of which we make use for therapeutic purposes in these affections, presupposes an unimpaired object-cathexis. [1915e, 3018]
But we cannot do that either. The talk of which psycho-analytic treatment consists brooks no listener; it cannot be demonstrated. A neurasthenic or hysterical patient can of course, like any other, be introduced to students in a psychiatric lecture. He will give an account of his complaints and symptoms, but of nothing else. The information required by analysis will be given by him only on condition of his having a special emotional attachment to the doctor; he would become silent as soon as he observed a single witness to whom he felt indifferent. For this information concerns what is most intimate in his mental life, everything that, as a socially independent person, he must conceal from other people, and, beyond that, everything that, as a homogeneous personality, he will not admit to himself. [1916-1917, 3131]

We come upon this other factor which prevents dreams from being lucid, this new contribution to dream-distortion, by noticing a gap in our technique. I have already admitted to you that it does sometimes really happen that nothing occurs to a person under analysis in response to particular elements of his dreams. It is true that this does not happen as often as he asserts; in a great many cases, with perseverance, an idea is extracted from him. But nevertheless there remain cases in which an association fails to emerge or, if it is extracted, does not give us what we expected from it. If this happens during a psycho-analytic treatment, it has a peculiar significance with which we are not here concerned. But it also happens in the interpretation of normal people's dreams or in that of our own. If we convince ourselves that in such case no amount of pressure is of any use, we eventually discover that this unwished-for event regularly occurs in connection with particular dream-elements, and we begin to recognize that a fresh general principle is at work where we had begun by thinking we were only faced by an exceptional failure of technique. [1916-1917, 3243]

Intellectual resistances are not the worst; one always remains superior to them. But the patient also knows how to put up resistances, without going outside the framework of the analysis, the overcoming of which is among the most difficult of technical problems. Instead of remembering, he repeats attitudes and emotional impulses from his early life which can be used as a resistance against the doctor and the treatment by means of what is known as 'transference'. If the patient is a man, he usually extracts this material from his relation to his father, into whose place he fits the doctor, and in that way he makes resistances out of his efforts to become independent in himself and in his judgements, out of his ambition, the first aim of which was to do things as well as his father or to get the better of him, or out of his unwillingness to burden himself for the second time in his life with a load of gratitude. Thus at times one has an impression that the patient has entirely replaced his better intention of making an end to his illness by the alternative one of putting the doctor in the wrong, of making him realize his impotence and of triumphing over him. Women have a masterly gift for exploiting an affectionate, erotically tinged transference to the doctor for the purposes of resistance. If this attachment reaches a certain height, all their interest in the immediate situation in the treatment and all the obligations they undertook at its commencement vanish; their jealousy, which is never absent, and their exasperation at their inevitable rejection, however considerately expressed, are bound to have a damaging effect on their personal understanding with the doctor and so to put out of operation one of the most powerful motive forces of the analysis. [1916-1917, 3365]
If we continue to concern ourselves only with our hysterics and obsessional neurotics, we are soon met by a second fact for which we were not in the least prepared. For after a while we cannot help noticing that these patients behave in a quite peculiar manner to us. We believed, to be sure, that we had reckoned with all the motives concerned in the treatment, that we had completely rationalized the situation between us and the patients so that it could be looked over at a glance like a sum in arithmetic; yet, in spite of all this, something seems to creep in which has not been taken into account in our sum. This unexpected novelty itself takes many shapes, and I will begin by describing to you the commoner and more easily understandable of the forms in which it appears.

We notice, then, that the patient, who ought to want nothing else but to find a way out of his distressing conflict, develops a special interest in the person of the doctor. Everything connected with the doctor seems to be more important to him than his own affairs and to be diverting him from his illness. For a time, accordingly, relations with him become very agreeable; he is particularly obliging, tries wherever possible to show his gratitude, reveals refinements and merits in his nature which we should not, perhaps, have expected to find in him. The doctor, too, thereupon forms a favourable opinion of the patient and appreciates the good fortune which has enabled him to give his assistance to such a particularly valuable personality. If the doctor has an opportunity of talking to the patient's relatives, he learns to his satisfaction that the liking is a mutual one. The patient never tires in his home of praising the doctor and of extolling ever new qualities in him. 'He's enthusiastic about you,' say his relatives, 'he trusts you blindly; everything you say is like a revelation to him.' Here and there someone in this chorus has sharper eyes and says: 'It's becoming a bore, the way he talks of nothing else but you and has your name on his lips all the time.'

Let us hope that the doctor is modest enough to attribute his patient's high opinion of him to the hopes he can rouse in him and to the widening of his intellectual horizon by the surprising and liberating enlightenment that the treatment brings with it. Under these conditions the analysis makes fine progress too. The patient understands what is interpreted to him and becomes engrossed in the tasks set him by the treatment; the material of memories and associations floods in upon him in plenty, the certainty and appositeness of his interpretations are a surprise to the doctor, and the latter can only take note with satisfaction that here is a patient who readily accepts all the psychological novelties which are apt to provoke the most bitter contradiction among healthy people in the outside world. Moreover the cordial relations that prevail during the work of analysis are accompanied by an objective improvement, which is recognized on all sides, in the patient's illness.
If we are able once more to clarify the position, we find that the cause of the disturbance is that the patient has transferred on to the doctor intense feelings of affection which are justified neither by the doctor's behaviour nor by the situation that has developed during the treatment. The form in which this affection is expressed and what its aims are depend of course on the personal relation between the two people involved. If those concerned are a young girl and a youngish man, we shall get the impression of a normal case of falling in love; we shall find it understandable that a girl should fall in love with a man with whom she can be much alone and talk of intimate things and who has the advantage of having met her as a helpful superior; and we shall probably overlook the fact that what we should expect from a neurotic girl would rather be an impediment in her capacity for love. The further the personal relations between doctor and patient diverge from this supposed case, the more we shall be surprised to find nevertheless the same emotional relationship constantly recurring. It may still pass muster if a woman who is unhappy in her marriage appears to be seized with a serious passion for a doctor who is still unattached, if she is ready to seek a divorce in order to be his or if, where there are social obstacles, she even expresses no hesitation about entering into a secret liaison with him. Such things come about even outside psycho-analysis. But in these circumstances we are astonished to hear declarations by married women and girls which bear witness to a quite particular attitude to the therapeutic problem: they had always known, they say, that they could only be cured by love, and before the treatment began they had expected that through this relation they would at last be granted what life had hitherto withheld from them; it had only been in this hope that they had taken so much trouble over the treatment and overcome all the difficulties in communicating their thoughts - and we on our part can add: and had so easily understood what is otherwise so hard to believe. But an admission of this sort surprises us: it throws all our calculations to the winds. Can it be that we have left the most important item out of our account? [1916-1917, 3483]

And indeed, the greater our experience the less we are able to resist making this correction, though having to do so puts our scientific pretensions to shame. On the first few occasions one might perhaps think that the analytic treatment had come up against a disturbance due to a chance event - an event, that is, not intended and not provoked by it. But when a similar affectionate attachment by the patient to the doctor is repeated regularly in every new case, when it comes to light again and again, under the most unfavourable conditions and where there are positively grotesque incongruities, even in elderly women and in relation to grey-bearded men, even where, in our judgement, there is nothing of any kind to entice - then we must abandon the idea of a chance disturbance and recognize that we are dealing with a phenomenon which is intimately bound up with the nature of the illness itself. [1916-1917, 3484]

This new fact, which we thus recognize so unwillingly, is known by us as transference. We mean a transference of feelings on to the person of the doctor, since we do not believe that the situation in the treatment could justify the development of such feelings. We suspect, on the contrary, that the whole readiness for these feelings is derived from elsewhere, that they were already prepared in the patient and, upon the opportunity offered by the analytic treatment, are transferred on to the person of the doctor. Transference can appear as a passionate demand for love or in more moderate forms; in place of a wish to be loved, a wish can emerge between a girl and an old man to be received as a favourite daughter; the libidinal desire can be toned down into a proposal for an inseparable, but ideally non-sensual, friendship. Some women succeed in sublimating the transference and in moulding it till it achieves a kind of viability; others must express it in its crude, original, and for the most part, impossible form. But at bottom it is always the same, and never allows its origin from the same source to be mistaken. [1916-1917, 3484]
Before we enquire where we are to find a place for this new fact, I will complete my
description of it. What happens with male patients? There at least one might hope to escape the
troublesome interference caused by difference of sex and by sexual attraction. Our answer,
however, must be much the same as in the case of women. There is the same attachment to
the doctor, the same overvaluation of his qualities, the same absorption in his interests, the
same jealousy of everyone close to him in real life. The sublimated forms of transference are
more frequent between one man and another and straightforward sexual demands are rarer, in
proportion as manifest homosexuality is unusual as compared with the other ways in which
these instinctual components are employed. With his male patients, again, more often than with
women, the doctor comes across a form of expression of the transference which seems at first
sight to contradict all our previous descriptions - a hostile or negative transference.
[1916-1917, 3484]

I must begin by making it clear that a transference is present in the patient from the beginning
of the treatment and for a while is the most powerful motive in its advance. We see no trace of it
and need not bother about it so long as it operates in favour of the joint work of analysis. If it
then changes into a resistance, we must turn our attention to it and we recognize that it alters its
relation to the treatment under two different and contrary conditions: firstly, if as an affectionate
trend it has become so powerful, and betrays signs of its origin in a sexual need so clearly, that
it inevitably provokes an internal opposition to itself, and, secondly, if it consists of hostile
instead of affectionate impulses. The hostile feelings make their appearance as a rule later than
the affectionate ones and behind them; their simultaneous presence gives a good picture of the
emotional ambivalence which is dominant in the majority of our intimate relations with other
people. The hostile feelings are as much an indication of an emotional tie as the affectionate
ones, in the same way as defiance signifies dependence as much as obedience does, though
with a 'minus' instead of a 'plus' sign before it. We can be in no doubt that the hostile feelings
owards the doctor deserve to be called a 'transference', since the situation in the treatment
quite certainly offers no adequate grounds for their origin; this necessary view of the negative
transference assures us, therefore, that we have not gone wrong in our judgement of the
positive or affectionate one.
[1916-1917, 3485]

But I should like to say a few words to you to relieve you of your surprise at the emergence of
this unexpected phenomenon. We must not forget that the patient's illness, which we have
undertaken to analyse, is not something which has been rounded off and become rigid but that
it is still growing and developing like a living organism. The beginning of the treatment does not
put an end to this development; when, however, the treatment has obtained mastery over the
patient, what happens is that the whole of his illness's new production is concentrated upon a
single point - his relation to the doctor. Thus the transference may be compared to the cambium
layer in a tree between the wood and the bark, from which the new formation of tissue and the
increase in the girth of the trunk derive. When the transference has risen to this significance,
work upon the patient's memories retreats far into the background. Thereafter it is not incorrect
to say that we are no longer concerned with the patient's earlier illness but with a newly created
and transformed neurosis which has taken the former's place. We have followed this new
edition of the old disorder from its start, we have observed its origin and growth, and we are
especially well able to find our way about in it since, as its object, we are situated at its very
centre. All the patient's symptoms have abandoned their original meaning and have take on a
new sense which lies in a relation to the transference; or only such symptoms have persisted as
are capable of undergoing such a transformation. But the mastering of this new, artificial
neurosis coincides with getting rid of the illness which was originally brought to the treatment -
with the accomplishment of our therapeutic task. A person who has become normal and free
from the operation of repressed instinctual impulse in his relation to the doctor will remain so in
his own life after the doctor has once more withdrawn from it.
[1916-1917, 3486]
A capacity for directing libidinal object-cathexes on to people must of course be attributed to every normal person. The tendency to transference of the neurotics I have spoken of is only an extraordinary increase of this universal characteristic. It would indeed be very strange if a human trait so widespread and so important had never been noticed or appreciated. And in fact it has been. Bernheim, with an unerring eye based his theory of hypnotic phenomena on the thesis that everyone is in some way 'suggestible'. His suggestibility was nothing other than the tendency to transference, somewhat too narrowly conceived, so that it did not include negative transference. But Bernheim was never able to say what suggestion actually was and how it came about. For him it was a fundamental fact on whose origin he could throw no light. He did not know that his 'suggestibilité' depended on sexuality, on the activity of the libido. And it must dawn on us that in our technique we have abandoned hypnosis only to rediscover suggestion in the shape of transference.

[1916-1917, 3488]

Let us begin with the former. I was a pupil of Bernheim's, whom I visited at Nancy in 1889 and whose book on suggestion I translated into German. I practised hypnotic treatment for many years, at first by prohibitory suggestion and later in combination with Breuer's method of questioning the patient. I can therefore speak of the results of hypnotic or suggestive therapy on the basis of a wide experience. If, in the words of the old medical aphorism, an ideal therapy should be rapid, reliable and not disagreeable for the patient, Bernheim's method fulfilled at least two of these requirements. It could be carried through much quicker - or, rather, infinitely quicker - than analytic treatment and it caused the patient neither trouble nor unpleasantness. For the doctor it became, in the long run, monotonous: in each case, in the same way, with the same ceremonial, forbidding the most variegated symptoms to exist, without being able to learn anything of their sense and meaning. It was hackwork and not a scientific activity, and it recalled magic, incantations and hocus-pocus. That could not weigh, however, against the patient's interest. But the third quality was lacking: the procedure was not reliable in any respect. It could be used with one patient, but not with another; it achieved a great deal with one and very little with another, and one never knew why. Worse than the capriciousness of the procedure was the lack of permanence in its successes. If, after a short time, one had news of the patient once more, the old ailment was back again or its place had been taken by a new one. One might hypnotize him again. But in the background there was the warning given by experienced workers against robbing the patient of his self-reliance by frequently repeated hypnosis and so making him an addict to this kind of therapy as though it were a narcotic. Admittedly sometimes things went entirely as one would wish: after a few efforts, success was complete and permanent. But the conditions determining such a favourable outcome remained unknown. On one occasion a severe condition in a woman, which I had entirely got rid of by a short hypnotic treatment, returned unchanged after the patient had, through no action on my part, got annoyed with me; after a reconciliation, I removed the trouble again and far more thoroughly; yet it returned once more after she had fallen foul of me a second time. On another occasion a woman patient, whom I had repeatedly helped out of neurotic states by hypnosis, suddenly, during the treatment of a specially obstinate situation, threw her arms round my neck. After this one could scarcely avoid, whether one wanted to or not, investigating the question of the nature and origin of one's authority in suggestive treatment.

[1916-1917, 3491]

¹ A passage in the first edition of my Interpretation of Dreams (1900a) will show at what an early stage I was occupied with this problem. On p. 670 of that work there is an analysis of a remark occurring in a dream: 'That's not obtainable any longer.' It is explained that the phrase originated from myself. 'A few days earlier I had explained to the patient that the earliest experiences of childhood were "not obtainable any longer" as such but were replaced in analysis by "transferences" and dreams.'

[1918b, 3538]
I shall now attempt to sketch out a synthetic survey of my patient's sexual development, beginning from its earliest indications. The first that we hear of it is in the disturbance of his appetite: for, taking other observations into account, I am inclined, though with due reservations, to regard that as a result of some process in the sphere of sexuality. I have been driven to regard as the earliest recognizable sexual organization the so-called 'cannibalistic' or 'oral' phase, during which the original attachment of sexual excitation to the nutritional instinct still dominates the scene. It is not to be expected that we should come upon direct manifestations of this phase, but only upon indications of it where disturbances have been set up. Impairment of the nutritional instinct (though this can of course have other causes) draws our attention to a failure on the part of the organism to master its sexual excitation. In this phase the sexual aim could only be cannibalism - devouring; it makes its appearance with our present patient through regression from a higher stage, in the form of fear of 'being eaten by the wolf'. We were, indeed, obliged to translate this into a fear of being copulated with by his father. It is well known that there is a neurosis in girls which occurs at a much later age, at the time of puberty or soon afterwards, and which expresses aversion to sexuality by means of anorexia. This neurosis will have to be brought into relation with the oral phase of sexual life. The erotic aim of the oral organization further makes its appearance at the height of a lover's paroxysm (in such phrases as 'I could eat you up with love') and in affectionate relations with children, when the grown-up person is pretending to be a child himself. I have elsewhere given voice to a suspicion that the father of our present patient used himself to indulge in 'affectionate abuse', and may have played at wolf or dog with the little boy and have threatened as a joke to gobble him up (p. 3524). The patient confirmed this suspicion by his curious behaviour in the transference. Whenever he shrank back on to the transference from the difficulties of the treatment, he used to threaten me with eating me up and later with all kinds of other ill-treatment - all of which was merely an expression of affection.

[1918b, 3583]

It is probable that the first meaning which a child's interest in faeces develops is that of 'gift' rather than 'gold' or 'money'. The child knows no money apart from what is given him - no money acquired and none inherited of his own. Since his faeces are his first gift, the child easily transfers his interest from that substance to the new one which he comes across as the most valuable gift in life. Those who question this derivation of gifts should consider their experience of psycho-analytic treatment, study the gifts they receive as doctors from their patients, and watch the storms of transference which a gift from them can rouse in their patients.

[1917c, 3603]

We have formulated our task as physicians thus: to bring to the patient's knowledge the unconscious, repressed impulses existing in him, and, for that purpose, to uncover the resistances that oppose this extension of his knowledge about himself. Does the uncovering of these resistances guarantee that they will also be overcome? Certainly not always; but our hope is to achieve this by exploiting the patient's transference to the person of the physician, so as to induce him to adopt our conviction of the inexpediency of the repressive process established in childhood and of the impossibility of conducting life on the pleasure principle. I have set out elsewhere the dynamic conditions prevailing in the fresh conflict through which we lead the patient and which we substitute in him for his previous conflict - that of his illness. I have nothing at the moment to alter in that account.

[1919a, 3628]
But it became ever clearer that the aim which had been set up - the aim that what was unconscious should become conscious - is not completely attainable by that method. The patient cannot remember the whole of what is repressed in him, and what he cannot remember may be precisely the essential part of it. Thus he acquires no sense of conviction of the correctness of the construction that has been communicated to him. He is obliged to repeat the repressed material as a contemporary experience instead of, as the physician would prefer to see, remembering it as something belonging to the past.¹ These reproductions, which emerge with such unwished-for exactitude, always have as their subject some portion of infantile sexual life - of the Oedipus complex, that is, and its derivatives; and they are invariably acted out in the sphere of the transference, of the patient's relation to the physician. When things have reached this stage, it may be said that the earlier neurosis has now been replaced by a fresh, 'transference neurosis'. It has been the physician's endeavour to keep this transference neurosis within the narrowest limits: to force as much as possible into the channel of memory and to allow as little as possible to emerge as repetition. The ratio between what is remembered and what is reproduced varies from case to case. The physician cannot as a rule spare his patient this phase of the treatment. He must get him to re-experience some portion of his forgotten life, but must see to it, on the other hand, that the patient retains some degree of aloofness, which will enable him, in spite of everything, to recognize that what appears to be reality is in fact only a reflection of a forgotten past. If this can be successfully achieved, the patient's sense of conviction is won, together with the therapeutic success that is dependent on it.

¹[1920g, 3723]

Patients repeat all of these unwanted situations and painful emotions in the transference and revive them with the greatest ingenuity. They seek to bring about the interruption of the treatment while it is still incomplete; they contrive once more to feel themselves scorned, to oblige the physician to speak severely to them and treat them coldly; they discover appropriate objects for their jealousy; instead of the passionately desired baby of their childhood, they produce a plan or a promise of some grand present - which turns out as a rule to be no less unreal. None of these things can have produced pleasure in the past, and it might be supposed that they would cause less unpleasure to-day if they emerged as memories or dreams instead of taking the form of fresh experiences. They are of course the activities of instincts intended to lead to satisfaction; but no lesson has been learnt from the old experience of these activities having led instead only to unpleasure. In spite of that, they are repeated, under pressure of a compulsion.

[1920g, 3725]
What psycho-analysis reveals in the transference phenomena of neurotics can also be observed in the lives of some normal people. The impression they give is of being pursued by a malignant fate or possessed by some 'daemonic' power; but psycho-analysis has always taken the view that their fate is for the most part arranged by themselves and determined by early infantile influences. The compulsion which is here in evidence differs in no way from the compulsion to repeat which we have found in neurotics, even though the people we are now considering have never shown any signs of dealing with a neurotic conflict by producing symptoms. Thus we have come across people all of whose human relationships have the same outcome: such as the benefactor who is abandoned in anger after a time by each of his protégés, however much they may otherwise differ from one another, and who thus seems doomed to taste all the bitterness of ingratitude; or the man whose friendships all end in betrayal by his friend; or the man who time after time in the course of his life raises someone else into a position of great private or public authority and then, after a certain interval, himself upsets that authority and replaces him by a new one; or, again, the lover each of whose love affairs with a woman passes through the same phases and reaches the same conclusion. This 'perpetual recurrence of the same thing' causes us no astonishment when it relates to active behaviour on the part of the person concerned and when we can discern in him an essential character-trait which always remains the same and which is compelled to find expression in a repetition of the same experiences. We are much more impressed by cases where the subject appears to have a passive experience, over which he has no influence, but in which he meets with a repetition of the same fatality. There is the case, for instance, of the woman who married three successive husbands each of whom fell ill soon afterwards and had to be nursed by her on their death-beds.¹ The most moving poetic picture of a fate such as this is given by Tasso in his romantic epic Gerusalemme Liberata. Its hero, Tancred, unwittingly kills his beloved Clorinda in a duel while she is disguised in the armour of an enemy knight. After her burial he makes his way into a strange magic forest which strikes the Crusaders' army with terror. He slashes with his sword at a tall tree; but blood streams from the cut and the voice of Clorinda, whose soul is imprisoned in the tree, is heard complaining that he has wounded his beloved once again.

[1920g, 3726]

But it is to be noted that only in rare instances can we observe the pure effects of the compulsion to repeat, unsupported by other motives. In the case of children’s play we have already laid stress on the other ways in which the emergence of the compulsion may be interpreted; the compulsion to repeat and instinctual satisfaction which is immediately pleasurable seem to converge here into an intimate partnership. The phenomena of transference are obviously exploited by the resistance which the ego maintains in its pertinacious insistence upon repression; the compulsion to repeat, which the treatment tries to bring into its service is, as it were, drawn over by the ego to its side (clinging as the ego does to the pleasure principle). A great deal of what might be described as the compulsion of destiny seems intelligible on a rational basis; so that we are under no necessity to call in a new and mysterious motive force to explain it.

[1920g, 3727]
The manifestations of a compulsion to repeat (which we have described as occurring in the early activities of infantile mental life as well as among the events of psycho-analytic treatment) exhibit to a high degree an instinctual character and, when they act in opposition to the pleasure principle, give the appearance of some ‘daemonic’ force at work. In the case of children’s play we seemed to see that children repeat unpleasurable experiences for the additional reason that they can master a powerful impression far more thoroughly by being active than they could by merely experiencing it passively. Each fresh repetition seems to strengthen the mastery they are in search of. Nor can children have their pleasurable experiences repeated often enough, and they are inexorable in their insistence that the repetition shall be an identical one. This character trait disappears later on. If a joke is heard for a second time it produces almost no effect; a theatrical production never creates so great an impression the second time as the first; indeed, it is hardly possible to persuade an adult who has very much enjoyed reading a book to re-read it immediately. Novelty is always the condition of enjoyment. But children will never tire of asking an adult to repeat a game that he has shown them or played with them, till he is too exhausted to go on. And if a child has been told a nice story, he will insist on hearing it over and over again rather than a new one; and he will remorselessly stipulate that the repetition shall be an identical one and will correct any alterations of which the narrator may be guilty - though they may actually have been made in the hope of gaining fresh approval. None of this contradicts the pleasure principle; repetition, the re-experiencing of something identical, is clearly in itself a source of pleasure. In the case of a person in analysis, on the contrary, the compulsion to repeat the events of his childhood in the transference evidently disregards the pleasure principle in every way. The patient behaves in a purely infantile fashion and thus shows us that the repressed memory-traces of his primaeval experiences are not present in him in a bound state and are indeed in a sense incapable of obeying the secondary process. It is to this fact of not being bound, moreover, that they owe their capacity for forming, in conjunction with the residues of the previous day, a wishful phantasy that emerges in a dream. This same compulsion to repeat frequently meets us as an obstacle to our treatment when at the end of an analysis we try to induce the patient to detach himself completely from his physician. It may be presumed, too, that when people unfamiliar with analysis feel an obscure fear - a dread of rousing something that, so they feel, is better left sleeping - what they are afraid of at bottom is the emergence of this compulsion with its hint of possession by some ‘daemonic’ power.

In the case of our patient, it was not doubt but the affective factor of revenge against her father that made her cool reserve possible, that divided the analysis into two distinct phases, and rendered the results of the first phase so complete and perspicuous. It seemed, further, as though nothing resembling a transference to the physician had been effected. That, however, is of course absurd, or, at least, is a loose way of expressing things. For some kind of relation to the analyst must come into being, and this relation is almost always transferred from an infantile one. In reality she transferred to me the sweeping repudiation of men which had dominated her ever since the disappointment she had suffered from her father. Bitterness against men is as a rule easy to gratify upon the physician; it need not evoke any violent emotional manifestations, it simply expresses itself by rendering futile all his endeavours and - by clinging to the illness. I know from experience how difficult it is to make a patient understand just precisely this mute kind of symptomatic behaviour and to make him aware of this latent, and often exceedingly strong, hostility without endangering the treatment. As soon, therefore, as I recognized the girl’s attitude to her father, I broke off the treatment and advised her parents that if they set store by the therapeutic procedure it should be continued by a woman doctor. The girl had in the meanwhile promised her father that at any rate she would give up seeing the ‘lady’, and I do not know whether my advice, the reasons for which are obvious, will be followed.

[1920g, 3738]
Transference. - If further proof were needed of the truth that the motive forces behind the formation of neurotic symptoms are of a sexual nature, it would be found in the fact that in the course of analytic treatment a special emotional relation is regularly formed between the patient and the physician. This goes far beyond rational limits. It varies between the most affectionate devotion and the most obstinate enmity and derives all of its characteristics from earlier erotic attitudes of the patient's which have become unconscious. This transference alike in its positive and in its negative form is used as a weapon by the resistance; but in the hands of the physician it becomes the most powerful therapeutic instrument and it plays a part scarcely to be over-estimated in the dynamics of the process of cure.
[1923a, 3924]

Narcissism. - The most important theoretical advance has certainly been the application of the libido theory to the repressing ego. The ego itself came to be regarded as a reservoir of what was described as narcissistic libido, from which the libidinal cathexes of objects flowed out and into which they could be once more withdrawn. By the help of this conception it became possible to embark upon the analysis of the ego and to make a clinical distinction of the psychoneuroses into transference neuroses and narcissistic disorders. In the former (hysteria and obsessional neurosis) the subject has at his disposal a quantity of libido striving to be transferred on to extraneous objects, and use is made of this in carrying out analytic treatment; on the other hand, the narcissistic disorders (dementia praecox, paranoia, melancholia) are characterized by a withdrawal of the libido from objects and they are therefore scarcely accessible to analytic therapy. But their therapeutic inaccessibility has not prevented analysis from making the most fruitful beginnings in the deeper study of these illnesses, which are counted among the psychoses.
[1923a, 3925]

It may well be that dreams during psycho-analysis succeed in bringing to light what is repressed to a greater extent than dreams outside that situation. But it cannot be proved, since the two situations are not comparable; the employment of dreams in analysis is something very remote from their original purpose. On the other hand, it cannot be doubted that within an analysis far more of the repressed is brought to light in connection with dreams than by any other method. In order to account for this, there must be some motive power, some unconscious force, which is better able to lend support to the purposes of analysis during the state of sleep than at other times. What is here in question cannot well be any factor other than the patient's compliance towards the analyst which is derived from his parental complex - in other words, the positive portion of what we call the transference; and in fact, in many dreams which recall what has been forgotten and repressed, it is impossible to discover any other unconscious wish to which the motive force for the formation of the dream can be attributed. So that if anyone wishes to maintain that most of the dreams that can be made use of in analysis are obliging dreams and owe their origin to suggestion, nothing can be said against that opinion from the point of view of analytic theory. In that case I need only add a reference to what I have said in my Introductory Lectures, where I have dealt with the relation between transference and suggestion and shown how little the trustworthiness of our results is affected by a recognition of the operation of suggestion in our sense.
[1923c, 4038]
After hypnosis was replaced by the technique of free association, Breuer’s cathartic procedure turned into psycho-analysis, which for more than a decade was developed by the author (Freud) alone. During that time psycho-analysis gradually acquired a theory which appeared to give a satisfactory account of the origin, meaning and purpose of neurotic symptoms and provided a rational basis for medical attempts at curing the complaint. I will once again enumerate the factors that go to make up this theory. They are: emphasis on instinctual life (affectivity), on mental dynamics, on the fact that even the apparently most obscure and arbitrary mental phenomena invariably have a meaning and a causation, the theory of psychical conflict and of the pathogenic nature of repression, the view that symptoms are substitutive satisfactions, the recognition of the aetiological importance of sexual life, and in particular of the beginnings of infantile sexuality. From a philosophical standpoint this theory was bound to adopt the view that the mental does not coincide with the conscious, that mental processes are in themselves unconscious and are only made conscious by the functioning of special organs (agencies or systems). By way of completing this list, I will add that among the affective attitudes of childhood the complicated emotional relation of children to their parents - what is known as the Oedipus complex - came into prominence. It became ever clearer that this was the nucleus of every case of neurosis, and in the patient's behaviour towards his analyst certain phenomena of his emotional transference emerged which came to be of great importance for theory and technique alike.

[1924f, 4107]

I have repeatedly attempted - most recently in my Autobiographical Study (1925d), in Grote's series, Die Medizin der Gegenwart - to define my share in the Studies which we published jointly. My merit lay chiefly in reviving in Breuer an interest which seemed to have become extinct, and in then urging him on to publication. A kind of reserve which was characteristic of him, an inner modesty, surprising in a man of such a brilliant personality, had led him to keep his astonishing discovery secret for so long that not all of it was any longer new. I found reason later to suppose that a purely emotional factor, too, had given him an aversion to further work on the elucidation of the neuroses. He had come up against something that is never absent - his patient's transference on to her physician, and he had not grasped the impersonal nature of the process. At the time when he submitted to my influence and was preparing the Studies for publication, his judgement of their significance seemed to be confirmed. 'I believe', he told me, 'that this is the most important thing we two have to give the world.'

[1925g, 4172]

During the years that followed the publication of the Studies, having reached these conclusions upon the part played by sexuality in the aetiology of the neuroses, I read some papers on the subject before various medical societies, but was only met with incredulity and contradiction. Breuer did what he could for some time longer to throw the great weight of his personal influence into the scales in my favour, but he effected nothing and it was easy to see that he too shrank from recognizing the sexual aetiology of the neuroses. He might have crushed me or at least disconcerted me by pointing to his own first patient, in whose case sexual factors had ostensibly played no part whatever. But he never did so, and I could not understand why this was, until I came to interpret the case correctly and to reconstruct, from some remarks which he had made, the conclusion of his treatment of it. After the work of catharsis had seemed to be completed, the girl had suddenly developed a condition of 'transference love'; he had not connected this with her illness, and had therefore retired in dismay. It was obviously painful to him to be reminded of this apparent contretemps. His attitude towards me oscillated for some time between appreciation and sharp criticism; then accidental difficulties arose, as they never fail to do in a strained situation, and we parted.

[1925d, 4203]
Another result of my taking up the study of nervous disorders in general was that I altered the technique of catharsis. I abandoned hypnotism and sought to replace it by some other method, because I was anxious not to be restricted to treating hysteriform conditions. Increasing experience had also given rise to two grave doubts in my mind as to the use of hypnotism even as a means to catharsis. The first was that even the most brilliant results were liable to be suddenly wiped away if my personal relation with the patient became disturbed. It was true that they would be re-established if a reconciliation could be effected; but such an occurrence proved that the personal emotional relation between doctor and patient was after all stronger than the whole cathartic process, and it was precisely that factor which escaped every effort at control. And one day I had an experience which showed me in the crudest light what I had long suspected. It related to one of my most acquiescent patients, with whom hypnotism had enabled me to bring about the most marvellous results, and whom I was engaged in relieving of her suffering by tracing back her attacks of pain to their origins. As she woke up on one occasion, she threw her arms round my neck. The unexpected entrance of a servant relieved us from a painful discussion, but from that time onwards there was a tacit understanding between us that the hypnotic treatment should be discontinued. I was modest enough not to attribute the event to my own irresistible personal attraction, and I felt that I had now grasped the nature of the mysterious element that was at work behind hypnotism. In order to exclude it, or at all events to isolate it, it was necessary to abandon hypnotism.

I now come to the description of a factor which adds an essential feature to my picture of analysis and which can claim, alike technically and theoretically, to be regarded as of the first importance. In every analytic treatment there arises, without the physician's agency, an intense emotional relationship between the patient and the analyst which is not to be accounted for by the actual situation. It can be of a positive or of a negative character and can vary between the extremes of a passionate, completely sensual love and the unbridled expression of an embittered defiance and hatred. This transference - to give it its short name - soon replaces in the patient's mind the desire to be cured, and, so long as it is affectionate and moderate, becomes the agent of the physician's influence and neither more nor less than the mainspring of the joint work of analysis. Later on, when it has become passionate or has been converted into hostility, it becomes the principal tool of the resistance. It may then happen that it will paralyse the patient's powers of associating and endanger the success of the treatment. Yet it would be senseless to try to evade it; for an analysis without transference is an impossibility. It must not be supposed, however, that transference is created by analysis and does not occur apart from it. Transference is merely uncovered and isolated by analysis. It is a universal phenomenon of the human mind, it decides the success of all medical influence, and in fact dominates the whole of each person's relations to his human environment. We can easily recognize it as the same dynamic factor which the hypnotists have named 'suggestibility', which is the agent of hypnotic rapport and whose incalculable behaviour led to difficulties with the cathartic method as well. When there is no inclination to a transference of emotion such as this, or when it has become entirely negative, as happens in dementia praecox or paranoia, then there is also no possibility of influencing the patient by psychological means.
It is perfectly true that psycho-analysis, like other psychotherapeutic methods, employs the instrument of suggestion (or transference). But the difference is this: that in analysis it is not allowed to play the decisive part in determining the therapeutic results. It is used instead to induce the patient to perform a piece of psychical work - the overcoming of his transference resistences - which involves a permanent alteration in his mental economy. The transference is made conscious to the patient by the analyst, and it is resolved by convincing him that in his transference-attitude he is re-experiencing emotional relations which had their origin in his earliest object-attachments during the repressed period of his childhood. In this way the transference is changed from the strongest weapon of the resistance into the best instrument of the analytic treatment. Nevertheless its handling remains the most difficult as well as the most important part of the technique of analysis.

[1925d, 4218]

Yes, it ought to. But there turns out to be an unexpected complication. It was perhaps the greatest of the analyst's surprises to find that the emotional relation which the patient adopts towards him is of a quite peculiar nature. The very first doctor who attempted an analysis - it was not myself - came up against this phenomenon and did not know what to make of it. For this emotional relation is, to put it plainly, in the nature of falling in love. Strange, is it not? Especially when you take into account that the analyst does nothing to provoke it but on the contrary rather keeps at a distance from the patient, speaking humanly, and surrounds himself with some degree of reserve - when you learn besides that this odd love-relationship disregards anything else that is really propitious and every variation in personal attraction, age, sex or class. This love is of a positively compulsive kind. Not that that characteristic need be absent from spontaneous falling in love. As you know, the contrary is often the case. But in the analytic situation it makes its appearance with complete regularity without there being any rational explanation for it. One would have thought that the patient's relation to the analyst called for no more than a certain amount of respect, trust, gratitude and human sympathy. Instead, there is this falling in love, which itself gives the impression of being a pathological phenomenon.

[1926e, 4367]

Yes. It is favourable to start with. But when this falling in love has grown deeper, its whole nature comes to light, much of which is incompatible with the task of analysis. The patient's love is not satisfied with being obedient; it grows exacting, calls for affectionate and sensual satisfactions, it demands exclusiveness, it develops jealousy, and it shows more and more clearly its reverse side, its readiness to become hostile and revengeful if it cannot obtain its ends. At the same time, like all falling in love, it drives away all other mental material; it extinguishes interest in the treatment and in recovery - in short, there can be no doubt that it has taken the place of the neurosis and that our work has had the result of driving out one form of illness with another.

[1926e, 4367]

We will begin by using the situation in order to learn something from it. What we learn may then perhaps help us to master it. Is it not an extremely noteworthy fact that we succeed in transforming every neurosis, whatever its content, into a condition of pathological love?
Our conviction that a portion of erotic life that has been abnormally employed lies at the basis of neuroses must be unshakeably strengthened by this experience. With this discovery we are once more on a firm footing and can venture to make this love itself the object of analysis. And we can make another observation. Analytic love is not manifested in every case as clearly and blatantly as I have tried to depict it. Why not? We can soon see. In proportion as the purely sensual and the hostile sides of his love try to show themselves, the patient’s opposition to them is aroused. He struggles against them and tries to repress them before our very eyes. And now we understand what is happening. The patient is repeating in the form of falling in love with the analyst mental experiences which he has already been through once before; he has transferred on to the analyst mental attitudes that were lying ready in him and were intimately connected with his neurosis. He is also repeating before our eyes his old defensive actions; he would like best to repeat in his relation to the analyst all the history of that forgotten period of his life. So what he is showing us is the kernel of his intimate life history: he is reproducing it tangibly, as though it were actually happening, instead of remembering it. In this way the riddle of the transference-love is solved and the analysis can proceed on its way - with the help of the new situation which had seemed such a menace to it.

[1926e, 4368]

‘And where do you suppose the neurotic experienced the prototype of his transference-love?’

[1926e, 4369]

In his childhood: as a rule in his relation with one of his parents. You will remember what importance we had to attribute to these earliest emotional ties. So here the circle closes.

[1926e, 4369]
Again, I attach no great importance to the argument that a lay analyst, because he must be prepared to consult a doctor, will have no authority in the eyes of his patients and will be treated with no more respect than such people as bone-setters or masseurs. Once again, the analogy is an imperfect one - quite apart from the fact that what governs patients in their recognition of authority is usually their emotional transference and that the possession of a medical diploma does not impress them nearly so much as doctors believe. A professional lay analyst will have no difficulty in winning as much respect as is due to a secular pastoral worker. Indeed, the words, 'secular pastoral worker', might well serve as a general formula for describing the function which the analyst, whether he is a doctor or a layman, has to perform in his relation to the public. Our friends among the protestant clergy, and more recently among the catholic clergy as well, are often able to relieve their parishioners of the inhibitions of their daily life by confirming their faith - after having first offered them a little analytic information about the nature of their conflicts. Our opponents, the Adlerian 'individual psychologists', endeavour to produce a similar result in people who have become unstable and inefficient by arousing their interest in the social community after having first thrown some light upon a single corner of their mental life and shown them the part played in their illness by their egoistic and distrustful impulses. Both of these procedures, which derive their power from being based on analysis, have their place in psychotherapy. We who are analysts set before us as our aim the most complete and profoundest possible analysis of whoever may be our patient. We do not seek to bring him relief by receiving him into the catholic, protestant or socialist community. We seek rather to enrich him from his own internal sources, by putting at the disposal of his ego those energies which, owing to repression, are inaccessibly confined in his unconscious, as well as those which his ego is obliged to squander in the fruitless task of maintaining these repressions. Such activity as this is pastoral work in the best sense of the words. Have we set ourselves too high an aim? Are the majority of our patients worth the pains that this work requires of us? Would it not be more economical to prop up their weaknesses from without rather than to rebuild them from within? I cannot say; but there is something else that I do know. In psycho-analysis there has existed from the very first an inseparable bond between cure and research. Knowledge brought therapeutic success. It was impossible to treat a patient without learning something new; it was impossible to gain fresh insight without perceiving its beneficent results. Our analytic procedure is the only one in which this precious conjunction is assured. It is only by carrying on our analytic pastoral work that we can deepen our dawning comprehension of the human mind. This prospect of scientific gain has been the proudest and happiest feature of analytic work. Are we to sacrifice it for the sake of any considerations of a practical sort?

[1926e, 4396]

The first task of psycho-analysis was the elucidation of nervous disorders. The analytic theory of the neuroses is based on three corner-stones: the recognition of (1) 'repression', of (2) the importance of the sexual instinct and of (3) 'transference'.

[1926f, 4405]

(3) By 'transference' is meant a striking peculiarity of neurotics. They develop towards their physician emotional relations, both of an affectionate and hostile character, which are not based upon the actual situation but are derived from their relations to their parents (the Oedipus complex). Transference is a proof of the fact that adults have not overcome their former childish dependence; it coincides with the force which has been named 'suggestion'; and it is only by learning to make use of it that the physician is enabled to induce the patient to overcome his internal resistances and do away with his repressions. Thus psycho-analytic treatment acts as a second education of the adult, as a corrective to his education as a child.

[1926f, 4406]
The very surprising sexual activity of little girls in relation to their mother is manifested chronologically in oral, sadistic, and finally even in phallic trends directed towards her. It is difficult to give a detailed account of these because they are often obscure instinctual impulses which it was impossible for the child to grasp psychically at the time of their occurrence, which were therefore only interpreted by her later, and which then appear in the analysis in forms of expression that were certainly not the original ones. Sometimes we come across them as transferences on to the later, father-object, where they do not belong and where they seriously interfere with our understanding of the situation. We find the little girl's aggressive oral and sadistic wishes in a form forced on them by early repression, as a fear of being killed by her mother - a fear which, in turn, justifies her death-wish against her mother, if that becomes conscious. It is impossible to say how often this fear of the mother is supported by an unconscious hostility on the mother's part which is sensed by the girl. (Hitherto, it is only in men that I have found the fear of being eaten up. This fear is referred to the father, but it is probably the product of a transformation of oral aggressivity directed to the mother. The child wants to eat up its mother from whom it has had its nourishment; in the case of the father there is no such obvious determinant for the wish.)

[1931b, 4601]

But it is far from being the case that his ego is content to play the part of passively and obediently bringing us the material we require and of believing and accepting our translation of it. A number of other things happen, a few of which we might have foreseen but others of which are bound to surprise us. The most remarkable thing is this. The patient is not satisfied with regarding the analyst in the light of reality as a helper and adviser who, moreover, is remunerated for the trouble he takes and who would himself be content with some such role as that of a guide on a difficult mountain climb. On the contrary, the patient sees in him the return, the reincarnation, of some important figure out of his childhood or past, and consequently transfers on to him feelings and reactions which undoubtedly applied to this prototype. This fact of transference soon proves to be a factor of undreamt-of importance, on the one hand an instrument of irreplaceable value and on the other hand a source of serious dangers. This transference is ambivalent: it comprises positive (affectionate) as well as negative (hostile) attitudes towards the analyst, who as a rule is put in the place of one or other of the patient's parents, his father or mother. So long as it is positive it serves us admirably. It alters the whole analytic situation; it pushes to one side the patient's rational aim of becoming healthy and free from his ailments. Instead of it there emerges the aim of pleasing the analyst and of winning his applause and love. It becomes the true motive force of the patient's collaboration; his weak ego becomes strong; under its influence he achieves things that would ordinarily be beyond his power; he leaves off his symptoms and seems apparently to have recovered - merely for the sake of the analyst. The analyst may shamefacedly admit to himself that he set out on a difficult undertaking without any suspicion of the extraordinary powers that would be at his command.

[1940a [1938], 4984]
Moreover, the relation of transference brings with it two further advantages. If the patient puts the analyst in the place of his father (or mother), he is also giving him the power which his super-ego exercises over his ego, since his parents were, as we know, the origin of his super-ego. The new super-ego now has an opportunity for a sort of after-education of the neurotic; it can correct mistakes for which his parents were responsible in educating him. But at this point a warning must be given against misusing this new influence. However much the analyst may be tempted to become a teacher, model and ideal for other people and to create men in his own image, he should not forget that that is not his task in the analytic relationship, and indeed that he will be disloyal to his task if he allows himself to be led on by his inclinations. If he does, he will only be repeating a mistake of the parents who crushed their child’s independence by their influence, and he will only be replacing the patient’s earlier dependence by a new one. In all his attempts at improving and educating the patient the analyst should respect his individuality. The amount of influence which he may legitimately allow himself will be determined by the degree of developmental inhibition present in the patient. Some neurotics have remained so infantile that in analysis too they can only be treated as children.

[1940a [1938], 4985]

And now for the other side of the situation. Since the transference reproduces the patient’s relation with his parents, it takes over the ambivalence of that relation as well. It almost inevitably happens that one day his positive attitude towards the analyst changes over into the negative, hostile one. This too is as a rule a repetition of the past. His obedience to his father (if it is his father that is in question), his courting of his father’s favour, had its roots in an erotic wish directed towards him. Some time or other that demand will press its way forward in the transference as well and insist on being satisfied. In the analytic situation it can only meet with frustration. Real sexual relations between patients and analysts are out of the question, and even the subtler methods of satisfaction, such as the giving of preference, intimacy and so on, are only sparingly granted by the analyst. A rejection of this kind is taken as the occasion for the change-over; probably things happened in the same way in the patient’s childhood.

[1940a [1938], 4986]
The therapeutic successes that occurred under the sway of the positive transference are open
to the suspicion of being of a suggestive nature. If the negative transference gains the upper
hand, they are blown away like chaff before the wind. We observe with horror that all our trouble
and labour hitherto have been in vain. Indeed, what we might have regarded as a permanent
intellectual gain by the patient, his understanding of psycho-analysis and his reliance on its
efficacy, suddenly vanish. He behaves like a child who has no power of judgement of his own
but blindly believes anyone whom he loves and no one who is a stranger to him. The danger of
these states of transference evidently lies in the patient's misunderstanding their nature and
taking them for fresh real experiences instead of reflections of the past. If he (or she) becomes
aware of the strong erotic desire that lies concealed behind the positive transference, he
believes that he has fallen passionately in love; if the transference changes over, then he feels
insulted and neglected, he hates the analyst as his enemy and is ready to abandon the
analysis. In both these extreme cases he has forgotten the pact that he made at the beginning
of the treatment and has become useless for continuing the common work. It is the analyst's
task constantly to tear the patient out of his menacing illusion and to show him again and again
that what he takes to be new real life is a reflection of the past. And lest he should fall into a
state in which he is inaccessible to all evidence, the analyst takes care that neither the love nor
the hostility reach an extreme height. This is effected by preparing him in good time for these
possibilities and by not overlooking the first signs of them. Careful handling of the transference
on these lines is as a rule richly rewarded. If we succeed, as we usually can, in enlightening the
patient on the true nature of the phenomena of transference, we shall have struck a powerful
weapon out of the hand of his resistance and shall have converted dangers into gains. For a
patient never forgets again what he has experienced in the form of transference; it carries a
greater force of conviction than anything he can acquire in other ways.
[1940a [1938], 4986]
In view of what I have said in the preceding section about the difficulties of my technique, which I have unsparingly exposed (I brought them together, incidentally, from the severest cases; things often turn out very much more conveniently) - in view of all this, then, everyone will no doubt feel inclined to ask whether it would not be more expedient, instead of putting up with all these troubles, to make a more energetic use of hypnosis or to restrict the use of the cathartic method to patients who can be put under deep hypnosis. As regards the latter proposal I should have to answer that in that case the number of suitable patients, so far as my skill is concerned, would dwindle far too much; and I would meet the first piece of advice with the suspicion that the forcible imposition of hypnosis might not spare us much resistance. My experiences on this point, oddly enough, have not been numerous, and I cannot, therefore, go beyond a suspicion. But where I have carried out a cathartic treatment under hypnosis instead of under concentration, I did not find that this diminished the work I had to do. Not long ago I completed a treatment of this kind in the course of which I caused a hysterical paralysis of the legs to clear up. The patient passed into a state which was very different psychically from waking and which was characterized physically by the fact that it was impossible for her to open her eyes or get up till I had called out to her: 'Now wake up!' None the less I have never come across greater resistance than in this case. I attached no importance to these physical signs, and towards the end of the treatment, which lasted ten months, they had ceased to be noticeable. But in spite of this the patient's state while we were working lost none of its psychical characteristics - the capacity she possessed for remembering unconscious material and her quite special relation to the figure of the physician. On the other hand, I have given an example in the case history of Frau Emmy von N. of a cathartic treatment in the deepest somnambulism in which resistance played scarcely any part. But it is also true that I learnt from that lady nothing whose telling might have called for any special overcoming of objections, nothing that she could not have told me even in a waking state, supposing we had been acquainted for some time and she had thought fairly highly of me. I never reached the true causes of her illness, which were no doubt identical with the causes of her relapse after my treatment (for this was my first attempt with this method); and the only occasion on which I happened to ask her for a reminiscence which involved an erotic element I found her just as reluctant and untrustworthy in what she told me as I did later with any of my non-somnambulistic patients. I have already spoken in that lady's case history of the resistance which she put up even during somnambulism to other requests and suggestions of mine. I have become altogether sceptical about the value of hypnosis in facilitating cathartic treatments, since I have experienced instances in which during deep somnambulism there has been absolute therapeutic recalcitrance, where in other respects the patient has been perfectly obedient. I reported a case of this kind briefly on p. 90 n., and I could add others. I may admit, too, that this experience has corresponded pretty well to the requirement I insist upon that there shall be a quantitative relation between cause and effect in the psychical field as well.

There is another kind of incompleteness which I myself have intentionally introduced. I have as a rule not reproduced the process of interpretation to which the patient's associations and communications had to be subjected, but only the results of that process. Apart from the dreams, therefore, the technique of the analytic work has been revealed in only a very few places. My object in this case history was to demonstrate the intimate structure of a neurotic disorder and the determination of its symptoms; and it would have led to nothing but hopeless confusion if I had tried to complete the other task at the same time. Before the technical rules, most of which have been arrived at empirically, could be properly laid down, it would be necessary to collect material from the histories of a large number of treatments. Nevertheless, the degree of shortening produced by the omission of the technique is not to be exaggerated in this particular case. Precisely that portion of the technical work which is the most difficult never came into question with the patient; for the factor of 'transference', which is considered at the end of the case history, did not come up for discussion during the short treatment.

[1905e, 1355]
Moreover, the re-appearance of the dream in the last few days forces me to the conclusion that you consider that the same situation has arisen once again, and that you have decided to give up the treatment - to which, after all, it is only your father who makes you come. The sequel showed how correct my guess had been. At this point my interpretation touches for a moment upon the subject of 'transference' - a theme which is of the highest practical and theoretical importance, but into which I shall not have much further opportunity of entering in the present paper.

The interpretation of the dream now seemed to me to be complete. But Dora brought me an addendum to the dream on the very next day. She had forgotten to relate, she said, that each time after waking up she had smelt smoke. Smoke, of course, fitted in well with fire, but it also showed that the dream had a special relation to myself; for when she used to assert that there was nothing concealed behind this or that, I would often say by way of rejoinder: 'There can be no smoke without fire!' Dora objected, however, to such a purely personal interpretation, saying that Herr K. and her father were passionate smokers - as I am too, for the matter of that. She herself had smoked during her stay by the lake, and Herr K. had rolled a cigarette for her before he began his unlucky proposal. She thought, too, that she clearly remembered having noticed the smell of smoke on the three occasions of the dream's occurrence at L--, and not for the first time at its recent reappearance. As she would give me no further information, it was left to me to determine how this addendum was to be introduced into the texture of the dream-thoughts. One thing which I had to go upon was the fact that the smell of smoke had only come up as an addendum to the dream, and must therefore have had to overcome a particularly strong effort on the part of repression. Accordingly it was probably related to the thoughts which were the most obscurely presented and the most successfully repressed in the dream, to the thoughts, that is, concerned with the temptation to show herself willing to yield to the man. If that were so, the addendum to the dream could scarcely mean anything else than the longing for a kiss, which, with a smoker, would necessarily smell of smoke. But a kiss had passed between Herr K. and Dora some two years further back, and it would certainly have been repeated more than once if she had given way to him. So the thoughts of temptation seemed in this way to have harked back to the earlier scene, and to have revived the memory of the kiss against whose seductive influence the little 'thumb-sucker' had defended herself at the time, by the feeling of disgust. Taking into consideration, finally, the indications which seemed to point to there having been a transference on to me - since I am a smoker too - I came to the conclusion that the idea had probably occurred to her one day during a session that she would like to have a kiss from me. This would have been the exciting cause which led her to repeat the warning dream and to form her intention of stopping the treatment. Everything fits together very satisfactorily upon this view; but owing to the characteristics of 'transference' its validity is not susceptible of definite proof.

If the theory of analytic technique is gone into, it become evident that transference is an inevitable necessity. Practical experience, at all events, shows conclusively that there is no means of avoiding it, and that this latest creation of the disease must be combated like all the earlier ones. This happens, however, to be by far the hardest part of the whole task. It is easy to learn how to interpret dreams, to extract from the patient's associations his unconscious thoughts and memories, and to practise similar explanatory arts: for these the patient himself will always provide the text. Transference is the one thing the presence of which has to be detected almost without assistance and with only the slightest clues to go upon, while at the same time the risk of making arbitrary inferences has to be avoided. Nevertheless, transference cannot be evaded, since use is made of it in setting up all the obstacles that make the material inaccessible to treatment, and since it is only after the transference has been resolved that a patient arrives at a sense of conviction of the validity of the connections which have been constructed during the analysis.
Some people may feel inclined to look upon it as a serious objection to a method which is in any case troublesome enough that it itself should multiply the labours of the physician by creating a new species of pathological mental products. They may even be tempted to infer from the existence of transferences that the patient will be injured by analytic treatment. Both these suppositions would be mistaken. The physician's labours are not multiplied by transference; it need make no difference to him whether he has to overcome any particular impulse of the patient's in connection with himself or with some one else. Nor does the treatment force upon the patient, in the shape of transference, any new task which he would not other wise have performed. It is true that neuroses may be cured in institutions from which psycho-analytic treatment is excluded, that hysteria may be said to be cured not by the method but by the physician, and that there is usually a sort of blind dependence and a permanent bond between a patient and the physician who has removed his symptoms by hypnotic suggestion; but the scientific explanation of all these facts is to be found in the existence of 'transferences' such as are regularly directed by patients on to their physicians. Psycho-analytic treatment does not create transferences, it merely brings them to light, like so many other hidden psychical factors. The only difference is this - that spontaneously a patient will only call up affectionate and friendly transferences to help towards his recovery; if they cannot be called up, he feels the physician is 'antipathetic' to him, and breaks away from him as fast as possible and without having been influenced by him. In psycho-analysis, on the other hand, since the play of motives is different, all the patient's tendencies, including hostile ones, are aroused; they are then turned to account for the purposes of the analysis by being made conscious, and in this way the transference is constantly being destroyed. Transference, which seems ordained to be the greatest obstacle to psycho-analysis, becomes its most powerful ally, if its presence can be detected each time and explained to the patient.¹

But the similarity between Gradiva's procedure and the analytic method of psychotherapy is not limited to these two points - the making conscious of what has been repressed and the coinciding of explanation with cure. It also extends to what turns out to be the essence of the whole change - to the awakening of feelings. Every disorder analogous to Hanold's delusion, what in scientific terms we are in the habit of calling 'psychoneuroses', has as its precondition the repression of a portion of instinctual life, or, as we can safely say, of the sexual instinct. At every attempt to introduce the unconscious and repressed causes of the illness into consciousness, the instinctual component concerned is necessarily aroused to a renewed struggle with the repressing powers, only to come to terms with them in the final outcome, often to the accompaniment of violent manifestations of reaction. The process of cure is accomplished in a relapse into love, if we combine all the many components of the sexual instinct under the term 'love'; and such a relapse is indispensable, for the symptoms on account of which the treatment has been undertaken are nothing other than precipitates of earlier struggles connected with repression or the return of the repressed, and they can only be resolved and washed away by a fresh high tide of the same passions. Every psycho-analytic treatment is an attempt at liberating repressed love which has found a meagre outlet in the compromise of a symptom. Indeed, the agreement between such treatments and the process of cure described by the author of Gradiva reaches its climax in the further fact that in analytic psychotherapy too the re-awakened passion, whether it is love or hate, invariably chooses as its object the figure of the doctor.

¹[1905e, 1451]
It is here that the differences begin, which made the case of Gradiva an ideal one which medical technique cannot attain. Gradiva was able to return the love which was making its way from the unconscious into consciousness, but the doctor cannot. Gradiva had herself been the object of the earlier, repressed love; her figure at once offered the liberated current of love a desirable aim. The doctor has been a stranger, and must endeavour to become a stranger once more after the cure; he is often at a loss what advice to give the patients he has cured as to how in real life they can use their recovered capacity to love. To indicate the expedients and substitutes of which the doctor therefore makes use to help him to approximate with more or less success to the model of a cure by love which has been shown us by our author - all this would take us much too far away from the task before us. [1907a, 1882]

I have not yet told you, Ladies and Gentlemen, of the most important of the observations which confirm our hypothesis of the sexual instinctual forces operating in neuroses. In every psycho-analytic treatment of a neurotic patient the strange phenomenon that is known as 'transference' makes its appearance. The patient, that is to say, directs towards the physician a degree of affectionate feeling (mingled, often enough, with hostility) which is based on no real relation between them and which - as is shown by every detail of its emergence - can only be traced back to old wishful phantasies of the patient's which have become unconscious. Thus the part of the patient's emotional life which he can no longer recall to memory is re-experienced by him in his relation to the physician; and it is only this re-experiencing in the 'transference' that convinces him of the existence and of the power of these unconscious sexual impulses. His symptoms, to take an analogy from chemistry, are precipitates of earlier experiences in the sphere of love (in the widest sense of the word), and it is only in the raised temperature of his experience of the transference that they can be resolved and reduced to other psychical products. In this reaction the physician, if I may borrow an apt phrase from Ferenczi (1909), plays the part of a catalytic ferment, which temporarily attracts to itself the affects liberated in the process. A study of transference, too, can give you the key to an understanding of hypnotic suggestion, which we employed to begin with as a technical method for investigating the unconscious in our patients. At that time hypnosis was found to be a help therapeutically, but a hindrance to the scientific understanding of the facts; for it cleared away the psychical resistances in a certain area while building them up into an unscalable wall at its frontiers. You must not suppose, moreover, that the phenomenon of transference (of which, unfortunately, I can tell you all too little to-day) is created by psycho-analytic influence. Transference arises spontaneously in all human relationships just as it does between the patient and the physician. It is everywhere the true vehicle of therapeutic influence; and the less its presence is suspected, the more powerfully it operates. So psycho-analysis does not create it, but merely reveals it to consciousness and gains control of it in order to guide psychical processes towards the desired goal. I cannot, however, leave the topic of transference without stressing the fact that this phenomenon plays a decisive part in bringing conviction not only to the patient but also to the physician. I know it to be true of all my followers that they were only convinced of the correctness of my assertions on the pathogenesis of the neuroses by their experiences with transference; and I can very well understand that such certainty of judgement cannot be attained before one has carried out psycho-analyses and has oneself observed the workings of transference. [1910a, 2236]
I will not dwell on the awkward predicament in which I was placed by this visit, but instead will consider the conduct of the practitioner who sent this lady to me. First, however, let us bear a reservation in mind which may possibly not be superfluous - indeed we will hope so. Long years of experience have taught me - as they could teach everyone else - not to accept straight away as true what patients, especially nervous patients, relate about their physician. Not only does a nerve-specialist easily become the object of many of his patients' hostile feelings, whatever method of treatment he employs; he must also sometimes resign himself to accepting responsibility, by a kind of projection, for the buried repressed wishes of his nervous patients. It is a melancholy but significant fact that such accusations nowhere find credence more readily than among other physicians.

[1910k, 2374]

The almost inexhaustible topic of transference has recently been dealt with by Wilhelm Stekel in this journal on descriptive lines. I should like in the following pages to add a few remarks to explain how it is that transference is necessarily brought about during a psycho-analytic treatment, and how it comes to play its familiar part in it.

[1912b, 2457]

There would be nothing more to discuss or worry about in this behaviour of transference, if it were not that two points remain unexplained about it which are of particular interest to psycho-analysis. Firstly, we do not understand why transference is so much more intense with neurotic subjects in analysis than it is with other such people who are not being analysed; and secondly, it remains a puzzle why in analysis transference emerges as the most powerful resistance to the treatment, whereas outside analysis it must be regarded as the vehicle of cure and the condition of success. For our experience has shown us - and the fact can be confirmed as often as we please - that if a patient's free associations fail the stoppage can invariably be removed by an assurance that he is being dominated at the moment by an association which is concerned with the doctor himself or with something connected with him. As soon as this explanation is given, the stoppage is removed, or the situation is changed from one in which the associations fail into one in which they are being kept back. At first sight it appears to be an immense disadvantage in psycho-analysis as a method that what is elsewhere the strongest factor towards success is changed in it into the most powerful medium of resistance. If, however, we examine the situation more closely, we can at least clear away the first of our two problems. It is not a fact that transference emerges with greater intensity and lack of restraint during psycho-analysis than outside it. In institutions in which nerve patients are treated non-analytically, we can observe transference occurring with the greatest intensity and in the most unworthy forms, extending to nothing less than mental bondage, and moreover showing the plainest erotic colouring. Gabriele Reuter, with her sharp powers of observation, described this at a time when there was no such thing as psycho-analysis, in a remarkable book which betrays in every respect the clearest insight into the nature and genesis of neuroses. These characteristics of transference are therefore to be attributed not to psycho-analysis but to neurosis itself.

[1912b, 2458]
If now we follow a pathogenic complex from its representation in the conscious (whether this is an obvious one in the form of a symptom or something quite inconspicuous) to its root in the unconscious, we shall soon enter a region in which the resistance makes itself felt so clearly that the next association must take account of it and appear as a compromise between its demands and those of the work of investigation. It is at this point, on the evidence of our experience, that transference enters on the scene. When anything in the complexive material (in the subject-matter of the complex) is suitable for being transferred on to the figure of the doctor, that transference is carried out; it produces the next association, and announces itself by indications of a resistance - by a stoppage, for instance. We infer from this experience that the transference-idea has penetrated into consciousness in front of any other possible associations because it satisfies the resistance. An event of this sort is repeated on countless occasions in the course of an analysis. Over and over again, when we come near to a pathogenic complex, the portion of that complex which is capable of transference is first pushed forward into consciousness and defended with the greatest obstinacy.¹

Thus transference in the analytic treatment invariably appears to us in the first instance as the strongest weapon of the resistance, and we may conclude that the intensity and persistence of the transference are an effect and an expression of the resistance. The mechanism of transference is, it is true, dealt with when we have traced it back to the state of readiness of the libido, which has remained in possession of infantile imagos; but the part transference plays in the treatment can only be explained if we enter into its relations with resistance.

How does it come about that transference is so admirably suited to be a means of resistance? It might be thought that the answer can be given without difficulty. For it is evident that it becomes particularly hard to admit to any proscribed wishful impulse if it has to be revealed in front of the very person to whom the impulse relates. Such a necessity gives rise to situations which in the real world seem scarcely possible. But it is precisely this that the patient is aiming at when he makes the object of his emotional impulses coincide with the doctor. Further consideration, however, shows that this apparent gain cannot provide the solution of the problem. Indeed, a relation of affectionate and devoted dependence can, on the contrary help a person over all the difficulties of making an admission In analogous real situations people will usually say: 'I feel no shame in front of you: I can say anything to you.' Thus the transference to the doctor might just as easily serve to facilitate admissions, and it is not clear why it should make things more difficult.

Thus the solution of the puzzle is that transference to the doctor is suitable for resistance to the treatment only in so far as it is a negative transference or a positive transference of repressed erotic impulses. If we 'remove' the transference by making it conscious, we are detaching only these two components of the emotional act from the person of the doctor; the other component, which is admissible to consciousness and unobjectionable, persists and is the vehicle of success in psycho-analysis exactly as it is in other methods of treatment. To this extent we readily admit that the results of psycho-analysis rest upon suggestion; by suggestion, however, we must understand, as Ferenczi (1909) does, the influencing of a person by means of the transference phenomena which are possible in his case. We take care of the patient's final independence by employing suggestion in order to get him to accomplish a piece of psychical work which has as its necessary result a permanent improvement in his psychical situation.
Among the situations which arise in this connection I shall select one which is very sharply circumscribed; and I shall select it, partly because it occurs so often and is so important in its real aspects and partly because of its theoretical interest. What I have in mind is the case in which a woman patient shows by unmistakable indications, or openly declares, that she has fallen in love, as any other mortal woman might, with the doctor who is analysing her. This situation has its distressing and comical aspects, as well as its serious ones. It is also determined by so many and such complicated factors, it is so unavoidable and so difficult to clear up, that a discussion of it to meet a vital need of analytic technique has long been overdue. But since we who laugh at other people's failings are not always free from them ourselves, we have not so far been precisely in a hurry to fulfil this task. We are constantly coming up against the obligation to professional discretion - a discretion which cannot be dispensed with in real life, but which is of no service in our science. In so far as psycho-analytic publications are a part of real life, too, we have here an insoluble contradiction. I have recently disregarded this matter of discretion at one point,¹ and shown how this same transference situation held back the development of psycho-analytic therapy during its first decade. [1915a, 2509]

Let us take the case of the second outcome of the situation we are considering. After the patient has fallen in love with her doctor, they part; the treatment is given up. But soon the patient's condition necessitates her making a second attempt at analysis, with another doctor. The next thing that happens is that she feels she has fallen in love with this second doctor too; and if she breaks off with him and begins yet again, the same thing will happen with the third doctor, and so on. This phenomenon, which occurs without fail and which is, as we know, one of the foundations of the psycho-analytic theory, may be evaluated from two points of view, that of the doctor who is carrying out the analysis and that of the patient who is in need of it. [1915a, 2510]

For the doctor the phenomenon signifies a valuable piece of enlightenment and a useful warning against any tendency to a counter-transference which may be present in his own mind. He must recognize that the patient's falling in love is induced by the analytic situation and is not to be attributed to the charms of his own person; so that he has no grounds whatever for being proud of such a 'conquest', as it would be called outside analysis. And it is always well to be reminded of this. For the patient, however, there are two alternatives: either she must relinquish psycho-analytic treatment or she must accept falling in love with her doctor as an inescapable fate.¹ [1915a, 2510]

I have no doubt that the patient's relatives and friends will decide as emphatically for the first of these two alternatives as the analyst will for the second. But I think that here is a case in which the decision cannot be left to the tender - or rather, the egoistic and jealous - concern of her relatives. The welfare of the patient alone should be the touchstone; her relatives' love cannot cure her neurosis. The analyst need not push himself forward, but he may insist that he is indispensable for the achievement of certain ends. Any relative who adopts Tolstoy's attitude to this problem can remain in undisturbed possession of his wife or daughter; but he will have to try to put up with the fact that she, for her part, retains her neurosis and the interference with her capacity for love which it involves. The situation, after all, is similar to that in a gynaecological treatment. Moreover, the jealous father or husband is greatly mistaken if he thinks that the patient will escape falling in love with her doctor if he hands her over to some kind of treatment other than analysis for combating her neurosis. The difference, on the contrary, will only be that a love of this kind, which is bound to remain unexpressed and unanalysed, can never make the contribution to the patient's recovery which analysis would have extracted from it. [1915a, 2511]
As regards the analyst's line of action, it is the first of these three features of transference-love which is the decisive factor. He has evoked this love by instituting analytic treatment in order to cure the neurosis. For him, it is an unavoidable consequence of a medical situation, like the exposure of a patient's body or the imparting of a vital secret. It is therefore plain to him that he must not derive any personal advantage from it. The patient's willingness makes no difference; it merely throws the whole responsibility on the analyst himself. Indeed, as he must know, the patient had been prepared for no other mechanism of cure. After all the difficulties have been successfully overcome, she will often confess to having had an anticipatory phantasy at the time when she entered the treatment, to the effect that if she behaved well she would be rewarded at the end by the doctor's affection.

[1915a, 2519]

The fact of the emergence of the transference in its crudely sexual form, whether affectionate or hostile, in every treatment of a neurosis, although this is neither desired nor induced by either doctor or patient, has always seemed to me the most irrefragable proof that the source of the driving forces of neurosis lies in sexual life. This argument has never received anything approaching the degree of attention that it merits, for if it had, investigations in this field would leave no other conclusion open. As far as I am concerned, this argument has remained the decisive one, over and above the more specific findings of analytic work.

[1914d, 2881]

If we continue to concern ourselves only with our hysterics and obsessional neurotics, we are soon met by a second fact for which we were not in the least prepared. For after a while we cannot help noticing that these patients behave in a quite peculiar manner to us. We believed, to be sure, that we had reckoned with all the motives concerned in the treatment, that we had completely rationalized the situation between us and the patients so that it could be looked over at a glance like a sum in arithmetic; yet, in spite of all this, something seems to creep in which has not been taken into account in our sum. This unexpected novelty itself takes many shapes, and I will begin by describing to you the commoner and more easily understandable of the forms in which it appears.

[1916-1917, 3481]
If we are able once more to clarify the position, we find that the cause of the disturbance is that the patient has transferred on to the doctor intense feelings of affection which are justified neither by the doctor’s behaviour nor by the situation that has developed during the treatment. The form in which this affection is expressed and what its aims are depend of course on the personal relation between the two people involved. If those concerned are a young girl and a youngish man, we shall get the impression of a normal case of falling in love; we shall find it understandable that a girl should fall in love with a man with whom she can be much alone and talk of intimate things and who has the advantage of having met her as a helpful superior; and we shall probably overlook the fact that what we should expect from a neurotic girl would rather be an impediment in her capacity for love. The further the personal relations between doctor and patient diverge from this supposed case, the more we shall be surprised to find nevertheless the same emotional relationship constantly recurring. It may still pass muster if a woman who is unhappy in her marriage appears to be seized with a serious passion for a doctor who is still unattached, if she is ready to seek a divorce in order to be his or if, where there are social obstacles, she even expresses no hesitation about entering into a secret liaison with him. Such things come about even outside psycho-analysis. But in these circumstances we are astonished to hear declarations by married women and girls which bear witness to a quite particular attitude to the therapeutic problem: they had always known, they say, that they could only be cured by love, and before the treatment began they had expected that through this relation they would at last be granted what life had hitherto withheld from them; it had only been in this hope that they had taken so much trouble over the treatment and overcome all the difficulties in communicating their thoughts - and we on our part can add: and had so easily understood what is otherwise so hard to believe. But an admission of this sort surprises us: it throws all our calculations to the winds. Can it be that we have left the most important item out of our account?

[1916-1917, 3483]

And indeed, the greater our experience the less we are able to resist making this correction, though having to do so puts our scientific pretensions to shame. On the first few occasions one might perhaps think that the analytic treatment had come up against a disturbance due to a chance event - an event, that is, not intended and not provoked by it. But when a similar affectionate attachment by the patient to the doctor is repeated regularly in every new case, when it comes to light again and again, under the most unfavourable conditions and where there are positively grotesque incongruities, even in elderly women and in relation to grey-bearded men, even where, in our judgement, there is nothing of any kind to entice - then we must abandon the idea of a chance disturbance and recognize that we are dealing with a phenomenon which is intimately bound up with the nature of the illness itself.

[1916-1917, 3484]

A capacity for directing libidinal object-cathexes on to people must of course be attributed to every normal person. The tendency to transference of the neurotics I have spoken of is only an extraordinary increase of this universal characteristic. It would indeed be very strange if a human trait so widespread and so important had never been noticed or appreciated. And in fact it has been. Bernheim, with an unerrong eye based his theory of hypnotic phenomena on the thesis that everyone is in some way ‘suggestible’. His suggestibility was nothing other than the tendency to transference, somewhat too narrowly conceived, so that it did not include negative transference. But Bernheim was never able to say what suggestion actually was and how it came about. For him it was a fundamental fact on whose origin he could throw no light. He did not know that his ‘suggéristibilité’ depended on sexuality, on the activity of the libido. And it must dawn on us that in our technique we have abandoned hypnosis only to rediscover suggestion in the shape of transference.

[1916-1917, 3488]
Let us begin with the former. I was a pupil of Bernheim's, whom I visited at Nancy in 1889 and whose book on suggestion I translated into German. I practised hypnotic treatment for many years, at first by prohibitory suggestion and later in combination with Breuer's method of questioning the patient. I can therefore speak of the results of hypnotic or suggestive therapy on the basis of a wide experience. If, in the words of the old medical aphorism, an ideal therapy should be rapid, reliable and not disagreeable for the patient, Bernheim's method fulfilled at least two of these requirements. It could be carried through much quicker - or, rather, infinitely quicker - than analytic treatment and it caused the patient neither trouble nor unpleasantness. For the doctor it became, in the long run, monotonous: in each case, in the same way, with the same ceremonial, forbidding the most variegated symptoms to exist, without being able to learn anything of their sense and meaning. It was hackwork and not a scientific activity, and it recalled magic, incantations and hocus-pocus. That could not weigh, however, against the patient's interest. But the third quality was lacking: the procedure was not reliable in any respect. It could be used with one patient, but not with another; it achieved a great deal with one and very little with another, and one never knew why. Worse than the capriciousness of the procedure was the lack of permanence in its successes. If, after a short time, one had news of the patient once more, the old ailment was back again or its place had been taken by a new one. One might hypnotize him again. But in the background there was the warning given by experienced workers against robbing the patient of his self-reliance by frequently repeated hypnosis and so making him an addict to this kind of therapy as though it were a narcotic. Admittedly sometimes things went entirely as one would wish: after a few efforts, success was complete and permanent. But the conditions determining such a favourable outcome remained unknown. On one occasion a severe condition in a woman, which I had entirely got rid of by a short hypnotic treatment, returned unchanged after the patient had, through no action on my part, got annoyed with me; after a reconciliation, I removed the trouble again and far more thoroughly; yet it returned once more after she had fallen foul of me a second time. On another occasion a woman patient, whom I had repeatedly helped out of neurotic states by hypnosis, suddenly, during the treatment of a specially obstinate situation, threw her arms round my neck. After this one could scarcely avoid, whether one wanted to or not, investigating the question of the nature and origin of one's authority in suggestive treatment.

[1916-1917, 3491]

But it became ever clearer that the aim which had been set up - the aim that what was unconscious should become conscious - is not completely attainable by that method. The patient cannot remember the whole of what is repressed in him, and what he cannot remember may be precisely the essential part of it. Thus he acquires no sense of conviction of the correctness of the construction that has been communicated to him. He is obliged to repeat the repressed material as a contemporary experience instead of, as the physician would prefer to see, remembering it as something belonging to the past.¹ These reproductions, which emerge with such unwished-for exactitude, always have as their subject some portion of infantile sexual life - of the Oedipus complex, that is, and its derivatives; and they are invariably acted out in the sphere of the transference, of the patient's relation to the physician. When things have reached this stage, it may be said that the earlier neurosis has now been replaced by a fresh, 'transference neurosis'. It has been the physician's endeavour to keep this transference neurosis within the narrowest limits: to force as much as possible into the channel of memory and to allow as little as possible to emerge as repetition. The ratio between what is remembered and what is reproduced varies from case to case. The physician cannot as a rule spare his patient this phase of the treatment. He must get him to re-experience some portion of his forgotten life, but must see to it, on the other hand, that the patient retains some degree of aloofness, which will enable him, in spite of everything, to recognize that what appears to be reality is in fact only a reflection of a forgotten past. If this can be successfully achieved, the patient's sense of conviction is won, together with the therapeutic success that is dependent on it.

[1920g, 3723]
In the case of our patient, it was not doubt but the affective factor of revenge against her father that made her cool reserve possible, that divided the analysis into two distinct phases, and rendered the results of the first phase so complete and perspicuous. It seemed, further, as though nothing resembling a transference to the physician had been effected. That, however, is of course absurd, or, at least, is a loose way of expressing things. For some kind of relation to the analyst must come into being, and this relation is almost always transferred from an infantile one. In reality she transferred to me the sweeping repudiation of men which had dominated her ever since the disappointment she had suffered from her father. Bitterness against men is as a rule easy to gratify upon the physician; it need not evoke any violent emotional manifestations, it simply expresses itself by rendering futile all his endeavours and - by clinging to the illness. I know from experience how difficult it is to make a patient understand just precisely this mute kind of symptomatic behaviour and to make him aware of this latent, and often exceedingly strong, hostility without endangering the treatment. As soon, therefore, as I recognized the girl's attitude to her father, I broke off the treatment and advised her parents that if they set store by the therapeutic procedure it should be continued by a woman doctor. The girl had in the meanwhile promised her father that at any rate she would give up seeing the 'lady', and I do not know whether my advice, the reasons for which are obvious, will be followed.

[1920a, 3853]

Transference. - If further proof were needed of the truth that the motive forces behind the formation of neurotic symptoms are of a sexual nature, it would be found in the fact that in the course of analytic treatment a special emotional relation is regularly formed between the patient and the physician. This goes far beyond rational limits. It varies between the most affectionate devotion and the most obstinate enmity and derives all of its characteristics from earlier erotic attitudes of the patient's which have become unconscious. This transference alike in its positive and in its negative form is used as a weapon by the resistance; but in the hands of the physician it becomes the most powerful therapeutic instrument and it plays a part scarcely to be over-estimated in the dynamics of the process of cure.

[1923a, 3924]

In the present discussion, moreover, I am only putting forward a hypothesis; I have no proof to offer. It seems a plausible view that this displaceable and neutral energy, which is no doubt active in both in the ego and in the id, proceeds from the narcissistic store of libido - that it is desexualized Eros. (The erotic instincts appear to be altogether more plastic, more readily diverted and displaced than the destructive instincts.) From this we can easily go on to assume that this displaceable libido is employed in the service of the pleasure principle to obviate blockages and to facilitate discharge. In this connection it is easy to observe a certain indifference as to the path along which the discharge takes place, so long as it takes place somehow. We know this trait; it is characteristic of the cathetic processes in the id. It is found in erotic cathexes, where a peculiar indifference in regard to the object displays itself; and it is especially evident in the transferences arising in analysis, which develop inevitably, irrespective of the persons who are their object. Not long ago Rank published some good examples of the way in which neurotic acts of revenge can be directed against the wrong people. Such behaviour on the part of the unconscious reminds one of the comic story of the three village tailors, one of whom had to be hanged because the only village blacksmith had committed a capital offence. Punishment must be exacted even if it does not fall upon the guilty. It was in studying the dream-work that we first came upon this kind of looseness in the displacements brought about by the primary process. In that case it was the objects that were thus relegated to a position of no more than secondary importance, just as in the case we are now discussing it is the paths of discharge. It would be characteristic of the ego to be more particular about the choice both of an object and of a path of discharge.

[1923b, 3979]
I have repeatedly attempted - most recently in my Autobiographical Study (1925d), in Grote's series, Die Medizin der Gegenwart - to define my share in the Studies which we published jointly. My merit lay chiefly in reviving in Breuer an interest which seemed to have become extinct, and in then urging him on to publication. A kind of reserve which was characteristic of him, an inner modesty, surprising in a man of such a brilliant personality, had led him to keep his astonishing discovery secret for so long that not all of it was any longer new. I found reason later to suppose that a purely emotional factor, too, had given him an aversion to further work on the elucidation of the neuroses. He had come up against something that is never absent - his patient's transference on to her physician, and he had not grasped the impersonal nature of the process. At the time when he submitted to my influence and was preparing the Studies for publication, his judgement of their significance seemed to be confirmed. 'I believe', he told me, 'that this is the most important thing we two have to give the world.'

I now come to the description of a factor which adds an essential feature to my picture of analysis and which can claim, alike technically and theoretically, to be regarded as of the first importance. In every analytic treatment there arises, without the physician's agency, an intense emotional relationship between the patient and the analyst which is not to be accounted for by the actual situation. It can be of a positive or of a negative character and can vary between the extremes of a passionate, completely sensual love and the unbridled expression of an embittered defiance and hatred. This transference - to give it its short name - soon replaces in the patient's mind the desire to be cured, and, so long as it is affectionate and moderate, becomes the agent of the physician's influence and neither more nor less than the mainspring of the joint work of analysis. Later on, when it has become passionate or has been converted into hostility, it becomes the principal tool of the resistance. It may then happen that it will paralyse the patient's powers of associating and endanger the success of the treatment. Yet it would be senseless to try to evade it; for an analysis without transference is an impossibility. It must not be supposed, however, that transference is created by analysis and does not occur apart from it. Transference is merely uncovered and isolated by analysis. It is a universal phenomenon of the human mind, it decides the success of all medical influence, and in fact dominates the whole of each person's relations to his human environment. We can easily recognize it as the same dynamic factor which the hypnotists have named 'suggestibility', which is the agent of hypnotic rapport and whose incalculable behaviour led to difficulties with the cathartic method as well. When there is no inclination to a transference of emotion such as this, or when it has become entirely negative, as happens in dementia praecox or paranoia, then there is also no possibility of influencing the patient by psychological means.

Yes, it ought to. But there turns out to be an unexpected complication. It was perhaps the greatest of the analyst's surprises to find that the emotional relation which the patient adopts towards him is of a quite peculiar nature. The very first doctor who attempted an analysis - it was not myself - came up against this phenomenon and did not know what to make of it. For this emotional relation is, to put it plainly, in the nature of falling in love. Strange, is it not? Especially when you take into account that the analyst does nothing to provoke it but on the contrary rather keeps at a distance from the patient, speaking humanly, and surrounds himself with some degree of reserve - when you learn besides that this odd love-relationship disregards anything else that is really propitious and every variation in personal attraction, age, sex or class. This love is of a positively compulsive kind. Not that that characteristic need be absent from spontaneous falling in love. As you know, the contrary is often the case. But in the analytic situation it makes its appearance with complete regularity without there being any rational explanation for it. One would have thought that the patient's relation to the analyst called for no more than a certain amount of respect, trust, gratitude and human sympathy. Instead, there is this falling in love, which itself gives the impression of being a pathological phenomenon.

[1925g, 4172]

[1925d, 4217]

[1926e, 4367]
'That does sound hopeless! What can be done about it? The analysis would have to be given up. But if, as you say, the same thing happens in every case, it would be impossible to carry through any analyses at all.'
[1926e, 4368]

We will begin by using the situation in order to learn something from it. What we learn may then perhaps help us to master it. Is it not an extremely noteworthy fact that we succeed in transforming every neurosis, whatever its content, into a condition of pathological love?
[1926e, 4368]
He once brought me a dream which represented the same conflict in relation to his transference on to the physician. He dreamt that my mother was dead; he was anxious to offer me his condolences, but was afraid that in doing so he might break into an impertinent laugh, as he had repeatedly done on similar occasions in the past. He preferred, therefore, to leave a card on me with 'p. c.' written on it; but as he was writing them the letters turned into 'p. f.'²

[1909d, 2152]

In conclusion, I will mention a particular type of dream which, in the nature of the case, occurs only in the course of psycho-analytic treatment, and may bewilder or mislead beginners. These are the corroborative dreams which, as it were 'tag along behind'; they are easily accessible to analysis, and their translation merely presents what the treatment has inferred during the last new days from the material of the daily associations. When this happens, it looks as though the patient has been amiable enough to bring us in dream-form exactly what we had been 'suggesting' to him immediately before. The more experienced analyst will no doubt have some difficulty in attributing any such amiability to the patient; he accepts such dreams as hoped-for confirmations, and recognizes that they are only observed under certain conditions brought about by the influence of the treatment. The great majority of dreams forge ahead of the analysis; so that, after subtraction of everything in them which is already known and understood, there still remains a more or less clear hint at something which has hitherto been hidden.

[1911e, 2454]

We notice, then, that the patient, who ought to want nothing else but to find a way out of his distressing conflict, develops a special interest in the person of the doctor. Everything connected with the doctor seems to be more important to him than his own affairs and to be diverting him from his illness. For a time, accordingly, relations with him become very agreeable; he is particularly obliging, tries wherever possible to show his gratitude, reveals refinements and merits in his nature which we should not, perhaps, have expected to find in him. The doctor, too, thereupon forms a favourable opinion of the patient and appreciates the good fortune which has enabled him to give his assistance to such a particularly valuable personality. If the doctor has an opportunity of talking to the patient's relatives, he learns to his satisfaction that the liking is a mutual one. The patient never tires in his home of praising the doctor and of extolling ever new qualities in him. 'He's enthusiastic about you,' say his relatives, 'he trusts you blindly; everything you say is like a revelation to him.' Here and there someone in this chorus has sharper eyes and says: 'It's becoming a bore, the way he talks of nothing else but you and has your name on his lips all the time.'

[1916-1917, 3481]
If we are able once more to clarify the position, we find that the cause of the disturbance is that the patient has transferred on to the doctor intense feelings of affection which are justified neither by the doctor's behaviour nor by the situation that has developed during the treatment. The form in which this affection is expressed and what its aims are depend of course on the personal relation between the two people involved. If those concerned are a young girl and a youngish man, we shall get the impression of a normal case of falling in love; we shall find it understandable that a girl should fall in love with a man with whom she can be much alone and talk of intimate things and who has the advantage of having met her as a helpful superior; and we shall probably overlook the fact that what we should expect from a neurotic girl would rather be an impediment in her capacity for love. The further the personal relations between doctor and patient diverge from this supposed case, the more we shall be surprised to find nevertheless the same emotional relationship constantly recurring. It may still pass muster if a woman who is unhappy in her marriage appears to be seized with a serious passion for a doctor who is still unattached, if she is ready to seek a divorce in order to be his or if, where there are social obstacles, she even expresses no hesitation about entering into a secret liaison with him. Such things come about even outside psycho-analysis. But in these circumstances we are astonished to hear declarations by married women and girls which bear witness to a quite particular attitude to the therapeutic problem: they had always known, they say, that they could only be cured by love, and before the treatment began they had expected that through this relation they would at last be granted what life had hitherto withheld from them; it had only been in this hope that they had taken so much trouble over the treatment and overcome all the difficulties in communicating their thoughts - and we on our part can add: and had so easily understood what is otherwise so hard to believe. But an admission of this sort surprises us: it throws all our calculations to the winds. Can it be that we have left the most important item out of our account?

[1916-1917, 3483]

I must begin by making it clear that a transference is present in the patient from the beginning of the treatment and for a while is the most powerful motive in its advance. We see no trace of it and need not bother about it so long as it operates in favour of the joint work of analysis. If it then changes into a resistance, we must turn our attention to it and we recognize that it alters its relation to the treatment under two different and contrary conditions: firstly, if as an affectionate trend it has become so powerful, and betrays signs of its origin in a sexual need so clearly, that it inevitably provokes an internal opposition to itself, and, secondly, if it consists of hostile instead of affectionate impulses. The hostile feelings make their appearance as a rule later than the affectionate ones and behind them; their simultaneous presence gives a good picture of the emotional ambivalence which is dominant in the majority of our intimate relations with other people. The hostile feelings are as much an indication of an emotional tie as the affectionate ones, in the same way as defiance signifies dependence as much as obedience does, though with a 'minus' instead of a 'plus' sign before it. We can be in no doubt that the hostile feelings towards the doctor deserve to be called a 'transference', since the situation in the treatment quite certainly offers no adequate grounds for their origin; this necessary view of the negative transference assures us, therefore, that we have not gone wrong in our judgement of the positive or affectionate one.

[1916-1917, 3485]
Let us at once agree upon what we mean by this activity. We have defined our therapeutic task as consisting of two things: making conscious the repressed material and uncovering the resistances. In that we are active enough, to be sure. But are we to leave it to the patient to deal alone with the resistances we have pointed out to him? Can we give him no other help in this besides the stimulus he gets from the transference? Does it not seem natural that we should help him in another way as well, by putting him into the mental situation most favourable to the solution of the conflict which is our aim? After all, what he can achieve depends, too, on a combination of external circumstances. Should we hesitate to alter this combination by intervening in a suitable manner? I think activity of such a kind on the part of the analysing physician is unobjectionable and entirely justified.

[1919a, 3631]

There was a single piece of material in the course of this analysis which I could regard as a positive transference, as a greatly weakened revival of the girl's original passionate love for her father. Even this manifestation was not quite free from other motives, but I mention it because it brings up, in another direction, an interesting problem of analytic technique. At a certain period, not long after the treatment had begun, the girl brought a series of dreams which, distorted according to rule and couched in the usual dream-language, could nevertheless be easily translated with certainty. Their content, when interpreted, was, however, remarkable. They anticipated the cure of the inversion through the treatment, expressed her joy over the prospects in life that would then be opened before her, confessed her longing for a man's love and for children, and so might have been welcomed as a gratifying preparation for the desired change. The contradiction between them and the girl's utterances in waking life at the time was very great. She did not conceal from me that she meant to marry, but only in order to escape from her father's tyranny and to follow her true inclinations undisturbed. As for the husband, she remarked rather contemptuously, she would easily deal with him, and besides, one could have sexual relations with a man and a woman at one and the same time, as the example of the adored lady showed. Warned through some slight impression or other, I told her one day that I did not believe these dreams, that I regarded them as false or hypocritical, and that she intended to deceive me just as she habitually deceived her father. I was right; after I had made this clear, this kind of dream ceased. But I still believe that, beside the intention to mislead me, the dreams partly expressed the wish to win my favour; they were also an attempt to gain my interest and my good opinion - perhaps in order to disappoint me all the more thoroughly later on.

[1920a, 3853]

Transference. - If further proof were needed of the truth that the motive forces behind the formation of neurotic symptoms are of a sexual nature, it would be found in the fact that in the course of analytic treatment a special emotional relation is regularly formed between the patient and the physician. This goes far beyond rational limits. It varies between the most affectionate devotion and the most obstinate enmity and derives all of its characteristics from earlier erotic attitudes of the patient's which have become unconscious. This transference alike in its positive and in its negative form is used as a weapon by the resistance; but in the hands of the physician it becomes the most powerful therapeutic instrument and it plays a part scarcely to be over-estimated in the dynamics of the process of cure.

[1923a, 3924]
It may well be that dreams during psycho-analysis succeed in bringing to light what is repressed to a greater extent than dreams outside that situation. But it cannot be proved, since the two situations are not comparable; the employment of dreams in analysis is something very remote from their original purpose. On the other hand, it cannot be doubted that within an analysis far more of the repressed is brought to light in connection with dreams than by any other method. In order to account for this, there must be some motive power, some unconscious force, which is better able to lend support to the purposes of analysis during the state of sleep than at other times. What is here in question cannot well be any factor other than the patient’s compliance towards the analyst which is derived from his parental complex - in other words, the positive portion of what we call the transference; and in fact, in many dreams which recall what has been forgotten and repressed, it is impossible to discover any other unconscious wish to which the motive force for the formation of the dream can be attributed. So that if anyone wishes to maintain that most of the dreams that can be made use of in analysis are obliging dreams and owe their origin to suggestion, nothing can be said against that opinion from the point of view of analytic theory. In that case I need only add a reference to what I have said in my Introductory Lectures, where I have dealt with the relation between transference and suggestion and shown how little the trustworthiness of our results is affected by a recognition of the operation of suggestion in our sense.

[1923c, 4038]

In Beyond the Pleasure Principle (1920g) I have dealt with the economic problem of how what are in every respect distressing experiences of the early infantile sexual period can succeed in forcing their way through to some kind of reproduction. I was obliged to ascribe to them an extraordinarily strong upward drive in the shape of the ‘compulsion to repeat’ - a force able to overcome the repression which, in obedience to the pleasure principle, weighs down upon them - though not until ‘the work of treatment has gone half-way to meet it and has loosened the repression’. Here we may add that it is the positive transference that gives this assistance to the compulsion to repeat. Thus an alliance has been made between the treatment and the compulsion to repeat, an alliance which is directed in the first instance against the pleasure principle but of which the ultimate purpose is the establishment of the dominion of the reality principle. As I have shown in the passage to which I am referring, it happens only too often that the compulsion to repeat throws over its obligations under this alliance and is not content with the return of the repressed merely in the form of dream-pictures.

[1923c, 4038]
I now come to the description of a factor which adds an essential feature to my picture of analysis and which can claim, alike technically and theoretically, to be regarded as of the first importance. In every analytic treatment there arises, without the physician's agency, an intense emotional relationship between the patient and the analyst which is not to be accounted for by the actual situation. It can be of a positive or of a negative character and can vary between the extremes of a passionate, completely sensual love and the unbridled expression of an embittered defiance and hatred. This transference - to give it its short name - soon replaces in the patient's mind the desire to be cured, and, so long as it is affectionate and moderate, becomes the agent of the physician's influence and neither more nor less than the mainspring of the joint work of analysis. Later on, when it has become passionate or has been converted into hostility, it becomes the principal tool of the resistance. It may then happen that it will paralyse the patient's powers of associating and endanger the success of the treatment. Yet it would be senseless to try to evade it; for an analysis without transference is an impossibility. It must not be supposed, however, that transference is created by analysis and does not occur apart from it. Transference is merely uncovered and isolated by analysis. It is a universal phenomenon of the human mind, it decides the success of all medical influence, and in fact dominates the whole of each person's relations to his human environment. We can easily recognize it as the same dynamic factor which the hypnotists have named 'suggestibility', which is the agent of hypnotic rapport and whose incalculable behaviour led to difficulties with the cathartic method as well. When there is no inclination to a transference of emotion such as this, or when it has become entirely negative, as happens in dementia praecox or paranoia, then there is also no possibility of influencing the patient by psychological means.

But it is far from being the case that his ego is content to play the part of passively and obediently bringing us the material we require and of believing and accepting our translation of it. A number of other things happen, a few of which we might have foreseen but others of which are bound to surprise us. The most remarkable thing is this. The patient is not satisfied with regarding the analyst in the light of reality as a helper and adviser who, moreover, is remunerated for the trouble he takes and who would himself be content with some such role as that of a guide on a difficult mountain climb. On the contrary, the patient sees in him the return, the reincarnation, of some important figure out of his childhood or past, and consequently transfers on to him feelings and reactions which undoubtedly applied to this prototype. This fact of transference soon proves to be a factor of undreamt-of importance, on the one hand an instrument of irreplaceable value and on the other hand a source of serious dangers. This transference is ambivalent: it comprises positive (affectionate) as well as negative (hostile) attitudes towards the analyst, who as a rule is put in the place of one or other of the patient's parents, his father or mother. So long as it is positive it serves us admirably. It alters the whole analytic situation; it pushes to one side the patient's rational aim of becoming healthy and free from his ailments. Instead of it there emerges the aim of pleasing the analyst and of winning his applause and love. It becomes the true motive force of the patient's collaboration; his weak ego becomes strong; under its influence he achieves things that would ordinarily be beyond his power; he leaves off his symptoms and seems apparently to have recovered - merely for the sake of the analyst. The analyst may shamefacedly admit to himself that he set out on a difficult undertaking without any suspicion of the extraordinary powers that would be at his command.
And now for the other side of the situation. Since the transference reproduces the patient's relation with his parents, it takes over the ambivalence of that relation as well. It almost inevitably happens that one day his positive attitude towards the analyst changes over into the negative, hostile one. This too is as a rule a repetition of the past. His obedience to his father (if it is his father that is in question), his courting of his father's favour, had its roots in an erotic wish directed towards him. Some time or other that demand will press its way forward in the transference as well and insist on being satisfied. In the analytic situation it can only meet with frustration. Real sexual relations between patients and analysts are out of the question, and even the subtler methods of satisfaction, such as the giving of preference, intimacy and so on, are only sparingly granted by the analyst. A rejection of this kind is taken as the occasion for the change-over; probably things happened in the same way in the patient's childhood.

[1940a [1938], 4986]

The therapeutic successes that occurred under the sway of the positive transference are open to the suspicion of being of a suggestive nature. If the negative transference gains the upper hand, they are blown away like chaff before the wind. We observe with horror that all our trouble and labour hitherto have been in vain. Indeed, what we might have regarded as a permanent intellectual gain by the patient, his understanding of psycho-analysis and his reliance on its efficacy, suddenly vanish. He behaves like a child who has no power of judgement of his own but blindly believes anyone whom he loves and no one who is a stranger to him. The danger of these states of transference evidently lies in the patient's misunderstanding their nature and taking them for fresh real experiences instead of reflections of the past. If he (or she) becomes aware of the strong erotic desire that lies concealed behind the positive transference, he believes that he has fallen passionately in love; if the transference changes over, then he feels insulted and neglected, he hates the analyst as his enemy and is ready to abandon the analysis. In both these extreme cases he has forgotten the pact that he made at the beginning of the treatment and has become useless for continuing the common work. It is the analyst's task constantly to tear the patient out of his menacing illusion and to show him again and again that what he takes to be new real life is a reflection of the past. And lest he should fall into a state in which he is inaccessible to all evidence, the analyst takes care that neither the love nor the hostility reach an extreme height. This is effected by preparing him in good time for these possibilities and by not overlooking the first signs of them. Careful handling of the transference on these lines is as a rule richly rewarded. If we succeed, as we usually can, in enlightening the patient on the true nature of the phenomena of transference, we shall have struck a powerful weapon out of the hand of his resistance and shall have converted dangers into gains. For a patient never forgets again what he has experienced in the form of transference; it carries a greater force of conviction than anything he can acquire in other ways.

[1940a [1938], 4986]
This brings me to two problems which arise directly out of analytic practice, as I hope to show by the following examples. A certain man, who had himself practised analysis with great success, came to the conclusion that his relations both to men and women - to the men who were his competitors and to the woman whom he loved - were nevertheless not free from neurotic impediments; and he therefore made himself the subject of an analysis by someone else whom he regarded as superior to himself. This critical illumination of his own self had a completely successful result. He married the woman he loved and turned into a friend and teacher of his supposed rivals. Many years passed in this way, during which his relations with his former analyst also remained unclouded. But then, for no assignable external reason, trouble arose. The man who had been analysed became antagonistic to the analyst and reproached him for having failed to give him a complete analysis. The analyst, he said, ought to have known and to have taken into account the fact that a transference-relation can never be purely positive; he should have given his attention to the possibilities of a negative transference. The analyst defended himself by saying that, at the time of the analysis, there was no sign of a negative transference. But even if he had failed to observe some very faint signs of it - which was not altogether ruled out, considering the limited horizon of analysis in those early days - it was still doubtful, he thought, whether he would have had the power to activate a topic (or, as we say, a 'complex') by merely pointing it out, so long as it was not currently active in the patient himself at the time. To activate it would certainly have required some unfriendly piece of behaviour in reality on the analyst's part. Furthermore, he added, not every good relation between an analyst and his subject during and after analysis was to be regarded as a transference; there were also friendly relations which were based on reality and which proved to be viable.

[1937c, 5019]

I do not know whether we can assert that the first of these two milder procedures is altogether ruled out in analysis. No experiments have been particularly made in this direction. But difficulties at once suggest themselves, which do not throw a very promising light on such an undertaking. In the first place, the choice of such situations for the transference is very limited. The patients cannot themselves bring all their conflicts into the transference; nor is the analyst able to call out all their possible instinctual conflicts from the transference situation. He may make them jealous or cause them to experience disappointments in love; but no technical purpose is required to bring this about. Such things happen of themselves in any case in most analyses. In the second place, we must not overlook the fact that all measures of this sort would oblige the analyst to behave in an unfriendly way to the patient, and this would have a damaging effect upon the affectionate attitude - upon the positive transference - which is the strongest motive for the patient's taking a share in the joint work of analysis. Thus we should on no account expect very much from this procedure.

[1937c, 5029]
Dora had listened to me without any of her usual contradictions. She seemed to be moved; she said good-bye to me very warmly, with the heartiest wishes for the New Year, and - came no more. Her father, who called on me two or three times afterwards, assured me that she would come back again, and said it was easy to see that she was eager for the treatment to continue. But it must be confessed that Dora's father was never entirely straightforward. He had given his support to the treatment so long as he could hope that I should 'talk' Dora out of her belief that there was something more than a friendship between him and Frau K. His interest faded when he observed that it was not my intention to bring about that result. I knew Dora would not come back again. Her breaking off so unexpectedly, just when my hopes of a successful termination of the treatment were at their highest, and her thus bringing those hopes to nothing - this was an unmistakable act of vengeance on her part. Her purpose of self-injury also profited by this action. No one who, like me, conjures up the most evil of those half-tamed demons that inhabit the human breast, and seeks to wrestle with them, can expect to come through the struggle unscathed. Might I perhaps have kept the girl under my treatment if I myself had acted a part, if I had exaggerated the importance to me of her staying on, and had shown a warm personal interest in her - a course which, even after allowing for my position as her physician, would have been tantamount to providing her with a substitute for the affection she longed for? I do not know. Since in every case a portion of the factors that are encountered under the form of resistance remains unknown, I have always avoided acting a part, and have contented myself with practising the humbler arts of psychology. In spite of every theoretical interest and of every endeavour to be of assistance as a physician, I keep the fact in mind that there must be some limits set to the extent to which psychological influence may be used, and I respect as one of these limits the patient's own will and understanding.

[1905e, 1444]
I have been obliged to speak of transference, for it is only by means of this factor that I can elucidate the peculiarities of Dora's analysis. Its great merit, namely, the unusual clarity which makes it seem so suitable as a first introductory publication, is closely bound up with its great defect, which led to its being broken off prematurely. I did not succeed in mastering the transference in good time. Owing to the readiness with which Dora put one part of the pathogenic material at my disposal during the treatment, I neglected the precaution of looking out for the first signs of transference, which was being prepared in connection with another part of the same material a part of which I was in ignorance. At the beginning it was clear that I was replacing her father in her imagination, which was not unlikely, in view of the difference between our ages. She was even constantly comparing me with him consciously, and kept anxiously trying to make sure whether I was being quite straightforward with her, for her father 'always preferred secrecy and roundabout ways'. But when the first dream came, in which she gave herself the warning that she had better leave my treatment just as she had formerly left Herr K.'s house, I ought to have listened to the warning myself. 'Now,' I ought to have said to her, 'it is from Herr K. that you have made a transference on to me. Have you noticed anything that leads you to suspect me of evil intentions similar (whether openly or in some sublimated form) to Herr K.?' Or have you been struck by anything about me or got to know anything about me which has caught your fancy, as happened previously with Herr K.' Her attention would then have been turned to some detail in our relations, or in my person or circumstances, behind which there lay concealed something analogous but immeasurably more important concerning Herr K. And when this transference had been cleared up, the analysis would have obtained access to new memories, dealing, probably, with actual events. But I was deaf to this first note of warning, thinking I had ample time before me, since no further stages of transference developed and the material for the analysis had not yet run dry. In this way the transference took me unawares, and, because of the unknown quantity in me which reminded Dora of Herr K., she took her revenge on me as she wanted to take her revenge on him, and deserted me as she believed herself to have been deceived and deserted by him. Thus she acted out an essential part of her recollections and phantasies instead of reproducing it in the treatment. What this unknown quantity was I naturally cannot tell. I suspect that it had to do with money, or with jealousy of another patient who had kept up relations with my family after her recovery. When it is possible to work transferences into the analysis at an early stage, the course of the analysis is retarded and obscured, but its existence is better guaranteed against sudden and overwhelming resistances.

[1905e, 1452]

If cruel impulses and revengeful motives, which have already been used in the patient's ordinary life for maintaining her symptoms, become transferred on to the physician during treatment, before he has had time to detach them from himself by tracing them back to their sources, then it is not to be wondered at if the patient's condition is unaffected by his therapeutic efforts. For how could the patient take a more effective revenge than by demonstrating upon her own person the helplessness and incapacity of the physician? Nevertheless, I am not inclined to put too low a value on the therapeutic results even of such a fragmentary treatment as Dora's.

[1905e, 1454]

Her alleged facial neuralgia was thus a self-punishment - remorse at having once given Herr K. a box on the ear, and at having transferred her feelings of revenge on to me. I do not know what kind of help she wanted from me, but I promised to forgive her for having deprived me of the satisfaction of affording her a far more radical cure for her troubles.

[1905e, 1456]
He once brought me a dream which represented the same conflict in relation to his transference on to the physician. He dreamt that my mother was dead; he was anxious to offer me his condolences, but was afraid that in doing so he might break into an *impertinent laugh*, as he had repeatedly done on similar occasions in the past. He preferred, therefore, to leave a card on me with 'p. c.' written on it; but as he was writing them the letters turned into 'p. f.'

I will not dwell on the awkward predicament in which I was placed by this visit, but instead will consider the conduct of the practitioner who sent this lady to me. First, however, let us bear a reservation in mind which may possibly not be superfluous - indeed we will hope so. Long years of experience have taught me - as they could teach everyone else - not to accept straight away as true what patients, especially nervous patients, relate about their physician. Not only does a nerve-specialist easily become the object of many of his patients' hostile feelings, whatever method of treatment he employs; he must also sometimes resign himself to accepting responsibility, by a kind of projection, for the buried repressed wishes of his nervous patients. It is a melancholy but significant fact that such accusations nowhere find credence more readily than among other physicians.

The negative transference deserves a detailed examination, which it cannot be given within the limits of the present paper. In the curable forms of psychoneurosis it is found side by side with the affectionate transference, often directed simultaneously towards the same person. Bleuler has coined the excellent term 'ambivalence' to describe this phenomenon.¹ Up to a point, ambivalence of feeling of this sort seems to be normal; but a high degree of it is certainly a special peculiarity of neurotic people. In obsessional neurotics an early separation of the 'pairs of opposites' seems to be characteristic of their instinctual life and to be one of their constitutional preconditions. Ambivalence in the emotional trends of neurotics is the best explanation of their ability to enlist their transferences in the service of resistance. Where the capacity for transference has become essentially limited to a negative one, as is the case with paranoics, there ceases to be any possibility of influence or cure.

But such fine weather cannot last for ever. One day it clouds over. Difficulties arise in the treatment; the patient declares that nothing more occurs to him. He gives the clearest impression of his interest being no longer in the work and of his cheerfully disregarding the instructions given him to say everything that comes into his head and not to give way to any critical obstacle to doing so. He behaves as though he were outside the treatment and as though he had not made this agreement with the doctor. He is evidently occupied with something, but intends to keep it to himself. This is a situation that is dangerous for the treatment. We are unmistakably confronted by a formidable resistance. But what has happened to account for it?
Before we enquire where we are to find a place for this new fact, I will complete my description of it. What happens with male patients? There at least one might hope to escape the troublesome interference caused by difference of sex and by sexual attraction. Our answer, however, must be much the same as in the case of women. There is the same attachment to the doctor, the same overvaluation of his qualities, the same absorption in his interests, the same jealousy of everyone close to him in real life. The sublimated forms of transference are more frequent between one man and another and straightforward sexual demands are rarer, in proportion as manifest homosexuality is unusual as compared with the other ways in which these instinctual components are employed. With his male patients, again, more often than with women, the doctor comes across a form of expression of the transference which seems at first sight to contradict all our previous descriptions - a hostile or negative transference.

I must begin by making it clear that a transference is present in the patient from the beginning of the treatment and for a while is the most powerful motive in its advance. We see no trace of it and need not bother about it so long as it operates in favour of the joint work of analysis. If it then changes into a resistance, we must turn our attention to it and we recognize that it alters its relation to the treatment under two different and contrary conditions: firstly, if as an affectionate trend it has become so powerful, and betrays signs of its origin in a sexual need so clearly, that it inevitably provokes an internal opposition to itself, and, secondly, if it consists of hostile instead of affectionate impulses. The hostile feelings make their appearance as a rule later than the affectionate ones and behind them; their simultaneous presence gives a good picture of the emotional ambivalence which is dominant in the majority of our intimate relations with other people. The hostile feelings are as much an indication of an emotional tie as the affectionate ones, in the same way as defiance signifies dependence as much as obedience does, though with a 'minus' instead of a 'plus' sign before it. We can be in no doubt that the hostile feelings towards the doctor deserve to be called a 'transference', since the situation in the treatment quite certainly offers no adequate grounds for their origin; this necessary view of the negative transference assures us, therefore, that we have not gone wrong in our judgement of the positive or affectionate one.

The acceptance of suggestions on individual points is no doubt discouraged by the fact that during the treatment we are struggling unceasingly against resistances which are able to transform themselves into negative (hostile) transferences. Nor must we fail to point out that a large number of the individual findings of analysis, which might otherwise be suspected to being products of suggestion, are confirmed from another and irreproachable source. Our guarantors in this case are the sufferers from dementia praecox and paranoia, who are of course far above any suspicion of being influenced by suggestion. The translations of symbols and the phantasies, which these patients produce for us and which in them have forced their way through into consciousness, coincide faithfully with the results of our investigations into the unconscious of transference neurotics and thus confirm the objective correctness of our interpretations, on which doubt is so often thrown. You will not, I think, be going astray if you trust analysis on these points.
In the case of our patient, it was not doubt but the affective factor of revenge against her father that made her cool reserve possible, that divided the analysis into two distinct phases, and rendered the results of the first phase so complete and perspicuous. It seemed, further, as though nothing resembling a transference to the physician had been effected. That, however, is of course absurd, or, at least, is a loose way of expressing things. For some kind of relation to the analyst must come into being, and this relation is almost always transferred from an infantile one. In reality she transferred to me the sweeping repudiation of men which had dominated her ever since the disappointment she had suffered from her father. Bitterness against men is as a rule easy to gratify upon the physician; it need not evoke any violent emotional manifestations, it simply expresses itself by rendering futile all his endeavours and - by clinging to the illness. I know from experience how difficult it is to make a patient understand just precisely this mute kind of symptomatic behaviour and to make him aware of this latent, and often exceedingly strong, hostility without endangering the treatment. As soon, therefore, as I recognized the girl's attitude to her father, I broke off the treatment and advised her parents that if they set store by the therapeutic procedure it should be continued by a woman doctor. The girl had in the meanwhile promised her father that at any rate she would give up seeing the 'lady', and I do not know whether my advice, the reasons for which are obvious, will be followed.

Transference. - If further proof were needed of the truth that the motive forces behind the formation of neurotic symptoms are of a sexual nature, it would be found in the fact that in the course of analytic treatment a special emotional relation is regularly formed between the patient and the physician. This goes far beyond rational limits. It varies between the most affectionate devotion and the most obstinate enmity and derives all of its characteristics from earlier erotic attitudes of the patient's which have become unconscious. This transference alike in its positive and in its negative form is used as a weapon by the resistance; but in the hands of the physician it becomes the most powerful therapeutic instrument and it plays a part scarcely to be over-estimated in the dynamics of the process of cure.

I now come to the description of a factor which adds an essential feature to my picture of analysis and which can claim, alike technically and theoretically, to be regarded as of the first importance. In every analytic treatment there arises, without the physician's agency, an intense emotional relationship between the patient and the analyst which is not to be accounted for by the actual situation. It can be of a positive or of a negative character and can vary between the extremes of a passionate, completely sensual love and the unbridled expression of an embittered defiance and hatred. This transference - to give it its short name - soon replaces in the patient's mind the desire to be cured, and, so long as it is affectionate and moderate, becomes the agent of the physician's influence and neither more nor less than the mainspring of the joint work of analysis. Later on, when it has become passionate or has been converted into hostility, it becomes the principal tool of the resistance. It may then happen that it will paralyse the patient's powers of associating and endanger the success of the treatment. Yet it would be senseless to try to evade it; for an analysis without transference is an impossibility. It must not be supposed, however, that transference is created by analysis and does not occur apart from it. Transference is merely uncovered and isolated by analysis. It is a universal phenomenon of the human mind, it decides the success of all medical influence, and in fact dominates the whole of each person's relations to his human environment. We can easily recognize it as the same dynamic factor which the hypnotists have named 'suggestibility', which is the agent of hypnotic rapport and whose incalculable behaviour led to difficulties with the cathartic method as well. When there is no inclination to a transference of emotion such as this, or when it has become entirely negative, as happens in dementia praecox or paranoia, then there is also no possibility of influencing the patient by psychological means.
But it is far from being the case that his ego is content to play the part of passively and obediently bringing us the material we require and of believing and accepting our translation of it. A number of other things happen, a few of which we might have foreseen but others of which are bound to surprise us. The most remarkable thing is this. The patient is not satisfied with regarding the analyst in the light of reality as a helper and adviser who, moreover, is remunerated for the trouble he takes and who would himself be content with some such role as that of a guide on a difficult mountain climb. On the contrary, the patient sees in him the return, the reincarnation, of some important figure out of his childhood or past, and consequently transfers on to him feelings and reactions which undoubtedly applied to this prototype. This fact of transference soon proves to be a factor of undreamt-of importance, on the one hand an instrument of irreplaceable value and on the other hand a source of serious dangers. This transference is ambivalent: it comprises positive (affectionate) as well as negative (hostile) attitudes towards the analyst, who as a rule is put in the place of one or other of the patient's parents, his father or mother. So long as it is positive it serves us admirably. It alters the whole analytic situation; it pushes to one side the patient's rational aim of becoming healthy and free from his ailments. Instead of it there emerges the aim of pleasing the analyst and of winning his applause and love. It becomes the true motive force of the patient's collaboration; his weak ego becomes strong; under its influence he achieves things that would ordinarily be beyond his power; he leaves off his symptoms and seems apparently to have recovered - merely for the sake of the analyst. The analyst may shamefacedly admit to himself that he set out on a difficult undertaking without any suspicion of the extraordinary powers that would be at his command. [1940a [1938], 4984]

And now for the other side of the situation. Since the transference reproduces the patient's relation with his parents, it takes over the ambivalence of that relation as well. It almost inevitably happens that one day his positive attitude towards the analyst changes over into the negative, hostile one. This too is as a rule a repetition of the past. His obedience to his father (if it is his father that is in question), his courting of his father's favour, had its roots in an erotic wish directed towards him. Some time or other that demand will press its way forward in the transference as well and insist on being satisfied. In the analytic situation it can only meet with frustration. Real sexual relations between patients and analysts are out of the question, and even the subtler methods of satisfaction, such as the giving of preference, intimacy and so on, are only sparingly granted by the analyst. A rejection of this kind is taken as the occasion for the change-over; probably things happened in the same way in the patient's childhood. [1940a [1938], 4986]
The therapeutic successes that occurred under the sway of the positive transference are open to the suspicion of being of a suggestive nature. If the negative transference gains the upper hand, they are blown away like chaff before the wind. We observe with horror that all our trouble and labour hitherto have been in vain. Indeed, what we might have regarded as a permanent intellectual gain by the patient, his understanding of psycho-analysis and his reliance on its efficacy, suddenly vanish. He behaves like a child who has no power of judgement of his own but blindly believes anyone whom he loves and no one who is a stranger to him. The danger of these states of transference evidently lies in the patient's misunderstanding their nature and taking them for fresh real experiences instead of reflections of the past. If he (or she) becomes aware of the strong erotic desire that lies concealed behind the positive transference, he believes that he has fallen passionately in love; if the transference changes over, then he feels insulted and neglected, he hates the analyst as his enemy and is ready to abandon the analysis. In both these extreme cases he has forgotten the pact that he made at the beginning of the treatment and has become useless for continuing the common work. It is the analyst's task constantly to tear the patient out of his menacing illusion and to show him again and again that what he takes to be new real life is a reflection of the past. And lest he should fall into a state in which he is inaccessible to all evidence, the analyst takes care that neither the love nor the hostility reach an extreme height. This is effected by preparing him in good time for these possibilities and by not overlooking the first signs of them. Careful handling of the transference on these lines is as a rule richly rewarded. If we succeed, as we usually can, in enlightening the patient on the true nature of the phenomena of transference, we shall have struck a powerful weapon out of the hand of his resistance and shall have converted dangers into gains. For a patient never forgets again what he has experienced in the form of transference; it carries a greater force of conviction than anything he can acquire in other ways.

[1940a [1938], 4986]

This brings me to two problems which arise directly out of analytic practice, as I hope to show by the following examples. A certain man, who had himself practised analysis with great success, came to the conclusion that his relations both to men and women - to the men who were his competitors and to the woman whom he loved - were nevertheless not free from neurotic impediments; and he therefore made himself the subject of an analysis by someone else whom he regarded as superior to himself. This critical illumination of his own self had a completely successful result. He married the woman he loved and turned into a friend and teacher of his supposed rivals. Many years passed in this way, during which his relations with his former analyst also remained unclouded. But then, for no assignable external reason, trouble arose. The man who had been analysed became antagonistic to the analyst and reproached him for having failed to give him a complete analysis. The analyst, he said, ought to have known and to have taken into account the fact that a transference-relation can never be purely positive; he should have given his attention to the possibilities of a negative transference. The analyst defended himself by saying that, at the time of the analysis, there was no sign of a negative transference. But even if he had failed to observe some very faint signs of it - which was not altogether ruled out, considering the limited horizon of analysis in those early days - it was still doubtful, he thought, whether he would have had the power to activate a topic (or, as we say, a 'complex') by merely pointing it out, so long as it was not currently active in the patient himself at the time. To activate it would certainly have required some unfriendly piece of behaviour in reality on the analyst's part. Furthermore, he added, not every good relation between an analyst and his subject during and after analysis was to be regarded as a transference; there were also friendly relations which were based on reality and which proved to be viable.

[1937c, 5019]
The answer to the question which has been repeated so often in these pages is not to be reached by further reflection but by what we discover when we examine individual transference resistances occurring during treatment. We find in the end that we cannot understand the employment of transference as resistance so long as we think simply of 'transference'. We must make up our minds to distinguish a 'positive' transference from a 'negative' one, the transference of affectionate feelings from that of hostile ones, and to treat the two sorts of transference to the doctor separately. Positive transference is then further divisible into transference of friendly or affectionate feelings which are admissible to consciousness and transference of prolongations of those feelings into the unconscious. As regards the latter, analysis shows that they invariably go back to erotic sources. And we are thus led to the discovery that all the emotional relations of sympathy, friendship, trust, and the like, which can be turned to good account in our lives, are genetically linked with sexuality and have developed from purely sexual desires through a softening of their sexual aim, however pure and unsensual they may appear to our conscious self-perception. Originally we knew only sexual objects; and psycho-analysis shows us that people who in our real life are merely admired or respected may still be sexual objects for our unconscious.

[1912b, 2462]

Thus the solution of the puzzle is that transference to the doctor is suitable for resistance to the treatment only in so far as it is a negative transference or a positive transference of repressed erotic impulses. If we 'remove' the transference by making it conscious, we are detaching only these two components of the emotional act from the person of the doctor; the other component, which is admissible to consciousness and unobjectionable, persists and is the vehicle of success in psycho-analysis exactly as it is in other methods of treatment. To this extent we readily admit that the results of psycho-analysis rest upon suggestion; by suggestion, however, we must understand, as Ferenczi (1909) does, the influencing of a person by means of the transference phenomena which are possible in his case. We take care of the patient's final independence by employing suggestion in order to get him to accomplish a piece of psychical work which has as its necessary result a permanent improvement in his psychical situation.

[1912b, 2462]

I must begin by making it clear that a transference is present in the patient from the beginning of the treatment and for a while is the most powerful motive in its advance. We see no trace of it and need not bother about it so long as it operates in favour of the joint work of analysis. If it then changes into a resistance, we must turn our attention to it and we recognize that it alters its relation to the treatment under two different and contrary conditions: firstly, if as an affectionate trend it has become so powerful, and betrays signs of its origin in a sexual need so clearly, that it inevitably provokes an internal opposition to itself, and, secondly, if it consists of hostile instead of affectionate impulses. The hostile feelings make their appearance as a rule later than the affectionate ones and behind them; their simultaneous presence gives a good picture of the emotional ambivalence which is dominant in the majority of our intimate relations with other people. The hostile feelings are as much an indication of an emotional tie as the affectionate ones, in the same way as defiance signifies dependence as much as obedience does, though with a 'minus' instead of a 'plus' sign before it. We can be in no doubt that the hostile feelings towards the doctor deserve to be called a 'transference', since the situation in the treatment quite certainly offers no adequate grounds for their origin; this necessary view of the negative transference assures us, therefore, that we have not gone wrong in our judgement of the positive or affectionate one.

[1916-1917, 3485]
And now for the other side of the situation. Since the transference reproduces the patient's relation with his parents, it takes over the ambivalence of that relation as well. It almost inevitably happens that one day his positive attitude towards the analyst changes over into the negative, hostile one. This too is as a rule a repetition of the past. His obedience to his father (if it is his father that is in question), his courting of his father's favour, had its roots in an erotic wish directed towards him. Some time or other that demand will press its way forward in the transference as well and insist on being satisfied. In the analytic situation it can only meet with frustration. Real sexual relations between patients and analysts are out of the question, and even the subtler methods of satisfaction, such as the giving of preference, intimacy and so on, are only sparingly granted by the analyst. A rejection of this kind is taken as the occasion for the change-over; probably things happened in the same way in the patient's childhood.

[1940a [1938], 4986]
I have a few words to add upon the further course of Fräulein Elisabeth von R.'s case. Some weeks after we had separated I received a despairing letter from her mother. At her first attempt, she told me, to discuss her daughter's affairs of the heart with her, the girl had rebelled violently and had since then suffered from severe pains once more. She was indignant with me for having betrayed her secret. She was entirely inaccessible, and the treatment had been a complete failure. What was to be done now? she asked. Elisabeth would have nothing more to do with me. I did not reply to this. It stood to reason that Elisabeth after leaving my care would make one more attempt to reject her mother's intervention and once more take refuge in isolation. But I had a kind of conviction that everything would come right and that the trouble I had taken had not been in vain. Two months later they were back in Vienna, and the colleague to whom I owed the introduction of the case gave me news that Elisabeth felt perfectly well and was behaving as though there was nothing wrong with her, though she still suffered occasionally from slight pains. Several times since then she has sent me similar messages and each time promised to come and see me. But it is a characteristic of the personal relationship which arises in treatments of this kind that she has never done so. As my colleague assures me, she is to be regarded as cured. Her brother-in-law's connection with the family has remained unaltered.

The procedure is laborious and time-consuming for the physician. It presupposes great interest in psychological happenings, but personal concern for the patients as well. I cannot imagine bringing myself to delve into the psychical mechanism of a hysteria in anyone who struck me as low-minded and repellent, and who, on closer acquaintance, would not be capable of arousing human sympathy; whereas I can keep the treatment of a tabetic or rheumatic patient apart from personal approval of this kind. The demands made on the patient are not less. The procedure is not applicable at all below a certain level of intelligence, and it is made very much more difficult by any trace of feebleness of mind. The complete consent and complete attention of the patients are needed, but above all their confidence, since the analysis invariably leads to the disclosure of the most intimate and secret psychical events. A good number of the patients who would be suitable for this form of treatment abandon the doctor as soon as the suspicion begins to dawn on them of the direction in which the investigation is leading. For patients such as these the doctor has remained a stranger. With others, who have decided to put themselves in his hands and place their confidence in him - a step which in other such situations is only taken voluntarily and never at the doctor's request - with these other patients, I say, it is almost inevitable that their personal relation to him will force itself, for a time at least, unduly into the foreground. It seems, indeed, as though an influence of this kind on the part of the doctor is a *sine qua non* to a solution of the problem. I do not think any essential difference is made in this respect whether hypnosis can be used or whether it has to be bypassed and replaced by something else. But reason demands that we should emphasize the fact that these drawbacks, though they are inseparable from our procedure, cannot be laid at its door. On the contrary, it is quite clear that they are based on the predetermining conditions of the neuroses that are to be cured and that they must attach to any medical activity which involves intense preoccupation with the patient and leads to a psychical change in him. I have not been able to attribute any deleterious effects or danger to the employment of hypnosis, though I made copious use of it in some of my cases. Where I caused damage, the reasons lay elsewhere and deeper. If I survey my therapeutic efforts during the last few years since the communications made by my honoured teacher and friend Josef Breuer showed me the use of the cathartic method, I believe that in spite of everything, I have done much more, and more frequent, good than harm and have accomplished some things which no other therapeutic procedure could have achieved. It has on the whole, as the 'Preliminary Communication' put it, brought 'considerable therapeutic advantages'.

[1895d, 145]

[1895d, 235]
To begin with I was greatly annoyed at this increase in my psychological work, till I came to see that the whole process followed a law; and I then noticed, too, that transference of this kind brought about no great addition to what I had to do. For the patient the work remained the same: she had to overcome the distressing affect aroused by having been able to entertain such a wish even for a moment; and it seemed to make no difference to the success of the treatment whether she made this psychical repudiation the theme of her work in the historical instance or in the recent one connected with me. The patients, too, gradually learnt to realize that in these transferences on to the figure of the physician it was a question of a compulsion and an illusion which melted away with the conclusion of the analysis. I believe, however, that if I had neglected to make the nature of the 'obstacle' clear to them I should simply have given them a new hysterical symptom - though, it is true, a milder one - in exchange for another which had been generated spontaneously.

There is another kind of incompleteness which I myself have intentionally introduced. I have as a rule not reproduced the process of interpretation to which the patient's associations and communications had to be subjected, but only the results of that process. Apart from the dreams, therefore, the technique of the analytic work has been revealed in only a very few places. My object in this case history was to demonstrate the intimate structure of a neurotic disorder and the determination of its symptoms; and it would have led to nothing but hopeless confusion if I had tried to complete the other task at the same time. Before the technical rules, most of which have been arrived at empirically, could be properly laid down, it would be necessary to collect material from the histories of a large number of treatments. Nevertheless, the degree of shortening produced by the omission of the technique is not to be exaggerated in this particular case. Precisely that portion of the technical work which is the most difficult never came into question with the patient; for the factor of 'transference', which is considered at the end of the case history, did not come up for discussion during the short treatment.

Nor is the case of whose history and treatment I have published a fragment in these pages well calculated to put the value of psycho-analytic therapy in its true light. Not only the briefness of the treatment (which hardly lasted three months) but another factor inherent in the nature of the case prevented results being brought about such as are attainable in other instances, where the improvement will be admitted by the patient and his relatives and will approximate more or less closely to a complete recovery. Satisfactory results of this kind are reached when the symptoms are maintained solely by the internal conflict between the impulses concerned with sexuality. In such cases the patient's condition will be seen improving in proportion as he is helped towards a solution of his mental problems by the translation of pathogenic into normal material. The course of events is very different when the symptoms have become enlisted in the service of external motives, as had happened with Dora during the two preceding years. It is surprising, and might easily be misleading, to find that the patient's condition shows no noticeable alteration even though considerable progress has been made with the work of analysis. But in reality things are not as bad as they seem. It is true that the symptoms do not disappear while the work is proceeding; but they disappear a little while later, when the relations between patient and physician have been dissolved. The postponement of recovery or improvement is really only caused by the physician's own person.
If the theory of analytic technique is gone into, it becomes evident that transference is an inevitable necessity. Practical experience, at all events, shows conclusively that there is no means of avoiding it, and that this latest creation of the disease must be combated like all the earlier ones. This happens, however, to be by far the hardest part of the whole task. It is easy to learn how to interpret dreams, to extract from the patient's associations his unconscious thoughts and memories, and to practise similar explanatory arts: for these the patient himself will always provide the text. Transference is the one thing the presence of which has to be detected almost without assistance and with only the slightest clues to go upon, while at the same time the risk of making arbitrary inferences has to be avoided. Nevertheless, transference cannot be evaded, since use is made of it in setting up all the obstacles that make the material inaccessible to treatment, and since it is only after the transference has been resolved that a patient arrives at a sense of conviction of the validity of the connections which have been constructed during the analysis.

Some people may feel inclined to look upon it as a serious objection to a method which is in any case troublesome enough that it itself should multiply the labours of the physician by creating a new species of pathological mental products. They may even be tempted to infer from the existence of transferences that the patient will be injured by analytic treatment. Both these suppositions would be mistaken. The physician's labours are not multiplied by transference; it need make no difference to him whether he has to overcome any particular impulse of the patient's in connection with himself or with some one else. Nor does the treatment force upon the patient, in the shape of transference, any new task which he would not otherwise have performed. It is true that neuroses may be cured in institutions from which psycho-analytic treatment is excluded, that hysteria may be said to be cured not by the method but by the physician, and that there is usually a sort of blind dependence and a permanent bond between a patient and the physician who has removed his symptoms by hypnotic suggestion; but the scientific explanation of all these facts is to be found in the existence of 'transferences' such as are regularly directed by patients on to their physicians. Psycho-analytic treatment does not create transferences, it merely brings them to light, like so many other hidden psychical factors. The only difference is this - that spontaneously a patient will only call up affectionate and friendly transferences to help towards his recovery; if they cannot be called up, he feels the physician is 'antipathetic' to him, and breaks away from him as fast as possible and without having been influenced by him. In psycho-analysis, on the other hand, since the play of motives is different, all the patient's tendencies, including hostile ones, are aroused; they are then turned to account for the purposes of the analysis by being made conscious, and in this way the transference is constantly being destroyed. Transference, which seems ordained to be the greatest obstacle to psycho-analysis, becomes its most powerful ally, if its presence can be detected each time and explained to the patient.¹

[1905e, 1450]

[1905e, 1451]
I have been obliged to speak of transference, for it is only by means of this factor that I can elucidate the peculiarities of Dora's analysis. Its great merit, namely, the unusual clarity which makes it seem so suitable as a first introductory publication, is closely bound up with its great defect, which led to its being broken off prematurely. I did not succeed in mastering the transference in good time. Owing to the readiness with which Dora put one part of the pathogenic material at my disposal during the treatment, I neglected the precaution of looking out for the first signs of transference, which was being prepared in connection with another part of the same material a part of which I was in ignorance. At the beginning it was clear that I was replacing her father in her imagination, which was not unlikely, in view of the difference between our ages. She was even constantly comparing me with him consciously, and kept anxiously trying to make sure whether I was being quite straightforward with her, for her father 'always preferred secrecy and roundabout ways'. But when the first dream came, in which she gave herself the warning that she had better leave my treatment just as she had formerly left Herr K.'s house, I ought to have listened to the warning myself. 'Now,' I ought to have said to her, 'it is from Herr K. that you have made a transference on to me. Have you noticed anything that leads you to suspect me of evil intentions similar (whether openly or in some sublimated form) to Herr K.'s? Or have you been struck by anything about me or got to know anything about me which has caught your fancy, as happened previously with Herr K.' Her attention would then have been turned to some detail in our relations, or in my person or circumstances, behind which there lay concealed something analogous but immeasurably more important concerning Herr K. And when this transference had been cleared up, the analysis would have obtained access to new memories, dealing, probably, with actual events. But I was deaf to this first note of warning, thinking I had ample time before me, since no further stages of transference developed and the material for the analysis had not yet run dry. In this way the transference took me unawares, and, because of the unknown quantity in me which reminded Dora of Herr K., she took her revenge on me as she wanted to take her revenge on him, and deserted me as she believed herself to have been deceived and deserted by him. Thus she acted out an essential part of her recollections and phantasies instead of reproducing it in the treatment. What this unknown quantity was I naturally cannot tell. I suspect that it had to do with money, or with jealousy of another patient who had kept up relations with my family after her recovery. When it is possible to work transferences into the analysis at an early stage, the course of the analysis is retarded and obscured, but its existence is better guaranteed against sudden and overwhelming resistances.

[1905e, 1452]

If cruel impulses and revengeful motives, which have already been used in the patient's ordinary life for maintaining her symptoms, become transferred on to the physician during treatment, before he has had time to detach them from himself by tracing them back to their sources, then it is not to be wondered at if the patient's condition is unaffected by his therapeutic efforts. For how could the patient take a more effective revenge than by demonstrating upon her own person the helplessness and incapacity of the physician? Nevertheless, I am not inclined to put too low a value on the therapeutic results even of such a fragmentary treatment as Dora's.

[1905e, 1454]
But the similarity between Gradiva's procedure and the analytic method of psychotherapy is not limited to these two points - the making conscious of what has been repressed and the coinciding of explanation with cure. It also extends to what turns out to be the essence of the whole change - to the awakening of feelings. Every disorder analogous to Hanold's delusion, what in scientific terms we are in the habit of calling 'psychoneuroses', has as its precondition the repression of a portion of instinctual life, or, as we can safely say, of the sexual instinct. At every attempt to introduce the unconscious and repressed causes of the illness into consciousness, the instinctual component concerned is necessarily aroused to a renewed struggle with the repressing powers, only to come to terms with them in the final outcome, often to the accompaniment of violent manifestations of reaction. The process of cure is accomplished in a relapse into love, if we combine all the many components of the sexual instinct under the term 'love'; and such a relapse is indispensable, for the symptoms on account of which the treatment has been undertaken are nothing other than precipitates of earlier struggles connected with repression or the return of the repressed, and they can only be resolved and washed away by a fresh high tide of the same passions. Every psycho-analytic treatment is an attempt at liberating repressed love which has found a meagre outlet in the compromise of a symptom. Indeed, the agreement between such treatments and the process of cure described by the author of Gradiva reaches its climax in the further fact that in analytic psychotherapy too the re-awakened passion, whether it is love or hate, invariably chooses as its object the figure of the doctor.

[1907a, 1881]

It is here that the differences begin, which made the case of Gradiva an ideal one which medical technique cannot attain. Gradiva was able to return the love which was making its way from the unconscious into consciousness, but the doctor cannot. Gradiva had herself been the object of the earlier, repressed love; her figure at once offered the liberated current of love a desirable aim. The doctor has been a stranger, and must endeavour to become a stranger once more after the cure; he is often at a loss what advice to give the patients he has cured as to how in real life they can use their recovered capacity to love. To indicate the expediens and substitutes of which the doctor therefore makes use to help him to approximate with more or less success to the model of a cure by love which has been shown us by our author - all this would take us much too far away from the task before us.

[1907a, 1882]
A discussion of this childhood scene will be found in the footnote, and here I will only remark that its emergence shook the patient for the first time in his refusal to believe that at some prehistoric period in his childhood he had been seized with fury (which had subsequently become latent) against the father whom he loved so much. I must confess that I had expected it to have a greater effect, for the incident had been described to him so often - even by his father himself - that there could be no doubt of its objective reality. But, with that capacity for being illogical which never fails to bewilder one in such highly intelligent people as obsessional neurotics, he kept urging against the evidential value of the story the fact that he himself could not remember the scene. And so it was only along the painful road of transference that he was able to reach a conviction that his relation to his father really necessitated the postulation of this unconscious complement. Things soon reached a point at which, in his dreams, his waking phantasies, and his associations, he began heaping the grossest and filthiest abuse upon me and my family, though in his deliberate actions he never treated me with anything but the greatest respect. His demeanour as he repeated these insults to me was that of a man in despair. 'How can a gentleman like you, sir,' he used to ask, 'let yourself be abused in this way by a low, good-for-nothing fellow like me? You ought to turn me out: that's all I deserve.' While he talked like this, he would get up from the sofa and roam about the room, - a habit which he explained at first as being due to delicacy of feeling: he could not bring himself, he said, to utter such horrible things while he was lying there so comfortably. But soon he himself found a more cogent explanation, namely, that he was avoiding my proximity for fear of my giving him a beating. If he stayed on the sofa he behaved like some one in desperate terror trying to save himself from castigations of terrific violence; he would bury his head in his hands, cover his face with his arm, jump up suddenly and rush away, his features distorted with pain, and so on. He recalled that his father had had a passionate temper, and sometimes in his violence had not known where to stop. Thus, little by little, in this school of suffering, the patient won the sense of conviction which he had lacked - though to any disinterested mind the truth would have been almost self-evident.

[1909d, 2163]
I have not yet told you, Ladies and Gentlemen, of the most important of the observations which confirm our hypothesis of the sexual instinctual forces operating in neuroses. In every psycho-analytic treatment of a neurotic patient the strange phenomenon that is known as ‘transference’ makes its appearance. The patient, that is to say, directs towards the physician a degree of affectionate feeling (mingled, often enough, with hostility) which is based on no real relation between them and which - as is shown by every detail of its emergence - can only be traced back to old wishful phantasies of the patient's which have become unconscious. Thus the part of the patient's emotional life which he can no longer recall to memory is re-experienced by him in his relation to the physician; and it is only this re-experiencing in the 'transference' that convinces him of the existence and of the power of these unconscious sexual impulses. His symptoms, to take an analogy from chemistry, are precipitates of earlier experiences in the sphere of love (in the widest sense of the word), and it is only in the raised temperature of his experience of the transference that they can be resolved and reduced to other psychical products. In this reaction the physician, if I may borrow an apt phrase from Ferenczi (1909), plays the part of a catalytic ferment, which temporarily attracts to itself the affects liberated in the process. A study of transference, too, can give you the key to an understanding of hypnotic suggestion, which we employed to begin with as a technical method for investigating the unconscious in our patients. At that time hypnosis was found to be a help therapeutically, but a hindrance to the scientific understanding of the facts; for it cleared away the psychical resistances in a certain area while building them up into an unscalable wall at its frontiers. You must not suppose, moreover, that the phenomenon of transference (of which, unfortunately, I can tell you all too little to-day) is created by psycho-analytic influence. Transference arises spontaneously in all human relationships just as it does between the patient and the physician. It is everywhere the true vehicle of therapeutic influence; and the less its presence is suspected, the more powerfully it operates. So psycho-analysis does not create it, but merely reveals it to consciousness and gains control of it in order to guide psychological processes towards the desired goal. I cannot, however, leave the topic of transference without stressing the fact that this phenomenon plays a decisive part in bringing conviction not only to the patient but also to the physician. I know it to be true of all my followers that they were only convinced of the correctness of my assertions on the pathogenesis of the neuroses by their experiences with transference; and I can very well understand that such certainty of judgement cannot be attained before one has carried out psycho-analyses and has oneself observed the workings of transference.

[1910a, 2236]
(a) Advances in our knowledge. We are, of course, still a long way from knowing all that is required for an understanding of the unconscious in our patients. It is clear that every advance in our knowledge means an increase in our therapeutic power. As long as we have understood nothing, we have accomplished nothing; the more we understand, the more we shall achieve. At its beginning psycho-analytic treatment was inexorable and exhausting. The patient had to say everything himself, and the physician's activity consisted of urging him on incessantly. To-day things have a more friendly air. The treatment is made up of two parts - what the physician infers and tells the patient, and the patient's working-over of what he has heard. The mechanism of our assistance is easy to understand: we give the patient the conscious anticipatory idea and he then finds the repressed unconscious idea in himself on the basis of its similarity to the anticipatory one. This is the intellectual help which makes it easier for him to overcome the resistances between conscious and unconscious. Incidentally, I may remark that it is not the only mechanism made use of in analytic treatment; you all know the far more powerful one which lies in the use of the 'transference'. It is my intention in the near future to deal with these various factors, which are so important for an understanding of the treatment, in an Allgemeine Methodik der Psychoanalyse. And further, in speaking to you I need not rebut the objection that the evidential value in support of the correctness of our hypotheses is obscured in our treatment as we practise it to-day; you will not forget that this evidence is to be found elsewhere, and that a therapeutic procedure cannot be carried out in the same way as a theoretical investigation.

Since, however, psycho-analysis cannot dispense with giving this information, it lays down that this shall not be done before two conditions have been fulfilled. First, the patient must, through preparation, himself have reached the neighbourhood of what he has repressed, and secondly, he must have formed a sufficient attachment (transference) to the physician for his emotional relationship to him to make a fresh flight impossible.

There would be nothing more to discuss or worry about in this behaviour of transference, if it were not that two points remain unexplained about it which are of particular interest to psycho-analysis. Firstly, we do not understand why transference is so much more intense with neurotic subjects in analysis than it is with other such people who are not being analysed; and secondly, it remains a puzzle why in analysis transference emerges as the most powerful resistance to the treatment, whereas outside analysis it must be regarded as the vehicle of cure and the condition of success. For our experience has shown us - and the fact can be confirmed as often as we please - that if a patient's free associations fail¹ the stoppage can invariably be removed by an assurance that he is being dominated at the moment by an association which is concerned with the doctor himself or with something connected with him. As soon as this explanation is given, the stoppage is removed, or the situation is changed from one in which the associations fail into one in which they are being kept back. At first sight it appears to be an immense disadvantage in psycho-analysis as a method that what is elsewhere the strongest factor towards success is changed in it into the most powerful medium of resistance. If, however, we examine the situation more closely, we can at least clear away the first of our two problems. It is not a fact that transference emerges with greater intensity and lack of restraint during psycho-analysis than outside it. In institutions in which nerve patients are treated non-analytically, we can observe transference occurring with the greatest intensity and in the most unworthy forms, extending to nothing less than mental bondage, and moreover showing the plainest erotic colouring. Gabriele Reuter, with her sharp powers of observation, described this at a time when there was no such thing as psycho-analysis, in a remarkable book which betrays in every respect the clearest insight into the nature and genesis of neuroses.² These characteristics of transference are therefore to be attributed not to psycho-analysis but to neurosis itself.

[1910d, 2307]

[1910k, 2379]

[1912b, 2458]
After it has been overcome, the overcoming of the other portions of the complex raises few further difficulties. The longer an analytic treatment lasts and the more clearly the patient realizes that distortions of the pathogenic material cannot by themselves offer any protection against its being uncovered, the more consistently does he make use of the one sort of distortion which obviously affords him the greatest advantages - distortion through transference. These circumstances tend towards a situation in which finally every conflict has to be fought out in the sphere of transference.

How does it come about that transference is so admirably suited to be a means of resistance? It might be thought that the answer can be given without difficulty. For it is evident that it becomes particularly hard to admit to any proscribed wishful impulse if it has to be revealed in front of the very person to whom the impulse relates. Such a necessity gives rise to situations which in the real world seem scarcely possible. But it is precisely this that the patient is aiming at when he makes the object of his emotional impulses coincide with the doctor. Further consideration, however, shows that this apparent gain cannot provide the solution of the problem. Indeed, a relation of affectionate and devoted dependence can, on the contrary help a person over all the difficulties of making an admission. In analogous real situations people will usually say: 'I feel no shame in front of you: I can say anything to you.' Thus the transference to the doctor might just as easily serve to facilitate admissions, and it is not clear why it should make things more difficult.

Thus the solution of the puzzle is that transference to the doctor is suitable for resistance to the treatment only in so far as it is a negative transference or a positive transference of repressed erotic impulses. If we 'remove' the transference by making it conscious, we are detaching only these two components of the emotional act from the person of the doctor; the other component, which is admissible to consciousness and unobjectionable, persists and is the vehicle of success in psycho-analysis exactly as it is in other methods of treatment. To this extent we readily admit that the results of psycho-analysis rest upon suggestion; by suggestion, however, we must understand, as Ferenczi (1909) does, the influencing of a person by means of the transference phenomena which are possible in his case. We take care of the patient's final independence by employing suggestion in order to get him to accomplish a piece of psychical work which has as its necessary result a permanent improvement in his psychical situation.
In the process of seeking out the libido which has escaped from the patient's conscious, we have penetrated into the realm of the unconscious. The reactions which we bring about reveal at the same time some of the characteristics which we have come to know from the study of dreams. The unconscious impulses do not want to be remembered in the way the treatment desires them to be, but endeavour to reproduce themselves in accordance with the timelessness of the unconscious and its capacity for hallucination. Just as happens in dreams, the patient regards the products of the awakening of his unconscious impulses as contemporaneous and real; he seeks to put his passions into action without taking any account of the real situation. The doctor tries to compel him to fit these emotional impulses into the nexus of the treatment and of his life-history, to submit them to intellectual consideration and to understand them in the light of their psychical value. This struggle between the doctor and the patient, between intellect and instinctual life, between understanding and seeking to act, is played out almost exclusively in the phenomena of transference. It is on that field that the victory must be won - the victory whose expression is the permanent cure of the neurosis. It cannot be disputed that controlling the phenomena of transference presents the psycho-analyst with the greatest difficulties. But it should not be forgotten that it is precisely they that do us the inestimable service of making the patient's hidden and forgotten erotic impulses immediate and manifest. For when all is said and done, it is impossible to destroy anyone in absentia or in effigie.

[1912b, 2464]

But in psycho-analytic relations things often happen differently from what the psychology of consciousness might lead us to expect. Experience does not speak in favour of an affective technique of this kind. Nor is it hard to see that it involves a departure from psycho-analytic principles and verges upon treatment by suggestion. It may induce the patient to bring forward sooner and with less difficulty things he already knows but would otherwise have kept back for a time through conventional resistances. But this technique achieves nothing towards the uncovering of what is unconscious to the patient. It makes him even more incapable of overcoming his deeper resistances, and in severer cases it invariably fails by encouraging the patient to be insatiable: he would like to reverse the situation, and finds the analysis of the doctor more interesting than his own. The resolution of the transference, too - one of the main tasks of the treatment - is made more difficult by an intimate attitude on the doctor's part, so that any gain there may be at the beginning is more than outweighed at the end. I have no hesitation, therefore, in condemning this kind of technique as incorrect. The doctor should be opaque to his patients and, like a mirror, should show them nothing but what is shown to him. In practice, it is true, there is nothing to be said against a psychotherapist combining a certain amount of analysis with some suggestive influence in order to achieve a perceptible result in a shorter time - as is necessary, for instance, in institutions. But one has a right to insist that he himself should be in no doubt about what he is doing and should know that his method is not that of true psycho-analysis.

[1912e, 2472]
It is now time for us to take a survey of the play of forces which is set in motion by the treatment. The primary motive force in the therapy is the patient's suffering and the wish to be cured that arises from it. The strength of this motive force is subtracted from by various factors - which are not discovered till the analysis is in progress - above all, by what we have called the 'secondary gain from illness'; but it must be maintained till the end of the treatment. Every improvement effects a diminution of it. By itself, however, this motive force is not sufficient to get rid of the illness. Two things are lacking in it for this: it does not know what paths to follow to reach this end; and it does not possess the necessary quota of energy with which to oppose the resistances. The analytic treatment helps to remedy both these deficiencies. It supplies the amounts of energy that are needed for overcoming the resistances by making mobile the energies which lie ready for the transference; and, by giving the patient information at the right time, it shows him the paths along which he should direct those energies. Often enough the transference is able to remove the symptoms of the disease by itself, but only for a while - only for as long as it itself lasts. In this case the treatment is a treatment by suggestion, and not a psycho-analysis at all. It only deserves the latter name if the intensity of the transference has been utilized for the overcoming of resistances. Only then has being ill become impossible, even when the transference has once more been dissolved, which is its destined end.

[1913c, 2494]

In the course of the treatment yet another helpful factor is aroused. This is the patient's intellectual interest and understanding. But this alone hardly comes into consideration in comparison with the other forces that are engaged in the struggle; for it is always in danger of losing its value, as a result of the clouding of judgement that arises from the resistances. Thus the new sources of strength for which the patient is indebted to his analyst are reducible to transference and instruction (through the communications made to him). The patient, however, only makes use of the instruction in so far as he is induced to do so by the transference; and it is for this reason that our first communication should be withheld until a strong transference has been established. And this, we may add, holds good of every subsequent communication. In each case we must wait until the disturbance of the transference by the successive emergence of transference-resistances has been removed.

[1913c, 2495]

The main instrument, however, for curbing the patient's compulsion to repeat and for turning it into a motive for remembering lies in the handling of the transference. We render the compulsion harmless, and indeed useful, by giving it the right to assert itself in a definite field. We admit it into the transference as a playground in which it is allowed to expand in almost complete freedom and in which it is expected to display to us everything in the way of pathogenic instincts that is hidden in the patient's mind. Provided only that the patient shows compliance enough to respect the necessary conditions of the analysis, we regularly succeed in giving all the symptoms of the illness a new transference meaning and in replacing his ordinary neurosis by a 'transference-neurosis' of which he can be cured by the therapeutic work. The transference thus creates an intermediate region between illness and real life through which the transition from the one to the other is made. The new condition has taken over all the features of the illness; but it represents an artificial illness which is at every point accessible to our intervention. It is a piece of real experience, but one which has been made possible by especially favourable conditions, and it is of a provisional nature. From the repetitive reactions which are exhibited in the transference we are led along the familiar paths to the awakening of the memories, which appear without difficulty, as it were, after the resistance has been overcome.

[1914g, 2505]
Every beginner in psycho-analysis probably feels alarmed at first at the difficulties in store for him when he comes to interpret the patient's associations and to deal with the reproduction of the repressed. When the time comes, however, he soon learns to look upon these difficulties as insignificant, and instead becomes convinced that the only really serious difficulties he has to meet lie in the management of the transference.

[1915a, 2509]

Among the situations which arise in this connection I shall select one which is very sharply circumscribed; and I shall select it, partly because it occurs so often and is so important in its real aspects and partly because of its theoretical interest. What I have in mind is the case in which a woman patient shows by unmistakable indications, or openly declares, that she has fallen in love, as any other mortal woman might, with the doctor who is analysing her. This situation has its distressing and comical aspects, as well as its serious ones. It is also determined by so many and such complicated factors, it is so unavoidable and so difficult to clear up, that a discussion of it to meet a vital need of analytic technique has long been overdue. But since we who laugh at other people's failings are not always free from them ourselves, we have not so far been precisely in a hurry to fulfil this task. We are constantly coming up against the obligation to professional discretion - a discretion which cannot be dispensed with in real life, but which is of no service in our science. In so far as psycho-analytic publications are a part of real life, too, we have here an insoluble contradiction. I have recently disregarded this matter of discretion at one point,¹ and shown how this same transference situation held back the development of psycho-analytic therapy during its first decade.

[1915a, 2509]

To a well-educated layman (for that is what the ideal civilized person is in regard to psycho-analysis) things that have to do with love are incommensurable with everything else; they are, as it were, written on a special page on which no other writing is tolerated. If a woman patient has fallen in love with her doctor it seems to such a layman that only two outcomes are possible. One, which happens comparatively rarely, is that all the circumstances allow of a permanent legal union between them; the other, which is more frequent, is that the doctor and the patient part and give up the work they have begun which was to have led to her recovery, as though it had been interrupted by some elemental phenomenon. There is, to be sure, a third conceivable outcome, which even seems compatible with a continuation of the treatment. This is that they should enter into a love-relationship which is illicit and which is not intended to last for ever. But such a course is made impossible by conventional morality and professional standards. Nevertheless, our layman will beg the analyst to reassure him as unambiguously as possible that this third alternative is excluded.

[1915a, 2510]

At a first glance it certainly does not look as if the patient's falling in love in the transference could result in any advantage to the treatment. No matter how amenable she has been up till then, she suddenly loses all understanding of the treatment and all interest in it, and will not speak or hear about anything but her love, which she demands to have returned. She gives up her symptoms or pays no attention to them; indeed, she declares that she is well. There is a complete change of scene; it is as though some piece of make-believe had been stopped by the sudden irruption of reality - as when, for instance, a cry of fire is raised during a theatrical performance. No doctor who experiences this for the first time will find it easy to retain his grasp on the analytic situation and to keep clear of the illusion that the treatment is really at an end.

[1915a, 2512]
If he has been guided by the calculation that this compliance on his part will ensure his domination over his patient and thus enable him to influence her to perform the tasks required by the treatment, and in this way to liberate herself permanently from her neurosis - then experience would inevitably show him that his calculation was wrong. The patient would achieve her aim, but he would never achieve his. What would happen to the doctor and the patient would only be what happened, according to the amusing anecdote, to the pastor and the insurance agent. The insurance agent, a free-thinker, lay at the point of death and his relatives insisted on bringing in a man of God to convert him before he died. The interview lasted so long that those who were waiting outside began to have hopes. At last the door of the sick-chamber opened. The free-thinker had not been converted; but the pastor went away insured. [1915a, 2515]

If the patient's advances were returned it would be a great triumph for her, but a complete defeat for the treatment. She would have succeeded in what all patients strive for in analysis - she would have succeeded in acting out, in repeating in real life, what she ought only to have remembered, to have reproduced as psychical material and to have kept within the sphere of psychical events.¹ In the further course of the love-relationship she would bring out all the inhibitions and pathological reactions of her erotic life, without there being any possibility of correcting them; and the distressing episode would end in remorse and a great strengthening of her propensity to repression. The love-relationship in fact destroys the patient's susceptibility to influence from analytic treatment. A combination of the two would be an impossibility. [1915a, 2516]

It is, therefore, just as disastrous for the analysis if the patient's craving for love is gratified as if it is suppressed. The course the analyst must pursue is neither of these; it is one for which there is no model in real life. He must take care not to steer away from the transference-love, or to repulse it or to make it distasteful to the patient; but he must just as resolutely withhold any response to it. He must keep firm hold of the transference-love, but treat it as something unreal, as a situation which has to be gone through in the treatment and traced back to its unconscious origins and which must assist in bringing all that is most deeply hidden in the patient's erotic life into her consciousness and therefore under her control. The more plainly the analyst lets it be seen that he is proof against every temptation, the more readily will he be able to extract from the situation its analytic content. The patient, whose sexual repression is of course not yet removed but merely pushed into the background, will then feel safe enough to allow all her preconditions for loving, all the phantasies springing from her sexual desires, all the detailed characteristics of her state of being in love, to come to light; and from these she will herself open the way to the infantile roots of her love. [1915a, 2516]

Many analysts will no doubt be agreed on the method by which other women, who are less violent in their love, can be gradually made to adopt the analytic attitude. What we do, above all, is to stress to the patient the unmistakable element of resistance in this 'love'. Genuine love, we say, would make her docile and intensify her readiness to solve the problems of her case, simply because the man she was in love with expected it of her. In such a case she would gladly choose the road to completion of the treatment, in order to acquire value in the doctor's eyes and to prepare herself for real life, where this feeling of love could find a proper place. Instead of this, we point out, she is showing a stubborn and rebellious spirit, she has thrown up all interest in her treatment, and clearly feels no respect for the doctor's well-founded convictions. She is thus bringing out a resistance under the guise of being in love with him; and in addition to this she has no compunction in placing him in a cleft stick. For if he refuses her love, as his duty and his understanding compel him to do, she can play the part of a woman scorned, and then withdraw from his therapeutic efforts out of revenge and resentment, exactly as she is now doing out of her ostensible love. [1915a, 2517]
As a second argument against the genuineness of this love we advance the fact that it exhibits not a single new feature arising from the present situation, but is entirely composed of repetitions and copies of earlier reactions, including infantile ones. We undertake to prove this by a detailed analysis of the patient's behaviour in love.

If the necessary amount of patience is added to these arguments, it is usually possible to overcome the difficult situation and to continue the work with a love which has been moderated or transformed; the work then aims at uncovering the patient's infantile object-choice and the phantasies woven round it.

I think we have told the patient the truth, but not the whole truth regardless of the consequences. Of our two arguments the first is the stronger. The part played by resistance in transference-love is unquestionable and very considerable. Nevertheless the resistance did not, after all, create this love; it finds it ready to hand, makes use of it and aggravates its manifestations. Nor is the genuineness of the phenomenon disproved by the resistance. The second argument is far weaker. It is true that the love consists of new editions of old traits and that it repeats infantile reactions. But this is the essential character of every state of being in love. There is no such state which does not reproduce infantile prototypes. It is precisely from this infantile determination that it receives its compulsive character, verging as it does on the pathological. Transference-love has perhaps a degree less of freedom than the love which appears in ordinary life and is called normal; it displays its dependence on the infantile pattern more clearly and is less adaptable and capable of modification; but that is all, and not what is essential.

As regards the analyst's line of action, it is the first of these three features of transference-love which is the decisive factor. He has evoked this love by instituting analytic treatment in order to cure the neurosis. For him, it is an unavoidable consequence of a medical situation, like the exposure of a patient's body or the imparting of a vital secret. It is therefore plain to him that he must not derive any personal advantage from it. The patient's willingness makes no difference; it merely throws the whole responsibility on the analyst himself. Indeed, as he must know, the patient had been prepared for no other mechanism of cure. After all the difficulties have been successfully overcome, she will often confess to having had an anticipatory phantasy at the time when she entered the treatment, to the effect that if she behaved well she would be rewarded at the end by the doctor's affection.
For the doctor, ethical motives unite with the technical ones to restrain him from giving the patient his love. The aim he has to keep in view is that this woman, whose capacity for love is impaired by infantile fixations, should gain free command over a function which is of such inestimable importance to her; that she should not, however, dissipate it in the treatment, but keep it ready for the time when, after her treatment, the demands of real life make themselves felt. He must not stage the scene of a dog-race in which the prize was to be a garland of sausages but which some humorist spoilt by throwing a single sausage on to the track. The result was, of course, that the dogs threw themselves upon it and forgot all about the race and about the garland that was luring them to victory in the far distance. I do not mean to say that it is always easy for the doctor to keep within the limits prescribed by ethics and technique. Those who are still youngish and not yet bound by strong ties may in particular find it a hard task. Sexual love is undoubtedly one of the chief things in life, and the union of mental and bodily satisfaction in the enjoyment of love is one of its culminating peaks. Apart from a few queer fanatics, all the world knows this and conducts its life accordingly; science alone is too delicate to admit it. Again, when a woman sues for love, to reject and refuse is a distressing part for a man to play; and, in spite of neurosis and resistance, there is an incomparable fascination in a woman of high principles who confesses her passion. It is not a patient's crudely sensual desires which constitute the temptation. These are more likely to repel, and it will call for all the doctor's tolerance if he is to regard them as natural phenomenon. It is rather, perhaps, a woman's subtler and aim-inhibited wishes which bring with them the danger of making a man forget his technique and his medical task for the sake of a fine experience.

And yet it is quite out of the question for the analyst to give way. However highly he may prize love he must prize even more highly the opportunity for helping his patient over a decisive stage in her life. She has to learn from him to overcome the pleasure principle, to give up a satisfaction which lies to hand but is socially not acceptable, in favour of a more distant one, which is perhaps altogether uncertain, but which is both psychologically and socially unimpeachable. To achieve this overcoming, she has to be led through the primal period of her mental development and on that path she has to acquire the extra piece of mental freedom which distinguishes conscious mental activity - in the systematic sense - from unconscious.

The analytic psychotherapist thus has a threefold battle to wage - in his own mind against the forces which seek to drag him down from the analytic level; outside the analysis, against opponents who dispute the importance he attaches to the sexual instinctual forces and hinder him from making use of them in his scientific technique; and inside the analysis, against his patients, who at first behave like opponents but later on reveal the overvaluation of sexual life which dominates them, and who try to make him captive to their socially untamed passion.
The form taken by the Neo-Zurich therapy under these influences can be conveyed in the
words of a patient who experienced it himself: ‘This time not a trace of attention was given to
the past or to the transference. Wherever I thought I recognized the latter it was pronounced to
be a pure libidinal symbol. The moral instruction was very fine and I followed it faithfully, but I
did not advance a step. It was even more annoying for me than for him, but how could I help it?
. . . Instead of freeing me by analysis, every day brought fresh tremendous demands on me,
which had to be fulfilled if the neurosis was to be conquered - for instance, inward concentration
by means of introversion, religious meditation, resuming life with my wife in loving devotion, etc.
It was almost beyond one's strength; it was aiming at a radical transformation of one's whole
inner nature. I left the analysis as a poor sinner with intense feelings of contrition and the best
resolutions, but at the same time in utter discouragement. Any clergyman would have advised
what he recommended, but where was I to find the strength?’ The patient, it is true, reported
that he had heard that analysis of the past and of the transference must be gone through first;
but he had been told that he had already had enough of it. Since this first kind of analysis had
not helped him more, the conclusion seems to me justified that the patient had not had enough
of it. Certainly the subsequent treatment, which no longer had any claim to be called psycho-
analysis, did not improve matters. It is remarkable that the members of the Zurich school should
have made the long journey round by way of Vienna in order to wind up at the nearby city of
Berne, where Dubois cures neuroses by ethical encouragement in a more considerate manner.¹
[1914d, 2926]

Intellectual resistances are not the worst; one always remains superior to them. But the
patient also knows how to put up resistances, without going outside the framework of the
analysis, the overcoming of which is among the most difficult of technical problems. Instead of
remembering, he repeats attitudes and emotional impulses from his early life which can be used
as a resistance against the doctor and the treatment by means of what is known as
‘transference’. If the patient is a man, he usually extracts this material from his relation to his
father, into whose place he fits the doctor, and in that way he makes resistances out of his
efforts to become independent in himself and in his judgements, out of his ambition, the first aim
of which was to do things as well as his father or to get the better of him, or out of his
unwillingness to burden himself for the second time in his life with a load of gratitude. Thus at
times one has an impression that the patient has entirely replaced his better intention of making
an end to his illness by the alternative one of putting the doctor in the wrong, of making him
realize his impotence and of triumphing over him. Women have a masterly gift for exploiting an
affectionate, erotically tinged transference to the doctor for the purposes of resistance. If this
attachment reaches a certain height, all their interest in the immediate situation in the treatment
and all the obligations they undertook at its commencement vanish; their jealousy, which is
never absent, and their exasperation at their inevitable rejection, however considerately
expressed, are bound to have a damaging effect on their personal understanding with the
doctor and so to put out of operation one of the most powerful motive forces of the analysis.
[1916-1917, 3365]
Resistances of this kind should not be one-sidedly condemned. They include so much of the most important material from the patient's past and bring it back in so convincing a fashion that they become some of the best supports of the analysis if a skilful technique knows how to give them the right turn. Nevertheless, it remains a remarkable fact that this material is always in the service of the resistance to begin with and brings to the fore a façade that is hostile to the treatment. It may also be said that what is being mobilized for fighting against the alterations we are striving for are character-traits, attitudes of the ego. In this connection we discover that these character-traits were formed in relation to the determinants of the neurosis and in reaction against its demands, and we come upon traits which cannot normally emerge, or not to the same extent, and which may be described as latent. Nor must you get an impression that we regard the appearance of these resistances as an unforeseen risk to analytic influence. No, we are aware that these resistances are bound to come to light; in fact we are dissatisfied if we cannot provoke them clearly enough and are unable to demonstrate them to the patient. Indeed we come finally to understand that the overcoming of these resistances is the essential function of analysis and is the only part of our work which gives us an assurance that we have achieved something with the patient.

[1916-1917, 3366]

There are, however, other forms of illness in which, in spite of the conditions being the same, our therapeutic procedure is never successful. In them, too, it had been a question of an original conflict between the ego and the libido which led to repression - though this may call for a different topographical description; in them, too, it is possible to trace the points in the patient's life at which the repressions occurred; we make use of the same procedure, are ready to make the same promises and give the same help by the offer of anticipatory ideas; and once again the lapse of time between the repressions and the present day favours a different outcome to the conflict. And yet we do not succeed in lifting a single resistance or getting rid of a single repression. These patients, paranoics, melancholics, sufferers from dementia praecox, remain on the whole unaffected and proof against psycho-analytic therapy. What can be the reason for this? Not any lack of intelligence. A certain amount of intellectual capacity is naturally required in our patients; but there is certainly no lack of it in, for instance, the extremely shrewd combinatory paranoics. Nor do any of the other motives seem to be absent. Thus the melancholics have a very high degree of consciousness, absent in paranoics, that they are ill and that that is why they suffer so much; but this does not make them more accessible. We are faced here by a fact which we do not understand and which therefore leads us to doubt whether we have really understood all the determinants of our possible success with the other neuroses.

[1916-1917, 3480]
I must begin by making it clear that a transference is present in the patient from the beginning of the treatment and for a while is the most powerful motive in its advance. We see no trace of it and need not bother about it so long as it operates in favour of the joint work of analysis. If it then changes into a resistance, we must turn our attention to it and we recognize that it alters its relation to the treatment under two different and contrary conditions: firstly, if as an affectionate trend it has become so powerful, and betrays signs of its origin in a sexual need so clearly, that it inevitably provokes an internal opposition to itself, and, secondly, if it consists of hostile instead of affectionate impulses. The hostile feelings make their appearance as a rule later than the affectionate ones and behind them; their simultaneous presence gives a good picture of the emotional ambivalence which is dominant in the majority of our intimate relations with other people. The hostile feelings are as much an indication of an emotional tie as the affectionate ones, in the same way as defiance signifies dependence as much as obedience does, though with a 'minus' instead of a 'plus' sign before it. We can be in no doubt that the hostile feelings towards the doctor deserve to be called a 'transference', since the situation in the treatment quite certainly offers no adequate grounds for their origin; this necessary view of the negative transference assures us, therefore, that we have not gone wrong in our judgement of the positive or affectionate one.

Where the transference arises, what difficulties it raises for us, how we overcome them and what advantages we eventually derive from it - these are questions to be dealt with in a technical guide to analysis, and I shall only touch on them lightly to-day. It is out of the question for us to yield to the patient's demands deriving from the transference; it would be absurd for us to reject them in an unfriendly, still more in an indignant, manner. We overcome the transference by pointing out to the patient that his feelings do not arise from the present situation and do not apply to the person of the doctor, but that they are repeating something that happened to him earlier. In this way we oblige him to transform his repetition into a memory. By that means the transference, which, whether affectionate or hostile, seemed in every case to constitute the greatest threat to the treatment, becomes its best tool, by whose help the most secret compartments of mental life can be opened.

But I should like to say a few words to you to relieve you of your surprise at the emergence of this unexpected phenomenon. We must not forget that the patient's illness, which we have undertaken to analyse, is not something which has been rounded off and become rigid but that it is still growing and developing like a living organism. The beginning of the treatment does not put an end to this development; when, however, the treatment has obtained mastery over the patient, what happens is that the whole of his illness's new production is concentrated upon a single point - his relation to the doctor. Thus the transference may be compared to the cambium layer in a tree between the wood and the bark, from which the new formation of tissue and the increase in the girth of the trunk derive. When the transference has risen to this significance, work upon the patient's memories retreats far into the background. Thereafter it is not incorrect to say that we are no longer concerned with the patient's earlier illness but with a newly created and transformed neurosis which has taken the former's place. We have followed this new edition of the old disorder from its start, we have observed its origin and growth, and we are especially well able to find our way about in it since, as its object, we are situated at its very centre. All the patient's symptoms have abandoned their original meaning and have take on a new sense which lies in a relation to the transference; or only such symptoms have persisted as are capable of undergoing such a transformation. But the mastering of this new, artificial neurosis coincides with getting rid of the illness which was originally brought to the treatment - with the accomplishment of our therapeutic task. A person who has become normal and free from the operation of repressed instinctual impulse in his relation to the doctor will remain so in his own life after the doctor has once more withdrawn from it.
There is every reason now for us to improve our earlier dynamic account of the therapeutic process and to bring it into harmony with our new realization. If the patient is to fight his way through the normal conflict with the resistances which we have uncovered for him in the analysis, he is in need of a powerful stimulus which will influence the decision in the sense which we desire, leading to recovery. Otherwise it might happen that he would choose in favour of repeating the earlier outcome and would allow what had been brought up into consciousness to slip back again into repression. At this point what turns the scale in his struggle is not his intellectual insight which is neither strong enough nor free enough for such an achievement - but simply and solely his relation to the doctor. In so far as his transference bears a 'plus' sign, it clothes the doctor with authority and is transformed into belief in his communications and explanations. In the absence of such a transference, or if it is a negative one, the patient would never even give a hearing to the doctor and his arguments. In this his belief is repeating the story of its own development; it is a derivative of love and, to start with, needed no arguments. Only later did he allow them enough room to submit them to examination, provided they were brought forward by someone he loved. Without such supports arguments carried no weight, and in most people's lives they never do. Thus in general a man is only accessible from the intellectual side too, in so far as he is capable of a libidinal cathexis of objects; and we have good reason to recognize and to dread in the amount of his narcissism a barrier against the possibility of being influenced by even the best analytic technique.

On the basis of our clinical impressions we maintained that these patients' object-cathexes must have been given up and that their object-libido must have been transformed into ego-libido. Through this characteristic we distinguished them from the first group of neurotics (sufferers from hysteria, anxiety-hysteria and obsessional neurosis). This suspicion is now confirmed by their behaviour in our attempts at therapy. They manifest no transference and for that reason are inaccessible to our efforts and cannot be cured by us.

LADIES AND GENTLEMEN, - You know what we are going to talk about to-day. You asked me why we do not make use of direct suggestion in psycho-analytic therapy, when we admit that our influence rests essentially on transference - that is, on suggestion; and you added a doubt whether, in view of this predominance of suggestion, we are still able to claim that our psychological discoveries are objective. I promised I would give you a detailed reply.
Let us begin with the former. I was a pupil of Bernheim's, whom I visited at Nancy in 1889 and whose book on suggestion I translated into German. I practised hypnotic treatment for many years, at first by prohibitory suggestion and later in combination with Breuer's method of questioning the patient. I can therefore speak of the results of hypnotic or suggestive therapy on the basis of a wide experience. If, in the words of the old medical aphorism, an ideal therapy should be rapid, reliable and not disagreeable for the patient, Bernheim's method fulfilled at least two of these requirements. It could be carried through much quicker - or, rather, infinitely quicker - than analytic treatment and it caused the patient neither trouble nor unpleasantness. For the doctor it became, in the long run, monotonous: in each case, in the same way, with the same ceremonial, forbidding the most variegated symptoms to exist, without being able to learn anything of their sense and meaning. It was hackwork and not a scientific activity, and it recalled magic, incantations and hocus-pocus. That could not weigh, however, against the patient's interest. But the third quality was lacking: the procedure was not reliable in any respect. It could be used with one patient, but not with another; it achieved a great deal with one and very little with another, and one never knew why. Worse than the capriciousness of the procedure was the lack of permanence in its successes. If, after a short time, one had news of the patient once more, the old ailment was back again or its place had been taken by a new one. One might hypnotize him again. But in the background there was the warning given by experienced workers against robbing the patient of his self-reliance by frequently repeated hypnosis and so making him an addict to this kind of therapy as though it were a narcotic. Admittedly sometimes things went entirely as one would wish: after a few efforts, success was complete and permanent. But the conditions determining such a favourable outcome remained unknown. On one occasion a severe condition in a woman, which I had entirely got rid of by a short hypnotic treatment, returned unchanged after the patient had, through no action on my part, got annoyed with me; after a reconciliation, I removed the trouble again and far more thoroughly; yet it returned once more after she had fallen foul of me a second time. On another occasion a woman patient, whom I had repeatedly helped out of neurotic states by hypnosis, suddenly, during the treatment of a specially obstinate situation, threw her arms round my neck. After this one could scarcely avoid, whether one wanted to or not, investigating the question of the nature and origin of one's authority in suggestive treatment.

I hope I have now made it clear to you in what way our method of employing suggestion therapeutically differs from the only method possible in hypnotic treatment. You will understand too, from the fact that suggestion can be traced back to transference, the capriciousness which struck us in hypnotic therapy, while analytic treatment remains calculable within its limits. In using hypnosis we are dependent on the state of the patient's capacity for transference without being able to influence it itself. The transference of a person who is to be hypnotized may be negative or, as most frequently, ambivalent, or he may have protected himself against his transference by adopting special attitudes; of that we learn nothing. In psycho-analysis we act upon the transference itself, resolve what opposes it, adjust the instrument with which we wish to make our impact. Thus it becomes possible for us to derive an entirely fresh advantage from the power of suggestion; we get it into our hands. The patient does not suggest to himself whatever he pleases: we guide his suggestion so far as he is in any way accessible to its influence.
But you will now tell me that, no matter whether we call the motive force of our analysis transference or suggestion, there is a risk that the influencing of our patient may make the objective certainty of our findings doubtful. What is advantageous to our therapy is damaging to our researches. This is the objection that is most often raised against psycho-analysis, and it must be admitted that, though it is groundless, it cannot be rejected as unreasonable. If it were justified, psycho-analysis would be nothing more than a particularly well-disguised and particularly effective form of suggestive treatment and we should have to attach little weight to all that it tells us about what influences our lives, the dynamics of the mind or the unconscious. That is what our opponents believe; and in especial they think that we have "talked" the patients into everything relating to the importance of sexual experiences - or even into those experiences themselves - after such notions have grown up in our own depraved imagination. These accusations are contradicted more easily by an appeal to experience than by the help of theory. Anyone who has himself carried out psycho-analyses will have been able to convince himself on countless occasions that it is impossible to make suggestions to a patient in that way. The doctor has no difficulty, of course, in making him a supporter of some particular theory and in thus making him share some possible error of his own. In this respect the patient is behaving like anyone else - like a pupil - but this only affects his intelligence, not his illness. After all, his conflicts will only be successfully solved and his resistances overcome if the anticipatory ideas he is given tally with what is real in him. Whatever in the doctor's conjectures is inaccurate drops out in the course of the analysis; it has to be withdrawn and replaced by something more correct. We endeavour by a careful technique to avoid the occurrence of premature successes due to suggestion; but no harm is done even if they do occur, for we are not satisfied by a first success. We do not regard an analysis as at an end until all the obscurities of the case are cleared up, the gaps in the patient's memory filled in, the precipitating causes of the repressions discovered. We look upon successes that set in too soon as obstacles rather than as a help to the work of analysis; and we put an end to such successes by constantly resolving the transference on which they are based. It is this last characteristic which is the fundamental distinction between analytic and purely suggestive therapy, and which frees the results of analysis from the suspicion of being successes due to suggestion. In every other kind of suggestive treatment the transference is carefully preserved and left untouched; in analysis it is itself subjected to treatment and is dissected in all the shapes in which it appears. At the end of an analytic treatment the transference must itself be cleared away; and if success is then obtained or continues, it rests, not on suggestion, but on the achievement by its means of an overcoming of internal resistances, on the internal change that has been brought about in the patient.
[1916-1917, 3493]
I will now complete my picture of the mechanism of cure by clothing it in the formulas of the libido theory. A neurotic is incapable of enjoyment and of efficiency - the former because his libido is not directed on to any real object and the latter because he is obliged to employ a great deal of this available energy on keeping his libido under repression and on warding off its assaults. He would become healthy if the conflict between his ego and his libido came to an end and if his ego had his libido again at its disposal. The therapeutic task consists, therefore, in freeing the libido from its present attachments, which are withdrawn from the ego, and in making it once more serviceable to the ego. Where, then, is the neurotic's libido situated? It is easily found: it is attached to the symptoms, which yield it the only substitutive satisfaction possible at the time. We must therefore make ourselves masters of the symptoms and resolve them - which is precisely the same thing that the patient requires of us. In order to resolve the symptoms, we must go back as far as their origin, we must renew the conflict from which they arose, and, with the help of motive forces which were not at the patient's disposal in the past, we must guide it to a different outcome. This revision of the process of repression can be accomplished only in part in connection with the memory traces of the processes which led to repression. The decisive part of the work is achieved by creating in the patient's relation to the doctor - in the 'transference' - new editions of the old conflicts; in these the patient would like to behave in the same way as he did in the past, while we, by summoning up every available mental force, compel him to come to a fresh decision. Thus the transference becomes the battlefield on which all the mutually struggling forces should meet one another.

[1916-1917, 3494]

All the libido, as well as everything opposing it, is made to converge solely on the relation with the doctor. In this process the symptoms are inevitably divested of libido. In place of his patient's true illness there appears the artificially constructed transference illness, in place of the various unreal objects of the libido there appears a single, and once more imaginary, object in the person of the doctor. But, by the help of the doctor's suggestion, the new struggle around this object is lifted to the highest psychical level: it takes place as a normal mental conflict. Since a fresh repression is avoided, the alienation between ego and libido is brought to an end and the subject's mental unity is restored. When the libido is released once more from its temporary object in the person of the doctor, it cannot return to its earlier objects, but is at the disposal of the ego. The forces against which we have been struggling during our work of therapy are, on the one hand, the ego's antipathy to certain trends of the libido - an antipathy expressed in a tendency to repression - and, on the other hand, the tenacity or adhesiveness of the libido, which dislikes leaving objects that it has once cathected.

[1916-1917, 3494]
Thus our therapeutic work falls into two phases. In the first, all the libido is forced from the symptoms into the transference and concentrated there; in the second, the struggle is waged around this new object and the libido is liberated from it. The change which is decisive for a favourable outcome is the elimination of repression in this renewed conflict so that the libido cannot withdraw once more from the ego by flight into the unconscious. This is made possible by the alteration of the ego which is accomplished under the influence of the doctor's suggestion. By means of the work of interpretation, which transforms what is unconscious into what is conscious, the ego is enlarged at the cost of this unconscious; by means of instruction, it is made conciliatory towards the libido and inclined to grant it some satisfaction, and its repugnance to the claims of the libido is diminished by the possibility of disposing of a portion of it by sublimation. The more closely events in the treatment coincide with this ideal description, the greater will be the success of the psycho-analytic therapy. It finds its limits in the lack of mobility of the libido, which may refuse to leave its objects, and the rigidity of narcissism, which will not allow transference on to objects to increase beyond certain bounds. Further light may perhaps be thrown on the dynamics of the process of cure if I say that we get hold of the whole of the libido which has been withdrawn from the dominance of the ego by attracting a portion of it on to ourselves by means of the transference.

[1916-1917, 3495]

It will not be out of place to give a warning that we can draw no direct conclusion from the distribution of the libido during and resulting from the treatment as to how it was distributed during the illness. Suppose we succeeded in bringing a case to a favourable conclusion by setting up and then resolving a strong father-transference to the doctor. It would not be correct to conclude that the patient had suffered previously from a similar unconscious attachment of his libido to his father. His father-transference was merely the battlefield on which we gained control of his libido; the patient's libido as directed to it from other positions. A battlefield need not necessarily coincide with one of the enemy's key fortresses. The defence of a hostile capital need not take place just in front of its gates. Not until after the transference has once more been resolved can we reconstruct in our thoughts the distribution of the libido which had prevailed during the illness.

[1916-1917, 3495]

The patient with whom I am here concerned remained for a long time unassailably entrenched behind an attitude of 'obliging apathy'. He listened, understood, and remained unapproachable. His unimpeachable intelligence was, as it were, cut off from the instinctual forces which governed his behaviour in the few relations of life that remained to him. It required a long education to induce him to take an independent share in the work; and when as a result of this exertion he began for the first time to feel relief, he immediately gave up working in order to avoid any further changes, and in order to remain comfortably in the situation which had been thus established. His shrinking from a self-sufficient existence was so great as to outweigh all the vexations of his illness. Only one way was to be found of overcoming it. I was obliged to wait until his attachment to myself had become strong enough to counter-balance this shrinking, and then played off this one factor against the other. I determined - but not until trustworthy signs had led me to judge that the right moment had come - that the treatment must be brought to an end at a particular fixed date, no matter how far it had advanced. I was resolved to keep to the date; and eventually the patient came to see that I was in earnest. Under the inexorable pressure of this fixed limit his resistance and his fixation to the illness gave way, and now in a disproportionately short time the analysis produced all the material which made it possible to clear up his inhibitions and remove his symptoms. All the information, too, which enabled me to understand his infantile neurosis is derived from this last period of the work, during which resistance temporarily disappeared and the patient gave an impression of lucidity which is usually attainable only in hypnosis.

[1918b, 3507]
We have formulated our task as physicians thus: to bring to the patient's knowledge the unconscious, repressed impulses existing in him, and, for that purpose, to uncover the resistances that oppose this extension of his knowledge about himself. Does the uncovering of these resistances guarantee that they will also be overcome? Certainly not always; but our hope is to achieve this by exploiting the patient's transference to the person of the physician, so as to induce him to adopt our conviction of the inexpediency of the repressive process established in childhood and of the impossibility of conducting life on the pleasure principle. I have set out elsewhere the dynamic conditions prevailing in the fresh conflict through which we lead the patient and which we substitute in him for his previous conflict - that of his illness. I have nothing at the moment to alter in that account.

Let us at once agree upon what we mean by this activity. We have defined our therapeutic task as consisting of two things: making conscious the repressed material and uncovering the resistances. In that we are active enough, to be sure. But are we to leave it to the patient to deal alone with the resistances we have pointed out to him? Can we give him no other help in this besides the stimulus he gets from the transference? Does it not seem natural that we should help him in another way as well, by putting him into the mental situation most favourable to the solution of the conflict which is our aim? After all, what he can achieve depends, too, on a combination of external circumstances. Should we hesitate to alter this combination by intervening in a suitable manner? I think activity of such a kind on the part of the analysing physician is unobjectionable and entirely justified.

In all such situations activity on the part of the physician must take the form of energetic opposition to premature substitutive satisfactions. It is easier for him, however, to prevent the second danger which jeopardizes the propelling force of the analysis, though it is not one to be under-estimated. The patient looks for his substitutive satisfactions above all in the treatment itself, in his transference-relationship with the physician; and he may even strive to compensate himself by this means for all the other privations laid upon him. Some concessions must of course be made to him, greater or less, according to the nature of the case and the patient's individuality. But it is not good to let them become too great. Any analyst who out of the fullness of his heart, perhaps, and his readiness to help, extends to the patient all that one human being may hope to receive from another, commits the same economic error as that of which our non-analytic institutions for nervous patients are guilty. Their one aim is to make everything as pleasant as possible for the patient, so that he may feel well there and be glad to take refuge there again from the trials of life. In so doing they make no attempt to give him more strength for facing life and more capacity for carrying out his actual tasks in it. In analytic treatment all such spoiling must be avoided. As far as his relations with the physician are concerned, the patient must be left with unfulfilled wishes in abundance. It is expedient to deny him precisely those satisfactions which he desires most intensely and expresses most importunately.

Twenty five years of intense work have had as their result that the immediate aims of psychoanalytic technique are quite other to-day than they were at the outset. At first the analysing physician could do no more than discover the unconscious material that was concealed from the patient, put it together, and, at the right moment, communicate it to him. Psychoanalysis was then first and foremost an art of interpreting. Since this did not solve the therapeutic problem, a further aim quickly came in view: to oblige the patient to confirm the analyst's construction from his own memory. In that endeavour the chief emphasis lay upon the patient's resistances: the art consisted now in uncovering these as quickly as possible, in pointing them out to the patient and in inducing him by human influence - this was where suggestion operating as 'transference' played its part - to abandon his resistances.
But it became ever clearer that the aim which had been set up - the aim that what was unconscious should become conscious - is not completely attainable by that method. The patient cannot remember the whole of what is repressed in him, and what he cannot remember may be precisely the essential part of it. Thus he acquires no sense of conviction of the correctness of the construction that has been communicated to him. He is obliged to repeat the repressed material as a contemporary experience instead of, as the physician would prefer to see, remembering it as something belonging to the past.¹ These reproductions, which emerge with such unwished-for exactitude, always have as their subject some portion of infantile sexual life - of the Oedipus complex, that is, and its derivatives; and they are invariably acted out in the sphere of the transference, of the patient's relation to the physician. When things have reached this stage, it may be said that the earlier neurosis has now been replaced by a fresh, 'transference neurosis'. It has been the physician's endeavour to keep this transference neurosis within the narrowest limits: to force as much as possible into the channel of memory and to allow as little as possible to emerge as repetition. The ratio between what is remembered and what is reproduced varies from case to case. The physician cannot as a rule spare his patient this phase of the treatment. He must get him to re-experience some portion of his forgotten life, but must see to it, on the other hand, that the patient retains some degree of aloofness, which will enable him, in spite of everything, to recognize that what appears to be reality is in fact only a reflection of a forgotten past. If this can be successfully achieved, the patient's sense of conviction is won, together with the therapeutic success that is dependent on it.
[1920g, 3723]

Patients repeat all of these unwanted situations and painful emotions in the transference and revive them with the greatest ingenuity. They seek to bring about the interruption of the treatment while it is still incomplete; they contrive once more to feel themselves scorned, to oblige the physician to speak severely to them and treat them coldly; they discover appropriate objects for their jealousy; instead of the passionately desired baby of their childhood, they produce a plan or a promise of some grand present - which turns out as a rule to be no less unreal. None of these things can have produced pleasure in the past, and it might be supposed that they would cause less unpleasure to-day if they emerged as memories or dreams instead of taking the form of fresh experiences. They are of course the activities of instincts intended to lead to satisfaction; but no lesson has been learnt from the old experience of these activities having led instead only to unpleasure. In spite of that, they are repeated, under pressure of a compulsion.
[1920g, 3725]
The manifestations of a compulsion to repeat (which we have described as occurring in the
early activities of infantile mental life as well as among the events of psycho-analytic treatment)
exist to a high degree an instinctual character and, when they act in opposition to the pleasure
principle, give the appearance of some 'daemonic' force at work. In the case of children's play
we seemed to see that children repeat unpleasurable experiences for the additional reason that
they can master a powerful impression far more thoroughly by being active than they could by
merely experiencing it passively. Each fresh repetition seems to strengthen the mastery they
are in search of. Nor can children have their *pleasurable* experiences repeated often enough,
and they are inexorable in their insistence that the repetition shall be an identical one. This
character trait disappears later on. If a joke is heard for a second time it produces almost no
effect; a theatrical production never creates so great an impression the second time as the first;
indeed, it is hardly possible to persuade an adult who has very much enjoyed reading a book to
re-read it immediately. Novelty is always the condition of enjoyment. But children will never tire
of asking an adult to repeat a game that he has shown them or played with them, till he is too
exhausted to go on. And if a child has been told a nice story, he will insist on hearing it over and
over again rather than a new one; and he will remorselessly stipulate that the repetition shall be
an identical one and will correct any alterations of which the narrator may be guilty - though they
may actually have been made in the hope of gaining fresh approval. None of this contradicts the
pleasure principle; repetition, the re-experiencing of something identical, is clearly in itself a
source of pleasure. In the case of a person in analysis, on the contrary, the compulsion to
repeat the events of his childhood in the transference evidently disregards the pleasure principle
in every way. The patient behaves in a purely infantile fashion and thus shows us that the
repressed memory-traces of his primaeval experiences are not present in him in a bound state
and are indeed in a sense incapable of obeying the secondary process. It is to this fact of not
being bound, moreover, that they owe their capacity for forming, in conjunction with the residues
of the previous day, a wishful phantasy that emerges in a dream. This same compulsion to
repeat frequently meets us as an obstacle to our treatment when at the end of an analysis we
try to induce the patient to detach himself completely from his physician. It may be presumed,
too, that when people unfamiliar with analysis feel an obscure fear - a dread of rousing
something that, so they feel, is better left sleeping - what they are afraid of at bottom is the
emergence of this compulsion with its hint of possession by some 'daemonic' power.

¹ This situation, in which the subject's attitude is unconsciously directed towards the hypnotist, while he
is consciously occupied with monotonous and uninteresting perceptions, finds a parallel among the events
of psycho-analytic treatment, which deserves to be mentioned here. At least once in the course of every
analysis a moment comes when the patient obstinately maintains that just now positively nothing whatever
occurs to his mind. His free associations come to a stop and the usual incentives for putting them in
motion fail in their effect. If the analyst insists, the patient is at last induced to admit that he is thinking of
the view from the consulting-room window, of the wall-paper that he sees before him, or of the gas-lamp
hanging from the ceiling. Then one knows at once that he has gone off into the transference and that he is
engaged upon what are still unconscious thoughts relating to the physician; and one sees the stoppage in
the patient's associations disappear, as soon as he has been given this explanation.
In the case of our patient, it was not doubt but the affective factor of revenge against her father that made her cool reserve possible, that divided the analysis into two distinct phases, and rendered the results of the first phase so complete and perspicuous. It seemed, further, as though nothing resembling a transference to the physician had been effected. That, however, is of course absurd, or, at least, is a loose way of expressing things. For some kind of relation to the analyst must come into being, and this relation is almost always transferred from an infantile one. In reality she transferred to me the sweeping repudiation of men which had dominated her ever since the disappointment she had suffered from her father. Bitterness against men is as a rule easy to gratify upon the physician; it need not evoke any violent emotional manifestations, it simply expresses itself by rendering futile all his endeavours and - by clinging to the illness. I know from experience how difficult it is to make a patient understand just precisely this mute kind of symptomatic behaviour and to make him aware of this latent, and often exceedingly strong, hostility without endangering the treatment. As soon, therefore, as I recognized the girl's attitude to her father, I broke off the treatment and advised her parents that if they set store by the therapeutic procedure it should be continued by a woman doctor. The girl had in the meanwhile promised her father that at any rate she would give up seeing the 'lady'; and I do not know whether my advice, the reasons for which are obvious, will be followed.

There was a single piece of material in the course of this analysis which I could regard as a positive transference, as a greatly weakened revival of the girl's original passionate love for her father. Even this manifestation was not quite free from other motives, but I mention it because it brings up, in another direction, an interesting problem of analytic technique. At a certain period, not long after the treatment had begun, the girl brought a series of dreams which, distorted according to rule and couched in the usual dream-language, could nevertheless be easily translated with certainty. Their content, when interpreted, was, however, remarkable. They anticipated the cure of the inversion through the treatment, expressed her joy over the prospects in life that would then be opened before her, confessed her longing for a man's love and for children, and so might have been welcomed as a gratifying preparation for the desired change. The contradiction between them and the girl's utterances in waking life at the time was very great. She did not conceal from me that she meant to marry, but only in order to escape from her father's tyranny and to follow her true inclinations undisturbed. As for the husband, she remarked rather contemptuously, she would easily deal with him, and besides, one could have sexual relations with a man and a woman at one and the same time, as the example of the adored lady showed. Warned through some slight impression or other, I told her one day that I did not believe these dreams, that I regarded them as false or hypocritical, and that she intended to mislead me just as she habitually deceived her father. I was right; after I had made this clear, this kind of dream ceased. But I still believe that, beside the intention to mislead me, the dreams partly expressed the wish to win my favour; they were also an attempt to gain my interest and my good opinion - perhaps in order to disappoint me all the more thoroughly later on.

Transference. - If further proof were needed of the truth that the motive forces behind the formation of neurotic symptoms are of a sexual nature, it would be found in the fact that in the course of analytic treatment a special emotional relation is regularly formed between the patient and the physician. This goes far beyond rational limits. It varies between the most affectionate devotion and the most obstinate enmity and derives all of its characteristics from earlier erotic attitudes of the patient's which have become unconscious. This transference alike in its positive and in its negative form is used as a weapon by the resistance; but in the hands of the physician it becomes the most powerful therapeutic instrument and it plays a part scarcely to be over-estimated in the dynamics of the process of cure.
From the other point of view, however, we see this same ego as a poor creature owing service to three masters and consequently menaced by three dangers: from the external world, from the libido of the id, and from the severity of the super-ego. Three kinds of anxiety correspond to these three dangers, since anxiety is the expression of a retreat from danger. As a frontier creature, the ego tries to mediate between the world and the id, to make the id pliable to the world and, by means of its muscular activity, to make the world fall in with the wishes of the id. In point of fact it behaves like the physician during an analytic treatment: it offers itself, with the attention it pays to the real world, as a libidinal object to the id, and aims at attaching the id’s libido to itself. It is not only a helper to the id; it is also a submissive slave who courts his master’s love. Whenever possible, it tries to remain on good terms with the id; it clothes the id’s *Ucs.* commands with its *Pcs.* rationalizations; it pretends that the id is showing obedience to the admonitions of reality, even when in fact it is remaining obstinate and unyielding; it disguises the id’s conflicts with reality and, if possible, its conflicts with the super-ego too. In its position midway between the id and reality, it only too often yields to the temptation to become sycophantic, opportunist and lying, like a politician who sees the truth but wants to keep his place in popular favour.

[1923b, 3990]

These two slight indications give us an idea of what the typical factor is which determines the negative side of the painter’s relation to his father. What he is rebelling against is his feminine attitude to him which culminates in a phantasy of bearing him a child (the nine years). We have an accurate knowledge of this resistance from our analyses, where it takes on very strange forms in the transference and gives us a great deal of trouble. With the painter’s mourning for his lost father, and the heightening of his longing for him, there also comes about in him a re-activation of his long-since repressed phantasy of pregnancy, and he is obliged to defend himself against it by a neurosis and by debasing his father.

[1923d, 4014]

Let us take as an example the so-called dreams of recovery. If a patient has had a dream of this kind, in which he seems to abandon the restrictions of his neurosis - if, for instance, he overcomes some phobia or gives up some emotional attachment - we are inclined to think that he has made a great step forward, that he is ready to take his place in a new state of life, that he has begun to reckon on his recovery, etc. This may often be true, but quite as often such dreams of recovery only have the value of dreams of convenience: they signify a wish to be well at last, in order to avoid another portion of the work of analysis which is felt to lie ahead. In this sense, dreams of recovery very frequently occur, for instance, when the patient is about to enter upon a new and disagreeable phase of the transference. He is behaving in this just like some neurotics who after a few hours of analysis declare they have been cured - because they want to escape all the unpleasantness that is bound to come up for discussion in the analysis. Sufferers from war neuroses, too, who gave up their symptoms because the therapy adopted by the army doctors succeeded in making being ill even more uncomfortable than serving at the front - these sufferers, too, were following the same economic laws and in both cases alike the cures have proved to be only temporary.

[1923c, 4033]
After hypnosis was replaced by the technique of free association, Breuer's cathartic procedure turned into psycho-analysis, which for more than a decade was developed by the author (Freud) alone. During that time psycho-analysis gradually acquired a theory which appeared to give a satisfactory account of the origin, meaning and purpose of neurotic symptoms and provided a rational basis for medical attempts at curing the complaint. I will once again enumerate the factors that go to make up this theory. They are: emphasis on instinctual life (affectivity), on mental dynamics, on the fact that even the apparently most obscure and arbitrary mental phenomena invariably have a meaning and a causation, the theory of psychical conflict and of the pathogenic nature of repression, the view that symptoms are substitutive satisfactions, the recognition of the aetiological importance of sexual life, and in particular of the beginnings of infantile sexuality. From a philosophical standpoint this theory was bound to adopt the view that the mental does not coincide with the conscious, that mental processes are in themselves unconscious and are only made conscious by the functioning of special organs (agencies or systems). By way of completing this list, I will add that among the affective attitudes of childhood the complicated emotional relation of children to their parents - what is known as the Oedipus complex - came into prominence. It became ever clearer that this was the nucleus of every case of neurosis, and in the patient's behaviour towards his analyst certain phenomena of his emotional transference emerged which came to be of great importance for theory and technique alike.

[1924f, 4107]

The second lesson has a somewhat conservative ring. It is to the effect that the work of education is something sui generis: it is not to be confused with psycho-analytic influence and cannot be replaced by it. Psycho-analysis can be called in by education as an auxiliary means of dealing with a child; but it is not a suitable substitute for education. Not only is such a substitution impossible on practical grounds but it is also to be disrecommended for theoretical reasons. The relation between education and psycho-analytic treatment will probably before long be the subject of a detailed investigation. Here I will only give a few hints. One should not be misled by the statement - incidentally a perfectly true one - that the psycho-analysis of an adult neurotic is equivalent to an after-education. A child, even a wayward and delinquent child, is still not a neurotic; and after-education is something quite different from the education of the immature. The possibility of analytic influence rests on quite definite preconditions which can be summed up under the term 'analytic situation'; it requires the development of certain psychical structures and a particular attitude to the analyst. Where these are lacking - as in the case of children, of juvenile delinquents, and, as a rule, of impulsive criminals - something other than analysis must be employed, though something which will be at one with analysis in its purpose. The theoretical chapters of the present volume will give the reader a preliminary grasp of the multiplicity of the decisions involved.

[1925f, 4168]
I now come to the description of a factor which adds an essential feature to my picture of analysis and which can claim, alike technically and theoretically, to be regarded as of the first importance. In every analytic treatment there arises, without the physician's agency, an intense emotional relationship between the patient and the analyst which is not to be accounted for by the actual situation. It can be of a positive or of a negative character and can vary between the extremes of a passionate, completely sensual love and the unbridled expression of an embittered defiance and hatred. This transference - to give it its short name - soon replaces in the patient's mind the desire to be cured, and, so long as it is affectionate and moderate, becomes the agent of the physician's influence and neither more nor less than the mainspring of the joint work of analysis. Later on, when it has become passionate or has been converted into hostility, it becomes the principal tool of the resistance. It may then happen that it will paralyse the patient's powers of associating and endanger the success of the treatment. Yet it would be senseless to try to evade it; for an analysis without transference is an impossibility. It must not be supposed, however, that transference is created by analysis and does not occur apart from it. Transference is merely uncovered and isolated by analysis. It is a universal phenomenon of the human mind, it decides the success of all medical influence, and in fact dominates the whole of each person's relations to his human environment. We can easily recognize it as the same dynamic factor which the hypnotists have named 'suggestibility', which is the agent of hypnotic rapport and whose incalculable behaviour led to difficulties with the cathartic method as well. When there is no inclination to a transference of emotion such as this, or when it has become entirely negative, as happens in dementia praecox or paranoia, then there is also no possibility of influencing the patient by psychological means.

[1925d, 4217]

It is perfectly true that psycho-analysis, like other psychotherapeutic methods, employs the instrument of suggestion (or transference). But the difference is this: that in analysis it is not allowed to play the decisive part in determining the therapeutic results. It is used instead to induce the patient to perform a piece of psychical work - the overcoming of his transference resistances - which involves a permanent alteration in his mental economy. The transference is made conscious to the patient by the analyst, and it is resolved by convincing him that in his transference-attitude he is re-experiencing emotional relations which had their origin in his earliest object-attachments during the repressed period of his childhood. In this way the transference is changed from the strongest weapon of the resistance into the best instrument of the analytic treatment. Nevertheless its handling remains the most difficult as well as the most important part of the technique of analysis.

[1925d, 4218]
The neuroses were the first subject of analysis, and for a long time they were the only one. No analyst could doubt that medical practice was wrong in separating those disorders from the psychoses and in attaching them to the organic nervous diseases. The theory of the neuroses belongs to psychiatry and is indispensable as an introduction to it. It would seem, however, that the analytic study of the psychoses is impracticable owing to its lack of therapeutic results. Mental patients are as a rule without the capacity for forming a positive transference, so that the principal instrument of analytic technique is inapplicable to them. There are nevertheless a number of methods of approach to be found. Transference is often not so completely absent but that it can be used to a certain extent; and analysis has achieved undoubted successes with cyclical depressions, light paranoic modifications, and partial schizophrenias. It has at least been a benefit to science that in many cases the diagnosis can oscillate for quite a long time between assuming the presence of a psychoneurosis or of a dementia praecox; for therapeutic attempts initiated in such cases have resulted in valuable discoveries before they have had to be broken off. But the chief consideration in this connection is that so many things that in the neuroses have to be laboriously fetched up from the depths are found in the psychoses on the surface, visible to every eye. For that reason the best subjects for the demonstration of many of the assertions of analysis are provided by the psychiatric clinic. It was thus bound to happen before long that analysis would find its way to the objects of psychiatric observation. I was able very early (1896) to establish in a case of paranoid dementia the presence of the same aetiological factors and the same emotional complexes as in the neuroses. Jung explained some most puzzling stereotypies in dments by bringing them into relation with the patients' life-histories; Bleuler demonstrated the existence in various psychoses of mechanisms like those which analysis had discovered in neurotics. Since then analysts have never relaxed their efforts to come to an understanding of the psychoses. Especially since it has been possible to work with the concept of narcissism, they have managed, now in this place and now in that, to get a glimpse beyond the wall. Most of all, no doubt, was achieved by Abraham in his elucidation of the melancholias. It is true that in this sphere all our knowledge is not yet converted into therapeutic power; but the mere theoretical gain is not to be despised, and we may be content to wait for its practical application. In the long run even the psychiatrists cannot resist the convincing force of their own clinical material. At the present time German psychiatry is undergoing a kind of 'peaceful penetration' by analytic views. While they continually declare that they will never be psycho-analysts, that they do not belong to the 'orthodox' school or agree with its exaggerations, and in particular that they do not believe in the predominance of the sexual factor, nevertheless the majority of the younger workers take over one piece or another of analytic theory and apply it in their own fashion to the material. All the signs point to the proximity of further developments in the same direction.

[1925d, 4235]

"If I ever felt any desire to poach on your preserves and try my hand at analysing someone else, what you tell me about the resistances would have cured me of it. But how about the special personal influence that you yourself have after all admitted? Does not that come into action against the resistances?"

[1926e, 4366]
It is a good thing you have asked me about that. This personal influence is our most powerful dynamic weapon. It is the new element which we introduce into the situation and by means of which we make it fluid. The intellectual content of our explanations cannot do it, for the patient, who shares all the prejudices of the world around him, need believe us as little as our scientific critics do. The neurotic sets to work because he has faith in the analyst, and he believes him because he acquires a special emotional attitude towards the figure of the analyst. Children, too, only believe people they are attached to. I have already told you what use we make of this particularly large 'suggestive' influence. Not for suppressing the symptoms - this distinguishes the analytic method from other psychotherapeutic procedures - but as a motive force to induce the patient to overcome his resistances.

'I should have thought all the same that it would be favourable for your analytic purposes. If someone is in love, he is amenable, and he will do anything in the world for the sake of the other person.'

Yes. It is favourable to start with. But when this falling in love has grown deeper, its whole nature comes to light, much of which is incompatible with the task of analysis. The patient's love is not satisfied with being obedient; it grows exacting, calls for affectionate and sensual satisfactions, it demands exclusiveness, it develops jealousy, and it shows more and more clearly its reverse side, its readiness to become hostile and revengeful if it cannot obtain its ends. At the same time, like all falling in love, it drives away all other mental material; it extinguishes interest in the treatment and in recovery - in short, there can be no doubt that it has taken the place of the neurosis and that our work has had the result of driving out one form of illness with another.

Our conviction that a portion of erotic life that has been abnormally employed lies at the basis of neuroses must be unshakeably strengthened by this experience. With this discovery we are once more on a firm footing and can venture to make this love itself the object of analysis. And we can make another observation. Analytic love is not manifested in every case as clearly and blatantly as I have tried to depict it. Why not? We can soon see. In proportion as the purely sensual and the hostile sides of his love try to show themselves, the patient's opposition to them is aroused. He struggles against them and tries to repress them before our very eyes. And now we understand what is happening. The patient is repeating in the form of falling in love with the analyst mental experiences which he has already been through once before; he has transferred on to the analyst mental attitudes that were lying ready in him and were intimately connected with his neurosis. He is also repeating before our eyes his old defensive actions; he would like best to repeat in his relation to the analyst all the history of that forgotten period of his life. So what he is showing us is the kernel of his intimate life history: he is reproducing it tangibly, as though it were actually happening, instead of remembering it. In this way the riddle of the transference-love is solved and the analysis can proceed on its way - with the help of the new situation which had seemed such a menace to it.
Everything now depends on that. And the whole skill in handling the 'transference' is devoted to bringing it about. As you see, the requirements of analytic technique reach their maximum at this point. Here the gravest mistakes can be made or the greatest successes be registered. It would be folly to attempt to evade the difficulties by suppressing or neglecting the transference; whatever else had been done in the treatment, it would not deserve the name of an analysis. To send the patient away as soon as the inconveniences of his transference neurosis make their appearance would be no more sensible, and would moreover be cowardly. It would be as though one had conjured up spirits and run away from them as soon as they appeared. Sometimes, it is true, nothing else is possible. There are cases in which one cannot master the unleashed transference and the analysis has to be broken off; but one must at least have struggled with the evil spirits to the best of one's strength. To yield to the demands of the transference, to fulfil the patient's wishes for affectionate and sensual satisfaction, is not only justly forbidden by moral considerations but is also completely ineffective as a technical method for attaining the purpose of the analysis. A neurotic cannot be cured by being enabled to reproduce uncorrected an unconscious stereotype plate that is ready to hand in him. If one engages in compromises with him by offering him partial satisfactions in exchange for his further collaboration in the analysis, one must beware of falling into the ridiculous situation of the cleric who was supposed to convert a sick insurance agent. The sick man remained unconverted but the cleric took his leave insured. The only possible way out of the transference situation is to trace it back to the patient's past, as he really experienced it or as he pictured it through the wish-fulfilling activity of his imagination. And this demands from the analyst much skill, patience, calm and self-abnegation.

There are at the moment two Institutes at which instruction in psycho-analysis is given. The first has been founded in Berlin by Dr. Max Eitingon, who is a member of the Society there. The second is maintained by the Vienna Psycho-Analytical Society at its own expense and at considerable sacrifice. The part played by the authorities is at present limited to the many difficulties which they put in the way of the young undertaking. A third training Institute is at this moment being opened in London by the Society there, under the direction of Dr. Ernest Jones. At these Institutes the candidates themselves are taken into analysis, receive theoretical instruction by lectures on all the subjects that are important for them, and enjoy the supervision of older and more experienced analysts when they are allowed to make their first trials with comparatively slight cases. A period of some two years is calculated for this training. Even after this period, of course, the candidate is only a beginner and not yet a master. What is still needed must be acquired by practice and by an exchange of ideas in the psycho-analytical societies in which young and old members meet together. Preparation for analytic activity is by no means so easy and simple. The work is hard, the responsibility great. But anyone who has passed through such a course of instruction, who has been analysed himself, who has mastered what can be taught to-day of the psychology of the unconscious, who is at home in the science of sexual life, who has learnt the delicate technique of psycho-analysis, the art of interpretation, of fighting resistances and of handling the transference - anyone who has accomplished all this is no longer a layman in the field of psycho-analysis. He is capable of undertaking the treatment of neurotic disorders, and will be able in time to achieve in that field whatever can be required from this form of therapy.
(3) By 'transference' is meant a striking peculiarity of neurotics. They develop towards their physician emotional relations, both of an affectionate and hostile character, which are not based upon the actual situation but are derived from their relations to their parents (the Oedipus complex). Transference is a proof of the fact that adults have not overcome their former childish dependence; it coincides with the force which has been named 'suggestion'; and it is only by learning to make use of it that the physician is enabled to induce the patient to overcome his internal resistances and do away with his repressions. Thus psycho-analytic treatment acts as a second education of the adult, as a corrective to his education as a child. [1926f, 4406]

Everything in the sphere of this first attachment to the mother seemed to me so difficult to grasp in analysis - so grey with age and shadowy and almost impossible to revivify - that it was as if it had succumbed to an especially inexorable repression. But perhaps I gained this impression because the women who were in analysis with me were able to cling to the very attachment to the father in which they had taken refuge from the early phase that was in question. It does indeed appear that women analysts - as, for instance, Jeanne Lampl-de Groot and Helene Deutsch - have been able to perceive these facts more easily and clearly because they were helped in dealing with those under their treatment by the transference to a suitable mother-substitute. Nor have I succeeded in seeing my way though any case completely, and I shall therefore confine myself to reporting the most general findings and shall give only a few examples of the new ideas which I have arrived at. Among these is a suspicion that this phase of attachment to the mother is especially intimately related to the aetiology of hysteria, which is not surprising when we reflect that both the phase and the neurosis are characteristically feminine, and further, that in this dependence on the mother we have the germ of later paranoia in women.¹ For this germ appears to be the surprising, yet regular, fear of being killed (?) devoured) by the mother. It is plausible to assume that this fear corresponds to a hostility which develops in the child towards her mother in consequence of the manifold restrictions imposed by the latter in the course of training and bodily care and that the mechanism of projection is favoured by the early age of the child's psychical organization. [1931b, 4591]

The first of these factors is often unjustly overlooked. However great may be the plasticity of mental life and the possibility of reviving old conditions, not everything can be brought to life again. Some changes seem to be definitive and correspond to scars formed when a process has run its course. On other occasions one has an impression of a general stiffening of mental life; the psychical processes, to which one could very well indicate other paths, seem incapable of abandoning the old ones. But perhaps this is the same thing as what I mentioned just now, only looked at differently. All too often one seems to see that it is only the treatment's lack of the necessary motive force that prevents one from bringing the change about. One particular dependent relation, one special instinctual component, is too powerful in comparison with the opposing forces that we are able to mobilize. This is quite generally true with the psychoses. We understand them well enough to know the point at which the levers should be applied, but they would not be able to move the weight. It is here, indeed, that hope for the future lies: the possibility that our knowledge of the operation of the hormones (you know what they are) may give us the means of successfully combating the quantitative factors of the illnesses: but we are far from that to-day. I realize that the uncertainty in all these matters is a constant instigation towards perfecting analysis and in particular the transference. Beginners in analysis especially are left in doubt in case of a failure whether they should blame the peculiarities of the case or their own clumsy handling of the therapeutic procedure. But, as I have said already, I do not think much can be achieved by efforts in this direction. [1933a, 4753]
Moreover, the relation of transference brings with it two further advantages. If the patient puts the analyst in the place of his father (or mother), he is also giving him the power which his super-ego exercises over his ego, since his parents were, as we know, the origin of his super-ego. The new super-ego now has an opportunity for a sort of *after-education* of the neurotic; it can correct mistakes for which his parents were responsible in educating him. But at this point a warning must be given against misusing this new influence. However much the analyst may be tempted to become a teacher, model and ideal for other people and to create men in his own image, he should not forget that that is not his task in the analytic relationship, and indeed that he will be disloyal to his task if he allows himself to be led on by his inclinations. If he does, he will only be repeating a mistake of the parents who crushed their child's independence by their influence, and he will only be replacing the patient's earlier dependence by a new one. In all his attempts at improving and educating the patient the analyst should respect his individuality. The amount of influence which he may legitimately allow himself will be determined by the degree of developmental inhibition present in the patient. Some neurotics have remained so infantile that in analysis too they can only be treated as children.

[1940a [1938], 4985]

Another advantage of transference, too, is that in it the patient produces before us with plastic clarity an important part of his life-story, of which he would otherwise have probably given us only an insufficient account. He acts it before us, as it were, instead of reporting it to us.

[1940a [1938], 4985]

And now for the other side of the situation. Since the transference reproduces the patient's relation with his parents, it takes over the ambivalence of that relation as well. It almost inevitably happens that one day his positive attitude towards the analyst changes over into the negative, hostile one. This too is as a rule a repetition of the past. His obedience to his father (if it is his father that is in question), his courting of his father's favour, had its roots in an erotic wish directed towards him. Some time or other that demand will press its way forward in the transference as well and insist on being satisfied. In the analytic situation it can only meet with frustration. Real sexual relations between patients and analysts are out of the question, and even the subtler methods of satisfaction, such as the giving of preference, intimacy and so on, are only sparingly granted by the analyst. A rejection of this kind is taken as the occasion for the change-over; probably things happened in the same way in the patient's childhood.

[1940a [1938], 4986]
The therapeutic successes that occurred under the sway of the positive transference are open to the suspicion of being of a suggestive nature. If the negative transference gains the upper hand, they are blown away like chaff before the wind. We observe with horror that all our trouble and labour hitherto have been in vain. Indeed, what we might have regarded as a permanent intellectual gain by the patient, his understanding of psycho-analysis and his reliance on its efficacy, suddenly vanish. He behaves like a child who has no power of judgement of his own but blindly believes anyone whom he loves and no one who is a stranger to him. The danger of these states of transference evidently lies in the patient's misunderstanding their nature and taking them for fresh real experiences instead of reflections of the past. If he (or she) becomes aware of the strong erotic desire that lies concealed behind the positive transference, he believes that he has fallen passionately in love; if the transference changes over, then he feels insulted and neglected, he hates the analyst as his enemy and is ready to abandon the analysis. In both these extreme cases he has forgotten the pact that he made at the beginning of the treatment and has become useless for continuing the common work. It is the analyst's task constantly to tear the patient out of his menacing illusion and to show him again and again that what he takes to be new real life is a reflection of the past. And lest he should fall into a state in which he is inaccessible to all evidence, the analyst takes care that neither the love nor the hostility reach an extreme height. This is effected by preparing him in good time for these possibilities and by not overlooking the first signs of them. Careful handling of the transference on these lines is as a rule richly rewarded. If we succeed, as we usually can, in enlightening the patient on the true nature of the phenomena of transference, we shall have struck a powerful weapon out of the hand of his resistance and shall have converted dangers into gains. For a patient never forgets again what he has experienced in the form of transference; it carries a greater force of conviction than anything he can acquire in other ways.

We think it most undesirable if the patient acts outside the transference instead of remembering. The ideal conduct for our purposes would be that he should behave as normally as possible outside the treatment and express his abnormal reactions only in the transference.
The method by which we strengthen the weakened ego has as a starting-point an extending of its self-knowledge. That is not, of course, the whole story but it is a first step. The loss of such knowledge signifies for the ego a surrender of power and influence; it is the first tangible sign that it is being hemmed in and hampered by the demands of the id and the super-ego. Accordingly, the first part of the help we have to offer is intellectual work on our side and encouragement to the patient to collaborate in it. This first kind of activity, as we know, is intended to pave the way to another, more difficult, task. We shall not lose sight of the dynamic element in this task, even during its preliminary stage. We gather the material for our work from a variety of sources - from what is conveyed to us by the information given us by the patient and by his free associations, from what he shows us in his transferences, from what we arrive at by interpreting his dreams and from what he betrays by his slips or parapraxes. All this material helps us to make constructions about what happened to him and has been forgotten as well as about what is happening in him now without his understanding it. But in all this we never fail to make a strict distinction between our knowledge and his knowledge. We avoid telling him at once things that we have often discovered at an early stage, and we avoid telling him the whole of what we think we have discovered. We reflect carefully over when we shall impart the knowledge of one of our constructions to him and we wait for what seems to us the suitable moment - which it is not always easy to decide. As a rule we put off telling him of a construction or explanation till he himself has so nearly arrived at it that only a single step remains to be taken, though that step is in fact the decisive synthesis. If we proceeded in another way and overwhelmed him with our interpretations before he was prepared for them, our information would either produce no effect or it would provoke a violent outbreak of resistance which would make the progress of our work more difficult or might even threaten to stop it altogether. But if we have prepared everything properly, it often happens that the patient will at once confirm our construction and himself recollect the internal or external event which he had forgotten. The more exactly the construction coincides with the details of what has been forgotten the easier will it be for him to assent. On that particular matter our knowledge will then have become his knowledge as well.

In a footnote added to this patient's case history in 1923, I have already reported that I was mistaken. When, towards the end of the war, he returned to Vienna, a refugee and destitute, I had to help him to master a part of the transference which had not been resolved. This was accomplished in a few months, and I was able to end my footnote with the statement that 'since then the patient has felt normal and has behaved unexceptionably, in spite of the war having robbed him of his home, his possessions, and all his family relationships'. Fifteen years have passed since then without disproving the truth of this verdict; but certain reservations have become necessary. The patient has stayed on in Vienna and has kept a place in society, if a humble one. But several times during this period his good state of health has been interrupted by attacks of illness which could only be construed as offshoots of his perennial neurosis. Thanks to the skill of one of my pupils, Dr. Ruth Mack Brunswick, a short course of treatment has on each occasion brought these conditions to an end. I hope that Dr. Mack Brunswick herself will shortly report on the circumstances. Some of these attacks were still concerned with residual portions of the transference; and, where this was so, short-lived though they were, they showed a distinctly paranoid character. In other attacks, however, the pathogenic material consisted of pieces of the patient's childhood history, which had not come to light while I was analysing him and which now came away - the comparison is unavoidable - like sutures after an operation, or small fragments of necrotic bone. I have found the history of this patient's recovery scarcely less interesting than that of his illness.
This brings me to two problems which arise directly out of analytic practice, as I hope to show by the following examples. A certain man, who had himself practised analysis with great success, came to the conclusion that his relations both to men and women - to the men who were his competitors and to the woman whom he loved - were nevertheless not free from neurotic impediments; and he therefore made himself the subject of an analysis by someone else whom he regarded as superior to himself. This critical illumination of his own self had a completely successful result. He married the woman he loved and turned into a friend and teacher of his supposed rivals. Many years passed in this way, during which his relations with his former analyst also remained unclouded. But then, for no assignable external reason, trouble arose. The man who had been analysed became antagonistic to the analyst and reproached him for having failed to give him a complete analysis. The analyst, he said, ought to have known and to have taken into account the fact that a transference-relation can never be purely positive; he should have given his attention to the possibilities of a negative transference. The analyst defended himself by saying that, at the time of the analysis, there was no sign of a negative transference. But even if he had failed to observe some very faint signs of it - which was not altogether ruled out, considering the limited horizon of analysis in those early days - it was still doubtful, he thought, whether he would have had the power to activate a topic (or, as we say, a 'complex') by merely pointing it out, so long as it was not currently active in the patient himself at the time. To activate it would certainly have required some unfriendly piece of behaviour in reality on the analyst's part. Furthermore, he added, not every good relation between an analyst and his subject during and after analysis was to be regarded as a transference; there were also friendly relations which were based on reality and which proved to be viable.

[1937c, 5019]

However much our therapeutic ambition may be tempted to undertake such tasks, experience flatly rejects the notion. If an instinctual conflict is not a currently active one, is not manifesting itself, we cannot influence it even by analysis. The warning that we should let sleeping dogs lie, which we have so often heard in connection with our efforts to explore the psychical underworld, is peculiarly inapposite when applied to the conditions of mental life. For if the instincts are causing disturbances, it is a proof that the dogs are not sleeping; and if they seem really to be sleeping, it is not in our power to awaken them. This last statement, however, does not seem to be quite accurate and calls for a more detailed discussion. Let us consider what means we have at our disposal for turning an instinctual conflict which is at the moment latent into one which is currently active. Obviously there are only two things that we can do. We can bring about situations in which the conflict does become currently active, or we can content ourselves with discussing it in the analysis and pointing out the possibility of its arising. The first of these two alternatives can be carried out in two ways: in reality, or in the transference - in either case by exposing the patient to a certain amount of real suffering through frustration and the damming up of libido. Now it is true that we already make use of a technique of this kind in our ordinary analytic procedure. What would otherwise be the meaning of the rule that analysis must be carried out 'in a state of frustration'? But this is a technique which we use in treating a conflict which is already currently active. We seek to bring this conflict to a head, to develop it to its highest pitch, in order to increase the instinctual force available for its solution. Analytic experience has taught us that the better is always the enemy of the good and that in every phase of the patient's recovery we have to fight against his inertia, which is ready to be content with an incomplete solution.

[1937c, 5027]
It will be objected that these remarks are quite unnecessary. Nobody thinks of purposely conjuring up new situations of suffering in order to make it possible for a latent instinctual conflict to be treated. This would not be much to boast of as a prophylactic achievement. We know, for instance, that a patient who has recovered from scarlet fever is immune to a return of the same illness; yet it never occurs to a doctor to take a healthy person who may possibly fall ill of scarlet fever and infect him with scarlet fever in order to make him immune to it. The protective measure must not produce the same situation of danger as is produced by the illness itself, but only something very much slighter, as is the case with vaccination against small-pox and many other similar procedures. In analytic prophylaxis against instinctual conflicts, therefore, the only methods which come into consideration are the other two which we have mentioned: the artificial production of new conflicts in the transference (conflicts which, after all, lack the character of reality), and the arousing of such conflicts in the patient's imagination by talking to him about them and making him familiar with their possibility.

[1937c, 5028]

I do not know whether we can assert that the first of these two milder procedures is altogether ruled out in analysis. No experiments have been particularly made in this direction. But difficulties at once suggest themselves, which do not throw a very promising light on such an undertaking. In the first place, the choice of such situations for the transference is very limited. The patients cannot themselves bring all their conflicts into the transference; nor is the analyst able to call out all their possible instinctual conflicts from the transference situation. He may make them jealous or cause them to experience disappointments in love; but no technical purpose is required to bring this about. Such things happen of themselves in any case in most analyses. In the second place, we must not overlook the fact that all measures of this sort would oblige the analyst to behave in an unfriendly way to the patient, and this would have a damaging effect upon the affectionate attitude - upon the positive transference - which is the strongest motive for the patient's taking a share in the joint work of analysis. Thus we should on no account expect very much from this procedure.

[1937c, 5029]
The therapeutic effect depends on making conscious what is repressed, in the widest sense of the word, in the id. We prepare the way for this making conscious by interpretations and constructions, but we have interpreted only for ourselves not for the patient so long as the ego holds on to its earlier defences and does not give up its resistances. Now these resistances, although they belong to the ego, are nevertheless unconscious and in some sense separated off within the ego. The analyst recognizes them more easily than he does the hidden material in the id. One might suppose that it would be sufficient to treat them like portions of the id and, by making them conscious, bring them into connection with the rest of the ego. In this way, we should suppose, one half of the task of analysis would be accomplished; we should not reckon on meeting with a resistance against the uncovering of resistances. But what happens is this. During the work on the resistances the ego withdraws - with a greater or less degree of seriousness - from the agreement on which the analytic situation is founded. The ego ceases to support our efforts at uncovering the id; it opposes them, disobeys the fundamental rule of analysis, and allows no further derivatives of the repressed to emerge. We cannot expect the patient to have a strong conviction of the curative power of analysis. He may have brought along with him a certain amount of confidence in his analyst, which will be strengthened to an effective point by the factors of the positive transference which will be aroused in him. Under the influence of the unpleasurable impulses which he feels as a result of the fresh activation of his defensive conflicts, negative transferences may now gain the upper hand and completely annul the analytic situation. The patient now regards the analyst as no more than a stranger who is making disagreeable demands on him, and he behaves towards him exactly like a child who does not like the stranger and does not believe anything he says. If the analyst tries to explain to the patient one of the distortions made by him for the purposes of defence, and to correct it, he finds him uncomprehending and inaccessible to sound arguments. Thus we see that there is a resistance against the uncovering of resistances, and the defensive mechanisms really do deserve the name which we gave them originally, before they had been more closely examined. They are resistances not only to the making conscious of contents of the id, but also to the analysis as a whole, and thus to recovery.

It is familiar ground that the work of analysis aims at inducing the patient to give up the repressions (using the word in the widest sense) belonging to his early development and to replace them by reactions of a sort that would correspond to a psychically mature condition. With this purpose in view he must be brought to recollect certain experiences and the affective impulses called up by them which he has for the time being forgotten. We know that his present symptoms and inhibitions are the consequences of repressions of this kind: thus that they are a substitute for these things that he has forgotten. What sort of material does he put at our disposal which we can make use of to put him on the way to recovering the lost memories? All kinds of things. He gives us fragments of these memories in his dreams, invaluable in themselves but seriously distorted as a rule by all the factors concerned in the formation of dreams. Again, he produces ideas, if he gives himself up to ‘free association’, in which we can discover allusions to the repressed experiences and derivatives of the suppressed affective impulses as well as of the reactions against them. And, finally, there are hints of repetitions of the affects belonging to the repressed material to be found in actions performed by the patient, some fairly important, some trivial, both inside and outside the analytic situation. Our experience has shown that the relation of transference, which becomes established towards the analyst, is particularly calculated to favour the return of these emotional connections. It is out of such raw material - if we may so describe it - that we have to put together what we are in search of.
The analyst, as we have said, works under more favourable conditions than the archaeologist since he has at his disposal material which can have no counterpart in excavations, such as the repetitions of reactions dating from infancy and all that is indicated by the transference in connection with these repetitions. But in addition to this it must be borne in mind that the excavator is dealing with destroyed objects of which large and important portions have quite certainly been lost, by mechanical violence, by fire and by plundering. No amount of effort can result in their discovery and lead to their being united with the surviving remains. The one and only course open is that of reconstruction, which for this reason can often reach only a certain degree of probability. But it is different with the psychical object whose early history the analyst is seeking to recover. Here we are regularly met by a situation which with the archaeological object occurs only in such rare circumstances as those of Pompeii or of the tomb of Tut'ankhamun. All of the essentials are preserved; even things that seem completely forgotten are present somehow and somewhere, and have merely been buried and made inaccessible to the subject. Indeed, it may, as we know, be doubted whether any psychical structure can really be the victim of total destruction. It depends only upon analytic technique whether we shall succeed in bringing what is concealed completely to light. There are only two other facts that weigh against the extraordinary advantage which is thus enjoyed by the work of analysis: namely, that psychical objects are incomparably more complicated than the excavator's material ones and that we have insufficient knowledge of what we may expect to find, since their finer structure contains so much that is still mysterious. But our comparison between the two forms of work can go no further than this; for the main difference between them lies in the fact that for the archaeologist the reconstruction is the aim and end of his endeavours while for analysis the construction is only a preliminary labour.

[1937d, 5051]
If the theory of analytic technique is gone into, it become, evident that transference is an inevitable necessity. Practical experience, at all events, shows conclusively that there is no means of avoiding it, and that this latest creation of the disease must be combated like all the earlier ones. This happens, however, to be by far the hardest part of the whole task. It is easy to learn how to interpret dreams, to extract from the patient's associations his unconscious thoughts and memories, and to practise similar explanatory arts: for these the patient himself will always provide the text. Transference is the one thing the presence of which has to be detected almost without assistance and with only the slightest clues to go upon, while at the same time the risk of making arbitrary inferences has to be avoided. Nevertheless, transference cannot be evaded, since use is made of it in setting up all the obstacles that make the material inaccessible to treatment, and since it is only after the transference has been resolved that a patient arrives at a sense of conviction of the validity of the connections which have been constructed during the analysis.

[1905e, 1450]

But in psycho-analytic relations things often happen differently from what the psychology of consciousness might lead us to expect. Experience does not speak in favour of an affective technique of this kind. Nor is it hard to see that it involves a departure from psycho-analytic principles and verges upon treatment by suggestion. It may induce the patient to bring forward sooner and with less difficulty things he already knows but would otherwise have kept back for a time through conventional resistances. But this technique achieves nothing towards the uncovering of what is unconscious to the patient. It makes him even more incapable of overcoming his deeper resistances, and in severer cases it invariably fails by encouraging the patient to be insatiable: he would like to reverse the situation, and finds the analysis of the doctor more interesting than his own. The resolution of the transference, too - one of the main tasks of the treatment - is made more difficult by an intimate attitude on the doctor's part, so that any gain there may be at the beginning is more than outweighed at the end. I have no hesitation, therefore, in condemning this kind of technique as incorrect. The doctor should be opaque to his patients and, like a mirror, should show them nothing but what is shown to him. In practice, it is true, there is nothing to be said against a psychotherapist combining a certain amount of analysis with some suggestive influence in order to achieve a perceptible result in a shorter time - as is necessary, for instance, in institutions. But one has a right to insist that he himself should be in no doubt about what he is doing and should know that his method is not that of true psycho-analysis.

[1912e, 2472]

Where the transference arises, what difficulties it raises for us, how we overcome them and what advantages we eventually derive from it - these are questions to be dealt with in a technical guide to analysis, and I shall only touch on them lightly to-day. It is out of the question for us to yield to the patient's demands deriving from the transference; it would be absurd for us to reject them in an unfriendly, still more in an indignant, manner. We overcome the transference by pointing out to the patient that his feelings do not arise from the present situation and do not apply to the person of the doctor, but that they are repeating something that happened to him earlier. In this way we oblige him to transform his repetition into a memory. By that means the transference, which, whether affectionate or hostile, seemed in every case to constitute the greatest threat to the treatment, becomes its best tool, by whose help the most secret compartments of mental life can be opened.

[1916-1917, 3485]
But I should like to say a few words to you to relieve you of your surprise at the emergence of this unexpected phenomenon. We must not forget that the patient's illness, which we have undertaken to analyse, is not something which has been rounded off and become rigid but that it is still growing and developing like a living organism. The beginning of the treatment does not put an end to this development; when, however, the treatment has obtained mastery over the patient, what happens is that the whole of his illness's new production is concentrated upon a single point - his relation to the doctor. Thus the transference may be compared to the cambium layer in a tree between the wood and the bark, from which the new formation of tissue and the increase in the girth of the trunk derive. When the transference has risen to this significance, work upon the patient's memories retreats far into the background. Thereafter it is not incorrect to say that we are no longer concerned with the patient's earlier illness but with a newly created and transformed neurosis which has taken the former's place. We have followed this new edition of the old disorder from its start, we have observed its origin and growth, and we are especially well able to find our way about in it since, as its object, we are situated at its very centre. All the patient's symptoms have abandoned their original meaning and have take on a new sense which lies in a relation to the transference; or only such symptoms have persisted as are capable of undergoing such a transformation. But the mastering of this new, artificial neurosis coincides with getting rid of the illness which was originally brought to the treatment - with the accomplishment of our therapeutic task. A person who has become normal and free from the operation of repressed instinctual impulse in his relation to the doctor will remain so in his own life after the doctor has once more withdrawn from it.
[1916-1917, 3486]
But you will now tell me that, no matter whether we call the motive force of our analysis transference or suggestion, there is a risk that the influencing of our patient may make the objective certainty of our findings doubtful. What is advantageous to our therapy is damaging to our researches. This is the objection that is most often raised against psycho-analysis, and it must be admitted that, though it is groundless, it cannot be rejected as unreasonable. If it were justified, psycho-analysis would be nothing more than a particularly well-disguised and particularly effective form of suggestive treatment and we should have to attach little weight to all that it tells us about what influences our lives, the dynamics of the mind or the unconscious. That is what our opponents believe; and in especial they think that we have "talked" the patients into everything relating to the importance of sexual experiences - or even into those experiences themselves - after such notions have grown up in our own depraved imagination. These accusations are contradicted more easily by an appeal to experience than by the help of theory. Anyone who has himself carried out psycho-analyses will have been able to convince himself on countless occasions that it is impossible to make suggestions to a patient in that way. The doctor has no difficulty, of course, in making him a supporter of some particular theory and in thus making him share some possible error of his own. In this respect the patient is behaving like anyone else - like a pupil - but this only affects his intelligence, not his illness. After all, his conflicts will only be successfully solved and his resistances overcome if the anticipatory ideas he is given tally with what is real in him. Whatever in the doctor's conjectures is inaccurate drops out in the course of the analysis; it has to be withdrawn and replaced by something more correct. We endeavour by a careful technique to avoid the occurrence of premature successes due to suggestion; but no harm is done even if they do occur, for we are not satisfied by a first success. We do not regard an analysis as at an end until all the obscurities of the case are cleared up, the gaps in the patient's memory filled in, the precipitating causes of the repressions discovered. We look upon successes that set in too soon as obstacles rather than as a help to the work of analysis; and we put an end to such successes by constantly resolving the transference on which they are based. It is this last characteristic which is the fundamental distinction between analytic and purely suggestive therapy, and which frees the results of analysis from the suspicion of being successes due to suggestion. In every other kind of suggestive treatment the transference is carefully preserved and left untouched; in analysis it is itself subjected to treatment and is dissected in all the shapes in which it appears. At the end of an analytic treatment the transference must itself be cleared away; and if success is then obtained or continues, it rests, not on suggestion, but on the achievement by its means of an overcoming of internal resistances, on the internal change that has been brought about in the patient.

[1916-1917, 3493]
I will now complete my picture of the mechanism of cure by clothing it in the formulas of the libido theory. A neurotic is incapable of enjoyment and of efficiency - the former because his libido is not directed on to any real object and the latter because he is obliged to employ a great deal of this available energy on keeping his libido under repression and on warding off its assaults. He would become healthy if the conflict between his ego and his libido came to an end and if his ego had his libido again at its disposal. The therapeutic task consists, therefore, in freeing the libido from its present attachments, which are withdrawn from the ego, and in making it once more serviceable to the ego. Where, then, is the neurotic's libido situated? It is easily found: it is attached to the symptoms, which yield it the only substitutive satisfaction possible at the time. We must therefore make ourselves masters of the symptoms and resolve them - which is precisely the same thing that the patient requires of us. In order to resolve the symptoms, we must go back as far as their origin, we must renew the conflict from which they arose, and, with the help of motive forces which were not at the patient's disposal in the past, we must guide it to a different outcome. This revision of the process of repression can be accomplished only in part in connection with the memory traces of the processes which led to repression. The decisive part of the work is achieved by creating in the patient's relation to the doctor - in the 'transference' - new editions of the old conflicts; in these the patient would like to behave in the same way as he did in the past, while we, by summoning up every available mental force, compel him to come to a fresh decision. Thus the transference becomes the battlefield on which all the mutually struggling forces should meet one another.

[1916-1917, 3494]

All the libido, as well as everything opposing it, is made to converge solely on the relation with the doctor. In this process the symptoms are inevitably divested of libido. In place of his patient's true illness there appears the artificially constructed transference illness, in place of the various unreal objects of the libido there appears a single, and once more imaginary, object in the person of the doctor. But, by the help of the doctor's suggestion, the new struggle around this object is lifted to the highest psychical level: it takes place as a normal mental conflict. Since a fresh repression is avoided, the alienation between ego and libido is brought to an end and the subject's mental unity is restored. When the libido is released once more from its temporary object in the person of the doctor, it cannot return to its earlier objects, but is at the disposal of the ego. The forces against which we have been struggling during our work of therapy are, on the one hand, the ego's antipathy to certain trends of the libido - an antipathy expressed in a tendency to repression - and, on the other hand, the tenacity or adhesiveness of the libido, which dislikes leaving objects that it has once cathexed.

[1916-1917, 3494]
Thus our therapeutic work falls into two phases. In the first, all the libido is forced from the symptoms into the transference and concentrated there; in the second, the struggle is waged around this new object and the libido is liberated from it. The change which is decisive for a favourable outcome is the elimination of repression in this renewed conflict so that the libido cannot withdraw once more from the ego by flight into the unconscious. This is made possible by the alteration of the ego which is accomplished under the influence of the doctor's suggestion. By means of the work of interpretation, which transforms what is unconscious into what is conscious, the ego is enlarged at the cost of this unconscious; by means of instruction, it is made conciliatory towards the libido and inclined to grant it some satisfaction, and its repugnance to the claims of the libido is diminished by the possibility of disposing of a portion of it by sublimation. The more closely events in the treatment coincide with this ideal description, the greater will be the success of the psycho-analytic therapy. It finds its limits in the lack of mobility of the libido, which may refuse to leave its objects, and the rigidity of narcissism, which will not allow transference on to objects to increase beyond certain bounds. Further light may perhaps be thrown on the dynamics of the process of cure if I say that we get hold of the whole of the libido which has been withdrawn from the dominance of the ego by attracting a portion of it on to ourselves by means of the transference.

[1916-1917, 3495]

It will not be out of place to give a warning that we can draw no direct conclusion from the distribution of the libido during and resulting from the treatment as to how it was distributed during the illness. Suppose we succeeded in bringing a case to a favourable conclusion by setting up and then resolving a strong father-transference to the doctor. It would not be correct to conclude that the patient had suffered previously from a similar unconscious attachment of his libido to his father. His father-transference was merely the battlefield on which we gained control of his libido; the patient's libido as directed to it from other positions. A battlefield need not necessarily coincide with one of the enemy's key fortresses. The defence of a hostile capital need not take place just in front of its gates. Not until after the transference has once more been resolved can we reconstruct in our thoughts the distribution of the libido which had prevailed during the illness.

[1916-1917, 3495]

The patient with whom I am here concerned remained for a long time unassailably entrenched behind an attitude of 'obliging apathy'. He listened, understood, and remained unapproachable. His unimpeachable intelligence was, as it were, cut off from the instinctual forces which governed his behaviour in the few relations of life that remained to him. It required a long education to induce him to take an independent share in the work; and when as a result of this exertion he began for the first time to feel relief, he immediately gave up working in order to avoid any further changes, and in order to remain comfortably in the situation which had been thus established. His shrinking from a self-sufficient existence was so great as to outweigh all the vexations of his illness. Only one way was to be found of overcoming it. I was obliged to wait until his attachment to myself had become strong enough to counter-balance this shrinking, and then played off this one factor against the other. I determined - but not until trustworthy signs had led me to judge that the right moment had come - that the treatment must be brought to an end at a particular fixed date, no matter how far it had advanced. I was resolved to keep to the date; and eventually the patient came to see that I was in earnest. Under the inexorable pressure of this fixed limit his resistance and his fixation to the illness gave way, and now in a disproportionately short time the analysis produced all the material which made it possible to clear up his inhibitions and remove his symptoms. All the information, too, which enabled me to understand his infantile neurosis is derived from this last period of the work, during which resistance temporarily disappeared and the patient gave an impression of lucidity which is usually attainable only in hypnosis.

[1918b, 3507]
But it became ever clearer that the aim which had been set up - the aim that what was unconscious should become conscious - is not completely attainable by that method. The patient cannot remember the whole of what is repressed in him, and what he cannot remember may be precisely the essential part of it. Thus he acquires no sense of conviction of the correctness of the construction that has been communicated to him. He is obliged to repeat the repressed material as a contemporary experience instead of, as the physician would prefer to see, remembering it as something belonging to the past.¹ These reproductions, which emerge with such unwished-for exactitude, always have as their subject some portion of infantile sexual life - of the Oedipus complex, that is, and its derivatives; and they are invariably acted out in the sphere of the transference, of the patient's relation to the physician. When things have reached this stage, it may be said that the earlier neurosis has now been replaced by a fresh, 'transference neurosis'. It has been the physician's endeavour to keep this transference neurosis within the narrowest limits: to force as much as possible into the channel of memory and to allow as little as possible to emerge as repetition. The ratio between what is remembered and what is reproduced varies from case to case. The physician cannot as a rule spare his patient this phase of the treatment. He must get him to re-experience some portion of his forgotten life, but must see to it, on the other hand, that the patient retains some degree of aloofness, which will enable him, in spite of everything, to recognize that what appears to be reality is in fact only a reflection of a forgotten past. If this can be successfully achieved, the patient's sense of conviction is won, together with the therapeutic success that is dependent on it.

[1916-1917, 3723]

I now come to the description of a factor which adds an essential feature to my picture of analysis and which can claim, alike technically and theoretically, to be regarded as of the first importance. In every analytic treatment there arises, without the physician's agency, an intense emotional relationship between the patient and the analyst which is not to be accounted for by the actual situation. It can be of a positive or of a negative character and can vary between the extremes of a passionate, completely sensual love and the unbridled expression of an embittered defiance and hatred. This transference - to give it its short name - soon replaces in the patient's mind the desire to be cured, and, so long as it is affectionate and moderate, becomes the agent of the physician's influence and neither more nor less than the mainspring of the joint work of analysis. Later on, when it has become passionate or has been converted into hostility, it becomes the principal tool of the resistance. It may then happen that it will paralyse the patient's powers of associating and endanger the success of the treatment. Yet it would be senseless to try to evade it; for an analysis without transference is an impossibility. It must not be supposed, however, that transference is created by analysis and does not occur apart from it. Transference is merely uncovered and isolated by analysis. It is a universal phenomenon of the human mind, it decides the success of all medical influence, and in fact dominates the whole of each person's relations to his human environment. We can easily recognize it as the same dynamic factor which the hypnotists have named 'suggestibility', which is the agent of hypnotic rapport and whose incalculable behaviour led to difficulties with the cathartic method as well. When there is no inclination to a transference of emotion such as this, or when it has become entirely negative, as happens in dementia praecox or paranoia, then there is also no possibility of influencing the patient by psychological means.

[1925d, 4217]
In a footnote added to this patient's case history in 1923, I have already reported that I was mistaken. When, towards the end of the war, he returned to Vienna, a refugee and destitute, I had to help him to master a part of the transference which had not been resolved. This was accomplished in a few months, and I was able to end my footnote with the statement that 'since then the patient has felt normal and has behaved unexceptionably, in spite of the war having robbed him of his home, his possessions, and all his family relationships'. Fifteen years have passed since then without disproving the truth of this verdict; but certain reservations have become necessary. The patient has stayed on in Vienna and has kept a place in society, if a humble one. But several times during this period his good state of health has been interrupted by attacks of illness which could only be construed as offshoots of his perennial neurosis. Thanks to the skill of one of my pupils, Dr. Ruth Mack Brunswick, a short course of treatment has on each occasion brought these conditions to an end. I hope that Dr. Mack Brunswick herself will shortly report on the circumstances. Some of these attacks were still concerned with residual portions of the transference; and, where this was so, short-lived though they were, they showed a distinctly paranoid character. In other attacks, however, the pathogenic material consisted of pieces of the patient's childhood history, which had not come to light while I was analysing him and which now came away - the comparison is unavoidable - like sutures after an operation, or small fragments of necrotic bone. I have found the history of this patient's recovery scarcely less interesting than that of his illness.

[1937c, 5016]
There would be nothing more to discuss or worry about in this behaviour of transference, if it were not that two points remain unexplained about it which are of particular interest to psycho-analysis. Firstly, we do not understand why transference is so much more intense with neurotic subjects in analysis than it is with other such people who are not being analysed; and secondly, it remains a puzzle why in analysis transference emerges as the most powerful resistance to the treatment, whereas outside analysis it must be regarded as the vehicle of cure and the condition of success. For our experience has shown us - and the fact can be confirmed as often as we please - that if a patient's free associations fail, the stoppage can invariably be removed by an assurance that he is being dominated at the moment by an association which is concerned with the doctor himself or with something connected with him. As soon as this explanation is given, the stoppage is removed, or the situation is changed from one in which the associations fail into one in which they are being kept back. At first sight it appears to be an immense disadvantage in psycho-analysis as a method that what is elsewhere the strongest factor towards success is changed in it into the most powerful medium of resistance. If, however, we examine the situation more closely, we can at least clear away the first of our two problems. It is not a fact that transference emerges with greater intensity and lack of restraint during psycho-analysis than outside it. In institutions in which nerve patients are treated non-analytically, we can observe transference occurring with the greatest intensity and in the most unworthy forms, extending to nothing less than mental bondage, and moreover showing the plainest erotic colouring. Gabriele Reuter, with her sharp powers of observation, described this at a time when there was no such thing as psycho-analysis, in a remarkable book which betrays in every respect the clearest insight into the nature and genesis of neuroses. These characteristics of transference are therefore to be attributed not to psycho-analysis but to neurosis itself.

The fact of the emergence of the transference in its crudely sexual form, whether affectionate or hostile, in every treatment of a neurosis, although this is neither desired nor induced by either doctor or patient, has always seemed to me the most irrefragable proof that the source of the driving forces of neurosis lies in sexual life. This argument has never received anything approaching the degree of attention that it merits, for if it had, investigations in this field would leave no other conclusion open. As far as I am concerned, this argument has remained the decisive one, over and above the more specific findings of analytic work.

The transference possesses this extraordinary, and for the treatment, positively central, importance in hysteria, anxiety hysteria and obsessional neurosis, which are for that reason rightly classed together as 'transference neuroses'. No one who has taken in a full impression of the fact of transference from his analytic work will any longer doubt the nature of the suppressed impulses that obtain expression in the symptoms of these neuroses, and will call for no more powerful evidence of their libidinal character. It may be said that our conviction of the significance of symptoms as substitutive satisfactions of the libido only received its final confirmation after the enlistment of the transference.

Transference. - If further proof were needed of the truth that the motive forces behind the formation of neurotic symptoms are of a sexual nature, it would be found in the fact that in the course of analytic treatment a special emotional relation is regularly formed between the patient and the physician. This goes far beyond rational limits. It varies between the most affectionate devotion and the most obstinate enmity and derives all of its characteristics from earlier erotic attitudes of the patient's which have become unconscious. This transference alike in its positive and in its negative form is used as a weapon by the resistance; but in the hands of the physician it becomes the most powerful therapeutic instrument and it plays a part scarcely to be over-estimated in the dynamics of the process of cure.
Our conviction that a portion of erotic life that has been abnormally employed lies at the basis of neuroses must be unshakeably strengthened by this experience. With this discovery we are once more on a firm footing and can venture to make this love itself the object of analysis. And we can make another observation. Analytic love is not manifested in every case as clearly and blatantly as I have tried to depict it. Why not? We can soon see. In proportion as the purely sensual and the hostile sides of his love try to show themselves, the patient's opposition to them is aroused. He struggles against them and tries to repress them before our very eyes. And now we understand what is happening. The patient is repeating in the form of falling in love with the analyst mental experiences which he has already been through once before; he has transferred on to the analyst mental attitudes that were lying ready in him and were intimately connected with his neurosis. He is also repeating before our eyes his old defensive actions; he would like best to repeat in his relation to the analyst all the history of that forgotten period of his life. So what he is showing us is the kernel of his intimate life history: he is reproducing it tangibly, as though it were actually happening, instead of remembering it. In this way the riddle of the transference-love is solved and the analysis can proceed on its way - with the help of the new situation which had seemed such a menace to it.
[1926e, 4368]
It is here that the differences begin, which made the case of Gradiva an ideal one which medical technique cannot attain. Gradiva was able to return the love which was making its way from the unconscious into consciousness, but the doctor cannot. Gradiva had herself been the object of the earlier, repressed love; her figure at once offered the liberated current of love a desirable aim. The doctor has been a stranger, and must endeavour to become a stranger once more after the cure; he is often at a loss what advice to give the patients he has cured as to how in real life they can use their recovered capacity to love. To indicate the expedients and substitutes of which the doctor therefore makes use to help him to approximate with more or less success to the model of a cure by love which has been shown us by our author - all this would take us much too far away from the task before us.

[1907a, 1882]

Other innovations in technique relate to the physician himself. We have become aware of the 'counter-transference', which arises in him as a result of the patient's influence on his unconscious feelings, and we are almost inclined to insist that he shall recognize this counter-transference in himself and overcome it. Now that a considerable number of people are practising psycho-analysis and exchanging their observations with one another, we have noticed that no psycho-analyst goes further than his own complexes and internal resistances permit; and we consequently require that he shall begin his activity with a self-analysis and continually carry it deeper while he is making his observations on his patients. Anyone who fails to produce results in a self-analysis of this kind may at once give up any idea of being able to treat patients by analysis.

[1910d, 2309]

For the doctor the phenomenon signifies a valuable piece of enlightenment and a useful warning against any tendency to a counter-transference which may be present in his own mind. He must recognize that the patient's falling in love is induced by the analytic situation and is not to be attributed to the charms of his own person; so that he has no grounds whatever for being proud of such a 'conquest', as it would be called outside analysis. And it is always well to be reminded of this. For the patient, however, there are two alternatives: either she must relinquish psycho-analytic treatment or she must accept falling in love with her doctor as an inescapable fate.¹

[1915a, 2510]

Just as little can I advocate a middle course, which would recommend itself to some people as being specially ingenious. This would consist in declaring that one returns the patient's fond feelings but at the same time in avoiding any physical implementation of this fondness until one is able to guide the relationship into calmer channels and raise it to a highest level. My objection to this expedient is that psycho-analytic treatment is founded on truthfulness. In this fact lies a great part of its educative effect and its ethical value. It is dangerous to depart from this foundation. Anyone who has become saturated in the analytic technique will no longer be able to make use of the lies and pretences which a doctor normally finds unavoidable; and if, with the best intentions, he does attempt to do so, he is very likely to betray himself. Since we demand strict truthfulness from our patients, we jeopardize our whole authority if we let ourselves be caught out by them in a departure from the truth. Besides, the experiment of letting oneself go a little way in tender feelings for the patient is not altogether without danger. Our control over ourselves is not so complete that we may not suddenly one day go further than we had intended. In my opinion, therefore, we ought not to give up the neutrality towards the patient, which we have acquired through keeping the counter-transference in check.

[1915a, 2514]
It is only in certain pathological mental conditions that the relation holding in normal adults between the psychical significance of an event and its retention in memory once more ceases to apply. For instance, a hysterical habitually shows amnesia for some or all of the experiences which led to the onset of his illness and which from that very fact have become important to him and, apart from that fact, may have been important on their own account. The analogy between pathological amnesia of this kind and the normal amnesia affecting our early years seems to me to give a valuable hint at the intimate connection that exists between the psychical content of neuroses and our infantile life.

[1899a, 488]

Before dealing with the psychological problems attaching to the earliest memories of childhood, it would of course be essential to make a collection of material by circularizing a fairly large number of normal adults and discovering what kind of recollections they are able to produce from these early years. A first step in this direction was taken in 1895 by V. and C. Henri, who sent round a paper of questions drawn up by them. The highly suggestive results of their questionnaire, which brought in replies from 123 persons, were published by the two authors in 1897. I have no intention at present of discussing the subject as a whole, and I shall therefore content myself with emphasizing the few points which will enable me to introduce the notion of what I have termed 'screen memories'.

[1899a, 488]

The age to which the content of the earliest memories of childhood is usually referred back is the period between the ages of two and four. (This is the case with 88 persons in the series observed by the Henris.) There are some, however, whose memory reaches back further - even to the time before the completion of their first year; and, on the other hand, there are some whose earliest recollections go back only to their sixth, seventh, or even eighth year. There is nothing at the moment to show what else is related to these individual differences; is to be noticed, say the Henris, that a person whose earliest recollection goes back to a very tender age - to the first year of his life, perhaps - will also have at his disposal further detached memories from the following years, and that he will be able to reproduce his experiences as a continuous chain from an earlier point of time - from about his fifth year - than is possible for other people, whose first recollection dates from a later time. Thus not only the date of the appearance of the first recollection but the whole function of memory may, in the case of some people, be advanced or retarded.

[1899a, 488]

Now, however, we are met by a fact that is diametrically opposed to our expectations and cannot fail to astonish us. We hear that there are some people whose earliest recollections of childhood are concerned with everyday and indifferent events which could not produce any emotional effect even in children, but which are recollected (too clearly, one is inclined to say) in every detail, while approximately contemporary events, even if, on the evidence of their parents, they moved them intensely at the time, have not been retained in their memory. Thus the Henris mention a professor of philology whose earliest memory, dating back to between the ages of three and four, showed him a table laid for a meal and on it a basin of ice. At the same period there occurred the death of his grandmother which, according to his parents, was a severe blow to the child. But the professor of philology, as he now is, has no recollection of this bereavement; all that he remembers of those days is the basin of ice. Another man reports that his earliest memory is an episode upon a walk in which he broke off a branch from a tree. He thinks he can still identify the spot where this happened. There were several other people present, and one of them helped him.

[1899a, 489]
The Henris describe such cases as rare. In my experience, based for the most part, it is true, on neurotics, they are quite frequent. One of the subjects of the Henris' investigation made an attempt at explaining the occurrence of these mnemic images, whose innocence makes them so mysterious, and his explanation seems to me very much to the point. He thinks that in such cases the relevant scene may perhaps have been only incompletely retained in the memory, and that that may be why it seems so unenlightening: the parts that have been forgotten probably contained everything that made the experience noteworthy. I am able to confirm the truth of this view, though I should prefer to speak of these elements of the experience being omitted rather than forgotten. I have often succeeded, by means of psycho-analytic treatment, in uncovering the missing portions of a childhood experience and in thus proving that when the impression, of which no more than a torso was retained in the memory, had been restored to completeness, it did in fact agree with the presumption that it is the most important things that are recollected. This, however, provides no explanation of the remarkable choice which memory has made among the elements of the experience. We must first enquire why it should be that precisely what is important is suppressed and what is indifferent retained; and we shall not find an explanation of this until we have investigated the mechanism of these processes more deeply. We shall then form a notion that two psychical forces are concerned in bringing about memories of this sort. One of these forces takes the importance of the experience as a motive for seeking to remember it, while the other - a resistance - tries to prevent any such preference from being shown. These two opposing forces do not cancel each other out, nor does one of them (whether with or without loss to itself) overpower the other. Instead, a compromise is brought about, somewhat on the analogy of the resultant in a parallelogram of forces. And the compromise is this. What is recorded as a mnemonic image is not the relevant experience itself - in this respect the resistance gets its way; what is recorded is another psychical element closely associated with the objectionable one - and in this respect the first principle shows its strength, the principle which endeavours to fix important impressions by establishing reproducible mnemonic images. The result of the conflict is therefore that, instead of the mnemonic image which would have been justified by the original event, another is produced which has been to some degree associatively displaced from the former one. And since the elements of the experience which aroused objection were precisely the important ones, the substituted memory will necessarily lack those important elements and will in consequence most probably strike us as trivial. It will seem incomprehensible to us because we are inclined to look for the reason for its retention in its own content, whereas in fact that retention is due to the relation holding between its own content and a different one which has been suppressed. There is a common saying among us about shams, that they are not made of gold themselves but have lain beside something that is made of gold. The same simile might well be applied to some of the experiences of childhood which have been retained in the memory.

[1899a, 490]

The processes of normal and pathological defence and the displacements in which they result are clearly of great importance. But to the best of my knowledge no study whatever has hitherto been made of them by psychologists; and it remains to be ascertained in what strata of psychical activity and under what conditions they come into operation. The reason for this neglect may well be that our mental life, so far as it is the object of our conscious internal perception, shows nothing of these processes, apart from instances which we classify as 'faulty reasoning' and some mental operations which aim at producing a comic effect. The assertion that a psychical intensity can be displaced from one presentation (which is then abandoned) on to another (which thenceforward plays the psychological part of the former one) is as bewildering to us as certain features of Greek mythology - as, for instance, when the gods are said to clothe someone with beauty as though it were with a veil, whereas we think only of a face transfigured by a change of expression.

[1899a, 491]
Further investigation of these indifferent childhood memories has taught me that they can originate in other ways as well and that an unsuspected wealth of meaning lies concealed behind their apparent innocence. But on this point I shall not content myself with a mere assertion but shall give a detailed report of one particular instance which seems to me the most instructive out of a considerable number of similar ones. Its value is certainly increased by the fact that it relates to someone who is not at all or only very slightly neurotic.

[1899a, 492]

'I have at my disposal a fair number of early memories of childhood which I can date with great certainty. For at the age of three I left the small place where I was born and moved to a large town; and all these memories of mine relate to my birth place and therefore date from my second and third years. They are mostly short scenes, but they are very well preserved and furnished with every detail of sense-perception, in complete contrast to my memories of adult years, which are entirely lacking in the visual element. From my third year onwards my recollections grow scantier and less clear; there are gaps in them which must cover more than a year; and it is not, I believe, until my sixth or seventh year that the stream of my memories becomes continuous. My memories up to the time of my leaving my first place of residence fall into three groups. The first group consists of scenes which my parents have repeatedly since described to me. As regards these, I feel uncertain whether I have had the mnemonic image from the beginning or whether I only construed it after hearing one of these descriptions. I may remark, however, that there are also events of which I have no mnemonic image in spite of their having been frequently retailed by my parents. I attach more importance to the second group. It comprises scenes which have not (so far as I know) been described to me and some of which, indeed, could not have been described to me, as I have not met the other participants in them (my nurse and playmates) since their occurrence. I shall come to the third group presently. As regards the content of these scenes and their consequent claim to being recollected, I should like to say that I am not entirely at sea. I cannot maintain, indeed, that what I have retained are memories of the most important events of the period, or what I should to-day judge to be the most important. I have no knowledge of the birth of a sister, who is two and a half years younger than I am; my departure, my first sight of the railway and the long carriage-drive before it - none of these has left a trace in my memory. On the other hand, I can remember two small occurrences during the railway-journey; these, as you will recollect, came up in the analysis of my phobia. But what should have made most impression on me was an injury to my face which caused a considerable loss of blood and for which I had to have some stitches put in by a surgeon. I can still feel the scar resulting from this accident, but I know of no recollection which points to it, either directly or indirectly. It is true that I may perhaps have been under two years old at the time.

[1899a, 492]
"It follows from this that I feel no surprise at the pictures and scenes of these first two groups. No doubt they are displaced memories from which the essential element has for the most part been omitted. But in a few of them it is at least hinted at, and in others it is easy for me to complete them by following certain pointers. By doing so I can establish a sound connection between the separate fragments of memories and arrive at a clear understanding of what the childish interest was that recommended these particular occurrences to my memory. This does not apply, however, to the content of the third group, which I have not so far discussed. There I am met by material - one rather long scene and several smaller pictures - with which I can make no headway at all. The scene appears to me fairly indifferent and I cannot understand why it should have become fixed in my memory. Let me describe it to you. I see a rectangular, rather steeply sloping piece of meadow-land, green and thickly grown; in the green there are a great number of yellow flowers - evidently common dandelions. At the top end of the meadow there is a cottage and in front of the cottage door two women are standing chatting busily, a peasant-woman with a handkerchief on her head and a children's nurse. Three children are playing in the grass. One of them is myself (between the age of two and three); the two others are my boy cousin, who is a year older than me, and his sister, who is almost exactly the same age as I am. We are picking the yellow flowers and each of us is holding a bunch of flowers we have already picked. The little girl has the best bunch; and, as though by mutual agreement, we - the two boys - fall on her and snatch away her flowers. She runs up the meadow in tears and as a consolation the peasant-woman gives her a big piece of black bread. Hardly have we seen this than we throw the flowers away, hurry to the cottage and ask to be given some bread too. And we are in fact given some; the peasant-woman cuts the loaf with a long knife. In my memory the bread tastes quite delicious - and at that point the scene breaks off.

Now what is there in this occurrence to justify the expenditure of memory which it has occasioned me? I have racked my brains in vain over it. Does the emphasis lie on our disagreeable behaviour to the little girl? Did the yellow colour of the dandelions - a flower which I am, of course, far from admiring to-day - so greatly please me? Or, as a result of my careering round the grass, did the bread taste so much nicer than usual that it made an unforgettable impression on me? Nor can I find any connection between this scene and the interest which (as I was able to discover without any difficulty) bound together the other scenes from my childhood. Altogether, there seems to me something not quite right about this scene. The yellow of the flowers is a disproportionately prominent element in the situation as a whole, and the nice taste of the bread seems to me exaggerated in an almost hallucinatory fashion. I cannot help being reminded of some pictures that I once saw in a burlesque exhibition. Certain portions of these pictures, and of course the most inappropriate ones, instead of being painted, were built up in three dimensions - for instance, the ladies' bustles. Well, can you point out any way of finding an explanation or interpretation of this redundant memory of my childhood?"
'I have not yet considered that point,' he replied. 'Now that you have raised the question, it seems to me almost a certainty that this childhood memory never occurred to me at all in my earlier years. But I can also recall the occasion which led to my recovering this and many other recollections of my earliest childhood. When I was seventeen and at my secondary school, I returned for the first time to my birthplace for the holidays, to stay with a family who had been our friends ever since that remote date. I know quite well what a wealth of impressions overwhelmed me at that time. But I see now that I shall have to tell you a whole big piece of my history: it belongs here, and you have brought it upon yourself by your question. So listen. I was the child of people who were originally well-to-do and who, I fancy, lived comfortably enough in that little corner of the provinces. When I was about three, the branch of industry in which my father was concerned met with a catastrophe. He lost all his means and we were forced to leave the place and move to a large town. Long and difficult years followed, of which, as it seems to me, nothing was worth remembering. I never felt really comfortable in the town. I believe now that I was never free from a longing for the beautiful woods near our home, in which (as one of my memories from those days tells me) I used to run off from my father, almost before I had learnt to walk. Those holidays, when I was seventeen, were my first holidays in the country, and, as I have said, I stayed with a family with whom we were friends and who had risen greatly in the world since our move. I could compare the comfort reigning there with our own style of living at home in the town. But it is no use evading the subject any longer: I must admit that there was something else that excited me powerfully. I was seventeen, and in the family where I was staying there was a daughter of fifteen, with whom I immediately fell in love. It was my first calf-love and sufficiently intense, but I kept it completely secret. After a few days the girl went off to her school (from which she too was home for the holidays) and it was this separation after such a short acquaintance that brought my longings to a really high pitch. I passed many hours in solitary walks through the lovely woods that I had found once more and spent my time building castles in the air. These, strangely enough, were not concerned with the future but sought to improve the past. If only the smash had not occurred! If only I had stopped at home and grown up in the country and grown as strong as the young men in the house, the brothers of my love! And then if only I had followed my father's profession and if I had finally married her - for I should have known her intimately all those years! I had not the slightest doubt, of course, that in the circumstances created by my imagination I should have loved her just as passionately as I really seemed to then. A strange thing. For when I see her now from time to time - she happens to have married someone here - she is quite exceptionally indifferent to me. Yet I can remember quite well for what a long time afterwards I was affected by the yellow colour of the dress she was wearing when we first met, whenever I saw the same colour anywhere else.'

[1899a, 494]

Then I am inclined to believe that the childhood scene we are considering emerged at this time, when you were struggling for your daily bread - provided, that is, that you can confirm my idea that it was during this same period that you first made the acquaintance of the Alps.

[1899a, 496]
There is in general no guarantee of the data produced by our memory. But I am ready to agree with you that the scene is genuine. If so, you selected it from innumerable others of a similar or another kind because, on account of its content (which in itself was indifferent) it was well adapted to represent the two phantasies, which were important enough to you. A recollection of this kind, whose value lies in the fact that it represents in the memory impressions and thoughts of a later date whose content is connected with its own by symbolic or similar links, may appropriately be called a 'screen memory'. In any case you will cease to feel any surprise that this scene should so often recur to your mind. It can no longer be regarded as an innocent one since, as we have discovered, it is calculated to illustrate the most momentous turning-points in your life, the influence of the two most powerful motive forces - hunger and love.

[1899a, 496]

And slips away into a childhood memory. You are quite right. It is precisely the coarsely sensual element in the phantasy which explains why it does not develop into a conscious phantasy but must be content to find its way allusively and under a flowery disguise into a childhood scene.

[1899a, 498]

'If that is so, I have lost all faith in the genuineness of the dandelion scene. This is how I look at it: On the two occasions in question, and with the support of very comprehensible realistic motives, the thought occurred to me: "If you had married this or that girl, your life would have become much pleasanter." The sensual current in my mind took hold of the thought which is contained in the protasis and repeated it in images of a kind capable of giving that same sensual current satisfaction. This second version of the thought remained unconscious on account of its incompatibility with the dominant sexual disposition; but this very fact of its remaining unconscious enabled it to persist in my mind long after changes in the real situation had quite got rid of the conscious version. In accordance, as you say, with a general law, the clause that had remained unconscious sought to transform itself into a childhood scene which, on account of its innocence, would be able to become conscious. With this end in view it had to undergo a fresh transformation, or rather two fresh transformations. One of these removed the objectionable element from the protasis by expressing it figuratively; the second forced the apodosis into a shape capable of visual representation - using for the purpose the intermediary ideas of "bread" and "bread-and-butter occupations". I see that by producing a phantasy like this I was providing, as it were, a fulfilment of the two suppressed wishes for deflowering a girl and for material comfort. But now that I have given such a complete account of the motives that led to my producing the dandelion phantasy, I cannot help concluding that what I am dealing with is something that never happened at all but has been unjustifiably smuggled in among my childhood memories.'

[1899a, 498]
I see that I must take up the defence of its genuineness. You are going too far. You have accepted my assertion that every suppressed phantasy of this kind tends to slip away into a childhood scene. But suppose now that this cannot occur unless there is a memory-trace the content of which offers the phantasy a point of contact - comes, as it were, half way to meet it. Once a point of contact of this kind has been found - in the present instance it was the deflowering, the taking away of the flowers - the remaining content of the phantasy is remodelled with the help of every legitimate intermediate idea - take the bread as an example - till it can find further points of contact with the content of the childhood scene. It is very possible that in the course of this process the childhood scene itself also undergoes changes; I regard it as certain that falsifications of memory may be brought about in this way too. In your case the childhood scene seems only to have had some of its lines engraved more deeply: think of the over-emphasis on the yellow and the exaggerated niceness of the bread. But the raw material was utilizable. If that had not been so, it would not have been possible for this particular memory, rather than any others, to make its way forward into consciousness. No such scene would have occurred to you as a childhood memory, or perhaps some other one would have - for you know how easily our ingenuity can build connecting bridges from any one point to any other. And apart from your own subjective feeling which I am not inclined to under-estimate, there is another thing that speaks in favour of the genuineness of your dandelion memory. It contains elements which have not been solved by what you have told me and which do not in fact fit in with the sense required by the phantasy. For instance, your boy cousin helping you to rob the little girl of her flowers - can you make any sense of the idea of being helped in deflowering someone? or of the peasant woman and the nurse in front of the cottage?

This analysis, which I have reproduced as accurately as possible, will, I hope, have to some extent clarified the concept of a 'screen memory' as one which owes its value as a memory not to its own content but to the relation existing between that content and some other, that has been suppressed. Different classes of screen memories can be distinguished according to the nature of that relation. We have found examples of two of these classes among what are described as the earliest memories of childhood - that is, if we include under the heading of screen memories the incomplete childhood scenes which are innocent by very reason of their incompleteness. It is to be anticipated that screen memories will also be formed from residues of memories relating to later life as well. Anyone who bears in mind their distinctive feature - namely that they are extremely well remembered but that their content is completely indifferent - will easily recall a number of examples of the sort from his own memory. Some of these screen memories dealing with events later in life owe their importance to a connection with experiences in early youth which have remained suppressed. The connection, that is, is the reverse of the one in the case which I have analysed, where a childhood memory was accounted for by later experiences. A screen memory may be described as 'retrogressive' or as having 'pushed forward' according as the one chronological relation or the other holds between the screen and the thing screened-off. From another point of view, we can distinguish positive screen memories from negative ones (or refractory memories) whose content stands in a contrary relation to the suppressed material. The whole subject deserves a more thorough examination; but I must content myself with pointing out what complicated processes - processes, incidentally, which are altogether analogous to the formation of hysterical symptoms - are involved in the building up of our store of memories.

[1899a, 499]

[1899a, 501]
There is another fact that affords even more convincing evidence in favour of this second view. Out of a number of childhood memories of significant experiences, all of them of similar distinctness and clarity, there will be some scenes which, when they are tested (for instance by the recollections of adults), turn out to have been falsified. Not that they are complete inventions; they are false in the sense that the they have shifted an event to a place where it did not occur - this is the case in one of the instances quoted by the Henris - or that they have merged two people into one or substituted one for the other, or the scenes as a whole give signs of being combinations of two separate experiences. Simple inaccuracy of recollection does not play any considerable part here, in view of the high degree of sensory intensity possessed by the images the and the efficiency of the function of memory in the young; close the investigation shows rather that these falsifications of memory are tendentious - that is, that they serve the purposes of the repression and replacement of objectionable or disagreeable impressions. It follows, therefore, that these falsified memories too, must have originated at a period of life when it has become the possible for conflicts of this kind and impulses towards repression to have made a place for themselves in mental life - far later, therefore, than the period to which their content belongs. But in these cases too the falsified memory is the first that we become aware of: the raw material of memory-traces out of which it was forged remains unknown to us in its original form.

[1899a, 503]

The folded coloured plate. While I was a medical student I was the constant victim of an impulse only to learn things out of monographs. In spite of my limited means, I succeeded in getting hold of a number of volumes of the proceedings of medical societies and was enthralled by their coloured plates. I was proud of my hankering for thoroughness. When I myself had begun to publish papers, I had been obliged to make my own drawings to illustrate them and I remembered that one of them had been so wretched that a friendly colleague had jeered at me over it. There followed, I could not quite make out how, a recollection from very early youth. It had once amused my father to hand over a book with coloured plates (an account of a journey through Persia) for me and my eldest sister to destroy. Not easy to justify from the educational point of view! I had been five years old at the time and my sister not yet three; and the picture of the two of us blissfully pulling the book to pieces (leaf by leaf, like an artichoke, I found myself saying) was almost the only plastic memory that I retained from that period of my life. Then, when I became a student, I had developed a passion for collecting and owning books, which was analogous to my liking for learning out of monographs: a favourite hobby. (The idea of 'favourite' had already appeared in connection with cyclamens and artichokes.) I had become a book-worm. I had always, from the time I first began to think about myself, referred this first passion of mine back to the childhood memory I have mentioned. Or rather, I had recognized that the childhood scene was a 'screen memory' for my later bibliophile propensities. And I had early discovered, of course, that passions often lead to sorrow. When I was seventeen I had run up a largish account at the bookseller's and had nothing to meet it with; and my father had scarcely taken it as an excuse that my inclinations might have chosen a worse outlet. The recollection of this experience from the later years of my youth at once brought back to my mind the conversation with my friend Dr. Königstein. For in the course of it we had discussed the same question of my being blamed for being too much absorbed in my favourite hobbies.

[1900a, 660]
In a second paper, which was published in the *Monatsschrift für Psychiatrie und Neurologie* (1899a), I was in a position to demonstrate at an unexpected point the tendentious nature of the workings of our memory. I started from the striking fact that a person's earliest childhood memories seem frequently to have preserved what is indifferent and unimportant, whereas (frequently, though certainly not universally) no trace is found in an adult's memory of impressions dating from that time which are important, impressive and rich in affect. It might be assumed from this - since it is known that the memory makes a selection from among the impressions offered to it - that in childhood the selection is conducted on entirely different principles from those which apply at the time of intellectual maturity. Careful investigation nevertheless shows that such an assumption is unnecessary. The indifferent memories of childhood owe their existence to a process of displacement: they are substitutes, in reproduction, for other impressions which are really significant. The memory of these significant impressions can be developed out of the indifferent ones by means of psychical analysis, but a resistance prevents them from being directly reproduced. As the indifferent memories owe their preservation not to their own content but to an associative relation between their content and another which is repressed, they have some claim to be called 'screen memories', the name by which I have described them.

In the paper which I have mentioned I only touched on and in no way exhausted the multiplicity of the relations and meanings of screen memories. In the example quoted there, of which I gave a detailed analysis, I laid special stress on the peculiarity of the chronological relation between the screen memory and the content which is screened off by it. In that example the content of the screen memory belonged to one of the earliest years of childhood, while the mental experiences which were replaced by it in the memory and which had remained almost unconscious occurred in the subject's later life, I described this sort of displacement as a retroactive or retrogressive one. The opposite relation is found perhaps still more frequently: an indifferent impression of recent date establishes itself in the memory as a screen memory, although it owes that privilege merely to its connection with an earlier experience which resistances prevent from being reproduced directly. These would be screen memories that have pushed ahead or been displaced forward. Here the essential thing with which the memory is occupied precedes the screen memory in time. Finally, we find yet a third possibility, in which the screen memory is connected with the impression that it screens not only by its content but also by contiguity in time: these are contemporary or contiguous screen memories.

How large a part of our store of memory falls into the category of screen memories, and what role they play in various neurotic thought-processes, are problems whose significance I neither discussed in my earlier paper nor shall enter into here. My only concern is to emphasize the similarity between the forgetting of proper names accompanied by paramnesia, and the formation of screen memories.
At first sight the differences between the two phenomena are much more striking than any analogies that may be found. The former phenomenon relates to proper names; the latter to whole impressions, things experienced either in reality or in thought. In the former we have a manifest failure of the function of memory; in the latter, an act of memory that strikes us as strange. In the former it is a case of momentary disturbance - for the name that has just been forgotten may have been produced correctly a hundred times before, and from tomorrow may be produced once again; in the latter it is a case of a permanent and constant memory, since the indifferent childhood memories seem to have the power of staying with us through a large part of our life. The problem in these two cases appears to be quite differently focused. In the former it is the forgetting, in the latter the retention which arouses our scientific curiosity. Closer study reveals that in spite of the dissimilarity between the two phenomena in regard to their psychical material and their duration, the points at which they agree far outbalance it. Both have to do with mistakes in remembering: what the memory reproduces is not what it should correctly have reproduced, but something else as a substitute. In the case of the forgetting of names the act of memory occurs, though in the form of substitute names; the case of the formation of screen memories has as its basis a forgetting of other more important impressions. In both instances an intellectual feeling gives us information of interference by some disturbing factor; but it takes two different forms. With the forgetting of names we know that the substitute names are false: with screen memories we are surprised that we possess them at all. If, now, psychological analysis establishes that the substitutive formation has come about in the same way in both cases, by means of displacement along a superficial association, it is precisely the dissimilarities between the two phenomena, in regard to their material, their duration and their focal point, which serve to heighten our expectation that we have discovered something of importance and of general validity. This general principle would assert that when the reproducing function fails or goes astray, the occurrence points, far more frequently than we suspect, to interference by a tendentious factor - that is, by a purpose which favours one memory while striving to work against another.

[1901b, 1139]

Of the childhood memories that have been retained a few strike us as perfectly understandable, while others seem odd or unintelligible. It is not difficult to correct certain errors regarding both sorts. If the memories that a person has retained are subjected to an analytic enquiry, it is easy to establish that there is no guarantee of their accuracy. Some of the mnemonic images are certainly falsified, incomplete or displaced in time and place. Any such statement by the subjects of the enquiry as that their first recollection comes from about their second year is clearly not to be trusted. Moreover, motives can soon be discovered which make the distortion and displacement of the experience intelligible, but which show at the same time that these mistakes in recollection cannot be caused simply by a treacherous memory. Strong forces from later life have been at work on the capacity of childhood experiences for being remembered - probably the same forces which are responsible for our having become so far removed in general from understanding our years of childhood.

[1901b, 1140]
Remembering in adults, as is well known, makes use of a variety of psychical material. Some people remember in visual images; their memories have a visual character. Other people can scarcely reproduce in their memory even the scantiest outlines of what they have experienced. Following Charcot's proposal, such people are called *auditifs* and *moteurs* in contrast to the *visuels*. In dreams these distinctions disappear: we all dream predominantly in visual images. But this development is similarly reversed in the case of childhood memories: they are plastically visual even in people whose later function of memory has to do without any visual element. Visual memory accordingly preserves the type of infantile memory. In my own case the earliest childhood memories are the only ones of a visual character: they are regular scenes worked out in plastic form, comparable only to representations on the stage. In these scenes of childhood, whether in fact they prove to be true or falsified, what one sees invariably includes oneself as a child, with a child's shape and clothes. This circumstance must cause surprise: in their recollections of later experiences adult *visuels* no longer see themselves. Furthermore it contradicts all that we have learnt to suppose that in his experiences a child's attention is directed to himself instead of exclusively to impressions from outside. One is thus forced by various considerations to suspect that in the so-called earliest childhood memories we possess not the genuine memory-trace but a later revision of it, a revision which may have been subjected to the influences of a variety of later psychical forces. Thus the 'childhood memories' of individuals come in general to acquire the significance of 'screen memories' and in doing so offer a remarkable analogy with the childhood memories that a nation preserves in its store of legends and myths.

[1901b, 1141]

Anyone who has investigated a number of people psychologically by the method of psychoanalysis will in the course of his work have collected numerous examples of every kind of screen memory. However, the reporting of these examples is made extraordinarily difficult owing to the nature of the relations, which I have just discussed, between childhood memories and later life. In order to show that a childhood memory is to be regarded as a screen memory, it would often be necessary to present the complete life history of the person in question. Only rarely is it possible to lift a single screen memory out of its context in order to give an account of it, as in the following good example.

[1901b, 1142]

A man of twenty-four has preserved the following picture from his fifth year. He is sitting in the garden of a summer villa, on a small chair beside his aunt, who is trying to teach him the letters of the alphabet. He is in difficulties over the difference between *m* and *n* and he asks his aunt to tell him how to know one from the other. His aunt points out to him that the *m* has a whole piece more than the *n* - the third stroke. There appeared to be no reason for challenging the trustworthiness of this childhood memory; it had, however, only acquired its meaning at a later date, when it showed itself suited to represent symbolically another of the boy's curiosities. For just as at that time he wanted to know the difference between *m* and *n*, so later he was anxious to find out the difference between boys and girls, and would have been very willing for this particular aunt to be the one to teach him. He also discovered then that the difference was a similar one - that a boy, too, has a whole piece more than a girl; and at the time when he acquired this piece of knowledge he called up the recollection of the parallel curiosity of his childhood.

[1901b, 1142]
Here is another example, from the later years of childhood. A man who is severely inhibited in his erotic life, and who is now over forty, is the eldest of nine children. At the time that the youngest of his brothers and sisters was born he was fifteen, yet he maintains firmly and obstinately that he had never noticed any of his mother's pregnancies. Under pressure from my scepticism a memory presented itself to him: once at the age of eleven or twelve he had seen his mother hurriedly unfasten her skirt in front of the mirror. He now added of his own accord that she had come in from the street and had been overcome by unexpected labour pains. The unfastening of the skirt was a screen memory for the confinement. We shall come across the use of 'verbal bridges' of this kind in further cases.

[1901b, 1142]
I should like now to give a single example of the way in which a childhood memory, which previously appeared to have no meaning, can acquire one as a result of being worked over by analysis. When I began in my forty-third year to direct my interest to what was left of my memory of my own childhood there came to my mind a scene which had for a long while back (from the remotest past, as it seemed to me) come into consciousness from time to time, and which I had good evidence for assigning to a date before the end of my third year. I saw myself standing in front of a cupboard demanding something and screaming, while my half-brother, my senior by twenty years, held it open. Then suddenly my mother, looking beautiful and slim, walked into the room, as if she had come in from the street. These were the words in which I described the scene, of which I had a plastic picture, but I did not know what more I could make of it. Whether my brother wanted to open or shut the cupboard - in my first translation of the picture I called it a 'wardrobe' - why I was crying, and what the arrival of my mother had to do with it all this was obscure to me. The explanation I was tempted to give myself was that what was in question was a memory of being teased by my elder brother and of my mother putting a stop to it. Such misunderstandings of a childhood scene which is preserved in the memory are by no means rare: a situation is recalled, but it is not clear what its central point is, and one does not know on which of its elements the psychical accent is to be placed. Analytic effort led me to take a quite unexpected view of the picture. I had missed my mother, and had come to suspect that she was shut up in this wardrobe or cupboard; and it was for that reason that I was demanding that my brother should open the cupboard. When he did what I asked and I had made certain that my mother was not in the cupboard, I began to scream. This is the moment that my memory has held fast; and it was followed at once by the appearance of my mother, which allayed my anxiety or longing. But how did the child get the idea of looking for his absent mother in the cupboard? Dreams which I had at the same time contained obscure allusions to a nurse of whom I had other recollections, such as, for example, that she used to insist on my dutifully handing over to her the small coins I received as presents - a detail which can itself claim to have the value of a screen memory for later experiences. I accordingly resolved that this time I would make the problem of interpretation easier for myself and would ask my mother, who was by then grown old, about the nurse. I learned a variety of details, among them that this clever but dishonest person had carried out considerable thefts in the house during my mother's confinement and had been taken to court on a charge preferred by my half-brother. This information threw a flood of light on the childhood scene, and so enabled me to understand it. The sudden disappearance of the nurse had not been a matter of indifference to me: the reason why I had turned in particular to this brother, and had asked him where she was, was probably because I had noticed that he played a part in her disappearance; and he had answered in the elusive and punning fashion that was characteristic of him: 'She's "boxed up".' At the time, I understood this answer in a child's way, but I stopped asking any more questions as there was nothing more to learn. When my mother left me a short while later, I suspected that my naughty brother had done the same thing to her that he had done to the nurse and I forced him to open the cupboard for me. I now understand, too, why in the translation of this visual childhood scene my mother's slimness was emphasized: it must have struck me as having just been restored to her. I am two and a half years older than the sister who was born at that time, and when I was three years old my half-brother and I ceased living in the same place.
¹ Dora's brother must have been concerned in some way with her having acquired the habit of masturbation; for in this connection she told me, with all the emphasis which betrays the presence of a 'screen memory', that her brother used regularly to pass on all his infectious illnesses to her, and that while he used to have them lightly she used, on the contrary, to have them severely. In the dream her brother as well as she was saved from 'destruction'; he, too, had been subject to bed-wetting, but had got over the habit before his sister. Her declaration that she had been able to keep abreast with her brother up to the time of her first illness, but that after that she had fallen behind him in her studies, was in a certain sense also a 'screen memory'. It was as though she had been a boy up till that moment, and had then become girlish for the first time. She had in truth been a wild creature; but after the 'asthma' she became quiet and well-behaved. That illness formed the boundary between two phases of her sexual life, of which the first was masculine in character, and the second feminine.

[1905e, 1417]

¹ [Footnote added 1920:] Deeper-going psycho-analytic research has raised a just criticism of Binet's assertion. All the observations dealing with this point have recorded a first meeting with the fetish at which it already aroused sexual interest without there being anything in the accompanying circumstances to explain the fact. Moreover, all of these 'early' sexual impressions relate to a time after the age of five or six, whereas psycho-analysis makes it doubtful whether fresh pathological fixations can occur so late as this. The true explanation is that behind the first recollection of the fetish's appearance there lies a submerged and forgotten phase of sexual development. The fetish, like a 'screen memory', represents this phase and is thus a remnant and precipitate of it. The fact that this early infantile phase turns in the direction of fetishism, as well as the choice of the fetish itself, are constitutionally determined.

[1905d, 1481]

SECOND PHASE OF INFANTILE MASTURBATION  The masturbation of early infancy seems to disappear after a short time; but it may persist uninterruptedly until puberty, and this would constitute the first great deviation from the course of development laid down for civilized men. At some point of childhood after early infancy, as a rule before the fourth year, the sexual instinct belonging to the genital zone usually revives and persists again for a time until it is once more suppressed, or it may continue without interruption. This second phase of infantile sexual activity may assume a variety of different forms which can only be determined by a precise analysis of individual cases. But all its details leave behind the deepest (unconscious) impressions in the subject's memory, determine the development of his character, if he is to remain healthy, and the symptomatology of his neurosis, if he is to fall ill after puberty.¹ In the latter case we find that this sexual period has been forgotten and that the conscious memories that bear witness to it have been displaced. (I have already mentioned that I am also inclined to relate normal infantile amnesia to this infantile sexual activity.) Psycho-analytic investigation enables us to make what has been forgotten conscious and thus do away with a compulsion that arises from the unconscious psychical material.

[1905d, 1509]
I do not think much of the objection that neurotics are a special class of people, marked by an innate disposition that is 'degenerate', from whose childhood life we must not be allowed to infer anything about the childhood of other people. Neurotics are people much like others. They cannot be sharply differentiated from normal people, and in their childhood they are not always easily distinguishable from those who remain healthy in later life. It is one of the most valuable results of our psycho-analytic investigations to have discovered that the neuroses of such people have no special mental content that is peculiar to them, but that, as Jung has expressed it, they fall ill of the same complexes against which we healthy people struggle as well. The only difference is that healthy people know how to overcome those complexes without any gross damage demonstrable in practical life, whereas in nervous cases the suppression of the complexes succeeds only at the price of costly substitutive formations - that is to say, from a practical point of view it is a failure. In childhood neurotic and normal people naturally approximate to each other much more closely than they do in later life, so that I cannot regard it as a methodological error to make use of the communications of neurotics about their childhood for drawing conclusions by analogy about normal childhood life. But since those who later become neurotics very often have in their inborn constitution an especially strong sexual instinct and a tendency to precocity and to a premature expression of that instinct, they make it possible for us to recognize a great deal of infantile activity more sharply and clearly than our capacity for observation (which is in any case a blunted one) would enable us to do in other children. But we shall of course only be able to assess the true value of these communications made by neurotic adults when, following Havelock Ellis's example, we shall have thought it worth while to collect the childhood memories of healthy adults as well.

¹ In psycho-analyses we frequently come across occurrences of this kind, dating back to the earliest years of the patient's childhood, in which his infantile sexual activity appears to reach its climax and often comes to a catastrophic end owing to some misfortune or punishment. Such occurrences are apt to appear in a shadowy way in dreams. Often they will become so clear that the analyst thinks he has a firm hold of them, and will nevertheless evade any final elucidation; and unless he proceeds with the greatest skill and caution he may be compelled to leave it undecided whether the scene in question actually took place or not. It will help to put us upon the right track in interpreting it, if we recognize that more than one version of the scene (each often differing greatly from the other) may be detected in the patient's unconscious phantasies. If we do not wish to go astray in our judgement of their historical reality, we must above all bear in mind that people's 'childhood memories' are only consolidated at a later period, usually at the age of puberty; and that this involves a complicated process of remodelling, analogous in every way to the process by which a nation constructs legends about its early history. It at once becomes evident that in his phantasies about his infancy the individual as he grows up endeavours to efface the recollection of his auto-erotic activities; and this he does by exalting their memory-traces to the level of object-love, just as a real historian will view the past in the light of the present. This explains why these phantasies abound in seductions and assaults, where the facts will have been confined to auto-erotic activities and the caresses or punishments that stimulated them. Furthermore, it becomes clear that in constructing phantasies about his childhood the individual sexualizes his memories; that is, he brings commonplace experiences into relation with his sexual activity, and extends his sexual interest to them - though in doing this he is probably following upon the traces of a really existing connection. No one who remembers my 'Analysis of a Phobia in a Five-Year-Old Boy' will need to be told that it is not my intention in these remarks to detract from the importance which I have hitherto attached to infantile sexuality by reducing it to nothing more than sexual interest at the age of puberty. I merely wish to give some technical advice that may help to clear up a class of phantasy which is calculated to falsify the picture of infantile sexual activity.
The content of the sexual life of infancy consists in auto-erotic activity on the part of the dominant sexual components, in traces of object-love, and in the formation of that complex which deserves to be called the nuclear complex of the neuroses. It is the complex which comprises the child's earliest impulses, alike tender and hostile, towards its parents and brothers and sisters, after its curiosity has been awakened - usually by the arrival of a new baby brother or sister. The uniformity of the content of the sexual life of children, together with the unvarying character of the modifying tendencies which are later brought to bear upon it, will easily account for the constant sameness which as a rule characterizes the phantasies that are constructed around the period of childhood, irrespective of how greatly or how little real experiences have contributed towards them. It is entirely characteristic of the nuclear complex of infancy that the child's father should be assigned the part of a sexual opponent and of an interferer with auto-erotic sexual activities; and real events are usually to a large extent responsible for bringing this about.

What we have here then is a childhood memory; and certainly one of the strangest sort. It is strange on account of its content and on account of the age to which it is assigned. That a person should be able to retain a memory of his suckling period is perhaps not impossible, but it cannot by any means be regarded as certain. What, however, this memory of Leonardo's asserts - namely that a vulture opened the child's mouth with its tail - sounds so improbable, so fabulous, that another view of it, which at a single stroke puts an end to both difficulties, has more to commend it to our judgement. On this view the scene with the vulture would not be a memory of Leonardo's but a phantasy, which he formed at a later date and transposed to his childhood.

² [Footnote added 1919:] In a friendly notice of this book Havelock Ellis (1910) has challenged the view put forward above. He objects that this memory of Leonardo's may very well have had a basis of reality; since children's memories often reach very much further back than is commonly supposed; the large bird in question need not of course have been a vulture. This is a point that I will gladly concede, and as a step towards lessening the difficulty I in turn will offer a suggestion - namely that his mother observed the large bird's visit to her child - an event which may easily have had the significance of an omen in her eyes - and repeatedly told him about it afterwards. As a result, I suggest, he retained the memory of his mother's story, and later, as so often happens, it became possible for him to take it for a memory of an experience of his own. However, this alteration does no damage to the force of my general account. It happens, indeed, as a general rule that the phantasies about their childhood which people construct at a late date are attached to trivial but real events of this early, and normally forgotten, period. There must thus have been some secret reason for bringing into prominence a real event of no importance and for elaborating it in the sort of way Leonardo did in his story of the bird, which he dubbed a vulture, and of its remarkable behaviour.
This is often the way in which childhood memories originate. Quite unlike conscious memories from the time of maturity, they are not fixed at the moment of being experienced and afterwards repeated, but are only elicited at a later age when childhood is already past; in the process they are altered and falsified, and are put into the service of later trends, so that generally speaking they cannot be sharply distinguished from phantasies. Their nature is perhaps best illustrated by a comparison with the way in which the writing of history originated among the peoples of antiquity. As long as a nation was small and weak it gave no thought to the writing of its history. Men tilled the soil of their land, fought for their existence against their neighbours, and tried to gain territory from them and to acquire wealth. It was an age of heroes, not of historians. Then came another age, an age of reflection: men felt themselves to be rich and powerful, and now felt a need to learn where they had come from and how they had developed. Historical writing, which had begun to keep a continuous record of the present, now also cast a glance back to the past, gathered traditions and legends, interpreted the traces of antiquity that survived in customs and usages, and in this way created a history of the past. It was inevitable that this early history should have been an expression of present beliefs and wishes rather than a true picture of the past; for many things had been dropped from the nation's memory, while others were distorted, and some remains of the past were given a wrong interpretation in order to fit in with contemporary ideas. Moreover people's motive for writing history was not objective curiosity but a desire to influence their contemporaries, to encourage and inspire them, or to hold a mirror up before them. A man's conscious memory of the events of his maturity is in every way comparable to the first kind of historical writing; while the memories that he has of his childhood correspond, as far as their origins and reliability are concerned, to the history of a nation's earliest days, which was compiled later and for tendentious reasons.

If, then, Leonardo's story about the vulture that visited him in his cradle is only a phantasy from a later period, one might suppose it could hardly be worth while spending much time on it. One might be satisfied with explaining it on the basis of his inclination, of which he makes no secret, to regard his preoccupation with the flight of birds as pre-ordained by destiny. Yet in underrating this story one would be committing just as great an injustice as if one were carelessly to reject the body of legends, traditions and interpretations found in a nation's early history. In spite of all the distortions and misunderstandings, they still represent the reality of the past: they are what a people forms out of the experience of its early days and under the dominance of motives that were once powerful and still operate to-day; and if it were only possible, by a knowledge of all the forces at work, to undo these distortions, there would be no difficulty in disclosing the historical truth lying behind the legendary material. The same holds good for the childhood memories or phantasies of an individual. What someone thinks he remembers from his childhood is not a matter of indifference; as a rule the residual memories - which he himself does not understand - cloak priceless pieces of evidence about the most important features in his mental development. As we now possess in the techniques of psycho-analysis excellent methods for helping us to bring this concealed material to light, we may venture to fill in the gap in Leonardo's life story by analysing his childhood phantasy. And if in doing so we remain dissatisfied with the degree of certainty which we achieve, we shall have to console ourselves with the reflection that so many other studies of this great and enigmatic man have met with no better fate.
Footnote added 1919: Since I wrote the above words I have attempted to make similar use of an unintelligible memory dating from the childhood of another man of genius. In the account of his life that Goethe wrote when he was about sixty (‘Dichtung und Warheit’) there is a description in the first few pages of how, with the encouragement of his neighbours, he slung first some small and then some large pieces of crockery out of the window into the street, so that they were smashed to pieces. This is, indeed, the only scene that he reports from the earliest years of childhood. The sheer inconsequentiality of its content, the way in which it corresponded with the childhood memories of other human beings who did not become particularly great, and the absence in this passage of any mention of the young brother who was born when Goethe was three and three-quarters, and who died when he was nearly ten - all this induced me to undertake an analysis of this childhood memory. (This child is in fact mentioned at a later point in the book, where Goethe dwells on the many illnesses of childhood.) I hoped to be able as a result to replace it by something which would be more in keeping with the context of Goethe’s account and whose content would make it worthy of preservation and of the place he has given it in the history of his life. The short analysis made it possible for the throwing-out of the crockery to be recognized as a magical act directed against a troublesome intruder; and at the place in the book where he describes the episode the intention is to triumph over the fact that a second son was not in the long run permitted to disturb Goethe’s close relation with his mother. If the earliest memory of childhood, preserved in disguises such as these, should be concerned - in Goethe’s case as well as in Leonardo's - with the mother, what would be so surprising in that?

Our aim in dissecting a childhood phantasy is to separate the real memory that it contains from the later motives that modify and distort it. In Leonardo’s case we believe that we now know the real content of the phantasy: the replacement of his mother by the vulture indicates that the child was aware of his father’s absence and found himself alone with his mother. The fact of Leonardo’s illegitimate birth is in harmony with his vulture phantasy; it was only on this account that he could compare himself to a vulture-child. But the next reliable fact that we possess about his youth is that by the time he was five he had been received into his father’s household. We are completely ignorant when that happened - whether it was a few months after his birth or whether it was a few weeks before the drawing-up of the land-register. It is here that the interpretation of the vulture phantasy comes in: Leonardo, it seems to tell us, spent the critical first years of his life not by the side of his father and stepmother, but with his poor, forsaken, real mother, so that he had time to feel the absence of his father. This seems a slender and yet a somewhat daring conclusion to have emerged from our psycho-analytic efforts, but its significance will increase as we continue our investigation. Its certainty is reinforced when we consider the circumstances that did in fact operate in Leonardo’s childhood. In the same year that Leonardo was born, the sources tell us, his father, Ser Piero da Vinci, married Donna Albiera, a lady of good birth; it was to the childlessness of this marriage that the boy owed his reception into his father’s (or rather his grandfather’s) house - an event which had taken place by the time he was five years old, as the document attests. Now it is not usual at the start of a marriage to put an illegitimate offspring into the care of the young bride who still expects to be blessed with children of her own. Years of disappointment must surely first have elapsed before it was decided to adopt the illegitimate child - who had probably grown up an attractive young boy - as a compensation for the absence of the legitimate children that had been hoped for. It fits in best with the interpretation of the vulture phantasy if at least three years of Leonardo’s life, and perhaps five, had elapsed before he could exchange the solitary person of his mother for a parental couple. And by then it was too late. In the first three or four years of life certain impressions become fixed and ways of reacting to the outside world are established which can never be deprived of their importance by later experiences.

[1910c, 2261]
If it is true that the unintelligible memories of a person's childhood and the phantasies that are built on them invariably emphasize the most important elements in his mental development, then it follows that the fact which the vulture phantasy confirms, namely that Leonardo spent the first years of his life alone with his mother, will have been of decisive influence in the formation of his inner life. An inevitable effect of this state of affairs was that the child - who was confronted in his early life with one problem more than other children - began to brood on this riddle with special intensity, and so at a tender age became a researcher, tormented as he was by the great question of where babies come from and what the father has to do with their origin. It was a vague suspicion that his researches and the history of his childhood were connected in this way which later prompted him to exclaim that he had been destined from the first to investigate the problem of the flight of birds since he had been visited by a vulture as he lay in his cradle. Later on it will not be difficult to show how his curiosity about the flight of birds was derived from the sexual researches of his childhood.

[1910c, 2267]

At this point a little reflection will remind us that we ought not to feel satisfied yet with the way the vulture's tail in Leonardo's childhood phantasy has been explained. Something more seems to be contained in it which we do not yet understand. Its most striking feature, after all, was that it changed sucking at the mother's breast into being suckled, that is, into passivity, and thus into a situation whose nature is undoubtedly homosexual. When we remember the historical probability of Leonardo having behaved in his life as one who was emotionally homosexual, the question is forced upon us whether this phantasy does not indicate the existence of a causal connection between Leonardo's relation with his mother in childhood and his later manifest, if ideal, homosexuality. We should not venture to infer a connection of this sort from Leonardo's distorted reminiscence if we did not know from the psycho-analytic study of homosexual patients that such a connection does exist and is in fact an intimate and necessary one.

[1910c, 2273]
To these phantasies which have succeeded in dominating the man's love in real life, the urge to rescue the loved one seems to bear merely a loose and superficial relation, and one that is fully accounted for by conscious reasons. By her propensity to be fickle and unfaithful the loved one brings herself into dangerous situations, and thus it is understandable that the lover should be at pains to protect her from these dangers by watching over her virtue and counteracting her bad inclinations. However, the study of people's screen-memories, phantasies and nocturnal dreams shows that we have here a particularly felicitous 'rationalization' of an unconscious motive, a process which may be compared to a successful secondary revision of a dream. In actual fact the 'rescue-motif' has a meaning and history of its own, and is an independent derivative of the mother-complex, or more accurately, of the parental complex. When a child hears that he owes his life to his parents, or that his mother gave him life, his feelings of tenderness unite with impulses which strive at power and independence, and they generate the wish to return this gift to the parents and to repay them with one of equal value. It is as though the boy's defiance were to make him say: 'I want nothing from my father; I will give him back all I have cost him.' He then forms the phantasy of rescuing his father from danger and saving his life; in this way he puts his account square with him. This phantasy is commonly enough displaced on to the emperor, king or some other great man; after being thus distorted it becomes admissible to consciousness, and may even be made use of by creative writers. In its application to a boy's father it is the defiant meaning in the idea of rescuing which is by far the most important; where his mother is concerned it is usually its tender meaning. The mother gave the child life, and it is not easy to find a substitute, of equal value for this unique gift. With a slight change of meaning, such as is easily effected in the unconscious and is comparable to the way in which in consciousness concepts shade into one another, rescuing his mother takes on the significance of giving her a child or making a child for her - needless to say, one like himself. This is not too remote from the original sense of rescuing, and the change in meaning is not an arbitrary one. His mother gave him a life - his own life - and in exchange he gives her another life, that of a child which has the greatest resemblance to himself. The son shows his gratitude by wishing to have by his mother a son who is like himself: in other words, in the rescue-phantasy he is completely identifying himself with his father. All his instincts, those of tenderness, gratitude, lustfulness, defiance and independence, find satisfaction in the single wish to be his own father. Even the element of danger has not been lost in the change of meaning; for the act of birth itself is the danger from which he was saved by his mother's efforts. Birth is both the first of all dangers to life and the prototype of all the later ones that cause us to feel anxiety, and the experience of birth has probably left behind in us the expression of affect which we call anxiety. Macduff of the Scottish legend, who was not born of his mother but ripped from her womb, was for that reason unacquainted with anxiety.

It is not surprising to find that psycho-analysis confirms our recognition of the important place which folk fairy tales have acquired in the mental life of our children. In a few people a recollection of their favourite fairy tales takes the place of memories of their own childhood; they have made the fairy tales into screen memories.

Psycho-analysis has been obliged to derive the mental life of adults from that of children, and has had to take seriously the old saying that the child is father to the man. It has traced the continuity between the infantile and adult mind, and has also noted the transformations and rearrangements that occur in the process. In most of us there is a gap in our memories covering the first years of our childhood, of which only a few fragmentary recollections survive. Psycho-analysis may be said to have filled in this gap and to have abolished man's infantile amnesia.

(See the section on 'Educational Interest' below.)
'Once when my uncle went away on a journey he asked me and my sister what we should like him to bring us back. My sister asked for a book, and I asked for a pocket-knife.' We now understood that this association which had emerged months before had in reality been a screen memory for the repressed recollection, and had been an attempt (rendered abortive by resistance) at telling the story of his imagined loss of his little finger - an unmistakable equivalent for his penis. The knife which his uncle did in fact bring him back was, as he clearly remembered, the same one that made its appearance in the episode which had been suppressed for so long.

[1914a, 2840]

A second remarkable fact to which I must draw your attention, and which comes on top of the first one, is that out of the void of memories that covers the earliest years of childhood there stand out a few well-preserved recollections, mostly perceived in plastic form, which cannot justify their survival. Our memory deals with the material of the impressions which impinge on us in later life by making a selection among them. It retains what is of any importance and drops what is unimportant. But this is not true of the childhood memories that have been retained. They do not necessarily correspond to the important experiences of childhood years, nor even to those which must have seemed important from the child's point of view. They are often so commonplace and insignificant that we can only ask ourselves in astonishment why this particular detail has escaped oblivion. I attempted long ago, with the help of analysis, to attack the enigma of childhood amnesia and of the residual memories which interrupt it, and I arrived at the conclusion that even in the case of children it is true in spite of everything that only what is important remains in the memory. But through the processes, already familiar to you, of condensation and more especially of displacement, what is important is replaced in memory by something else which appears unimportant. For this reason I have called these childhood memories 'screen memories', and with a thorough analysis everything that has been forgotten can be extracted from them.

[1916-1917, 3290]

I have warned you that we still have something new to learn; it is indeed something surprising and perplexing. By means of analysis, as you know, starting from the symptoms, we arrive at a knowledge of the infantile experiences to which the libido is fixated and out of which the symptoms are made. Well, the surprise lies in the fact that these scenes from infancy are not always true. Indeed, they are not true in the majority of cases, and in a few of them they are the direct opposite of the historical truth. As you will see, this discovery is calculated more than any other to discredit either analysis, which has led to this result, or the patients, on whose statements the analysis and our whole understanding of the neuroses are founded. But there is something else remarkably perplexing about it. If the infantile experiences brought to light by analysis were invariably real, we should feel that we were standing on firm ground; if they were regularly falsified and revealed as inventions, as phantasies of the patient, we should be obliged to abandon this shaky ground and look for salvation elsewhere. But neither of these things is the case: the position can be shown to be that the childhood experiences constructed or remembered in analysis are sometimes indisputably false and sometimes equally certainly correct, and in most cases compounded of truth and falsehood. Sometimes, then, symptoms represent events which really took place and to which we may attribute an influence on the fixation of the libido, and sometimes they represent phantasies of the patient's which are not, of course, suited to playing an aetiological role. It is difficult to find one's way about in this. We can make a first start, perhaps, with a similar discovery - namely, that the isolated childhood memories that people have possessed consciously from time immemorial and before there was any such thing as analysis may equally be falsified or at least may combine truth and falsehood in plenty. In their case there is seldom any difficulty in showing their incorrectness; so we at least have the reassurance of knowing that the responsibility for this unexpected disappointment lies, not with analysis, but in some way with the patients.

[1916-1917, 3424]
After a little reflection we shall easily understand what it is about this state of things that perplexes us so much. It is the low valuation of reality, the neglect of the distinction between it and phantasy. We are tempted to feel offended at the patient's having taken up our time with invented stories. Reality seems to us something worlds apart from invention, and we set a very different value on it. Moreover the patient, too, looks at things in this light in his normal thinking. When he brings up the material which leads from behind his symptoms to the wishful situations modelled on his infantile experiences, we are in doubt to begin with whether we are dealing with reality or phantasies. Later, we are enabled by certain indications to come to a decision and we are faced by the task of conveying it to the patient. This, however, invariably gives rise to difficulties. If we begin by telling him straight away that he is now engaged in bringing to light the phantasies with which he has disguised the history of his childhood (just as every nation disguises its forgotten prehistory by constructing legends), we observe that his interest in pursuing the subject further suddenly diminishes in an undesirable fashion. He too wants to experience realities and despises everything that is merely 'imaginary'. If, however, we leave him, till this piece of work is finished, in the belief that we are occupied in investigating the real events of his childhood, we run the risk of his later on accusing us of being mistaken and laughing at us for our apparent credulity. It will be a long time before he can take in our proposal that we should equate phantasy and reality and not bother to begin with whether the childhood experiences under examination are the one or the other. Yet this is clearly the only correct attitude to adopt towards these mental productions. They too possess a reality of a sort. It remains a fact that the patient has created these phantasies for himself, and this fact is of scarcely less importance for his neurosis than if he had really experienced what the phantasies contain. The phantasies possess psychical as contrasted with material reality, and we gradually learn to understand that in the world of the neuroses it is psychical reality which is the decisive kind.

[1916-1917, 3425]
Among the occurrences which recur again and again in the youthful history of neurotics - which are scarcely ever absent - there are a few of particular importance, which also deserve, on that account, I think, to be brought into greater prominence than the rest. As specimens of this class I will enumerate these: observation of parental intercourse, seduction by an adult and threat of being castrated. It would be a mistake to suppose that they are never characterized by material reality; on the contrary, this is often established incontestably through enquiries from older members of the patient's family. It is by no means a rare thing, for instance, for a little boy, who is beginning to play with his penis in a naughty way and is not yet aware that one must conceal such activities, to be threatened by a parent or nurse with having his penis or his sinful hand cut off. Parents will often admit this when they are asked, since they think they have done something useful in making such a threat; a number of people have a correct conscious memory of such a threat, especially if it was made at a somewhat later period. If the threat is delivered by the mother or some other female she usually shifts its performance on to the father or the doctor. In *Struwwelpeter*, the famous work of the Frankfurt paediatrician Hoffmann (which owes its popularity precisely to an understanding of the sexual and other complexes of childhood), you will find castration softened into a cutting-off of the thumbs as a punishment for obstinate sucking. But it is highly improbable that children are threatened with castration as often as it appears in the analyses of neurotics. We shall be satisfied by realizing that the child puts a threat of this kind together in his imagination on the basis of hints, helped out by a knowledge that auto-erotic satisfaction is forbidden and under the impression of his discovery of the female genitals. Nor is it only in proletarian families that it is perfectly possible for a child, while he is not yet credited with possessing an understanding or a memory, to be a witness of the sexual act between his parents or other grown-up people; and the possibility cannot be rejected that he will be able to understand and react to the impression in retrospect. If, however, the intercourse is described with the most minute details, which would be difficult to observe, or if, as happens most frequently, it turns out to have been intercourse from behind *more ferarum* [in the manner of animals], there can be no remaining doubt that the phantasy is based on an observation of intercourse between animals (such as dogs) and that its motive was the child's unsatisfied scopophilia during puberty. The extreme achievement on these lines is a phantasy of observing parental intercourse while one is still an unborn baby in the womb. Phantasies of being seduced are of particular interest, because so often they are not phantasies but real memories. Fortunately, however, they are nevertheless not real as often as seemed at first to be shown by the findings of analysis. Seduction by an older child or by one of the same age is even more frequent than by an adult; and if in the case of girls who produce such an event in the story of their childhood their father figures fairly regularly as the seducer, there can be no doubt either of the imaginary nature of the accusation or of the motive that has led to it. A phantasy of being seduced when no seduction has occurred is usually employed by a child to screen the auto-erotic period of his sexual activity. He spares himself shame about masturbation by retrospectively phantasying a desired object into these earliest times. You must not suppose, however, that sexual abuse of a child by its nearest male relatives belongs entirely to the realm of phantasy. Most analysts will have treated cases in which such events were real and could be unimpeachably established; but even so they related to the later years of childhood and had been transposed into earlier times.

[1916-1917, 3426]
As far back as he could remember he was looked after by a nurse, an uneducated old woman of peasant birth, with an untiring affection for him. He served her as a substitute for a son of her own who had died young. The family lived on a country estate, from which they used to move to another for the summer. The two estates were not far from a large town. There was a break in his childhood when his parents sold the estates and moved into the town. Near relatives used often to pay them long visits upon one estate or the other - brothers of his father, sisters of his mother and their children, and his grandparents on his mother's side. During the summer his parents used to be away for a few weeks. In a screen memory he saw himself with his nurse looking after the carriage which was driving off with his father, mother and sister, and then going peaceably back into the house. He must have been very small at that time.¹ Next summer his sister was left at home, and an English governess was engaged, who became responsible for the supervision of the children.

[1918b, 3509]

It is easy to understand that the first suspicion fell upon the English governess, for the change in the boy made its appearance while she was there. Two screen memories had persisted, which were incomprehensible in themselves, and which related to her. On one occasion, as she was walking along in front of them, she said: 'Do look at my little tail!' Another time, when they were on a drive, her hat flew away, to the two children's great satisfaction. This pointed to the castration complex, and might permit of a construction being made to the effect that a threat uttered by her against the boy had been largely responsible for originating his abnormal conduct. There is no danger at all in communicating constructions of this kind to the person under analysis; they never do any damage to the analysis if they are mistaken; but at the same time they are not put forward unless there is some prospect of reaching a nearer approximation to the truth by means of them. The first effect of this supposition was the appearance of some dreams, which it was not possible to interpret completely, but all of which seemed to centre around the same material. As far as they could be understood, they were concerned with aggressive actions on the boy's part against his sister or against the governess and with energetic reproofs and punishments on account of them. It was as though . . . after her bath . . . he had tried . . . to undress his sister . . . to tear off her coverings . . . or veils - and so on. But it was not possible to get at any firm content from the interpretation; and since these dreams gave an impression of always working over the same material in various different ways, the correct reading of these ostensible reminiscences became assured: it could only be a question of phantasies, which the dreamer had made on the subject of his childhood at some time or other, probably at the age of puberty, and which had now come to the surface again in this unrecognizable form.

[1918b, 3512]
I am anxious not to be misunderstood. Every analyst knows - and he has met with the experience on countless occasions - that in the course of a successful treatment the patient brings up a large number of spontaneous recollections from his childhood, for the appearance of which (a first appearance, perhaps) the physician feels himself entirely blameless, since he has not made any attempt at a construction which could have put any material of the sort into the patient's head. It does not necessarily follow that these previously unconscious recollections are always true. They may be; but they are often distorted from the truth, and interspersed with imaginary elements, just like the so-called screen memories which are preserved spontaneously. All that I mean to say is this: scenes, like this one in my present patient's case, which date from such an early period and exhibit a similar content, and which further lay claim to such an extraordinary significance for the history of the case, are as a rule not reproduced as recollections, but have to be divined - constructed - gradually and laboriously from an aggregate of indications. Moreover, it would be sufficient for the purposes of the argument if my admission that scenes of this kind do not become conscious in the shape of recollections applied only to cases of obsessional neurosis, or even if I were to limit my assertion to the case which we are studying here. [1918b, 3538]

The deeper significance of our patient's early screen memory, to the effect that he had his first fit of rage because he was not given enough presents one Christmas, is now revealed to us. What he was feeling the want of was sexual satisfaction, which he had taken as being anal. His sexual researches came during the course of the dream to understand what they had been prepared for finding before the dream, namely, that the sexual act solved the problem of the origin of babies. Even before the dream he had disliked babies. Once, when he had come upon a small unfledged bird that had fallen out of its nest, he had taken it for a human baby and been horrified at it. The analysis showed that all small animals, such as caterpillars and insects, that he had been so enraged with, had had the meaning of babies to him.¹ His position in regard to his elder sister had given him every opportunity for reflecting upon the relation between elder and younger children. His Nanya had once told him that his mother was so fond of him because he was the youngest, and this gave him good grounds for wishing that no younger child might come after him. His dread of this youngest child was revived under the influence of the dream which brought up before him his parents' intercourse. [1918b, 3564]

This memory recurred occasionally during the analysis, and called for an explanation; but for a long time none was to be found. Nevertheless it was to be assumed as a matter of course that a detail like this had not kept its place in his recollection on its own account, but that it was a screen-memory, representing something of more importance with which it was in some way connected. One day he told me that in his language a butterfly was called 'babushka', 'granny'. He added that in general butterflies had seemed to him like women and girls, and beetles and caterpillars like boys. So there could be little doubt that in this anxiety scene a recollection of some female person had been aroused. I will not hide the fact that at that time I put forward the possibility that the yellow stripes on the butterfly had reminded him of similar stripes on a piece of clothing worn by some woman. I only mention this as an illustration to show how inadequate the physician's constructive efforts usually are for clearing up questions that arise, and how unjust it is to attribute the results of analysis to the physician's imagination and suggestion. [1918b, 3571]

Many months later, in quite another connection, the patient remarked that the opening and shutting of the butterfly's wings while it was settled on the flower had given him an uncanny feeling. It had looked, so he said, like a woman opening her legs, and the legs then made the shape of a Roman V, which, as we know, was the hour at which, in his boyhood, and even up to the time of the treatment, he used to fall into a depressed state of mind. [1918b, 3572]
It thus became clear that behind the screen memory of the hunted butterfly the memory of the nursery-maid lay concealed. But the yellow stripes were not on her dress, but on the pear whose name was the same as hers. What, however, was the origin of the anxiety which had arisen when the memory of her had been activated? The obvious answer to this might have been the crude hypothesis that it had been this girl whom, when he was a small child, he had first seen making the movements with her legs which he had fixed in his mind with the Roman V - movements which allow access to the genitals. We spared ourselves such theorizing as this and waited for more material.

[1918b, 3573]

In every psycho-analytic investigation of a life-history it is always possible to explain the meaning of the earliest childhood memories along these lines. Indeed, it usually happens that the very recollection to which the patient gives precedence, which he relates first, with which he introduces the story of his life, proves to be the most important, the very one that holds the key to the secret pages of his mind. But the little childish episode related in Dichtung und Wahrheit does not rise to our expectations. The ways and means that with our patients lead to interpretation are of course not available to us here; the episode does not seem in itself to admit of any traceable connection with important impressions at a later date. A mischievous trick with damaging effects on the household economy, carried out under the spur of outside encouragement, is certainly no fitting headpiece for all that Goethe has to tell us of his richly filled life. An impression of utter innocence and irrelevance clings to this childish memory, and it might be taken as a warning not to stretch the claims of psycho-analysis too far nor to apply it in unsuitable places.

[1917b, 3619]
The little series of reminiscences must engage our attention for a while longer. I have stated elsewhere that such scenes of childhood are 'screen memories' selected at a later period, put together, and not infrequently falsified in the process. This subsequent remodelling serves a purpose that is sometimes easy to guess. In our case one can almost hear the writer's ego glorifying or soothing itself by means of this series of recollections. 'I was from infancy a particularly noble and compassionate creature. I learnt quite early that animals have souls as we have, and could not endure cruelty to animals. The sins of the flesh were far from me and I preserved my chastity till late in life.' With declarations such as these she was loudly contradicting the inferences that we have to make about her early childhood on the basis of our analytical experience, namely, that she had an abundance of premature sexual impulses and violent feelings of hatred for her mother and her younger brothers and sisters. (Besides the genital significance I have just assigned to it, the little bird may also be a symbol of a child, like all small animals; her recollection thus accentuated very insistently the fact that this small creature had the same right to exist as she herself.) Hence the short series of recollections furnishes a very nice example of a mental structure with a twofold aspect. Viewed superficially, we may find in it the expression of an abstract idea, here, as usually, with an ethical reference. In Silberer's nomenclature the structure has an anagogic content. On deeper investigation it reveals itself as a chain of phenomena belonging to the region of the repressed life of the instincts - it displays its psycho-analytic content. As you know, Silberer, who was among the first to issue a warning to us not to lose sight of the nobler side of the human soul, has put forward the view that all or nearly all dreams permit such a twofold interpretation, a purer, anagogic one beside the ignoble, psycho-analytic one. This is, however, unfortunately not so. On the contrary, an over-interpretation of this kind is rarely possible. To my knowledge no valid example of such a dream-analysis with a double meaning has been published up to the present time. But observations of this kind can often be made upon the series of associations that our patients produce during analytic treatment. On the one hand the successive ideas are linked by a line of association which is plain to the eye, while on the other hand you become aware of an underlying theme which is kept secret but which at the same time plays a part in all these ideas. The contrast between the two themes that dominate the same series of ideas is not always one between the lofty anagogic and the low psycho-analytic, but one rather between offensive and respectable or indifferent ideas - a fact that easily explains why such a chain of associations with a twofold determination arises. In our present example it is of course not accidental that the anagogic and the psycho-analytic interpretations stood in such a sharp contrast to each other; both related to the same material, and the later trend was no other than that of the reaction-formations which had been erected against the disowned instinctual impulses.

[1922a, 3894]

(1) (a) All these traumas occur in early childhood up to about the fifth year. Impressions from the time at which a child is beginning to talk stand out as being of particular interest; the periods between the ages of two and four seem to be the most important; it cannot be determined with certainty how long after birth this period of receptivity begins. (b) The experiences in question are as a rule totally forgotten, they are not accessible to memory and fall within the period of infantile amnesia, which is usually broken into by a few separate mnemic residues, what are known as 'screen memories'. (c) They relate to impressions of a sexual and aggressive nature, and no doubt also to early injuries to the ego (narcissistic mortifications). In this connection it should be remarked that such young children make no sharp distinction between sexual and aggressive acts, as they do later. (Cf. the misunderstanding of the sexual act in a sadistic sense.) The predominance of the sexual factor is, of course, most striking and calls for theoretical consideration.

[1939a, 4900]
Information of this kind may, as a rule, be employed as absolutely authentic material. So it may seem tempting to take the easy course of filling up the gaps in a patient's memory by making enquiries from the older members of his family; but I cannot advise too strongly against such a technique. Any stories that may be told by relatives in reply to enquiries and requests are at the mercy of every critical misgiving that can come into play. One invariably regrets having made oneself dependent upon such information; at the same time confidence in the analysis is shaken and a court of appeal is set up over it. Whatever can be remembered at all will anyhow come to light in the further course of analysis.

But his seduction by his sister was certainly not a phantasy. Its credibility was increased by some information which had never been forgotten and which dated from a later part of his life, when he was grown up. A cousin who was more than ten years his elder told him in a conversation about his sister that he very well remembered what a forward and sensual little thing she had been: once, when she was a child of four or five, she had sat on his lap and opened his trousers to take hold of his penis.

Let me return to your question about certainty. We have become quite generally convinced from the direct analytic examination of children that we were right in our interpretation of what adults told us about their childhood. In a number of cases, however, another sort of confirmation has become possible. The material of the analysis of some patients has enabled us to reconstruct certain external happenings, certain impressive events of their childhood years, of which they have preserved no conscious memory. Lucky accidents, information from parents or nurses, have afterwards provided irrefutable evidence that these occurrences which we had inferred really did take place. This, of course, has not happened often, but when it has it has made an overwhelming impression. The correct reconstruction, you must know, of such forgotten experiences of childhood always has a great therapeutic effect, whether they permit of objective confirmation or not. These events owe their importance, of course, to their having occurred at such an early age, at a time when they could still produce a traumatic effect on the feeble ego.
I have been obliged to speak of transference, for it is only by means of this factor that I can elucidate the peculiarities of Dora's analysis. Its great merit, namely, the unusual clarity which makes it seem so suitable as a first introductory publication, is closely bound up with its great defect, which led to its being broken off prematurely. I did not succeed in mastering the transference in good time. Owing to the readiness with which Dora put one part of the pathogenic material at my disposal during the treatment, I neglected the precaution of looking out for the first signs of transference, which was being prepared in connection with another part of the same material a part of which I was in ignorance. At the beginning it was clear that I was replacing her father in her imagination, which was not unlikely, in view of the difference between our ages. She was even constantly comparing me with him consciously, and kept anxiously trying to make sure whether I was being quite straightforward with her, for her father 'always preferred secrecy and roundabout ways'. But when the first dream came, in which she gave herself the warning that she had better leave my treatment just as she had formerly left Herr K.'s house, I ought to have listened to the warning myself. 'Now,' I ought to have said to her, 'it is from Herr K. that you have made a transference on to me. Have you noticed anything that leads you to suspect me of evil intentions similar (whether openly or in some sublimated form) to Herr K.'s? Or have you been struck by anything about me or got to know anything about me which has caught your fancy, as happened previously with Herr K.' Her attention would then have been turned to some detail in our relations, or in my person or circumstances, behind which there lay concealed something analogous but immeasurably more important concerning Herr K. And when this transference had been cleared up, the analysis would have obtained access to new memories, dealing, probably, with actual events. But I was deaf to this first note of warning, thinking I had ample time before me, since no further stages of transference developed and the material for the analysis had not yet run dry. In this way the transference took me unawares, and, because of the unknown quantity in me which reminded Dora of Herr K., she took her revenge on me as she wanted to take her revenge on him, and deserted me as she believed herself to have been deceived and deserted by him. Thus she acted out an essential part of her recollections and phantasies instead of reproducing it in the treatment. What this unknown quantity was I naturally cannot tell. I suspect that it had to do with money, or with jealousy of another patient who had kept up relations with my family after her recovery. When it is possible to work transferences into the analysis at an early stage, the course of the analysis is retarded and obscured, but its existence is better guaranteed against sudden and overwhelming resistances.

Under the new technique very little, and often nothing, is left of this delightfully smooth course of events. There are some cases which behave like those under the hypnotic technique up to a point and only later cease to do so; but others behave differently from the beginning. If we confine ourselves to this second type in order to bring out the difference, we may say that the patient does not remember anything of what he has forgotten and repressed, but acts it out. He reproduces it not as a memory but as an action; he repeats it, without, of course, knowing that he is repeating it.

For instance, the patient does not say that he remembers that he used to be defiant and critical towards his parents' authority; instead, he behaves in that way to the doctor. He does not remember how he came to a helpless and hopeless deadlock in his infantile sexual researches; but he produces a mass of confused dreams and associations, complains that he cannot succeed in anything and asserts that he is fated never to carry through what he undertakes. He does not remember having been intensely ashamed of certain sexual activities and afraid of their being found out; but he makes it clear that he is ashamed of the treatment on which he is now embarked and tries to keep it secret from everybody. And so on.
Above all, the patient will begin his treatment with a repetition of this kind. When one has announced the fundamental rule of psycho-analysis to a patient with an eventful life-history and a long story of illness and has then asked him to say what occurs to his mind, one expects him to pour out a flood of information; but often the first thing that happens is that he has nothing to say. He is silent and declares that nothing occurs to him. This, of course, is merely a repetition of a homosexual attitude which comes to the fore as a resistance against remembering anything. As long as the patient is in the treatment he cannot escape from this compulsion to repeat; and in the end we understand that this is his way of remembering.

What interests us most of all is naturally the relation of this compulsion to repeat to the transference and to resistance. We soon perceive that the transference is itself only a piece of repetition, and that the repetition is a transference of the forgotten past not only on to the doctor but also on to all the other aspects of the current situation. We must be prepared to find, therefore, that the patient yields to the compulsion to repeat, which now replaces the impulsion to remember, not only in his personal attitude to his doctor but also in every other activity and relationship which may occupy his life at the time - if, for instance, he falls in love or undertakes a task or starts an enterprise during the treatment. The part played by resistance, too, is easily recognized. The greater the resistance, the more extensively will acting out (repetition) replace remembering. For the ideal remembering of what has been forgotten which occurs in hypnosis corresponds to a state in which resistance has been put completely on one side. If the patient starts his treatment under the auspices of a mild and unpronounced positive transference it makes it possible at first for him to unearth his memories just as he would under hypnosis, and during this time his pathological symptoms themselves are quiescent. But if, as the analysis proceeds, the transference becomes hostile or unduly intense and therefore in need of repression, remembering at once gives way to acting out. From then onwards the resistances determine the sequence of the material which is to be repeated. The patient brings out of the armoury of the past the weapons with which he defends himself against the progress of the treatment - weapons which we must wrest from him one by one.

We have learnt that the patient repeats instead of remembering, and repeats under the conditions of resistance. We may now ask what it is that he in fact repeats or acts out. The answer is that he repeats everything that has already made its way from the sources of the repressed into his manifest personality - his inhibitions and unserviceable attitudes and his pathological character-traits. He also repeats all his symptoms in the course of the treatment. And now we can see that in drawing attention to the compulsion to repeat we have acquired no new fact but only a more comprehensive view. We have only made it clear to ourselves that the patient's state of being ill cannot cease with the beginning of his analysis, and that we must treat his illness, not as an event of the past, but as a present-day force. This state of illness is brought, piece by piece, within the field and range of operation of the treatment, and while the patient experiences it as something real and contemporary, we have to do our therapeutic work on it, which consists in a large measure in tracing it back to the past.

Remembering, as it was induced in hypnosis, could not but give the impression of an experiment carried out in the laboratory. Repeating, as it is induced in analytic treatment according to the newer technique, on the other hand, implies conjuring up a piece of real life; and for that reason it cannot always be harmless and unobjectionable. This consideration opens up the whole problem of what is so often unavoidable - 'deterioration during treatment'.

[1914g, 2501]

[1914g, 2502]
Further dangers arise from the fact that in the course of the treatment new and deeper-lying instinctual impulses, which have not hitherto made themselves felt, may come to be 'repeated'. Finally, it is possible that the patient's actions outside the transference may do him temporary harm in his ordinary life, or even have been so chosen as permanently to invalidate his prospects of recovery.

The tactics to be adopted by the physician in this situation are easily justified. For him, remembering in the old manner - reproduction in the psychical field - is the aim to which he adheres, even though he knows that such an aim cannot be achieved in the new technique. He is prepared for a perpetual struggle with his patient to keep in the psychical sphere all the impulses which the patient would like to direct into the motor sphere; and he celebrates it as a triumph for the treatment if he can bring it about that something that the patient wishes to discharge in action is disposed of through the work of remembering. If the attachment through transference has grown into something at all serviceable, the treatment is able to prevent the patient from executing any of the more important repetitive actions and to utilize his intention to do so in statu nascendi as material for the therapeutic work. One best protects the patient from injuries brought about through carrying out one of his impulses by making him promise not to take any important decisions affecting his life during the time of his treatment - for instance, not to choose any profession or definitive love-object - but to postpone all such plans until after his recovery.

At the same time one willingly leaves untouched as much of the patient's personal freedom as is compatible with these restrictions, nor does one hinder him from carrying out unimportant intentions, even if they are foolish; one does not forget that it is in fact only through his own experience and mishaps that a person learns sense. There are also people whom one cannot restrain from plunging into some quite undesirable project during the treatment and who only afterwards become ready for, and accessible to, analysis. Occasionally, too, it is bound to happen that the untamed instincts assert themselves before there is time to put the reins of the transference on them, or that the bonds which attach the patient to the treatment are broken by him in a repetitive action. As an extreme example of this, I may cite the case of an elderly lady who had repeatedly fled from her house and her husband in a twilight state and gone no one knew where, without ever having become conscious of her motive for decamping in this way. She came to treatment with a marked affectionate transference which grew in intensity with uncanny rapidity in the first few days; by the end of the week she had decamped from me, too, before I had had time to say anything to her which might have prevented this repetition.
The main instrument, however, for curbing the patient's compulsion to repeat and for turning it into a motive for remembering lies in the handling of the transference. We render the compulsion harmless, and indeed useful, by giving it the right to assert itself in a definite field. We admit it into the transference as a playground in which it is allowed to expand in almost complete freedom and in which it is expected to display to us everything in the way of pathogenic instincts that is hidden in the patient's mind. Provided only that the patient shows compliance enough to respect the necessary conditions of the analysis, we regularly succeed in giving all the symptoms of the illness a new transference meaning and in replacing his ordinary neurosis by a 'transference-neurosis' of which he can be cured by the therapeutic work. The transference thus creates an intermediate region between illness and real life through which the transition from the one to the other is made. The new condition has taken over all the features of the illness; but it represents an artificial illness which is at every point accessible to our intervention. It is a piece of real experience, but one which has been made possible by especially favourable conditions, and it is of a provisional nature. From the repetitive reactions which are exhibited in the transference we are led along the familiar paths to the awakening of the memories, which appear without difficulty, as it were, after the resistance has been overcome.

If the patient's advances were returned it would be a great triumph for her, but a complete defeat for the treatment. She would have succeeded in what all patients strive for in analysis - she would have succeeded in acting out, in repeating in real life, what she ought only to have remembered, to have reproduced as psychical material and to have kept within the sphere of psychical events.¹ In the further course of the love-relationship she would bring out all the inhibitions and pathological reactions of her erotic life, without there being any possibility of correcting them; and the distressing episode would end in remorse and a great strengthening of her propensity to repression. The love-relationship in fact destroys the patient's susceptibility to influence from analytic treatment. A combination of the two would be an impossibility.

But it became ever clearer that the aim which had been set up - the aim that what was unconscious should become conscious - is not completely attainable by that method. The patient cannot remember the whole of what is repressed in him, and what he cannot remember may be precisely the essential part of it. Thus he acquires no sense of conviction of the correctness of the construction that has been communicated to him. He is obliged to repeat the repressed material as a contemporary experience instead of, as the physician would prefer to see, remembering it as something belonging to the past.¹ These reproductions, which emerge with such unwished-for exactitude, always have as their subject some portion of infantile sexual life - of the Oedipus complex, that is, and its derivatives; and they are invariably acted out in the sphere of the transference, of the patient's relation to the physician. When things have reached this stage, it may be said that the earlier neurosis has now been replaced by a fresh, 'transference neurosis'. It has been the physician's endeavour to keep this transference neurosis within the narrowest limits: to force as much as possible into the channel of memory and to allow as little as possible to emerge as repetition. The ratio between what is remembered and what is reproduced varies from case to case. The physician cannot as a rule spare his patient this phase of the treatment. He must get him to re-experience some portion of his forgotten life, but must see to it, on the other hand, that the patient retains some degree of aloofness, which will enable him, in spite of everything, to recognize that what appears to be reality is in fact only a reflection of a forgotten past. If this can be successfully achieved, the patient's sense of conviction is won, together with the therapeutic success that is dependent on it.

[1914g, 2505]

[1915a, 2516]

[1920g, 3723]
It must not be supposed that these emendations provide us with a complete survey of all the kinds of resistance that are met with in analysis. Further investigation of the subject shows that the analyst has to combat no less than five kinds of resistance, emanating from three directions - the ego, the id and the super-ego. The ego is the source of three of these, each differing in its dynamic nature. The first of these three ego-resistances is the repression resistance, which we have already discussed above and about which there is least new to be added. Next there is the transference resistance, which is of the same nature but which has different and much clearer effects in analysis, since it succeeds in establishing a relation to the analytic situation or the analyst himself and thus re-animating a repression which should only have been recollected. The third resistance, though also an ego-resistance, is of quite a different nature. It proceeds from the gain from illness and is based upon an assimilation of the symptom into the ego. It represents an unwillingness to renounce any satisfaction or relief that has been obtained. The fourth variety, arising from the id, is the resistance which, as we have just seen, necessitates 'working-through'. The fifth, coming from the super-ego and the last to be discovered, is also the most obscure though not always the least powerful one. It seems to originate from the sense of guilt or the need for punishment; and it opposes every move towards success, including, therefore, the patient's own recovery through analysis.

[1926d, 4313]

It would be worth while to understand how it was that the monotheist idea made such a deep impression precisely on the Jewish people and that they were able to maintain it so tenaciously. It is possible, I think, to find an answer. Fate had brought the great deed and misdeed of primaeval days, the killing of the father, closer to the Jewish people by causing them to repeat it on the person of Moses, an outstanding father-figure. It was a case of 'acting out' instead of remembering, as happens so often with neurotics during the work of analysis. To the suggestion that they should remember, which was made to them by the doctrine of Moses, they reacted, however, by disavowing their action; they remained halted at the recognition of the great father and thus blocked their access to the point from which Paul was later to start his continuation of the primal history. It is scarcely a matter of indifference or of chance that the violent killing of another great man became the starting-point of Paul's new religious creation as well. This was a man whom a small number of adherents in Judaea regarded as the Son of God and as the Messiah who had been announced, and to whom, too, a part of the childhood story invented for Moses was later carried over, but of whom in fact we know scarcely more with certainty than of Moses - whether he was really the great teacher portrayed by the Gospels or whether, rather, it was not the fact and circumstances of his death which were decisive for the importance which his figure acquired. Paul, who became his apostle, had not known him himself.

[1939a, 4912]

Another advantage of transference, too, is that in it the patient produces before us with plastic clarity an important part of his life-story, of which he would otherwise have probably given us only an insufficient account. He acts it before us, as it were, instead of reporting it to us.

[1940a [1938], 4985]
And now for the other side of the situation. Since the transference reproduces the patient's relation with his parents, it takes over the ambivalence of that relation as well. It almost inevitably happens that one day his positive attitude towards the analyst changes over into the negative, hostile one. This too is as a rule a repetition of the past. His obedience to his father (if it is his father that is in question), his courting of his father's favour, had its roots in an erotic wish directed towards him. Some time or other that demand will press its way forward in the transference as well and insist on being satisfied. In the analytic situation it can only meet with frustration. Real sexual relations between patients and analysts are out of the question, and even the subtler methods of satisfaction, such as the giving of preference, intimacy and so on, are only sparingly granted by the analyst. A rejection of this kind is taken as the occasion for the change-over; probably things happened in the same way in the patient's childhood. [1940a [1938], 4986]

We think it most undesirable if the patient acts outside the transference instead of remembering. The ideal conduct for our purposes would be that he should behave as normally as possible outside the treatment and express his abnormal reactions only in the transference. [1940a [1938], 4987]
Hitherto, this authority, with its enormous weight of suggestion, has been against us. All our therapeutic successes have been achieved in the face of this suggestion: it is surprising that any successes at all could be gained in such circumstances. I must not let myself be led into describing my agreeable experiences during the period when I alone represented psycho-analysis. I can only say that when I assured my patients that I knew how to relieve them permanently of their sufferings they looked round my modest abode, reflected on my lack of fame and title, and regarded me like the possessor of an infallible system at a gambling-resort, of whom people say that if he could do what he professes he would look very different himself. Nor was it really pleasant to carry out a psychical operation while the colleagues whose duty it should have been to assist took particular pleasure in spitting into the field of operation, and while at the first signs of blood or restlessness in the patient his relatives began threatening the operating surgeon. An operation is surely entitled to produce reactions; in surgery we became accustomed to that long ago. People simply did not believe me, just as even to-day people do not much believe any of us. Under such conditions not a few attempts were bound to fail. To estimate the increase in our therapeutic prospects when we have received general recognition, you should think of the position of a gynaecologist in Turkey and in the West. In Turkey, all he may do is to feel the pulse of all arm stretched out to him through a hole in the wall: and his medical achievements are in proportion to the inaccessibility of their object. Our opponents in the West wish to allow us much the same degree of access to our patient's minds. But now that the force of social suggestion drives sick women to the gynaecologist, he has become their helper and saviour. I trust you will not say that the fact of the authority of society coming to our aid and increasing our successes so greatly would do nothing to prove the validity of our hypotheses - arguing as you might that, since suggestion is supposed to be able to do anything, our successes would then be successes of suggestion and not of psycho-analysis. Social suggestion is at present favourable to treating nervous patients by hydropathy, dieting and electro-therapy, but that does not enable such measures to get the better of neuroses. Time will show whether psycho-analytic treatment can accomplish more.

\[1910d, 2311\]

\(e\) I cannot advise my colleagues too urgently to model themselves during psycho-analytic treatment on the surgeon, who puts aside all his feelings, even his human sympathy, and concentrates his mental forces on the simple aim of performing the operation as skilfully as possible. Under present-day conditions the feeling that is most dangerous to a psycho-analyst is the therapeutic ambition to achieve by this novel and much disputed method something that will produce a convincing effect upon other people. This will not only put him into a state of mind which is unfavourable for his work, but will make him helpless against certain resistances of the patient, whose recovery, as we know, primarily depends on the interplay of forces in him. The justification for requiring this emotional coldness in the analyst is that it creates the most advantageous conditions for both parties: for the doctor a desirable protection for his own emotional life and for the patient the largest amount of help that we can give him to-day. A surgeon of earlier times took as his motto the words: "Je le pansai, Dieu le guérit." The analyst should be content with something similar.

\[1912e, 2470\]
The question then arises whether the advantage gained by the patient would not to some extent counterbalance the sacrifice made by the physician. I may venture to form a judgement about this, since for ten years or so I set aside one hour a day, and sometimes two, for gratuitous treatments, because I wanted, in order to find my way about in the neuroses, to work in the face of as little resistance as possible. The advantages I sought by this means were not forthcoming. Free treatment enormously increases some of a neurotic's resistances - in young women, for instance, the temptation which is inherent in their transference-relation, and in young men, their opposition to an obligation to feel grateful, an opposition which arises from their father-complex and which presents one of the most troublesome hindrances to the acceptance of medical help. The absence of the regulating effect offered by the payment of a fee to the doctor makes itself very painfully felt; the whole relationship is removed from the real world, and the patient is deprived of a strong motive for endeavouring to bring the treatment to an end.

What interests us most of all is naturally the relation of this compulsion to repeat to the transference and to resistance. We soon perceive that the transference is itself only a piece of repetition, and that the repetition is a transference of the forgotten past not only on to the doctor but also on to all the other aspects of the current situation. We must be prepared to find, therefore, that the patient yields to the compulsion to repeat, which now replaces the impulsion to remember, not only in his personal attitude to his doctor but also in every other activity and relationship which may occupy his life at the time - if, for instance, he falls in love or undertakes a task or starts an enterprise during the treatment. The part played by resistance, too, is easily recognized. The greater the resistance, the more extensively will acting out (repetition) replace remembering. For the ideal remembering of what has been forgotten which occurs in hypnosis corresponds to a state in which resistance has been put completely on one side. If the patient starts his treatment under the auspices of a mild and unpronounced positive transference it makes it possible at first for him to unearth his memories just as he would under hypnosis, and during this time his pathological symptoms themselves are quiescent. But if, as the analysis proceeds, the transference becomes hostile or unduly intense and therefore in need of repression, remembering at once gives way to acting out. From then onwards the resistances determine the sequence of the material which is to be repeated. The patient brings out of the armoury of the past the weapons with which he defends himself against the progress of the treatment - weapons which we must wrest from him one by one.

I can, however, assume this much - that you know that psycho-analysis is a procedure for the medical treatment of neurotic patients. And here I can at once give you an instance of how in this field a number of things take place in a different way - often, indeed, in an opposite way - from what they do elsewhere in medical practice. When elsewhere we introduce a patient to a medical technique which is new to him, we usually minimize its inconveniences and give him confident assurances of the success of the treatment. I think we are justified in this, since by doing so we are increasing the probability of success. But when we take a neurotic patient into psycho-analytic treatment, we act differently. We point out the difficulties of the method to him, its long duration, the efforts and sacrifices it calls for; and as regards its success, we tell him we cannot promise it with certainty, that it depends on his own conduct, his understanding, his adaptability and his perseverance. We have good reasons, of course, for such apparently wrong-headed behaviour, as you will perhaps come to appreciate later on.
Think it over! You have learnt all that is essential about the determinants of falling ill as well as all the factors that come into effect after the patient has fallen ill. Where do these leave room for any therapeutic influence? In the first place there is hereditary disposition. We have not talked about it very often because it is emphatically stressed from other directions and we have nothing new to say about it. But do not suppose that we underestimate it; precisely as therapists we come to realize its power clearly enough. In any case we can do nothing to alter it; we too must take it as something given, which sets a limit to our efforts. Next there is the influence of early experiences in childhood, to which we are in the habit of giving prominence in analysis: they belong to the past and we cannot undo them. Then comes everything that we have summarized as 'real frustration' - the misfortunes of life from which arise deprivation of love, poverty, family quarrels, ill-judged choice of a partner in marriage, unfavourable social circumstances, and the strictness of the ethical standards to whose pressure the individual is subject. Here, to be sure, there would be handles enough for a very effective therapy, but it would have to be of the kind which Viennese folklore attributes to the Emperor Joseph - the benevolent interference of a powerful personage before whose will people bow and difficulties vanish. But who are we, that we should be able to adopt benevolence of this kind as an instrument of our therapy? Poor ourselves and socially powerless, and compelled to earn our livelihood from our medical activity, we are not even in a position to extend our efforts to people without means, as other doctors with other methods of treatment are after all able to do. Our therapy is too time-consuming and too laborious for that to be possible. Perhaps, however, you are clutching at one of the factors I have mentioned and believe that there you have found the point at which our influence can make its attack. If the ethical restrictions demanded by society play a part in the deprivation imposed on the patient, treatment can, after all, give him the courage, or perhaps a direct injunction, to disregard those barriers and achieve satisfaction and recovery while forgoing the fulfilment of an ideal that is exalted, but so often not adhered to, by society. The patient will thus become healthy by 'living a full life' sexually. This, it is true, casts a shadow on analytic treatment for not serving general morality. What it has given to the individual it will have taken from the community.

[1916-1917, 3475]
Many attempts at treatment miscarried during the early period of analysis because they were undertaken in cases which were altogether unsuited to the procedure and which we should exclude to-day on the basis of our present view of the indications for treatment. But these indications, too, could only be arrived at by experiment. In those days we did not know a priori that paranoia and dementia praecox in strongly marked forms are inaccessible, and we had a right to make trial of the method on all kinds of disorders. But most of the failures of those early years were due not to the doctor's fault or an unsuitable choice of patients but to unfavourable external conditions. Here we have only dealt with internal resistances, those of the patient, which are inevitable and can be overcome. The external resistances which arise from the patient's circumstances, from his environment, are of small theoretical interest but of the greatest practical importance. Psycho-analytic treatment may be compared with a surgical operation and may similarly claim to be carried out under arrangements that will be the most favourable for its success. You know the precautionary measures adopted by a surgeon: a suitable room, good lighting, assistants, exclusion of the patient's relatives, and so on. Ask yourselves now how many of these operations would turn out successfully if they had to take place in the presence of all the members of the patient's family, who would stick their noses into the field of the operation and exclaim aloud at every incision. In psycho-analytic treatments the intervention of relatives is a positive danger and a danger one does not know how to meet. One is armed against the patient's internal resistances which one knows are inevitable, but how can one ward off these external resistances? No kind of explanations make any impression on the patient's relatives; they cannot be induced to keep at a distance from the whole business, and one cannot make common cause with them because of the risk of losing the confidence of the patient, who - quite rightly moreover - expects the person in whom he has put his trust to take his side. No one who has any experience of the rifts which so often divide a family will, if he is an analyst, be surprised to find that the patient's closest relatives sometimes betray less interest in his recovering than in his remaining as he is. When, as so often, the neurosis is related to conflicts between members of a family, the healthy party will not hesitate long in choosing between his own interest and the sick party's recovery. It is not to be wondered at, indeed, if a husband looks with disfavour on a treatment in which, as he may rightly suspect, the whole catalogue of his sins will be brought to light. Nor do we wonder at it; but we cannot in that case blame ourselves if our efforts remain unsuccessful and the treatment is broken off prematurely because the husband's resistance is added to that of his sick wife. We had in fact undertaken something which in the prevailing circumstances was unrealizable.

In the years before the war, when arrivals from many foreign countries made me independent of the favour or disfavour of my own city, I followed a rule of not taking on patient for treatment unless he was sui juris, not dependent on anyone else in the essential relations of his life. This is not possible, however, for every psycho-analyst. Perhaps you may conclude from my warning against relatives that patients designed for psycho-analysis should be removed from their families and that this kind of treatment should accordingly be restricted to inmates of hospitals for nervous diseases. I could not, however, follow you in that. It is much more advantageous for patients, (in so far as they are not in a phase of severe exhaustion) to remain during the treatment in the conditions in which they have to struggle with the tasks that face them. But the patients' relatives ought not to cancel out this advantage by their conduct and should not offer any hostile opposition to the doctor's efforts. But how do you propose to influence in that direction factors like these which are inaccessible to us? And you will guess, of course, how much the prospects of a treatment are determined by the patient's social milieu and the cultural level of his family.

[1916-1917, 3498]

[1916-1917, 3500]
You will remember that it was a frustration that made the patient ill, and that his symptoms serve him as substitutive satisfactions. It is possible to observe during the treatment that every improvement in his condition reduces the rate at which he recovers and diminishes the instinctual force impelling him towards recovery. But this instinctual force is indispensible; reduction of it endangers our aim - the patient's restoration to health. What, then, is the conclusion that forces itself inevitably upon us? Cruel though it may sound, we must see to it that the patient's suffering, to a degree that is in some way or other effective, does not come to an end prematurely. If, owing to the symptoms having been taken apart and having lost their value, his suffering becomes mitigated, we must reinstate it elsewhere in the form of some appreciable privation; otherwise we run the danger of never achieving any improvements except quite insignificant and transitory ones.

[1919a, 3632]

Of the three factors which we have recognized as being decisive for the success or otherwise of analytic treatment - the influence of traumas, the constitutional strength of the instincts and alterations of the ego - what concerns us here is only the second, the strength of the instincts. A moment's reflection raises a doubt whether the restrictive use of the adjective 'constitutional' (or 'congenital') is essential. However true it may be that the constitutional factor is of decisive importance from the very beginning, it is nevertheless conceivable that a reinforcement of instinct coming later in life might produce the same effects. If so, we should have to modify our formula and say 'the strength of the instincts at the time' instead of 'the constitutional strength of the instincts'. The first of our questions was: 'Is it possible by means of analytic therapy to dispose of a conflict between an instinct and the ego, or of a pathogenic instincutal demand upon the ego, permanently and definitively?' To avoid misunderstanding it is not unnecessary, perhaps, to explain more exactly what is meant by 'permanently disposing of an instinctual demand'. Certainly not 'causing the demand to disappear so that nothing more is ever heard from it again'. This is in general impossible, nor is it at all to be desired. No, we mean something else, something which may be roughly described as a 'taming' of the instinct. That is to say, the instinct is brought completely into the harmony of the ego, becomes accessible to all the influences of the other trends in the ego and no longer seeks to go its independent way to satisfaction. If we are asked by what methods and means this result is achieved, it is not easy to find an answer. We can only say: 'So muss denn doch die Hexe dran!' - the Witch Metapsychology. Without metapsychological speculation and theorizing - I had almost said 'phantasising' - we shall not get another step forward. Unfortunately, here as elsewhere, what our Witch reveals is neither very clear nor very detailed. We have only a single clue to start from - though it is a clue of the highest value - namely, the antithesis between the primary and the secondary processes; and to that antithesis I shall at this point turn.

[1937c, 5022]
Since the publication of a work by Abraham (1908) - which that conscientious author has attributed to my instigation - we have tried to base our characterization of Kraepelin's 'dementia praecox' (Bleuler's 'schizophrenia') on its position with reference to the antithesis between ego and object. In the transference neuroses (anxiety hysteria, conversion hysteria and obsessional neurosis) there was nothing to give special prominence to this antithesis. We knew, indeed, that frustration in regard to the object brings on the outbreak of the neurosis and that the neurosis involves a renunciation of the real object; we knew too that the libido that is withdrawn from the real object reverts first to a phantasied object and then to one that had been repressed (introversion). But in these disorders object-cathexis in general is retained with great energy, and more detailed examination of the process of repression has obliged us to assume that object-cathexis persists in the system Ucs. in spite of - or rather in consequence of - repression. Indeed, the capacity for transference, of which we make use for therapeutic purposes in these affections, presupposes an unimpaired object-cathexis.

[1915e, 3018]

Thus our therapeutic work falls into two phases. In the first, all the libido is forced from the symptoms into the transference and concentrated there; in the second, the struggle is waged around this new object and the libido is liberated from it. The change which is decisive for a favourable outcome is the elimination of repression in this renewed conflict so that the libido cannot withdraw once more from the ego by flight into the unconscious. This is made possible by the alteration of the ego which is accomplished under the influence of the doctor's suggestion. By means of the work of interpretation, which transforms what is unconscious into what is conscious, the ego is enlarged at the cost of this unconscious; by means of instruction, it is made conciliatory towards the libido and inclined to grant it some satisfaction, and its repugnance to the claims of the libido is diminished by the possibility of disposing of a portion of it by sublimation. The more closely events in the treatment coincide with this ideal description, the greater will be the success of the psycho-analytic therapy. It finds its limits in the lack of mobility of the libido, which may refuse to leave its objects, and the rigidity of narcissism, which will not allow transference on to objects to increase beyond certain bounds. Further light may perhaps be thrown on the dynamics of the process of cure if I say that we get hold of the whole of the libido which has been withdrawn from the dominance of the ego by attracting a portion of it on to ourselves by means of the transference.

[1916-1917, 3495]
To a physician who was to undertake psycho-analytic treatment of the girl there were many grounds for misgiving. The situation he had to deal with was not the one that analysis demands, in which alone it can demonstrate its effectiveness. As is well known, the ideal situation for analysis is when someone who is otherwise his own master is suffering from an inner conflict which he is unable to resolve alone, so that he brings his trouble to the analyst and begs for his help. The physician then works hand in hand with one portion of the pathologically divided personality, against the other party in the conflict. Any situation which differs from this is to a greater or lesser degree unfavourable for psycho-analysis and adds fresh difficulties to the internal ones already present. Situations like that of a prospective house-owner who orders an architect to build him a villa to his own tastes and requirements, or of a pious donor who commissions an artist to paint a sacred picture in the corner of which is to be a portrait of himself in adoration, are at bottom incompatible with the conditions necessary for psycho-analysis. Thus, it constantly happens that a husband instructs the physician as follows: 'My wife suffers from nerves, and for that reason gets on badly with me; please cure her, so that we may lead a happy married life again.' But often enough it turns out that such a request is impossible to fulfil - that is to say, the physician cannot bring about the result for which the husband sought the treatment. As soon as the wife is freed from her neurotic inhibitions she sets about getting a separation, for her neurosis was the sole condition under which the marriage could be maintained. Or else parents expect one to cure their nervous and unruly child. By a healthy child they mean one who never causes his parents trouble, and gives them nothing but pleasure. The physician may succeed in curing the child, but after that it goes its own way all the more decidedly, and the parents are now far more dissatisfied than before. In short, it is not a matter of indifference whether someone comes to analysis of his own accord or because he is brought to it - whether it is he himself who desires to be changed, or only his relatives, who love him (or who might be expected to love him).

I now come to the description of a factor which adds an essential feature to my picture of analysis and which can claim, alike technically and theoretically, to be regarded as of the first importance. In every analytic treatment there arises, without the physician's agency, an intense emotional relationship between the patient and the analyst which is not to be accounted for by the actual situation. It can be of a positive or of a negative character and can vary between the extremes of a passionate, completely sensual love and the unbridled expression of an embittered defiance and hatred. This transference - to give it its short name - soon replaces in the patient's mind the desire to be cured, and, so long as it is affectionate and moderate, becomes the agent of the physician's influence and neither more nor less than the mainspring of the joint work of analysis. Later on, when it has become passionate or has been converted into hostility, it becomes the principal tool of the resistance. It may then happen that it will paralyse the patient's powers of associating and endanger the success of the treatment. Yet it would be senseless to try to evade it; for an analysis without transference is an impossibility. It must not be supposed, however, that transference is created by analysis and does not occur apart from it. Transference is merely uncovered and isolated by analysis. It is a universal phenomenon of the human mind, it decides the success of all medical influence, and in fact dominates the whole of each person's relations to his human environment. We can easily recognize it as the same dynamic factor which the hypnotists have named 'suggestibility', which is the agent of hypnotic rapport and whose incalculable behaviour led to difficulties with the cathartic method as well. When there is no inclination to a transference of emotion such as this, or when it has become entirely negative, as happens in dementia praecox or paranoia, then there is also no possibility of influencing the patient by psychological means.

[1920a, 3840]

[1925d, 4217]
The neuroses were the first subject of analysis, and for a long time they were the only one. No analyst could doubt that medical practice was wrong in separating those disorders from the psychoses and in attaching them to the organic nervous diseases. The theory of the neuroses belongs to psychiatry and is indispensable as an introduction to it. It would seem, however, that the analytic study of the psychoses is impracticable owing to its lack of therapeutic results. Mental patients are as a rule without the capacity for forming a positive transference, so that the principal instrument of analytic technique is inapplicable to them. There are nevertheless a number of methods of approach to be found. Transference is often not so completely absent but that it can be used to a certain extent; and analysis has achieved undoubted successes with cyclical depressions, light paranoid modifications, and partial schizophrenias. It has at least been a benefit to science that in many cases the diagnosis can oscillate for quite a long time between assuming the presence of a psychoneurosis or of a dementia praecox; for therapeutic attempts initiated in such cases have resulted in valuable discoveries before they have had to be broken off. But the chief consideration in this connection is that so many things that in the neuroses have to be laboriously fetched up from the depths are found in the psychoses on the surface, visible to every eye. For that reason the best subjects for the demonstration of many of the assertions of analysis are provided by the psychiatric clinic. It was thus bound to happen before long that analysis would find its way to the objects of psychiatric observation. I was able very early (1896) to establish in a case of paranoid dementia the presence of the same aetiological factors and the same emotional complexes as in the neuroses. Jung explained some most puzzling stereotypies in dments by bringing them into relation with the patients' life-histories; Bleuler demonstrated the existence in various psychoses of mechanisms like those which analysis had discovered in neurotics. Since then analysts have never relaxed their efforts to come to an understanding of the psychoses. Especially since it has been possible to work with the concept of narcissism, they have managed, now in this place and now in that, to get a glimpse beyond the wall. Most of all, no doubt, was achieved by Abraham in his elucidation of the melancholias. It is true that in this sphere all our knowledge is not yet converted into therapeutic power; but the mere theoretical gain is not to be despised, and we may be content to wait for its practical application. In the long run even the psychiatrists cannot resist the convincing force of their own clinical material. At the present time German psychiatry is undergoing a kind of 'peaceful penetration' by analytic views. While they continually declare that they will never be psycho-analysts, that they do not belong to the 'orthodox' school or agree with its exaggerations, and in particular that they do not believe in the predominance of the sexual factor, nevertheless the majority of the younger workers take over one piece or another of analytic theory and apply it in their own fashion to the material. All the signs point to the proximity of further developments in the same direction. [1925d, 4235]
The therapeutic effect depends on making conscious what is repressed, in the widest sense of the word, in the id. We prepare the way for this making conscious by interpretations and constructions, but we have interpreted only for ourselves not for the patient so long as the ego holds on to its earlier defences and does not give up its resistances. Now these resistances, although they belong to the ego, are nevertheless unconscious and in some sense separated off within the ego. The analyst recognizes them more easily than he does the hidden material in the id. One might suppose that it would be sufficient to treat them like portions of the id and, by making them conscious, bring them into connection with the rest of the ego. In this way, we should suppose, one half of the task of analysis would be accomplished; we should not reckon on meeting with a resistance against the uncovering of resistances. But what happens is this. During the work on the resistances the ego withdraws - with a greater or less degree of seriousness - from the agreement on which the analytic situation is founded. The ego ceases to support our efforts at uncovering the id; it opposes them, disobeys the fundamental rule of analysis, and allows no further derivatives of the repressed to emerge. We cannot expect the patient to have a strong conviction of the curative power of analysis. He may have brought along with him a certain amount of confidence in his analyst, which will be strengthened to an effective point by the factors of the positive transference which will be aroused in him. Under the influence of the unpleasurable impulses which he feels as a result of the fresh activation of his defensive conflicts, negative transferences may now gain the upper hand and completely annul the analytic situation. The patient now regards the analyst as no more than a stranger who is making disagreeable demands on him, and he behaves towards him exactly like a child who does not like the stranger and does not believe anything he says. If the analyst tries to explain to the patient one of the distortions made by him for the purposes of defence, and to correct it, he finds him uncomprehending and inaccessible to sound arguments. Thus we see that there is a resistance against the uncovering of resistances, and the defensive mechanisms really do deserve the name which we gave them originally, before they had been more closely examined. They are resistances not only to the making conscious of contents of the id, but also to the analysis as a whole, and thus to recovery.
[1937c, 5034]
Various qualifications are required of anyone who is to be beneficially affected by psycho-analysis. To begin with, he must be capable of a psychically normal condition; during periods of confusion or melancholic depression nothing can be accomplished even in cases of hysteria. Furthermore, a certain measure of natural intelligence and ethical development are to be required of him; if the physician has to deal with a worthless character, he soon loses the interest which makes it possible for him to enter profoundly into the patient's mental life. Deep-rooted malformations of character, traits of an actually degenerate constitution, show themselves during treatment as sources of a resistance that can scarcely be overcome. In this respect the constitution of the patient sets a general limit to the curative effect of psychotherapy. If the patient's age is in the neighbourhood of the fifties the conditions for psycho-analysis become unfavourable. The mass of psychical material is then no longer manageable; the time required for recovery is too long; and the ability to undo psychical processes begins to grow weaker.

[1904a, 1560]

(i) To what extent should the patient's intellectual co-operation be sought for in the treatment? It is difficult to say anything of general applicability on this point: the patient's personality is the determining factor. But in any case caution and self-restraint must be observed in this connection. It is wrong to set a patient tasks, such as collecting his memories or thinking over some particular period of his life. On the contrary, he has to learn above all - what never comes easily to anyone - that mental activities such as thinking something over or concentrating the attention solve none of the riddles of a neurosis; that can only be done by patiently obeying the psycho-analytic rule, which enjoins the exclusion of all criticism of the unconscious or of its derivatives. One must be especially unyielding about obedience to that rule with patients who practise the art of sheering off into intellectual discussion during their treatment, who speculate a great deal and often very wisely about their condition and in that way avoid doing anything to overcome it. For this reason I dislike making use of analytic writings as an assistance to my patients; I require them to learn by personal experience, and I assure them that they will acquire wider and more valuable knowledge than the whole literature of psycho-analysis could teach them. I recognize, however, that under institutional conditions it may be of great advantage to employ reading as a preparation for patients in analysis and as a means of creating an atmosphere of influence.

[1912e, 2474]
Let us once more glance over the situation which we have reached in our attempt at bringing help to the patient's neurotic ego. That ego is no longer able to fulfil the task set it by the external world (including human society). Not all of its experiences are at its disposal, a large proportion of its store of memories have escaped it. Its activity is inhibited by strict prohibitions from the super-ego, its energy is consumed in vain attempts at fending off the demands of the id. Beyond this, as a result of continuous irruptions by the id, its organization is impaired, it is no longer capable of any proper synthesis, it is torn by mutually opposed urges, by unsettled conflicts and by unsolved doubts. To start with, we get the patient's thus weakened ego to take part in the purely intellectual work of interpretation, which aims at provisionally filling the gaps in his mental assets, and to transfer to us the authority of his super-ego; we encourage it to take up the struggle over each individual demand made by the id and to conquer the resistances which arise in connection with it. At the same time we restore order in the ego by detecting the material and urges which have forced their way in from the unconscious, and expose them to criticism by tracing them back to their origin. We serve the patient in various functions, as an authority and a substitute for his parents, as a teacher and educator; and we have done the best for him if, as analysts, we raise the mental processes in his ego to a normal level, transform what has become unconscious and repressed into preconscious material and thus return it once more to the possession of his ego. On the patient's side a few rational factors work in our favour, such as the need for recovery which has its motive in his sufferings, and the intellectual interest that we may awaken in him in the theories and revelations of psychoanalysis; but of far greater force is the positive transference with which he meets us. Fighting against us, on the other hand, are the negative transference, the ego's resistance due to repression (that is, its unpleasure at having to lay itself open to the hard work imposed on it), the sense of guilt arising from its relation to the super-ego and the need to be ill due to deep-going changes in the economics of his instincts. The share taken by the last two factors decides whether the case is to be regarded as slight or severe. Apart from these, a few other factors may be discerned as having a favourable or unfavourable bearing. A certain psychical inertia, a sluggishness of the libido, which is unwilling to abandon its fixations cannot be welcome to us; the patient's capacity for sublimating his instincts plays a large part and so does his capacity for rising above the crude life of the instincts; so, too, does the relative power of his intellectual functions.

[1940a [1938], 4990]
To what extent should the patient's intellectual co-operation be sought for in the treatment? It is difficult to say anything of general applicability on this point: the patient's personality is the determining factor. But in any case caution and self-restraint must be observed in this connection. It is wrong to set a patient tasks, such as collecting his memories or thinking over some particular period of his life. On the contrary, he has to learn above all - what never comes easily to anyone - that mental activities such as thinking something over or concentrating the attention solve none of the riddles of a neurosis; that can only be done by patiently obeying the psycho-analytic rule, which enjoins the exclusion of all criticism of the unconscious or of its derivatives. One must be especially unyielding about obedience to that rule with patients who practise the art of sheering off into intellectual discussion during their treatment, who speculate a great deal and often very wisely about their condition and in that way avoid doing anything to overcome it. For this reason I dislike making use of analytic writings as an assistance to my patients; I require them to learn by personal experience, and I assure them that they will acquire wider and more valuable knowledge than the whole literature of psycho-analysis could teach them. I recognize, however, that under institutional conditions it may be of great advantage to employ reading as a preparation for patients in analysis and as a means of creating an atmosphere of influence.

[1912e, 2474]
Various qualifications are required of anyone who is to be beneficially affected by psychoanalysis. To begin with, he must be capable of a psychically normal condition; during periods of confusion or melancholic depression nothing can be accomplished even in cases of hysteria. Furthermore, a certain measure of natural intelligence and ethical development are to be required of him; if the physician has to deal with a worthless character, he soon loses the interest which makes it possible for him to enter profoundly into the patient's mental life. Deep-rooted malformations of character, traits of an actually degenerate constitution, show themselves during treatment as sources of a resistance that can scarcely be overcome. In this respect the constitution of the patient sets a general limit to the curative effect of psychotherapy. If the patient's age is in the neighbourhood of the fifties the conditions for psycho-analysis become unfavourable. The mass of psychical material is then no longer manageable; the time required for recovery is too long; and the ability to undo psychical processes begins to grow weaker.

[1904a, 1560]

No sooner have we taken this step than a first disappointment awaits us, a first warning against over-confidence. If the patient's ego is to be a useful ally in our common work, it must, however hard it may be pressed by the hostile powers, have retained a certain amount of coherence and some fragment of understanding for the demands of reality. But this is not to be expected of the ego of a psychotic; it cannot observe a pact of this kind, indeed it can scarcely enter into one. It will very soon have tossed us away and the help we offer it and sent us to join the portions of the external world which no longer mean anything to it. Thus we discover that we must renounce the idea of trying our plan of cure upon psychotics - renounce it perhaps for ever or perhaps only for the time being, till we have found some other plan better adapted for them.

[1940a [1938], 4983]

The overcoming of resistances is the part of our work that requires the most time and the greatest trouble. It is worth while, however, for it brings about an advantageous alteration of the ego which will be maintained independently of the outcome of the transference and will hold good in life. We have also worked simultaneously at getting rid of the alteration of the ego which had been brought about under the influence of the unconscious; for whenever we have been able to detect any of its derivatives in the ego we have pointed out their illegitimate origin and have instigated the ego to reject them. It will be remembered that it was one of the necessary preconditions of our pact of assistance that any such alteration of the ego due to the intrusion of unconscious elements should not have gone beyond a certain amount.

[1940a [1938], 4989]
Every analyst will have treated a few cases which have had this gratifying outcome. He has succeeded in clearing up the patient's neurotic disturbance, and it has not returned and has not been replaced by any other such disturbance. Nor are we without some insight into the determinants of these successes. The patient's ego had not been noticeably altered and the aetiology of his disturbance had been essentially traumatic. The aetiology of every neurotic disturbance is, after all, a mixed one. It is a question either of the instincts being excessively strong - that is to say, recalcitrant to taming by the ego - or of the effects of early (i.e. premature) traumas which the immature ego was unable to master. As a rule there is a combination of both factors, the constitutional and the accidental. The stronger the constitutional factor, the more readily will a trauma lead to a fixation and leave behind a developmental disturbance; the stronger the trauma, the more certainly will its injurious effects become manifest even when the instinctual situation is normal. There is no doubt that an aetiology of the traumatic sort offers by far the more favourable field for analysis. Only when a case is a predominantly traumatic one will analysis succeed in doing what it is so superlatively able to do; only then will it, thanks to having strengthened the patient's ego, succeed in replacing by a correct solution the inadequate decision made in his early life. Only in such cases can one speak of an analysis having been definitively ended. In them, analysis has done all that it should and does not need to be continued. It is true that, if the patient who has been restored in this way never produces another disorder calling for analysis, we do not know how much his immunity may not be due to a kind fate which has spared him ordeals that are too severe.

A constitutional strength of instinct and an unfavourable alteration of the ego acquired in its defensive struggle in the sense of its being dislocated and restricted - these are the factors which are prejudicial to the effectiveness of analysis and which may make its duration interminable. One is tempted to make the first factor - strength of instinct - responsible as well for the emergence of the second - the alteration of the ego; but it seems that the latter too has an aetiology of its own. And, indeed, it must be admitted that our knowledge of these matters is as yet insufficient. They are only now becoming the subject of analytic study. In this field the interest of analysts seems to me to be quite wrongly directed. Instead of an enquiry into how a cure by analysis comes about (a matter which I think has been sufficiently elucidated) the question should be asked of what are the obstacles that stand in the way of such a cure.
Of the three factors which we have recognized as being decisive for the success or otherwise of analytic treatment - the influence of traumas, the constitutional strength of the instincts and alterations of the ego - what concerns us here is only the second, the strength of the instincts. A moment's reflection raises a doubt whether the restrictive use of the adjective 'constitutional' (or 'congenital') is essential. However true it may be that the constitutional factor is of decisive importance from the very beginning, it is nevertheless conceivable that a reinforcement of instinct coming later in life might produce the same effects. If so, we should have to modify our formula and say 'the strength of the instincts at the time' instead of 'the constitutional strength of the instincts'. The first of our questions was: 'Is it possible by means of analytic therapy to dispose of a conflict between an instinct and the ego, or of a pathogenic instinctual demand upon the ego, permanently and definitively?' To avoid misunderstanding it is not unnecessary, perhaps, to explain more exactly what is meant by 'permanently disposing of an instinctual demand'. Certainly not 'causing the demand to disappear so that nothing more is ever heard from it again'. This is in general impossible, nor is it at all to be desired. No, we mean something else, something which may be roughly described as a 'taming' of the instinct. That is to say, the instinct is brought completely into the harmony of the ego, becomes accessible to all the influences of the other trends in the ego and no longer seeks to go its independent way to satisfaction. If we are asked by what methods and means this result is achieved, it is not easy to find an answer. We can only say: 'So muss denn doch die Hexe dran!' - the Witch Metapsychology. Without metapsychological speculation and theorizing - I had almost said 'phantasying' - we shall not get another step forward. Unfortunately, here as elsewhere, what our Witch reveals is neither very clear nor very detailed. We have only a single clue to start from - though it is a clue of the highest value - namely, the antithesis between the primary and the secondary processes; and to that antithesis I shall at this point turn.

We started from the question of how we can shorten the inconveniently long duration of analytic treatment, and, still with this question of time in mind, we went on to consider whether it is possible to achieve a permanent cure or even to prevent future illness by prophylactic treatment. In doing so, we found that the factors which were decisive for the success of our therapeutic efforts were the influence of traumatic aetiology, the relative strength of the instincts which have to be controlled, and something which we have called an alteration of the ego. Only the second of these factors has been discussed by us in any detail, and in connection with it we have had occasion to recognize the paramount importance of the quantitative factor and to stress the claim of the metapsychological line of approach to be taken into account in any attempt at explanation.

Concerning the third factor, the alteration of the ego, we have as yet said nothing. When we turn our attention to it, the first impression we receive is that there is much to ask and much to answer here, and that what we have to say about it will prove to be very inadequate. This first impression is confirmed when we go further into the problem. As is well known, the analytic situation consists in our allyng ourselves with the ego of the person under treatment, in order to subdue portions of his id which are uncontrolled - that is to say to include them in the synthesis of his ego. The fact that a co-operation of this kind habitually fails in the case of psychotics affords us a first solid footing for our judgement. The ego, if we are to be able to make such a pact with it, must be a normal one. But a normal ego of this sort is, like normality in general, an ideal fiction. The abnormal ego, which is unserviceable for our purposes, is unfortunately no fiction. Every normal person, in fact, is only normal on the average. His ego approximates to that of the psychotic in some part or other and to a greater or lesser extent; and the degree of its remoteness from one end of the series and of its proximity to the other will furnish us with a provisional measure of what we have so indefinitely termed an 'alteration of the ego'.

At the moment, however, we are not concerned with the pathogenic role of the defensive mechanisms. What we are trying to discover is what influence the alteration of the ego which corresponds to them has upon our therapeutic efforts. The material for an answer to this question is given in the volume by Anna Freud to which I have already referred. The essential point is that the patient repeats these modes of reaction during the work of analysis as well, that he produces them before our eyes, as it were. In fact, it is only in this way that we get to know them. This does not mean that they make analysis impossible. On the contrary, they constitute half of our analytic task. The other half, the one which was first tackled by analysis in its early days, is the uncovering of what is hidden in the id. During the treatment our therapeutic work is constantly swinging backwards and forwards like a pendulum between a piece of id-analysis and a piece of ego-analysis. In the one case we want to make something from the id conscious, in the other we want to correct something in the ego. The crux of the matter is that the defensive mechanisms directed against former danger recur in the treatment as resistances against recovery. It follows from this that the ego treats recovery itself as a new danger.

The effect brought about in the ego by the defences can rightly be described as an 'alteration of the ego' if by that we understand a deviation from the fiction of a normal ego which would guarantee unshakable loyalty to the work of analysis. It is easy, then, to accept the fact, shown by daily experience, that the outcome of an analytic treatment depends essentially on the strength and on the depth of root of these resistances that bring about an alteration of the ego. Once again we are confronted with the importance of the quantitative factor, and once again we are reminded that analysis can only draw upon definite and limited amounts of energy which have to be measured against the hostile forces. And it seems as if victory is in fact as a rule on the side of the big battalions.

In 1927, Ferenczi read an instructive paper on the problem of the termination of analyses. It ends with a comforting assurance that 'analysis is not an endless process, but one which can be brought to a natural end with sufficient skill and patience on the analyst's part'. The paper as a whole, however, seems to me to be in the nature of a warning not to aim at shortening analysis but at deepening it. Ferenczi makes the further important point that success depends very largely on the analyst's having learnt sufficiently from his own 'errors and mistakes' and having got the better of 'the weak points in his own personality'. This provides an important supplement to our theme. Among the factors which influence the prospects of analytic treatment and add to its difficulties in the same manner as the resistances, must be reckoned not only the nature of the patient's ego but the individuality of the analyst.
Every analyst will have treated a few cases which have had this gratifying outcome. He has succeeded in clearing up the patient's neurotic disturbance, and it has not returned and has not been replaced by any other such disturbance. Nor are we without some insight into the determinants of these successes. The patient's ego had not been noticeably altered and the aetiology of his disturbance had been essentially traumatic. The aetiology of every neurotic disturbance is, after all, a mixed one. It is a question either of the instincts being excessively strong - that is to say, recalcitrant to taming by the ego - or of the effects of early (i.e. premature) traumas which the immature ego was unable to master. As a rule there is a combination of both factors, the constitutional and the accidental. The stronger the constitutional factor, the more readily will a trauma lead to a fixation and leave behind a developmental disturbance; the stronger the trauma, the more certainly will its injurious effects become manifest even when the instinctual situation is normal. There is no doubt that an aetiology of the traumatic sort offers by far the more favourable field for analysis. Only when a case is a predominantly traumatic one will analysis succeed in doing what it is so superlatively able to do; only then will it, thanks to having strengthened the patient's ego, succeed in replacing by a correct solution the inadequate decision made in his early life. Only in such cases can one speak of an analysis having been definitively ended. In them, analysis has done all that it should and does not need to be continued. It is true that, if the patient who has been restored in this way never produces another disorder calling for analysis, we do not know how much his immunity may not be due to a kind fate which has spared him ordeals that are too severe. [1937c, 5018]

Of the three factors which we have recognized as being decisive for the success or otherwise of analytic treatment - the influence of traumas, the constitutional strength of the instincts and alterations of the ego - what concerns us here is only the second, the strength of the instincts. A moment's reflection raises a doubt whether the restrictive use of the adjective 'constitutional' (or 'congenital') is essential. However true it may be that the constitutional factor is of decisive importance from the very beginning, it is nevertheless conceivable that a reinforcement of instinct coming later in life might produce the same effects. If so, we should have to modify our formula and say 'the strength of the instincts at the time' instead of 'the constitutional strength of the instincts'. The first of our questions was: 'Is it possible by means of analytic therapy to dispose of a conflict between an instinct and the ego, or of a pathogenic instinctual demand upon the ego, permanently and definitively?' To avoid misunderstanding it is not unnecessary, perhaps, to explain more exactly what is meant by 'permanently disposing of an instinctual demand'. Certainly not 'causing the demand to disappear so that nothing more is ever heard from it again'. This is in general impossible, nor is it at all to be desired. No, we mean something else, something which may be roughly described as a 'taming' of the instinct. That is to say, the instinct is brought completely into the harmony of the ego, becomes accessible to all the influences of the other trends in the ego and no longer seeks to go its independent way to satisfaction. If we are asked by what methods and means this result is achieved, it is not easy to find an answer. We can only say: 'So muss denn doch die Hexe dran!' - the Witch Metapsychology. [1937c, 5030]
Various qualifications are required of anyone who is to be beneficially affected by psycho-analysis. To begin with, he must be capable of a psychically normal condition; during periods of confusion or melancholic depression nothing can be accomplished even in cases of hysteria. Furthermore, a certain measure of natural intelligence and ethical development are to be required of him; if the physician has to deal with a worthless character, he soon loses the interest which makes it possible for him to enter profoundly into the patient's mental life. Deep-rooted malformations of character, traits of an actually degenerate constitution, show themselves during treatment as sources of a resistance that can scarcely be overcome. In this respect the constitution of the patient sets a general limit to the curative effect of psychotherapy. If the patient's age is in the neighbourhood of the fifties the conditions for psycho-analysis become unfavourable. The mass of psychical material is then no longer manageable; the time required for recovery is too long; and the ability to undo psychical processes begins to grow weaker.

[1904a, 1560]

To this unimpeachable body of evidence we shall be able to add fresh material, if we turn to the history of the masturbatory side of our patient's sexual activities. There is a conflict between the opinions of doctors and patients on this subject which has not hitherto been properly appreciated. The patients are unanimous in their belief that masturbation, by which they mean masturbation during puberty, is the root and origin of all their troubles. The doctors are, upon the whole, unable to decide what line to take; but, influenced by the knowledge that not only neurotics but most normal people pass through a period of masturbation during their puberty, the majority of them are inclined to dismiss the patients' assertions as gross exaggerations. In my opinion the patients are once again nearer to a correct view than the doctors; for the patients have some glimmering notion of the truth, while the doctors are in danger of overlooking an essential point. The thesis propounded by the patients certainly does not correspond to the facts in the sense in which they themselves construe it, namely, that masturbation during puberty (which may almost be described as a typical occurrence) is responsible for all neurotic disturbances. Their thesis requires interpretation. The masturbation of puberty is in fact no more than a revival of the masturbation of infancy, a subject which has hitherto invariably been neglected. Infantile masturbation reaches a kind of climax, as a rule, between the ages of three and four or five; and it is the clearest expression of a child's sexual constitution, in which the aetiology of subsequent neuroses must be sought. In this disguised way, therefore, the patients are putting the blame for their illnesses upon their infantile sexuality; and they are perfectly right in doing so. On the other hand, the problem of masturbation becomes insoluble if we attempt to treat it as a clinical unit, and forget that it can represent the discharge of every variety of sexual component and of every sort of phantasy to which such components can give rise. The injurious effects of masturbation are only in a very small degree autonomous - that is to say, determined by its own nature. They are in substance merely part and parcel of the pathogenic significance of the subject's sexual life as a whole. The fact that so many people can tolerate masturbation - that is, a certain amount of it - without injury merely shows that their sexual constitution and the course of development of their sexual life have been such as to allow them to exercise the sexual function within the limits of what is culturally permissible; whereas other people, because their sexual constitution has been less favourable or their development has been disturbed, fall ill as a result of their sexuality - they cannot, that is, achieve the necessary suppression or sublimation of their sexual components without having recourse to inhibitions or substitutes.¹

[1909d, 2159]
Where, then, does the libido find the fixations which it requires in order to break through the repressions? In the activities and experiences of infantile sexuality, in the abandoned component trends, in the objects of childhood which have been given up. It is to them, accordingly, that the libido returns. The significance of this period of childhood is twofold: on the one hand, during it the instinctual trends which the child has inherited with his innate disposition first become manifest, and secondly, others of his instincts are for the first time awakened and made active by external impressions and accidental experiences. There is no doubt, I think, that we are justified in making this twofold division. The manifestation of the innate disposition is indeed not open to any critical doubts, but analytic experience actually compels us to assume that purely chance experiences in childhood are able to leave fixations of the libido behind them. Nor do I see any theoretical difficulty in this. Constitutional dispositions are also undoubtedly after-effects of experiences by ancestors in the past; they too were once acquired. Without such acquisition there would be no heredity. And is it conceivable that acquisition such as this, leading to inheritance, would come to an end precisely with the generation we are considering? The significance of infantile experiences should not be totally neglected, as people like doing, in comparison with the experiences of the subject's ancestors and of his own maturity; on the contrary, they call for particular consideration. They are all the more momentous because they occur in times of incomplete development and are for that very reason liable to have traumatic effects. The studies on developmental mechanics by Roux and others have shown that the prick of a needle into an embryonic germinal layer in the act of cell-division results in a severe disturbance of development. The same injury inflicted on a larval or fully grown animal would do no damage.

These facts have a certain interest from the point of view of education, which plans the prevention of neuroses by intervening at an early stage in children's sexual development. So long as one focuses attention principally on infantile sexual experiences, one must suppose that one has done everything for the prophylaxis of nervous illnesses by taking care that the child's development is delayed and that it is spared experiences of the sort. We already know, however, that the preconditions for the causation of neuroses are complex and cannot be influenced in general if we take account of only a single factor. Strict protection of the young loses value because it is powerless against the constitutional factor. Besides, it is more difficult to carry out than educationists imagine and it brings with it two fresh dangers which must not be underestimated: the fact that it may achieve too much - that it may encourage an excess of sexual repression, with damaging results, and the fact that it may send the child out into life without any defence against the onrush of sexual demands that is to be looked for at puberty. Thus it remains extremely doubtful how far prophylaxis in childhood can be carried with advantage and whether an altered attitude to the immediate situation may not offer a better angle of approach for the prevention of neuroses.
You will no doubt have observed that in these last discussions I have introduced a fresh factor into the structure of the aetiological chain - namely the quantity, the magnitude, of the energies concerned. We have still to take this factor into account everywhere. A purely qualitative analysis of the aetiological determinants is not enough. Or, to put it another way, a merely dynamic view of these mental processes is insufficient; an economic line of approach is also needed. We must tell ourselves that the conflict between two trends does not break out till certain intensities of cathexis have been reached, even though the determinants for it have long been present so far as their subject-matter is concerned. In the same way, the pathogenic significance of the constitutional factors must be weighed according to how much more of one component instinct than of another is present in the inherited disposition. It may even be supposed that the disposition of all human beings is qualitatively alike and that they differ only owing to these quantitative conditions. The quantitative factor is no less decisive as regards capacity to resist neurotic illness. It is a matter of what quota of unemployed libido a person is able to hold in suspension and of how large a fraction of his libido he is able to divert from sexual to sublimated aims. The ultimate aim of mental activity, which may be described qualitatively as an endeavour to obtain pleasure and avoid unpleasure, emerges, looked at from the economic point of view, as the task of mastering the amounts of excitation (mass of stimuli) operating in the mental apparatus and of keeping down their accumulation which creates unpleasure.

[1916-1917, 3429]

The fact of there being a connection between sexual restraint and anxiety states is, so far as I know, no longer disputed even by physicians who have no contact with psycho-analysis. But I can well believe that an attempt is made to reverse the relation and to put forward the view that the people concerned are such as are already inclined to apprehensiveness and for that reason practise restraint in sexual matters as well. This, however, is decisively contradicted by the behaviour of women, whose sexual activity is essentially of a passive nature - is determined, that is to say, by their treatment by the man. The more passionate a woman is - the more inclined, therefore, to sexual intercourse and the more capable of being satisfied - the more certain she is to react with manifestations of anxiety to a man's impotence or to coitus interruptus, whereas in the case of anaesthetic women or those without much libido such ill-treatment plays a far smaller part.

[1916-1917, 3449]

Of course, the sexual abstinence now so warmly recommended by doctors only has the same importance in generating anxiety states when the libido which is prevented from finding a satisfying discharge is correspondingly strong and has not been dealt with for the greater part by sublimation. Indeed, the decision on whether the outcome is to be illness or not always lies with quantitative factors. Even where what is in question is not illness but the form assumed by a person's character, it is easy to recognize that sexual restriction goes hand in hand with some kind of anxiousness and hesitancy, while intrepidity and impudent daring bring along with them a free indulgence of sexual needs. However much these relations are altered and complicated by a variety of cultural influences, it nevertheless remains true of the average of mankind that anxiety has a close connection with sexual limitation.

[1916-1917, 3449]
If, then, there are children who come some way to meet this education in anxiety, and who go on to find dangers themselves that they have not been warned against, this is sufficiently explained by the fact that they have a greater amount of innate libidinal need in their constitution or have been prematurely spoiled by libidinal satisfaction. It is not to be wondered at if such children include, too, the later neurotics: as we know, what most facilitates the development of a neurosis is an incapacity to tolerate a considerable damming-up of libido over any great length of time. You will observe that here once more the constitutional factor comes into its rights - and these, indeed, we have never sought to dispute. We are only on our guard against those who in its favour neglect all other claims, and who introduce the constitutional factor at points at which the combined results of observation and analysis show that it does not belong or must take the last place.

I will digress for a moment to ask if you know what is meant by a causal therapy. That is how we describe procedure which does not take the symptoms of an illness as its point of attack but sets about removing its causes. Well, then, is our psycho-analytic method a causal therapy or not? The reply is not a simple one, but it may perhaps give us an opportunity of realizing the worthlessness of a question framed in this way. In so far as analytic therapy does not make it its first task to remove the symptoms, it is behaving like a causal therapy. In another respect, you may say, it is not. For we long ago traced the causal chain back through the repressions to the instinctual dispositions, their relative intensities in the constitution and the deviations in the course of their development. Supposing, now, that it was possible, by some chemical means, perhaps, to interfere in this mechanism, to increase or diminish the quantity of libido present at a given time or to strengthen one instinct at the cost of another - this then would be a causal therapy in the true sense of the word, for which our analysis would have carried out the indispensable preliminary work of reconnaissance. At present, as you know, there is no question of any such method of influencing libidinal processes; with our psychical therapy we attack at a different point in the combination - not exactly at what we know are the roots of the phenomena, but nevertheless far enough away from the symptoms, at a point which has been made accessible to us by some very remarkable circumstances.

The distinction between nervous health and neurosis is thus reduced to a practical question and is decided by the outcome - by whether the subject is left with a sufficient amount of capacity for enjoyment and of efficiency. It probably goes back to the relative sizes of the quota of energy that remains free and of that which is bound by repression, and is of a quantitative not of a qualitative nature. I need not tell you that this discovery is the theoretical justification for our conviction that neuroses are in principle curable in spite of their being based on constitutional disposition.
Only let us hold fast to this: the nodal point and pivot of the whole situation is the relative
strength of the ego organization. We shall then find it easy to complete our aetiological survey.
As what may be called the normal causes of neurotic illness we already know the feebleness of
the childhood ego, the task of dealing with the early sexual impulses and the effects of the more
or less chance experiences of childhood. Is it not possible, however, that yet other factors play a
part, derived from the time before the beginning of the child’s life? For instance, an innate
strength and unruliness of the instinctual life in the id, which from the outset sets the ego tasks
too hard for it? Or a special developmental feebleness of the ego due to unknown reasons?
Such factors must of course acquire an aetiological importance, in some cases a transcendent
one. We have invariably to reckon with the instinctual strength of the id; if it has developed to
excess, the prospects of our therapy are poor. We still know too little of the causes of a
developmental inhibition of the ego. These then would be the cases of neurosis with an
essentially constitutional basis. Without some such constitutional, congenital favouring factors a
neurosis can, no doubt, scarcely come about.
[1926e, 4383]

(2) For cultural reasons the most intense repression falls upon the sexual instincts; but it is
precisely in connection with them that repression most easily miscarries, so that neurotic
symptoms are found to be substitutive satisfactions of repressed sexuality. The belief that in
man sexual life begins only at puberty is incorrect. On the contrary, signs of it can be detected
from the beginning of extra-uterine existence; it reaches a first culminating point at or before the
fifth year (‘early period’), after which it is inhibited or interrupted (‘latency period’) until the age of
puberty, which is the second climax of its development. This diphasic onset of sexual
development seems to be distinctive of the genus Homo. All experiences during the first period
of childhood are of the greatest importance to the individual, and in combination with his
inherited sexual constitution form the dispositions for the subsequent development of character
and disease. It is wrong to make sexuality coincide with ‘genitality’. The sexual instincts pass
through a complicated course of development, and it is only at the end of it that the ‘primacy of
the genital zones’ is attained. Before this there are a number of ‘pregenital’ organizations of the
libido - points at which it may become ‘fixated’ and to which, in the event of subsequent
repression, it will return (‘regression’). The infantile fixations of the libido are what determine the
form of any later neurosis. Thus the neuroses are to be regarded as inhibitions in the
development of the libido. There are no specific causes of nervous disorders; the question
whether a conflict finds a healthy solution or leads to a neurotic inhibition of function depends
upon quantitative considerations.
[1926f, 4405]
Compared with the other psychotherapeutic procedures psycho-analysis is beyond any doubt the most powerful. It is just and fair, too, that this should be so for it is also the most laborious and time-consuming; it would not be used on slight cases. In suitable cases it is possible by its means to get rid of disturbances and bring about changes for which in pre-analytic times one would not have ventured to hope. But it has its very appreciable limits. The therapeutic ambition of some of my adherents has made the greatest efforts to overcome these obstacles so that every sort of neurotic disorder might be curable by psycho-analysis. They have endeavoured to compress the work of analysis into a shorter duration, to intensify transference so that it may be able to overcome any resistance, to unite other forms of influence with it so as to compel a cure. These efforts are certainly praiseworthy, but, in my opinion, they are vain. They bring with them, too, a danger of being oneself forced away from analysis and drawn into a boundless course of experimentation. The expectation that every neurotic phenomenon can be cured may, I suspect, be derived from the layman's belief that the neuroses are something quite unnecessary which have no right whatever to exist. Whereas in fact they are severe, constitutionally fixed illnesses, which rarely restrict themselves to only a few attacks but persist as a rule over long periods or throughout life. Our analytic experience that they can be extensively influenced, if the historical precipitating causes and accidental auxiliary factors of the illness can be dealt with, has led us to neglect the constitutional factor in our therapeutic practice, and in any case we can do nothing about it; but in theory we ought always to bear it in mind. The radical inaccessibility of the psychoses to analytic treatment should, in view of their close relationship to the neuroses, restrict our pretensions in regard to these latter. The therapeutic effectiveness of psycho-analysis remains cramped by a number of weighty and scarcely assailable factors. In the case of children, where one might count on the greatest successes, the difficulties are the external ones connected with their relation to their parents, though these difficulties are after all a necessary part of being a child. In the case of adults the difficulties arise in the first instance from two factors: the amount of psychical rigidity present and the form of the illness with all that covers in the way of deeper determinants.

[1933a, 4752]

We need not be at a loss to find an answer to this question. Quantitative disharmonies are what must be held responsible for the inadequacy and sufferings of neurotics. The determining cause of all the forms taken by human mental life, is, indeed, to be sought in the reciprocal action between innate dispositions and accidental experiences. Now a particular instinct may be too strong or too weak innately, or a particular capacity may be stunted or insufficiently developed in life. On the other hand, external impressions and experiences may make demands of differing strength on different people; and what one person's constitution can deal with may prove an unmanageable task for another's. These quantitative differences will determine the variety of the results.

[1940a [1938], 4992]
Every analyst will have treated a few cases which have had this gratifying outcome. He has
succeeded in clearing up the patient's neurotic disturbance, and it has not returned and has not
been replaced by any other such disturbance. Nor are we without some insight into the
determinants of these successes. The patient's ego had not been noticeably altered and the
aetiology of his disturbance had been essentially traumatic. The aetiology of every neurotic
disturbance is, after all, a mixed one. It is a question either of the instincts being excessively
strong - that is to say, recalcitrant to taming by the ego - or of the effects of early (i.e.
premature) traumas which the immature ego was unable to master. As a rule there is a
combination of both factors, the constitutional and the accidental. The stronger the constitutional
factor, the more readily will a trauma lead to a fixation and leave behind a developmental
disturbance; the stronger the trauma, the more certainly will its injurious effects become
manifest even when the instinctual situation is normal. There is no doubt that an aetiology of the
traumatic sort offers by far the more favourable field for analysis. Only when a case is a
predominantly traumatic one will analysis succeed in doing what it is so superlatively able to do;
only then will it, thanks to having strengthened the patient's ego, succeed in replacing by a
correct solution the inadequate decision made in his early life. Only in such cases can one
speak of an analysis having been definitively ended. In them, analysis has done all that it should
and does not need to be continued. It is true that, if the patient who has been restored in this
way never produces another disorder calling for analysis, we do not know how much his
immunity may not be due to a kind fate which has spared him ordeals that are too severe.
[1937c, 5018]

A constitutional strength of instinct and an unfavourable alteration of the ego acquired in its
defensive struggle in the sense of its being dislocated and restricted - these are the factors
which are prejudicial to the effectiveness of analysis and which may make its duration
interminable. One is tempted to make the first factor - strength of instinct - responsible as well
for the emergence of the second - the alteration of the ego; but it seems that the latter too has
an aetiology of its own. And, indeed, it must be admitted that our knowledge of these matters is
as yet insufficient. They are only now becoming the subject of analytic study. In this field the
interest of analysts seems to me to be quite wrongly directed. Instead of an enquiry into how a
cure by analysis comes about (a matter which I think has been sufficiently elucidated) the
question should be asked of what are the obstacles that stand in the way of such a cure.
[1937c, 5019]
Of the three factors which we have recognized as being decisive for the success or otherwise of analytic treatment - the influence of traumas, the constitutional strength of the instincts and alterations of the ego - what concerns us here is only the second, the strength of the instincts. A moment's reflection raises a doubt whether the restrictive use of the adjective 'constitutional' (or 'congenital') is essential. However true it may be that the constitutional factor is of decisive importance from the very beginning, it is nevertheless conceivable that a reinforcement of instinct coming later in life might produce the same effects. If so, we should have to modify our formula and say 'the strength of the instincts at the time' instead of 'the constitutional strength of the instincts'. The first of our questions was: 'Is it possible by means of analytic therapy to dispose of a conflict between an instinct and the ego, or of a pathogenic instinctual demand upon the ego, permanently and definitively?' To avoid misunderstanding it is not unnecessary, perhaps, to explain more exactly what is meant by 'permanently disposing of an instinctual demand'. Certainly not 'causing the demand to disappear so that nothing more is ever heard from it again'. This is in general impossible, nor is it at all to be desired. No, we mean something else, something which may be roughly described as a 'taming' of the instinct. That is to say, the instinct is brought completely into the harmony of the ego, becomes accessible to all the influences of the other trends in the ego and no longer seeks to go its independent way to satisfaction. If we are asked by what methods and means this result is achieved, it is not easy to find an answer. We can only say: 'So muss denn doch die Hexe dran!' - the Witch Metapsychology. Without metapsychological speculation and theorizing - I had almost said 'phantasying' - we shall not get another step forward. Unfortunately, here as elsewhere, what our Witch reveals is neither very clear nor very detailed. We have only a single clue to start from - though it is a clue of the highest value - namely, the antithesis between the primary and the secondary processes; and to that antithesis I shall at this point turn.

If now we take up our first question once more, we find that our new line of approach inevitably leads us to a particular conclusion. The question was whether it is possible to dispose of an instinctual conflict permanently and definitively - i.e. to 'tame' an instinctual demand in that fashion. Formulated in these terms, the question makes no mention at all of the strength of the instinct; but it is precisely on this that the outcome depends. Let us start from the assumption that what analysis achieves for neurotics is nothing other than what normal people bring about for themselves without its help. Everyday experience, however, teaches us that in a normal person any solution of an instinctual conflict only holds good for a particular strength of instinct, or, more correctly, only for a particular relation between the strength of the instinct and the strength of the ego.¹ If the strength of the ego diminishes, whether through illness or exhaustion, or from some similar cause, all the instincts which have so far been successfully tamed may renew their demands and strive to obtain substitutive satisfactions in abnormal ways.² Irrefutable proof of this statement is supplied by our nightly dreams; they react to the sleeping attitude assumed by the ego with an awakening of instinctual demands.

¹ Or, to be perfectly accurate, where that relation falls within certain limits.

² [1937c, 5023]
We started from the question of how we can shorten the inconveniently long duration of analytic treatment, and, still with this question of time in mind, we went on to consider whether it is possible to achieve a permanent cure or even to prevent future illness by prophylactic treatment. In doing so, we found that the factors which were decisive for the success of our therapeutic efforts were the influence of traumatic aetiology, the relative strength of the instincts which have to be controlled, and something which we have called an alteration of the ego. Only the second of these factors has been discussed by us in any detail, and in connection with it we have had occasion to recognize the paramount importance of the quantitative factor and to stress the claim of the metapsychological line of approach to be taken into account in any attempt at explanation.

[1937c, 5030]
The reproaches against her father for having made her ill, together with the self-reproach underlying them, the leucorrhoea, the playing with the reticule, the bed-wetting after her sixth year, the secret which she would not allow the doctors to tear from her - the circumstantial evidence of her having masturbated in childhood seems to me complete and without a flaw. In the present case I had begun to suspect the masturbation when she had told me of her cousin's gastric pains, and had then identified herself with her by complaining for days together of similar painful sensations. It is well known that gastric pains occur especially often in those who masturbate. According to a personal communication made to me by Wilhelm Fliess, it is precisely gastralgias of this character which can be interrupted by an application of cocaine to the 'gastric spot' discovered by him in the nose, and which can be cured by the cauterization of the same spot. In confirmation of my suspicion Dora gave me two facts from her conscious knowledge: she herself had frequently suffered from gastric pains, and she had good reasons for believing that her cousin was a masturbator. It is a very common thing for patients to recognize in other people a connection which, on account of their emotional resistances, they cannot perceive in themselves. And, indeed, Dora no longer denied my supposition, although she still remembered nothing. Even the date which she assigned to the bed-wetting, when she said that it lasted 'till a short time before the appearance of the nervous asthma', appears to me to be of clinical significance. Hysterical symptoms hardly ever appear so long as children are masturbating, but only afterwards, when a period of abstinence has set in;¹ they form a substitute for masturbatory satisfaction, the desire for which continues to persist in the unconscious until another and more normal kind of satisfaction appears - where that is still attainable. For upon whether it is still attainable or not depends the possibility of a hysteria being cured by marriage and normal sexual intercourse. But if the satisfaction afforded in marriage is again removed - as it may be owing to coitus interruptus, psychological estrangement, or other causes - then the libido flows back again into its old channel and manifests itself once more in hysterical symptoms.

[1905e, 1415]

(h) Another temptation arises out of the educative activity which, in psycho-analytic treatment, devolves on the doctor without any deliberate intention on his part. When the developmental inhibitions are resolved, it happens of itself that the doctor finds himself in a position to indicate new aims for the trends that have been liberated. It is then no more than a natural ambition if he endeavours to make something specially excellent of a person whom he has been at such pains to free from his neurosis and if he prescribes high aims for his wishes. But here again the doctor should hold himself in check, and take the patient's capacities rather than his own desires as guide. Not every neurotic has a high talent for sublimation; one can assume of many of them that they would not have fallen ill at all if they had possessed the art of sublimating their instincts. If we press them unduly towards sublimation and cut them off from the most accessible and convenient instinctual satisfactions, we shall usually make life even harder for them than they feel it in any case. As a doctor, one must above all be tolerant to the weakness of a patient, and must be content if one has won back some degree of capacity for work and enjoyment for a person even of only moderate worth. Educative ambition is of as little use as therapeutic ambition. It must further be borne in mind that many people fall ill precisely from an attempt to sublimate their instincts beyond the degree permitted by their organization and that in those who have a capacity for sublimation the process usually takes place of itself as soon as their inhibitions have been overcome by analysis. In my opinion, therefore, efforts invariably to make use of the analytic treatment to bring about sublimation of instinct are, though no doubt always laudable, far from being in every case advisable.

[1912e, 2473]
With this as a starting-point we go on to make our first important discovery. We learn that, when we try to understand neurotic disorders, by far the greater significance attaches to the sexual instincts; that in fact neuroses are the specific disorders, so to speak, of the sexual function; that in general whether or not a person develops a neurosis depends on the quantity of his libido, and on the possibility of satisfying it and of discharging it through satisfaction; that the form taken by the disease is determined by the way in which the individual passes through the course of development of his sexual function, or, as we put it, by the fixations his libido has undergone in the course of its development; and, further, that by a special, not very simple technique for influencing the mind we are able to throw light on the nature of some groups of neuroses and at the same time to do away with them. Our therapeutic efforts have their greatest success with a certain class of neuroses which proceed from a conflict between the ego-instincts and the sexual instincts. For in human beings it may happen that the demands of the sexual instincts, whose reach of course extends far beyond the individual, seem to the ego to constitute a danger which threatens its self-preservation or its self-esteem. The ego then assumes the defensive, denies the sexual instincts the satisfaction they desire and forces them into those by-paths of substitutive satisfaction which become manifest as nervous symptoms. [1917a, 3609]

Psycho-analysis leads to less simple and satisfactory conclusions. What I have to say in this connection has long been familiar and I have nothing new to add. If the ego succeeds in protecting itself from a dangerous instinctual impulse, through, for instance, the process of repression, it has certainly inhibited and damaged the particular part of the id concerned; but it has at the same time given it some independence and has renounced some of its own sovereignty. This is inevitable from the nature of repression, which is, fundamentally, an attempt at flight. The repressed is now, as it were, an outlaw; it is excluded from the great organization of the ego and is subject only to the laws which govern the realm of the unconscious. If, now, the danger-situation changes so that the ego has no reason for fending off a new instinctual impulse analogous to the repressed one, the consequence of the restriction of the ego which has taken place will become manifest. The new impulse will run its course under an automatic influence - or, as I should prefer to say, under the influence of the compulsion to repeat. It will follow the same path as the earlier, repressed impulse, as though the danger-situation that had been overcome still existed. The fixating factor in repression, then, is the unconscious id's compulsion to repeat - a compulsion which in normal circumstances is only done away with by the freely mobile function of the ego. The ego may occasionally manage to break down the barriers of repression which it has itself put up and to recover its influence over the instinctual impulse and direct the course of the new impulse in accordance with the changed danger-situation. But in point of fact the ego very seldom succeeds in doing this: it cannot undo its repressions. It is possible that the way the struggle will go depends upon quantitative relations. In some cases one has the impression that the outcome is an enforced one: the regressive attraction exerted by the repressed impulse and the strength of the repression are so great that the new impulse has no choice but to obey the compulsion to repeat. In other cases we perceive a contribution from another play of forces: the attraction exerted by the repressed prototype is reinforced by a repulsion coming from the direction of difficulties in real life which stand in the way of any different course that might be taken by the new instinctual impulse. [1926d, 4307]
The sexual instinct - or, more correctly, the sexual instincts, for analytic investigation teaches us that the sexual instinct is made up of many separate constituents or component instincts - is probably more strongly developed in man than in most of the higher animals; it is certainly more constant, since it has almost entirely overcome the periodicity to which it is tied in animals. It places extraordinarily large amounts of force at the disposal of civilized activity, and it does this in virtue of its especially marked characteristic of being able to displace its aim without materially diminishing in intensity. This capacity to exchange its originally sexual aim for another one, which is no longer sexual but which is psychically related to the first aim, is called the capacity for *sublimation*. In contrast to this displaceability, in which its value for civilization lies, the sexual instinct may also exhibit a particularly obstinate fixation which renders it unserviceable and which sometimes causes it to degenerate into what are described as abnormalities. The original strength of the sexual instinct probably varies in each individual; certainly the proportion of it which is suitable for sublimation varies. It seems to us that it is the innate constitution of each individual which decides in the first instance how large a part of his sexual instinct it will be possible to sublimate and make use of. In addition to this, the effects of experience and the intellectual influences upon his mental apparatus succeed in bringing about the sublimation of a further portion of it. To extend this process of displacement indefinitely is, however, certainly not possible, any more than is the case with the transformation of heat into mechanical energy in our machines. A certain amount of direct sexual satisfaction seems to be indispensable for most organizations, and a deficiency in this amount, which varies from individual to individual, is visited by phenomena which, on account of their detrimental effects on functioning and their subjective quality of unpleasure, must be regarded as an illness.

The retardation of sexual development and sexual activity at which our education and civilization aim is certainly not injurious to begin with. It is seen to be a necessity, when one considers the late age at which young people of the educated classes reach independence and are able to earn a living. (This reminds one, incidentally, of the intimate interconnection between all our cultural institutions and of the difficulty of altering any part of them without regard to the whole.) But abstinence continued long after the age of twenty is no longer unobjectionable for a young man; and it leads to other damage even when it does not lead to neurosis. People say, to be sure, that the struggle against such a powerful instinct, and the strengthening of all the ethical and aesthetic forces which are necessary for this struggle, 'steel' the character; and this is true for a few specially favourably organized natures. It must also be admitted that the differentiation of individual character, which is so marked in our day, has only become possible with the existence of sexual restriction. But in the vast majority of cases the struggle against sexuality eats up the energy available in a character and this at the very time when a young man is in need of all his forces in order to win his share and place in society. The relationship between the amount of sublimation possible and the amount of sexual activity necessary naturally varies very much from person to person and even from one calling to another. An abstinent artist is hardly conceivable; but an abstinent young *savant* is certainly no rarity. The latter can, by his self-restraint, liberate forces for his studies; while the former probably finds his artistic achievements powerfully stimulated by his sexual experience. In general, I have not gained the impression that sexual abstinence helps to bring about energetic and self-reliant men of action or original thinkers or bold emancipators and reformers. Far more often it goes to produce well-behaved weaklings who later become lost in the great mass of people that tends to follow, unwillingly, the leads given by strong individuals.
But even if the historical material at our disposal were very abundant, and if the psychical mechanisms could be dealt with with the greatest assurance, there are two important points at which a psycho-analytic enquiry would not be able to make us understand how inevitable it was that the person concerned should have turned out in the way he did and in no other way. In Leonardo’s case we have had to maintain the view that the accident of his illegitimate birth and the excessive tenderness of his mother had the most decisive influence on the formation of his character and on his later fortune, since the sexual repression which set in after this phase of childhood caused him to sublimate his libido into the urge to know, and established his sexual inactivity for the whole of his later life. But this repression after the first erotic satisfactions of childhood need not necessarily have taken place; in someone else it might perhaps not have taken place or might have assumed much less extensive proportions. We must recognize here a degree of freedom which cannot be resolved any further by psycho-analytic means. Equally, one has no right to claim that the consequence of this wave of repression was the only possible one. It is probable that another person would not have succeeded in withdrawing the major portion of his libido from repression by sublimating it into a craving for knowledge; under the same influences he would have sustained a permanent injury to his intellectual activity or have acquired an insurmountable disposition to obsessional neurosis. We are left, then, with these two characteristics of Leonardo which are inexplicable by the efforts of psycho-analysis: his quite special tendency towards instinctual repressions, and his extraordinary capacity for sublimating the primitive instincts.

[1910c, 2303]

(h) Another temptation arises out of the educative activity which, in psycho-analytic treatment, devolves on the doctor without any deliberate intention on his part. When the developmental inhibitions are resolved, it happens of itself that the doctor finds himself in a position to indicate new aims for the trends that have been liberated. It is then no more than a natural ambition if he endeavours to make something specially excellent of a person whom he has been at such pains to free from his neurosis and if he prescribes high aims for his wishes. But here again the doctor should hold himself in check, and take the patient’s capacities rather than his own desires as guide. Not every neurotic has a high talent for sublimation; one can assume of many of them that they would not have fallen ill at all if they had possessed the art of sublimating their instincts. If we press them unduly towards sublimation and cut them off from the most accessible and convenient instinctual satisfactions, we shall usually make life even harder for them than they feel it in any case. As a doctor, one must above all be tolerant to the weakness of a patient, and must be content if one has won back some degree of capacity for work and enjoyment for a person even of only moderate worth. Educative ambition is of as little use as therapeutic ambition. It must further be borne in mind that many people fall ill precisely from an attempt to sublimate their instincts beyond the degree permitted by their organization and that in those who have a capacity for sublimation the process usually takes place of itself as soon as their inhibitions have been overcome by analysis. In my opinion, therefore, efforts invariably to make use of the analytic treatment to bring about sublimation of instinct are, though no doubt always laudable, far from being in every case advisable.

[1912e, 2473]
(d) Just as the third type has brought the dispositional determinant before us almost in isolation, so the fourth type, which now follows, draws our attention to another factor, which comes into consideration in every single case and might easily for that very reason be overlooked in a theoretical discussion. We see people fall ill who have hitherto been healthy, who have met with no fresh experience and whose relation to the external world has undergone no change, so that the onset of their illness inevitably gives an impression of spontaneity. A closer consideration of such cases, however, shows us that none the less a change has taken place in them whose importance we must rate very highly as a cause of illness. As a result of their having reached a particular period of life, and in conformity with regular biological processes, the quantity of libido in their mental economy has experienced an increase which is in itself enough to upset the equilibrium of their health and to set up the necessary conditions for a neurosis. It is well known that more or less sudden increases of libido of this kind are habitually associated with puberty and the menopause - with the attainment of a certain age in women; in some people they may in addition be manifested in periodicities that are still unknown. Here the damming-up of libido is the primary factor; it becomes pathogenic as a consequence of a relative frustration on the part of the external world, which would still have granted satisfaction to a smaller claim by the libido. The unsatisfied and dammed-up libido can once again open up paths to regression and kindle the same conflicts which we have demonstrated in the case of absolute external frustration. We are reminded in this way that the quantitative factor should not be left out of account in any consideration of the precipitating causes of illness. All the other factors - frustration, fixation, developmental inhibition - remain ineffective unless they affect a certain amount of libido and bring about a damming-up of libido of a certain height. It is true that we are unable to measure this amount of libido which seems to us indispensable for a pathogenic effect; we can only postulate it after the resulting illness has started. There is only one direction in which we can determine it more precisely. We may assume that it is not a question of an absolute quantity, but of the relation between the quota of libido in operation and the quantity of libido which the individual ego is able to deal with - that is, to hold under tension, to sublimate or to employ directly. For this reason a relative increase in the quantity of libido may have the same effects as an absolute one. An enfeeblement of the ego owing to organic illness or owing to some special demand upon its energy will be able to cause the emergence of neuroses which would otherwise have remained latent in spite of any disposition that might be present.

[1912c, 2563]
In further pursuing the discussion of this thesis, are we to consider the nature of the frustration or the peculiar character of those who are affected by it? It is extremely seldom, after all, that frustration is universal and absolute. In order to operate pathogenically it must no doubt affect the mode of satisfaction which alone the subject desires, of which alone he is capable. There are in general very many ways of tolerating deprivation of libidinal satisfaction without falling ill as a result. In the first place, we know people who are able to put up with a deprivation of this kind without being injured: they are not happy, they suffer from longing, but they do not fall ill. Next, we must bear in mind that the sexual instinctual impulses in particular are extraordinarily plastic, if I may so express it. One of them can take the place of another, one of them can take over another's intensity; if the satisfaction of one of them is frustrated by reality, the satisfaction of another can afford complete compensation. They are related to one another like a network of intercommunicating channels filled with a liquid; and this is so in spite of their being subject to the primacy of the genitals - a state of affairs that is not at all easily combined in a single picture. Further, the component instincts of sexuality, as well as the sexual current which is compounded from them, exhibit a large capacity for changing their object, for taking another in its place - and one, therefore, that is more easily attainable. This displaceability and readiness to accept a substitute must operate powerfully against the pathogenic effect of a frustration. Among these protective processes against falling ill owing to deprivation there is one which has gained special cultural significance. It consists in the sexual trend abandoning its aim of obtaining a component or a reproductive pleasure and taking on another which is related genetically to the abandoned one but is itself no longer sexual and must be described as social. We call this process 'sublimation', in accordance with the general estimate that places social aims higher than the sexual ones, which are at bottom self-interested. Sublimation is, incidentally, only a special case of the way in which sexual trends are attached to other, non-sexual ones. We shall have to discuss it again in another connection.

You may now have an impression that deprivation has been reduced to insignificance owing to all these methods of tolerating it. But no, it retains its pathogenic power. The counter-measures are on the whole insufficient. There is a limit to the amount of unsatisfied libido that human beings on the average can put up with. The plasticity or free mobility of the libido is by no means fully preserved in everyone, and sublimation is never able to deal with more than a certain fraction of libido, quite apart from the fact that many people are gifted with only a small amount of capacity to sublimate. The most important of these limitations is evidently that upon the mobility of the libido, since it makes a person's satisfaction depend on the attainment of only a very small number of aims and objects. You have only to recall that an imperfect development of the libido leaves behind it very fertile and perhaps, too, very numerous libidinal fixations to early phases of the organization and of the finding of objects, which are for the most part incapable of real satisfaction, and you will recognize in libidinal fixation the second powerful factor which combines with frustration as the cause of illness. You can declare, as a schematic abbreviation, that libidinal fixation represents the predisposing, internal factor in the aetiology of the neuroses, while frustration represents the accidental, external one.
You will no doubt have observed that in these last discussions I have introduced a fresh factor into the structure of the aetiological chain - namely the quantity, the magnitude, of the energies concerned. We have still to take this factor into account everywhere. A purely qualitative analysis of the aetiological determinants is not enough. Or, to put it another way, a merely *dynamic* view of these mental processes is insufficient; an *economic* line of approach is also needed. We must tell ourselves that the conflict between two trends does not break out till certain intensities of cathexis have been reached, even though the determinants for it have long been present so far as their subject-matter is concerned. In the same way, the pathogenic significance of the constitutional factors must be weighed according to how much more of one component instinct than of another is present in the inherited disposition. It may even be supposed that the disposition of all human beings is qualitatively alike and that they differ only owing to these quantitative conditions. The quantitative factor is no less decisive as regards capacity to resist neurotic illness. It is a matter of *what quota* of unemployed libido a person is able to hold in suspension and of *how large a fraction* of his libido he is able to divert from sexual to sublimated aims. The ultimate aim of mental activity, which may be described qualitatively as an endeavour to obtain pleasure and avoid unpleasure, emerges, looked at from the economic point of view, as the task of mastering the amounts of excitation (mass of stimuli) operating in the mental apparatus and of keeping down their accumulation which creates unpleasure.

[1916-1917, 3429]

Of course, the sexual abstinence now so warmly recommended by doctors only has the same importance in generating anxiety states when the libido which is prevented from finding a satisfying discharge is correspondingly strong and has not been dealt with for the greater part by sublimation. Indeed, the decision on whether the outcome is to be illness or not always lies with quantitative factors. Even where what is in question is not illness but the form assumed by a person's character, it is easy to recognize that sexual restriction goes hand in hand with some kind of anxiousness and hesitancy, while intrepidity and impudent daring bring along with them a free indulgence of sexual needs. However much these relations are altered and complicated by a variety of cultural influences, it nevertheless remains true of the average of mankind that anxiety has a close connection with sexual limitation.

[1916-1917, 3449]
Let us once more glance over the situation which we have reached in our attempt at bringing help to the patient's neurotic ego. That ego is no longer able to fulfil the task set it by the external world (including human society). Not all of its experiences are at its disposal, a large proportion of its store of memories have escaped it. Its activity is inhibited by strict prohibitions from the super-ego, its energy is consumed in vain attempts at fending off the demands of the id. Beyond this, as a result of continuous irruptions by the id, its organization is impaired, it is no longer capable of any proper synthesis, it is torn by mutually opposed urges, by unsettled conflicts and by unsolved doubts. To start with, we get the patient's thus weakened ego to take part in the purely intellectual work of interpretation, which aims at provisionally filling the gaps in his mental assets, and to transfer to us the authority of his super-ego; we encourage it to take up the struggle over each individual demand made by the id and to conquer the resistances which arise in connection with it. At the same time we restore order in the ego by detecting the material and urges which have forced their way in from the unconscious, and expose them to criticism by tracing them back to their origin. We serve the patient in various functions, as an authority and a substitute for his parents, as a teacher and educator; and we have done the best for him if, as analysts, we raise the mental processes in his ego to a normal level, transform what has become unconscious and repressed into preconscious material and thus return it once more to the possession of his ego. On the patient's side a few rational factors work in our favour, such as the need for recovery which has its motive in his sufferings, and the intellectual interest that we may awaken in him in the theories and revelations of psycho-analysis; but of far greater force is the positive transference with which he meets us. Fighting against us, on the other hand, are the negative transference, the ego's resistance due to repression (that is, its unpleasure at having to lay itself open to the hard work imposed on it), the sense of guilt arising from its relation to the super-ego and the need to be ill due to deep-going changes in the economics of his instincts. The share taken by the last two factors decides whether the case is to be regarded as slight or severe. Apart from these, a few other factors may be discerned as having a favourable or unfavourable bearing. A certain psychical inertia, a sluggishness of the libido, which is unwilling to abandon its fixations cannot be welcome to us; the patient's capacity for sublimating his instincts plays a large part and so does his capacity for rising above the crude life of the instincts; so, too, does the relative power of his intellectual functions.

[1940a [1938], 4990]
What means have we at our disposal for overcoming this continual resistance? Few, but they include almost all those by which one man can ordinarily exert a psychical influence on another. In the first place, we must reflect that a psychical resistance, especially one that has been in force for a long time, can only be resolved slowly and by degrees, and we must wait patiently. In the next place, we may reckon on the intellectual interest which the patient begins to feel after working for a short time. By explaining things to him, by giving him information about the marvellous world of psychical processes into which we ourselves only gained insight by such analyses, we make him himself into a collaborator, induce him to regard himself with the objective interest of an investigator, and thus push back his resistance, resting as it does on an affective basis. But lastly - and this remains the strongest lever - we must endeavour, after we have discovered the motives for his defence, to deprive them of their value or even to replace them by more powerful ones. This no doubt is where it ceases to be possible to state psychotherapeutic activity in formulas. One works to the best of one's power, as an elucidator (where ignorance has given rise to fear), as a teacher, as the representative of a freer or superior view of the world, as a father confessor who gives absolution, as it were, by a continuance of his sympathy and respect after the confession has been made. One tries to give the patient human assistance, so far as this is allowed by the capacity of one's own personality and by the amount of sympathy that one can feel for the particular case. It is an essential precondition for such psychical activity that we should have more or less divined the nature of the case and the motives of the defence operating in it, and fortunately the technique of insistence and pressure takes us as far as this. The more such riddles we have already solved, the easier we may find it to guess a new one and the sooner we shall be able to start on the truly curative psychical work. For it is well to recognize this clearly: the patient only gets free from the hysterical symptom by reproducing the pathogenic impressions that caused it and by giving utterance to them with an expression of affect, and thus the therapeutic task consists solely in inducing him to do so; when once this task has been accomplished there is nothing left for the physician to correct or to remove. Whatever may be required for this purpose in the way of counter-suggestions has already been expended during the struggle against the resistance. The situation may be compared with the unlocking of a locked door, after which opening it by turning the handle offers no further difficulty.

The chief difference has already been named. In the neurotic the secret is hidden from his own consciousness; in the criminal it is hidden only from you. In the former there is a genuine ignorance, though not an ignorance in every sense, while in the latter there is nothing but a pretence of ignorance. Connected with this is another difference, which is in practice of importance. In psycho-analysis the patient assists with his conscious efforts to combat his resistance, because he expects to gain something from the investigation, namely, his recovery. The criminal, on the other hand, does not work with you; if he did, he would be working against his whole ego. As though to make up for this, however, all you are endeavouring to arrive at in your investigation is an objective certainty on your part, whereas our therapy demands that the patient himself should also arrive at the same certainty. But it remains to be seen how far your procedure will be rendered more difficult or be altered by the lack of co-operation on the part of the subject of your examination. This is a situation which you can never create in your experiments in seminars, since the colleague who is playing the part of the accused man remains a fellow-worker after all, and assists you in spite of his conscious determination not to betray himself.
It is now time for us to take a survey of the play of forces which is set in motion by the treatment. The primary motive force in the therapy is the patient's suffering and the wish to be cured that arises from it. The strength of this motive force is subtracted from by various factors - which are not discovered till the analysis is in progress - above all, by what we have called the 'secondary gain from illness'; but it must be maintained till the end of the treatment. Every improvement effects a diminution of it. By itself, however, this motive force is not sufficient to get rid of the illness. Two things are lacking in it for this: it does not know what paths to follow to reach this end; and it does not possess the necessary quota of energy with which to oppose the resistances. The analytic treatment helps to remedy both these deficiencies. It supplies the amounts of energy that are needed for overcoming the resistances by making mobile the energies which lie ready for the transference; and, by giving the patient information at the right time, it shows him the paths along which he should direct those energies. Often enough the transference is able to remove the symptoms of the disease by itself, but only for a while - only for as long as it itself lasts. In this case the treatment is a treatment by suggestion, and not a psycho-analysis at all. It only deserves the latter name if the intensity of the transference has been utilized for the overcoming of resistances. Only then has being ill become impossible, even when the transference has once more been dissolved, which is its destined end.

[1913c, 2494]

How do we remove the resistance? In the same way: by discovering it and showing it to the patient. Indeed, the resistance too is derived from a repression - from the same one that we are endeavouring to resolve, or from one that took place earlier. It was set up by the anticathexis which arose in order to repress the objectionable impulse. Thus we now do the same thing that we tried to do to begin with: interpret, discover and communicate; but now we are doing it at the right place. The anticathexis or the resistance does not form part of the unconscious but of the ego, which is our collaborator, and is so even if it is not conscious. As we know, the word 'unconscious' is being used here in two senses: on the one hand as a phenomenon and on the other as a system. This sounds very difficult and obscure; but is it not only repeating what we have already said in earlier passages? We have long been prepared for it. We expect that this resistance will be given up and the anticathexis withdrawn when our interpretation has made it possible for the ego to recognize it. What are the motive forces that we work with in such a case? First with the patient's desire for recovery, which has induced him to take part with us in our joint work, and secondly with the help of his intelligence, to which we give support by our interpretation. There is no doubt that it is easier for the patient's intelligence to recognize the resistance and to find the translation corresponding to what is repressed if we have previously given him the appropriate anticipatory ideas. If I say to you: 'Look up at the sky! There's a balloon there!' you will discover it much more easily than if I simply tell you to look up and see if you can see anything. In the same way, a student who is looking through a microscope for the first time is instructed by his teacher as to what he will see; otherwise he does not see it at all, though it is there and visible.

[1916-1917, 3479]
Let us once more glance over the situation which we have reached in our attempt at bringing help to the patient's neurotic ego. That ego is no longer able to fulfil the task set it by the external world (including human society). Not all of its experiences are at its disposal, a large proportion of its store of memories have escaped it. Its activity is inhibited by strict prohibitions from the super-ego, its energy is consumed in vain attempts at fending off the demands of the id. Beyond this, as a result of continuous irruptions by the id, its organization is impaired, it is no longer capable of any proper synthesis, it is torn by mutually opposed urges, by unsettled conflicts and by unsolved doubts. To start with, we get the patient's thus weakened ego to take part in the purely intellectual work of interpretation, which aims at provisionally filling the gaps in his mental assets, and to transfer to us the authority of his super-ego; we encourage it to take up the struggle over each individual demand made by the id and to conquer the resistances which arise in connection with it. At the same time we restore order in the ego by detecting the material and urges which have forced their way in from the unconscious, and expose them to criticism by tracing them back to their origin. We serve the patient in various functions, as an authority and a substitute for his parents, as a teacher and educator; and we have done the best for him if, as analysts, we raise the mental processes in his ego to a normal level, transform what has become unconscious and repressed into preconscious material and thus return it once more to the possession of his ego. On the patient's side a few rational factors work in our favour, such as the need for recovery which has its motive in his sufferings, and the intellectual interest that we may awaken in him in the theories and revelations of psycho-analysis; but of far greater force is the positive transference with which he meets us. Fighting against us, on the other hand, are the negative transference, the ego's resistance due to repression (that is, its unpleasure at having to lay itself open to the hard work imposed on it), the sense of guilt arising from its relation to the super-ego and the need to be ill due to deep-going changes in the economics of his instincts. The share taken by the last two factors decides whether the case is to be regarded as slight or severe. Apart from these, a few other factors may be discerned as having a favourable or unfavourable bearing. A certain psychical inertia, a sluggishness of the libido, which is unwilling to abandon its fixations cannot be welcome to us; the patient's capacity for sublimating his instincts plays a large part and so does his capacity for rising above the crude life of the instincts; so, too, does the relative power of his intellectual functions.

[1940a [1938], 4990]
The therapeutic effect depends on making conscious what is repressed, in the widest sense of the word, in the id. We prepare the way for this making conscious by interpretations and constructions, but we have interpreted only for ourselves not for the patient so long as the ego holds on to its earlier defences and does not give up its resistances. Now these resistances, although they belong to the ego, are nevertheless unconscious and in some sense separated off within the ego. The analyst recognizes them more easily than he does the hidden material in the id. One might suppose that it would be sufficient to treat them like portions of the id and, by making them conscious, bring them into connection with the rest of the ego. In this way, we should suppose, one half of the task of analysis would be accomplished; we should not reckon on meeting with a resistance against the uncovering of resistances. But what happens is this. During the work on the resistances the ego withdraws - with a greater or less degree of seriousness - from the agreement on which the analytic situation is founded. The ego ceases to support our efforts at uncovering the id; it opposes them, disobeys the fundamental rule of analysis, and allows no further derivatives of the repressed to emerge. We cannot expect the patient to have a strong conviction of the curative power of analysis. He may have brought along with him a certain amount of confidence in his analyst, which will be strengthened to an effective point by the factors of the positive transference which will be aroused in him. Under the influence of the unpleasurable impulses which he feels as a result of the fresh activation of his defensive conflicts, negative transferences may now gain the upper hand and completely annul the analytic situation. The patient now regards the analyst as no more than a stranger who is making disagreeable demands on him, and he behaves towards him exactly like a child who does not like the stranger and does not believe anything he says. If the analyst tries to explain to the patient one of the distortions made by him for the purposes of defence, and to correct it, he finds him uncomprehending and inaccessible to sound arguments. Thus we see that there is a resistance against the uncovering of resistances, and the defensive mechanisms really do deserve the name which we gave them originally, before they had been more closely examined. They are resistances not only to the making conscious of contents of the id, but also to the analysis as a whole, and thus to recovery.

[1937c, 5034]
Therapeutic success, however, is not our primary aim; we endeavour rather to enable the patient to obtain a conscious grasp of his unconscious wishes. And this we can achieve by working upon the basis of the hints he throws out, and so, with the help of our interpretative technique, presenting the unconscious complex to his consciousness in our own words. There will be a certain degree of similarity between that which he hears from us and that which he is looking for, and which, in spite of all resistances, is trying to force its way through to consciousness; and it is this similarity that will enable him to discover the unconscious material. The physician is a step in front of him in knowledge; and the patient follows along his own road, until the two meet at the appointed goal. Beginners in psycho-analysis are apt to assimilate these two events, and to suppose that the moment at which one of the patient's unconscious complexes has become known to them is also the moment at which the patient himself recognizes it. They are expecting too much when they think that they will cure the patient by informing him of this piece of knowledge; for he can do no more with the information than make use of it to help himself in discovering the unconscious complex where it is anchored in his unconscious. A first success of this sort had now been achieved with Hans. Having partly mastered his castration complex, he was now able to communicate his wishes in regard to his mother. He did so, in what was still a distorted form, by means of the phantasy of the two giraffes, one of which was calling out in vain because Hans had taken possession of the other. He represented the 'taking possession of' pictorially as 'sitting down on'. His father recognized the phantasy as a reproduction of a bedroom scene which used to take place in the morning between the boy and his parents; and he quickly stripped the underlying wish of the disguise which it still wore. The boy's father and mother were the two giraffes. The reason for the choice of a giraffe-phantasy for the purposes of disguise was fully explained by a visit that the boy had paid to those same large beasts at Schönbrunn a few days earlier, by the giraffe-drawing, belonging to an earlier period, which had been preserved by his father, and also, perhaps, by an unconscious comparison based upon the giraffe's long, stiff neck.¹ It may be remarked that the giraffe, as being a large animal and interesting on account of its widdler, was a possible competitor with the horse for the role of bugbear; moreover, the fact that both his father and his mother appeared as giraffes offered a hint which had not yet been followed up, as regards the interpretation of the anxiety-horses.

In order to make it easier to understand this 'compulsion to repeat', which emerges during the psycho-analytic treatment of neurotics, we must above all get rid of the mistaken notion that what we are dealing with in our struggle against resistances is resistance on the part of the unconscious. The unconscious - that is to say, the 'repressed' - offers no resistance whatever to the efforts of the treatment. Indeed, it itself has no other endeavour than to break through the pressure weighing down on it and force its way either to consciousness or to a discharge through some real action. Resistance during treatment arises from the same higher strata and systems of the mind which originally carried out repression. But the fact that, as we know from experience, the motives of the resistances, and indeed the resistances themselves, are unconscious at first during the treatment, is a hint to us that we should correct a shortcoming in our terminology. We shall avoid a lack of clarity if we make our contrast not between the conscious and the unconscious but between the coherent ego and the repressed. It is certain that much of the ego is itself unconscious, and notably what we may describe as its nucleus; only a small part of it is covered by the term 'preconscious'. Having replaced a purely descriptive terminology by one which is systematic or dynamic, we can say that the patient's resistance arises from his ego, and we then at once perceive that the compulsion to repeat must be ascribed to the unconscious repressed. It seems probable that the compulsion can only express itself after the work of treatment has gone half-way to meet it and has loosened the repression.¹

[1909b, 2103]

[1920g, 3724]
In *Beyond the Pleasure Principle* (1920) I have dealt with the economic problem of how what are in every respect distressing experiences of the early infantile sexual period can succeed in forcing their way through to some kind of reproduction. I was obliged to ascribe to them an extraordinarily strong upward drive in the shape of the 'compulsion to repeat' - a force able to overcome the repression which, in obedience to the pleasure principle, weighs down upon them - though not until 'the work of treatment has gone half-way to meet it and has loosened the repression'. Here we may add that it is the positive transference that gives this assistance to the compulsion to repeat. Thus an alliance has been made between the treatment and the compulsion to repeat, an alliance which is directed in the first instance against the pleasure principle but of which the ultimate purpose is the establishment of the dominion of the reality principle. As I have shown in the passage to which I am referring, it happens only too often that the compulsion to repeat throws over its obligations under this alliance and is not content with the return of the repressed merely in the form of dream-pictures.

Now, however, another problem awaits us - at the opposite end of the ego, as we might put it. It is presented to us by an observation during the work of analysis, an observation which is actually a very old one. As not infrequently happens, it has taken a long time to come to the point of appreciating its importance. The whole theory of psycho-analysis is, as you know, in fact built up on the perception of the resistance offered to us by the patient when we attempt to make his unconscious conscious to him. The objective sign of this resistance is that his associations fail or depart widely from the topic that is being dealt with. He may also recognize the resistance subjectively by the fact that he has distressing feelings when he approaches the topic. But this last sign may also be absent. We then say to the patient that we infer from his behaviour that he is now in a state of resistance; and he replies that he knows nothing of that, and is only aware that his associations have become more difficult. It turns out that we were right; but in that case his resistance was unconscious too, just as unconscious as the repressed, at the lifting of which we were working. We then long ago have asked the question: from what part of his mind does an unconscious resistance like this arise? The beginner in psycho-analysis will be ready at once with the answer: it is, of course, the resistance of the unconscious. An ambiguous and unserviceable answer! If it means that the resistance arises from the repressed, we must rejoin: certainly not! We must rather attribute to the repressed a strong upward drive, an impulsion to break through into consciousness. The resistance can only be a manifestation of the ego, which originally put the repression into force and now wishes to maintain it. That, moreover, is the view we always took. Since we have come to assume a special agency in the ego, the super-ego, which represents demands of a restrictive and rejecting character, we may say that repression is the work of this super-ego and that it is carried out either by itself or by the ego in obedience to its orders. If then we are met by the case of the resistance in analysis not being conscious to the patient, this means either that in quite important situations the super-ego and the ego can operate unconsciously, or - and this would be still more important - that portions of both of them, the ego and the super-ego themselves, are unconscious. In both cases we have to reckon with the disagreeable discovery that on the one hand (super-) ego and conscious and on the other hand repressed and unconscious are far from coinciding.

[1923c, 4038]

[1933a, 4677]
With the mention of resistance we have reached the second and more important part of our task. We have already learnt that the ego protects itself against the invasion of undesired elements from the unconscious and repressed id by means of anticathexes, which must remain intact if it is to function normally. The more hard-pressed the ego feels, the more convulsively it clings (as though in a fright) to these anticathexes, in order to protect what remains of itself from further irruptions. But this defensive purpose does not by any means accord with the aims of our treatment. What we desire, on the contrary, is that the ego, emboldened by the certainty of our help, shall dare to take the offensive in order to reconquer what has been lost. And it is here that we become aware of the strength of these anticathexes in the form of resistances to our work. The ego draws back in alarm from such undertakings, which seem dangerous and threaten unpleasure; it must be constantly encouraged and soothed if it is not to fail us. This resistance, which persists throughout the whole treatment and is renewed at every fresh piece of work, is known, not quite correctly, as the resistance due to repression. We shall find that it is not the only one that faces us. It is interesting to notice that in this situation the party-divisions are to some extent reversed: for the ego struggles against our instigation, while the unconscious, which is ordinarily our opponent, comes to our help, since it has a natural 'upward drive' and desires nothing better than to press forward across its settled frontiers into the ego and so to consciousness. The struggle which develops, if we gain our end and can induce the ego to overcome its resistances, is carried through under our direction and with our assistance. Its outcome is a matter of indifference: whether it results in the ego accepting, after a fresh examination, an instinctual demand which it has hitherto rejected, or whether it dismisses it once more, this time for good and all. In either case a permanent danger has been disposed of, the compass of the ego has been extended and a wasteful expenditure of energy has been made unnecessary.

[1940a [1938], 4988]

I shall conclude this brief paper with a few remarks which open up a wider perspective. I have been struck by the manner in which, in certain analyses, the communication of an obviously apt construction has evoked in the patients a surprising and at first incomprehensible phenomenon. They have had lively recollections called up in them - which they themselves have described as 'ultra-clear' - but what they have recollected has not been the event that was the subject of the construction but details relating to that subject. For instance, they have recollected with abnormal sharpness the faces of the people involved in the construction or the rooms in which something of the sort might have happened, or, a step further away, the furniture in such rooms - on the subject of which the construction had naturally no possibility of any knowledge. This has occurred both in dreams immediately after the construction had been put forward and in waking states resembling phantasies. These recollections have themselves led to nothing further and it has seemed plausible to regard them as the product of a compromise. The 'upward drive' of the repressed, stirred into activity by the putting forward of the construction, has striven to carry the important memory-traces into consciousness; but a resistance has succeeded, not, it is true, in stopping that movement, but in displacing it on to adjacent objects of minor significance.

[1937d, 5057]
In conclusion, I will mention a particular type of dream which, in the nature of the case, occurs only in the course of psycho-analytic treatment, and may bewilder or mislead beginners. These are the corroborative dreams which, as it were 'tag along behind'; they are easily accessible to analysis, and their translation merely presents what the treatment has inferred during the last few days from the material of the daily associations. When this happens, it looks as though the patient has been amiable enough to bring us in dream-form exactly what we had been 'suggesting' to him immediately before. The more experienced analyst will no doubt have some difficulty in attributing any such amiability to the patient; he accepts such dreams as hoped-for confirmations, and recognizes that they are only observed under certain conditions brought about by the influence of the treatment. The great majority of dreams forge ahead of the analysis; so that, after subtraction of everything in them which is already known and understood, there still remains a more or less clear hint at something which has hitherto been hidden.

What interests us most of all is naturally the relation of this compulsion to repeat to the transference and to resistance. We soon perceive that the transference is itself only a piece of repetition, and that the repetition is a transference of the forgotten past not only on to the doctor but also on to all the other aspects of the current situation. We must be prepared to find, therefore, that the patient yields to the compulsion to repeat, which now replaces the impulsion to remember, not only in his personal attitude to his doctor but also in every other activity and relationship which may occupy his life at the time - if, for instance, he falls in love or undertakes a task or starts an enterprise during the treatment. The part played by resistance, too, is easily recognized. The greater the resistance, the more extensively will acting out (repetition) replace remembering. For the ideal remembering of what has been forgotten which occurs in hypnosis corresponds to a state in which resistance has been put completely on one side. If the patient starts his treatment under the auspices of a mild and unpronounced positive transference it makes it possible at first for him to unearth his memories just as he would under hypnosis, and during this time his pathological symptoms themselves are quiescent. But if, as the analysis proceeds, the transference becomes hostile or unduly intense and therefore in need of repression, remembering at once gives way to acting out. From then onwards the resistances determine the sequence of the material which is to be repeated. The patient brings out of the armoury of the past the weapons with which he defends himself against the progress of the treatment - weapons which we must wrest from him one by one.

We notice, then, that the patient, who ought to want nothing else but to find a way out of his distressing conflict, develops a special interest in the person of the doctor. Everything connected with the doctor seems to be more important to him than his own affairs and to be diverting him from his illness. For a time, accordingly, relations with him become very agreeable; he is particularly obliging, tries wherever possible to show his gratitude, reveals refinements and merits in his nature which we should not, perhaps, have expected to find in him. The doctor, too, thereupon forms a favourable opinion of the patient and appreciates the good fortune which has enabled him to give his assistance to such a particularly valuable personality. If the doctor has an opportunity of talking to the patient's relatives, he learns to his satisfaction that the liking is a mutual one. The patient never tires in his home of praising the doctor and of extolling ever new qualities in him. 'He's enthusiastic about you,' say his relatives, 'he trusts you blindly; everything you say is like a revelation to him.' Here and there someone in this chorus has sharper eyes and says: 'It's becoming a bore, the way he talks of nothing else but you and has your name on his lips all the time.'
Let us hope that the doctor is modest enough to attribute his patient's high opinion of him to the hopes he can rouse in him and to the widening of his intellectual horizon by the surprising and liberating enlightenment that the treatment brings with it. Under these conditions the analysis makes fine progress too. The patient understands what is interpreted to him and becomes engrossed in the tasks set him by the treatment; the material of memories and associations floods in upon him in plenty, the certainty and appositeness of his interpretations are a surprise to the doctor, and the latter can only take note with satisfaction that here is a patient who readily accepts all the psychological novelties which are apt to provoke the most bitter contradiction among healthy people in the outside world. Moreover the cordial relations that prevail during the work of analysis are accompanied by an objective improvement, which is recognized on all sides, in the patient's illness.

If we are able once more to clarify the position, we find that the cause of the disturbance is that the patient has transferred on to the doctor intense feelings of affection which are justified neither by the doctor's behaviour nor by the situation that has developed during the treatment. The form in which this affection is expressed and what its aims are depend of course on the personal relation between the two people involved. If those concerned are a young girl and a youngish man, we shall get the impression of a normal case of falling in love; we shall find it understandable that a girl should fall in love with a man with whom she can be much alone and talk of intimate things and who has the advantage of having met her as a helpful superior; and we shall probably overlook the fact that what we should expect from a neurotic girl would rather be an impediment in her capacity for love. The further the personal relations between doctor and patient diverge from this supposed case, the more we shall be surprised to find nevertheless the same emotional relationship constantly recurring. It may still pass muster if a woman who is unhappy in her marriage appears to be seized with a serious passion for a doctor who is still unattached, if she is ready to seek a divorce in order to be his or if, where there are social obstacles, she even expresses no hesitation about entering into a secret liaison with him. Such things come about even outside psycho-analysis. But in these circumstances we are astonished to hear declarations by married women and girls which bear witness to a quite particular attitude to the therapeutic problem: they had always known, they say, that they could only be cured by love, and before the treatment began they had expected that through this relation they would at last be granted what life had hitherto withheld from them; it had only been in this hope that they had taken so much trouble over the treatment and overcome all the difficulties in communicating their thoughts - and we on our part can add: and had so easily understood what is otherwise so hard to believe. But an admission of this sort surprises us: it throws all our calculations to the winds. Can it be that we have left the most important item out of our account?

[1916-1917, 3482]

[1916-1917, 3483]
I must begin by making it clear that a transference is present in the patient from the beginning of the treatment and for a while is the most powerful motive in its advance. We see no trace of it and need not bother about it so long as it operates in favour of the joint work of analysis. If it then changes into a resistance, we must turn our attention to it and we recognize that it alters its relation to the treatment under two different and contrary conditions: firstly, if as an affectionate trend it has become so powerful, and betrays signs of its origin in a sexual need so clearly, that it inevitably provokes an internal opposition to itself, and, secondly, if it consists of hostile instead of affectionate impulses. The hostile feelings make their appearance as a rule later than the affectionate ones and behind them; their simultaneous presence gives a good picture of the emotional ambivalence which is dominant in the majority of our intimate relations with other people. The hostile feelings are as much an indication of an emotional tie as the affectionate ones, in the same way as defiance signifies dependence as much as obedience does, though with a 'minus' instead of a 'plus' sign before it. We can be in no doubt that the hostile feelings towards the doctor deserve to be called a 'transference', since the situation in the treatment quite certainly offers no adequate grounds for their origin; this necessary view of the negative transference assures us, therefore, that we have not gone wrong in our judgement of the positive or affectionate one.

[1916-1917, 3485]

There is every reason now for us to improve our earlier dynamic account of the therapeutic process and to bring it into harmony with our new realization. If the patient is to fight his way through the normal conflict with the resistances which we have uncovered for him in the analysis, he is in need of a powerful stimulus which will influence the decision in the sense which we desire, leading to recovery. Otherwise it might happen that he would choose in favour of repeating the earlier outcome and would allow what had been brought up into consciousness to slip back again into repression. At this point what turns the scale in his struggle is not his intellectual insight which is neither strong enough nor free enough for such an achievement - but simply and solely his relation to the doctor. In so far as his transference bears a 'plus' sign, it clothes the doctor with authority and is transformed into belief in his communications and explanations. In the absence of such a transference, or if it is a negative one, the patient would never even give a hearing to the doctor and his arguments. In this his belief is repeating the story of its own development; it is a derivative of love and, to start with, needed no arguments. Only later did he allow them enough room to submit them to examination, provided they were brought forward by someone he loved. Without such supports arguments carried no weight, and in most people’s lives they never do. Thus in general a man is only accessible from the intellectual side too, in so far as he is capable of a libidinal cathexis of objects; and we have good reason to recognize and to dread in the amount of his narcissism a barrier against the possibility of being influenced by even the best analytic technique.

[1916-1917, 3487]

We have formulated our task as physicians thus: to bring to the patient’s knowledge the unconscious, repressed impulses existing in him, and, for that purpose, to uncover the resistances that oppose this extension of his knowledge about himself. Does the uncovering of these resistances guarantee that they will also be overcome? Certainly not always; but our hope is to achieve this by exploiting the patient's transference to the person of the physician, so as to induce him to adopt our conviction of the inexpediency of the repressive process established in childhood and of the impossibility of conducting life on the pleasure principle. I have set out elsewhere the dynamic conditions prevailing in the fresh conflict through which we lead the patient and which we substitute in him for his previous conflict - that of his illness. I have nothing at the moment to alter in that account.

[1919a, 3628]
Let us at once agree upon what we mean by this activity. We have defined our therapeutic task as consisting of two things: making conscious the repressed material and uncovering the resistances. In that we are active enough, to be sure. But are we to leave it to the patient to deal alone with the resistances we have pointed out to him? Can we give him no other help in this besides the stimulus he gets from the transference? Does it not seem natural that we should help him in another way as well, by putting him into the mental situation most favourable to the solution of the conflict which is our aim? After all, what he can achieve depends, too, on a combination of external circumstances. Should we hesitate to alter this combination by intervening in a suitable manner? I think activity of such a kind on the part of the analysing physician is unobjectionable and entirely justified.

Transference. - If further proof were needed of the truth that the motive forces behind the formation of neurotic symptoms are of a sexual nature, it would be found in the fact that in the course of analytic treatment a special emotional relation is regularly formed between the patient and the physician. This goes far beyond rational limits. It varies between the most affectionate devotion and the most obstinate enmity and derives all of its characteristics from earlier erotic attitudes of the patient's which have become unconscious. This transference alike in its positive and in its negative form is used as a weapon by the resistance; but in the hands of the physician it becomes the most powerful therapeutic instrument and it plays a part scarcely to be over-estimated in the dynamics of the process of cure.

It may well be that dreams during psycho-analysis succeed in bringing to light what is repressed to a greater extent than dreams outside that situation. But it cannot be proved, since the two situations are not comparable; the employment of dreams in analysis is something very remote from their original purpose. On the other hand, it cannot be doubted that within an analysis far more of the repressed is brought to light in connection with dreams than by any other method. In order to account for this, there must be some motive power, some unconscious force, which is better able to lend support to the purposes of analysis during the state of sleep than at other times. What is here in question cannot well be any factor other than the patient's compliance towards the analyst which is derived from his parental complex - in other words, the positive portion of what we call the transference; and in fact, in many dreams which recall what has been forgotten and repressed, it is impossible to discover any other unconscious wish to which the motive force for the formation of the dream can be attributed. So that if anyone wishes to maintain that most of the dreams that can be made use of in analysis are obliging dreams and owe their origin to suggestion, nothing can be said against that opinion from the point of view of analytic theory. In that case I need only add a reference to what I have said in my Introductory Lectures, where I have dealt with the relation between transference and suggestion and shown how little the trustworthiness of our results is affected by a recognition of the operation of suggestion in our sense.

[1919a, 3631]

[1923a, 3924]

[1923c, 4038]
The neuroses were the first subject of analysis, and for a long time they were the only one. No analyst could doubt that medical practice was wrong in separating those disorders from the psychoses and in attaching them to the organic nervous diseases. The theory of the neuroses belongs to psychiatry and is indispensable as an introduction to it. It would seem, however, that the analytic study of the psychoses is impracticable owing to its lack of therapeutic results. Mental patients are as a rule without the capacity for forming a positive transference, so that the principal instrument of analytic technique is inapplicable to them. There are nevertheless a number of methods of approach to be found. Transference is often not so completely absent but that it can be used to a certain extent; and analysis has achieved undoubted successes with cyclical depressions, light paranoic modifications, and partial schizophrenias. It has at least been a benefit to science that in many cases the diagnosis can oscillate for quite a long time between assuming the presence of a psychoneurosis or of a dementia praecox; for therapeutic attempts initiated in such cases have resulted in valuable discoveries before they have had to be broken off. But the chief consideration in this connection is that so many things that in the neuroses have to be laboriously fetched up from the depths are found in the psychoses on the surface, visible to every eye. For that reason the best subjects for the demonstration of many of the assertions of analysis are provided by the psychiatric clinic. It was thus bound to happen before long that analysis would find its way to the objects of psychiatric observation. I was able very early (1896) to establish in a case of paranoid dementia the presence of the same aetiological factors and the same emotional complexes as in the neuroses. Jung explained some most puzzling stereotypies in dments by bringing them into relation with the patients' life-histories; Bleuler demonstrated the existence in various psychoses of mechanisms like those which analysis had discovered in neurotics. Since then analysts have never relaxed their efforts to come to an understanding of the psychoses. Especially since it has been possible to work with the concept of narcissism, they have managed, now in this place and now in that, to get a glimpse beyond the wall. Most of all, no doubt, was achieved by Abraham in his elucidation of the melancholias. It is true that in this sphere all our knowledge is not yet converted into therapeutic power; but the mere theoretical gain is not to be despised, and we may be content to wait for its practical application. In the long run even the psychiatrists cannot resist the convincing force of their own clinical material. At the present time German psychiatry is undergoing a kind of 'peaceful penetration' by analytic views. While they continually declare that they will never be psycho-analysts, that they do not belong to the 'orthodox' school or agree with its exaggerations, and in particular that they do not believe in the predominance of the sexual factor, nevertheless the majority of the younger workers take over one piece or another of analytic theory and apply it in their own fashion to the material. All the signs point to the proximity of further developments in the same direction.

[1925d, 4235]

"If I ever felt any desire to poach on your preserves and try my hand at analysing someone else, what you tell me about the resistances would have cured me of it. But how about the special personal influence that you yourself have after all admitted? Does not that come into action against the resistances?"

[1926e, 4366]
But it is far from being the case that his ego is content to play the part of passively and obediently bringing us the material we require and of believing and accepting our translation of it. A number of other things happen, a few of which we might have foreseen but others of which are bound to surprise us. The most remarkable thing is this. The patient is not satisfied with regarding the analyst in the light of reality as a helper and adviser who, moreover, is remunerated for the trouble he takes and who would himself be content with some such role as that of a guide on a difficult mountain climb. On the contrary, the patient sees in him the return, the reincarnation, of some important figure out of his childhood or past, and consequently transfers on to him feelings and reactions which undoubtedly applied to this prototype. This fact of transference soon proves to be a factor of undreamt-of importance, on the one hand an instrument of irreplaceable value and on the other hand a source of serious dangers. This transference is ambivalent: it comprises positive (affectionate) as well as negative (hostile) attitudes towards the analyst, who as a rule is put in the place of one or other of the patient's parents, his father or mother. So long as it is positive it serves us admirably. It alters the whole analytic situation; it pushes to one side the patient's rational aim of becoming healthy and free from his ailments. Instead of it there emerges the aim of pleasing the analyst and of winning his applause and love. It becomes the true motive force of the patient's collaboration; his weak ego becomes strong; under its influence he achieves things that would ordinarily be beyond his power; he leaves off his symptoms and seems apparently to have recovered - merely for the sake of the analyst. The analyst may shamefacedly admit to himself that he set out on a difficult undertaking without any suspicion of the extraordinary powers that would be at his command.

The therapeutic successes that occurred under the sway of the positive transference are open to the suspicion of being of a suggestive nature. If the negative transference gains the upper hand, they are blown away like chaff before the wind. We observe with horror that all our trouble and labour hitherto have been in vain. Indeed, what we might have regarded as a permanent intellectual gain by the patient, his understanding of psycho-analysis and his reliance on its efficacy, suddenly vanish. He behaves like a child who has no power of judgement of his own but blindly believes anyone whom he loves and no one who is a stranger to him. The danger of these states of transference evidently lies in the patient's misunderstanding their nature and taking them for fresh real experiences instead of reflections of the past. If he (or she) becomes aware of the strong erotic desire that lies concealed behind the positive transference, he believes that he has fallen passionately in love; if the transference changes over, then he feels insulted and neglected, he hates the analyst as his enemy and is ready to abandon the analysis. In both these extreme cases he has forgotten the pact that he made at the beginning of the treatment and has become useless for continuing the common work. It is the analyst's task constantly to tear the patient out of his menacing illusion and to show him again and again that what he takes to be new real life is a reflection of the past. And lest he should fall into a state in which he is inaccessible to all evidence, the analyst takes care that neither the love nor the hostility reach an extreme height. This is effected by preparing him in good time for these possibilities and by not overlooking the first signs of them. Careful handling of the transference on these lines is as a rule richly rewarded. If we succeed, as we usually can, in enlightening the patient on the true nature of the phenomena of transference, we shall have struck a powerful weapon out of the hand of his resistance and shall have converted dangers into gains. For a patient never forgets again what he has experienced in the form of transference; it carries a greater force of conviction than anything he can acquire in other ways.

[1940a [1938], 4986]
Let us once more glance over the situation which we have reached in our attempt at bringing help to the patient's neurotic ego. That ego is no longer able to fulfil the task set it by the external world (including human society). Not all of its experiences are at its disposal, a large proportion of its store of memories have escaped it. Its activity is inhibited by strict prohibitions from the super-ego, its energy is consumed in vain attempts at fending off the demands of the id. Beyond this, as a result of continuous irruptions by the id, its organization is impaired, it is no longer capable of any proper synthesis, it is torn by mutually opposed urges, by unsettled conflicts and by unsolved doubts. To start with, we get the patient's thus weakened ego to take part in the purely intellectual work of interpretation, which aims at provisionally filling the gaps in his mental assets, and to transfer to us the authority of his super-ego; we encourage it to take up the struggle over each individual demand made by the id and to conquer the resistances which arise in connection with it. At the same time we restore order in the ego by detecting the material and urges which have forced their way in from the unconscious, and expose them to criticism by tracing them back to their origin. We serve the patient in various functions, as an authority and a substitute for his parents, as a teacher and educator; and we have done the best for him if, as analysts, we raise the mental processes in his ego to a normal level, transform what has become unconscious and repressed into preconscious material and thus return it once more to the possession of his ego. On the patient's side a few rational factors work in our favour, such as the need for recovery which has its motive in his sufferings, and the intellectual interest that we may awaken in him in the theories and revelations of psychoanalysis; but of far greater force is the positive transference with which he meets us. Fighting against us, on the other hand, are the negative transference, the ego's resistance due to repression (that is, its displeasure at having to lay itself open to the hard work imposed on it), the sense of guilt arising from its relation to the super-ego and the need to be ill due to deep-going changes in the economics of his instincts. The share taken by the last two factors decides whether the case is to be regarded as slight or severe. Apart from these, a few other factors may be discerned as having a favourable or unfavourable bearing. A certain psychical inertia, a sluggishness of the libido, which is unwilling to abandon its fixations cannot be welcome to us; the patient's capacity for sublimating his instincts plays a large part and so does his capacity for rising above the crude life of the instincts; so, too, does the relative power of his intellectual functions.

[1940a [1938], 4990]

I do not know whether we can assert that the first of these two milder procedures is altogether ruled out in analysis. No experiments have been particularly made in this direction. But difficulties at once suggest themselves, which do not throw a very promising light on such an undertaking. In the first place, the choice of such situations for the transference is very limited. The patients cannot themselves bring all their conflicts into the transference; nor is the analyst able to call out all their possible instinctual conflicts from the transference situation. He may make them jealous or cause them to experience disappointments in love; but no technical purpose is required to bring this about. Such things happen of themselves in any case in most analyses. In the second place, we must not overlook the fact that all measures of this sort would oblige the analyst to behave in an unfriendly way to the patient, and this would have a damaging effect upon the affectionate attitude - upon the positive transference - which is the strongest motive for the patient's taking a share in the joint work of analysis. Thus we should on no account expect very much from this procedure.

[1937c, 5029]
The therapeutic effect depends on making conscious what is repressed, in the widest sense of the word, in the id. We prepare the way for this making conscious by interpretations and constructions, but we have interpreted only for ourselves not for the patient so long as the ego holds on to its earlier defences and does not give up its resistances. Now these resistances, although they belong to the ego, are nevertheless unconscious and in some sense separated off within the ego. The analyst recognizes them more easily than he does the hidden material in the id. One might suppose that it would be sufficient to treat them like portions of the id and, by making them conscious, bring them into connection with the rest of the ego. In this way, we should suppose, one half of the task of analysis would be accomplished; we should not reckon on meeting with a resistance against the uncovering of resistances. But what happens is this. During the work on the resistances the ego withdraws - with a greater or less degree of seriousness - from the agreement on which the analytic situation is founded. The ego ceases to support our efforts at uncovering the id; it opposes them, disobeys the fundamental rule of analysis, and allows no further derivatives of the repressed to emerge. We cannot expect the patient to have a strong conviction of the curative power of analysis. He may have brought along with him a certain amount of confidence in his analyst, which will be strengthened to an effective point by the factors of the positive transference which will be aroused in him. Under the influence of the unpleasurable impulses which he feels as a result of the fresh activation of his defensive conflicts, negative transferences may now gain the upper hand and completely annul the analytic situation. The patient now regards the analyst as no more than a stranger who is making disagreeable demands on him, and he behaves towards him exactly like a child who does not like the stranger and does not believe anything he says. If the analyst tries to explain to the patient one of the distortions made by him for the purposes of defence, and to correct it, he finds him uncomprehending and inaccessible to sound arguments. Thus we see that there is a resistance against the uncovering of resistances, and the defensive mechanisms really do deserve the name which we gave them originally, before they had been more closely examined. They are resistances not only to the making conscious of contents of the id, but also to the analysis as a whole, and thus to recovery.

[1937c, 5034]
What means have we at our disposal for overcoming this continual resistance? Few, but they include almost all those by which one man can ordinarily exert a psychical influence on another. In the first place, we must reflect that a psychical resistance, especially one that has been in force for a long time, can only be resolved slowly and by degrees, and we must wait patiently. In the next place, we may reckon on the intellectual interest which the patient begins to feel after working for a short time. By explaining things to him, by giving him information about the marvellous world of psychical processes into which we ourselves only gained insight by such analyses, we make him himself into a collaborator, induce him to regard himself with the objective interest of an investigator, and thus push back his resistance, resting as it does on an affective basis. But lastly - and this remains the strongest lever - we must endeavour, after we have discovered the motives for his defence, to deprive them of their value or even to replace them by more powerful ones. This no doubt is where it ceases to be possible to state psychotherapeutic activity in formulas. One works to the best of one’s power, as an elucidator (where ignorance has given rise to fear), as a teacher, as the representative of a freer or superior view of the world, as a father confessor who gives absolution, as it were, by a continuance of his sympathy and respect after the confession has been made. One tries to give the patient human assistance, so far as this is allowed by the capacity of one’s own personality and by the amount of sympathy that one can feel for the particular case. It is an essential precondition for such psychical activity that we should have more or less divined the nature of the case and the motives of the defence operating in it, and fortunately the technique of insistence and pressure takes us as far as this. The more such riddles we have already solved, the easier we may find it to guess a new one and the sooner we shall be able to start on the truly curative psychical work. For it is well to recognize this clearly: the patient only gets free from the hysterical symptom by reproducing the pathogenic impressions that caused it and by giving utterance to them with an expression of affect, and thus the therapeutic task consists solely in inducing him to do so; when once this task has been accomplished there is nothing left for the physician to correct or to remove. Whatever may be required for this purpose in the way of counter-suggestions has already been expended during the struggle against the resistance. The situation may be compared with the unlocking of a locked door, after which opening it by turning the handle offers no further difficulty.

[1895d, 249]
Let us once more glance over the situation which we have reached in our attempt at bringing help to the patient's neurotic ego. That ego is no longer able to fulfil the task set it by the external world (including human society). Not all of its experiences are at its disposal, a large proportion of its store of memories have escaped it. Its activity is inhibited by strict prohibitions from the super-ego, its energy is consumed in vain attempts at fending off the demands of the id. Beyond this, as a result of continuous irruptions by the id, its organization is impaired, it is no longer capable of any proper synthesis, it is torn by mutually opposed urges, by unsettled conflicts and by unsolved doubts. To start with, we get the patient's thus weakened ego to take part in the purely intellectual work of interpretation, which aims at provisionally filling the gaps in his mental assets, and to transfer to us the authority of his super-ego; we encourage it to take up the struggle over each individual demand made by the id and to conquer the resistances which arise in connection with it. At the same time we restore order in the ego by detecting the material and urges which have forced their way in from the unconscious, and expose them to criticism by tracing them back to their origin. We serve the patient in various functions, as an authority and a substitute for his parents, as a teacher and educator; and we have done the best for him if, as analysts, we raise the mental processes in his ego to a normal level, transform what has become unconscious and repressed into preconscious material and thus return it once more to the possession of his ego. On the patient's side a few rational factors work in our favour, such as the need for recovery which has its motive in his sufferings, and the intellectual interest that we may awaken in him in the theories and revelations of psycho-analysis; but of far greater force is the positive transference with which he meets us. Fighting against us, on the other hand, are the negative transference, the ego's resistance due to repression (that is, its unpleasure at having to lay itself open to the hard work imposed on it), the sense of guilt arising from its relation to the super-ego and the need to be ill due to deep-going changes in the economics of his instincts. The share taken by the last two factors decides whether the case is to be regarded as slight or severe. Apart from these, a few other factors may be discerned as having a favourable or unfavourable bearing. A certain psychical inertia, a sluggishness of the libido, which is unwilling to abandon its fixations cannot be welcome to us; the patient's capacity for sublimating his instincts plays a large part and so does his capacity for rising above the crude life of the instincts; so, too, does the relative power of his intellectual functions.

[1940a [1938], 4990]
I have finally to discuss yet another topic, which plays an undesirably large part in the carrying out of cathartic analyses such as these. I have already admitted the possibility of the pressure technique failing, of its not eliciting any reminiscence in spite of every assurance and insistence. If this happens, I said, there are two possibilities: either, at the point at which we are investigating, there is really nothing more to be found - and this we can recognize from the complete calmness of the patient's facial expression; or we have come up against a resistance which can only be overcome later, we are faced by a new stratum into which we cannot yet penetrate - and this, once more, we can infer from the patient's facial expression, which is tense and gives evidence of mental effort. But there is yet a third possibility which bears witness equally to an obstacle, but an external obstacle, and not one inherent in the material. This happens when the patient's relation to the physician is disturbed, and it is the worst obstacle that we can come across. We can, however, reckon on meeting it in every comparatively serious analysis.

Hitherto, this authority, with its enormous weight of suggestion, has been against us. All our therapeutic successes have been achieved in the face of this suggestion: it is surprising that any successes at all could be gained in such circumstances. I must not let myself be led into describing my agreeable experiences during the period when I alone represented psycho-analysis. I can only say that when I assured my patients that I knew how to relieve them permanently of their sufferings they looked round my modest abode, reflected on my lack of fame and title, and regarded me like the possessor of an infallible system at a gambling-resort, of whom people say that if he could do what he professes he would look very different himself. Nor was it really pleasant to carry out a psychical operation while the colleagues whose duty it should have been to assist took particular pleasure in spitting into the field of operation, and while at the first signs of blood or restlessness in the patient his relatives began threatening the operating surgeon. An operation is surely entitled to produce reactions; in surgery we became accustomed to that long ago. People simply did not believe me, just as even to-day people do not much believe any of us. Under such conditions not a few attempts were bound to fail. To estimate the increase in our therapeutic prospects when we have received general recognition, you should think of the position of a gynaecologist in Turkey and in the West. In Turkey, all he may do is to feel the pulse of all arm stretched out to him through a hole in the wall: and his medical achievements are in proportion to the inaccessibility of their object. Our opponents in the West wish to allow us much the same degree of access to our patient's minds. But now that the force of social suggestion drives sick women to the gynaecologist, he has become their helper and saviour. I trust you will not say that the fact of the authority of society coming to our aid and increasing our successes so greatly would do nothing to prove the validity of our hypotheses - arguing as you might that, since suggestion is supposed to be able to do anything, our successes would then be successes of suggestion and not of psycho-analysis. Social suggestion is at present favourable to treating nervous patients by hydropathy, dieting and electro-therapy, but that does not enable such measures to get the better of neuroses. Time will show whether psycho-analytic treatment can accomplish more.
It is now time for us to take a survey of the play of forces which is set in motion by the treatment. The primary motive force in the therapy is the patient's suffering and the wish to be cured that arises from it. The strength of this motive force is subtracted from by various factors - which are not discovered till the analysis is in progress - above all, by what we have called the 'secondary gain from illness'; but it must be maintained till the end of the treatment. Every improvement effects a diminution of it. By itself, however, this motive force is not sufficient to get rid of the illness. Two things are lacking in it for this: it does not know what paths to follow to reach this end; and it does not possess the necessary quota of energy with which to oppose the resistances. The analytic treatment helps to remedy both these deficiencies. It supplies the amounts of energy that are needed for overcoming the resistances by making mobile the energies which lie ready for the transference; and, by giving the patient information at the right time, it shows him the paths along which he should direct those energies. Often enough the transference is able to remove the symptoms of the disease by itself, but only for a while - only for as long as it itself lasts. In this case the treatment is a treatment by suggestion, and not a psycho-analysis at all. It only deserves the latter name if the intensity of the transference has been utilized for the overcoming of resistances. Only then has being ill become impossible, even when the transference has once more been dissolved, which is its destined end.

All the libido, as well as everything opposing it, is made to converge solely on the relation with the doctor. In this process the symptoms are inevitably divested of libido. In place of his patient's true illness there appears the artificially constructed transference illness, in place of the various unreal objects of the libido there appears a single, and once more imaginary, object in the person of the doctor. But, by the help of he doctor's suggestion, the new struggle around this object is lifted to the highest psychical level: it takes place as a normal mental conflict. Since a fresh repression is avoided, the alienation between ego and libido is brought to an end and the subject's mental unity is restored. When the libido is released once more from its temporary object in the person of the doctor, it cannot return to its earlier objects, but is at the disposal of the ego. The forces against which we have been struggling during our work of therapy are, on the one hand, the ego's antipathy to certain trends of the libido - an antipathy expressed in a tendency to repression - and, on the other hand, the tenacity or adhesiveness of the libido, which dislikes leaving objects that it has once cathected.

Thus our therapeutic work falls into two phases. In the first, all the libido is forced from the symptoms into the transference and concentrated there; in the second, the struggle is waged around this new object and the libido is liberated from it. The change which is decisive for a favourable outcome is the elimination of repression in this renewed conflict so that the libido cannot withdraw once more from the ego by flight into the unconscious. This is made possible by the alteration of the ego which is accomplished under the influence of the doctor's suggestion. By means of the work of interpretation, which transforms what is unconscious into what is conscious, the ego is enlarged at the cost of this unconscious; by means of instruction, it is made conciliatory towards the libido and inclined to grant it some satisfaction, and its repugnance to the claims of the libido is diminished by the possibility of disposing of a portion of it by sublimation. The more closely events in the treatment coincide with this ideal description, the greater will be the success of the psycho-analytic therapy. It finds its limits in the lack of mobility of the libido, which may refuse to leave its objects, and the rigidity of narcissism, which will not allow transference on to objects to increase beyond certain bounds. Further light may perhaps be thrown on the dynamics of the process of cure if I say that we get hold of the whole of the libido which has been withdrawn from the dominance of the ego by attracting a portion of it on to ourselves by means of the transference.
The manifestations of a compulsion to repeat (which we have described as occurring in the early activities of infantile mental life as well as among the events of psycho-analytic treatment) exhibit to a high degree an instinctual character and, when they act in opposition to the pleasure principle, give the appearance of some 'daemonic' force at work. In the case of children's play we seemed to see that children repeat unpleasurable experiences for the additional reason that they can master a powerful impression far more thoroughly by being active than they could by merely experiencing it passively. Each fresh repetition seems to strengthen the mastery they are in search of. Nor can children have their pleasurable experiences repeated often enough, and they are inexorable in their insistence that the repetition shall be an identical one. This character trait disappears later on. If a joke is heard for a second time it produces almost no effect; a theatrical production never creates so great an impression the second time as the first; indeed, it is hardly possible to persuade an adult who has very much enjoyed reading a book to re-read it immediately. Novelty is always the condition of enjoyment. But children will never tire of asking an adult to repeat a game that he has shown them or played with them, till he is too exhausted to go on. And if a child has been told a nice story, he will insist on hearing it over and over again rather than a new one; and he will remorselessly stipulate that the repetition shall be an identical one and will correct any alterations of which the narrator may be guilty - though they may actually have been made in the hope of gaining fresh approval. None of this contradicts the pleasure principle; repetition, the re-experiencing of something identical, is clearly in itself a source of pleasure. In the case of a person in analysis, on the contrary, the compulsion to repeat the events of his childhood in the transference evidently disregards the pleasure principle in every way. The patient behaves in a purely infantile fashion and thus shows us that the repressed memory-traces of his primaeval experiences are not present in him in a bound state and are indeed in a sense incapable of obeying the secondary process. It is to this fact of not being bound, moreover, that they owe their capacity for forming, in conjunction with the residues of the previous day, a wishful phantasy that emerges in a dream. This same compulsion to repeat frequently meets us as an obstacle to our treatment when at the end of an analysis we try to induce the patient to detach himself completely from his physician. It may be presumed, too, that when people unfamiliar with analysis feel an obscure fear - a dread of rousing something that, so they feel, is better left sleeping - what they are afraid of at bottom is the emergence of this compulsion with its hint of possession by some 'daemonic' power.

There is no doubt that there is something in these people that sets itself against their recovery, and its approach is dreaded as though it were a danger. We are accustomed to say that the need for illness has got the upper hand in them over the desire for recovery. If we analyse this resistance in the usual way then, even after allowance has been made for an attitude of defiance towards the physician and for fixation to the various forms of gain from illness, the greater part of it is still left over; and this reveals itself as the most powerful of all obstacles to recovery, more powerful than the familiar ones of narcissistic inaccessibility, a negative attitude towards the physician and clinging to the gain from illness.

In the end we come to see that we are dealing with what may be called a 'moral' factor, a sense of guilt, which is finding its satisfaction in the illness and refuses to give up the punishment of suffering. We shall be right in regarding this disheartening explanation as final. But as far as the patient is concerned this sense of guilt is dumb; it does not tell him he is guilty; he does not feel guilty, he feels ill. This sense of guilt expresses itself only as a resistance to recovery which it is extremely difficult to overcome. It is also particularly difficult to convince the patient that this motive lies behind his continuing to be ill; he holds fast to the more obvious explanation that treatment by analysis is not the right remedy for his case.
The description we have given applies to the most extreme instances of this state of affairs, but in a lesser measure this factor has to be reckoned with in very many cases, perhaps in all comparatively severe cases of neurosis. In fact it may be precisely this element in the situation, the attitude of the ego ideal, that determines the severity of a neurotic illness. We shall not hesitate, therefore, to discuss rather more fully the way in which the sense of guilt expresses itself under different conditions.

[1923b, 3984]

¹ The battle with the obstacle of an unconscious sense of guilt is not made easy for the analyst. Nothing can be done against it directly, and nothing indirectly but the slow procedure of unmasking its unconscious repressed roots, and of thus gradually changing it into a conscious sense of guilt. One has a special opportunity for influencing it when this Ucs. sense of guilt is a 'borrowed' one - when it is the product of an identification with some other person who was once the object of an erotic cathexis. A sense of guilt that has been adopted in this way is often the sole remaining trace of the abandoned love-relation and not at all easy to recognize as such. (The likeness between this process and what happens in melancholia is unmistakable.) If one can unmask this former object-cathexis behind the Ucs. sense of guilt, the therapeutic success is often brilliant, but otherwise the outcome of one's efforts is by no means certain. It depends principally on the intensity of the sense of guilt; there is often no counteracting force of a similar order of strength which the treatment can oppose to it. Perhaps it may depend, too, on whether the personality of the analyst allows of the patient's putting him in the place of his ego ideal, and this involves a temptation for the analyst to play the part of prophet, saviour and redeemer to the patient. Since the rules of analysis are diametrically opposed to the physician's making use of his personality in any such manner, it must be honestly confessed that here we have another limitation to the effectiveness of analysis; after all, analysis does not set out to make pathological reactions impossible, but to give the patient's ego freedom to decide one way or the other.

[1923b, 3984]

All of this results in what is familiar to us as the 'secondary) gain from illness' which follows a neurosis. This gain comes to the assistance of the ego in its endeavour to incorporate the symptom and increases the symptom's fixation. When the analyst tries subsequently to help the ego in its struggle against the symptom, he finds that these conciliatory bonds between ego and symptom operate on the side of the resistances and that they are not easy to loosen.

[1926d, 4260]
We showed on an earlier occasion that the resistance that has to be overcome in analysis proceeds from the ego, which clings to its anticathexes. It is hard for the ego to direct its attention to perceptions and ideas which it has up till now made a rule of avoiding, or to acknowledge as belonging to itself impulses that are the complete opposite of those which it knows as its own. Our fight against resistance in analysis is based upon this view of the facts. If the resistance is itself unconscious, as so often happens owing to its connection with the repressed material, we make it conscious. If it is conscious, or when it has become conscious, we bring forward logical arguments against it; we promise the ego rewards and advantages if it will give up its resistance. There can be no doubt or mistake about the existence of this resistance on the part of the ego. But we have to ask ourselves whether it covers the whole state of affairs in analysis. For we find that even after the ego has decided to relinquish its resistances it still has difficulty in undoing the repressions; and we have called the period of strenuous effort which follows after its praiseworthy decision, the phase of 'working-through'. The dynamic factor which makes a working-through of this kind necessary and comprehensible is not far to seek. It must be that after the ego's resistance has been removed the power of the compulsion to repeat - the attraction exerted by the unconscious prototype upon the repressed instinctual process - has still to be overcome. There is nothing to be said against describing this factor as the *resistance of the unconscious*. There is no need to be discouraged by these emendations. They are to be welcomed if they add something to our knowledge, and they are no disgrace to us so long as they enrich rather than invalidate our earlier views - by limiting some statement, perhaps, that was too general or by enlarging some idea that was too narrowly formulated.

[1926d, 4312]

It must not be supposed that these emendations provide us with a complete survey of all the kinds of resistance that are met with in analysis. Further investigation of the subject shows that the analyst has to combat no less than five kinds of resistance, emanating from three directions - the ego, the id and the super-ego. The ego is the source of three of these, each differing in its dynamic nature. The first of these three ego-resistances is the *repression* resistance, which we have already discussed above and about which there is least new to be added. Next there is the *transference* resistance, which is of the same nature but which has different and much clearer effects in analysis, since it succeeds in establishing a relation to the analytic situation or the analyst himself and thus re-animating a repression which should only have been recollected. The third resistance, though also an ego-resistance, is of quite a different nature. It proceeds from the *gain from illness* and is based upon an assimilation of the symptom into the ego. It represents an unwillingness to renounce any satisfaction or relief that has been obtained. The fourth variety, arising from the *id*, is the resistance which, as we have just seen, necessitates 'working-through'. The fifth, coming from the *super-ego* and the last to be discovered, is also the most obscure though not always the least powerful one. It seems to originate from the sense of guilt or the need for punishment; and it opposes every move towards success, including, therefore, the patient's own recovery through analysis.

[1926d, 4313]
Compared with the other psychotherapeutic procedures psycho-analysis is beyond any doubt the most powerful. It is just and fair, too, that this should be so for it is also the most laborious and time-consuming; it would not be used on slight cases. In suitable cases it is possible by its means to get rid of disturbances and bring about changes for which in pre-analytic times one would not have ventured to hope. But it has its very appreciable limits. The therapeutic ambition of some of my adherents has made the greatest efforts to overcome these obstacles so that every sort of neurotic disorder might be curable by psycho-analysis. They have endeavoured to compress the work of analysis into a shorter duration, to intensify transference so that it may be able to overcome any resistance, to unite other forms of influence with it so as to compel a cure. These efforts are certainly praiseworthy, but, in my opinion, they are vain. They bring with them, too, a danger of being oneself forced away from analysis and drawn into a boundless course of experimentation. The expectation that every neurotic phenomenon can be cured may, I suspect, be derived from the layman's belief that the neuroses are something quite unnecessary which have no right whatever to exist. Whereas in fact they are severe, constitutionally fixed illnesses, which rarely restrict themselves to only a few attacks but persist as a rule over long periods or throughout life. Our analytic experience that they can be extensively influenced, if the historical precipitating causes and accidental auxiliary factors of the illness can be dealt with, has led us to neglect the constitutional factor in our therapeutic practice, and in any case we can do nothing about it; but in theory we ought always to bear it in mind. The radical inaccessibility of the psychoses to analytic treatment should, in view of their close relationship to the neuroses, restrict our pretensions in regard to these latter. The therapeutic effectiveness of psycho-analysis remains cramped by a number of weighty and scarcely assailable factors. In the case of children, where one might count on the greatest successes, the difficulties are the external ones connected with their relation to their parents, though these difficulties are after all a necessary part of being a child. In the case of adults the difficulties arise in the first instance from two factors: the amount of psychical rigidity present and the form of the illness with all that that covers in the way of deeper determinants.

[1933a, 4752]

The first of these factors is often unjustly overlooked. However great may be the plasticity of mental life and the possibility of reviving old conditions, not everything can be brought to life again. Some changes seem to be definitive and correspond to scars formed when a process has run its course. On other occasions one has an impression of a general stiffening of mental life; the psychical processes, to which one could very well indicate other paths, seem incapable of abandoning the old ones. But perhaps this is the same thing as what I mentioned just now, only looked at differently. All too often one seems to see that it is only the treatment's lack of the necessary motive force that prevents one from bringing the change about. One particular dependent relation, one special instinctual component, is too powerful in comparison with the opposing forces that we are able to mobilize. This is quite generally true with the psychoses. We understand them well enough to know the point at which the levers should be applied, but they would not be able to move the weight. It is here, indeed, that hope for the future lies: the possibility that our knowledge of the operation of the hormones (you know what they are) may give us the means of successfully combating the quantitative factors of the illnesses: but we are far from that to-day. I realize that the uncertainty in all these matters is a constant instigation towards perfecting analysis and in particular the transference. Beginners in analysis especially are left in doubt in case of a failure whether they should blame the peculiarities of the case or their own clumsy handling of the therapeutic procedure. But, as I have said already, I do not think much can be achieved by efforts in this direction.

[1933a, 4753]
The second limitation upon analytic successes is given by the form of the illness. You know already that the field of application of analytic therapy lies in the transference neuroses - phobias, hysteria, obsessional neurosis - and further, abnormalities of character which have been developed in place of these illnesses. Everything differing from these, narcissistic and psychotic conditions, is unsuitable to a greater or less extent. It would be entirely legitimate to guard against failures by carefully excluding such cases. This precaution would lead to a great improvement in the statistics of analysis. There is, however, a pitfall here. Our diagnoses are very often made only after the event. They resemble the Scottish King’s test for identifying witches that I read about in Victor Hugo. This king declared that he was in possession of an infallible method of recognizing a witch. He had the women stewed in a cauldron of boiling water and then tasted the broth. Afterwards he was able to say: 'That was a witch', or 'No, that was not one.' It is the same with us, except that we are the sufferers. We cannot judge the patient who comes for treatment (or, in the same way, the candidate who comes for training) till we have studied him analytically for a few weeks or months. We are in fact buying a pig in a poke. The patient brings along indefinite general ailments which do not admit of a conclusive diagnosis. After this period of testing it may turn out that the case is an unsuitable one. If so we send him away if he is a candidate, or continue the trial a little longer if he is a patient on the chance that we may yet see things in a more favourable light. The patient has his revenge by adding to our list of failures, and the rejected candidate does so perhaps, if he is paranoid, by writing books on psycho-analysis himself. As you see, our precautions have been of no avail.

Let us once more glance over the situation which we have reached in our attempt at bringing help to the patient's neurotic ego. That ego is no longer able to fulfil the task set it by the external world (including human society). Not all of its experiences are at its disposal, a large proportion of its store of memories have escaped it. Its activity is inhibited by strict prohibitions from the super-ego, its energy is consumed in vain attempts at fending off the demands of the id. Beyond this, as a result of continuous irruptions by the id, its organization is impaired, it is no longer capable of any proper synthesis, it is torn by mutually opposed urges, by unsettled conflicts and by unsolved doubts. To start with, we get the patient's thus weakened ego to take part in the purely intellectual work of interpretation, which aims at provisionally filling the gaps in his mental assets, and to transfer to us the authority of his super-ego; we encourage it to take up the struggle over each individual demand made by the id and to conquer the resistances which arise in connection with it. At the same time we restore order in the ego by detecting the material and urges which have forced their way in from the unconscious, and expose them to criticism by tracing them back to their origin. We serve the patient in various functions, as an authority and a substitute for his parents, as a teacher and educator; and we have done the best for him if, as analysts, we raise the mental processes in his ego to a normal level, transform what has become unconscious and repressed into preconscious material and thus return it once more to the possession of his ego. On the patient's side a few rational factors work in our favour, such as the need for recovery which has its motive in his sufferings, and the intellectual interest that we may awaken in him in the theories and revelations of psycho-analysis; but of far greater force is the positive transference with which he meets us. Fighting against us, on the other hand, are the negative transference, the ego's resistance due to repression (that is, its unpleasure at having to lay itself open to the hard work imposed on it), the sense of guilt arising from its relation to the super-ego and the need to be ill due to deep-going changes in the economics of his instincts. The share taken by the last two factors decides whether the case is to be regarded as slight or severe. Apart from these, a few other factors may be discerned as having a favourable or unfavourable bearing. A certain psychical inertia, a sluggishness of the libido, which is unwilling to abandon its fixations cannot be welcome to us; the patient's capacity for sublimating his instincts plays a large part and so does his capacity for rising above the crude life of the instincts; so, too, does the relative power of his intellectual functions.

[1933a, 4754]

[1940a [1938], 4990]
A constitutional strength of instinct and an unfavourable alteration of the ego acquired in its defensive struggle in the sense of its being dislocated and restricted - these are the factors which are prejudicial to the effectiveness of analysis and which may make its duration interminable. One is tempted to make the first factor - strength of instinct - responsible as well for the emergence of the second - the alteration of the ego; but it seems that the latter too has an aetiology of its own. And, indeed, it must be admitted that our knowledge of these matters is as yet insufficient. They are only now becoming the subject of analytic study. In this field the interest of analysts seems to me to be quite wrongly directed. Instead of an enquiry into how a cure by analysis comes about (a matter which I think has been sufficiently elucidated) the question should be asked of what are the obstacles that stand in the way of such a cure.

Both in therapeutic and in character-analyses we notice that two themes come into especial prominence and give the analyst an unusual amount of trouble. It soon becomes evident that a general principle is at work here. The two themes are tied to the distinction between the sexes; one is as characteristic of males as the other is of females. In spite of the dissimilarity of their content, there is an obvious correspondence between them. Something which both sexes have in common has been forced, by the difference between the sexes, into different forms of expression.

The two corresponding themes are in the female, an envy for the penis - a positive striving to possess a male genital - and, in the male, a struggle against his passive or feminine attitude to another male. What is common to the two themes was singled out at an early date by psychoanalytic nomenclature as an attitude towards the castration complex. Subsequently Alfred Adler brought the term 'masculine protest' into current use. It fits the case of males perfectly; but I think that, from the start, 'repudiation of femininity' would have been the correct description of this remarkable feature in the psychical life of human beings.

In trying to introduce this factor into the structure of our theory, we must not overlook the fact that it cannot, by its very nature, occupy the same position in both sexes. In males the striving to be masculine is completely ego-syntonic from the first; the passive attitude, since it presupposes an acceptance of castration, is energetically repressed, and often its presence is only indicated by excessive overcompensations. In females, too, the striving to be masculine is ego-syntonic at a certain period - namely in the phallic phase, before the development to femininity has set in. But it then succumbs to the momentous process of repression whose outcome, as has so often been shown, determines the fortunes of a woman's femininity. A great deal depends on whether a sufficient amount of her masculinity complex escapes repression and exercises a permanent influence on her character. Normally, large portions of the complex are transformed and contribute to the construction of her femininity: the appeased wish for a penis is destined to be converted into a wish for a baby and for a husband, who possesses a penis. It is strange, however, how often we find that the wish for masculinity has been retained in the unconscious and, from out of its state of repression, exercises a disturbing influence.
The paramount importance of these two themes - in females the wish for a penis and in males the struggle against passivity - did not escape Ferenczi's notice. In the paper read by him in 1927 he made it a requirement that in every successful analysis those two complexes must have been mastered.¹ I should like to add that, speaking from my own experience, I think that in this Ferenczi was asking a very great deal. At no other point in one's analytic work does one suffer more from an oppressive feeling that all one's repeated efforts have been in vain, and from a suspicion that one has been 'preaching to the winds', than when one is trying to persuade a woman to abandon her wish for a penis on the ground of its being unrealizable or when one is seeking to convince a man that a passive attitude to men does not always signify castration and that it is indispensable in many relationships in life. The rebellious overcompensation of the male produces one of the strongest transference-resistances. He refuses to subject himself to a father-substitute, or to feel indebted to him for anything, and consequently he refuses to accept his recovery from the doctor. No analogous transference can arise from the female's wish for a penis, but it is the source of outbreaks of severe depression in her, owing to an internal conviction that the analysis will be of no use and that nothing can be done to help her. And we can only agree that she is right, when we learn that her strongest motive in coming for treatment was the hope that, after all, she might still obtain a male organ, the lack of which was so painful to her.

[1937c, 5045]

But we also learn from this that it is not important in what form the resistance appears, whether as a transference or not. The decisive thing remains that the resistance prevents any change from taking place - that everything stays as it was. We often have the impression that with the wish for a penis and the masculine protest we have penetrated through all the psychological strata and have reached bedrock, and that thus our activities are at an end. This is probably true, since, for the psychical field, the biological field does in fact play the part of the underlying bedrock. The repudiation of femininity can be nothing else than a biological fact, a part of the great riddle of sex.¹ It would be hard to say whether and when we have succeeded in mastering this factor in an analytic treatment. We can only console ourselves with the certainty that we have given the person analysed every possible encouragement to re-examine and alter his attitude to it.

[1937c, 5046]
It is possible that this answer, 'I don't know', was correct; but it may quite as well have indicated reluctance to talk about the causes of the stammering. I have since observed in other patients that the greater the effort they have made to repress a thing from their consciousness the more difficulty they have in remembering it under hypnosis as well as in waking life.

[1895d, 55]

I was still not satisfied. There might, I thought, be something else at work as well that had aroused or reinforced the hysterical disposition of a girl who had till then been normal. My suspicions turned to her monthly periods as an appropriate factor, and I asked: 'Do you know at what time in the month your period came on?' The question was not a welcome one. 'Do you expect me to know that, too? I can only tell you that I had them very seldom then and very irregularly. When I was seventeen I only had one once.' - 'Very well, then, we will find out when this once was by counting over.' I did the counting over, and she decided definitely on one particular month and hesitated between two days immediately preceding the date of a fixed holiday. 'Does that fit in somehow with the date of the ball?' She answered sheepishly: 'The ball was on the holiday. And now I remember, too, what an impression it made on me that my only period that year should have had to come on just before the ball. It was my first ball.'

[1895d, 100]
Before I resume my account of the case I will add a few words on the patient's behaviour during this second phase of the treatment. Throughout the analysis I made use of the technique of bringing out pictures and ideas by means of pressing on the patient's head, a method, that is, which would be unworkable without the patient's full co-operation and willing attention. Sometimes, indeed, her behaviour fulfilled my highest expectations, and during such periods it was surprising with what promptitude the different scenes relating to a given theme emerged in a strictly chronological order. It was as though she were reading a lengthy book of pictures, whose pages were being turned over before her eyes. At other times there seemed to be impediments of whose nature I had no suspicion then. When I pressed her head she would maintain that nothing occurred to her. I would repeat my pressure and tell her to wait, but still nothing appeared. The first few times when this recalcitrance exhibited itself I allowed myself to be led into breaking off the work: it was an unfavourable day; we would try another time. Two observations, however, decided me to alter my attitude. I noticed, in the first place, that the method failed in this way only when I found Elisabeth in a cheerful state and free from pain, never when she was feeling badly. In the second place, that she often made such assertions as that she saw nothing, after she had allowed a long interval to pass during which her tense and preoccupied expression of face nevertheless betrayed the fact that a mental process was taking place in her. I resolved, therefore, to adopt the hypothesis that the procedure never failed: that on every occasion under the pressure of my hand some idea occurred to Elisabeth or some picture came before her eyes, but that she was not always prepared to communicate it to me, and tried to suppress once more what had been conjured up. I could think of two motives for this concealment. Either she was applying criticism to the idea, which she had no right to do, on the ground of its not being important enough or of its being an irrelevant reply to the question she had been asked; or she hesitated to produce it because she found it too disagreeable to tell. I therefore proceeded as though I was completely convinced of the trustworthiness of my technique. I no longer accepted her declaration that nothing had occurred to her, but assured her that something must have occurred to her. Perhaps, I said, she had not been sufficiently attentive, in which case I should be glad to repeat my pressure. Or perhaps she thought that her idea was not the right one. This, I told her, was not her affair; she was under an obligation to remain completely objective and say what had come into her head, whether it was appropriate or not. Finally I declared that I knew very well that something had occurred to her and that she was concealing it from me; but she would never be free of her pains so long as she concealed anything. By thus insisting, I brought it about that from that time forward my pressure on her head never failed in its effect. I could not but conclude that I had formed a correct opinion of the state of affairs, and I derived from this analysis a literally unqualified reliance on my technique. It often happened that it was not until I had pressed her head three times that she produced a piece of information; but she herself would remark afterwards: 'I could have said it to you the first time.' - 'And why didn't you?' - 'I thought it wasn't what was wanted', or 'I thought I could avoid it, but it came back each time.' In the course of this difficult work I began to attach a deeper significance to the resistance offered by the patient in the reproduction of her memories and to make a careful collection of the occasions on which it was particularly marked. [1895d, 139]
I have now arrived at the third period of the treatment. The patient was better. She had been mentally relieved and was now capable of successful effort. But her pains had manifestly, not been removed; they recurred from time to time, and with all their old severity. This incomplete therapeutic result corresponded to an incompleteness in the analysis. I still did not know exactly at what moment and by what mechanism the pains had originated. During the reproduction of the great variety of scenes in the second period and while I was observing the patient's resistance to telling me about them, I had formed a particular suspicion. I did not venture yet, however, to adopt it as the basis of my further action. But a chance occurrence decided the matter. One day while I was working with the patient, I heard a man's footsteps in the next room and a pleasant voice which seemed to be asking some question. My patient thereupon got up and asked that we might break off for the day: she had heard her brother-in-law arrive and enquire for her. Up to that point she had been free from pain, but after the interruption her facial expression and gait betrayed the sudden emergence of severe pains. My suspicion was strengthened by this and I determined to precipitate the decisive explanation.

Everything was now clear. The analyst's labours were richly rewarded. The concepts of the 'fending off' of an incompatible idea, of the genesis of hysterical symptoms through the conversion of psychical excitations into something physical and the formation of a separate psychical group through the act of will which led to the fending-off - all these things were, in that moment, brought before my eyes in concrete form. Thus and in no other way had things come about in the present case. This girl felt towards her brother-in-law a tenderness whose acceptance into consciousness was resisted by her whole moral being. She succeeded in sparing herself the painful conviction that she loved her sister's husband, by inducing physical pains in herself instead; and it was in the moments when this conviction sought to force itself upon her (on her walk with him, during her morning reverie, in the bath, by her sister's bedside) that her pains had come on, thanks to successful conversion. At the time when I started her treatment the group of ideas relating to her love had already been separated from her knowledge. Otherwise she would never, I think, have agreed to embarking on the treatment. The resistance with which she had repeatedly met the reproduction of scenes which operated traumatically corresponded in fact to the energy with which the incompatible idea had been forced out of her associations.

We can answer this question if we take into account two facts which we can make use of as being established with certainty. (1) Simultaneously with the formation of this separate psychical group the patient developed her hysterical pains. (2) The patient offered strong resistance to the attempt to bring about an association between the separate psychical group and the rest of the content of her consciousness; and when, in spite of this, the connection was accomplished she felt great psychical pain. Our view of hysteria brings these two facts into relation with the splitting of her consciousness by asserting that the second of them indicates the motive for the splitting of consciousness, while the first indicates its mechanism. The motive was that of defence, the refusal on the part of the patient's whole ego to come to terms with this ideational group. The mechanism was that of conversion: i.e. in place of the mental pains which she avoided, physical pains made their appearance. In this way a transformation was effected which had the advantage that the patient escaped from an intolerable mental condition; though, it is true, this was at the cost of a psychical abnormality - the splitting of consciousness that came about - and of a physical illness - her pains, on which an astasia-abasia was built up.
Hitherto I have been so warm in my praises of the achievements of pressure as an auxiliary procedure, and I have the whole time so greatly neglected the aspect of defence or resistance, that I may no doubt have created an impression that this little device has put us in a position to master the psychical obstacles to a cathartic treatment. But to believe this would be to make a serious mistake. Gains of this kind, so far as I can see, are not to be looked for in treatment. Here, as elsewhere, a large change requires a large amount of work. The procedure by pressure is no more than a trick for temporarily taking unawares an ego which is eager for defence. In all fairly serious cases the ego recalls its aims once more and proceeds with its resistance.

I must mention the different forms in which this resistance appears. One is that, as a rule, the pressure procedure fails on the first or second occasion. The patient then declares, very disappointedly: 'I expected something would occur to me, but all I thought was how tensely I was expecting it. Nothing came.' The fact of the patient putting himself on his guard like this does not yet amount to an obstacle. We can say in reply: 'It's precisely because you were too curious; it will work next time.' And in fact it does work. It is remarkable how often patients, even the most docile and intelligent, can completely forget their undertaking, though they had agreed to it beforehand. They promised to say whatever occurred to them under the pressure of my hand, irrespectively of whether it seemed to them relevant or not, and of whether it was agreeable to them to say it or not - to say it, that is, without selecting and without being influenced by criticism or affect. But they do not keep this promise; it is evidently beyond their strength to do so. The work keeps on coming to a stop and they keep on maintaining that this time nothing has occurred to them. We must not believe what they say, we must always assume, and tell them, too, that they have kept something back because they thought it unimportant or found it distressing. We must insist on this, we must repeat the pressure and represent ourselves as infallible, till at last we are really told something. The patient then adds: 'I could have told you that the first time.' 'Why didn't you say it?' 'I couldn't believe it could be that. It was only when it came back every time that I made up my mind to say it.' Or else: 'I hoped it wouldn't be that of all things. I could well do without saying that. It was only when it refused to be repressed that I saw I shouldn't be let off.' Thus after the event the patient betrays the motives for a resistance which he refused to admit to begin with. He is evidently quite unable to do anything but put up resistance.

This resistance often conceals itself behind some remarkable excuses. 'My mind is distracted to-day; the clock (or the piano in the next room) is disturbing me.' I have learned to answer such remarks: 'Not at all. You have at this moment come up against something that you had rather not say. It won't do any good. Go on thinking about it.' The longer the pause between my hand-pressure and the patient's beginning to speak, the more suspicious I become and the more it is to be feared that the patient is re-arranging what has occurred to him and is mutilating it in his reproduction of it. A most important piece of information is often announced as being a redundant accessory, like an opera prince disguised as a beggar. 'Something has occurred to me now, but it has nothing to do with the subject. I'm only saying it because you want to know every thing.' Accompanying words such as these usually introduce the long-sought solution. I always prick up my ears when I hear a patient speak so disparagingly of something that has occurred to him. For it is an indication that defence has been successful if the pathogenic ideas seem, when they re-emerge, to have so little importance. From this we can infer in what the process of defence consisted: it consisted in turning a strong idea into a weak one, in robbing it of its affect.
Thus even with the assistance of the pressure technique the work is by no means easy. The one advantage that we gain is of learning from the results of this procedure the direction in which we have to conduct our enquiries and the things that we have to insist upon to the patient. With some cases this suffices. The principal point is that I should guess the secret and tell it to the patient straight out; and he is then as a rule obliged to abandon his rejection of it. In other cases more is required. The patient's persisting resistance is indicated by the fact that connections are broken, solutions fail to appear, the pictures are recalled indistinctly and incompletely. Looking back from a later period of an analysis to an earlier one, we are often astonished to realize in what a mutilated manner all the ideas and scenes emerged which we extracted from the patient by the procedure of pressing. Precisely the essential elements of the picture were missing - its relation to himself or to the main contents of his thoughts - and that is why it remained unintelligible.

What means have we at our disposal for overcoming this continual resistance? Few, but they include almost all those by which one man can ordinarily exert a psychical influence on another. In the first place, we must reflect that a psychical resistance, especially one that has been in force for a long time, can only be resolved slowly and by degrees, and we must wait patiently. In the next place, we may reckon on the intellectual interest which the patient begins to feel after working for a short time. By explaining things to him, by giving him information about the marvellous world of psychical processes into which we ourselves only gained insight by such analyses, we make him himself into a collaborator, induce him to regard himself with the objective interest of an investigator, and thus push back his resistance, resting as it does on an affective basis. But lastly - and this remains the strongest lever - we must endeavour, after we have discovered the motives for his defence, to deprive them of their value or even to replace them by more powerful ones. This no doubt is where it ceases to be possible to state psychotherapeutic activity in formulas. One works to the best of one's power, as an elucidator (where ignorance has given rise to fear), as a teacher, as the representative of a freer or superior view of the world, as a father confessor who gives absolution, as it were, by a continuance of his sympathy and respect after the confession has been made. One tries to give the patient human assistance, so far as this is allowed by the capacity of one's own personality and by the amount of sympathy that one can feel for the particular case. It is an essential precondition for such psychical activity that we should have more or less divined the nature of the case and the motives of the defence operating in it, and fortunately the technique of insistence and pressure takes us as far as this. The more such riddles we have already solved, the easier we may find it to guess a new one and the sooner we shall be able to start on the truly curative psychical work. For it is well to recognize this clearly: the patient only gets free from the hysterical symptom by reproducing the pathogenic impressions that caused it and by giving utterance to them with an expression of affect, and thus the therapeutic task consists solely in inducing him to do so; when once this task has been accomplished there is nothing left for the physician to correct or to remove. Whatever may be required for this purpose in the way of counter-suggestions has already been expended during the struggle against the resistance. The situation may be compared with the unlocking of a locked door, after which opening it by turning the handle offers no further difficulty.
In view of what I have said in the preceding section about the difficulties of my technique, which I have unsparingly exposed (I brought them together, incidentally, from the severest cases; things often turn out very much more conveniently) - in view of all this, then, everyone will no doubt feel inclined to ask whether it would not be more expedient, instead of putting up with all these troubles, to make a more energetic use of hypnosis or to restrict the use of the cathartic method to patients who can be put under deep hypnosis. As regards the latter proposal I should have to answer that in that case the number of suitable patients, so far as my skill is concerned, would dwindle far too much; and I would meet the first piece of advice with the suspicion that the forcible imposition of hypnosis might not spare us much resistance. My experiences on this point, oddly enough, have not been numerous, and I cannot, therefore, go beyond a suspicion. But where I have carried out a cathartic treatment under hypnosis instead of under concentration, I did not find that this diminished the work I had to do. Not long ago I completed a treatment of this kind in the course of which I caused a hysterical paralysis of the legs to clear up. The patient passed into a state which was very different psychically from waking and which was characterized physically by the fact that it was impossible for her to open her eyes or get up till I had called out to her: 'Now wake up!' None the less I have never come across greater resistance than in this case. I attached no importance to these physical signs, and towards the end of the treatment, which lasted ten months, they had ceased to be noticeable. But in spite of this the patient's state while we were working lost none of its psychical characteristics - the capacity she possessed for remembering unconscious material and her quite special relation to the figure of the physician. On the other hand, I have given an example in the case history of Frau Emmy von N. of a cathartic treatment in the deepest somnambulism in which resistance played scarcely any part. But it is also true that I learnt from that lady nothing whose telling might have called for any special overcoming of objections, nothing that she could not have told me even in a waking state, supposing we had been acquainted for some time and she had thought fairly highly of me. I never reached the true causes of her illness, which were no doubt identical with the causes of her relapse after my treatment (for this was my first attempt with this method); and the only occasion on which I happened to ask her for a reminiscence which involved an erotic element I found her just as reluctant and untrustworthy in what she told me as I did later with any of my non-somnambulistic patients. I have already spoken in that lady's case history of the resistance which she put up even during somnambulism to other requests and suggestions of mine. I have become altogether sceptical about the value of hypnosis in facilitating cathartic treatments, since I have experienced instances in which during deep somnambulism there has been absolute therapeutic recalcitrance, where in other respects the patient has been perfectly obedient. I reported a case of this kind briefly on p. 90, and I could add others. I may admit, too, that this experience has corresponded pretty well to the requirement I insist upon that there shall be a quantitative relation between cause and effect in the psychical field as well.

But if we examine with a critical eye the account that the patient has given us without much trouble or resistance, we shall quite infallibly discover gaps and imperfections in it. At one point the train of thought will be visibly interrupted and patched up by the patient as best he may, with a turn of speech or an inadequate explanation; at another point we come upon a motive which would have to be described as a feeble one in a normal person. The patient will not recognize these deficiencies when his attention is drawn to them. But the physician will be right in looking behind the weak spots for an approach to the material in the deeper layers and in hoping that he will discover precisely there the connecting threads for which he is seeking with the pressure procedure. Accordingly, we say to the patient: 'You are mistaken; what you are putting forward can have nothing to do with the present subject. We must expect to come upon something else here, and this will occur to you under the pressure of my hand.'
In this way, then, by detecting lacunas in the patient's first description, lacunas which are often covered by 'false connections', we get hold of a piece of the logical thread at the periphery, and from this point on we clear a further path by the pressure technique. 

[1895d, 259]

It is easy to imagine how complicated a work of this kind can become. We force our way into the internal strata, overcoming resistances all the time; we get to know the themes accumulated in one of these strata and the threads running through it, and we experiment how far we can advance with our present means and the knowledge we have acquired; we obtain preliminary information about the contents of the next strata by means of the pressure technique; we drop threads and pick them up again; we follow them as far as nodal points; we are constantly making up arrears; and every time that we pursue a file of memories we are led to some side-path, which nevertheless eventually joins up again. By this method we at last reach a point at which we can stop working in strata and can penetrate by a main path straight to the nucleus of the pathogenic organization. With this the struggle is won, though not yet ended. We must go back and take up the other threads and exhaust the material. But now the patient helps us energetically. His resistance is for the most part broken. 

[1895d, 260]

I have turned observations of this kind to account in my therapeutic work by leading back the attention of patients with phobias and obsessions to the repressed sexual ideas in spite of all their protestations, and, wherever possible, by stopping up the sources from which those ideas sprang. I cannot, of course, assert that all phobias and obsessions arise in the manner I have shown here. In the first place, my experience of them includes only a limited number compared with the frequency of these neuroses; and in the second place, I myself am aware that such 'psychasthenic' symptoms, as Janet terms them, are not all equivalent. There are, for instance, purely hysterical phobias. Nevertheless, I think that it will be possible to show the presence of the mechanism of transposition of affect in the great majority of phobias and obsessions, and I would therefore urge that these neuroses, which are found in an isolated state as often as in combination with hysteria or neurasthenia, should not be thrown into a heap along with common neurasthenia, for the basic symptoms of which there is no ground at all to assume a psychological mechanism.

[1894a, 312]

How is it possible to remain convinced of the reality of these analytic confessions which claim to be memories preserved from the earliest childhood? and how is one to arm oneself against the tendency to lies and the facility of invention which are attributed to hysterical subjects? I should accuse myself of blame-worthy credulity if I did not possess more conclusive evidence. But the fact is that these patients never repeat these stories spontaneously, nor do they ever in the course of a treatment suddenly present the physician with the complete recollection of a scene of this kind. One only succeeds in awakening the psychical trace of a precocious sexual event under the most energetic pressure of the analytic procedure, and against an enormous resistance. Moreover, the memory must be extracted from them piece by piece, and while it is being awakened in their consciousness they become the prey to an emotion which it would be hard to counterfeit. 

[1896a, 377]
What I have to report about this patient concerns the aetiology of the case and the mechanism of the hallucinations. I discovered the aetiology when I applied Breuer's method, exactly as in a case of hysteria - in the first instance for the investigation and removal of the hallucinations. In doing so, I started out from the assumption that in this case of paranoia, just as in the two other defence neuroses with which I was familiar, there must be unconscious thoughts and repressed memories which could be brought into consciousness in the same way as they were in those neuroses, by overcoming a certain resistance. The patient at once confirmed my expectation, for she behaved in analysis exactly like, for instance, a hysterical patient; with her attention on the pressure of my hand,¹ she produced thoughts which she could not remember having had, which at first she did not understand and which were contrary to her expectations. The presence of significant unconscious ideas was thus demonstrated in a case of paranoia as well, and I was able to hope that I might trace the compulsion of paranoia, too, to repression. The only peculiarity was that the thoughts which arose from the unconscious were for the most part heard inwardly or hallucinated by the patient, in the same way as her voices.

[1896b, 397]

GENTLEMEN, - When we set out to form an opinion about the causation of a pathological state such as hysteria, we begin by adopting the method of anamnestic investigation: we question the patient or those about him in order to find out to what harmful influences they themselves attribute his having fallen ill and developed these neurotic symptoms. What we discover in this way is, of course, falsified by all the factors which commonly hide the knowledge of his own state from a patient - by his lack of scientific understanding of aetiological influences, by the fallacy of post hoc, propter hoc, by his reluctance to think about or mention certain noxae and traumas. Thus in making an anamnestic investigation of this sort, we keep to the principle of not adopting the patients' belief without a thorough critical examination, of not allowing them to lay down our scientific opinion for us on the aetiology of the neurosis. Although we do, on the one hand, acknowledge the truth of certain constantly repeated assertions, such as that the hysterical state is a long-persisting after-effect of an emotion experienced in the past, we have, on the other hand, introduced into the aetiology of hysteria a factor which the patient himself never brings forward and whose validity he only reluctantly admits - namely, the hereditary disposition derived from his progenitors. As you know, in the view of the influential school of Charcot heredity alone deserves to be recognized as the true cause of hysteria, while all other noxae of the most various nature and intensity only play the part of incidental causes, of 'agents provocateurs'.

[1896c, 407]
But other people, too, although they may be less averse to psychological theories of hysteria, will be tempted, when considering our analytic findings, to ask what degree of certainty the application of psycho-analysis offers. Is it not very possible either that the physician forces such scenes upon his docile patients, alleging that they are memories, or else that the patients tell the physician things which they have deliberately invented or have imagined and that he accepts those things as true? Well, my answer to this is that the general doubt about the reliability of the psycho-analytic method can be appraised and removed only when a complete presentation of its technique and results is available. Doubts about the genuineness of the infantile sexual scenes can, however, be deprived of their force here and now by more than one argument. In the first place, the behaviour of patients while they are reproducing these infantile experiences is in every respect incompatible with the assumption that the scenes are anything else than a reality which is being felt with distress and reproduced with the greatest reluctance. Before they come for analysis the patients know nothing about these scenes. They are indignant as a rule if we warn them that such scenes are going to emerge. Only the strongest compulsion of the treatment can induce them to embark on a reproduction of them. While they are recalling these infantile experiences to consciousness, they suffer under the most violent sensations, of which they are ashamed and which they try to conceal; and, even after they have gone through them once more in such a convincing manner, they still attempt to withhold belief from them, by emphasizing the fact that, unlike what happens in the case of other forgotten material, they have no feeling of remembering the scenes.¹

Having diagnosed a case of neurasthenic neurosis with certainty and having classified its symptoms correctly, we are in a position to translate the symptomatology into aetiology; and we may then boldly demand confirmation of our suspicions from the patient. We must not be led astray by initial denials. If we keep firmly to what we have inferred, we shall in the end conquer every resistance by emphasizing the unshakeable nature of our convictions. In this way we learn all sorts of things about the sexual life of men and women, which might well fill a useful and instructive volume; and we learn, too, to regret from every point of view that sexual science is even to-day still regarded as disreputable. Since minor deviations from a normal vita sexualis are much too common for us to attach any value to their discovery, we shall only allow a serious and long continued abnormality in the sexual life of a neurotic patient to carry weight as an explanation. Moreover, the idea that one might, by one’s insistence, cause a patient who is psychically normal to accuse himself falsely of sexual misdemeanours is an imaginary danger.

¹ [1896c, 418]

[1897b, 461]
I then recalled that there was still a piece of the dream which the interpretation had not touched. After the idea had occurred to me that R. was my uncle, I had had a warm feeling of affection for him in the dream. Where did that feeling belong? I had naturally never had any feeling of affection for my Uncle Josef. I had been fond of my friend R. and had esteemed him for many years; but if I had gone up to him and expressed my sentiments in terms approaching the degree of affection I had felt in the dream, there could be no doubt that he would have been astonished. My affection for him struck me as ungeniune and exaggerated - like the judgement of his intellectual qualities which I had expressed by fusing his personality with my uncle's, though there the exaggeration had been in the opposite direction. But a new light began to dawn on me. The affection in the dream did not belong to the latent content, to the thoughts that lay behind the dream; it stood in contradiction to them and was calculated to conceal the true interpretation of the dream. And probably that was precisely its raison d'être. I recalled my resistance against embarking on the interpretation, how long I had put it off and how I had declared that the dream was sheer nonsense. My psycho-analytic treatments taught me how a repudiation of that kind was to be interpreted: it had no value as a judgement but was simply an expression of emotion. If my little daughter did not want an apple that was offered to her, she asserted that the apple tasted sour without having tasted it. And if my patients behaved like the child, I knew that they were concerned with an idea which they wanted to repress. The same was true of my dream. I did not want to interpret it, because the interpretation contained something that I was struggling against. When I had completed the interpretation I learnt what it was that I had been struggling against - namely, the assertion that R. was a simpleton. The affection that I felt for R. could not be derived from the latent dream-thoughts; but no doubt it originated from this struggle of mine. If my dream was distorted in this respect from its latent content - and distorted into its opposite - then the affection that was manifest in the dream served the purpose of this distortion. In other words, distortion was shown in this case to be deliberate and to be a means of dissimulation. My dream thoughts had contained a slander against R.; and, in order that I might not notice this, what appeared in the dream was the opposite, a feeling of affection for him.

As I have already explained, when I undertake the analytic treatment of a psycho-neurotic patient his dreams are invariably discussed between us. In the course of these discussions I am obliged to give him all the psychological explanations which have enabled me myself to reach an understanding of his symptoms. I am thereupon subjected to a remorseless criticism, certainly no less severe than I have to expect from the members of my own profession. And my patients invariably contradict my assertion that all dreams are fulfilments of wishes. Here, then, are some instances from the material of dreams that have been brought up against me as evidence to the contrary.

The very frequent dreams, which appear to stand in contradiction to my theory because their subject-matter is the frustration of a wish or the occurrence of something clearly unwished-for, may be brought together under the heading of 'counter-wish dreams'. If these dreams are considered as a whole, it seems to me possible to trace them back to two principles; I have not yet mentioned one of these, although it plays a large part not only in people's dreams but in their lives as well. One of the two motive forces leading to such dreams is the wish that I may be wrong. These dreams appear regularly in the course of my treatments when a patient is in a state of resistance to me; and I can count almost certainly on provoking one of them after I have explained to a patient for the first time my theory that dreams are fulfilments of wishes.¹ Indeed, it is to be expected that the same thing will happen to some of the readers of the present book: they will be quite ready to have one of their wishes frustrated in a dream if only their wish that I may be wrong can be fulfilled.
Moreover I am in a position to offer an ocular demonstration of the fact that the forgetting of dreams is to a great extent a product of resistance. One of my patients will tell me he has had a dream but has forgotten every trace of it: it is therefore just as though it had never happened. We proceed with our work. I come up against a resistance; I therefore explain something to the patient and help him by encouragement and pressure to come to terms with some disagreeable thought. Hardly have I succeeded in this than he exclaims: 'Now I remember what it was I dreamt.' The same resistance which interfered with our work that day also made him forget the dream. By overcoming this resistance I have recalled the dream to his memory.

If we make use of it on someone else, let us say on a patient with a phobia, we require him to direct his attention on to the idea in question, not, however, to reflect upon it as he has done so often already, but to take notice of whatever occurs to his mind without any exception and report it to the physician. If he should then assert that his attention is unable to grasp anything at all, we dismiss this with an energetic assurance that a complete absence of any ideational subject-matter is quite impossible. And in fact very soon numerous ideas will occur to him and will lead on to others; but they will invariably be prefaced by a judgement on the part of the self-observer to the effect that they are senseless or unimportant, that they are irrelevant, and that they occurred to him by chance and without any connection with the topic under consideration. We perceive at once that it was this critical attitude which prevented the subject from reporting any of these ideas, and which indeed had previously prevented them from becoming conscious. If we can induce him to abandon his criticism of the ideas that occur to him, and to continue pursuing the trains of thought which will emerge so long as he keeps his attention turned upon them, we find ourselves in possession of a quantity of psychical material, which we soon find is clearly connected with the pathological idea which was our starting-point; this material will soon reveal connections between the pathological idea and other ideas, and will eventually enable us to replace the pathological idea by a new one which fits into the nexus of thought in an intelligible fashion.

The contrast between the manifest and latent content of dreams is clearly of significance only for dreams of the second and more particularly of the third category. It is there that we are faced by riddles which only disappear after we have replaced the manifest dream by the latent thoughts behind it; and it was on a specimen of the last category - a confused and unintelligible dream - that the analysis which I have just recorded was carried out. Contrary to our expectation, however, we came up against motives which prevented us from becoming fully acquainted with the latent dream-thoughts. A repetition of similar experiences may lead us to suspect that there is an intimate and regular relation between the unintelligible and confused nature of dreams and the difficulty of reporting the thoughts behind them. Before enquiring into the nature of this relation, we may with advantage turn our attention to the more easily intelligible dreams of the first category, in which the manifest and latent content coincide, and there appears to be a consequent saving in dream-work.
A patient, whose psycho-analytic treatment was interrupted by the summer holidays at a time when he was in a state of resistance and felt unwell, put his bunch of keys in its usual place - or so he thought - when he undressed for the night. Then he remembered that there were a few more things that he needed for his journey next day - the last day of treatment and the date on which his fee was due - and he went to get them out of the writing-desk, in which he had also put his money. But the keys had disappeared. He began to make a systematic but increasingly agitated search of his small flat - with no success. Since he recognized the "mislaying" of the keys as a symptomatic act - that is, as something he had done intentionally - he woke his servant in order to continue the search with the aid of an "unprejudiced" person. After another hour he gave it up and was afraid he had lost the keys. Next morning he ordered new keys from the makers of the desk, and they were hastily made for him. Two friends, who had come home with him in the same cab, thought they remembered hearing something fall with a clink on the ground as he stepped out of the cab. He was convinced that his keys had fallen from his pocket. That evening the servant triumphantly presented him with the keys. They had been found lying between a thick book and a thin pamphlet (a work by one of my pupils) which he wanted to take away to read on his holiday. They were so cleverly placed that no one would have suspected they were there. He found himself afterwards unable to replace them so that they were equally invisible. The unconscious dexterity with which an object is mislaid on account of hidden but powerful motives is very reminiscent of "somnambulistic certainty". The motive, as one would expect, was ill-temper at the treatment being interrupted and secret rage at having to pay a high fee when he was feeling so unwell.

¹ This physician was the only one in whom she showed any confidence, because this episode showed her that he had not penetrated her secret. She felt afraid of any other doctor about whom she had not yet been able to form a judgement, and we can now see that the motive of her fear was the possibility that he might guess her secret.

Dora had listened to me without any of her usual contradictions. She seemed to be moved; she said good-bye to me very warmly, with the heartiest wishes for the New Year, and - came no more. Her father, who called on me two or three times afterwards, assured me that she would come back again, and said it was easy to see that she was eager for the treatment to continue. But it must be confessed that Dora's father was never entirely straightforward. He had given his support to the treatment so long as he could hope that I should 'talk' Dora out of her belief that there was something more than a friendship between him and Frau K. His interest faded when he observed that it was not my intention to bring about that result. I knew Dora would not come back again. Her breaking off so unexpectedly, just when my hopes of a successful termination of the treatment were at their highest, and her thus bringing those hopes to nothing - this was an unmistakable act of vengeance on her part. Her purpose of self-injury also profited by this action. No one who, like me, conjures up the most evil of those half-tamed demons that inhabit the human breast, and seeks to wrestle with them, can expect to come through the struggle unscathed. Might I perhaps have kept the girl under my treatment if I myself had acted a part, if I had exaggerated the importance to me of her staying on, and had shown a warm personal interest in her - a course which, even after allowing for my position as her physician, would have been tantamount to providing her with a substitute for the affection she longed for? I do not know. Since in every case a portion of the factors that are encountered under the form of resistance remains unknown, I have always avoided acting a part, and have contented myself with practising the humbler arts of psychology. In spite of every theoretical interest and of every endeavour to be of assistance as a physician, I keep the fact in mind that there must be some limits set to the extent to which psychological influence may be used, and I respect as one of these limits the patient's own will and understanding.
In order to secure these ideas and associations he asks the patient to 'let himself go' in what he says, 'as you would do in a conversation in which you were rambling on quite disconnectedly and at random'. Before he asks them for a detailed account of their case history he insists that they must include in it whatever comes into their heads, even if they think it unimportant or irrelevant or nonsensical; he lays special stress on their not omitting any thought or idea from their story because to relate it would be embarrassing or distressing to them. In the course of collecting this material of otherwise neglected ideas Freud made the observations which became the determining factor of his entire theory. Gaps appear in the patient's memory even while he narrates his case: actual occurrences are forgotten, the chronological order is confused, or causal connections are broken, with unintelligible results. No neurotic case history is without amnesia of some kind or other. If the patient is urged to fill these gaps in his memory by an increased application of attention, it is noticed that all the ideas which occur to him are pushed back by every possible critical expedient, until at last he feels positive discomfort when the memory really returns. From this experience Freud concludes that the amnesias are the result of a process which he calls 'repression' and the motive for which he finds in feelings of displeasure. The psychical forces which have brought about this repression can also be detected, according to him, in the 'resistance' which operates against the recovery of the lost memories.
[1904a, 1557]

The factor of resistance has become one of the corner-stones of his theory. The ideas which are normally pushed aside on every sort of excuse - such as those mentioned above - are regarded by him as derivatives of the repressed psychical phenomena (thoughts and impulses), distorted owing to the resistance against their reproduction. Ideas which are normally pushed aside on every sort of excuse - such as those mentioned above - are regarded by him as derivatives of the repressed psychical phenomena (thoughts and impulses), distorted owing to the resistance against their reproduction.
[1904a, 1557]

The greater the resistance, the greater is the distortion. The value of these unintentional thoughts for the purposes of therapeutic technique lies in this relation of theirs to the repressed psychical material. If one possesses a procedure which makes it possible to arrive at the repressed material from the associations, at the distorted material from the distortions, then what was formerly unconscious in mental life can be made accessible to consciousness even without hypnosis.
[1904a, 1558]
(a) I have observed that this method is very often confused with hypnotic treatment by suggestion; I have noticed this because it happens comparatively often that colleagues who do not ordinarily confide their cases to me send me patients refractory patients, of course - with a request that I should hypnotize them. Now I have not used hypnosis for therapeutic purposes for some eight years (except for a few special experiments) so that I habitually send back these cases with the recommendation that anyone who relies upon hypnosis may employ it himself. There is, actually, the greatest possible antithesis between suggestive and analytic technique - the same antithesis which, in regard to the fine arts, the great Leonardo da Vinci summed up in the formulas: *per via di porre* and *per via di levare*. Painting, says Leonardo, works *per via di porre*, for it applies a substance - particles of colour - where there was no thing before, on the colourless canvas; sculpture, however, proceeds *per via di levare*, since it takes away from the block of stone all that hides the surface of the statue contained in it. In a similar way, the technique of suggestion aims at proceeding *per via di porre*; it is not concerned with the origin, strength and meaning of the morbid symptoms, but instead, it superimposes something - a suggestion - in the expectation that it will be strong enough to restrain the pathogenic idea from coming to expression. Analytic therapy, on the other hand, does not seek to add or to introduce anything new, but to take away something, to bring out something; and to this end concerns itself with the genesis of the morbid symptoms and the psychical context of the pathogenic idea which it seeks to remove. It is by the use of this mode of investigation that analytic therapy has increased our knowledge so notably. I gave up the suggestive technique, and with it hypnosis, so early in my practice because I despaired of making suggestion powerful and enduring enough to effect permanent cures. In every severe case I saw the suggestions which had been applied crumble away again; after which the disease or some substitute for it was back once more. Besides all this I have another reproach to make against this method, namely, that it conceals from us all insight into the play of mental forces; it does not permit us, for example, to recognize the *resistance* with which the patient clings to his disease and thus even fights against his own recovery; yet it is this phenomenon of resistance which alone makes it possible to understand his behaviour in daily life.

[1905a, 1566]
(c) From certain of my remarks you will have gathered that there are many characteristics in
the analytic method which prevent it from being an ideal form of therapy. Tuto, cito, jucunde:
investigation and probing do not indicate speedy results, and the resistance I have mentioned
would prepare you to expect unpleasantness of various kinds. Psycho-analytic treatment
certainly makes great demands upon the patient as well as upon the physician. From the patient
it requires perfect sincerity - a sacrifice in itself; it absorbs time and is therefore also costly; for
the physician it is no less time-absorbing, and the technique which he must study and practise
is fairly laborious. I consider it quite justifiable to resort to more convenient methods of treatment
as long as there is any prospect of achieving anything by their means. That, after all, is the only
point at issue. If the more difficult and lengthy method accomplishes considerably more than the
short and easy one, then, in spite of everything, the use of the former is justified. Only consider,
Gentlemen, how much more inconvenient and costly is the Finsen therapy of lupus than the
method of cauterizing and scraping previously employed; and yet the use of the former signifies
a great advance, for it performs a radical cure. Although I do not wish to carry this comparison
to extremes, the psycho-analytic method may claim a similar privilege. Actually, I have been
able to elaborate and to test my therapeutic method only on severe, indeed on the severest
cases; at first my material consisted entirely of patients who had tried everything else without
success, and had spent long years in sanatoria. I have scarcely been able to bring together
sufficient material to enable me to say how my method works with those slighter, episodic cases
which we see recovering under all kinds of influences and even spontaneously. Psycho-analytic
therapy was created through and for the treatment of patients permanently unfit for existence,
and its triumph has been that it has made a satisfactorily large number of these permanently fit
for existence. In the face of such an achievement all the effort expended seems trivial. We
cannot conceal from ourselves what, as physicians, we are in the habit of denying to our
patients, namely, that a severe neurosis is no less serious for the sufferer than any cachexia or
any of the dreaded major diseases.
[1905a, 1568]

There is, however, another angle from which you may seek to understand the psycho-analytic
method. The uncovering and translating of the unconscious occurs in the face of a continuous
resistance on the part of the patient. The process of bringing this unconscious material to light is
associated with unpleasure, and because of this the patient rejects it again and again. It is for
you then to interpose in this conflict in the patient’s mental life. If you succeed in persuading him
to accept, by virtue of a better understanding, something that up to now, in consequence of this
automatic regulation by unpleasure, he has rejected (repressed), you will have accomplished
something towards his education. For it is education even to induce someone who dislikes
going up early to do so all the same. Psycho-analytic treatment may in general be conceived
of as such a re-education in overcoming internal resistances. Re-education of this kind is,
however, in no respect more necessary to nervous patients than in regard to the mental
element in their sexual life. For nowhere else have civilization and education done so much
harm as in this field, and this is the point, as experience will show you, at which to look for those
aetiologies of the neuroses that are amenable to influence; for the other aetiological factor, the
constitutional component, consists of something fixed and unalterable. And from this it follows
that one important qualification is required of the physician in this work: not only must his own
character be irreproachable - ‘As to morals, that goes without saying’, as the hero of Vischer’s
novel Auch Einer was in the habit of declaring - but he must also have overcome in his own
mind that mixture of prurience and prudery with which, unfortunately, so many people habitually
consider sexual problems.
[1905a, 1571]
But the series of possibilities grows wider; and psychological drama turns into psychopathological drama when the source of the suffering in which we take part and from which we are meant to derive pleasure is no longer a conflict between two almost equally conscious impulses but between a conscious impulse and a repressed one. Here the precondition of enjoyment is that the spectator should himself be a neurotic, for it is only such people who can derive pleasure instead of simple aversion from the revelation and the more or less conscious recognition of a repressed impulse. In anyone who is not neurotic this recognition will meet only with aversion and will call up a readiness to repeat the act of repression which has earlier been successfully brought to bear on the impulse: for in such people a single expenditure of repression has been enough to hold the repressed impulse completely in check. But in neurotics the repression is on the brink of failing; it is unstable and needs a constant renewal of expenditure, and this expenditure is spared if recognition of the impulse is brought about. Thus it is only in neurotics that a struggle can occur of a kind which can be made the subject of a drama; but even in them the dramatist will provoke not merely an enjoyment of the liberation but a resistance to it as well.

[1942a [1905], 1610]

It is worth while pausing in order to convince oneself from pathological cases how sensitive a human mind becomes in states of repression to any approach by what has been repressed, and how even trivial similarities suffice for the repressed to emerge behind the repressing force and take effect by means of it. I once had under medical treatment a young man - he was still almost a boy - who, after he had first unwillingly become acquainted with the processes of sex, had taken flight from every sexual desire that arose in him. For that purpose he made use of various methods of repression:- he intensified his zeal in learning, exaggerated his dependence on his mother, and in general assumed a childish character. I will not here enter into the manner in which his repressed sexuality broke through once more precisely in his relation to his mother; but I will describe a rarer and stranger instance of how another of his bulwarks collapsed on an occasion which could scarcely be regarded as sufficient. Mathematics enjoys the greatest reputation as a diversion from sexuality. This had been the very advice to which Jean Jacques Rousseau was obliged to listen from a lady who was dissatisfied with him: 'Lascia le donne e studia la matematica!'¹ So too our fugitive threw himself with special eagerness into the mathematics and geometry which he was taught at school, till suddenly one day his powers of comprehension were paralysed in the face of some apparently innocent problems. It was possible to establish two of these problems: 'Two bodies come together, one with a speed of . . . etc.' and 'On a cylinder, the diameter of whose surface is \(m\), describe a cone . . . etc.' Other people would certainly not have regarded these as very striking allusions to sexual events; but he felt that he had been betrayed by mathematics as well, and took flight from it too.

[1907a, 1838]
The procedure which the author makes his Zoe adopt for curing her childhood friend's delusion shows a far-reaching similarity - no, a complete agreement in its essence - with a therapeutic method which was introduced into medical practice in 1895 by Dr. Josef Breuer and myself, and to the perfecting of which I have since then devoted myself. This method of treatment, to which Breuer first gave the name of 'cathartic' but which I prefer to describe as 'analytic', consists, as applied to patients suffering from disorders analogous to Hanold's delusion, in bringing to their consciousness, to some extent forcibly, the unconscious whose repression led to their falling ill - exactly as Gradiva did with the repressed memories of their childhood relations. Gradiva, it is true, could carry out this task more easily than a doctor: in several respects she was in what may be described as an ideal position for it. The doctor, who has no pre-existing knowledge of his patient and possesses no conscious memory of what is unconsciously at work in him, must call a complicated technique to his help in order to make up for this disadvantage. He must learn how to infer with great certainty from the conscious associations and communications of the patient what is repressed in him, how to discover his unconscious as it betrays itself behind his conscious words and acts. He then brings about something like what Norbert Hanold grasped at the end of the story when he translated back the name 'Gradiva' into 'Bertgang'. The disorder vanishes while being traced back to its origin; analysis, too, brings simultaneous cure.
[1907a, 1881]

But the similarity between Gradiva's procedure and the analytic method of psychotherapy is not limited to these two points - the making conscious of what has been repressed and the coinciding of explanation with cure. It also extends to what turns out to be the essence of the whole change - to the awakening of feelings. Every disorder analogous to Hanold's delusion, what in scientific terms we are in the habit of calling 'psychoneuroses', has as its precondition the repression of a portion of instinctual life, or, as we can safely say, of the sexual instinct. At every attempt to introduce the unconscious and repressed causes of the illness into consciousness, the instinctual component concerned is necessarily aroused to a renewed struggle with the repressing powers, only to come to terms with them in the final outcome, often to the accompaniment of violent manifestations of reaction. The process of cure is accomplished in a relapse into love, if we combine all the many components of the sexual instinct under the term 'love'; and such a relapse is indispensable, for the symptoms on account of which the treatment has been undertaken are nothing other than precipitates of earlier struggles connected with repression or the return of the repressed, and they can only be resolved and washed away by a fresh high tide of the same passions. Every psycho-analytic treatment is an attempt at liberating repressed love which has found a meagre outlet in the compromise of a symptom. Indeed, the agreement between such treatments and the process of cure described by the author of *Gradiva* reaches its climax in the further fact that in analytic psychotherapy too the re-awakened passion, whether it is love or hate, invariably chooses as its object the figure of the doctor.
[1907a, 1881]
It will interest you, from the point of view of your own profession, to hear how we doctors proceed in psycho-analysis. After the patient has given us a first account of his history, we ask him to give himself up to the thoughts that occur to him spontaneously and to say without any critical reserve whatever comes into his head. We start, as you see, on the assumption, which he does not share in the least, that these spontaneous thoughts will not be arbitrarily chosen but will be determined by their relation to his secret - to his 'complex' - and may, as it were, be regarded as derivatives of that complex. You will note that this is the same assumption as the one with the help of which you were able to interpret the association experiments. But although we have instructed the patient to follow the rule of communicating all the thoughts that occur to him, he seems to be unable to do so. He soon begins to hold back first one thought and then another. He gives various reasons to account for this: either the thought was quite unimportant, or it was irrelevant or it was totally meaningless. We thereupon demand that he shall tell us the thought in spite of these objections and shall follow it up; for the very fact of his criticism proves to us that the thought belongs to the 'complex' which we are seeking to uncover. We recognize in this behaviour of the patient's a manifestation of the 'resistance' present in him, which we are never free from through the whole duration of the treatment. I will merely indicate briefly that this concept of resistance has acquired the highest importance for us in understanding the origin of an illness as well as the mechanism of its cure.

[1906c, 1893]

In your experiments you do not directly observe criticisms like these of his spontaneous ideas by the subject; while we, on the other hand, are able in our psycho-analyses to observe all the indications of a complex which come to your notice. When the patient no longer ventures to evade the rule which has been laid down for him, we nevertheless note that he stops or hesitates from time to time or pauses in the reproduction of his ideas. Every hesitation of this kind is, as we see it, an expression of his resistance and serves as an indication of a connection with the 'complex'. Indeed, we regard it as the most important sign of such a connection, just as is in your case the analogous prolongation of the \textit{reaction-time}. We are accustomed to interpret hesitation in this sense even when the content of the idea that is being held back does not seem to be at all objectionable and when the patient assures us he cannot imagine why he should hesitate to tell it to us. The pauses which occur in psycho-analysis are as a rule many times longer than the delays that you observe in the reaction experiments.

[1906c, 1893]

If you look more deeply into the comparison between the two situations it will become clear to you in general that psycho-analysis is concerned with a simpler, special, form of the task of uncovering what is hidden in the mind; whereas in your work the task is a more comprehensive one. That the case of the psychoneurotic is invariably concerned with a repressed sexual complex (in the widest sense) is a difference which you need not take into account. But there is something else that you must. The aim of psycho-analysis is absolutely uniform in every case: complexes have to be uncovered which have been repressed because of feelings of unpleasure and which produce signs of resistance if an attempt is made to bring them into consciousness. This resistance is as it were localized; it arises at the frontier between unconscious and conscious. In your cases what is concerned is a resistance which comes entirely from consciousness. You cannot dismiss this difference out of hand. You will first have to determine experimentally whether conscious resistance is betrayed by exactly the same indications as unconscious resistance. Further, you cannot yet be certain, in my opinion, whether you may interpret your objective indications of a complex as a 'resistance', as we psycho-therapists do. It may happen with your experimental subjects - even though not very frequently with criminals - that the complex you touch on is pleasurably toned; and the question then arises whether such a complex will produce the same reaction as a complex that is unpleasurably toned.

[1906c, 1896]
He made this reply without having any sense of guilt as yet. But this was the occasion of his acquiring the 'castration complex', the presence of which we are so often obliged to infer in analysing neurotics, though they one and all struggle violently against recognizing it. There is much of importance to be said upon the significance of this element in the life of a child. The 'castration complex' has left marked traces behind it in myths (and not only in Greek myths); in a passage in my Interpretation of Dreams, and elsewhere, I have touched upon the part it plays.

Therapeutic success, however, is not our primary aim; we endeavour rather to enable the patient to obtain a conscious grasp of his unconscious wishes. And this we can achieve by working upon the basis of the hints he throws out, and so, with the help of our interpretative technique, presenting the unconscious complex to his consciousness in our own words. There will be a certain degree of similarity between that which he hears from us and that which he is looking for, and which, in spite of all resistances, is trying to force its way through to consciousness; and it is this similarity that will enable him to discover the unconscious material. The physician is a step in front of him in knowledge; and the patient follows along his own road, until the two meet at the appointed goal. Beginners in psycho-analysis are apt to assimilate these two events, and to suppose that the moment at which one of the patient's unconscious complexes has become known to them is also the moment at which the patient himself recognizes it. They are expecting too much when they think that they will cure the patient by informing him of this piece of knowledge; for he can do no more with the information than make use of it to help himself in discovering the unconscious complex where it is anchored in his unconscious. A first success of this sort had now been achieved with Hans. Having partly mastered his castration complex, he was now able to communicate his wishes in regard to his mother. He did so, in what was still a distorted form, by means of the phantasy of the two giraffes, one of which was calling out in vain because Hans had taken possession of the other. He represented the 'taking possession' of pictorially as 'sitting down on'. His father recognized the phantasy as a reproduction of a bedroom scene which used to take place in the morning between the boy and his parents; and he quickly stripped the underlying wish of the disguise which it still wore. The boy's father and mother were the two giraffes. The reason for the choice of a giraffe-phantasy for the purposes of disguise was fully explained by a visit that the boy had paid to those same large beasts at Schönbrunn a few days earlier, by the giraffe-drawing, belonging to an earlier period, which had been preserved by his father, and also, perhaps, by an unconscious comparison based upon the giraffe's long, stiff neck. It may be remarked that the giraffe, as being a large animal and interesting on account of its widdler, was a possible competitor with the horse for the role of bugbear; moreover, the fact that both his father and his mother appeared as giraffes offered a hint which had not yet been followed up, as regards the interpretation of the anxiety-horses.

By enlightening Hans on this subject I had cleared away his most powerful resistance against allowing his unconscious thoughts to be made conscious; for his father was himself acting as his physician. The worst of the attack was now over; there was a plentiful flow of material; the little patient summoned up courage to describe the details of his phobia, and soon began to take an active share in the conduct of the analysis.

¹ Even in analyses in which the physician and the patient are strangers, fear of the father plays one of the most important parts as a resistance against the reproduction of the unconscious pathogenic material. Resistances are sometimes in the nature of 'motifs'. But sometimes, as in the present instance, one piece of the unconscious material is capable from its actual content of operating as an inhibition against the reproduction of another piece.
Such is my excuse for having curtailed so drastically the history of this case and its treatment. And I can offer still more cogent reasons for having confined myself to the statement only of some disconnected results of the psycho-analytic investigation of obsessional neuroses. I must confess that I have not yet succeeded in completely penetrating the complicated texture of a severe case of obsessional neurosis, and that, if I were to reproduce the analysis, it would be impossible for me to make the structure, such as by the help of analysis we know or suspect it to be, visible to others through the mass of therapeutic work superimposed upon it. What add so greatly to the difficulty of doing this are the resistances of the patients and the forms in which they are expressed. But even apart from this it must be admitted that an obsessional neurosis is in itself not an easy thing to understand - much less so than a case of hysteria. Actually, indeed, we should have expected to find the contrary. The language of an obsessional neurosis - the means by which it expresses its secret thoughts - is, as it were, only a dialect of the language of hysteria; but it is a dialect in which we ought to be able to find our way about more easily, since it is more nearly related to the forms of expression adopted by our conscious thought than is the language of hysteria. Above all, it does not involve the leap from a mental process to a somatic innervation - hysterical conversion - which can never be fully comprehensible to us.

[1909d, 2128]

Here the patient broke off, got up from the sofa, and begged me to spare him the recital of the details. I assured him that I myself had no taste whatever for cruelty, and certainly had no desire to torment him, but that naturally I could not grant him something which was beyond my power. He might just as well ask me to give him the moon. The overcoming of resistances was a law of the treatment, and on no consideration could it be dispensed with. (I had explained the idea of 'resistance' to him at the beginning of the hour, when he told me there was much in himself which he would have to overcome if he was to relate this experience of his.) I went on to say that I would do all I could, nevertheless, to guess the full meaning of any hints he gave me. Was he perhaps thinking of impalement? - 'No, not that; ... the criminal was tied up ...' - he expressed himself so indistinctly that I could not immediately guess in what position - 'a pot was turned upside down on his buttocks ... some rats were put into it ... and they ...' - he had again got up, and was showing every sign of horror and resistance - '... bored their way in ...' - Into his anus, I helped him out.

[1909d, 2136]

After he had left his friend and returned to his family his doubts had overtaken him afresh. His friend's arguments, he saw, had been no different from his own, and he was under no delusion that his temporary relief was attributable to anything more than his friend's personal influence. His determination to consult a doctor was woven into his delirium in the following ingenious manner. He thought he would get a doctor to give him a certificate to the effect that it was necessary for him, in order to recover his health, to perform some such action as he had planned in connection with Lieutenant A.; and the lieutenant would no doubt let himself be persuaded by the certificate into accepting the 3.80 crowns from him. The chance that one of my books happened to fall into his hands just at that moment directed his choice to me. There was no question of getting a certificate from me, however; all that he asked of me was, very reasonably, to be freed of his obsessions. Many months later, when his resistance was at its height, he once more felt a temptation to travel to P-- after all, to look up Lieutenant A. and to go through the farce of returning him the money.

[1909d, 2141]
At the next session, which was the seventh, he took up the same subject once more. He could not believe, he said, that he had ever entertained such a wish against his father. He remembered a story of Sudermann's, he went on, that had made a deep impression upon him. In this story there was a woman who, as she sat by her sister's sick-bed, felt a wish that her sister should die so that she herself might marry her husband. The woman thereupon committed suicide, thinking she was not fit to live after being guilty of such baseness. He could understand this, he said, and it would be only right if his thoughts were the death of him, for he deserved nothing less.¹ - I remarked that it was well known to us that patients derived a certain satisfaction from their sufferings, so that in reality they all resisted their own recovery to some extent. He must never lose sight of the fact that a treatment like ours proceeded to the accompaniment of a constant resistance; I should be repeatedly reminding him of this fact. [1909d, 2146]

As was to be expected, the patient did not, to begin with, accept my elucidation of the matter. He could not imagine, he said, that the plan of marriage could have had any such effects: it had not made the slightest impression on him at the time. But in the further course of treatment he was forcibly brought to believe in the truth of my suspicion, and in a most singular manner. With the help of a transference phantasy, he experienced, as though it were new and belonged to the present, the very episode from the past which he had forgotten, or which had only passed though his mind unconsciously. There came an obscure and difficult period in the treatment; eventually it turned out that he had once met a young girl on the stairs in my house and had on the spot promoted her into being my daughter. She had pleased him, and he pictured to himself that the only reason I was so kind and incredibly patient with him was that I wanted to have him for a son-in-law. At the same time he raised the wealth and position of my family to a level which agreed with the model he had in mind. But his undying love for his lady fought against the temptation. After we had gone though a series of the severest resistances and bitterest vituperations on his part, he could no longer remain blind to the overwhelming effect of the perfect analogy between the transference phantasy and the actual state of affairs in the past. I will repeat one of the dreams which he had at this period, so as to give an example of his manner of treating the subject. He dreamt that he saw my daughter in front of him; she had two patches of dung instead of eyes. No one who understands the language of dreams will find much difficulty in translating this one: it declared that he was marrying my daughter not for her 'beaux yeux' but for her money. [1909d, 2157]

Our patient was to a high degree superstitious, and this although he was a highly educated and enlightened man of considerable acumen, and although he was able at times to assure me that he did not believe a word of all this rubbish. Thus he was at once superstitious and not superstitious; and there was a clear distinction between his attitude and the superstition of uneducated people who feel themselves at one with their belief. He seemed to understand that his superstition was dependent upon his obsessional thinking, although at times he gave way to it completely. The meaning of this inconsistent and vacillating behaviour can be most easily, grasped if it is regarded in the light of a hypothesis which I shall now proceed to mention. I did not hesitate to assume that the truth was not that the patient still had an open mind upon this subject, but that he had two separate and contradictory convictions upon it. His oscillation between these two views quite obviously depended upon his momentary attitude towards his obsessional disorder. As soon as he had got the better of one of these obsessions, he used to smile in a superior way at his own credulity, and no events then occurred that were calculated to shake his firmness; but the moment he came under the sway of another obsession which had not been cleared up - or, what amounts to the same thing, of a resistance - the strangest coincidences would happen, to support him in his credulous belief. [1909d, 2179]
His superstition was nevertheless that of an educated man, and he avoided such vulgar prejudices as being afraid of Friday or of the number thirteen, and so on. But he believed in premonitions and in prophetic dreams; he would constantly meet the very person of whom, for some inexplicable reason, he had just been thinking; or he would receive a letter from some one who had suddenly come into his mind after being forgotten for many years. At the same time he was honest enough - or rather, he was loyal enough to his official conviction - not to have forgotten instances in which his strangest forebodings had come to nothing. On one occasion, for instance, when he went away for his summer holidays, he had felt morally certain that he would never return to Vienna alive. He also admitted that the great majority of his premonitions related to things which had no special personal importance to him, and that, when he met an acquaintance of whom, until a few moments previously, he had not thought for a very long time, nothing further took place between himself and the miraculous apparition. And he naturally could not deny that all the important events of his life had occurred without his having had any premonition of them, and that, for instance, his father's death had taken him entirely by surprise. But arguments such as these had no effect upon the discrepancy in his convictions. They merely served to prove the obsessional nature of his superstitions, and that could already be inferred from the way in which they came and went with the increase and decrease of his resistance.

[1909d, 2180]

If we wish to obtain a grasp of the psychical forces whose interplay built up this neurosis, we must turn back to what we have learnt from the patient on the subject of the precipitating causes of his falling ill as a grown-up man and as a child. He fell ill when he was in his twenties on being faced with a temptation to marry another woman instead of the one whom he had loved so long; and he avoided a decision of this conflict by postponing all the necessary preliminary actions. The means for doing this was given him by his neurosis. His hesitation between the lady he loved and the other girl can be reduced to a conflict between his father's influence and his love for his lady, or, in other words, to a conflicting choice between his father and his sexual object, such as had already subsisted (judging from his recollections and obsessional ideas) in his remote childhood. All through his life, moreover, he was unmistakably victim to a conflict between love and hatred, in regard both to his lady and to his father. His phantasies of revenge and such obsessional phenomena as his obsession for understanding and his exploit with the stone in the road bore witness to his divided feelings; and they were to a certain degree comprehensible and normal, for the lady by her original refusal and subsequently by her coolness had given him some excuse for hostility. But his relations with his father were dominated by a similar division of feeling, as we have seen from our translation of his obsessional thoughts; and his father, too, must have given him an excuse for hostility in his childhood, as indeed we have been able to establish almost beyond question. His attitude towards the lady - a compound of tenderness and hostility - came to a great extent within the scope of his conscious knowledge; at most he deceived himself over the degree and violence of his negative feelings. But his hostility towards his father, on the contrary, though he had once been acutely conscious of it, had long since vanished from his ken, and it was only in the teeth of the most violent resistance that it could be brought back into his consciousness. We may regard the repression of his infantile hatred of his father as the event which brought his whole subsequent career under the dominion of the neurosis.

[1909d, 2185]
A second observation of Breuer’s, again, compels us to attach great importance, among the characteristics of the pathological chain of events, to states of consciousness. Breuer's patient exhibited, alongside of her normal state, a number of mental peculiarities: conditions of 'absence', confusion, and alterations of character. In her normal state she knew nothing of the pathogenic scenes or their connection with her symptoms; she had forgotten the scenes, or at all events had severed the pathogenic link. When she was put under hypnosis, it was possible, at the expense of a considerable amount of labour, to recall the scenes to her memory; and, through this work of recollecting, the symptoms were removed. The explanation of this fact would be a most awkward business, were it not that the way is pointed by experiences and experiments in hypnotism. The study of hypnotic phenomena has accustomed us to what was at first a bewildering realization that in one and the same individual there can be several mental groupings, which can remain more or less independent of one another, which can 'know nothing' of one another and which can alternate with one another in their hold upon consciousness. Cases of this kind, too, occasionally appear spontaneously, and are then described as examples of 'double conscience'.¹ If, where a splitting of the personality such as this has occurred, consciousness remains attached regularly to one of the two states, we call it the conscious mental state and the other, which is detached from it, the unconscious one. In the familiar condition known as 'post-hypnotic suggestion', a command given under hypnosis is slavishly carried out subsequently in the normal state. This phenomenon affords an admirable example of the influences which the unconscious state can exercise over the conscious one; moreover, it provides a pattern upon which we can account for the phenomena of hysteria. Breuer adopted a hypothesis that hysterical symptoms arise in peculiar mental conditions to which he gave the name of 'hypnoid'. On this view, excitations occurring during these hypnoid states can easily become pathogenic because such states do not provide opportunities for the normal discharge of the process of excitation. There consequently arises from the process of excitation an unusual product - the symptom. This finds its way, like a foreign body, into the normal state, which in turn is in ignorance of the hypnoid pathogenic situation. Wherever there is a symptom there is also an amnesia, a gap in the memory, and filling up this gap implies the removal of the conditions which led to the production of the symptom.

[1910a, 2208]

I did not abandon it, however, before the observations I made during my use of it afforded me decisive evidence. I found confirmation of the fact that the forgotten memories were not lost. They were in the patient's possession and were ready to emerge in association to what was still known by him; but there was some force that prevented them from becoming conscious and compelled them to remain unconscious. The existence of this force could be assumed with certainty, since one became aware of an effort corresponding to it if, in opposition to it, one tried to introduce the unconscious memories into the patient's consciousness. The force which was maintaining the pathological condition became apparent in the form of resistance on the part of the patient.

[1910a, 2212]

It was on this idea of resistance, then, that I based my view of the course of psychical events in hysteria. In order to effect a recovery, it had proved necessary to remove these resistances. Starting out from the mechanism of cure, it now became possible to construct quite definite ideas of the origin of the illness. The same forces which, in the form of resistance, were now offering opposition to the forgotten material's being made conscious, must formerly have brought about the forgetting and must have pushed the pathogenic experiences in question out of consciousness. I gave the name of 'repression' to this hypothetical process, and I considered that it was proved by the undeniable existence of resistance.

[1910a, 2212]
To put the matter more directly. The investigation of hysterical patients and of other neurotics leads us to the conclusion that their repression of the idea to which the intolerable wish is attached has been a failure. It is true that they have driven it out of consciousness and out of memory and have apparently saved themselves a large amount of unpleasure. But the repressed wishful impulse continues to exist in the unconscious. It is on the look-out for an opportunity of being activated, and when that happens it succeeds in sending into consciousness a disguised and unrecognizable substitute for what had been repressed, and to this there soon become attached the same feelings of unpleasure which it was hoped had been saved by the repression. This substitute for the repressed idea - the symptom - is proof against further attacks from the defensive ego; and in place of the short conflict an ailment now appears which is not brought to an end by the passage of time. Alongside the indication of distortion in the symptom, we can trace in it the remains of some kind of indirect resemblance to the idea that was originally repressed. The paths along which the substitution was effected can be traced in the course of the patient's psycho-analytic treatment; and in order to bring about recovery, the symptom must be led back along the same paths and once more turned into the repressed idea. If what was repressed is brought back again into conscious mental activity - a process which presupposes the overcoming of considerable resistances - the resulting psychical conflict, which the patient had tried to avoid, can, under the physician's guidance, reach a better outcome than was offered by repression. There are a number of such opportune solutions, which may bring the conflict and the neurosis to a happy end, and which may in certain instances be combined. The patient's personality may be convinced that it has been wrong in rejecting the pathogenic wish and may be led into accepting it wholly or in part; or the wish itself may be directed to a higher and consequently unobjectionable aim (this is what we call its 'sublimation'); or the rejection of the wish may be recognized as a justifiable one, but the automatic and therefore inefficient mechanism of repression may be replaced by a condemning judgement with the help of the highest human mental functions - conscious control of the wish is attained.

[1910a, 2215]

While I was thus at a loss, I clung to a prejudice the scientific justification for which was proved years later by my friend C. G. Jung and his pupils in Zurich. I am bound to say that it is sometimes most useful to have prejudices. I cherished a high opinion of the strictness with which mental processes are determined, and I found it impossible to believe that an idea produced by a patient while his attention was on the stretch could be an arbitrary one and unrelated to the idea we were in search of. The fact that the two ideas were not identical could be satisfactorily explained from the postulated psychological state of affairs. In the patient under treatment two forces were in operation against each other: on the one hand, his conscious endeavour to bring into consciousness the forgotten idea in his unconscious, and on the other hand, the resistance we already know about, which was striving to prevent what was repressed or its derivatives from thus becoming conscious. If this resistance amounted to little or nothing, what had been forgotten became conscious without distortion. It was accordingly plausible to suppose that the greater the resistance against what we were in search of becoming conscious, the greater would be its distortion. The idea which occurred to the patient in place of what we were in search of had thus itself originated like a symptom: it was a new, artificial and ephemeral substitute for what had been repressed, and was dissimilar to it in proportion to the degree of distortion it had undergone under the influence of the resistance. But, owing to its nature as a symptom, it must nevertheless have a certain similarity to what we were in search of; and if the resistance were not too great, we ought to be able to guess the latter from the former. The idea occurring to the patient must be in the nature of an allusion to the repressed element, like a representation of it in indirect speech.

[1910a, 2217]
When we come to putting this procedure into effect, we are subject to yet another interference. For the patient will often pause and come to a stop, and assert that he can think of nothing to say, and that nothing whatever occurs to his mind. If this were so and if the patient were right, then our procedure would once again have proved ineffective. But closer observation shows that such a stoppage of the flow of ideas never in fact occurs. It appears to happen only because the patient holds back or gets rid of the idea that he has become aware of, under the influence of the resistances which disguise themselves as various critical judgements about the value of the idea that has occurred to him. We can protect ourselves against this by warning him beforehand of this behaviour and requiring him to take no notice of such criticisms. He must, we tell him, entirely renounce any critical selection of this kind and say whatever comes into his head, even if he considers it incorrect or irrelevant or nonsensical, and above all if he finds it disagreeable to let himself think about what has occurred to him. So long as this ordinance is carried out we are certain of obtaining the material which will put us on the track of the repressed complexes.

[1910a, 2219]

You may have formed an impression that the technique through whose armoury I have just conducted you is particularly difficult. In my opinion that technique is entirely in conformity with the material with which it has to deal. But this much at least is clear: it is not a self-evident one and it must be learnt just as the techniques of histology or surgery must be learnt. You will perhaps be surprised to hear that in Europe we have heard a large number of judgements on psycho-analysis from people who know nothing of this technique and do not employ it; and who go on to demand with apparent scorn that we shall prove to them the correctness of our findings. Among these adversaries there are no doubt some to whom a scientific mode of thought is not as a rule alien, who, for instance, would not reject the results of a microscopic examination because it could not be confirmed on the anatomical preparation with the naked eye, but who would first form a judgement on the matter themselves with the help of a microscope. But, where psycho-analysis is concerned, the prospects of recognition are in truth less favourable. Psycho-analysis is seeking to bring to conscious recognition the things in mental life which are repressed; and everyone who forms a judgement on it is himself a human being, who possesses similar repressions and may perhaps be maintaining them with difficulty. They are therefore bound to call up the same resistance in him as in our patients; and that resistance finds it easy to disguise itself is an intellectual rejection and to bring up arguments like those which we ward off in our patients by means of the fundamental rule of psycho-analysis. We often become aware in our opponents, just as we do in our patients, that their power of judgement is very noticeably influenced affectively in the sense of being diminished. The arrogance of consciousness (in rejecting dreams with such contempt, for instance) is one of the most powerful of the devices with which we are provided as a universal protection against the incursion of unconscious complexes. That is why it is so hard to convince people of the reality of the unconscious and to teach them to recognize something new which is in contradiction to their conscious knowledge.

[1910a, 2226]
LADIES AND GENTLEMEN, - With the discovery of infantile sexuality and the tracing back of neurotic symptoms to erotic instinctual components we have arrived at some unexpected formulas concerning the nature and purposes of neurotic illnesses. We see that human beings fall ill when, as a result of external obstacles or of an internal lack of adaptation, the satisfaction of their erotic needs in reality frustrated. We see that they then take flight into illness in order that by its help they may find a satisfaction to take the place of what has been frustrated. We recognize that the pathological symptoms constitute a portion of the subject's sexual activity or even the whole of his sexual life, and we find that the withdrawal from reality is the main purpose of the illness but also the main damage caused by it. We suspect that our patients' resistance to recovery is no simple one, but compounded of several motives. Not only does the patient's ego rebel against giving up the repressions by means of which it has risen above its original disposition, but the sexual instincts are unwilling to renounce their substitutive satisfaction so long as it is uncertain whether reality will offer them anything better.

[1910a, 2234]

(a) Advances in our knowledge. We are, of course, still a long way from knowing all that is required for an understanding of the unconscious in our patients. It is clear that every advance in our knowledge means an increase in our therapeutic power. As long as we have understood nothing, we have accomplished nothing; the more we understand, the more we shall achieve. At its beginning psycho- analytic treatment was inexorable and exhausting. The patient had to say everything himself, and the physician's activity consisted of urging him on incessantly. To-day things have a more friendly air. The treatment is made up of two parts - what the physician infers and tells the patient, and the patient's working-over of what he has heard. The mechanism of our assistance is easy to understand: we give the patient the conscious anticipatory idea and he then finds the repressed unconscious idea in himself on the basis of its similarity to the anticipatory one. This is the intellectual help which makes it easier for him to overcome the resistances between conscious and unconscious. Incidentally, I may remark that it is not the only mechanism made use of in analytic treatment; you all know the far more powerful one which lies in the use of the 'transference'. It is my intention in the near future to deal with these various factors, which are so important for an understanding of the treatment, in an Allgemeine Methodik der Psychoanalyse. And further, in speaking to you I need not rebut the objection that the evidential value in support of the correctness of our hypotheses is obscured in our treatment as we practise it to-day; you will not forget that this evidence is to be found elsewhere, and that a therapeutic procedure cannot be carried out in the same way as a theoretical investigation.

[1910d, 2307]

Now, however, I must once more damp your expectations. Society will not be in a hurry to grant us authority. It is bound to offer us resistance, for we adopt a critical attitude towards it; we point out to it that it itself plays a great part in causing neuroses. Just as we make an individual our enemy by uncovering what is repressed in him, so society cannot respond with sympathy to a relentless exposure of its injurious effects and deficiencies. Because we destroy illusions we are accused of endangering ideals. It might seem, therefore, as though the condition from which I expect such great advantages for our therapeutic prospects will never be fulfilled. And yet the situation is not so hopeless as one might think at the present time. Powerful though men's emotions and self-interest may be, yet intellect is a power too - a power which makes itself felt, not, it is true, immediately, but all the more certainly in the end. The harshest truths are heard and recognized at last, after the interests they have injured and the emotions they have roused have exhausted their fury. It has always been so, and the unwelcome truths which we psycho- analysts have to tell the world will have the same fate. Only it will not happen very quickly; we must be able to wait.

[1910d, 2311]
Only when these conditions have been fulfilled is it possible to recognize and to master the resistances which have led to the repression and the ignorance. Psycho-analytic intervention, therefore, absolutely requires a fairly long period of contact with the patient. Attempts to 'rush' him at first consultation, by brusquely telling him the secrets which have been discovered by the physician, are technically objectionable. And they mostly bring their own punishment by inspiring a hearty enmity towards the physician on the patient's part and cutting him off from having any further influence.

[1910k, 2379]

The question with which I now intend to deal is not that of the technique of dream-interpretation: neither the methods by which dreams should be interpreted nor the use of such interpretations when made will be considered, but only the way in which the analyst should employ the art of interpretation in the psycho-analytic treatment of patients. There are undoubtedly different ways of going to work in the matter, but then the answer to questions of technique in analysis is never a matter of course. Although there may perhaps be more than one good road to follow, still there are very many bad ones, and a comparison of the various methods cannot fail to be illuminating, even if it should not lead to a decision in favour of any particular one.

[1911e, 2450]

It will now be asked whether we shall not be giving up too much valuable material which might throw light on the unconscious if dream-interpretation is only to be carried out subject to such restrictions of method. The answer to this is that the loss is by no means so great as might appear from a superficial view of the matter. To begin with, it must be recognized that in cases of severe neurosis any elaborate dream-productions must from the nature of things be regarded as incapable of complete solution. A dream of this kind is often based on the entire pathogenic material of the case, as yet unknown to both doctor and patient (so called 'programme-dreams' and biographical dreams), and is sometimes equivalent to a translation into dream-language of the whole content of the neurosis. In the attempt to interpret such a dream all the latent, as yet untouched, resistances will be roused to activity and soon set a limit to its understanding. The full interpretation of such a dream will coincide with the completion of the whole analysis; if a note is made of it at the beginning, it may be possible to understand it at the end, many months later. It is the same as with the elucidation of a single symptom (the main symptom, perhaps). The whole analysis is needed to explain it; in the course of the treatment one must endeavour to lay hold first of this, then of that, fragment of the symptom's meaning, one after another, until they can all be pieced together. Similarly, no more can be expected of a dream occurring in the early stages of the analysis; one must be content if the attempt at interpretation brings a single pathogenic wishful impulse to light.

[1911e, 2451]
Our second problem - the problem of why transference appears in psycho-analysis as resistance - has been left for the moment untouched; and we must now approach it more closely. Let us picture the psychological situation during the treatment. An invariable and indispensable precondition of every onset of a psychoneurosis is the process to which Jung has given the appropriate name of 'introversion'.¹ That is to say: the portion of libido which is capable of becoming conscious and is directed towards reality is diminished, and the portion which is directed away from reality and is unconscious, and which, though it may still feed the subject's phantasies, nevertheless belongs to the unconscious, is proportionately increased. The libido (whether wholly or in part) has entered on a regressive course and has revived the subject's infantile imagos.² The analytic treatment now proceeds to follow it; it seeks to track down the libido, to make it accessible to consciousness and, in the end, serviceable for reality. Where the investigations of analysis come upon the libido withdrawn into its hiding-place, a struggle is bound to break out; all the forces which have caused the libido to regress will rise up as 'resistances' against the work of analysis, in order to conserve the new state of things. For if the libido's introversion or regression had not been justified by a particular relation between the subject and the external world - stated in the most general terms, by the frustration of satisfaction - and if it had not for the moment even become expedient, it could never have taken place at all. But the resistances from this source are not the only ones or indeed the most powerful. The libido at the disposal of the subject's personality had always been under the influence of the attraction of his unconscious complexes (or more correctly, of the portions of those complexes belonging to the unconscious), and it entered on a regressive course because the attraction of reality had diminished. In order to liberate it, this attraction of the unconscious has to be overcome; that is, the repression of the unconscious instincts and of their productions, which has meanwhile been set up in the subject, must be removed. This is responsible for by far the largest part of the resistance, which so often causes the illness to persist even after the turning away from reality has lost its temporary justification. The analysis has to struggle against the resistances from both these sources. The resistance accompanies the treatment step by step. Every single association, every act of the person under treatment must reckon with the resistance and represents a compromise between the forces that are striving towards recovery and the opposing ones which I have described.

[1912b, 2459]

If now we follow a pathogenic complex from its representation in the conscious (whether this is an obvious one in the form of a symptom or something quite inconspicuous) to its root in the unconscious, we shall soon enter a region in which the resistance makes itself felt so clearly that the next association must take account of it and appear as a compromise between its demands and those of the work of investigation. It is at this point, on the evidence of our experience, that transference enters on the scene. When anything in the complexive material (in the subject-matter of the complex) is suitable for being transferred on to the figure of the doctor, that transference is carried out; it produces the next association, and announces itself by indications of a resistance - by a stoppage, for instance. We infer from this experience that the transference-idea has penetrated into consciousness in front of any other possible associations because it satisfies the resistance. An event of this sort is repeated on countless occasions in the course of an analysis. Over and over again, when we come near to a pathogenic complex, the portion of that complex which is capable of transference is first pushed forward into consciousness and defended with the greatest obstinacy.¹

[1912b, 2460]
(e) I cannot advise my colleagues too urgently to model themselves during psycho-analytic treatment on the surgeon, who puts aside all his feelings, even his human sympathy, and concentrates his mental forces on the simple aim of performing the operation as skilfully as possible. Under present-day conditions the feeling that is most dangerous to a psycho-analyst is the therapeutic ambition to achieve by this novel and much disputed method something that will produce a convincing effect upon other people. This will not only put him into a state of mind which is unfavourable for his work, but will make him helpless against certain resistances of the patient, whose recovery, as we know, primarily depends on the interplay of forces in him. The justification for requiring this emotional coldness in the analyst is that it creates the most advantageous conditions for both parties: for the doctor a desirable protection for his own emotional life and for the patient the largest amount of help that we can give him to-day. A surgeon of earlier times took as his motto the words: 'Je le pansai, Dieu le guérit.'¹ The analyst should be content with something similar.
[1912e, 2470]

(i) To what extent should the patient's intellectual co-operation be sought for in the treatment? It is difficult to say anything of general applicability on this point: the patient's personality is the determining factor. But in any case caution and self-restraint must be observed in this connection. It is wrong to set a patient tasks, such as collecting his memories or thinking over some particular period of his life. On the contrary, he has to learn above all - what never comes easily to anyone - that mental activities such as thinking something over or concentrating the attention solve none of the riddles of a neurosis; that can only be done by patiently obeying the psycho-analytic rule, which enjoins the exclusion of all criticism of the unconscious or of its derivatives. One must be especially unyielding about obedience to that rule with patients who practise the art of sheering off into intellectual discussion during their treatment, who speculate a great deal and often very wisely about their condition and in that way avoid doing anything to overcome it. For this reason I dislike making use of analytic writings as an assistance to my patients; I require them to learn by personal experience, and I assure them that they will acquire wider and more valuable knowledge than the whole literature of psycho-analysis could teach them. I recognize, however, that under institutional conditions it may be of great advantage to employ reading as a preparation for patients in analysis and as a means of creating an atmosphere of influence.
[1912e, 2474]

Both lay public and doctors - still ready to confuse psycho-analysis with treatment by suggestion - are inclined to attribute great importance to the expectations which the patient brings to the new treatment. They often believe in the case of one patient that he will not give much trouble, because he has great confidence in psycho-analysis and is fully convinced of its truth and efficacy; whereas in the case of another, they think that he will undoubtedly prove more difficult, because he has a sceptical outlook and will not believe anything until he has experienced its successful results on his own person. Actually, however, this attitude on the part of the patient has very little importance. His initial trust or distrust is almost negligible compared with the internal resistances which hold the neurosis firmly in place. It is true that the patient's happy trustfulness makes our earliest relationship with him a very pleasant one; we are grateful to him for that, but we warn him that his favourable prepossession will be shattered by the first difficulty that arises in the analysis. To the sceptic we say that the analysis requires no faith, that he may be as critical and suspicious as he pleases and that we do not regard his attitude as the effect of his judgement at all, for he is not in a position to form a reliable judgement on these matters; his distrust is only a symptom like his other symptoms and it will not be an interference, provided he conscientiously carries out what the rule of the treatment requires of him.
[1913c, 2479]
No one who is familiar with the nature of neurosis will be astonished to hear that even a man who is very well able to carry out an analysis on other people can behave like any other mortal and be capable of producing the most intense resistances as soon as he himself becomes the object of analytic investigation. When this happens we are once again reminded of the dimension of depth in the mind, and it does not surprise us to find that the neurosis has its roots in psychical strata to which an intellectual knowledge of analysis has not penetrated.

The question then arises whether the advantage gained by the patient would not to some extent counterbalance the sacrifice made by the physician. I may venture to form a judgement about this, since for ten years or so I set aside one hour a day, and sometimes two, for gratuitous treatments, because I wanted, in order to find my way about in the neuroses, to work in the face of as little resistance as possible. The advantages I sought by this means were not forthcoming. Free treatment enormously increases some of a neurotic's resistances - in young women, for instance, the temptation which is inherent in their transference-relation, and in young men, their opposition to an obligation to feel grateful, an opposition which arises from their father-complex and which presents one of the most troublesome hindrances to the acceptance of medical help. The absence of the regulating effect offered by the payment of a fee to the doctor makes itself very painfully felt; the whole relationship is removed from the real world, and the patient is deprived of a strong motive for endeavouring to bring the treatment to an end.

¹ Much might be said about our experiences with the fundamental rule of psycho-analysis. One occasionally comes across people who behave as if they had made this rule for themselves. Others offend against it from the very beginning. It is indispensable, and also advantageous, to lay down the rule in the first stages of the treatment. Later, under the dominance of the resistances, obedience to it weakens, and there comes a time in every analysis when the patient disregards it. We must remember from our own self-analysis how irresistible the temptation is to yield to these pretexts put forward by critical judgement for rejecting certain ideas. How small is the effect of such agreements as one makes with the patient in laying down the fundamental rule is regularly demonstrated when something intimate about a third person comes up in his mind for the first time. He knows that he is supposed to say everything, but he turns discretion about other people into a new obstacle! 'Must I really say everything? I thought that only applied to things that concern myself.' It is naturally impossible to carry out analysis if the patient's relations with other people and his thoughts about them are excluded. Pour faire une omelette il faut casser des œufs. An honourable man readily forgets such of the private affairs of strangers as do not seem to him important to know. Nor can an exception be made in the case of names. Otherwise the patient's narratives became a little shadowy, like the scenes in Goethe's play Die natürliche Tochter [The Natural Daughter], and do not lodge in the doctor's memory. Moreover, the names that are withheld screen the approach to all sorts of important connections. But one may perhaps allow names to be left on one side until the patient has become more familiar with the doctor and the procedure of analysis. It is very remarkable how the whole task becomes impossible if a reservation is allowed at any single place. But we have only to reflect what would happen if the right of asylum existed at any one point in a town; how long would it be before all the riff-raff of the town had collected there? I once treated a high official who was bound by his oath of office not to communicate certain things because they were state secrets, and the analysis came to grief as a consequence of this restriction. Psycho-analytic treatment must have no regard for any consideration, because the neurosis and its resistances are themselves without any such regard.

[1913c, 2479]

[1913c, 2485]

³ Much might be said about our experiences with the fundamental rule of psycho-analysis. One occasionally comes across people who behave as if they had made this rule for themselves. Others offend against it from the very beginning. It is indispensable, and also advantageous, to lay down the rule in the first stages of the treatment. Later, under the dominance of the resistances, obedience to it weakens, and there comes a time in every analysis when the patient disregards it. We must remember from our own self-analysis how irresistible the temptation is to yield to these pretexts put forward by critical judgement for rejecting certain ideas. How small is the effect of such agreements as one makes with the patient in laying down the fundamental rule is regularly demonstrated when something intimate about a third person comes up in his mind for the first time. He knows that he is supposed to say everything, but he turns discretion about other people into a new obstacle! 'Must I really say everything? I thought that only applied to things that concern myself.' It is naturally impossible to carry out analysis if the patient's relations with other people and his thoughts about them are excluded. Pour faire une omelette il faut casser des œufs. An honourable man readily forgets such of the private affairs of strangers as do not seem to him important to know. Nor can an exception be made in the case of names. Otherwise the patient's narratives became a little shadowy, like the scenes in Goethe's play Die natürliche Tochter [The Natural Daughter], and do not lodge in the doctor's memory. Moreover, the names that are withheld screen the approach to all sorts of important connections. But one may perhaps allow names to be left on one side until the patient has become more familiar with the doctor and the procedure of analysis. It is very remarkable how the whole task becomes impossible if a reservation is allowed at any single place. But we have only to reflect what would happen if the right of asylum existed at any one point in a town; how long would it be before all the riff-raff of the town had collected there? I once treated a high official who was bound by his oath of office not to communicate certain things because they were state secrets, and the analysis came to grief as a consequence of this restriction. Psycho-analytic treatment must have no regard for any consideration, because the neurosis and its resistances are themselves without any such regard.

[1913c, 2488]
There are patients who from the very first hours carefully prepare what they are going to communicate, ostensibly so as to be sure of making better use of the time devoted to the treatment. What is thus disguising itself as eagerness is resistance. Any preparation of this sort should be disrecommended, for it is only employed to guard against unwelcome thoughts cropping up.¹ However genuinely the patient may believe in his excellent intentions, the resistance will play its part in this deliberate method of preparation and will see to it that the most valuable material escapes communication. One will soon find that the patient devises yet other means by which what is required may be withheld from the treatment. He may talk over the treatment every day with some intimate friend, and bring into this discussion all the thoughts which should come forward in the presence of the doctor. The treatment thus has a leak which lets through precisely what is most valuable. When this happens, the patient must, without much delay, be advised to treat his analysis as a matter between himself and his doctor and to exclude everyone else from sharing in the knowledge of it, no matter how close to him they may be, or how inquisitive. In later stages of the treatment the patient is usually not subjected to temptations of this sort.

[1913c, 2489]

In one particular case the mother of a hysterical girl had confided to me the homosexual experience which had greatly contributed to the fixation of the girl's attacks. The mother had herself surprised the scene; but the patient had completely forgotten it, though it had occurred when she was already approaching puberty. I was now able to make a most instructive observation. Every time I repeated her mother's story to the girl she reacted with a hysterical attack, and after this she forgot the story once more. There is no doubt that the patient was expressing a violent resistance against the knowledge that was being forced upon her. Finally she simulated feeble-mindedness and a complete loss of memory in order to protect herself against what I had told her. After this, there was no choice but to cease attributing to the fact of knowing, in itself, the importance that had previously been given to it and to place the emphasis on the resistances which had in the past brought about the state of not knowing and which were still ready to defend that state. Conscious knowledge, even if it was not subsequently driven out again, was powerless against those resistances.

[1913c, 2493]

What interests us most of all is naturally the relation of this compulsion to repeat to the transference and to resistance. We soon perceive that the transference is itself only a piece of repetition, and that the repetition is a transference of the forgotten past not only on to the doctor but also on to all the other aspects of the current situation. We must be prepared to find, therefore, that the patient yields to the compulsion to repeat, which now replaces the impulsion to remember, not only in his personal attitude to his doctor but also in every other activity and relationship which may occupy his life at the time - if, for instance, he falls in love or undertakes a task or starts an enterprise during the treatment. The part played by resistance, too, is easily recognized. The greater the resistance, the more extensively will acting out (repetition) replace remembering. For the ideal remembering of what has been forgotten which occurs in hypnosis corresponds to a state in which resistance has been put completely on one side. If the patient starts his treatment under the auspices of a mild and unpronounced positive transference it makes it possible at first for him to unearth his memories just as he would under hypnosis, and during this time his pathological symptoms themselves are quiescent. But if, as the analysis proceeds, the transference becomes hostile or unduly intense and therefore in need of repression, remembering at once gives way to acting out. From then onwards the resistances determine the sequence of the material which is to be repeated. The patient brings out of the armoury of the past the weapons with which he defends himself against the progress of the treatment - weapons which we must wrest from him one by one.

[1914g, 2502]
First and foremost, the initiation of the treatment in itself brings about a change in the patient's conscious attitude to his illness. He has usually been content with lamenting it, despising it as nonsensical and under-estimating its importance; for the rest, he has extended to its manifestations the ostrich-like policy of repression which he adopted towards its origins. Thus it can happen that he does not properly know under what conditions his phobia breaks out or does not listen to the precise wording of his obsessional ideas or does not grasp the actual purpose of his obsessional impulse. The treatment, of course, is not helped by this. He must find the courage to direct his attention to the phenomena of his illness. His illness itself must no longer seem to him contemptible, but must become an enemy worthy of his mettle, a piece of his personality, which has solid ground for its existence and out of which things of value for his future life have to be derived. The way is thus paved from the beginning for a reconciliation with the repressed material which is coming to expression in his symptoms, while at the same time place is found for a certain tolerance for the state of being ill. If this new attitude towards the illness intensifies the conflicts and brings to the fore symptoms which till then had been indistinct, one can easily console the patient by pointing out that these are only necessary and temporary aggravations and that one cannot overcome an enemy who is absent or not within range. The resistance, however, may exploit the situation for its own ends and abuse the licence to be ill. It seems to say: ‘See what happens if I really give way to such things. Was I not right to consign them to repression?’ Young and childish people in particular are inclined to make the necessity imposed by the treatment for paying attention to their illness a welcome excuse for luxuriating in their symptoms.

Now we do not know whether these two modes of psychical activity are identical or essentially divergent from their beginning, but we may ask why they should become different in the course of psychical action. To this last question psycho-analysis gives a clear and unhesitating answer. It is by no means impossible for the product of unconscious activity to pierce into consciousness, but a certain amount of exertion is needed for this task. When we try to do it in ourselves, we become aware of a distinct feeling of repulsion¹ which must be overcome, and when we produce it in a patient we get the most unquestionable signs of what we call his resistance to it. So we learn that the unconscious idea is excluded from consciousness by living forces which oppose themselves to its reception, while they do not object to other ideas, the foreconscious ones. Psycho-analysis leaves no room for doubt that the repulsion from unconscious ideas is only provoked by the tendencies embodied in their contents. The next and most probable theory which can be formulated at this stage of our knowledge is the following. Unconsciousness is a regular and inevitable phase in the processes constituting our psychical activity; every psychical act begins as an unconscious one, and it may either remain so or go on developing into consciousness, according as it meets with resistance or not. The distinction between foreconscious and unconscious activity is not a primary one, but comes to be established after repulsion has sprung up. Only then the difference between foreconscious ideas, which can appear in consciousness and reappear at any moment, and unconscious ideas which cannot do so gains a theoretical as well as a practical value. A rough but not inadequate analogy to this supposed relation of conscious to unconscious activity might be drawn from the field of ordinary photography. The first stage of the photograph is the 'negative'; every photographic picture has to pass through the 'negative process', and some of these negatives which have held good in examination are admitted to the 'positive process' ending in the picture.

[1912g, 2581]
There is another kind of fausse reconnaissance which not infrequently makes its appearance at the close of a treatment, much to the physician's satisfaction. After he has succeeded in forcing the repressed event (whether it was of a real or of a psychical nature) upon the patient's acceptance in the teeth of all resistances, and has succeeded, as it were, in rehabilitating it - the patient may say: 'Now I feel as though I had known it all the time.' With this the work of the analysis has been completed.
[1914a, 2842]

Among the other new factors which were added to the cathartic procedure as a result of my work and which transformed it into psycho-analysis, I may mention in particular the theory of repression and resistance, the recognition of infantile sexuality, and the interpreting and exploiting of dreams as a source of knowledge of the unconscious.
[1914d, 2884]

The theory of repression is the corner-stone on which the whole structure of psycho-analysis rests. It is the most essential part of it; and yet it is nothing but a theoretical formulation of a phenomenon which may be observed as often as one pleases if one undertakes an analysis of a neurotic without resorting to hypnosis. In such cases one comes across a resistance which opposes the work of analysis and in order to frustrate it pleads a failure of memory. The use of hypnosis was bound to hide this resistance; the history of psycho-analysis proper, therefore, only begins with the new technique that dispenses with hypnosis. The theoretical consideration of the fact that this resistance coincides with an amnesia leads inevitably to the view of unconscious mental activity which is peculiar to psycho-analysis and which, too, distinguishes it quite clearly from philosophical speculations about the unconscious. It may thus be said that the theory of psycho-analysis is an attempt to account for two striking and unexpected facts of observation which emerge whenever an attempt is made to trace the symptoms of a neurotic back to their sources in his past life: the facts of transference and of resistance. Any line of investigation which recognizes these two facts and takes them as the starting-point of its work has a right to call itself psycho-analysis, even though it arrives at results other than my own. But anyone who takes up other sides of the problem while avoiding these two hypotheses will hardly escape a charge of misappropriation of property by attempted impersonation, if he persists in calling himself a psycho-analyst.
[1914d, 2885]
Whatever personal sensitiveness I possessed became blunted during those years, to my advantage. I was saved from becoming embittered, however, by a circumstance which is not always present to help lonely discoverers. Such people are as a rule tormented by the need to account for the lack of sympathy or the aversion of their contemporaries, and feel this attitude as a distressing contradiction of the security of their own sense of conviction. There was no need for me to feel so; for psycho-analytic theory enabled me to understand this attitude in my contemporaries and to see it as a necessary consequence of fundamental analytic premisses. If it was true that the set of facts I had discovered were kept from the knowledge of patients themselves by internal resistances of an affective kind, then these resistances would be bound to appear in healthy people too, as soon as some external source confronted them with what was repressed. It was not surprising that they should be able to justify this rejection of my ideas on intellectual grounds though it was actually affective in origin. The same thing happened equally often with patients; the arguments they advanced were the same and were not precisely brilliant. In Falstaff's words, reasons are 'as plenty as blackberries'. The only difference was that with patients one was in a position to bring pressure to bear on them so as to induce them to get insight into their resistances and overcome them, whereas one had to do without this advantage in dealing with people who were ostensibly healthy. How to compel these healthy people to examine the matter in a cool and scientifically objective spirit was an unsolved problem which was best left to time to clear up. In the history of science one can clearly see that often the very proposition which has at first called out nothing but contradiction has later come to be accepted, although no new proofs in support of it have been brought forward.

[1914d, 2891]

I must now mention two secessions which have taken place among the adherents of psycho-analysis; the first occurred between the founding of the Association in 1910 and the Weimar Congress in 1911; the second took place after this and became manifest at Munich in 1913. The disappointment that they caused me might have been averted if I had paid more attention to the reactions of patients under analytic treatment. I knew very well of course that anyone may take to flight at his first approach to the unwelcome truths of analysis; I had always myself maintained that everyone's understanding of it is limited by his own repressions (or rather, by the resistances which sustain them) so that he cannot go beyond a particular point in his relation to analysis. But I had not expected that anyone who had reached a certain depth in his understanding of analysis could renounce that understanding and lose it. And yet daily experience with patients had shown that total rejection of analytic knowledge may result whenever a specially strong resistance arises at any depth in the mind; one may have succeeded in laboriously bringing a patient to grasp some parts of analytic knowledge and to handle them like possessions of his own, and yet one may see him, under the domination of the very next resistance, throw all he has learnt to the winds and stand on the defensive as he did in the days when he was a carefree beginner. I had to learn that the very same thing can happen with psycho-analysts as with patients in analysis.

[1914d, 2911]
The first task confronting psycho-analysis was to explain the neuroses; it used the two facts of resistance and transference as starting-points, and, taking into consideration the third fact of amnesia, accounted for them with its theories of repression, of the sexual motive forces in neurosis and of the unconscious. Psycho-analysis has never claimed to provide a complete theory of human mentality in general, but only expected that what it offered should be applied to supplement and correct the knowledge acquired by other means. Adler's theory, however, goes far beyond this point; it seeks at one stroke to explain the behaviour and character of human beings as well as their neurotic and psychotic illnesses. It is actually more suited to any other field than that of neurosis, although for reasons connected with the history of its development it still places this in the foreground. For many years I had opportunities of studying Dr. Adler and have never refused to recognize his unusual ability, combined with a particularly speculative disposition. As an instance of the 'persecution' to which he asserts he has been subjected by me, I can point to the fact that after the Association was founded I made over to him the leadership of the Vienna group. It was not until urgent demands were put forward by all the members of the society that I let myself be persuaded to take the chair again at its scientific meetings. When I perceived how little gift Adler had precisely for judging unconscious material, my view changed to an expectation that he would succeed in discovering the connections of psycho-analysis with psychology and with the biological foundations of instinctual processes - an expectation which was in some sense justified by the valuable work he had done on 'organ-inferiority'. And he did in fact effect something of the kind; but his work conveys an impression 'as if' - to speak in his own 'jargon' - it was intended to prove that psycho-analysis was wrong in everything and that it had only attributed so much importance to sexual motive forces because of its credulity in accepting the assertions of neurotics. I may even speak publicly of the personal motive for his work, since he himself announced it in the presence of a small circle of members of the Vienna group: - 'Do you think it gives me such great pleasure to stand in your shadow my whole life long?' To be sure, I see nothing reprehensible in a younger man freely admitting his ambition, which one would in any case guess was among the incentives for his work. But even though a man is dominated by a motive of this kind he should know how to avoid being what the English, with their fine social tact, call 'unfair' - which in German can only be expressed by a much cruder word. How little Adler has succeeded in this is shown by the profusion of petty outbursts of malice which disfigure his writings and by the indications they contain of an uncontrolled craving for priority. At the Vienna Psycho-Analytical Society we once actually heard him claim priority for the conception of the 'unity of the neuroses' and for the 'dynamic view' of them. This came as a great surprise to me, for I had always believed that these two principles were stated by me before I ever made Adler's acquaintance.
[1914d, 2913]
Everything that Adler has to say about dreams, the shibboleth of psycho-analysis, is equally empty and unmeaning. At first he regarded dreams as a turning away from the feminine to the masculine line - which is simply a translation of the wish-fulfilment theory of dreams into the language of the 'masculine protest'. Later he found that the essence of dreams lies in enabling men to accomplish unconsciously what they are denied consciously. Adler must also be credited with priority in confusing dreams with latent dream-thoughts - a confusion on which the discovery of his 'prospective tendency' rests. Maeder followed his lead in this later. Here the fact is readily overlooked that every interpretation of a dream which is incomprehensible in its manifest form is based on the very method of dream-interpretation whose premisses and conclusions are being disputed. In regard to resistance Adler informs us that it serves the purpose of putting into effect the patient's opposition to the physician. This is certainly true; it is as much as to say that it serves the purpose of resistance. Where it comes from, however, or how it happens that its phenomena are at the disposal of the patient is not further enquired into, as being of no interest to the ego. The detailed mechanism of the symptoms and manifestations of diseases, the explanation of the manifold variety of those diseases and their forms of expression, are disregarded in toto; for everything alike is pressed into the service of the masculine protest, self-assertion and the aggrandizement of the personality. The system is complete; to produce it has cost an enormous amount of labour in the recasting of interpretations, while it has not furnished a single new observation. I fancy I have made it clear that it has nothing to do with psycho-analysis.

[1914d, 2920]

The view that the sexual representation of 'higher' thoughts in dreams and neurosis is nothing but an archaic mode of expression is of course irreconcilable with the fact that in neurosis these sexual complexes prove to be the bearers of the quantities of libido which have been withdrawn from utilization in real life. If it was merely a question of a sexual 'jargon', the economy of the libido could not have been altered in any way by it. Jung admits this himself in his *Darstellung der psychoanalytischen Theorie* and formulates the task of therapy as the detaching of libidinal cathexes from these complexes. This can never be achieved, however, by directing the patient away from them and urging him to sublimate, but only by exhaustive examination of them and by making them fully and completely conscious. The first piece of reality which the patient must deal with is his illness. Efforts to spare him that task point to the physician's incapacity to help him to overcome his resistances, or else to the physician's dread of the results of the work.

[1914d, 2927]

How are we to arrive at a knowledge of the unconscious? It is of course only as something conscious that we know it, after it has undergone transformation or translation into something conscious. Psycho-analytic work shows us every day that translation of this kind is possible. In order that this should come about, the person under analysis must overcome certain resistances - the same resistances as those which, earlier, made the material concerned into something repressed by rejecting it from the conscious.

[1915e, 2991]
There is, however, another symptom in our fellow-citizens of the world which has perhaps astonished and shocked us no less than the descent from their ethical heights which has given us so much pain. What I have in mind is the want of insight shown by the best intellects, their obduracy, their inaccessibility to the most forcible arguments and their uncritical credulity towards the most disputable assertions. This indeed presents a lamentable picture, and I wish to say emphatically that in this I am by no means a blind partisan who finds all the intellectual shortcomings on one side. But this phenomenon is much easier to account for and much less disquieting than the one we have just considered. Students of human nature and philosophers have long taught us that we are mistaken in regarding our intelligence as an independent force and in overlooking its dependence on emotional life. Our intellect, they teach us, can function reliably only when it is removed from the influences of strong emotional impulses; otherwise it behaves merely as an instrument of the will and delivers the inference which the will requires. Thus, in their view, logical arguments are impotent against affective interests, and that is why disputes backed by reasons, which in Falstaff's phrase are 'as plenty as blackberries', are so unfruitful in the world of interests. Psycho-analytic experience has, if possible, further confirmed this statement. It can show every day that the shrewdest people will all of a sudden behave without insight, like imbeciles, as soon as the necessary insight is confronted by an emotional resistance, but that they will completely regain their understanding once that resistance has been overcome. The logical bedazzlement which this war has conjured up in our fellow-citizens, many of them the best of their kind, is therefore a secondary phenomenon, a consequence of emotional excitement, and is bound, we may hope, to disappear with it.

[1915b, 3079]

When a doctor carries out the psycho-analytic treatment of a neurotic, his interest is by no means directed in the first instance to the patient's character. He would much rather know what the symptoms mean, what instinctual impulses are concealed behind them and are satisfied by them, and what course was followed by the mysterious path that has led from the instinctual wishes to the symptoms. But the technique which he is obliged to follow soon compels him to direct his immediate curiosity towards other objectives. He observes that his investigation is threatened by resistances set up against him by the patient, and these resistances he may justly count as part of the latter's character. This now acquires the first claim on his interest.

[1916d, 3100]

What opposes the doctor's efforts is not always those traits of character which the patient recognizes in himself and which are attributed to him by people round him. Peculiarities in him which he had seemed to possess only to a modest degree are often brought to light in surprisingly increased intensity, or attitudes reveal themselves in him which had not been betrayed in other relations of life. The pages which follow will be devoted to describing and tracing back a few of these surprising traits of character.

[1916d, 3100]
For that is in fact the case. You will recall that when we began to make use of our technique of free association we made a surprising discovery. We became aware that our efforts at proceeding from the dream-element to the unconscious element for which it is a substitute were being met by a resistance. This resistance, we said, could be of different magnitudes, sometimes enormous and sometimes quite insignificant. In the latter case we need to pass through only a small number of intermediate links in our work of interpretation; but when the resistance is large we have to traverse long chains of associations from the dream-element, we are led far away from it and on our path we have to overcome all the difficulties which represent themselves as critical objections to the ideas that occur. What we met with as resistance in our work of interpretation must now be introduced into the dream-work in the form of the dream-censorship. The resistance to interpretation is only a putting into effect of the dream-censorship. It also proves to us that the force of the censorship is not exhausted in bringing about the distortion of dreams and thereafter extinguished, but that the censorship persists as a permanent institution which has as its aim the maintenance of the distortion. Moreover, just as the strength of the resistance varies in the interpretation of each element in a dream, so too the magnitude of the distortion introduced by the censorship varies for each element in the same dream. If we compare the manifest and the latent dream, we shall find that some particular latent elements have been completely eliminated, others modified to a greater or less extent, while yet others have been carried over into the manifest content of the dream unaltered or even perhaps strengthened.

[1916-1917, 3236]

Yes, indeed! Both simpler and more satisfactory - but not necessarily on that account more correct. Let us give ourselves time: the matter is not yet ripe for judgement. And first we can further strengthen the criticism of our dream-interpretations. The fact that the findings from them are so disagreeable and repellent need not, perhaps, carry very great weight. A stronger argument is that the dreamers to whom we are led to attribute such wishful purposes by the interpretation of their dreams reject them most emphatically and for good reasons. 'What?' says one of them, 'you want to convince me from this dream that I regret the money I have spent on my sister's dowry and my brother's education? But that cannot be so. I work entirely for my brothers and sisters; I have no other interest in life but to fulfil my duties to them, which, as the eldest of the family, I promised our departed mother I would do.' Or a woman dreamer would say: 'You think I wish my husband was dead? That is a shocking piece of nonsense! It is not only that we are most happily married - you would probably not believe me if I said that - but his death would rob me of everything I possess in the world.' Or another man would answer us: 'You say that I have sensual desires for my sister? That is ridiculous! She means nothing at all to me. We are on bad terms with each other and I have not exchanged a word with her for years.' We might still take it lightly, perhaps, if these dreamers neither confirmed nor denied the purposes we attribute to them; we might say that these were just things they did not know about themselves. But when they feel in themselves the precise contrary of the wish we have interpreted to them and when they are able to prove to us by the lives they lead that they are dominated by this contrary wish, it must surely take us aback. Has not the time come to throw aside the whole work we have done on dream-interpretation as something which its findings have reduced ad absurdum?

[1916-1917, 3239]
But can psycho-analysis do more here? Yes, it actually can. I hope to be able to show you that, even in a case so hard of access as this, it can discover something which makes a first understanding possible. And to begin with I would draw your attention to the inconspicuous detail that the patient herself positively provoked the anonymous letter, which now gave support to her delusion, by informing the scheming housemaid on the previous day that it would cause her the greatest unhappiness if her husband had a love affair with a young girl. In this way she first put the notion of sending the anonymous Letter into the housemaid's head. Thus the delusion acquires a certain independence of the letter; it had been present already in the patient as a fear - or was it as a wish? Let us now add to this the small further indications yielded by only two analytic sessions. The patient, indeed, behaved in a very unco-operative way when, after telling me her story, she was asked for her further thoughts, ideas and memories. She said that nothing occurred to her, that she had told me everything already, and after two sessions the experiment with me had in fact to be broken off because she announced that she already felt well and that she was sure the pathological idea would not come back. She only said this, of course, from resistance and from dread of the continuation of the analysis. Nevertheless, during these two sessions she let fall a few remarks which allowed of, and indeed necessitated, a particular interpretation; and this interpretation threw a clear light on the genesis of her delusion of jealousy. She herself was intensely in love with a young man, with the same son-in-law who had persuaded her to come to me as a patient. She herself knew nothing, or perhaps only a very little, of this love; in the family relationship that existed between them it was easy for this passionate liking to disguise itself as innocent affection. After all our experiences elsewhere, it is not hard for us to feel our way into the mental life of this upright wife and worthy mother, of the age of fifty-three. Being in love like this, a monstrous and impossible thing, could not become conscious; but it remained in existence and, even though it was unconscious, it exercised a severe pressure. Something had to become of it, some relief had to be looked for; and the easiest mitigation was offered, no doubt, by the mechanism of displacement which plays a part so regularly in the generating of delusional jealousy. If not only were she, the old woman, in love with a young man, but if also her old husband were having a love affair with a young girl, then her conscience would be relieved of the weight of her unfaithfulness. The phantasy of her husband's unfaithfulness thus acted as a cooling compress on her burning wound. Her own love had not become conscious to her, but its mirror-reflection, which brought her such an advantage, now became conscious as an obsession and delusion. No arguments against it could, of course, have any effect, for they were only directed against the mirror-image and not against the original which gave the other its strength and which lay hidden, inviolable, in the unconscious.

[1916-1917, 3334]

If only that was how things happened! We came upon discoveries in this connection for which we were at first unprepared. Knowledge is not always the same as knowledge: there are different sorts of knowledge, which are far from equivalent psychologically. 'Il y a fagots et fagots', as Molière has said. The doctor's knowledge is not the same as the patient's and cannot produce the same effects. If the doctor transfers his knowledge to the patient as a piece of information, it has no result. No, it would be wrong to say that. It does not have the result of removing the symptoms, but it has another one - of setting the analysis in motion, of which the first signs are often expressions of denial. The patient knows after this what he did not know before - the sense of his symptom; yet he knows it just as little as he did. Thus we learn that there is more than one kind of ignorance. We shall need to have a somewhat deeper understanding of psychology to show us in what these differences consist. But our thesis that the symptoms vanish when their sense is known remains true in spite of this. All we have to add is that the knowledge must rest on an internal change in the patient such as can only be brought about by a piece of psychical work with a particular aim. We are faced here by problems which will presently be brought together into the dynamics of the construction of symptoms.

[1916-1917, 3358]
How do we remove the resistance? In the same way: by discovering it and showing it to the patient. Indeed, the resistance too is derived from a repression - from the same one that we are endeavouring to resolve, or from one that took place earlier. It was set up by the anticathexis which arose in order to repress the objectionable impulse. Thus we now do the same thing that we tried to do to begin with: interpret, discover and communicate; but now we are doing it at the right place. The anticathexis or the resistance does not form part of the unconscious but of the ego, which is our collaborator, and is so even if it is not conscious. As we know, the word 'unconscious' is being used here in two senses: on the one hand as a phenomenon and on the other as a system. This sounds very difficult and obscure; but is it not only repeating what we have already said in earlier passages? We have long been prepared for it. We expect that this resistance will be given up and the anticathexis withdrawn when our interpretation has made it possible for the ego to recognize it. What are the motive forces that we work with in such a case? First with the patient's desire for recovery, which has induced him to take part with us in our joint work, and secondly with the help of his intelligence, to which we give support by our interpretation. There is no doubt that it is easier for the patient's intelligence to recognize the resistance and to find the translation corresponding to what is repressed if we have previously given him the appropriate anticipatory ideas. If I say to you: 'Look up at the sky! There's a balloon there!' you will discover it much more easily than if I simply tell you to look up and see if you can see anything. In the same way, a student who is looking through a microscope for the first time is instructed by his teacher as to what he will see; otherwise he does not see it at all, though it is there and visible.

[1916-1917, 3479]

In order to make it easier to understand this 'compulsion to repeat', which emerges during the psycho-analytic treatment of neurotics, we must above all get rid of the mistaken notion that what we are dealing with in our struggle against resistances is resistance on the part of the unconscious. The unconscious - that is to say, the 'repressed' - offers no resistance whatever to the efforts of the treatment. Indeed, it itself has no other endeavour than to break through the pressure weighing down on it and force its way either to consciousness or to a discharge through some real action. Resistance during treatment arises from the same higher strata and systems of the mind which originally carried out repression. But the fact that, as we know from experience, the motives of the resistances, and indeed the resistances themselves, are unconscious at first during the treatment, is a hint to us that we should correct a shortcoming in our terminology. We shall avoid a lack of clarity if we make our contrast not between the conscious and the unconscious but between the coherent ego and the repressed. It is certain that much of the ego is itself unconscious, and notably what we may describe as its nucleus; only a small part of it is covered by the term 'preconscious'. Having replaced a purely descriptive terminology by one which is systematic or dynamic, we can say that the patient's resistance arises from his ego, and we then at once perceive that the compulsion to repeat must be ascribed to the unconscious repressed. It seems probable that the compulsion can only express itself after the work of treatment has gone half-way to meet it and has loosened the repression.¹

[1920g, 3724]
The Theory of Repression. - These theoretical considerations, taken together with the immediate impressions derived from analytic work, lead to a view of the neuroses which may be described in the roughest outline as follows. The neuroses are the expression of conflicts between the ego and such of the sexual impulses as seem to the ego incompatible with its integrity or with its ethical standards. Since these impulses are not ego-syntonic, the ego has repressed them: that is to say, it has withdrawn its interest from them and has shut them off from becoming conscious as well as from obtaining satisfaction by motor discharge. If in the course of analytic work one attempts to make these repressed impulses conscious, one becomes aware of the repressive forces in the form of resistance. But the achievement of repression fails particularly readily in the case of the sexual instincts. Their dammed-up libido finds other ways out from the unconscious: for it regresses to earlier phases of development and earlier attitudes towards objects, and, at weak points in the libidinal development where there are infantile fixations, it breaks through into consciousness and obtains discharge. What results is a symptom and consequently in its essence a substitutive sexual satisfaction. Nevertheless the symptom cannot entirely escape from the repressive forces of the ego and must therefore submit to modifications and displacements exactly as happens with dreams - by means of which its characteristic of being a sexual satisfaction becomes unrecognizable. Consequently symptoms are in the nature of compromises between the repressed sexual instincts and the repressing ego-instances; they represent a wish-fulfilment for both partners to the conflict simultaneously, but one which is incomplete for each of them. This is quite strictly true of the symptoms of hysteria, while in the symptoms of obsessional neurosis there is often a stronger emphasis upon the side of the repressing function owing to the erection of reaction-formations, which are assurances against sexual satisfaction.

[1923a, 3923]

But we have arrived at the term or concept of the unconscious along another path, by considering certain experiences in which mental dynamics play a part. We have found - that is, we have been obliged to assume - that very powerful mental processes or ideas exist (and here a quantitative or economic factor comes into question for the first time) which can produce all the effects in mental life that ordinary ideas do (including effects that can in their turn become conscious as ideas), though they themselves do not become conscious. It is unnecessary to repeat in detail here what has been explained so often before. It is enough to say that at this point psycho-analytic theory steps in and asserts that the reason why such ideas cannot become conscious is that a certain force opposes them, that otherwise they could become conscious, and that it would then be apparent how little they differ from other elements which are admittedly psychical. The fact that in the technique of psycho-analysis a means has been found by which the opposing force can be removed and the ideas in question made conscious renders this theory irrefutable. The state in which the ideas existed before being made conscious is called by us repression, and we assert that the force which instituted the repression and maintains it is perceived as resistance during the work of analysis. [1923b, 3948]
In the further course of psycho-analytic work, however, even these distinctions have proved to be inadequate and, for practical purposes, insufficient. This has become clear in more ways than one; but the decisive instance is as follows. We have formed the idea that in each individual there is a coherent organization of mental processes; and we call this his ego. It is to this ego that consciousness is attached; the ego controls the approaches to motility - that is, to the discharge of excitations into the external world; it is the mental agency which supervises all its own constituent processes, and which goes to sleep at night, though even then it exercises the censorship on dreams. From this ego proceed the repressions, too, by means of which it is sought to exclude certain trends in the mind not merely from consciousness but also from other forms of effectiveness and activity. In analysis these trends which have been shut out stand in opposition to the ego, and the analysis is faced with the task of removing the resistances which the ego displays against concerning itself with the repressed. Now we find during analysis that, when we put certain tasks before the patient, he gets into difficulties; his associations fail when they should be coming near the repressed. We then tell him that he is dominated by a resistance; but he is quite unaware of the fact, and, even if he guesses from his unpleasurable feelings that a resistance is now at work in him, he does not know what it is or how to describe it. Since, however, there can be no question but that this resistance emanates from his ego and belongs to it, we find ourselves in an unforeseen situation. We have come upon something in the ego itself which is also unconscious, which behaves exactly like the repressed - that is, which produces powerful effects without itself being conscious and which requires special work before it can be made conscious. From the point of view of analytic practice, the consequence of this discovery is that we land in endless obscurities and difficulties if we keep to our habitual forms of expression and try, for instance, to derive neuroses from a conflict between the conscious and the unconscious. We shall have to substitute for this antithesis another, taken from our insight into the structural conditions of the mind - the antithesis between the coherent ego and the repressed which is split off from it.¹

[1923b, 3951]

It looked as though our work had been made much more difficult and complicated; but the inestimable gain was that an insight was now obtained into an interplay of forces which had been concealed from the observer by the hypnotic state. It became evident that the work of uncovering what had been pathogenically forgotten had to struggle against a constant and very intense resistance. The critical objections which the patient raised in order to avoid communicating the ideas which occurred to him, and against which the fundamental rule of psycho-analysis was directed, had themselves already been manifestations of this resistance. A consideration of the phenomena of resistance led to one of the corner-stones of the psycho-analytic theory of the neuroses - the theory of repression. It was plausible to suppose that the same forces which were now struggling against the pathogenic material being made conscious had at an earlier time made the same efforts with success. A gap in the aetiology of neurotic symptoms was thus filled. The impressions and mental impulses, for which the symptoms were now serving as substitutes, had not been forgotten without reason or on account of a constitutional incapacity for synthesis (as Janet supposed); they had, though the influence of other mental forces, met with a repression the success and evidence of which was precisely their being debarred from consciousness and excluded from memory. It was only in consequence of this repression that they had become pathogenic - that is, had succeeded in manifesting themselves along unusual paths as symptoms.

[1924f, 4106]
How had it come about that the patients had forgotten so many of the facts of their external and internal lives but could nevertheless recollect them if a particular technique was applied? Observation supplied an exhaustive answer to these questions. Everything that had been forgotten had in some way or other been distressing; it had been either alarming or painful or shameful by the standards of the subject's personality. It was impossible not to conclude that that was precisely why it had been forgotten - that is, why it had not remained conscious. In order to make it conscious again in spite of this, it was necessary to overcome something that fought against one in the patient; it was necessary to make efforts on one's own part so as to urge and compel him to remember. The amount of effort required of the physician varied in different cases; it increased in direct proportion to the difficulty of what had to be remembered. The expenditure of force on the part of the physician was evidently the measure of a resistance on the part of the patient. It was only necessary to translate into words what I myself had observed, and I was in possession of the theory of repression.

[1925d, 4206]

It may seem surprising that this method of free association, carried out subject to the observation of the fundamental rule of psycho-analysis, should have achieved what was expected of it, namely the bringing into consciousness of the repressed material which was held back by resistances. We must, however, bear in mind that free association is not really free. The patient remains under the influence of the analytic situation even though he is not directing his mental activities on to a particular subject. We shall be justified in assuming that nothing will occur to him that has not some reference to that situation. His resistance against reproducing the repressed material will now be expressed in two ways. Firstly it will be shown by critical objections; and it was to deal with these that the fundamental rule of psycho-analysis was invented. But if the patient observes that rule and so overcomes his reticences, the resistance will find another means of expression. It will so arrange it that the repressed material itself will never occur to the patient but only something which approximates to it in an allusive way; and the greater the resistance, the more remote from the actual idea that the analyst is in search of will be the substitutive association which the patient has to report. The analyst, who listens composedly but without any constrained effort to the stream of associations and who, from his experience, has a general notion of what to expect, can make use of the material brought to light by the patient according to two possibilities. If the resistance is slight he will be able from the patient's allusions to infer the unconscious material itself; or if the resistance is stronger he will be able to recognize its character from the associations, as they seem to become more remote from the topic in hand, and will explain it to the patient. Uncovering the resistance, however, is the first step towards overcoming it. Thus the work of analysis involves an art of interpretation, the successful handling of which may require tact and practice but which is not hard to acquire. But it is not only in the saving of labour that the method of free association has an advantage over the earlier method. It exposes the patient to the least possible amount of compulsion, it never allows of contact being lost with the actual current situation, it guarantees to a great extent that no factor in the structure of the neurosis will be overlooked and that nothing will be introduced into it by the expectations of the analyst. It is left to the patient in all essentials to determine the course of the analysis and the arrangement of the material; any systematic handling of particular symptoms or complexes thus becomes impossible. In complete contrast to what happened with hypnotism and with the urging method, interrelated material makes its appearance at different times and at different points in the treatment. To a spectator, therefore - though in fact there must be none - an analytic treatment would seem completely obscure.

[1925d, 4216]
It must not be supposed that these emendations provide us with a complete survey of all the kinds of resistance that are met with in analysis. Further investigation of the subject shows that the analyst has to combat no less than five kinds of resistance, emanating from three directions - the ego, the id and the super-ego. The ego is the source of three of these, each differing in its dynamic nature. The first of these three ego-resistances is the *repression* resistance, which we have already discussed above and about which there is least new to be added. Next there is the *transference* resistance, which is of the same nature but which has different and much clearer effects in analysis, since it succeeds in establishing a relation to the analytic situation or the analyst himself and thus re-animating a repression which should only have been recollected. The third resistance, though also an ego-resistance, is of quite a different nature. It proceeds from the *gain from illness* and is based upon an assimilation of the symptom into the ego. It represents an unwillingness to renounce any satisfaction or relief that has been obtained. The fourth variety, arising from the *id*, is the resistance which, as we have just seen, necessitates 'working-through'. The fifth, coming from the *super-ego* and the last to be discovered, is also the most obscure though not always the least powerful one. It seems to originate from the sense of guilt or the need for punishment; and it opposes every move towards success, including, therefore, the patient's own recovery through analysis.

[1926d, 4313]

Yes, we are only beginning to appreciate the significance of all these important circumstances. That is why my description was bound to turn out so obscure. But now I can proceed. We describe all the forces that oppose the work of recovery as the patient's 'resistances'. The gain from illness is one such resistance. The 'unconscious sense of guilt' represents the super-ego's resistance; it is the most powerful factor, and the one most dreaded by us. We meet with still other resistances during the treatment. If the ego during the early period has set up a repression out of fear, then the fear still persists and manifests itself as a resistance if the ego approaches the repressed material. And finally, as you can imagine, there are likely to be difficulties if an instinctual process which has been going along a particular path for whole decades is suddenly expected to take a new path that has just been made open for it. That might be called the id's resistance. The struggle against all these resistances is our main work during an analytic treatment; the task of making interpretations is nothing compared to it. But as a result of this struggle and of the overcoming of the resistances, the patient's ego is so much altered and strengthened that we can look forward calmly to his future behaviour when the treatment is over. On the other hand, you can understand now why we need such long treatments. The length of the path of development and the wealth of the material are not the decisive factors. It is more a question of whether the path is clear. An army can be held up for weeks on a stretch of country which in peace time an express train crosses in a couple of hours - if the army has to overcome the enemy's resistance there. Such battles call for time in mental life too. I am unfortunately obliged to tell you that every effort to hasten analytic treatment appreciably has hitherto failed. The best way of shortening it seems to be to carry it out according to the rules.

[1926e, 4366]
Now, however, another problem awaits us - at the opposite end of the ego, as we might put it. It is presented to us by an observation during the work of analysis, an observation which is actually a very old one. As not infrequently happens, it has taken a long time to come to the point of appreciating its importance. The whole theory of psycho-analysis is, as you know, in fact built up on the perception of the resistance offered to us by the patient when we attempt to make his unconscious conscious to him. The objective sign of this resistance is that his associations fail or depart widely from the topic that is being dealt with. He may also recognize the resistance subjectively by the fact that he has distressing feelings when he approaches the topic. But this last sign may also be absent. We then say to the patient that we infer from his behaviour that he is now in a state of resistance; and he replies that he knows nothing of that, and is only aware that his associations have become more difficult. It turns out that we were right; but in that case his resistance was unconscious too, just as unconscious as the repressed, at the lifting of which we were working. We should long ago have asked the question: from what part of his mind does an unconscious resistance like this arise? The beginner in psycho-analysis will be ready at once with the answer: it is, of course, the resistance of the unconscious. An ambiguous and unserviceable answer! If it means that the resistance arises from the repressed, we must rejoin: certainly not! We must rather attribute to the repressed a strong upward drive, an impulsion to break through into consciousness. The resistance can only be a manifestation of the ego, which originally put the repression into force and now wishes to maintain it. That, moreover, is the view we always took. Since we have come to assume a special agency in the ego, the super-ego, which represents demands of a restrictive and rejecting character, we may say that repression is the work of this super-ego and that it is carried out either by itself or by the ego in obedience to its orders. If then we are met by the case of the resistance in analysis not being conscious to the patient, this means either that in quite important situations the super-ego and the ego can operate unconsciously, or - and this would be still more important - that portions of both of them, the ego and the super-ego themselves, are unconscious. In both cases we have to reckon with the disagreeable discovery that on the one hand (super-) ego and conscious and on the other hand repressed and unconscious are far from coinciding.

[1933a, 4677]
With the mention of resistance we have reached the second and more important part of our task. We have already learnt that the ego protects itself against the invasion of undesired elements from the unconscious and repressed id by means of anticathexes, which must remain intact if it is to function normally. The more hard-pressed the ego feels, the more convulsively it clings (as though in a fright) to these anticathexes, in order to protect what remains of itself from further irruptions. But this defensive purpose does not by any means accord with the aims of our treatment. What we desire, on the contrary, is that the ego, emboldened by the certainty of our help, shall dare to take the offensive in order to reconquer what has been lost. And it is here that we become aware of the strength of these anticathexes in the form of resistances to our work. The ego draws back in alarm from such undertakings, which seem dangerous and threaten unpleasure; it must be constantly encouraged and soothed if it is not to fail us. This resistance, which persists throughout the whole treatment and is renewed at every fresh piece of work, is known, not quite correctly, as the *resistance due to repression*. We shall find that it is not the only one that faces us. It is interesting to notice that in this situation the party-divisions are to some extent reversed: for the ego struggles against our instigation, while the unconscious, which is ordinarily our opponent, comes to our help, since it has a natural 'upward drive' and desires nothing better than to press forward across its settled frontiers into the ego and so to consciousness. The struggle which develops, if we gain our end and can induce the ego to overcome its resistances, is carried through under our direction and with our assistance. Its outcome is a matter of indifference: whether it results in the ego accepting, after a fresh examination, an instinctual demand which it has hitherto rejected, or whether it dismisses it once more, this time for good and all. In either case a permanent danger has been disposed of, the compass of the ego has been extended and a wasteful expenditure of energy has been made unnecessary.

[1940a [1938], 4988]
The therapeutic effect depends on making conscious what is repressed, in the widest sense of the word, in the id. We prepare the way for this making conscious by interpretations and constructions, but we have interpreted only for ourselves not for the patient so long as the ego holds on to its earlier defences and does not give up its resistances. Now these resistances, although they belong to the ego, are nevertheless unconscious and in some sense separated off within the ego. The analyst recognizes them more easily than he does the hidden material in the id. One might suppose that it would be sufficient to treat them like portions of the id and, by making them conscious, bring them into connection with the rest of the ego. In this way, we should suppose, one half of the task of analysis would be accomplished; we should not reckon on meeting with a resistance against the uncovering of resistances. But what happens is this. During the work on the resistances the ego withdraws - with a greater or less degree of seriousness - from the agreement on which the analytic situation is founded. The ego ceases to support our efforts at uncovering the id; it opposes them, disobeys the fundamental rule of analysis, and allows no further derivatives of the repressed to emerge. We cannot expect the patient to have a strong conviction of the curative power of analysis. He may have brought along with him a certain amount of confidence in his analyst, which will be strengthened to an effective point by the factors of the positive transference which will be aroused in him. Under the influence of the unpleasurable impulses which he feels as a result of the fresh activation of his defensive conflicts, negative transferences may now gain the upper hand and completely annul the analytic situation. The patient now regards the analyst as no more than a stranger who is making disagreeable demands on him, and he behaves towards him exactly like a child who does not like the stranger and does not believe anything he says. If the analyst tries to explain to the patient one of the distortions made by him for the purposes of defence, and to correct it, he finds him uncomprehending and inaccessible to sound arguments. Thus we see that there is a resistance against the uncovering of resistances, and the defensive mechanisms really do deserve the name which we gave them originally, before they had been more closely examined. They are resistances not only to the making conscious of contents of the id, but also to the analysis as a whole, and thus to recovery.

[1937c, 5034]
If we make use of it on someone else, let us say on a patient with a phobia, we require him to direct his attention on to the idea in question, not, however, to reflect upon it as he has done so often already, but to take notice of \textit{whatever occurs to his mind without any exception} and report it to the physician. If he should then assert that his attention is unable to grasp anything at all, we dismiss this with an energetic assurance that a complete absence of any ideational subject-matter is quite impossible. And in fact very soon numerous ideas will occur to him and will lead on to others; but they will invariably be prefaced by a judgement on the part of the self-observer to the effect that they are senseless or unimportant, that they are irrelevant, and that they occurred to him by chance and without any connection with the topic under consideration. We perceive at once that it was this critical attitude which prevented the subject from reporting any of these ideas, and which indeed had previously prevented them from becoming conscious. If we can induce him to abandon his criticism of the ideas that occur to him, and to continue pursuing the trains of thought which will emerge so long as he keeps his attention turned upon them, we find ourselves in possession of a quantity of psychical material, which we soon find is clearly connected with the pathological idea which was our starting-point; this material will soon reveal connections between the pathological idea and other ideas, and will eventually enable us to replace the pathological idea by a new one which fits into the nexus of thought in an intelligible fashion.

Dora had listened to me without any of her usual contradictions. She seemed to be moved; she said good-bye to me very warmly, with the heartiest wishes for the New Year, and - came no more. Her father, who called on me two or three times afterwards, assured me that she would come back again, and said it was easy to see that she was eager for the treatment to continue. But it must be confessed that Dora's father was never entirely straightforward. He had given his support to the treatment so long as he could hope that I should 'talk' Dora out of her belief that there was something more than a friendship between him and Frau K. His interest faded when he observed that it was not my intention to bring about that result. I knew Dora would not come back again. Her breaking off so unexpectedly, just when my hopes of a successful termination of the treatment were at their highest, and her thus bringing those hopes to nothing - this was an unmistakable act of vengeance on her part. Her purpose of self-injury also profited by this action. No one who, like me, conjures up the most evil of those half-tamed demons that inhabit the human breast, and seeks to wrestle with them, can expect to come through the struggle unscathed. Might I perhaps have kept the girl under my treatment if I myself had acted a part, if I had exaggerated the importance to me of her staying on, and had shown a warm personal interest in her - a course which, even after allowing for my position as her physician, would have been tantamount to providing her with a substitute for the affection she longed for? I do not know. Since in every case a portion of the factors that are encountered under the form of resistance remains unknown, I have always avoided acting a part, and have contented myself with practising the humbler arts of psychology. In spite of every theoretical interest and of every endeavour to be of assistance as a physician, I keep the fact in mind that there must be some limits set to the extent to which psychological influence may be used, and I respect as one of these limits the patient's own will and understanding.
In order to secure these ideas and associations he asks the patient to 'let himself go' in what he says, 'as you would do in a conversation in which you were rambling on quite disconnectedly and at random'. Before he asks them for a detailed account of their case history he insists that they must include in it whatever comes into their heads, even if they think it unimportant or irrelevant or nonsensical; he lays special stress on their not omitting any thought or idea from their story because to relate it would be embarrassing or distressing to them. In the course of collecting this material of otherwise neglected ideas Freud made the observations which became the determining factor of his entire theory. Gaps appear in the patient's memory even while he narrates his case: actual occurrences are forgotten, the chronological order is confused, or causal connections are broken, with unintelligible results. No neurotic case history is without amnesia of some kind or other. If the patient is urged to fill these gaps in his memory by an increased application of attention, it is noticed that all the ideas which occur to him are pushed back by every possible critical expedient, until at last he feels positive discomfort when the memory really returns. From this experience Freud concludes that the amnesias are the result of a process which he calls 'repression' and the motive for which he finds in feelings of unpleasure. The psychical forces which have brought about this repression can also be detected, according to him, in the 'resistance' which operates against the recovery of the lost memories.

[1904a, 1557]

The factor of resistance has become one of the corner-stones of his theory. The ideas which are normally pushed aside on every sort of excuse - such as those mentioned above - are regarded by him as derivatives of the repressed psychical phenomena (thoughts and impulses), distorted owing to the resistance against their reproduction. Ideas which are normally pushed aside on every sort of excuse - such as those mentioned above - are regarded by him as derivatives of the repressed psychical phenomena (thoughts and impulses), distorted owing to the resistance against their reproduction.

[1904a, 1557]

There is, however, another angle from which you may seek to understand the psycho-analytic method. The uncovering and translating of the unconscious occurs in the face of a continuous resistance on the part of the patient. The process of bringing this unconscious material to light is associated with unpleasure, and because of this the patient rejects it again and again. It is for you then to interpose in this conflict in the patient's mental life. If you succeed in persuading him to accept, by virtue of a better understanding, something that up to now, in consequence of this automatic regulation by unpleasure, he has rejected (repressed), you will have accomplished something towards his education. For it is education even to induce someone who dislikes getting up early to do so all the same. Psycho-analytic treatment may in general be conceived of as such a re-education in overcoming internal resistances. Re-education of this kind is, however, in no respect more necessary to nervous patients than in regard to the mental element in their sexual life. For nowhere else have civilization and education done so much harm as in this field, and this is the point, as experience will show you, at which to look for those aetiologies of the neuroses that are amenable to influence; for the other aetiological factor, the constitutional component, consists of something fixed and unalterable. And from this it follows that one important qualification is required of the physician in this work: not only must his own character be irreproachable - 'As to morals, that goes without saying', as the hero of Vischer's novel Auch Einer was in the habit of declaring - but he must also have overcome in his own mind that mixture of prurience and prudery with which, unfortunately, so many people habitually consider sexual problems.

[1905a, 1571]
If you look more deeply into the comparison between the two situations it will become clear to you in general that psycho-analysis is concerned with a simpler, special, form of the task of uncovering what is hidden in the mind; whereas in your work the task is a more comprehensive one. That the case of the psychoneurotic is invariably concerned with a repressed sexual complex (in the widest sense) is a difference which you need not take into account. But there is something else that you must. The aim of psycho-analysis is absolutely uniform in every case: complexes have to be uncovered which have been repressed because of feelings of displeasure and which produce signs of resistance if an attempt is made to bring them into consciousness. This resistance is as it were localized; it arises at the frontier between unconscious and conscious. In your cases what is concerned is a resistance which comes entirely from consciousness. You cannot dismiss this difference out of hand. You will first have to determine experimentally whether conscious resistance is betrayed by exactly the same indications as unconscious resistance. Further, you cannot yet be certain, in my opinion, whether you may interpret your objective indications of a complex as a 'resistance', as we psycho-therapists do. It may happen with your experimental subjects - even though not very frequently with criminals - that the complex you touch on is pleasurably toned; and the question then arises whether such a complex will produce the same reaction as a complex that is unpleasurably toned. [1906c, 1896]

By enlightening Hans on this subject I had cleared away his most powerful resistance against allowing his unconscious thoughts to be made conscious; for his father was himself acting as his physician. The worst of the attack was now over; there was a plentiful flow of material; the little patient summoned up courage to describe the details of his phobia, and soon began to take an active share in the conduct of the analysis.¹ [1909b, 2105]

¹ Even in analyses in which the physician and the patient are strangers, fear of the father plays one of the most important parts as a resistance against the reproduction of the unconscious pathogenic material. Resistances are sometimes in the nature of 'motifs'. But sometimes, as in the present instance, one piece of the unconscious material is capable from its actual content of operating as an inhibition against the reproduction of another piece. [1909b, 2105]

Such is my excuse for having curtailed so drastically the history of this case and its treatment. And I can offer still more cogent reasons for having confined myself to the statement only of some disconnected results of the psycho-analytic investigation of obsessional neuroses. I must confess that I have not yet succeeded in completely penetrating the complicated texture of a severe case of obsessional neurosis, and that, if I were to reproduce the analysis, it would be impossible for me to make the structure, such as by the help of analysis we know or suspect it to be, visible to others through the mass of therapeutic work superimposed upon it. What add so greatly to the difficulty of doing this are the resistances of the patients and the forms in which they are expressed. But even apart from this it must be admitted that an obsessional neurosis is in itself not an easy thing to understand - much less so than a case of hysteria. Actually, indeed, we should have expected to find the contrary. The language of an obsessional neurosis - the means by which it expresses its secret thoughts - is, as it were, only a dialect of the language of hysteria; but it is a dialect in which we ought to be able to find our way about more easily, since it is more nearly related to the forms of expression adopted by our conscious thought than is the language of hysteria. Above all, it does not involve the leap from a mental process to a somatic innervation - hysterical conversion - which can never be fully comprehensible to us. [1909d, 2128]
It was on this idea of resistance, then, that I based my view of the course of psychical events in hysteria. In order to effect a recovery, it had proved necessary to remove these resistances. Starting out from the mechanism of cure, it now became possible to construct quite definite ideas of the origin of the illness. The same forces which, in the form of resistance, were now offering opposition to the forgotten material's being made conscious, must formerly have brought about the forgetting and must have pushed the pathogenic experiences in question out of consciousness. I gave the name of 'repression' to this hypothetical process, and I considered that it was proved by the undeniable existence of resistance. [1910a, 2212]

Perhaps I may give you a more vivid picture of repression and of its necessary relation to resistance, by a rough analogy derived from our actual situation at the present moment. Let us suppose that in this lecture-room and among this audience, whose exemplary quiet and attentiveness I cannot sufficiently commend, there is nevertheless someone who is causing a disturbance and whose ill-mannered laughter, chattering and shuffling with his feet are distracting my attention from my task. I have to announce that I cannot proceed with my lecture; and thereupon three or four of you who are strong men stand up and, after a short struggle, put the interrupter outside the door. So now he is 'repressed', and I can continue my lecture. But in order that the interruption shall not be repeated, in case the individual who has been expelled should try to enter the room once more, the gentlemen who have put my will into effect place their chairs up against the door and thus establish a 'resistance' after the repression has been accomplished. If you will now translate the two localities concerned into psychical terms as the 'conscious' and the 'unconscious', you will have before you a fairly good picture of the process of repression. [1910a, 2213]

LADIES AND GENTLEMEN, - With the discovery of infantile sexuality and the tracing back of neurotic symptoms to erotic instinctual components we have arrived at some unexpected formulas concerning the nature and purposes of neurotic illnesses. We see that human beings fall ill when, as a result of external obstacles or of an internal lack of adaptation, the satisfaction of their erotic needs in reality frustrated. We see that they then take flight into illness in order that by its help they may find a satisfaction to take the place of what has been frustrated. We recognize that the pathological symptoms constitute a portion of the subject's sexual activity or even the whole of his sexual life, and we find that the withdrawal from reality is the main purpose of the illness but also the main damage caused by it. We suspect that our patients' resistance to recovery is no simple one, but compounded of several motives. Not only does the patient's ego rebel against giving up the repressions by means of which it has risen above its original disposition, but the sexual instincts are unwilling to renounce their substitutive satisfaction so long as it is uncertain whether reality will offer them anything better. [1910a, 2234]

The question with which I now intend to deal is not that of the technique of dream-interpretation; neither the methods by which dreams should be interpreted nor the use of such interpretations when made will be considered, but only the way in which the analyst should employ the art of interpretation in the psycho-analytic treatment of patients. There are undoubtedly different ways of going to work in the matter, but then the answer to questions of technique in analysis is never a matter of course. Although there may perhaps be more than one good road to follow, still there are very many bad ones, and a comparison of the various methods cannot fail to be illuminating, even if it should not lead to a decision in favour of any particular one. [1911e, 2450]
Anyone coming from dream-interpretation to analytic practice will retain his interest in the content of dreams, and his inclination will be to interpret as fully as possible every dream related by the patient. But he will soon remark that he is now working under quite different conditions, and that if he attempts to carry out his intention he will come into collision with the most immediate tasks of the treatment. Even if a patient's first dream proves to be admirably suited for the introduction of the first explanations to be given, other dreams will promptly appear, so long and so obscure that the full meaning cannot be extracted from them in the limited session of one day's work. If the doctor continues the work of interpretation during the following days, fresh dreams will be produced in the meantime and these will have to be put aside until he can regard the first dream as finally resolved. The production of dreams is at times so copious, and the patient's progress towards comprehension of them so hesitant, that a suspicion will force itself on the analyst that the appearance of the material in this manner may be simply a manifestation of the patient's resistance taking advantage of the discovery that the method is unable to master what is so presented. Moreover, the treatment will meanwhile have fallen quite a distance behind the present and have lost touch with actuality. In opposition to such a technique stands the rule that it is of the greatest importance for the treatment that the analyst should always be aware of the surface of the patient's mind at any given moment, that he should know what complexes and resistances are active in him at the time and what conscious reaction to them will govern his behaviour. It is scarcely ever right to sacrifice this therapeutic aim to an interest in dream-interpretation.

What then, if we bear this rule in mind, is to be our attitude to interpreting dreams in analysis? More or less as follows: The amount of interpretation which can be achieved in one session should be taken as sufficient and it is not to be regarded as a loss if the content of the dream is not fully discovered. On the following day, the interpretation of the dream is not to be taken up again as a matter of course, until it has become evident that nothing else has meanwhile forced its way into the foreground of the patient's thoughts. Thus no exception in favour of an interrupted dream-interpretation is to be made to the rule that the first thing that comes into the patient's head is the first thing to be dealt with. If fresh dreams occur before the earlier ones have been disposed of, the more recent productions are to be attended to, and no uneasiness need be felt about neglecting the older ones. If the dreams become altogether too diffuse and voluminous, all hope of completely unravelling them should tacitly be given up from the start. One must in general guard against displaying very special interest in the interpretation of dreams, or arousing an idea in the patient that the work would come to a standstill if he were to bring up no dreams; otherwise there is a danger of the resistance being directed to the production of dreams, with a consequent cessation of them. The patient must be brought to believe, on the contrary, that the analysis invariably finds material for its continuation, regardless of whether or no he brings up dreams or what amount of attention is devoted to them.
There would be nothing more to discuss or worry about in this behaviour of transference, if it were not that two points remain unexplained about it which are of particular interest to psycho-analysis. Firstly, we do not understand why transference is so much more intense with neurotic subjects in analysis than it is with other such people who are not being analysed; and secondly, it remains a puzzle why in analysis transference emerges as the most powerful resistance to the treatment, whereas outside analysis it must be regarded as the vehicle of cure and the condition of success. For our experience has shown us - and the fact can be confirmed as often as we please - that if a patient's free associations fail the stoppage can invariably be removed by an assurance that he is being dominated at the moment by an association which is concerned with the doctor himself or with something connected with him. As soon as this explanation is given, the stoppage is removed, or the situation is changed from one in which the associations fail into one in which they are being kept back. At first sight it appears to be an immense disadvantage in psycho-analysis as a method that what is elsewhere the strongest factor towards success is changed in it into the most powerful medium of resistance. If, however, we examine the situation more closely, we can at least clear away the first of our two problems. It is not a fact that transference emerges with greater intensity and lack of restraint during psycho-analysis than outside it. In institutions in which nerve patients are treated non-analytically, we can observe transference occurring with the greatest intensity and in the most unworthy forms, extending to nothing less than mental bondage, and moreover showing the plainest erotic colouring. Gabriele Reuter, with her sharp powers of observation, described this at a time when there was no such thing as psycho-analysis, in a remarkable book which betrays in every respect the clearest insight into the nature and genesis of neuroses. These characteristics of transference are therefore to be attributed not to psycho-analysis but to neurosis itself.

[1912b, 2458]
Our second problem - the problem of why transference appears in psycho-analysis as resistance - has been left for the moment untouched; and we must now approach it more closely. Let us picture the psychological situation during the treatment. An invariable and indispensable precondition of every onset of a psychoneurosis is the process to which Jung has given the appropriate name of 'introversion'.¹ That is to say: the portion of libido which is capable of becoming conscious and is directed towards reality is diminished, and the portion which is directed away from reality and is unconscious, and which, though it may still feed the subject's phantasies, nevertheless belongs to the unconscious, is proportionately increased. The libido (whether wholly or in part) has entered on a regressive course and has revived the subject's infantile imagos.² The analytic treatment now proceeds to follow it; it seeks to track down the libido, to make it accessible to consciousness and, in the end, serviceable for reality. Where the investigations of analysis come upon the libido withdrawn into its hiding-place, a struggle is bound to break out; all the forces which have caused the libido to regress will rise up as 'resistances' against the work of analysis, in order to conserve the new state of things. For if the libido's introversion or regression had not been justified by a particular relation between the subject and the external world - stated in the most general terms, by the frustration of satisfaction - and if it had not for the moment even become expedient, it could never have taken place at all. But the resistances from this source are not the only ones or indeed the most powerful. The libido at the disposal of the subject's personality had always been under the influence of the attraction of his unconscious complexes (or more correctly, of the portions of those complexes belonging to the unconscious), and it entered on a regressive course because the attraction of reality had diminished. In order to liberate it, this attraction of the unconscious has to be overcome; that is, the repression of the unconscious instincts and of their productions, which has meanwhile been set up in the subject, must be removed. This is responsible for by far the largest part of the resistance, which so often causes the illness to persist even after the turning away from reality has lost its temporary justification. The analysis has to struggle against the resistances from both these sources. The resistance accompanies the treatment step by step. Every single association, every act of the person under treatment must reckon with the resistance and represents a compromise between the forces that are striving towards recovery and the opposing ones which I have described.

[1912b, 2459]

If now we follow a pathogenic complex from its representation in the conscious (whether this is an obvious one in the form of a symptom or something quite inconspicuous) to its root in the unconscious, we shall soon enter a region in which the resistance makes itself felt so clearly that the next association must take account of it and appear as a compromise between its demands and those of the work of investigation. It is at this point, on the evidence of our experience, that transference enters on the scene. When anything in the complexive material (in the subject-matter of the complex) is suitable for being transferred on to the figure of the doctor, that transference is carried out; it produces the next association, and announces itself by indications of a resistance - by a stoppage, for instance. We infer from this experience that the transference-idea has penetrated into consciousness in front of any other possible associations because it satisfies the resistance. An event of this sort is repeated on countless occasions in the course of an analysis. Over and over again, when we come near to a pathogenic complex, the portion of that complex which is capable of transference is first pushed forward into consciousness and defended with the greatest obstinacy.¹

[1912b, 2460]
(i) To what extent should the patient's intellectual co-operation be sought for in the treatment? It is difficult to say anything of general applicability on this point: the patient's personality is the determining factor. But in any case caution and self-restraint must be observed in this connection. It is wrong to set a patient tasks, such as collecting his memories or thinking over some particular period of his life. On the contrary, he has to learn above all - what never comes easily to anyone - that mental activities such as thinking something over or concentrating the attention solve none of the riddles of a neurosis; that can only be done by patiently obeying the psycho-analytic rule, which enjoins the exclusion of all criticism of the unconscious or of its derivatives. One must be especially unyielding about obedience to that rule with patients who practise the art of sheering off into intellectual discussion during their treatment, who speculate a great deal and often very wisely about their condition and in that way avoid doing anything to overcome it. For this reason I dislike making use of analytic writings as an assistance to my patients; I require them to learn by personal experience, and I assure them that they will acquire wider and more valuable knowledge than the whole literature of psycho-analysis could teach them. I recognize, however, that under institutional conditions it may be of great advantage to employ reading as a preparation for patients in analysis and as a means of creating an atmosphere of influence.

[1912e, 2474]

A little reflection enables one to find one's bearings. First and foremost, one keeps in mind the suspicion that anything that interferes with the continuation of the treatment may be an expression of resistance. There can be no doubt that the outbreak of a passionate demand for love is largely the work of resistance. One will have long since noticed in the patient the signs of an affectionate transference, and one will have been able to feel certain that her docility, her acceptance of the analytic explanations, her remarkable comprehension and the high degree of intelligence she showed were to be attributed to this attitude towards her doctor. Now all this is swept away. She has become quite without insight and seems to be swallowed up in her love. Moreover, this change quite regularly occurs precisely at a point of time when one is having to try to bring her to admit or remember some particularly distressing and heavily repressed piece of her life-history. She has been in love, therefore, for a long time; but now the resistance is beginning to make use of her love in order to hinder the continuation of the treatment, to deflect all her interest from the work and to put the analyst in an awkward position.

[1915a, 2512]
Now we do not know whether these two modes of psychical activity are identical or essentially divergent from their beginning, but we may ask why they should become different in the course of psychical action. To this last question psycho-analysis gives a clear and unhesitating answer. It is by no means impossible for the product of unconscious activity to pierce into consciousness, but a certain amount of exertion is needed for this task. When we try to do it in ourselves, we become aware of a distinct feeling of repulsion which must be overcome, and when we produce it in a patient we get the most unquestionable signs of what we call his resistance to it. So we learn that the unconscious idea is excluded from consciousness by living forces which oppose themselves to its reception, while they do not object to other ideas, the foreconscious ones. Psycho-analysis leaves no room for doubt that the repulsion from unconscious ideas is only provoked by the tendencies embodied in their contents. The next and most probable theory which can be formulated at this stage of our knowledge is the following. Unconsciousness is a regular and inevitable phase in the processes constituting our psychical activity; every psychical act begins as an unconscious one, and it may either remain so or go on developing into consciousness, according as it meets with resistance or not. The distinction between foreconscious and unconscious activity is not a primary one, but comes to be established after repulsion has sprung up. Only then the difference between foreconscious ideas, which can appear in consciousness and reappear at any moment, and unconscious ideas which cannot do so gains a theoretical as well as a practical value. A rough but not inadequate analogy to this supposed relation of conscious to unconscious activity might be drawn from the field of ordinary photography. The first stage of the photograph is the ‘negative’; every photographic picture has to pass through the ‘negative process’, and some of these negatives which have held good in examination are admitted to the ‘positive process’ ending in the picture.

[1912g, 2581]

How are we to arrive at a knowledge of the unconscious? It is of course only as something conscious that we know it, after it has undergone transformation or translation into something conscious. Psycho-analytic work shows us every day that translation of this kind is possible. In order that this should come about, the person under analysis must overcome certain resistances - the same resistances as those which, earlier, made the material concerned into something repressed by rejecting it from the conscious.

[1915e, 2991]

But we wanted to enquire what are the purposes which exercise the censorship and against what purposes it is directed. Now this question, which is fundamental for the understanding of dreams and perhaps, indeed, of human life, is easy to answer if we look through the series of dreams which have been interpreted. The purposes which exercise the censorship are those which are acknowledged by the dreamer’s waking judgement, those with which he feels himself at one. You may be sure that if you reject an interpretation of one of your own dreams which has been correctly carried out, you are doing so for the same motives for which the dream-censorship has been exercised, the dream-distortion brought about and the interpretation made necessary. Take the dream of our fifty-year-old lady. She thought her dream disgusting without having analysed it, and she would have been still more indignant if Dr. von Hug-Hellmuth had told her anything of its inevitable interpretation; it was precisely because of this condemnation by the dreamer that the objectionable passages in her dream were replaced by a mumble.

[1916-1917, 3237]

The patient’s resistance is of very many sorts, extremely subtle and often hard to detect; and it exhibits protean changes in the forms in which it manifests itself. The doctor must be distrustful and remain on his guard against it.

[1916-1917, 3362]
The first thing we achieve by setting up this fundamental technical rule is that it becomes the target for the attacks of the resistance. The patient endeavours in every sort of way to extricate himself from its provisions. At one moment he declares that nothing occurs to him, at the next that so many things are crowding in on him that he cannot get hold of anything. Presently we observe with pained astonishment that he has given way first to one and then to another critical objection: he betrays this to us by the long pauses that he introduces into his remarks. He then admits that there is something he really cannot say - he would be ashamed to; and he allows this reason to prevail against his promise. Or he says that something has occurred to him, but it concerns another person and not himself and is therefore exempt from being reported. Or, what has now occurred to him is really too unimportant, too silly and senseless: I cannot possibly have meant him to enter into thoughts like that. So it goes on in innumerable variations, and one can only reply that 'to say everything' really does mean 'to say everything'.

[1916-1917, 3363]

Obsessional neurotics understand perfectly how to make the technical rule almost useless by applying their over-conscientiousness and doubts to it. Patients suffering from anxiety hysteria occasionally succeed in carrying the rule ad absurdum by producing only associations which are so remote from what we are in search of that they contribute nothing to the analysis. But it is not my intention to induct you into the handling of these technical difficulties. It is enough to say that in the end, through resolution and perseverance, we succeed in extorting a certain amount of obedience to the fundamental technical rule from the resistance - which thereupon jumps over to another sphere.

[1916-1917, 3364]

It now appears as an intellectual resistance, it fights by means of arguments and exploits all the difficulties and improbabilities which normal but uninstructed thinking finds in the theories of analysis. It is now our fate to hear from this single voice all the criticisms and objections which assail our ears in a chorus in the scientific literature of the subject. And for this reason none of the shouts that reach us from outside sound unfamiliar. It is a regular storm in a tea-cup. But the patient is willing to be argued with; he is anxious to get us to instruct him, teach him, contradict him, introduce him to the literature, so that he can find further instruction. He is quite ready to become an adherent of psycho-analysis - on condition that analysis spares him personally. But we recognize this curiosity as a resistance, as a diversion from our particular tasks, and we repel it. In the case of an obsessional neurotic we have to expect special tactics of resistance. He will often allow the analysis to proceed on its way uninhibited, so that it is able to shed an ever-increasing light upon the riddle of his illness. We begin to wonder in the end, however, why this enlightenment is accompanied by no practical advance, no diminution of the symptoms. We are then able to realize that resistance has withdrawn on to the doubt belonging to the obsessional neurosis and from that position is successfully defying us. It is as though the patient were saying: 'Yes, that's all very nice and interesting, and I'll be very glad to go on with it further. It would change my illness a lot if it were true. But I don't in the least believe that it is true; and, so long as I don't believe it, it makes no difference to my illness.' Things can proceed like this for a long time, till finally one comes up against this uncommitted attitude itself, and the decisive struggle then breaks out.

[1916-1917, 3364]
Intellectual resistances are not the worst; one always remains superior to them. But the patient also knows how to put up resistances, without going outside the framework of the analysis, the overcoming of which is among the most difficult of technical problems. Instead of remembering, he repeats attitudes and emotional impulses from his early life which can be used as a resistance against the doctor and the treatment by means of what is known as ‘transference’. If the patient is a man, he usually extracts this material from his relation to his father, into whose place he fits the doctor, and in that way he makes resistances out of his efforts to become independent in himself and in his judgements, out of his ambition, the first aim of which was to do things as well as his father or to get the better of him, or out of his unwillingness to burden himself for the second time in his life with a load of gratitude. Thus at times one has an impression that the patient has entirely replaced his better intention of making an end to his illness by the alternative one of putting the doctor in the wrong, of making him realize his impotence and of triumphing over him. Women have a masterly gift for exploiting an affectionate, erotically tinged transference to the doctor for the purposes of resistance. If this attachment reaches a certain height, all their interest in the immediate situation in the treatment and all the obligations they undertook at its commencement vanish; their jealousy, which is never absent, and their exasperation at their inevitable rejection, however considerably expressed, are bound to have a damaging effect on their personal understanding with the doctor and so to put out of operation one of the most powerful motive forces of the analysis. [1916-1917, 3365]

Resistances of this kind should not be one-sidedly condemned. They include so much of the most important material from the patient’s past and bring it back in so convincing a fashion that they become some of the best supports of the analysis if a skilful technique knows how to give them the right turn. Nevertheless, it remains a remarkable fact that this material is always in the service of the resistance to begin with and brings to the fore a façade that is hostile to the treatment. It may also be said that what is being mobilized for fighting against the alterations we are striving for are character-traits, attitudes of the ego. In this connection we discover that these character-traits were formed in relation to the determinants of the neurosis and in reaction against its demands, and we come upon traits which cannot normally emerge, or not to the same extent, and which may be described as latent. Nor must you get an impression that we regard the appearance of these resistances as an unforeseen risk to analytic influence. No, we are aware that these resistances are bound to come to light; in fact we are dissatisfied if we cannot provoke them clearly enough and are unable to demonstrate them to the patient. Indeed we come finally to understand that the overcoming of these resistances is the essential function of analysis and is the only part of our work which gives us an assurance that we have achieved something with the patient. [1916-1917, 3366]

If you further consider that the patient makes all the chance events that occur during his analysis into interferences with it, that he uses as reasons for slackening his efforts every diversion outside the analysis, every comment by a person of authority in his environment who is hostile to analysis, any chance organic illness or any that complicates his neurosis and, even, indeed, every improvement in his condition - if you consider all this, you will have obtained an approximate, though still incomplete, picture of the forms and methods of the resistance, the struggle against which accompanies every analysis. [1916-1917, 3366]
If, however, the recognition of resistance has become so important, we should do well to find room for a cautious doubt whether we have not been too light-heartedly assuming resistances. Perhaps there really are cases of neurosis in which associations fail for other reasons, perhaps the arguments against our hypotheses really deserve to have their content examined, and perhaps we are doing patients an injustice in so conveniently setting aside their intellectual criticisms as resistance. But, Gentlemen, we did not arrive at this judgement lightly. We have had occasion to observe all these critical patients at the moment of the emergence of a resistance and after its disappearance. For resistance is constantly altering its intensity during the course of a treatment; it always increases when we are approaching a new topic, it is at its most intense while we are at the climax of dealing with that topic, and it dies away when the topic has been disposed of. Nor do we ever, unless we have been guilty of special clumsiness in our technique, have to meet the full amount of resistance of which a patient is capable. We have therefore been able to convince ourselves that on countless occasions in the course of his analysis the same man will abandon his critical attitude and then take it up again. If we are on the point of bringing a specially distressing piece of unconscious material to his consciousness, he is extremely critical; he may previously have understood and accepted a great deal, but now it is just as though those acquisitions have been swept away; in his efforts for opposition at any price, he may offer a complete picture of someone who is an emotional imbecile. But if we succeed in helping him to overcome this new resistance, he recovers his insight and understanding. Thus his critical faculty is not an independent function, to be respected as such, it is the tool of his emotional attitudes and is directed by his resistance. If there is something he does not like, he can put up a shrewd fight against it and appear highly critical; but if something suits his book, he can, on the contrary, show himself most credulous. Perhaps none of us are very different; a man who is being analysed only reveals this dependence of the intellect upon emotional life so clearly because in analysis we are putting such great pressure on him.

[1916-1917, 3367]

How, then, do we account for our observation that the patient fights with such energy against the removal of his symptoms and the setting of his mental processes on a normal course? We tell ourselves that we have succeeded in discovering powerful forces here which oppose any alteration of the patient's condition; they must be the same ones which in the past brought this condition about. During the construction of his symptoms something must have taken place which we can now reconstruct from our experiences during the resolution of his symptoms. We already know from Breuer's observation that there is a precondition for the existence of a symptom: some mental process must not have been brought to an end normally - so that it could become conscious. The symptom is a substitute for what did not happen at that point. We now know the point at which we must locate the operation of the force which we have surmised. A violent opposition must have started against the entry into consciousness of the questionable mental process, and for that reason it remained unconscious. As being something unconscious, it had the power to construct a symptom. This same opposition, during psycho. analytic treatment, sets itself up once more against our effort to transform what is unconscious into what is conscious. This is what we perceive as resistance. We have proposed to give the pathogenic process which is demonstrated by the resistance the name of repression.

[1916-1917, 3368]
The crudest idea of these systems is the most convenient for us - a spatial one. Let us therefore compare the system of the unconscious to a large entrance hall, in which the mental impulses jostle one another like separate individuals. Adjoining this entrance hall there is a second, narrower, room - a kind of drawing-room - in which consciousness, too, resides. But on the threshold between these two rooms a watchman performs his function: he examines the different mental impulses, acts as a censor, and will not admit them into the drawing-room if they displease him. You will see at once that it does not make much difference if the watchman turns away a particular impulse at the threshold itself or if he pushes it back across the threshold after it has entered the drawing-room. This is merely a question of the degree of his watchfulness and of how early he carries out his act of recognition. If we keep to this picture, we shall be able to extend our nomenclature further. The impulses in the entrance hall of the unconscious are out of sight of the conscious, which is in the other room; to begin with they must remain unconscious. If they have already pushed their way forward to the threshold and have been turned back by the watchman, then they are inadmissible to consciousness; we speak of them as repressed. But even the impulses which the watchman has allowed to cross the threshold are not on that account necessarily conscious as well; they can only become so if they succeed in catching the eye of consciousness. We are therefore justified in calling this second room the system of the preconscious. In that case becoming conscious retains its purely descriptive sense. For any particular impulse, however, the vicissitude of repression consists in its not being allowed by the watchman to pass from the system of the unconscious into that of the preconscious. It is the same watchman whom we get to know as resistance when we try to lift the repression by means of the analytic treatment.

[1916-1917, 3369]

What, then, must we do in order to replace what is unconscious in our patients by what is conscious? There was a time when we thought this was a very simple matter: all that was necessary was for us to discover this unconscious material and communicate it to the patient. But we know already that this was a short-sighted error. Our knowledge about the unconscious material is not equivalent to his knowledge; if we communicate our knowledge to him, he does not receive it instead of his unconscious material but beside it; and that makes very little change in it. We must rather picture this unconscious material topographically, we must look for it in his memory at the place where it became unconscious owing to a repression. The repression must be got rid of - after which the substitution of the conscious material for the unconscious can proceed smoothly. How, then, do we lift a repression of this kind? Here our task enters a second phase. First, the search for the repression and then the removal of the resistance which maintains the repression.

[1916-1917, 3478]
How do we remove the resistance? In the same way: by discovering it and showing it to the patient. Indeed, the resistance too is derived from a repression - from the same one that we are endeavouring to resolve, or from one that took place earlier. It was set up by the anticathexis which arose in order to repress the objectionable impulse. Thus we now do the same thing that we tried to do to begin with: interpret, discover and communicate; but now we are doing it at the right place. The anticathexis or the resistance does not form part of the unconscious but of the ego, which is our collaborator, and is so even if it is not conscious. As we know, the word 'unconscious' is being used here in two senses: on the one hand as a phenomenon and on the other as a system. This sounds very difficult and obscure; but is it not only repeating what we have already said in earlier passages? We have long been prepared for it. We expect that this resistance will be given up and the anticathexis withdrawn when our interpretation has made it possible for the ego to recognize it. What are the motive forces that we work with in such a case? First with the patient's desire for recovery, which has induced him to take part with us in our joint work, and secondly with the help of his intelligence, to which we give support by our interpretation. There is no doubt that it is easier for the patient's intelligence to recognize the resistance and to find the translation corresponding to what is repressed if we have previously given him the appropriate anticipatory ideas. If I say to you: 'Look up at the sky! There's a balloon there!' you will discover it much more easily than if I simply tell you to look up and see if you can see anything. In the same way, a student who is looking through a microscope for the first time is instructed by his teacher as to what he will see; otherwise he does not see it at all, though it is there and visible.

[1916-1917, 3479]

All the libido, as well as everything opposing it, is made to converge solely on the relation with the doctor. In this process the symptoms are inevitably divested of libido. In place of his patient's true illness there appears the artificially constructed transference illness, in place of the various unreal objects of the libido there appears a single, and once more imaginary, object in the person of the doctor. But, by the help of his doctor's suggestion, the new struggle around this object is lifted to the highest psychical level: it takes place as a normal mental conflict. Since a fresh repression is avoided, the alienation between ego and libido is brought to an end and the subject's mental unity is restored. When the libido is released once more from its temporary object in the person of the doctor, it cannot return to its earlier objects, but is at the disposal of the ego. The forces against which we have been struggling during our work of therapy are, on the one hand, the ego's antipathy to certain trends of the libido - an antipathy expressed in a tendency to repression - and, on the other hand, the tenacity or adhesiveness of the libido, which dislikes leaving objects that it has once cathected.

[1916-1917, 3494]
The patient with whom I am here concerned remained for a long time unassailably entrenched behind an attitude of 'obliging apathy'. He listened, understood, and remained unapproachable. His unimpeachable intelligence was, as it were, cut off from the instinctual forces which governed his behaviour in the few relations of life that remained to him. It required a long education to induce him to take an independent share in the work; and when as a result of this exertion he began for the first time to feel relief, he immediately gave up working in order to avoid any further changes, and in order to remain comfortably in the situation which had been thus established. His shrinking from a self-sufficient existence was so great as to outweigh all the vexations of his illness. Only one way was to be found of overcoming it. I was obliged to wait until his attachment to myself had become strong enough to counter-balance this shrinking, and then played off this one factor against the other. I determined - but not until trustworthy signs had led me to judge that the right moment had come - that the treatment must be brought to an end at a particular fixed date, no matter how far it had advanced. I was resolved to keep to the date; and eventually the patient came to see that I was in earnest. Under the inexorable pressure of this fixed limit his resistance and his fixation to the illness gave way, and now in a disproportionately short time the analysis produced all the material which made it possible to clear up his inhibitions and remove his symptoms. All the information, too, which enabled me to understand his infantile neurosis is derived from this last period of the work, during which resistance temporarily disappeared and the patient gave an impression of lucidity which is usually attainable only in hypnosis.

[1918b, 3507]

In order to make it easier to understand this 'compulsion to repeat', which emerges during the psycho-analytic treatment of neurotics, we must above all get rid of the mistaken notion that what we are dealing with in our struggle against resistances is resistance on the part of the unconscious. The unconscious - that is to say, the 'repressed' - offers no resistance whatever to the efforts of the treatment. Indeed, it itself has no other endeavour than to break through the pressure weighing down on it and force its way either to consciousness or to a discharge through some real action. Resistance during treatment arises from the same higher strata and systems of the mind which originally carried out repression. But the fact that, as we know from experience, the motives of the resistances, and indeed the resistances themselves, are unconscious at first during the treatment, is a hint to us that we should correct a shortcoming in our terminology. We shall avoid a lack of clarity if we make our contrast not between the conscious and the unconscious but between the coherent ego and the repressed. It is certain that much of the ego is itself unconscious, and notably what we may describe as its nucleus; only a small part of it is covered by the term 'preconscious'. Having replaced a purely descriptive terminology by one which is systematic or dynamic, we can say that the patient's resistance arises from his ego, and we then at once perceive that the compulsion to repeat must be ascribed to the unconscious repressed. It seems probable that the compulsion can only express itself after the work of treatment has gone half-way to meet it and has loosened the repression.¹

[1920g, 3724]
There is no doubt that the resistance of the conscious and unconscious ego operates under the sway of the pleasure principle: it seeks to avoid the unpleasure which would be produced by the liberation of the repressed. Our efforts, on the other hand, are directed towards procuring the toleration of that unpleasure by an appeal to the reality principle. But how is the compulsion to repeat - the manifestation of the power of the repressed - related to the pleasure principle? It is clear that the greater part of what is re-experienced under the compulsion to repeat must cause the ego unpleasure, since it brings to light activities of repressed instinctual impulses. That, however, is unpleasure of a kind we have already considered and does not contradict the pleasure principle: unpleasure for one system and simultaneously satisfaction for the other. But we come now to a new and remarkable fact, namely that the compulsion to repeat also recalls from the past experiences which include no possibility of pleasure, and which can never, even long ago, have brought satisfaction even to instinctual impulses which have since been repressed.

But it is to be noted that only in rare instances can we observe the pure effects of the compulsion to repeat, unsupported by other motives. In the case of children's play we have already laid stress on the other ways in which the emergence of the compulsion may be interpreted; the compulsion to repeat and instinctual satisfaction which is immediately pleasurable seem to converge here into an intimate partnership. The phenomena of transference are obviously exploited by the resistance which the ego maintains in its pertinacious insistence upon repression; the compulsion to repeat, which the treatment tries to bring into its service is, as it were, drawn over by the ego to its side (clinging as the ego does to the pleasure principle). A great deal of what might be described as the compulsion of destiny seems intelligible on a rational basis; so that we are under no necessity to call in a new and mysterious motive force to explain it.

In the girl's account of her conscious motives the father did not figure at all; there was not even any mention of fear of his anger. In the motives laid bare by the analysis, on the other hand, he played the principal part. Her relation to her father had the same decisive importance for the course and outcome of the analytic treatment, or rather, analytic exploration. Behind her pretended consideration for her parents, for whose sake she had been willing to make the attempt to be transformed, lay concealed her attitude of defiance and revenge against her father which held her fast to her homosexuality. Secure under this cover, the resistance set a considerable region free to analytic investigation. The analysis went forward almost without any signs of resistance, the patient participating actively with her intellect, though absolutely tranquil emotionally. Once when I expounded to her a specially important part of the theory, one touching her nearly, she replied in an inimitable tone, 'How very interesting', as though she were a grande dame being taken over a museum and glancing through her lorgnon at objects to which she was completely indifferent. The impression one had of her analysis was not unlike that of a hypnotic treatment, where the resistance has in the same way withdrawn to a certain boundary line, beyond which it proves to be unconquerable. The resistance very often pursues similar tactics - Russian tactics, as they might be called - in cases of obsessional neurosis. For a time, consequently, these cases yield the clearest results and permit a deep insight into the causation of the symptoms. But presently one begins to wonder how it is that such marked progress in analytic understanding can be unaccompanied by even the slightest change in the patient's compulsions and inhibitions, until at last one perceives that everything that has been accomplished is subject to a mental reservation of doubt, and that behind this protective barrier the neurosis can feel secure. 'It would be all very fine', thinks the patient, often quite consciously, 'if I were obliged to believe what the man says, but there is no question of that, and so long as this is so I need change nothing.' Then, when one comes to close quarters with the motives for this doubt, the fight with the resistances breaks out in earnest.
The Theory of Repression. - These theoretical considerations, taken together with the immediate impressions derived from analytic work, lead to a view of the neuroses which may be described in the roughest outline as follows. The neuroses are the expression of conflicts between the ego and such of the sexual impulses as seem to the ego incompatible with its integrity or with its ethical standards. Since these impulses are not ego-syntonic, the ego has repressed them: that is to say, it has withdrawn its interest from them and has shut them off from becoming conscious as well as from obtaining satisfaction by motor discharge. If in the course of analytic work one attempts to make these repressed impulses conscious, one becomes aware of the repressive forces in the form of resistance. But the achievement of repression fails particularly readily in the case of the sexual instincts. Their dammed-up libido finds other ways out from the unconscious: for it regresses to earlier phases of development and earlier attitudes towards objects, and, at weak points in the libidinal development where there are infantile fixations, it breaks through into consciousness and obtains discharge. What results is a symptom and consequently in its essence a substitutive sexual satisfaction. Nevertheless the symptom cannot entirely escape from the repressive forces of the ego and must therefore submit to modifications and displacements exactly as happens with dreams - by means of which its characteristic of being a sexual satisfaction becomes unrecognizable. Consequently symptoms are in the nature of compromises between the repressed sexual instincts and the repressing ego-instincts; they represent a wish-fulfilment for both partners to the conflict simultaneously, but one which is incomplete for each of them. This is quite strictly true of the symptoms of hysteria, while in the symptoms of obsessional neurosis there is often a stronger emphasis upon the side of the repressing function owing to the erection of reaction-formations, which are assurances against sexual satisfaction.

Transference. - If further proof were needed of the truth that the motive forces behind the formation of neurotic symptoms are of a sexual nature, it would be found in the fact that in the course of analytic treatment a special emotional relation is regularly formed between the patient and the physician. This goes far beyond rational limits. It varies between the most affectionate devotion and the most obstinate enmity and derives all of its characteristics from earlier erotic attitudes of the patient's which have become unconscious. This transference alike in its positive and in its negative form is used as a weapon by the resistance; but in the hands of the physician it becomes the most powerful therapeutic instrument and it plays a part scarcely to be over-estimated in the dynamics of the process of cure.

But we have arrived at the term or concept of the unconscious along another path, by considering certain experiences in which mental dynamics play a part. We have found - that is, we have been obliged to assume - that very powerful mental processes or ideas exist (and here a quantitative or economic factor comes into question for the first time) which can produce all the effects in mental life that ordinary ideas do (including effects that can in their turn become conscious as ideas), though they themselves do not become conscious. It is unnecessary to repeat in detail here what has been explained so often before. It is enough to say that at this point psycho-analytic theory steps in and asserts that the reason why such ideas cannot become conscious is that a certain force opposes them, that otherwise they could become conscious, and that it would then be apparent how little they differ from other elements which are admittedly psychic. The fact that in the technique of psycho-analysis a means has been found by which the opposing force can be removed and the ideas in question made conscious renders this theory irrefutable. The state in which the ideas existed before being made conscious is called by us repression, and we assert that the force which instituted the repression and maintains it is perceived as resistance during the work of analysis.
In the further course of psycho-analytic work, however, even these distinctions have proved to be inadequate and, for practical purposes, insufficient. This has become clear in more ways than one; but the decisive instance is as follows. We have formed the idea that in each individual there is a coherent organization of mental processes; and we call this his ego. It is to this ego that consciousness is attached; the ego controls the approaches to motility - that is, to the discharge of excitations into the external world; it is the mental agency which supervises all its own constituent processes, and which goes to sleep at night, though even then it exercises the censorship on dreams. From this ego proceed the repressions, too, by means of which it is sought to exclude certain trends in the mind not merely from consciousness but also from other forms of effectiveness and activity. In analysis these trends which have been shut out stand in opposition to the ego, and the analysis is faced with the task of removing the resistances which the ego displays against concerning itself with the repressed. Now we find during analysis that, when we put certain tasks before the patient, he gets into difficulties; his associations fail when they should be coming near the repressed. We then tell him that he is dominated by a resistance; but he is quite unaware of the fact, and, even if he guesses from his unpleasant feelings that a resistance is now at work in him, he does not know what it is or how to describe it. Since, however, there can be no question but that this resistance emanates from his ego and belongs to it, we find ourselves in an unforeseen situation. We have come upon something in the ego itself which is also unconscious, which behaves exactly like the repressed - that is, which produces powerful effects without itself being conscious and which requires special work before it can be made conscious. From the point of view of analytic practice, the consequence of this discovery is that we land in endless obscurities and difficulties if we keep to our habitual forms of expression and try, for instance, to derive neuroses from a conflict between the conscious and the unconscious. We shall have to substitute for this antithesis another, taken from our insight into the structural conditions of the mind - the antithesis between the coherent ego and the repressed which is split off from it.¹

[1923b, 3951]

But the repressed merges into the id as well, and is merely a part of it. The repressed is only cut off sharply from the ego by the resistances of repression; it can communicate with the ego through the id. We at once realize that almost all the lines of demarcation we have drawn at the instigation of pathology relate only to the superficial strata of the mental apparatus - the only ones known to us. The state of things which we have been describing can be represented diagrammatically (Fig. 1); though it must be remarked that the form chosen has no pretensions to any special applicability, but is merely intended to serve for purposes of exposition. [1923b, 3958]

Is it possible, then, that corroborative dreams are really the result of suggestion, that they are 'obliging' dreams? The patients who produce only corroborative dreams are the same patients in whom doubt plays the principal part in resistance. One makes no attempt at shouting down this doubt by means of one's authority or at reducing it by arguments. It must persist until it is brought to an end in the further course of the analysis. The analyst, too, may himself retain a doubt of the same kind in some particular instances. What makes him certain in the end is precisely the complication of the problem before him, which is like the solution of a jigsaw puzzle. A coloured picture, pasted upon a thin sheet of wood and fitting exactly into a wooden frame, is cut into a large number of pieces of the most irregular and crooked shapes. If one succeeds in arranging the confused heap of fragments, each of which bears upon it an unintelligible piece of drawing, so that the picture acquires a meaning, so that there is no gap anywhere in the design and so that the whole fits into the frame - if all these conditions are fulfilled, then one knows that one has solved the puzzle and that there is no alternative solution. [1923c, 4037]
Let us keep to a habit of our technique and consider first the extreme and unmistakably pathological form of this masochism. I have described elsewhere⁰ how in analytic treatment we come across patients to whom, owing to their behaviour towards its therapeutic influence, we are obliged to ascribe an 'unconscious' sense of guilt. I pointed out the sign by which such people can be recognized (a 'negative therapeutic reaction') and I did not conceal the fact that the strength of such an impulse constitutes one of the most serious resistances and the greatest danger to the success of our medical or educative aims. The satisfaction of this unconscious sense of guilt is perhaps the most powerful bastion in the subject's (usually composite) gain from illness - in the sum of forces which struggle against his recovery and refuse to surrender his state of illness. The suffering entailed by neuroses is precisely the factor that makes them valuable to the masochistic trend. It is instructive, too, to find, contrary to all theory and expectation, that a neurosis which has defied every therapeutic effort may vanish if the subject becomes involved in the misery of an unhappy marriage, or loses all his money, or develops a dangerous organic disease. In such instances one form of suffering has been replaced by another; and we see that all that mattered was that it should be possible to maintain a certain amount of suffering.

[1924c, 4078]

It looked as though our work had been made much more difficult and complicated; but the inestimable gain was that an insight was now obtained into an interplay of forces which had been concealed from the observer by the hypnotic state. It became evident that the work of uncovering what had been pathogenically forgotten had to struggle against a constant and very intense resistance. The critical objections which the patient raised in order to avoid communicating the ideas which occurred to him, and against which the fundamental rule of psycho-analysis was directed, had themselves already been manifestations of this resistance. A consideration of the phenomena of resistance led to one of the corner-stones of the psycho-analytic theory of the neuroses - the theory of repression. It was plausible to suppose that the same forces which were now struggling against the pathogenic material being made conscious had at an earlier time made the same efforts with success. A gap in the aetiology of neurotic symptoms was thus filled. The impressions and mental impulses, for which the symptoms were now serving as substitutes, had not been forgotten without reason or on account of a constitutional incapacity for synthesis (as Janet supposed); they had, though the influence of other mental forces, met with a repression the success and evidence of which was precisely their being debarred from consciousness and excluded from memory. It was only in consequence of this repression that they had become pathogenic - that is, had succeeded in manifesting themselves along unusual paths as symptoms.

[1924f, 4106]

How had it come about that the patients had forgotten so many of the facts of their external and internal lives but could nevertheless recollect them if a particular technique was applied? Observation supplied an exhaustive answer to these questions. Everything that had been forgotten had in some way or other been distressing; it had been either alarming or painful or shameful by the standards of the subject's personality. It was impossible not to conclude that that was precisely why it had been forgotten - that is, why it had not remained conscious. In order to make it conscious again in spite of this, it was necessary to overcome something that fought against one in the patient; it was necessary to make efforts on one's own part so as to urge and compel him to remember. The amount of effort required of the physician varied in different cases; it increased in direct proportion to the difficulty of what had to be remembered. The expenditure of force on the part of the physician was evidently the measure of a resistance on the part of the patient. It was only necessary to translate into words what I myself had observed, and I was in possession of the theory of repression.

[1925d, 4206]
An important element in the theory of repression is the view that repression is not an event that occurs once but that it requires a permanent expenditure. If this expenditure were to cease, the repressed impulse, which is being fed all the time from its sources, would on the next occasion flow along the channels from which it had been forced away, and the repression would either fail in its purpose or would have to be repeated an indefinite number of times. Thus it is because instincts are continuous in their nature that the ego has to make its defensive action secure by a permanent expenditure. This action undertaken to protect repression is observable in analytic treatment as resistance. Resistance presupposes the existence of what I have called anticathexis. An anticathexis of this kind is clearly seen in obsessional neurosis. It appears there in the form of an alteration of the ego, as a reaction-formation in the ego, and is effected by the reinforcement of the attitude which is the opposite of the instinctual trend that has to be repressed - as, for instance, in pity, conscientiousness and cleanliness. These reaction-formations of obsessional neurosis are essentially exaggerations of the normal traits of character which develop during the latency period. The presence of an anticathexis in hysteria is much more difficult to detect, though theoretically it is equally indispensable. In hysteria, too, a certain amount of alteration of the ego through reaction-formation is unmistakable and in some circumstances becomes so marked that it forces itself on our attention as the principal symptom. The conflict due to ambivalence, for instance, is resolved in hysteria by this means. The subject's hatred of a person whom he loves is kept down by an exaggerated amount of tenderness for him and apprehensiveness about him. But the difference between reaction-formations in obsessional neurosis and in hysteria is that in the latter they do not have the universality of a character-trait but are confined to particular relationships. A hysterical woman, for instance, may be specially affectionate with her own children whom at bottom she hates; but she will not on that account be more loving in general than other women or even more affectionate to other children. The reaction-formation of hysteria clings tenaciously to a particular object and never spreads over into a general disposition of the ego, whereas what is characteristic of obsessional neurosis is precisely a spreading-over of this kind - a loosening of relations to the object and a facilitation of displacement in the choice of object.

[1926d, 4310]

It must not be supposed that these emendations provide us with a complete survey of all the kinds of resistance that are met with in analysis. Further investigation of the subject shows that the analyst has to combat no less than five kinds of resistance, emanating from three directions - the ego, the id and the super-ego. The ego is the source of three of these, each differing in its dynamic nature. The first of these three ego-resistances is the repression resistance, which we have already discussed above and about which there is least new to be added. Next there is the transference resistance, which is of the same nature but which has different and much clearer effects in analysis, since it succeeds in establishing a relation to the analytic situation or the analyst himself and thus re-animating a repression which should only have been recollected. The third resistance, though also an ego-resistance, is of quite a different nature. It proceeds from the gain from illness and is based upon an assimilation of the symptom into the ego. It represents an unwillingness to renounce any satisfaction or relief that has been obtained. The fourth variety, arising from the id, is the resistance which, as we have just seen, necessitates 'working-through'. The fifth, coming from the super-ego and the last to be discovered, is also the most obscure though not always the least powerful one. It seems to originate from the sense of guilt or the need for punishment; and it opposes every move towards success, including, therefore, the patient's own recovery through analysis.

[1926d, 4313]
Now, however, another problem awaits us - at the opposite end of the ego, as we might put it. It is presented to us by an observation during the work of analysis, an observation which is actually a very old one. As not infrequently happens, it has taken a long time to come to the point of appreciating its importance. The whole theory of psycho-analysis is, as you know, in fact built up on the perception of the resistance offered to us by the patient when we attempt to make his unconscious conscious to him. The objective sign of this resistance is that his associations fail or depart widely from the topic that is being dealt with. He may also recognize the resistance subjectively by the fact that he has distressing feelings when he approaches the topic. But this last sign may also be absent. We then say to the patient that we infer from his behaviour that he is now in a state of resistance; and he replies that he knows nothing of that, and is only aware that his associations have become more difficult. It turns out that we were right; but in that case his resistance was unconscious too, just as unconscious as the repressed, at the lifting of which we were working. We should long ago have asked the question: from what part of his mind does an unconscious resistance like this arise? The beginner in psycho-analysis will be ready at once with the answer: it is, of course, the resistance of the unconscious. An ambiguous and unserviceable answer! If it means that the resistance arises from the repressed, we must rejoin: certainly not! We must rather attribute to the repressed a strong upward drive, an impulsion to break through into consciousness. The resistance can only be a manifestation of the ego, which originally put the repression into force and now wishes to maintain it. That, moreover, is the view we always took. Since we have come to assume a special agency in the ego, the super-ego, which represents demands of a restrictive and rejecting character, we may say that repression is the work of this super-ego and that it is carried out either by itself or by the ego in obedience to its orders. If then we are met by the case of the resistance in analysis not being conscious to the patient, this means either that in quite important situations the super-ego and the ego can operate unconsciously, or - and this would be still more important - that portions of both of them, the ego and the super-ego themselves, are unconscious. In both cases we have to reckon with the disagreeable discovery that on the one hand (super-) ego and conscious and on the other hand repressed and unconscious are far from coinciding.

We have travelled somewhat far from our basis. I will tell you in retrospect the starting-point of these reflections on the theory of the instincts. It was the same as that which led us to revise the relation between the ego and the unconscious - the impression derived from the work of analysis that the patient who puts up a resistance is so often unaware of that resistance. Not only the fact of the resistance is unconscious to him, however, but its motives as well. We were obliged to search out these motives or motive, and to our surprise we found them in a powerful need for punishment which we could only class with masochistic wishes. The practical significance of this discovery is not less than its theoretical one, for the need for punishment is the worst enemy of our therapeutic efforts. It is satisfied by the suffering which is linked to the neurosis, and for that reason holds fast to being ill. It seems that this factor, an unconscious need for punishment, has a share in every neurotic illness. And here those cases in which the neurotic suffering can be replaced by suffering of another kind are wholly convincing. I will report an experience of this kind.

[1933a, 4677]

[1933a, 4712]
With the mention of resistance we have reached the second and more important part of our task. We have already learnt that the ego protects itself against the invasion of undesired elements from the unconscious and repressed id by means of anticathexes, which must remain intact if it is to function normally. The more hard-pressed the ego feels, the more convulsively it clings (as though in a fright) to these anticathexes, in order to protect what remains of itself from further irruptions. But this defensive purpose does not by any means accord with the aims of our treatment. What we desire, on the contrary, is that the ego, emboldened by the certainty of our help, shall dare to take the offensive in order to reconquer what has been lost. And it is here that we become aware of the strength of these anticathexes in the form of resistances to our work. The ego draws back in alarm from such undertakings, which seem dangerous and threaten unpleasure; it must be constantly encouraged and soothed if it is not to fail us. This resistance, which persists throughout the whole treatment and is renewed at every fresh piece of work, is known, not quite correctly, as the resistance due to repression. We shall find that it is not the only one that faces us. It is interesting to notice that in this situation the party-divisions are to some extent reversed: for the ego struggles against our instigation, while the unconscious, which is ordinarily our opponent, comes to our help, since it has a natural 'upward drive' and desires nothing better than to press forward across its settled frontiers into the ego and so to consciousness. The struggle which develops, if we gain our end and can induce the ego to overcome its resistances, is carried through under our direction and with our assistance. Its outcome is a matter of indifference: whether it results in the ego accepting, after a fresh examination, an instinctual demand which it has hitherto rejected, or whether it dismisses it once more, this time for good and all. In either case a permanent danger has been disposed of, the compass of the ego has been extended and a wasteful expenditure of energy has been made unnecessary.

[1940a [1938], 4988]

At the moment, however, we are not concerned with the pathogenic role of the defensive mechanisms. What we are trying to discover is what influence the alteration of the ego which corresponds to them has upon our therapeutic efforts. The material for an answer to this question is given in the volume by Anna Freud to which I have already referred. The essential point is that the patient repeats these modes of reaction during the work of analysis as well, that he produces them before our eyes, as it were. In fact, it is only in this way that we get to know them. This does not mean that they make analysis impossible. On the contrary, they constitute half of our analytic task. The other half, the one which was first tackled by analysis in its early days, is the uncovering of what is hidden in the id. During the treatment our therapeutic work is constantly swinging backwards and forwards like a pendulum between a piece of id-analysis and a piece of ego-analysis. In the one case we want to make something from the id conscious, in the other we want to correct something in the ego. The crux of the matter is that the defensive mechanisms directed against former danger recur in the treatment as resistances against recovery. It follows from this that the ego treats recovery itself as a new danger.

[1937c, 5034]
The therapeutic effect depends on making conscious what is repressed, in the widest sense of the word, in the id. We prepare the way for this making conscious by interpretations and constructions, but we have interpreted only for ourselves not for the patient so long as the ego holds on to its earlier defences and does not give up its resistances. Now these resistances, although they belong to the ego, are nevertheless unconscious and in some sense separated off within the ego. The analyst recognizes them more easily than he does the hidden material in the id. One might suppose that it would be sufficient to treat them like portions of the id and, by making them conscious, bring them into connection with the rest of the ego. In this way, we should suppose, one half of the task of analysis would be accomplished; we should not reckon on meeting with a resistance against the uncovering of resistances. But what happens is this. During the work on the resistances the ego withdraws - with a greater or less degree of seriousness - from the agreement on which the analytic situation is founded. The ego ceases to support our efforts at uncovering the id; it opposes them, disobeys the fundamental rule of analysis, and allows no further derivatives of the repressed to emerge. We cannot expect the patient to have a strong conviction of the curative power of analysis. He may have brought along with him a certain amount of confidence in his analyst, which will be strengthened to an effective point by the factors of the positive transference which will be aroused in him. Under the influence of the unpleasurable impulses which he feels as a result of the fresh activation of his defensive conflicts, negative transferences may now gain the upper hand and completely annul the analytic situation. The patient now regards the analyst as no more than a stranger who is making disagreeable demands on him, and he behaves towards him exactly like a child who does not like the stranger and does not believe anything he says. If the analyst tries to explain to the patient one of the distortions made by him for the purposes of defence, and to correct it, he finds him uncomprehending and inaccessible to sound arguments. Thus we see that there is a resistance against the uncovering of resistances, and the defensive mechanisms really do deserve the name which we gave them originally, before they had been more closely examined. They are resistances not only to the making conscious of contents of the id, but also to the analysis as a whole, and thus to recovery.

With the recognition that the properties of the ego which we meet with in the form of resistances can equally well be determined by heredity as acquired in defensive struggles, the topographical distinction between what is ego and what is id loses much of its value for our investigation. If we advance a step further in our analytic experience, we come upon resistances of another kind, which we can no longer localize and which seem to depend on fundamental conditions in the mental apparatus. I can only give a few examples of this type of resistance; the whole field of enquiry is still bewilderingly strange and insufficiently explored. We come across people, for instance, to whom we should be inclined to attribute a special 'adhesiveness of the libido'. The processes which the treatment sets in motion in them are so much slower than in other people because, apparently, they cannot make up their minds to detach libidinal cathexes from one object and displace them on to another, although we can discover no special reason for this cathetic loyalty. One meets with the opposite type of person, too, in whom the libido seems particularly mobile; it enters readily upon the new cathexes suggested by analysis, abandoning its former ones in exchange for them. The difference between the two types is comparable to the one felt by a sculptor, according to whether he works in hard stone or soft clay. Unfortunately, in this second type the results of analysis often turn out to be very impermanent: the new cathexes are soon given up once more, and we have an impression, not of having worked in clay, but of having written on water. In the words of the proverb: 'Soon got, soon gone.'
A plain 'Yes' from a patient is by no means unambiguous. It can indeed signify that he recognizes the correctness of the construction that has been presented to him; but it can also be meaningless, or can even deserve to be described as 'hypocritical', since it may be convenient for his resistance to make use of an assent in such circumstances in order to prolong the concealment of a truth that has not been discovered. The 'Yes' has no value unless it is followed by indirect confirmations, unless the patient, immediately after his 'Yes', produces new memories which complete and extend the construction. Only in such an event do we consider that the 'Yes' has dealt completely with the subject under discussion.
[1937d, 5054]

A 'No' from a person in analysis is quite as ambiguous as a 'Yes', and is indeed of even less value. In some rare cases it turns out to be the expression of a legitimate dissent. Far more frequently it expresses a resistance which may have been evoked by the subject-matter of the construction that has been put forward but which may just as easily have arisen from some other factor in the complex analytic situation. Thus, a patient's 'No' is no evidence of the correctness of a construction, though it is perfectly compatible with it. Since every such construction is an incomplete one, since it covers only a small fragment of the forgotten events, we are free to suppose that the patient is not in fact disputing what has been said to him but is basing his contradiction upon the part that has not yet been uncovered. As a rule he will not give his assent until he has learnt the whole truth - which often covers a very great deal of ground. So that the only safe interpretation of his 'No' is that it points to incompleteness; there can be no doubt that the construction has not told him everything.
[1937d, 5054]
The factor of resistance has become one of the corner-stones of his theory. The ideas which are normally pushed aside on every sort of excuse - such as those mentioned above - are regarded by him as derivatives of the repressed psychical phenomena (thoughts and impulses), distorted owing to the resistance against their reproduction. Ideas which are normally pushed aside on every sort of excuse - such as those mentioned above - are regarded by him as derivatives of the repressed psychical phenomena (thoughts and impulses), distorted owing to the resistance against their reproduction.

[1904a, 1557]

The greater the resistance, the greater is the distortion. The value of these unintentional thoughts for the purposes of therapeutic technique lies in this relation of theirs to the repressed psychical material. If one possesses a procedure which makes it possible to arrive at the repressed material from the associations, at the distorted material from the distortions, then what was formerly unconscious in mental life can be made accessible to consciousness even without hypnosis.

[1904a, 1558]
I did not abandon it, however, before the observations I made during my use of it afforded me decisive evidence. I found confirmation of the fact that the forgotten memories were not lost. They were in the patient's possession and were ready to emerge in association to what was still known by him; but there was some force that prevented them from becoming conscious and compelled them to remain unconscious. The existence of this force could be assumed with certainty, since one became aware of an effort corresponding to it if, in opposition to it, one tried to introduce the unconscious memories into the patient's consciousness. The force which was maintaining the pathological condition became apparent in the form of resistance on the part of the patient.

[1910a, 2212]

It may seem surprising that this method of free association, carried out subject to the observation of the fundamental rule of psycho-analysis, should have achieved what was expected of it, namely the bringing into consciousness of the repressed material which was held back by resistances. We must, however, bear in mind that free association is not really free. The patient remains under the influence of the analytic situation even though he is not directing his mental activities on to a particular subject. We shall be justified in assuming that nothing will occur to him that has not some reference to that situation. His resistance against reproducing the repressed material will now be expressed in two ways. Firstly it will be shown by critical objections; and it was to deal with these that the fundamental rule of psycho-analysis was invented. But if the patient observes that rule and so overcomes his reticences, the resistance will find another means of expression. It will so arrange it that the repressed material itself will never occur to the patient but only something which approximates to it in an allusive way; and the greater the resistance, the more remote from the actual idea that the analyst is in search of will be the substitutive association which the patient has to report. The analyst, who listens composedly but without any constrained effort to the stream of associations and who, from his experience, has a general notion of what to expect, can make use of the material brought to light by the patient according to two possibilities. If the resistance is slight he will be able from the patient's allusions to infer the unconscious material itself; or if the resistance is stronger he will be able to recognize its character from the associations, as they seem to become more remote from the topic in hand, and will explain it to the patient. Uncovering the resistance, however, is the first step towards overcoming it. Thus the work of analysis involves an art of interpretation, the successful handling of which may require tact and practice but which is not hard to acquire. But it is not only in the saving of labour that the method of free association has an advantage over the earlier method. It exposes the patient to the least possible amount of compulsion, it never allows of contact being lost with the actual current situation, it guarantees to a great extent that no factor in the structure of the neurosis will be overlooked and that nothing will be introduced into it by the expectations of the analyst. It is left to the patient in all essentials to determine the course of the analysis and the arrangement of the material; any systematic handling of particular symptoms or complexes thus becomes impossible. In complete contrast to what happened with hypnotism and with the urging method, interrelated material makes its appearance at different times and at different points in the treatment. To a spectator, therefore - though in fact there must be none - an analytic treatment would seem completely obscure.

[1925d, 4216]
Thus we have attributed three qualities to psychical processes: they are either conscious, preconscious or unconscious. The division between the three classes of material which possess these qualities is neither absolute nor permanent. What is preconscious becomes conscious, as we have seen, without any assistance from us; what is unconscious can, through our efforts, be made conscious, and in the process we may have a feeling that we are often overcoming very strong resistances. When we attempt to do this with someone else, we should not forget that the conscious filling-in of the gaps in his perceptions - the construction we are presenting him with - does not mean as yet that we have made the unconscious material in question conscious to him. All that is true so far is that the material is present in him in two records, once in the conscious reconstruction he has been given, and besides this in its original unconscious state. Our continued efforts usually succeed eventually in making this unconscious material conscious to him himself, as a result of which the two records are brought to coincide. The amount of effort we have to use, by which we estimate the resistance against the material becoming conscious, varies in magnitude in individual cases. For instance, what comes about in an analytic treatment as a result of our efforts can also occur spontaneously: material which is ordinarily unconscious can transform itself into preconscious material and then becomes conscious - a thing that happens to a large extent in psychotic states. From this we infer that the maintenance of certain internal resistances is a *sine qua non* of normality. A relaxation of resistances such as this, with a consequent pushing forward of unconscious material, takes place regularly in the state of sleep, and thus brings about a necessary precondition for the construction of dreams. Conversely, preconscious material can become temporarily inaccessible and cut off by resistances, as happens when something is temporarily forgotten or escapes the memory; or a preconscious thought can even be temporarily put back into the unconscious state, as seems to be a precondition in the case of jokes. We shall see that a similar transformation back of preconscious material or processes into the unconscious state plays a great part in the causation of neurotic disorders.

[1940a [1938], 4970]
Instead of being annoyed by the dreamer's disobedience, we may take advantage of these experiences by learning something new from them - something which is all the more important the less we are expecting it. We perceive that the work of interpreting dreams is carried out in the face of a resistance, which opposes it and of which the critical objections are manifestations. This resistance is independent of the dreamer's theoretical conviction. We learn still more, indeed. We discover that a critical objection of this kind never turns out to be justified. On the contrary, the ideas which people try to suppress in this way turn out invariably to be the most important ones and those which are decisive in our search for the unconscious material. It amounts, in fact, to a special distinguishing mark, if an idea is accompanied by an objection like this. [1916-1917, 3211]

This resistance is something entirely new: a phenomenon which we have come upon in connection with our premisses, but one which was not included among them. The appearance of this new factor in our reckoning comes to us as a not altogether pleasant surprise. We suspect at once that it is not going to make our work any easier. It might mislead us into abandoning our whole concern with dreams: something so unimportant as a dream and, on top of that, all these difficulties instead of a simple straightforward technique! But, on the other hand, the difficulties might act precisely as a stimulus and make us suspect that the work will be worth the trouble. We regularly come up against resistance when we try to make our way forward from the substitute which is the dream-element to the unconscious material hidden behind it. So we may conclude that there must be something of importance concealed behind the substitute. Otherwise, what is the point of the difficulties that are trying to keep the concealment going? If a child refuses to open his clenched fist to show what he has in it, we may feel sure that it is something wrong - something he ought not to have. [1916-1917, 3212]

The moment we introduce the dynamic idea of a resistance into the facts of the case, we must simultaneously reflect that this factor is something variable in quantity. There may be greater and smaller resistances, and we are prepared to find these differences showing themselves during our work as well. We may perhaps be able to link with this another experience we also meet with during the work of interpreting dreams: sometimes it requires only a single response, or no more than a few, to lead us from a dream-element to the unconscious material behind it, while on other occasions long chains of associations and the overcoming of many critical objections are required for bringing this about. We shall conclude that these differences relate to the changing magnitude of the resistance, and we shall probably turn out to be right. If the resistance is small, the substitute cannot be far distant from the unconscious material; but a greater resistance means that the unconscious material will be greatly distorted and that the path will be a long one from the substitute back to the unconscious material. [1916-1917, 3212]
In the first place, then, when we undertake to restore a patient to health, to relieve him of the symptoms of his illness, he meets us with a violent and tenacious resistance, which persists throughout the whole length of the treatment. This is such a strange fact that we cannot expect it to find much credence. It is best to say nothing about it to the patient's relatives, for they invariably regard it as an excuse on our part for the length or failure of our treatment. The patient, too, produces all the phenomena of this resistance without recognizing it as such, and if we can induce him to take our view of it and to reckon with its existence, that already counts as a great success. Only think of it! The patient, who is suffering so much from his symptoms and is causing those about him to share his sufferings, who is ready to undertake so many sacrifices in time, money, effort and self-discipline in order to be freed from those symptoms we are to believe that this same patient puts up a struggle in the interest of his illness against the person who is helping him. How improbable such an assertion must sound! Yet it is true; and when its improbability is pointed out to us, we need only reply that it is not without analogies. A man who has gone to the dentist because of an unbearable toothache will nevertheless try to hold the dentist back when he approaches the sick tooth with a pair of forceps.

The patient's resistance is of very many sorts, extremely subtle and often hard to detect; and it exhibits protean changes in the forms in which it manifests itself. The doctor must be distrustful and remain on his guard against it.

The first thing we achieve by setting up this fundamental technical rule is that it becomes the target for the attacks of the resistance. The patient endeavours in every sort of way to extricate himself from its provisions. At one moment he declares that nothing occurs to him, at the next that so many things are crowding in on him that he cannot get hold of anything. Presently we observe with pained astonishment that he has given way first to one and then to another critical objection: he betrays this to us by the long pauses that he introduces into his remarks. He then admits that there is something he really cannot say - he would be ashamed to; and he allows this reason to prevail against his promise. Or he says that something has occurred to him, but it concerns another person and not himself and is therefore exempt from being reported. Or, what has now occurred to him is really too unimportant, too silly and senseless: I cannot possibly have meant him to enter into thoughts like that. So it goes on in innumerable variations, and one can only reply that 'to say everything' really does mean 'to say everything'.

[1916-1917, 3362]

[1916-1917, 3363]
It now appears as an *intellectual* resistance, it fights by means of arguments and exploits all the difficulties and improbabilities which normal but uninstructed thinking finds in the theories of analysis. It is now our fate to hear from this single voice all the criticisms and objections which assail our ears in a chorus in the scientific literature of the subject. And for this reason none of the shouts that reach us from outside sound unfamiliar. It is a regular storm in a tea-cup. But the patient is willing to be argued with; he is anxious to get us to instruct him, teach him, contradict him, introduce him to the literature, so that he can find further instruction. He is quite ready to become an adherent of psycho-analysis - on condition that analysis spares him personally. But we recognize this curiosity as a resistance, as a diversion from our particular tasks, and we repel it. In the case of an obsessional neurotic we have to expect special tactics of resistance. He will often allow the analysis to proceed on its way uninhibited, so that it is able to shed an ever-increasing light upon the riddle of his illness. We begin to wonder in the end, however, why this enlightenment is accompanied by no practical advance, no diminution of the symptoms. We are then able to realize that resistance has withdrawn on to the doubt belonging to the obsessional neurosis and from that position is successfully defying us. It is as though the patient were saying: 'Yes, that's all very nice and interesting, and I'll be very glad to go on with it further. It would change my illness a lot if it were true. But I don't in the least believe that it is true; and, so long as I don't believe it, it makes no difference to my illness.' Things can proceed like this for a long time, till finally one comes up against this uncommitted attitude itself, and the decisive struggle then breaks out.

*1916-1917, 3364*

Intellectual resistances are not the worst; one always remains superior to them. But the patient also knows how to put up resistances, without going outside the framework of the analysis, the overcoming of which is among the most difficult of technical problems. Instead of remembering, he *repeats* attitudes and emotional impulses from his early life which can be used as a resistance against the doctor and the treatment by means of what is known as 'transference'. If the patient is a man, he usually extracts this material from his relation to his father, into whose place he fits the doctor, and in that way he makes resistances out of his efforts to become independent in himself and in his judgements, out of his ambition, the first aim of which was to do things as well as his father or to get the better of him, or out of his unwillingness to burden himself for the second time in his life with a load of gratitude. Thus at times one has an impression that the patient has entirely replaced his better intention of making an end to his illness by the alternative one of putting the doctor in the wrong, of making him realize his impotence and of triumphing over him. Women have a masterly gift for exploiting an affectionate, erotically tinged transference to the doctor for the purposes of resistance. If this attachment reaches a certain height, all their interest in the immediate situation in the treatment and all the obligations they undertook at its commencement vanish; their jealousy, which is never absent, and their exasperation at their inevitable rejection, however considerately expressed, are bound to have a damaging effect on their personal understanding with the doctor and so to put out of operation one of the most powerful motive forces of the analysis.

*1916-1917, 3365*
Resistances of this kind should not be one-sidedly condemned. They include so much of the most important material from the patient's past and bring it back in so convincing a fashion that they become some of the best supports of the analysis if a skilful technique knows how to give them the right turn. Nevertheless, it remains a remarkable fact that this material is always in the service of the resistance to begin with and brings to the fore a façade that is hostile to the treatment. It may also be said that what is being mobilized for fighting against the alterations we are striving for are character-traits, attitudes of the ego. In this connection we discover that these character-traits were formed in relation to the determinants of the neurosis and in reaction against its demands, and we come upon traits which cannot normally emerge, or not to the same extent, and which may be described as latent. Nor must you get an impression that we regard the appearance of these resistances as an unforeseen risk to analytic influence. No, we are aware that these resistances are bound to come to light; in fact we are dissatisfied if we cannot provoke them clearly enough and are unable to demonstrate them to the patient. Indeed we come finally to understand that the overcoming of these resistances is the essential function of analysis and is the only part of our work which gives us an assurance that we have achieved something with the patient.

If you further consider that the patient makes all the chance events that occur during his analysis into interferences with it, that he uses as reasons for slackening his efforts every diversion outside the analysis, every comment by a person of authority in his environment who is hostile to analysis, any chance organic illness or any that complicates his neurosis and, even, indeed, every improvement in his condition - if you consider all this, you will have obtained an approximate, though still incomplete, picture of the forms and methods of the resistance, the struggle against which accompanies every analysis.

I have treated this point in such great detail because I must now inform you that this experience of ours with the resistance of neurotics to the removal of their symptoms became the basis of our dynamic view of the neuroses. Originally Breuer and I myself carried out psychotherapy by means of hypnosis; Breuer's first patient was treated throughout under hypnotic influence, and to begin with I followed him in this. I admit that at that period the work proceeded more easily and pleasantly, and also in a much shorter time. But results were capricious and not lasting; and for that reason I finally dropped hypnosis. And I then understood that an insight into the dynamics of these illnesses had not been possible so long as hypnosis was employed. That state was precisely able to withhold the existence of the resistance from the doctor's perception. It pushed the resistance back, making a certain area free for analytic work, and dammed it up at the frontiers of that area in such a way as to be impenetrable, just as doubt does in obsessional neurosis. For that reason I have been able to say that psycho-analysis proper began when I dispensed with the help of hypnosis.
If, however, the recognition of resistance has become so important, we should do well to find room for a cautious doubt whether we have not been too light-heartedly assuming resistances. Perhaps there really are cases of neurosis in which associations fail for other reasons, perhaps the arguments against our hypotheses really deserve to have their content examined, and perhaps we are doing patients an injustice in so conveniently setting aside their intellectual criticisms as resistance. But, Gentlemen, we did not arrive at this judgement lightly. We have had occasion to observe all these critical patients at the moment of the emergence of a resistance and after its disappearance. For resistance is constantly altering its intensity during the course of a treatment; it always increases when we are approaching a new topic, it is at its most intense while we are at the climax of dealing with that topic, and it dies away when the topic has been disposed of. Nor do we ever, unless we have been guilty of special clumsiness in our technique, have to meet the full amount of resistance of which a patient is capable. We have therefore been able to convince ourselves that on countless occasions in the course of his analysis the same man will abandon his critical attitude and then take it up again. If we are on the point of bringing a specially distressing piece of unconscious material to his consciousness, he is extremely critical; he may previously have understood and accepted a great deal, but now it is just as though those acquisitions have been swept away; in his efforts for opposition at any price, he may offer a complete picture of someone who is an emotional imbecile. But if we succeed in helping him to overcome this new resistance, he recovers his insight and understanding. Thus his critical faculty is not an independent function, to be respected as such, it is the tool of his emotional attitudes and is directed by his resistance. If there is something he does not like, he can put up a shrewd fight against it and appear highly critical; but if something suits his book, he can, on the contrary, show himself most credulous. Perhaps none of us are very different; a man who is being analysed only reveals this dependence of the intellect upon emotional life so clearly because in analysis we are putting such great pressure on him.

How, then, do we account for our observation that the patient fights with such energy against the removal of his symptoms and the setting of his mental processes on a normal course? We tell ourselves that we have succeeded in discovering powerful forces here which oppose any alteration of the patient's condition; they must be the same ones which in the past brought this condition about. During the construction of his symptoms something must have taken place which we can now reconstruct from our experiences during the resolution of his symptoms. We already know from Breuer's observation that there is a precondition for the existence of a symptom: some mental process must not have been brought to an end normally - so that it could become conscious. The symptom is a substitute for what did not happen at that point. We now know the point at which we must locate the operation of the force which we have surmised. A violent opposition must have started against the entry into consciousness of the questionable mental process, and for that reason it remained unconscious. As being something unconscious, it had the power to construct a symptom. This same opposition, during psychoanalytic treatment, sets itself up once more against our effort to transform what is unconscious into what is conscious. This is what we perceive as resistance. We have proposed to give the pathogenic process which is demonstrated by the resistance the name of repression.
The crudest idea of these systems is the most convenient for us - a spatial one. Let us therefore compare the system of the unconscious to a large entrance hall, in which the mental impulses jostle one another like separate individuals. Adjoining this entrance hall there is a second, narrower, room - a kind of drawing-room - in which consciousness, too, resides. But on the threshold between these two rooms a watchman performs his function: he examines the different mental impulses, acts as a censor, and will not admit them into the drawing-room if they displease him. You will see at once that it does not make much difference if the watchman turns away a particular impulse at the threshold itself or if he pushes it back across the threshold after it has entered the drawing-room. This is merely a question of the degree of his watchfulness and of how early he carries out his act of recognition. If we keep to this picture, we shall be able to extend our nomenclature further. The impulses in the entrance hall of the unconscious are out of sight of the conscious, which is in the other room; to begin with they must remain unconscious. If they have already pushed their way forward to the threshold and have been turned back by the watchman, then they are inadmissible to consciousness; we speak of them as repressed. But even the impulses which the watchman has allowed to cross the threshold are not on that account necessarily conscious as well; they can only become so if they succeed in catching the eye of consciousness. We are therefore justified in calling this second room the system of the preconscious. In that case becoming conscious retains its purely descriptive sense. For any particular impulse, however, the vicissitude of repression consists in its not being allowed by the watchman to pass from the system of the unconscious into that of the preconscious. It is the same watchman whom we get to know as resistance when we try to lift the repression by means of the analytic treatment.

[1916-1917, 3369]

In your contact as doctors with neurotics, Gentlemen, you will soon give up expecting that the ones who raise the most lamentations and complaints about their illness will be the most eager to co-operate and will offer you the least resistance. It is rather the opposite. But of course you will easily realize that everything that contributes to the gain from illness will intensify the resistance due to repression and will increase the therapeutic difficulties. But to the portion of gain from illness which is, so to say, born with the illness we have to add another portion which arises later. When a psychical organization like an illness has lasted for some time, it behaves eventually like an independent organism; it manifests something like a self-preservative instinct; it establishes a kind of modus vivendi between itself and other parts of the mind, even with those which are at bottom hostile to it; and there can scarcely fail to be occasions when it proves once again useful and expedient and acquires, as it were, a secondary function which strengthens its stability afresh. Instead of an example from pathology, let us take a glaring instance from daily life. A capable working-man, who earns his living, is crippled by an accident in the course of his occupation. The injured man can no longer work, but eventually he obtains a small disablement pension, and he learns how to exploit his mutilation by begging. His new, though worsened, means of livelihood is based precisely on the very thing that deprived him of his former means of livelihood. If you could put an end to his injury you would make him, to begin with, without means of subsistence; the question would arise of whether he was still capable of taking up his earlier work again. What corresponds in the case of neuroses to a secondary exploitation like this of an illness may be described as the secondary gain from illness in contrast to the primary one.

[1916-1917, 3437]
I have now led you into the region in which the next advances in the work of analysis are to be expected. Since we have ventured to operate with the concept of ego-libido the narcissistic neuroses have become accessible to us; the task before us is to arrive at a dynamic elucidation of these disorders and at the same time to complete our knowledge of mental life by coming to understand the ego. The ego-psychology after which we are seeking must not be based on the data of our self-perceptions but (as in the case of the libido) on the analysis of disturbances and disruptions of the ego. It is likely that we shall have a low opinion of our present knowledge of the vicissitudes of the libido, which we have gained from a study of the transference neuroses, when we have achieved this greater task. But hitherto we have not made much progress with it. The narcissistic neuroses can scarcely be attacked with the technique that has served us with the transference neuroses. You will soon learn why. What always happens with them is that, after proceeding for a short distance, we come up against a wall which brings us to a stop. Even with the transference neuroses, as you know, we met with barriers of resistance, but we were able to demolish them bit by bit. In the narcissistic neuroses the resistance is unconquerable; at the most, we are able to cast an inquisitive glance over the top of the wall and spy out what is going on on the other side of it. Our technical methods must accordingly be replaced by others; and we do not know yet whether we shall succeed in finding substitute. Nevertheless, we have no lack of material with these patients either. They make a large number of remarks, even if they do not answer our questions, and for the time being it is our business to interpret these remarks with the help of the understanding we have gained from the symptoms of the transference neuroses. The agreement is great enough to guarantee us some initial advantage. It remains to be seen how far this technique will take us.

What, then, must we do in order to replace what is unconscious in our patients by what is conscious? There was a time when we thought this was a very simple matter: all that was necessary was for us to discover this unconscious material and communicate it to the patient. But we know already that this was a short-sighted error. Our knowledge about the unconscious material is not equivalent to his knowledge; if we communicate our knowledge to him, he does not receive it instead of his unconscious material but beside it; and that makes very little change in it. We must rather picture this unconscious material topographically, we must look for it in his memory at the place where it became unconscious owing to a repression. The repression must be got rid of - after which the substitution of the conscious material for the unconscious can proceed smoothly. How, then, do we lift a repression of this kind? Here our task enters a second phase. First, the search for the repression and then the removal of the resistance which maintains the repression.
There is every reason now for us to improve our earlier dynamic account of the therapeutic process and to bring it into harmony with our new realization. If the patient is to fight his way through the normal conflict with the resistances which we have uncovered for him in the analysis, he is in need of a powerful stimulus which will influence the decision in the sense which we desire, leading to recovery. Otherwise it might happen that he would choose in favour of repeating the earlier outcome and would allow what had been brought up into consciousness to slip back again into repression. At this point what turns the scale in his struggle is not his intellectual insight which is neither strong enough nor free enough for such an achievement - but simply and solely his relation to the doctor. In so far as his transference bears a 'plus' sign, it clothes the doctor with authority and is transformed into belief in his communications and explanations. In the absence of such a transference, or if it is a negative one, the patient would never even give a hearing to the doctor and his arguments. In this his belief is repeating the story of its own development; it is a derivative of love and, to start with, needed no arguments. Only later did he allow them enough room to submit them to examination, provided they were brought forward by someone he loved. Without such supports arguments carried no weight, and in most people's lives they never do. Thus in general a man is only accessible from the intellectual side too, in so far as he is capable of a libidinal cathexis of objects; and we have good reason to recognize and to dread in the amount of his narcissism a barrier against the possibility of being influenced by even the best analytic technique.

[1916-1917, 3487]

The acceptance of suggestions on individual points is no doubt discouraged by the fact that during the treatment we are struggling unceasingly against resistances which are able to transform themselves into negative (hostile) transferences. Nor must we fail to point out that a large number of the individual findings of analysis, which might otherwise be suspected to being products of suggestion, are confirmed from another and irreproachable source. Our guarantors in this case are the sufferers from dementia praecox and paranoia, who are of course far above any suspicion of being influenced by suggestion. The translations of symbols and the phantasies, which these patients produce for us and which in them have forced their way through into consciousness, coincide faithfully with the results of our investigations into the unconscious of transference neurotics and thus confirm the objective correctness of our interpretations, on which doubt is so often thrown. You will not, I think, be going astray if you trust analysis on these points.

[1916-1917, 3493]
Many attempts at treatment miscarried during the early period of analysis because they were undertaken in cases which were altogether unsuited to the procedure and which we should exclude to-day on the basis of our present view of the indications for treatment. But these indications, too, could only be arrived at by experiment. In those days we did not know a priori that paranoia and dementia praecox in strongly marked forms are inaccessible, and we had a right to make trial of the method on all kinds of disorders. But most of the failures of those early years were due not to the doctor's fault or an unsuitable choice of patients but to unfavourable external conditions. Here we have only dealt with internal resistances, those of the patient, which are inevitable and can be overcome. The external resistances which arise from the patient's circumstances, from his environment, are of small theoretical interest but of the greatest practical importance. Psycho-analytic treatment may be compared with a surgical operation and may similarly claim to be carried out under arrangements that will be the most favourable for its success. You know the precautionary measures adopted by a surgeon: a suitable room, good lighting, assistants, exclusion of the patient's relatives, and so on. Ask yourselves now how many of these operations would turn out successfully if they had to take place in the presence of all the members of the patient's family, who would stick their noses into the field of the operation and exclaim aloud at every incision. In psycho-analytic treatments the intervention of relatives is a positive danger and a danger one does not know how to meet. One is armed against the patient's internal resistances which one knows are inevitable, but how can one ward off these external resistances? No kind of explanations make any impression on the patient's relatives; they cannot be induced to keep at a distance from the whole business, and one cannot make common cause with them because of the risk of losing the confidence of the patient, who - quite rightly moreover - expects the person in whom he has put his trust to take his side. No one who has any experience of the rifts which so often divide a family will, if he is an analyst, be surprised to find that the patient's closest relatives sometimes betray less interest in his recovering than in his remaining as he is. When, as so often, the neurosis is related to conflicts between members of a family, the healthy party will not hesitate long in choosing between his own interest and the sick party's recovery. It is not to be wondered at, indeed, if a husband looks with disfavour on a treatment in which, as he may rightly suspect, the whole catalogue of his sins will be brought to light. Nor do we wonder at it; but we cannot in that case blame ourselves if our efforts remain unsuccessful and the treatment is broken off prematurely because the husband's resistance is added to that of his sick wife. We had in fact undertaken something which in the prevailing circumstances was unrealizable. [1916-1917, 3498]

Thus the course of this treatment illustrates a maxim whose truth has long been appreciated in the technique of analysis. The length of the road over which an analysis must travel with the patient, and the quantity of material which must be mastered on the way, are of no importance in comparison with the resistance which is met with in the course of the work, and are only of importance at all in so far as they are necessarily proportional to the resistance. The situation is the same as when to-day an enemy army needs weeks and months to make its way across a stretch of country which in times of peace was traversed by an express train in a few hours and which only a short time before had been passed over by the defending army in a few days. [1918b, 3507]
We have formulated our task as physicians thus: to bring to the patient's knowledge the unconscious, repressed impulses existing in him, and, for that purpose, to uncover the resistances that oppose this extension of his knowledge about himself. Does the uncovering of these resistances guarantee that they will also be overcome? Certainly not always; but our hope is to achieve this by exploiting the patient's transference to the person of the physician, so as to induce him to adopt our conviction of the inexpediency of the repressive process established in childhood and of the impossibility of conducting life on the pleasure principle. I have set out elsewhere the dynamic conditions prevailing in the fresh conflict through which we lead the patient and which we substitute in him for his previous conflict - that of his illness. I have nothing at the moment to alter in that account.

[1919a, 3628]

In order to make it easier to understand this 'compulsion to repeat', which emerges during the psycho-analytic treatment of neurotics, we must above all get rid of the mistaken notion that what we are dealing with in our struggle against resistances is resistance on the part of the unconscious. The unconscious - that is to say, the 'repressed' - offers no resistance whatever to the efforts of the treatment. Indeed, it itself has no other endeavour than to break through the pressure weighing down on it and force its way either to consciousness or to a discharge through some real action. Resistance during treatment arises from the same higher strata and systems of the mind which originally carried out repression. But the fact that, as we know from experience, the motives of the resistances, and indeed the resistances themselves, are unconscious at first during the treatment, is a hint to us that we should correct a shortcoming in our terminology. We shall avoid a lack of clarity if we make our contrast not between the conscious and the unconscious but between the coherent ego and the repressed. It is certain that much of the ego is itself unconscious, and notably what we may describe as its nucleus; only a small part of it is covered by the term 'preconscious'. Having replaced a purely descriptive terminology by one which is systematic or dynamic, we can say that the patient's resistance arises from his ego, and we then at once perceive that the compulsion to repeat must be ascribed to the unconscious repressed. It seems probable that the compulsion can only express itself after the work of treatment has gone half-way to meet it and has loosened the repression.¹

[1920g, 3724]

There is no doubt that the resistance of the conscious and unconscious ego operates under the sway of the pleasure principle: it seeks to avoid the unpleasure which would be produced by the liberation of the repressed. Our efforts, on the other hand, are directed towards procuring the toleration of that unpleasure by an appeal to the reality principle. But how is the compulsion to repeat - the manifestation of the power of the repressed - related to the pleasure principle? It is clear that the greater part of what is re-experienced under the compulsion to repeat must cause the ego unpleasure, since it brings to light activities of repressed instinctual impulses. That, however, is unpleasure of a kind we have already considered and does not contradict the pleasure principle: unpleasure for one system and simultaneously satisfaction for the other. But we come now to a new and remarkable fact, namely that the compulsion to repeat also recalls from the past experiences which include no possibility of pleasure, and which can never, even long ago, have brought satisfaction even to instinctual impulses which have since been repressed.

[1920g, 3725]
But it is to be noted that only in rare instances can we observe the pure effects of the compulsion to repeat, unsupported by other motives. In the case of children’s play we have already laid stress on the other ways in which the emergence of the compulsion may be interpreted; the compulsion to repeat and instinctual satisfaction which is immediately pleasurable seem to converge here into an intimate partnership. The phenomena of transference are obviously exploited by the resistance which the ego maintains in its pertinacious insistence upon repression; the compulsion to repeat, which the treatment tries to bring into its service is, as it were, drawn over by the ego to its side (clinging as the ego does to the pleasure principle). A great deal of what might be described as the compulsion of destiny seems intelligible on a rational basis; so that we are under no necessity to call in a new and mysterious motive force to explain it.

[1920g, 3727]

Trotter gives as the list of instincts which he considers as primary those of self-preservation, of nutrition, of sex, and of the herd. The last often comes into opposition with the others. The feelings of guilt and of duty are the peculiar possessions of a gregarious animal. Trotter also derives from the herd instinct the repressive forces which psycho-analysis has shown to exist in the ego, and from the same source accordingly the resistances which the physician comes up against in psycho-analytic treatment. Speech owes its importance to its aptitude for mutual understanding in the herd, and upon it the identification of the individuals with one another largely rests.

[1921c, 3810]

In the girl’s account of her conscious motives the father did not figure at all; there was not even any mention of fear of his anger. In the motives laid bare by the analysis, on the other hand, he played the principal part. Her relation to her father had the same decisive importance for the course and outcome of the analytic treatment, or rather, analytic exploration. Behind her pretended consideration for her parents, for whose sake she had been willing to make the attempt to be transformed, lay concealed her attitude of defiance and revenge against her father which held her fast to her homosexuality. Secure under this cover, the resistance set a considerable region free to analytic investigation. The analysis went forward almost without any signs of resistance, the patient participating actively with her intellect, though absolutely tranquil emotionally. Once when I expounded to her a specially important part of the theory, one touching her nearly, she replied in an inimitable tone, ‘How very interesting’, as though she were a grande dame being taken over a museum and glancing through her lorgnon at objects to which she was completely indifferent. The impression one had of her analysis was not unlike that of a hypnotic treatment, where the resistance has in the same way withdrawn to a certain boundary line, beyond which it proves to be unconquerable. The resistance very often pursues similar tactics - Russian tactics, as they might be called - in cases of obsessional neurosis. For a time, consequently, these cases yield the clearest results and permit a deep insight into the causation of the symptoms. But presently one begins to wonder how it is that such marked progress in analytic understanding can be unaccompanied by even the slightest change in the patient’s compulsions and inhibitions, until at last one perceives that everything that has been accomplished is subject to a mental reservation of doubt, and that behind this protective barrier the neurosis can feel secure. 'It would be all very fine,' thinks the patient, often quite consciously, ‘if I were obliged to believe what the man says, but there is no question of that, and so long as this is so I need change nothing.’ Then, when one comes to close quarters with the motives for this doubt, the fight with the resistances breaks out in earnest.

[1920a, 3852]
The Theory of Repression. - These theoretical considerations, taken together with the immediate impressions derived from analytic work, lead to a view of the neuroses which may be described in the roughest outline as follows. The neuroses are the expression of conflicts between the ego and such of the sexual impulses as seem to the ego incompatible with its integrity or with its ethical standards. Since these impulses are not ego-syntonic, the ego has repressed them: that is to say, it has withdrawn its interest from them and has shut them off from becoming conscious as well as from obtaining satisfaction by motor discharge. If in the course of analytic work one attempts to make these repressed impulses conscious, one becomes aware of the repressive forces in the form of resistance. But the achievement of repression fails particularly readily in the case of the sexual instincts. Their dammed-up libido finds other ways out from the unconscious: for it regresses to earlier phases of development and earlier attitudes towards objects, and, at weak points in the libidinal development where there are infantile fixations, it breaks through into consciousness and obtains discharge. What results is a symptom and consequently in its essence a substitutive sexual satisfaction. Nevertheless the symptom cannot entirely escape from the repressive forces of the ego and must therefore submit to modifications and displacements exactly as happens with dreams - by means of which its characteristic of being a sexual satisfaction becomes unrecognizable. Consequently symptoms are in the nature of compromises between the repressed sexual instincts and the repressing ego-instincts; they represent a wish-fulfilment for both partners to the conflict simultaneously, but one which is incomplete for each of them. This is quite strictly true of the symptoms of hysteria, while in the symptoms of obsessional neurosis there is often a stronger emphasis upon the side of the repressing function owing to the erection of reaction-formations, which are assurances against sexual satisfaction.

In the further course of psycho-analytic work, however, even these distinctions have proved to be inadequate and, for practical purposes, insufficient. This has become clear in more ways than one; but the decisive instance is as follows. We have formed the idea that in each individual there is a coherent organization of mental processes; and we call this his ego. It is to this ego that consciousness is attached; the ego controls the approaches to motility - that is, to the discharge of excitations into the external world; it is the mental agency which supervises all its own constituent processes, and which goes to sleep at night, though even then it exercises the censorship on dreams. From this ego proceed the repressions, too, by means of which it is sought to exclude certain trends in the mind not merely from consciousness but also from other forms of effectiveness and activity. In analysis these trends which have been shut out stand in opposition to the ego, and the analysis is faced with the task of removing the resistances which the ego displays against concerning itself with the repressed. Now we find during analysis that, when we put certain tasks before the patient, he gets into difficulties; his associations fail when they should be coming near the repressed. We then tell him that he is dominated by a resistance; but he is quite unaware of the fact, and, even if he guesses from his unpleasurable feelings that a resistance is now at work in him, he does not know what it is or how to describe it. Since, however, there can be no question but that this resistance emanates from his ego and belongs to it, we find ourselves in an unforeseen situation. We have come upon something in the ego itself which is also unconscious, which behaves exactly like the repressed - that is, which produces powerful effects without itself being conscious and which requires special work before it can be made conscious. From the point of view of analytic practice, the consequence of this discovery is that we land in endless obscurities and difficulties if we keep to our habitual forms of expression and try, for instance, to derive neuroses from a conflict between the conscious and the unconscious. We shall have to substitute for this antithesis another, taken from our insight into the structural conditions of the mind - the antithesis between the coherent ego and the repressed which is split off from it.¹

[1923a, 3923]

[1923b, 3951]
It looked as though our work had been made much more difficult and complicated; but the inestimable gain was that an insight was now obtained into an interplay of forces which had been concealed from the observer by the hypnotic state. It became evident that the work of uncovering what had been pathogenically forgotten had to struggle against a constant and very intense resistance. The critical objections which the patient raised in order to avoid communicating the ideas which occurred to him, and against which the fundamental rule of psycho-analysis was directed, had themselves already been manifestations of this resistance. A consideration of the phenomena of resistance led to one of the corner-stones of the psycho-analytic theory of the neuroses - the theory of repression. It was plausible to suppose that the same forces which were now struggling against the pathogenic material being made conscious had at an earlier time made the same efforts with success. A gap in the aetiology of neurotic symptoms was thus filled. The impressions and mental impulses, for which the symptoms were now serving as substitutes, had not been forgotten without reason or on account of a constitutional incapacity for synthesis (as Janet supposed); they had, though the influence of other mental forces, met with a repression the success and evidence of which was precisely their being debarred from consciousness and excluded from memory. It was only in consequence of this repression that they had become pathogenic - that is, had succeeded in manifesting themselves along unusual paths as symptoms.

The reception given it in the scientific world was, however, no friendly one. For some ten years no one took any notice of Freud's works. About the year 1907 attention was drawn to psycho-analysis by a group of Swiss psychiatrists (Bleuler and Jung, in Zurich), and a storm of indignation, which was not precisely fastidious in its methods and arguments, thereupon broke out, particularly in Germany. In this, psycho-analysis was sharing the fate of many novelties which, after a certain lapse of time, have found general recognition. Nevertheless it lay in its nature that it should inevitably arouse particularly violent opposition. It wounded the prejudices of civilized humanity at some specially sensitive spots. It subjected every individual, as it were, to the analytic reaction, by uncovering what had by universal agreement been repressed into the unconscious; and in this way it forced its contemporaries to behave like patients who, under analytic treatment, above all else bring their resistances to the fore. It must also be admitted that it was no easy thing to become convinced of the correctness of the psycho-analytic theories, nor to obtain instruction in the practice of analysis.

Thus the strongest resistances to psycho-analysis were not of an intellectual kind but arose from emotional sources. This explained their passionate character as well as their poverty in logic. The situation obeyed a simple formula: men in the mass behaved to psycho-analysis in precisely the same way as individual neurotics under treatment for their disorders. It is possible, however, by patient work to convince these latter individuals that everything happened as we maintained it did: we had not invented it ourselves but had arrived at it from a study of other neurotics covering a period of twenty or thirty years. The position was at once alarming and consoling: alarming because it was no small thing to have the whole human race as one's patient, and consoling because after all everything was taking place as the hypotheses of psycho-analysis declared that it was bound to.
How had it come about that the patients had forgotten so many of the facts of their external and internal lives but could nevertheless recollect them if a particular technique was applied? Observation supplied an exhaustive answer to these questions. Everything that had been forgotten had in some way or other been distressing; it had been either alarming or painful or shameful by the standards of the subject's personality. It was impossible not to conclude that that was precisely why it had been forgotten - that is, why it had not remained conscious. In order to make it conscious again in spite of this, it was necessary to overcome something that fought against one in the patient; it was necessary to make efforts on one's own part so as to urge and compel him to remember. The amount of effort required of the physician varied in different cases; it increased in direct proportion to the difficulty of what had to be remembered. The expenditure of force on the part of the physician was evidently the measure of a resistance on the part of the patient. It was only necessary to translate into words what I myself had observed, and I was in possession of the theory of repression.

[1925d, 4206]

The means which I first adopted for overcoming the patient's resistance, by insistence and encouragement, had been indispensable for the purpose of giving me a first general survey of what was to be expected. But in the long run it proved to be too much of a strain on both sides, and further, it seemed open to certain obvious criticisms. It therefore gave place to another method which was in one sense its opposite. Instead of urging the patient to say something upon some particular subject, I now asked him to abandon himself to a process of free association - that is, to say whatever came into his head, while ceasing to give any conscious direction to his thoughts. It was essential, however, that he should bind himself to report literally everything that occurred to his self-perception and not to give way to critical objections which sought to put certain associations on one side on the ground that they were not sufficiently important or that they were irrelevant or that they were altogether meaningless. There was no necessity to repeat explicitly the demand for candour on the patient's part in reporting his thoughts, for it was the precondition of the whole analytic treatment.

[1925d, 4215]
An important element in the theory of repression is the view that repression is not an event that occurs once but that it requires a permanent expenditure. If this expenditure were to cease, the repressed impulse, which is being fed all the time from its sources, would on the next occasion flow along the channels from which it had been forced away, and the repression would either fail in its purpose or would have to be repeated an indefinite number of times. Thus it is because instincts are continuous in their nature that the ego has to make its defensive action secure by a permanent expenditure. This action undertaken to protect repression is observable in analytic treatment as resistance. Resistance presupposes the existence of what I have called anticathexis. An anticathexis of this kind is clearly seen in obsessional neurosis. It appears there in the form of an alteration of the ego, as a reaction-formation in the ego, and is effected by the reinforcement of the attitude which is the opposite of the instinctual trend that has to be repressed - as, for instance, in pity, conscientiousness and cleanliness. These reaction-formations of obsessional neurosis are essentially exaggerations of the normal traits of character which develop during the latency period. The presence of an anticathexis in hysteria is much more difficult to detect, though theoretically it is equally indispensable. In hysteria, too, a certain amount of alteration of the ego through reaction-formation is unmistakable and in some circumstances becomes so marked that it forces itself on our attention as the principal symptom. The conflict due to ambivalence, for instance, is resolved in hysteria by this means. The subject's hatred of a person whom he loves is kept down by an exaggerated amount of tenderness for him and apprehensiveness about him. But the difference between reaction-formations in obsessional neurosis and in hysteria is that in the latter they do not have the universality of a character-trait but are confined to particular relationships. A hysterical woman, for instance, may be specially affectionate with her own children whom at bottom she hates; but she will not on that account be more loving in general than other women or even more affectionate to other children. The reaction-formation of hysteria clings tenaciously to a particular object and never spreads over into a general disposition of the ego, whereas what is characteristic of obsessional neurosis is precisely a spreading-over of this kind - a loosening of relations to the object and a facilitation of displacement in the choice of object. [1926d, 4310]

We showed on an earlier occasion that the resistance that has to be overcome in analysis proceeds from the ego, which clings to its anticathexes. It is hard for the ego to direct its attention to perceptions and ideas which it has up till now made a rule of avoiding, or to acknowledge as belonging to itself impulses that are the complete opposite of those which it knows as its own. Our fight against resistance in analysis is based upon this view of the facts. If the resistance is itself unconscious, as so often happens owing to its connection with the repressed material, we make it conscious. If it is conscious, or when it has become conscious, we bring forward logical arguments against it; we promise the ego rewards and advantages if it will give up its resistance. There can be no doubt or mistake about the existence of this resistance on the part of the ego. But we have to ask ourselves whether it covers the whole state of affairs in analysis. For we find that even after the ego has decided to relinquish its resistances it still has difficulty in undoing the repressions; and we have called the period of strenuous effort which follows after its praiseworthy decision, the phase of 'working-through'. The dynamic factor which makes a working-through of this kind necessary and comprehensible is not far to seek. It must be that after the ego's resistance has been removed the power of the compulsion to repeat - the attraction exerted by the unconscious prototype upon the repressed instinctual process - has still to be overcome. There is nothing to be said against describing this factor as the resistance of the unconscious. There is no need to be discouraged by these emendations. They are to be welcomed if they add something to our knowledge, and they are no disgrace to us so long as they enrich rather than invalidate our earlier views - by limiting some statement, perhaps, that was too general or by enlarging some idea that was too narrowly formulated. [1926d, 4312]
It must not be supposed that these emendations provide us with a complete survey of all the kinds of resistance that are met with in analysis. Further investigation of the subject shows that the analyst has to combat no less than five kinds of resistance, emanating from three directions - the ego, the id and the super-ego. The ego is the source of three of these, each differing in its dynamic nature. The first of these three ego-resistances is the repression resistance, which we have already discussed above and about which there is least new to be added. Next there is the transference resistance, which is of the same nature but which has different and much clearer effects in analysis, since it succeeds in establishing a relation to the analytic situation or the analyst himself and thus re-animating a repression which should only have been recollected. The third resistance, though also an ego-resistance, is of quite a different nature. It proceeds from the gain from illness and is based upon an assimilation of the symptom into the ego. It represents an unwillingness to renounce any satisfaction or relief that has been obtained. The fourth variety, arising from the id, is the resistance which, as we have just seen, necessitates 'working-through'. The fifth, coming from the super-ego and the last to be discovered, is also the most obscure though not always the least powerful one. It seems to originate from the sense of guilt or the need for punishment; and it opposes every move towards success, including, therefore, the patient's own recovery through analysis.

That you have been deceived in your patient; that you cannot count in the slightest on his collaboration and compliance; that he is ready to place every possible difficulty in the way of your common work - in a word, that he has no wish whatever to be cured.

'If I ever felt any desire to poach on your preserves and try my hand at analysing someone else, what you tell me about the resistances would have cured me of it. But how about the special personal influence that you yourself have after all admitted? Does not that come into action against the resistances?'

Now, however, another problem awaits us - at the opposite end of the ego, as we might put it. It is presented to us by an observation during the work of analysis, an observation which is actually a very old one. As not infrequently happens, it has taken a long time to come to the point of appreciating its importance. The whole theory of psycho-analysis is, as you know, in fact built up on the perception of the resistance offered to us by the patient when we attempt to make his unconscious conscious to him. The objective sign of this resistance is that his associations fail or depart widely from the topic that is being dealt with. He may also recognize the resistance subjectively by the fact that he has distressing feelings when he approaches the topic. But this last sign may also be absent. We then say to the patient that we infer from his behaviour that he is now in a state of resistance; and he replies that he knows nothing of that, and is only aware that his associations have become more difficult. It turns out that we were right; but in that case his resistance was unconscious too, just as unconscious as the repressed, at the lifting of which we were working. We should long ago have asked the question: from what part of his mind does an unconscious resistance like this arise? The beginner in psycho-analysis will be ready at once with the answer: it is, of course, the resistance of the unconscious. An ambiguous and unserviceable answer! If it means that the resistance arises from the repressed, we must rejoin: certainly not! We must rather attribute to the repressed a strong upward drive, an impulsion to break through into consciousness. The resistance can only be a manifestation of the ego, which originally put the repression into force and now wishes to maintain it. That, moreover, is the view we always took. Since we have come to assume a special agency in the ego, the super-ego, which represents demands of a restrictive and rejecting character, we may say that repression is the work of this super-ego and that it is carried out either by itself or by the ego in obedience to its orders. If then we are met by the case of the resistance in analysis not being conscious to the patient, this means either that in quite important situations the super-ego and the ego can operate unconsciously, or - and this would be still more important - that portions of both of them, the ego and the super-ego themselves, are unconscious. In both cases we have to reckon with the disagreeable discovery that on the one hand (super-) ego and conscious and on the other hand repressed and unconscious are far from coinciding.

[1933a, 4677]
With the mention of resistance we have reached the second and more important part of our task. We have already learnt that the ego protects itself against the invasion of undesired elements from the unconscious and repressed id by means of anticathexes, which must remain intact if it is to function normally. The more hard-pressed the ego feels, the more convulsively it clings (as though in a fright) to these anticathexes, in order to protect what remains of itself from further irritations. But this defensive purpose does not by any means accord with the aims of our treatment. What we desire, on the contrary, is that the ego, emboldened by the certainty of our help, shall dare to take the offensive in order to reconquer what has been lost. And it is here that we become aware of the strength of these anticathexes in the form of resistances to our work. The ego draws back in alarm from such undertakings, which seem dangerous and threaten unpleasure; it must be constantly encouraged and soothed if it is not to fail us. This resistance, which persists throughout the whole treatment and is renewed at every fresh piece of work, is known, not quite correctly, as the resistance due to repression. We shall find that it is not the only one that faces us. It is interesting to notice that in this situation the party-divisions are to some extent reversed: for the ego struggles against our instigation, while the unconscious, which is ordinarily our opponent, comes to our help, since it has a natural 'upward drive' and desires nothing better than to press forward across its settled frontiers into the ego and so to consciousness. The struggle which develops, if we gain our end and can induce the ego to overcome its resistances, is carried through under our direction and with our assistance. Its outcome is a matter of indifference: whether it results in the ego accepting, after a fresh examination, an instinctual demand which it has hitherto rejected, or whether it dismisses it once more, this time for good and all. In either case a permanent danger has been disposed of, the compass of the ego has been extended and a wasteful expenditure of energy has been made unnecessary.

The overcoming of resistances is the part of our work that requires the most time and the greatest trouble. It is worth while, however, for it brings about an advantageous alteration of the ego which will be maintained independently of the outcome of the transference and will hold good in life. We have also worked simultaneously at getting rid of the alteration of the ego which had been brought about under the influence of the unconscious; for whenever we have been able to detect any of its derivatives in the ego we have pointed out their illegitimate origin and have instigated the ego to reject them. It will be remembered that it was one of the necessary preconditions of our pact of assistance that any such alteration of the ego due to the intrusion of unconscious elements should not have gone beyond a certain amount.

[1940a [1938], 4988]
I myself had adopted another way of speeding up an analytic treatment even before the war. At that time I had taken on the case of a young Russian, a man spoilt by wealth, who had come to Vienna in a state of complete helplessness, accompanied by a private doctor and an attendant.¹ In the course of a few years it was possible to give him back a large amount of his independence, to awaken his interest in life and to adjust his relations to the people most important to him. But there progress came to a stop. We advanced no further in clearing up the neurosis of his childhood, on which his later illness was based, and it was obvious that the patient found his present position highly comfortable and had no wish to take any step forward which would bring him nearer to the end of his treatment. It was a case of the treatment inhibiting itself: it was in danger of failing as a result of its - partial - success. In this predicament I resorted to the heroic measure of fixing a time limit for the analysis. At the beginning of a year's work I informed the patient that the coming year was to be the last one of his treatment, no matter what he achieved in the time still left to him. At first he did not believe me, but once he was convinced that I was in deadly earnest, the desired change set in. His resistances shrank up, and in these last months of his treatment he was able to reproduce all the memories and to discover all the connections which seemed necessary for understanding his early neurosis and mastering his present one. When he left me in the midsummer of 1914, with as little suspicion as the rest of us of what lay so shortly ahead, I believed that his cure was radical and permanent.

[1937c, 5015]
I have finally to discuss yet another topic, which plays an undesirably large part in the carrying out of cathartic analyses such as these. I have already admitted the possibility of the pressure technique failing, of its not eliciting any reminiscence in spite of every assurance and insistence. If this happens, I said, there are two possibilities: either, at the point at which we are investigating, there is really nothing more to be found - and this we can recognize from the complete calmness of the patient's facial expression; or we have come up against a resistance which can only be overcome later, we are faced by a new stratum into which we cannot yet penetrate - and this, once more, we can infer from the patient's facial expression, which is tense and gives evidence of mental effort. But there is yet a third possibility which bears witness equally to an obstacle, but an external obstacle, and not one inherent in the material. This happens when the patient's relation to the physician is disturbed, and it is the worst obstacle that we can come across. We can, however, reckon on meeting it in every comparatively serious analysis.

Among the various factors, therefore, which contribute to a failure in recollection or a loss of memory, the part played by repression must not be overlooked; and it can be demonstrated not only in neurotics but (in a manner that is qualitatively the same) in normal people as well. It may be asserted quite generally that the ease (and ultimately the faithfulness, too) with which a given impression is awakened in the memory depends not only on the psychical constitution of the individual, the strength of the impression when it was fresh, the interest directed towards it at the time, the psychical constellation at the present time, the interest that is now devoted to its awakening, the connections into which the impression has been drawn, and so on - not only on such things but also on the favourable or unfavourable attitude of a particular psychical factor which refuses to reproduce anything that might liberate unpleasure, or that might subsequently lead to the liberation of unpleasure. Thus the function of memory, which we like to regard as an archive open to anyone who is curious, is in this way subjected to restriction by a trend of the will, just as is any part of our activity directed to the external world. Half the secret of hysterical amnesia is uncovered when we say that hysterical people do not know what they do not want to know; and psycho-analytic treatment, which endeavours to fill up such gaps of memory in the course of its work, leads us to the discovery that the bringing back of those lost memories is opposed by a certain resistance which has to be counterbalanced by work proportionate to its magnitude. In the case of psychical processes which are on the whole normal, it cannot, of course, be claimed that the influence of this one-sided factor in the revival of memories in any way regularly overcomes all the other factors that must be taken into account.¹

¹ [1898b, 483]
(a) I have observed that this method is very often confused with hypnotic treatment by suggestion; I have noticed this because it happens comparatively often that colleagues who do not ordinarily confide their cases to me send me patients refractory patients, of course - with a request that I should hypnotize them. Now I have not used hypnosis for therapeutic purposes for some eight years (except for a few special experiments) so that I habitually send back these cases with the recommendation that anyone who relies upon hypnosis may employ it himself. There is, actually, the greatest possible antithesis between suggestive and analytic technique - the same antithesis which, in regard to the fine arts, the great Leonardo da Vinci summed up in the formulas: per via di porre and per via di levare. Painting, says Leonardo, works per via di porre, for it applies a substance - particles of colour - where there was no thing before, on the colourless canvas; sculpture, however, proceeds per via di levare, since it takes away from the block of stone all that hides the surface of the statue contained in it. In a similar way, the technique of suggestion aims at proceeding per via di porre; it is not concerned with the origin, strength and meaning of the morbid symptoms, but instead, it superimposes something - a suggestion - in the expectation that it will be strong enough to restrain the pathogenic idea from coming to expression. Analytic therapy, on the other hand, does not seek to add or to introduce anything new, but to take away something, to bring out something; and to this end concerns itself with the genesis of the morbid symptoms and the psychical context of the pathogenic idea which it seeks to remove. It is by the use of this mode of investigation that analytic therapy has increased our knowledge so notably. I gave up the suggestive technique, and with it hypnosis, so early in my practice because I despaired of making suggestion powerful and enduring enough to effect permanent cures. In every severe case I saw the suggestions which had been applied crumble away again; after which the disease or some substitute for it was back once more. Besides all this I have another reproach to make against this method, namely, that it conceals from us all insight into the play of mental forces; it does not permit us, for example, to recognize the resistance with which the patient clings to his disease and thus even fights against his own recovery; yet it is this phenomenon of resistance which alone makes it possible to understand his behaviour in daily life.

The procedure which the author makes his Zoe adopt for curing her childhood friend's delusion shows a far-reaching similarity - no, a complete agreement in its essence - with a therapeutic method which was introduced into medical practice in 1895 by Dr. Josef Breuer and myself, and to the perfecting of which I have since then devoted myself. This method of treatment, to which Breuer first gave the name of 'cathartic' but which I prefer to describe as 'analytic', consists, as applied to patients suffering from disorders analogous to Hanold's delusion, in bringing to their consciousness, to some extent forcibly, the unconscious whose repression led to their falling ill - exactly as Gradiva did with the repressed memories of their childhood relations. Gradiva, it is true, could carry out this task more easily than a doctor: in several respects she was in what may be described as an ideal position for it. The doctor, who has no pre-existing knowledge of his patient and possesses no conscious memory of what is unconsciously at work in him, must call a complicated technique to his help in order to make up for this disadvantage. He must learn how to infer with great certainty from the conscious associations and communications of the patient what is repressed in him, how to discover his unconscious as it betrays itself behind his conscious words and acts. He then brings about something like what Norbert Hanold grasped at the end of the story when he translated back the name 'Gradiva' into 'Bertgang'. The disorder vanishes while being traced back to its origin; analysis, too, brings simultaneous cure.
It will interest you, from the point of view of your own profession, to hear how we doctors proceed in psycho-analysis. After the patient has given us a first account of his history, we ask him to give himself up to the thoughts that occur to him spontaneously and to say without any critical reserve whatever comes into his head. We start, as you see, on the assumption, which he does not share in the least, that these spontaneous thoughts will not be arbitrarily chosen but will be determined by their relation to his secret - to his 'complex' - and may, as it were, be regarded as derivatives of that complex. You will note that this is the same assumption as the one with the help of which you were able to interpret the association experiments. But although we have instructed the patient to follow the rule of communicating all the thoughts that occur to him, he seems to be unable to do so. He soon begins to hold back first one thought and then another. He gives various reasons to account for this: either the thought was quite unimportant, or it was irrelevant or it was totally meaningless. We thereupon demand that he shall tell us the thought in spite of these objections and shall follow it up; for the very fact of his criticism proves to us that the thought belongs to the 'complex' which we are seeking to uncover. We recognize in this behaviour of the patient's a manifestation of the 'resistance' present in him, which we are never free from through the whole duration of the treatment. I will merely indicate briefly that this concept of resistance has acquired the highest importance for us in understanding the origin of an illness as well as the mechanism of its cure.

[1906c, 1893]

In your experiments you do not directly observe criticisms like these of his spontaneous ideas by the subject; while we, on the other hand, are able in our psycho-analyses to observe all the indications of a complex which come to your notice. When the patient no longer ventures to evade the rule which has been laid down for him, we nevertheless note that he stops or hesitates from time to time or pauses in the reproduction of his ideas. Every hesitation of this kind is, as we see it, an expression of his resistance and serves as an indication of a connection with the 'complex'. Indeed, we regard it as the most important sign of such a connection, just as is in your case the analogous prolongation of the reaction-time. We are accustomed to interpret hesitation in this sense even when the content of the idea that is being held back does not seem to be at all objectionable and when the patient assures us he cannot imagine why he should hesitate to tell it to us. The pauses which occur in psycho-analysis are as a rule many times longer than the delays that you observe in the reaction experiments.

[1906c, 1893]

By enlightening Hans on this subject I had cleared away his most powerful resistance against allowing his unconscious thoughts to be made conscious; for his father was himself acting as his physician. The worst of the attack was now over; there was a plentiful flow of material; the little patient summoned up courage to describe the details of his phobia, and soon began to take an active share in the conduct of the analysis.¹

[1909b, 2105]

At the next session, which was the seventh, he took up the same subject once more. He could not believe, he said, that he had ever entertained such a wish against his father. He remembered a story of Sudermann's, he went on, that had made a deep impression upon him. In this story there was a woman who, as she sat by her sister's sick-bed, felt a wish that her sister should die so that she herself might marry her husband. The woman thereupon committed suicide, thinking she was not fit to live after being guilty of such baseness. He could understand this, he said, and it would be only right if his thoughts were the death of him, for he deserved nothing less.¹ - I remarked that it was well known to us that patients derived a certain satisfaction from their sufferings, so that in reality they all resisted their own recovery to some extent. He must never lose sight of the fact that a treatment like ours proceeded to the accompaniment of a constant resistance; I should be repeatedly reminding him of this fact.

[1909d, 2146]
To return to the beginning of the treatment. Patients are occasionally met with who start the
treatment by assuring us that they cannot think of anything to say, although the whole field of
their life-history and the story of their illness is open to them to choose from. Their request that
we should tell them what to talk about must not be granted on this first occasion any more than
on any later one. We must bear in mind what is involved here. A strong resistance has come to
the front in order to defend the neurosis; we must take up the challenge then and there and
come to grips with it. Energetic and repeated assurances to the patient that it is impossible for
no ideas at all to occur to him at the beginning, and that what is in question is a resistance
against the analysis, soon oblige him to make the expected admissions or to uncover a first
piece of his complexes. It is a bad sign if he has to confess that while he was listening to the
fundamental rule of analysis he made a mental reservation that he would nevertheless keep this
or that to himself; it is not so serious if all he has to tell us is how mistrustful he is of analysis or
the horrifying things he has heard about it. If he denies these and similar possibilities when they
are put before him, he can be driven by our insistence to acknowledge that he has nevertheless
overlooked certain thoughts which were occupying his mind. He had thought of the treatment
itself, though nothing definite about it, or he had been occupied with the picture of the room in
which he was, or he could not help thinking of the objects in the consulting room and of the fact
that he was lying here on a sofa - all of which he has replaced by the word 'nothing'. These
indications are intelligible enough: everything connected with the present situation represents a
transference to the doctor, which proves suitable to serve as a first resistance. We are thus
obliged to begin by uncovering this transference; and a path from it will give rapid access to the
patient's pathogenic material. Women who are prepared by events in their past history to be
subjected to sexual aggression and men with over-strong repressed homosexuality are the
most apt thus to withhold the ideas that occur to them at the outset of their analysis.

[1913c, 2490]

In the first place, then, when we undertake to restore a patient to health, to relieve him of the
symptoms of his illness, he meets us with a violent and tenacious resistance, which persists
throughout the whole length of the treatment. This is such a strange fact that we cannot expect
it to find much credence. It is best to say nothing about it to the patient's relatives, for they
invariably regard it as an excuse on our part for the length or failure of our treatment. The
patient, too, produces all the phenomena of this resistance without recognizing it as such, and if
we can induce him to take our view of it and to reckon with its existence, that already counts as
a great success. Only think of it! The patient, who is suffering so much from his symptoms and
is causing those about him to share his sufferings, who is ready to undertake so many sacrifices
in time, money, effort and self-discipline in order to be freed from those symptoms we are to
believe that this same patient puts up a struggle in the interest of his illness against the person
who is helping him. How improbable such an assertion must sound! Yet it is true; and when its
improbability is pointed out to us, we need only reply that it is not without analogies. A man who
has gone to the dentist because of an unbearable toothache will nevertheless try to hold the
dentist back when he approaches the sick tooth with a pair of forceps.

[1916-1917, 3362]
What, then, must we do in order to replace what is unconscious in our patients by what is conscious? There was a time when we thought this was a very simple matter: all that was necessary was for us to discover this unconscious material and communicate it to the patient. But we know already that this was a short-sighted error. Our knowledge about the unconscious material is not equivalent to his knowledge; if we communicate our knowledge to him, he does not receive it instead of his unconscious material but beside it; and that makes very little change in it. We must rather picture this unconscious material topographically, we must look for it in his memory at the place where it became unconscious owing to a repression. The repression must be got rid of - after which the substitution of the conscious material for the unconscious can proceed smoothly. How, then, do we lift a repression of this kind? Here our task enters a second phase. First, the search for the repression and then the removal of the resistance which maintains the repression.

[1916-1917, 3478]

There is no doubt that the resistance of the conscious and unconscious ego operates under the sway of the pleasure principle: it seeks to avoid the unpleasure which would be produced by the liberation of the repressed. Our efforts, on the other hand, are directed towards procuring the toleration of that unpleasure by an appeal to the reality principle. But how is the compulsion to repeat - the manifestation of the power of the repressed - related to the pleasure principle? It is clear that the greater part of what is re-experienced under the compulsion to repeat must cause the ego unpleasure, since it brings to light activities of repressed instinctual impulses. That, however, is unpleasure of a kind we have already considered and does not contradict the pleasure principle: unpleasure for one system and simultaneously satisfaction for the other. But we come now to a new and remarkable fact, namely that the compulsion to repeat also recalls from the past experiences which include no possibility of pleasure, and which can never, even long ago, have brought satisfaction even to instinctual impulses which have since been repressed.

[1920g, 3725]

In 1927, Ferenczi read an instructive paper on the problem of the termination of analyses. It ends with a comforting assurance that 'analysis is not an endless process, but one which can be brought to a natural end with sufficient skill and patience on the analyst's part'. The paper as a whole, however, seems to me to be in the nature of a warning not to aim at shortening analysis but at deepening it. Ferenczi makes the further important point that success depends very largely on the analyst's having learnt sufficiently from his own 'errors and mistakes' and having got the better of 'the weak points in his own personality'. This provides an important supplement to our theme. Among the factors which influence the prospects of analytic treatment and add to its difficulties in the same manner as the resistances, must be reckoned not only the nature of the patient's ego but the individuality of the analyst.

[1937c, 5041]
At the next session, which was the seventh, he took up the same subject once more. He could not believe, he said, that he had ever entertained such a wish against his father. He remembered a story of Sudermann's, he went on, that had made a deep impression upon him. In this story there was a woman who, as she sat by her sister's sick-bed, felt a wish that her sister should die so that she herself might marry her husband. The woman thereupon committed suicide, thinking she was not fit to live after being guilty of such baseness. He could understand this, he said, and it would be only right if his thoughts were the death of him, for he deserved nothing less.¹ - I remarked that it was well known to us that patients derived a certain satisfaction from their sufferings, so that in reality they all resisted their own recovery to some extent. He must never lose sight of the fact that a treatment like ours proceeded to the accompaniment of a constant resistance; I should be repeatedly reminding him of this fact.

[LADIES AND GENTLEMEN, - With the discovery of infantile sexuality and the tracing back of neurotic symptoms to erotic instinctual components we have arrived at some unexpected formulas concerning the nature and purposes of neurotic illnesses. We see that human beings fall ill when, as a result of external obstacles or of an internal lack of adaptation, the satisfaction of their erotic needs in reality frustrated. We see that they then take flight into illness in order that by its help they may find a satisfaction to take the place of what has been frustrated. We recognize that the pathological symptoms constitute a portion of the subject's sexual activity or even the whole of his sexual life, and we find that the withdrawal from reality is the main purpose of the illness but also the main damage caused by it. We suspect that our patients' resistance to recovery is no simple one, but compounded of several motives. Not only does the patient's ego rebel against giving up the repressions by means of which it has risen above its original disposition, but the sexual instincts are unwilling to renounce their substitutive satisfaction so long as it is uncertain whether reality will offer them anything better.]

[1910a, 2234]

There are certain people who behave in a quite peculiar fashion during the work of analysis. When one speaks hopefully to them or expresses satisfaction with the progress of the treatment, they show signs of discontent and their condition invariably becomes worse. One begins by regarding this as defiance and as an attempt to prove their superiority to the physician, but later one comes to take a deeper and juster view. One becomes convinced, not only that such people cannot endure any praise or appreciation, but that they react inversely to the progress of the treatment. Every partial solution that ought to result, and in other people does result, in an improvement or a temporary suspension of symptoms produces in them for the time being an exacerbation of their illness; they get worse during the treatment instead of getting better. They exhibit what is known as a 'negative therapeutic reaction'.

[1923b, 3983]

There is no doubt that there is something in these people that sets itself against their recovery, and its approach is dreaded as though it were a danger. We are accustomed to say that the need for illness has got the upper hand in them over the desire for recovery. If we analyse this resistance in the usual way then, even after allowance has been made for an attitude of defiance towards the physician and for fixation to the various forms of gain from illness, the greater part of it is still left over; and this reveals itself as the most powerful of all obstacles to recovery, more powerful than the familiar ones of narcissistic inaccessibility, a negative attitude towards the physician and clinging to the gain from illness.

[1923b, 3983]

That you have been deceived in your patient; that you cannot count in the slightest on his collaboration and compliance; that he is ready to place every possible difficulty in the way of your common work - in a word, that he has no wish whatever to be cured.

[1926e, 4363]
'Well! that is the craziest thing you have told me yet. And I do not believe it either. The patient who is suffering so much, who complains so movingly about his troubles, who is making so great a sacrifice for the treatment - you say he has no wish to be cured! But of course you do not mean what you say.'
[1926e, 4363]

Calm yourself! I do mean it. What I said was the truth - not the whole truth, no doubt, but a very noteworthy part of it. The patient wants to be cured - but he also wants not to be. His ego has lost its unity, and for that reason his will has no unity either. If that were not so, he would be no neurotic.
[1926e, 4363]

People in whom this unconscious sense of guilt is excessively strong betray themselves in analytic treatment by the negative therapeutic reaction which is so disagreeable from the prognostic point of view. When one has given them the solution of a symptom, which should normally be followed by at least its temporary disappearance, what they produce instead is a momentary exacerbation of the symptom and of the illness. It is often enough to praise them for their behaviour in the treatment or to say a few hopeful words about the progress of the analysis in order to bring about an unmistakable worsening of their condition. A non-analyst would say that the 'will to recovery' was absent. If you follow the analytic way of thinking, you will see in this behaviour a manifestation of the unconscious sense of guilt, for which being ill, with its sufferings and impediments, is just what is wanted. The problems which the unconscious sense of guilt has opened up, its connections with morality, education, crime and delinquency, are at present the preferred field of work for psycho-analysts.
[1933a, 4714]

At the moment, however, we are not concerned with the pathogenic role of the defensive mechanisms. What we are trying to discover is what influence the alteration of the ego which corresponds to them has upon our therapeutic efforts. The material for an answer to this question is given in the volume by Anna Freud to which I have already referred. The essential point is that the patient repeats these modes of reaction during the work of analysis as well, that he produces them before our eyes, as it were. In fact, it is only in this way that we get to know them. This does not mean that they make analysis impossible. On the contrary, they constitute half of our analytic task. The other half, the one which was first tackled by analysis in its early days, is the uncovering of what is hidden in the id. During the treatment our therapeutic work is constantly swinging backwards and forwards like a pendulum between a piece of id-analysis and a piece of ego-analysis. In the one case we want to make something from the id conscious, in the other we want to correct something in the ego. The crux of the matter is that the defensive mechanisms directed against former danger recur in the treatment as resistances against recovery. It follows from this that the ego treats recovery itself as a new danger.
[1937c, 5034]
The therapeutic effect depends on making conscious what is repressed, in the widest sense of the word, in the id. We prepare the way for this making conscious by interpretations and constructions, but we have interpreted only for ourselves not for the patient so long as the ego holds on to its earlier defences and does not give up its resistances. Now these resistances, although they belong to the ego, are nevertheless unconscious and in some sense separated off within the ego. The analyst recognizes them more easily than he does the hidden material in the id. One might suppose that it would be sufficient to treat them like portions of the id and, by making them conscious, bring them into connection with the rest of the ego. In this way, we should suppose, one half of the task of analysis would be accomplished; we should not reckon on meeting with a resistance against the uncovering of resistances. But what happens is this. During the work on the resistances the ego withdraws - with a greater or less degree of seriousness - from the agreement on which the analytic situation is founded. The ego ceases to support our efforts at uncovering the id; it opposes them, disobeys the fundamental rule of analysis, and allows no further derivatives of the repressed to emerge. We cannot expect the patient to have a strong conviction of the curative power of analysis. He may have brought along with him a certain amount of confidence in his analyst, which will be strengthened to an effective point by the factors of the positive transference which will be aroused in him. Under the influence of the unpleasurable impulses which he feels as a result of the fresh activation of his defensive conflicts, negative transferences may now gain the upper hand and completely annul the analytic situation. The patient now regards the analyst as no more than a stranger who is making disagreeable demands on him, and he behaves towards him exactly like a child who does not like the stranger and does not believe anything he says. If the analyst tries to explain to the patient one of the distortions made by him for the purposes of defence, and to correct it, he finds him uncomprehending and inaccessible to sound arguments. Thus we see that there is a resistance against the uncovering of resistances, and the defensive mechanisms really do deserve the name which we gave them originally, before they had been more closely examined. They are resistances not only to the making conscious of contents of the id, but also to the analysis as a whole, and thus to recovery.

[1937c, 5034]
(a) I have observed that this method is very often confused with hypnotic treatment by suggestion; I have noticed this because it happens comparatively often that colleagues who do not ordinarily confide their cases to me send me patients refractory patients, of course - with a request that I should hypnotize them. Now I have not used hypnosis for therapeutic purposes for some eight years (except for a few special experiments) so that I habitually send back these cases with the recommendation that anyone who relies upon hypnosis may employ it himself. There is, actually, the greatest possible antithesis between suggestive and analytic technique - the same antithesis which, in regard to the fine arts, the great Leonardo da Vinci summed up in the formulas: per via di porre and per via di levare. Painting, says Leonardo, works per via di porre, for it applies a substance - particles of colour - where there was no thing before, on the colourless canvas; sculpture, however, proceeds per via di levare, since it takes away from the block of stone all that hides the surface of the statue contained in it. In a similar way, the technique of suggestion aims at proceeding per via di porre; it is not concerned with the origin, strength and meaning of the morbid symptoms, but instead, it superimposes something - a suggestion - in the expectation that it will be strong enough to restrain the pathogenic idea from coming to expression. Analytic therapy, on the other hand, does not seek to add or to introduce anything new, but to take away something, to bring out something; and to this end concerns itself with the genesis of the morbid symptoms and the psychical context of the pathogenic idea which it seeks to remove. It is by the use of this mode of investigation that analytic therapy has increased our knowledge so notably. I gave up the suggestive technique, and with it hypnosis, so early in my practice because I despaired of making suggestion powerful and enduring enough to effect permanent cures. In every severe case I saw the suggestions which had been applied crumble away again; after which the disease or some substitute for it was back once more. Besides all this I have another reproach to make against this method, namely, that it conceals from us all insight into the play of mental forces; it does not permit us, for example, to recognize the resistance with which the patient clings to his disease and thus even fights against his own recovery; yet it is this phenomenon of resistance which alone makes it possible to understand his behaviour in daily life.

At the next session, which was the seventh, he took up the same subject once more. He could not believe, he said, that he had ever entertained such a wish against his father. He remembered a story of Sudermann's, he went on, that had made a deep impression upon him. In this story there was a woman who, as she sat by her sister's sick-bed, felt a wish that her sister should die so that she herself might marry her husband. The woman thereupon committed suicide, thinking she was not fit to live after being guilty of such baseness. He could understand this, he said, and it would be only right if his thoughts were the death of him, for he deserved nothing less.¹ - I remarked that it was well known to us that patients derived a certain satisfaction from their sufferings, so that in reality they all resisted their own recovery to some extent. He must never lose sight of the fact that a treatment like ours proceeded to the accompaniment of a constant resistance; I should be repeatedly reminding him of this fact.

¹ [1909d, 2146]
In the first place, then, when we undertake to restore a patient to health, to relieve him of the symptoms of his illness, he meets us with a violent and tenacious resistance, which persists throughout the whole length of the treatment. This is such a strange fact that we cannot expect it to find much credence. It is best to say nothing about it to the patient's relatives, for they invariably regard it as an excuse on our part for the length or failure of our treatment. The patient, too, produces all the phenomena of this resistance without recognizing it as such, and if we can induce him to take our view of it and to reckon with its existence, that already counts as a great success. Only think of it! The patient, who is suffering so much from his symptoms and is causing those about him to share his sufferings, who is ready to undertake so many sacrifices in time, money, effort and self-discipline in order to be freed from those symptoms we are to believe that this same patient puts up a struggle in the interest of his illness against the person who is helping him. How improbable such an assertion must sound! Yet it is true; and when its improbability is pointed out to us, we need only reply that it is not without analogies. A man who has gone to the dentist because of an unbearable toothache will nevertheless try to hold the dentist back when he approaches the sick tooth with a pair of forceps.

There is every reason now for us to improve our earlier dynamic account of the therapeutic process and to bring it into harmony with our new realization. If the patient is to fight his way through the normal conflict with the resistances which we have uncovered for him in the analysis, he is in need of a powerful stimulus which will influence the decision in the sense which we desire, leading to recovery. Otherwise it might happen that he would choose in favour of repeating the earlier outcome and would allow what had been brought up into consciousness to slip back again into repression. At this point what turns the scale in his struggle is not his intellectual insight which is neither strong enough nor free enough for such an achievement - but simply and solely his relation to the doctor. In so far as his transference bears a ‘plus’ sign, it clothes the doctor with authority and is transformed into belief in his communications and explanations. In the absence of such a transference, or if it is a negative one, the patient would never even give a hearing to the doctor and his arguments. In this his belief is repeating the story of its own development; it is a derivative of love and, to start with, needed no arguments. Only later did he allow them enough room to submit them to examination, provided they were brought forward by someone he loved. Without such supports arguments carried no weight, and in most people's lives they never do. Thus in general a man is only accessible from the intellectual side too, in so far as he is capable of a libidinal cathexis of objects; and we have good reason to recognize and to dread in the amount of his narcissism a barrier against the possibility of being influenced by even the best analytic technique.

[1916-1917, 3362]

[1916-1917, 3487]
In the first place, then, when we undertake to restore a patient to health, to relieve him of the symptoms of his illness, he meets us with a violent and tenacious resistance, which persists throughout the whole length of the treatment. This is such a strange fact that we cannot expect it to find much credence. It is best to say nothing about it to the patient's relatives, for they invariably regard it as an excuse on our part for the length or failure of our treatment. The patient, too, produces all the phenomena of this resistance without recognizing it as such, and if we can induce him to take our view of it and to reckon with its existence, that already counts as a great success. Only think of it! How improbable such an assertion must sound! Yet it is true; and when its improbability is pointed out to us, we need only reply that it is not without analogies. A man who has gone to the dentist because of an unbearable toothache will nevertheless try to hold the dentist back when he approaches the sick tooth with a pair of forceps. [1916-1917, 3362]

How do we remove the resistance? In the same way: by discovering it and showing it to the patient. Indeed, the resistance too is derived from a repression - from the same one that we are endeavouring to resolve, or from one that took place earlier. It was set up by the anticathexis which arose in order to repress the objectionable impulse. Thus we now do the same thing that we tried to do to begin with: interpret, discover and communicate; but now we are doing it at the right place. The anticathexis or the resistance does not form part of the unconscious but of the ego, which is our collaborator, and is so even if it is not conscious. As we know, the word 'unconscious' is being used here in two senses: on the one hand as a phenomenon and on the other as a system. This sounds very difficult and obscure; but is it not only repeating what we have already said in earlier passages? We have long been prepared for it. We expect that this resistance will be given up and the anticathexis withdrawn when our interpretation has made it possible for the ego to recognize it. What are the motive forces that we work with in such a case? First with the patient's desire for recovery, which has induced him to take part with us in our joint work, and secondly with the help of his intelligence, to which we give support by our interpretation. There is no doubt that it is easier for the patient's intelligence to recognize the resistance and to find the translation corresponding to what is repressed if we have previously given him the appropriate anticipatory ideas. If I say to you: 'Look up at the sky! There's a balloon there!' you will discover it much more easily than if I simply tell you to look up and see if you can see anything. In the same way, a student who is looking through a microscope for the first time is instructed by his teacher as to what he will see; otherwise he does not see it at all, though it is there and visible. [1916-1917, 3479]
In order to make it easier to understand this 'compulsion to repeat', which emerges during the psycho-analytic treatment of neurotics, we must above all get rid of the mistaken notion that what we are dealing with in our struggle against resistances is resistance on the part of the unconscious. The unconscious - that is to say, the 'repressed' - offers no resistance whatever to the efforts of the treatment. Indeed, it itself has no other endeavour than to break through the pressure weighing down on it and force its way either to consciousness or to a discharge through some real action. Resistance during treatment arises from the same higher strata and systems of the mind which originally carried out repression. But the fact that, as we know from experience, the motives of the resistances, and indeed the resistances themselves, are unconscious at first during the treatment, is a hint to us that we should correct a shortcoming in our terminology. We shall avoid a lack of clarity if we make our contrast not between the conscious and the unconscious but between the coherent ego and the repressed. It is certain that much of the ego is itself unconscious, and notably what we may describe as its nucleus; only a small part of it is covered by the term 'preconscious'. Having replaced a purely descriptive terminology by one which is systematic or dynamic, we can say that the patient's resistance arises from his ego, and we then at once perceive that the compulsion to repeat must be ascribed to the unconscious repressed. It seems probable that the compulsion can only express itself after the work of treatment has gone half-way to meet it and has loosened the repression.¹

There is another phenomenon, however, which is far stranger. In our analyses we discover that there are people in whom the faculties of self-criticism and conscience - mental activities, that is, that rank as extremely high ones - are unconscious and unconsciously produce effects of the greatest importance; the example of resistance remaining unconscious during analysis is therefore by no means unique. But this new discovery, which compels us, in spite of our better critical judgement, to speak of an 'unconscious sense of guilt', bewilders us far more than the other and sets us fresh problems, especially when we gradually come to see that in a great number of neuroses an unconscious sense of guilt of this kind plays a decisive economic part and puts the most powerful obstacles in the way of recovery. If we come back once more to our scale of values, we shall have to say that not only what is lowest but also what is highest in the ego can be unconscious. It is as if we were thus supplied with a proof of what we have just asserted of the conscious ego: that it is first and foremost a body-ego.

¹ [1920g, 3724]

[1923b, 3961]
We showed on an earlier occasion that the resistance that has to be overcome in analysis proceeds from the ego, which clings to its anticathexes. It is hard for the ego to direct its attention to perceptions and ideas which it has up till now made a rule of avoiding, or to acknowledge as belonging to itself impulses that are the complete opposite of those which it knows as its own. Our fight against resistance in analysis is based upon this view of the facts. If the resistance is itself unconscious, as so often happens owing to its connection with the repressed material, we make it conscious. If it is conscious, or when it has become conscious, we bring forward logical arguments against it; we promise the ego rewards and advantages if it will give up its resistance. There can be no doubt or mistake about the existence of this resistance on the part of the ego. But we have to ask ourselves whether it covers the whole state of affairs in analysis. For we find that even after the ego has decided to relinquish its resistances it still has difficulty in undoing the repressions; and we have called the period of strenuous effort which follows after its praiseworthy decision, the phase of ‘working-through’. The dynamic factor which makes a working-through of this kind necessary and comprehensible is not far to seek. It must be that after the ego's resistance has been removed the power of the compulsion to repeat - the attraction exerted by the unconscious prototype upon the repressed instinctual process - has still to be overcome. There is nothing to be said against describing this factor as the resistance of the unconscious. There is no need to be discouraged by these emendations. They are to be welcomed if they add something to our knowledge, and they are no disgrace to us so long as they enrich rather than invalidate our earlier views - by limiting some statement, perhaps, that was too general or by enlarging some idea that was too narrowly formulated.

Now, however, another problem awaits us - at the opposite end of the ego, as we might put it. It is presented to us by an observation during the work of analysis, an observation which is actually a very old one. As not infrequently happens, it has taken a long time to come to the point of appreciating its importance. The whole theory of psycho-analysis is, as you know, in fact built up on the perception of the resistance offered to us by the patient when we attempt to make his unconscious conscious to him. The objective sign of this resistance is that his associations fail or depart widely from the topic that is being dealt with. He may also recognize the resistance subjectively by the fact that he has distressing feelings when he approaches the topic. But this last sign may also be absent. We then say to the patient that we infer from his behaviour that he is now in a state of resistance; and he replies that he knows nothing of that, and is only aware that his associations have become more difficult. It turns out that we were right; but in that case his resistance was unconscious too, just as unconscious as the repressed, at the lifting of which we were working. We should long ago have asked the question: from what part of his mind does an unconscious resistance like this arise? The beginner in psycho-analysis will be ready at once with the answer: it is, of course, the resistance of the unconscious. An ambiguous and unserviceable answer! If it means that the resistance arises from the repressed, we must rejoin: certainly not! We must rather attribute to the repressed a strong upward drive, an impulsion to break through into consciousness. The resistance can only be a manifestation of the ego, which originally put the repression into force and now wishes to maintain it. That, moreover, is the view we always took. Since we have come to assume a special agency in the ego, the super-ego, which represents demands of a restrictive and rejecting character, we may say that repression is the work of this super-ego and that it is carried out either by itself or by the ego in obedience to its orders. If then we are met by the case of the resistance in analysis not being conscious to the patient, this means either that in quite important situations the super-ego and the ego can operate unconsciously, or - and this would be still more important - that portions of both of them, the ego and the super-ego themselves, are unconscious. In both cases we have to reckon with the disagreeable discovery that on the one hand (super-) ego and conscious and on the other hand repressed and unconscious are far from coinciding.

[1926d, 4312]

[1933a, 4677]
We have travelled somewhat far from our basis. I will tell you in retrospect the starting-point of these reflections on the theory of the instincts. It was the same as that which led us to revise the relation between the ego and the unconscious - the impression derived from the work of analysis that the patient who puts up a resistance is so often unaware of that resistance. Not only the fact of the resistance is unconscious to him, however, but its motives as well. We were obliged to search out these motives or motive, and to our surprise we found them in a powerful need for punishment which we could only class with masochistic wishes. The practical significance of this discovery is not less than its theoretical one, for the need for punishment is the worst enemy of our therapeutic efforts. It is satisfied by the suffering which is linked to the neurosis, and for that reason holds fast to being ill. It seems that this factor, an unconscious need for punishment, has a share in every neurotic illness. And here those cases in which the neurotic suffering can be replaced by suffering of another kind are wholly convincing. I will report an experience of this kind. [1933a, 4712]

The therapeutic effect depends on making conscious what is repressed, in the widest sense of the word, in the id. We prepare the way for this making conscious by interpretations and constructions, but we have interpreted only for ourselves not for the patient so long as the ego holds on to its earlier defences and does not give up its resistances. Now these resistances, although they belong to the ego, are nevertheless unconscious and in some sense separated off within the ego. The analyst recognizes them more easily than he does the hidden material in the id. One might suppose that it would be sufficient to treat them like portions of the id and, by making them conscious, bring them into connection with the rest of the ego. In this way, we should suppose, one half of the task of analysis would be accomplished; we should not reckon on meeting with a resistance against the uncovering of resistances. But what happens is this. During the work on the resistances the ego withdraws - with a greater or less degree of seriousness - from the agreement on which the analytic situation is founded. The ego ceases to support our efforts at uncovering the id; it opposes them, disobeys the fundamental rule of analysis, and allows no further derivatives of the repressed to emerge. We cannot expect the patient to have a strong conviction of the curative power of analysis. He may have brought along with him a certain amount of confidence in his analyst, which will be strengthened to an effective point by the factors of the positive transference which will be aroused in him. Under the influence of the unpleasurable impulses which he feels as a result of the fresh activation of his defensive conflicts, negative transferences may now gain the upper hand and completely annul the analytic situation. The patient now regards the analyst as no more than a stranger who is making disagreeable demands on him, and he behaves towards him exactly like a child who does not like the stranger and does not believe anything he says. If the analyst tries to explain to the patient one of the distortions made by him for the purposes of defence, and to correct it, he finds him uncomprehending and inaccessible to sound arguments. Thus we see that there is a resistance against the uncovering of resistances, and the defensive mechanisms really do deserve the name which we gave them originally, before they had been more closely examined. They are resistances not only to the making conscious of contents of the id, but also to the analysis as a whole, and thus to recovery. [1937c, 5034]
It is impossible to carry any analysis to a conclusion unless we know how to meet the resistance arising in these three ways. But we can find a way of doing so if we make up our minds that this new symptom that has been produced on the old model must be treated in the same way as the old symptoms. Our first task is to make the 'obstacle' conscious to the patient. In one of my patients, for instance, the pressure procedure suddenly failed. I had reason to suppose that there was an unconscious idea of the kind mentioned under (2) above, and I dealt with it at the first attempt by taking her by surprise. I told her that some obstacle must have arisen to continuing the treatment, but that the pressure procedure had at least the power to show her what this obstacle was; I pressed on her head, and she said in astonishment: 'I see you sitting on the chair here; but that's nonsense. What can it mean?' I was then able to enlighten her. With another patient the 'obstacle' used not to appear directly as a result of my pressure, but I was always able to discover it if I took the patient back to the moment at which it had originated. The pressure procedure never failed to bring this moment back for us. When the obstacle had been discovered and demonstrated the first difficulty was cleared out of the way. But a greater one remained. It lay in inducing the patient to produce information where apparently personal relations were concerned and where the third person coincided with the figure of the physician.

To begin with I was greatly annoyed at this increase in my psychological work, till I came to see that the whole process followed a law; and I then noticed, too, that transference of this kind brought about no great addition to what I had to do. For the patient the work remained the same: she had to overcome the distressing affect aroused by having been able to entertain such a wish even for a moment; and it seemed to make no difference to the success of the treatment whether she made this psychical repudiation the theme of her work in the historical instance or in the recent one connected with me. The patients, too, gradually learnt to realize that in these transferences on to the figure of the physician it was a question of a compulsion and an illusion which melted away with the conclusion of the analysis. I believe, however, that if I had neglected to make the nature of the 'obstacle' clear to them I should simply have given them a new hysterical symptom - though, it is true, a milder one - in exchange for another which had been generated spontaneously.

(b) I will hasten on to the innovations in the field of technique, where indeed nearly everything still awaits final settlement, and much is only now beginning to become clear. There are now two aims in psycho-analytic technique: to save the physician effort and to give the patient the most unrestricted access to his unconscious. As you know, our technique has undergone a fundamental transformation. At the time of the cathartic treatment what we aimed at was the elucidation of the symptoms; we then turned away from the symptoms and devoted ourselves instead to uncovering the 'complexes', to use a word which Jung has made indispensable; now, however, our work is aimed directly at finding out and overcoming the 'resistances', and we can justifiably rely on the complexes coming to light without difficulty as soon as the resistances have been recognized and removed. Some of you have since felt a need to be able to make a survey of these resistances and classify them. I will ask you to examine your material and see whether you can confirm the generalized statement that in male patients the most important resistances in the treatment seem to be derived from the father-complex and to express themselves in fear of the father, in defiance of the father and in disbelief of the father.
This brings us to the technical errors which are to be seen in the doctor's procedure in this alleged case. It is a long superseded idea, and one derived from superficial appearances, that the patient suffers from a sort of ignorance, and that if one removes this ignorance by giving him information (about the causal connection of his illness with his life, about his experiences in childhood, and so on) he is bound to recover. The pathological factor is not his ignorance in itself, but the root of this ignorance in his inner resistances; it was they that first called this ignorance into being, and they still maintain it now. The task of the treatment lies in combating these resistances. Informing the patient of what he does not know because he has repressed it is only one of the necessary preliminaries to the treatment. If knowledge about the unconscious were as important for the patient as people inexperienced in psycho-analysis imagine, listening to lectures or reading books would be enough to cure him. Such measures, however, have as much influence on the symptoms of nervous illness as a distribution of menu-cards in a time of famine has upon hunger. The analogy goes even further than its immediate application; for informing the patient of his unconscious regularly results in an intensification of the conflict in him and an exacerbation of his troubles.

The view that the sexual representation of 'higher' thoughts in dreams and neurosis is nothing but an archaic mode of expression is of course irreconcilable with the fact that in neurosis these sexual complexes prove to be the bearers of the quantities of libido which have been withdrawn from utilization in real life. If it was merely a question of a sexual 'jargon', the economy of the libido could not have been altered in any way by it. Jung admits this himself in his *Darstellung der psychoanalytischen Theorie* and formulates the task of therapy as the detaching of libidinal cathexes from these complexes. This can never be achieved, however, by directing the patient away from them and urging him to sublimate, but only by exhaustive examination of them and by making them fully and completely conscious. The first piece of reality which the patient must deal with is his illness. Efforts to spare him that task point to the physician's incapacity to help him to overcome his resistances, or else to the physician's dread of the results of the work.

Resistances of this kind should not be one-sidedly condemned. They include so much of the most important material from the patient's past and bring it back in so convincing a fashion that they become some of the best supports of the analysis if a skilful technique knows how to give them the right turn. Nevertheless, it remains a remarkable fact that this material is always in the service of the resistance to begin with and brings to the fore a façade that is hostile to the treatment. It may also be said that what is being mobilized for fighting against the alterations we are striving for are character-traits, attitudes of the ego. In this connection we discover that these character-traits were formed in relation to the determinants of the neurosis and in reaction against its demands, and we come upon traits which cannot normally emerge, or not to the same extent, and which may be described as latent. Nor must you get an impression that we regard the appearance of these resistances as an unforeseen risk to analytic influence. No, we are aware that these resistances are bound to come to light; in fact we are dissatisfied if we cannot provoke them clearly enough and are unable to demonstrate them to the patient. Indeed we come finally to understand that the overcoming of these resistances is the essential function of analysis and is the only part of our work which gives us an assurance that we have achieved something with the patient.
If you further consider that the patient makes all the chance events that occur during his analysis into interferences with it, that he uses as reasons for slackening his efforts every diversion outside the analysis, every comment by a person of authority in his environment who is hostile to analysis, any chance organic illness or any that complicates his neurosis and, even, indeed, every improvement in his condition - if you consider all this, you will have obtained an approximate, though still incomplete, picture of the forms and methods of the resistance, the struggle against which accompanies every analysis.

[1916-1917, 3366]

You will ask whether it may not be possible, however, to do justice to the part played by the ego in neurotic states and in the formation of symptoms without at the same time grossly neglecting the factors revealed by psycho-analysis. My reply is that that must certainly be possible and will sooner or later be done; but the road followed by the work of psycho-analysis does not admit of actually beginning with this. It is of course possible to foresee when psycho-analysis will be confronted by this task. There are neuroses in which the ego plays a far more intensive part than in those we have studied hitherto; we call them the 'narcissistic' neuroses. The investigation of these disorders will enable us to form an impartial and trustworthy judgement of the share taken by the ego in the onset of neuroses.

[1916-1917, 3434]

In your contact as doctors with neurotics, Gentlemen, you will soon give up expecting that the ones who raise the most lamentations and complaints about their illness will be the most eager to co-operate and will offer you the least resistance. It is rather the opposite. But of course you will easily realize that everything that contributes to the gain from illness will intensify the resistance due to repression and will increase the therapeutic difficulties. But to the portion of gain from illness which is, so to say, born with the illness we have to add another portion which arises later. When a psychical organization like an illness has lasted for some time, it behaves eventually like an independent organism; it manifests something like a self-preservative instinct; it establishes a kind of modus vivendi between itself and other parts of the mind, even with those which are at bottom hostile to it; and there can scarcely fail to be occasions when it proves once again useful and expedient and acquires, as it were, a secondary function which strengthens its stability afresh. Instead of an example from pathology, let us take a glaring instance from daily life. A capable working-man, who earns his living, is crippled by an accident in the course of his occupation. The injured man can no longer work, but eventually he obtains a small disablement pension, and he learns how to exploit his mutilation by begging. His new, though worsened, means of livelihood is based precisely on the very thing that deprived him of his former means of livelihood. If you could put an end to his injury you would make him, to begin with, without means of subsistence; the question would arise of whether he was still capable of taking up his earlier work again. What corresponds in the case of neuroses to a secondary exploitation like this of an illness may be described as the secondary gain from illness in contrast to the primary one.

[1916-1917, 3437]
I have now led you into the region in which the next advances in the work of analysis are to be expected. Since we have ventured to operate with the concept of ego-libido the narcissistic neuroses have become accessible to us: the task before us is to arrive at a dynamic elucidation of these disorders and at the same time to complete our knowledge of mental life by coming to understand the ego. The ego-psychology after which we are seeking must not be based on the data of our self-perceptions but (as in the case of the libido) on the analysis of disturbances and disruptions of the ego. It is likely that we shall have a low opinion of our present knowledge of the vicissitudes of the libido, which we have gained from a study of the transference neuroses, when we have achieved this greater task. But hitherto we have not made much progress with it. The narcissistic neuroses can scarcely be attacked with the technique that has served us with the transference neuroses. You will soon learn why. What always happens with them is that, after proceeding for a short distance, we come up against a wall which brings us to a stop. Even with the transference neuroses, as you know, we met with barriers of resistance, but we were able to demolish them bit by bit. In the narcissistic neuroses the resistance is unconquerable; at the most, we are able to cast an inquisitive glance over the top of the wall and spy out what is going on on the other side of it. Our technical methods must accordingly be replaced by others; and we do not know yet whether we shall succeed in finding substitute. Nevertheless, we have no lack of material with these patients either. They make a large number of remarks, even if they do not answer our questions, and for the time being it is our business to interpret these remarks with the help of the understanding we have gained from the symptoms of the transference neuroses. The agreement is great enough to guarantee us some initial advantage. It remains to be seen how far this technique will take us.

[1916-1917, 3476]

But, Ladies and Gentlemen, who has so seriously misinformed you? A recommendation to the patient to 'live a full life' sexually could not possibly play a part in analytic therapy - if only because we ourselves have declared that an obstinate conflict is taking place in him between a libidinal impulse and sexual repression, between a sensual and an ascetic trend. This conflict would not be solved by our helping one of these trends to victory over its opponent. We see, indeed, that in neurotics asceticism has the upper hand; and the consequence of this is precisely that the suppressed sexual tendency finds a way out in symptoms. If, on the contrary, we were to secure victory for sensuality, then the sexual repression that had been put on one side would necessarily be replaced by symptom. Neither of these two alternative decisions could end the internal conflict; in either case one party to it would remain unsatisfied. There are only a few cases in which the conflict is so unstable that a factor such as the doctor's taking sides could decide it; and such cases do not in fact stand in need of analytic treatment. Anyone on whom the doctor could have so much influence would have found the same way out without the doctor. You must be aware that if an abstinent young man decides in favour of illicit sexual intercourse or if an unsatisfied wife seeks relief with another man, they have not as a rule waited for permission from a doctor or even from their analyst.

[1916-1917, 3476]
What, then, must we do in order to replace what is unconscious in our patients by what is conscious? There was a time when we thought this was a very simple matter: all that was necessary was for us to discover this unconscious material and communicate it to the patient. But we know already that this was a short-sighted error. Our knowledge about the unconscious material is not equivalent to his knowledge; if we communicate our knowledge to him, he does not receive it instead of his unconscious material but beside it; and that makes very little change in it. We must rather picture this unconscious material topographically, we must look for it in his memory at the place where it became unconscious owing to a repression. The repression must be got rid of - after which the substitution of the conscious material for the unconscious can proceed smoothly. How, then, do we lift a repression of this kind? Here our task enters a second phase. First, the search for the repression and then the removal of the resistance which maintains the repression.

How do we remove the resistance? In the same way: by discovering it and showing it to the patient. Indeed, the resistance too is derived from a repression - from the same one that we are endeavouring to resolve, or from one that took place earlier. It was set up by the anticathexis which arose in order to repress the objectionable impulse. Thus we now do the same thing that we tried to do to begin with: interpret, discover and communicate; but now we are doing it at the right place. The anticathexis or the resistance does not form part of the unconscious but of the ego, which is our collaborator, and is so even if it is not conscious. As we know, the word 'unconscious' is being used here in two senses: on the one hand as a phenomenon and on the other as a system. This sounds very difficult and obscure; but is it not only repeating what we have already said in earlier passages? We have long been prepared for it. We expect that this resistance will be given up and the anticathexis withdrawn when our interpretation has made it possible for the ego to recognize it. What are the motive forces that we work with in such a case? First with the patient's desire for recovery, which has induced him to take part with us in our joint work, and secondly with the help of his intelligence, to which we give support by our interpretation. There is no doubt that it is easier for the patient's intelligence to recognize the resistance and to find the translation corresponding to what is repressed if we have previously given him the appropriate anticipatory ideas. If I say to you: 'Look up at the sky! There's a balloon there!' you will discover it much more easily than if I simply tell you to look up and see if you can see anything. In the same way, a student who is looking through a microscope for the first time is instructed by his teacher as to what he will see; otherwise he does not see it at all, though it is there and visible.
There is every reason now for us to improve our earlier dynamic account of the therapeutic process and to bring it into harmony with our new realization. If the patient is to fight his way through the normal conflict with the resistances which we have uncovered for him in the analysis, he is in need of a powerful stimulus which will influence the decision in the sense which we desire, leading to recovery. Otherwise it might happen that he would choose in favour of repeating the earlier outcome and would allow what had been brought up into consciousness to slip back again into repression. At this point what turns the scale in his struggle is not his intellectual insight which is neither strong enough nor free enough for such an achievement - but simply and solely his relation to the doctor. In so far as his transference bears a 'plus' sign, it clothes the doctor with authority and is transformed into belief in his communications and explanations. In the absence of such a transference, or if it is a negative one, the patient would never even give a hearing to the doctor and his arguments. In this his belief is repeating the story of its own development; it is a derivative of love and, to start with, needed no arguments. Only later did he allow them enough room to submit them to examination, provided they were brought forward by someone he loved. Without such supports arguments carried no weight, and in most people's lives they never do. Thus in general a man is only accessible from the intellectual side too, in so far as he is capable of a libidinal cathexis of objects; and we have good reason to recognize and to dread in the amount of his narcissism a barrier against the possibility of being influenced by even the best analytic technique. [1916-1917, 3487]

In the light of the knowledge we have gained from psycho-analysis we can describe the difference between hypnotic and psycho-analytic suggestion as follows. Hypnotic treatment seeks to cover up and gloss over something in mental life; analytic treatment seeks to expose and get rid of something. The former acts like a cosmetic, the latter like surgery. The former makes use of suggestion in order to forbid the symptoms; it strengthens the repressions, but, apart from that, leaves all the processes that have led to the formation of the symptoms unaltered. Analytic treatment makes its impact further back towards the roots, where the conflicts are which gave rise to the symptoms, and uses suggestion in order to alter the outcome of those conflicts. Hypnotic treatment leaves the patient inert and unchanged, and for that reason, too, equally unable to resist any fresh occasion for falling ill. An analytic treatment demands from both doctor and patient the accomplishment of serious work, which is employed in lifting internal resistances. Through the overcoming of these resistances the patient's mental life is permanently changed, is raised to a high level of development and remains protected against fresh possibilities of falling ill. This work of overcoming resistances is the essential function of analytic treatment; the patient has to accomplish it and the doctor makes this possible for him with the help of suggestion operating in an educative sense. For that reason psycho-analytic treatment has justly been described as a kind of after-education. [1916-1917, 3492]
But you will now tell me that, no matter whether we call the motive force of our analysis transference or suggestion, there is a risk that the influencing of our patient may make the objective certainty of our findings doubtful. What is advantageous to our therapy is damaging to our researches. This is the objection that is most often raised against psycho-analysis, and it must be admitted that, though it is groundless, it cannot be rejected as unreasonable. If it were justified, psycho-analysis would be nothing more than a particularly well-disguised and particularly effective form of suggestive treatment and we should have to attach little weight to all that it tells us about what influences our lives, the dynamics of the mind or the unconscious. That is what our opponents believe; and in especial they think that we have 'talked' the patients into everything relating to the importance of sexual experiences - or even into those experiences themselves - after such notions have grown up in our own depraved imagination. These accusations are contradicted more easily by an appeal to experience than by the help of theory. Anyone who has himself carried out psycho-analyses will have been able to convince himself on countless occasions that it is impossible to make suggestions to a patient in that way. The doctor has no difficulty, of course, in making him a supporter of some particular theory and in thus making him share some possible error of his own. In this respect the patient is behaving like anyone else - like a pupil - but this only affects his intelligence, not his illness. After all, his conflicts will only be successfully solved and his resistances overcome if the anticipatory ideas he is given tally with what is real in him. Whatever in the doctor's conjectures is inaccurate drops out in the course of the analysis; it has to be withdrawn and replaced by something more correct. We endeavour by a careful technique to avoid the occurrence of premature successes due to suggestion; but no harm is done even if they do occur, for we are not satisfied by a first success. We do not regard an analysis as at an end until all the obscurities of the case are cleared up, the gaps in the patient's memory filled in, the precipitating causes of the repressions discovered. We look upon successes that set in too soon as obstacles rather than as a help to the work of analysis; and we put an end to such successes by constantly resolving the transference on which they are based. It is this last characteristic which is the fundamental distinction between analytic and purely suggestive therapy, and which frees the results of analysis from the suspicion of being successes due to suggestion. In every other kind of suggestive treatment the transference is carefully preserved and left untouched; in analysis it is itself subjected to treatment and is dissected in all the shapes in which it appears. At the end of an analytic treatment the transference must itself be cleared away; and if success is then obtained or continues, it rests, not on suggestion, but on the achievement by its means of an overcoming of internal resistances, on the internal change that has been brought about in the patient.

Thus the course of this treatment illustrates a maxim whose truth has long been appreciated in the technique of analysis. The length of the road over which an analysis must travel with the patient, and the quantity of material which must be mastered on the way, are of no importance in comparison with the resistance which is met with in the course of the work, and are only of importance at all in so far as they are necessarily proportional to the resistance. The situation is the same as when to-day an enemy army needs weeks and months to make its way across a stretch of country which in times of peace was traversed by an express train in a few hours and which only a short time before had been passed over by the defending army in a few days.
We have formulated our task as physicians thus: to bring to the patient's knowledge the unconscious, repressed impulses existing in him, and, for that purpose, to uncover the resistances that oppose this extension of his knowledge about himself. Does the uncovering of these resistances guarantee that they will also be overcome? Certainly not always; but our hope is to achieve this by exploiting the patient's transference to the person of the physician, so as to induce him to adopt our conviction of the inexpediency of the repressive process established in childhood and of the impossibility of conducting life on the pleasure principle. I have set out elsewhere the dynamic conditions prevailing in the fresh conflict through which we lead the patient and which we substitute in him for his previous conflict - that of his illness. I have nothing at the moment to alter in that account.

In actual fact, indeed, the neurotic patient presents us with a torn mind, divided by resistances. As we analyse it and remove the resistances, it grows together; the great unity which we call his ego fits into itself all the instinctual impulses which before had been split off and held apart from it. The psycho-synthesis is thus achieved during analytic treatment without our intervention, automatically and inevitably. We have created the conditions for it by breaking up the symptoms into their elements and by removing the resistances. It is not true that something in the patient has been divided into its components and is now quietly waiting for us to put it somehow together again.

Let us at once agree upon what we mean by this activity. We have defined our therapeutic task as consisting of two things: making conscious the repressed material and uncovering the resistances. In that we are active enough, to be sure. But are we to leave it to the patient to deal alone with the resistances we have pointed out to him? Can we give him no other help in this besides the stimulus he gets from the transference? Does it not seem natural that we should help him in another way as well, by putting him into the mental situation most favourable to the solution of the conflict which is our aim? After all, what he can achieve depends, too, on a combination of external circumstances. Should we hesitate to alter this combination by intervening in a suitable manner? I think activity of such a kind on the part of the analysing physician is unobjectionable and entirely justified.

Twenty five years of intense work have had as their result that the immediate aims of psycho-analytic technique are quite other to-day than they were at the outset. At first the analysing physician could do no more than discover the unconscious material that was concealed from the patient, put it together, and, at the right moment, communicate it to him. Psychoanalysis was then first and foremost an art of interpreting. Since this did not solve the therapeutic problem, a further aim quickly came in view: to oblige the patient to confirm the analyst's construction from his own memory. In that endeavour the chief emphasis lay upon the patient's resistances: the art consisted now in uncovering these as quickly as possible, in pointing them out to the patient and in inducing him by human influence - this was where suggestion operating as 'transference' played its part - to abandon his resistances.
In order to make it easier to understand this 'compulsion to repeat', which emerges during the psycho-analytic treatment of neurotics, we must above all get rid of the mistaken notion that what we are dealing with in our struggle against resistances is resistance on the part of the unconscious. The unconscious - that is to say, the 'repressed' - offers no resistance whatever to the efforts of the treatment. Indeed, it itself has no other endeavour than to break through the pressure weighing down on it and force its way either to consciousness or to a discharge through some real action. Resistance during treatment arises from the same higher strata and systems of the mind which originally carried out repression. But the fact that, as we know from experience, the motives of the resistances, and indeed the resistances themselves, are unconscious at first during the treatment, is a hint to us that we should correct a shortcoming in our terminology. We shall avoid a lack of clarity if we make our contrast not between the conscious and the unconscious but between the coherent ego and the repressed. It is certain that much of the ego is itself unconscious, and notably what we may describe as its nucleus; only a small part of it is covered by the term 'preconscious'. Having replaced a purely descriptive terminology by one which is systematic or dynamic, we can say that the patient's resistance arises from his ego, and we then at once perceive that the compulsion to repeat must be ascribed to the unconscious repressed. It seems probable that the compulsion can only express itself after the work of treatment has gone half-way to meet it and has loosened the repression.¹

There is no doubt that the resistance of the conscious and unconscious ego operates under the sway of the pleasure principle: it seeks to avoid the unpleasure which would be produced by the liberation of the repressed. Our efforts, on the other hand, are directed towards procuring the toleration of that unpleasure by an appeal to the reality principle. But how is the compulsion to repeat - the manifestation of the power of the repressed - related to the pleasure principle? It is clear that the greater part of what is re-experienced under the compulsion to repeat must cause the ego unpleasure, since it brings to light activities of repressed instinctual impulses. That, however, is unpleasure of a kind we have already considered and does not contradict the pleasure principle: unpleasure for one system and simultaneously satisfaction for the other. But we come now to a new and remarkable fact, namely that the compulsion to repeat also recalls from the past experiences which include no possibility of pleasure, and which can never, even long ago, have brought satisfaction even to instinctual impulses which have since been repressed.

But it is to be noted that only in rare instances can we observe the pure effects of the compulsion to repeat, unsupported by other motives. In the case of children's play we have already laid stress on the other ways in which the emergence of the compulsion may be interpreted; the compulsion to repeat and instinctual satisfaction which is immediately pleasurable seem to converge here into an intimate partnership. The phenomena of transference are obviously exploited by the resistance which the ego maintains in its pertinacious insistence upon repression; the compulsion to repeat, which the treatment tries to bring into its service is, as it were, drawn over by the ego to its side (clinging as the ego does to the pleasure principle). A great deal of what might be described as the compulsion of destiny seems intelligible on a rational basis; so that we are under no necessity to call in a new and mysterious motive force to explain it.

[1920g, 3725]

[1920g, 3727]
Trotter gives as the list of instincts which he considers as primary those of self-preservation, of nutrition, of sex, and of the herd. The last often comes into opposition with the others. The feelings of guilt and of duty are the peculiar possessions of a gregarious animal. Trotter also derives from the herd instinct the repressive forces which psycho-analysis has shown to exist in the ego, and from the same source accordingly the resistances which the physician comes up against in psycho-analytic treatment. Speech owes its importance to its aptitude for mutual understanding in the herd, and upon it the identification of the individuals with one another largely rests.
[1921c, 3810]

For these reasons I refrained altogether from holding out to the parents any prospect of their wish being fulfilled. I merely said I was prepared to study the girl carefully for a few weeks or months, so as then to be able to pronounce how far a continuation of the analysis would be likely to influence her. In quite a number of cases, indeed, an analysis falls into two clearly distinguishable phases. In the first, the physician procures from the patient the necessary information, makes him familiar with the premises and postulates of psycho-analysis, and unfolds to him the reconstruction of the genesis of his disorder as deduced from the material brought up in the analysis. In the second phase the patient himself gets hold of the material put before him; he works on it, recollects what he can of the apparently repressed memories, and tries to repeat the rest as if he were in some way living it over again. In this way he can confirm, supplement, and correct the inferences made by the physician. It is only during this work that he experiences, through overcoming resistances, the inner change aimed at, and acquires for himself the convictions that make him independent of the physician's authority. These two phases in the course of the analytic treatment are not always sharply divided from each other; this can only happen when the resistance obeys certain conditions. But when this is so, one may bring up as an analogy the two stages of a journey. The first comprises all the necessary preparations, to-day so complicated and hard to effect, before, ticket in hand, one can at last go on to the platform and secure a seat in the train. One then has the right, and the possibility, of travelling into a distant country; but after all these preliminary exertions one is not yet there - indeed, one is not a single mile nearer to one's goal. For this to happen one has to make the journey itself from one station to the other, and this part of the performance may well be compared with the second phase of the analysis.
[1920a, 3842]
In the girl's account of her conscious motives the father did not figure at all; there was not even any mention of fear of his anger. In the motives laid bare by the analysis, on the other hand, he played the principal part. Her relation to her father had the same decisive importance for the course and outcome of the analytic treatment, or rather, analytic exploration. Behind her pretended consideration for her parents, for whose sake she had been willing to make the attempt to be transformed, lay concealed her attitude of defiance and revenge against her father which held her fast to her homosexuality. Secure under this cover, the resistance set a considerable region free to analytic investigation. The analysis went forward almost without any signs of resistance, the patient participating actively with her intellect, though absolutely tranquil emotionally. Once when I expounded to her a specially important part of the theory, one touching her nearly, she replied in an inimitable tone, 'How very interesting', as though she were a grande dame being taken over a museum and glancing through her lorgnon at objects to which she was completely indifferent. The impression one had of her analysis was not unlike that of a hypnotic treatment, where the resistance has in the same way withdrawn to a certain boundary line, beyond which it proves to be unconquerable. The resistance very often pursues similar tactics - Russian tactics, as they might be called - in cases of obsessional neurosis. For a time, consequently, these cases yield the clearest results and permit a deep insight into the causation of the symptoms. But presently one begins to wonder how it is that such marked progress in analytic understanding can be unaccompanied by even the slightest change in the patient's compulsions and inhibitions, until at last one perceives that everything that has been accomplished is subject to a mental reservation of doubt, and that behind this protective barrier the neurosis can feel secure. 'It would be all very fine', thinks the patient, often quite consciously, 'if I were obliged to believe what the man says, but there is no question of that, and so long as this is so I need change nothing.' Then, when one comes to close quarters with the motives for this doubt, the fight with the resistances breaks out in earnest.

[1920a, 3852]

In the case of our patient, it was not doubt but the affective factor of revenge against her father that made her cool reserve possible, that divided the analysis into two distinct phases, and rendered the results of the first phase so complete and perspicuous. It seemed, further, as though nothing resembling a transference to the physician had been effected. That, however, is of course absurd, or, at least, is a loose way of expressing things. For some kind of relation to the analyst must come into being, and this relation is almost always transferred from an infantile one. In reality she transferred to me the sweeping repudiation of men which had dominated her ever since the disappointment she had suffered from her father. Bitterness against men is as a rule easy to gratify upon the physician; it need not evoke any violent emotional manifestations, it simply expresses itself by rendering futile all his endeavours and - by clinging to the illness. I know from experience how difficult it is to make a patient understand just precisely this mute kind of symptomatic behaviour and to make him aware of this latent, and often exceedingly strong, hostility without endangering the treatment. As soon, therefore, as I recognized the girl's attitude to her father, I broke off the treatment and advised her parents that if they set store by the therapeutic procedure it should be continued by a woman doctor. The girl had in the meanwhile promised her father that at any rate she would give up seeing the 'lady', and I do not know whether my advice, the reasons for which are obvious, will be followed.

[1920a, 3853]
The Theory of Repression. - These theoretical considerations, taken together with the immediate impressions derived from analytic work, lead to a view of the neuroses which may be described in the roughest outline as follows. The neuroses are the expression of conflicts between the ego and such of the sexual impulses as seem to the ego incompatible with its integrity or with its ethical standards. Since these impulses are not ego-syntonic, the ego has repressed them: that is to say, it has withdrawn its interest from them and has shut them off from becoming conscious as well as from obtaining satisfaction by motor discharge. If in the course of analytic work one attempts to make these repressed impulses conscious, one becomes aware of the repressive forces in the form of resistance. But the achievement of repression fails particularly readily in the case of the sexual instincts. Their dammed-up libido finds other ways out from the unconscious: for it regresses to earlier phases of development and earlier attitudes towards objects, and, at weak points in the libidinal development where there are infantile fixations, it breaks through into consciousness and obtains discharge. What results is a symptom and consequently in its essence a substitutive sexual satisfaction. Nevertheless the symptom cannot entirely escape from the repressive forces of the ego and must therefore submit to modifications and displacements exactly as happens with dreams - by means of which its characteristic of being a sexual satisfaction becomes unrecognizable. Consequently symptoms are in the nature of compromises between the repressed sexual instincts and the repressing ego-instincts; they represent a wish-fulfilment for both partners to the conflict simultaneously, but one which is incomplete for each of them. This is quite strictly true of the symptoms of hysteria, while in the symptoms of obsessional neurosis there is often a stronger emphasis upon the side of the repressing function owing to the erection of reaction-formations, which are assurances against sexual satisfaction.

[1923a, 3923]

Development of Technique. - After the analyst's curiosity had, as it were, been gratified by the elaboration of the technique of interpretation, it was inevitable that interest should turn to the problem of discovering the most effective way of influencing the patient. It soon became evident that the physician's immediate task was to assist the patient in getting to know, and afterwards in overcoming, the resistances which emerged in him during treatment and of which, to begin with, he himself was unaware. And it was found at the same time that the essential part of the process of cure lay in the overcoming of these resistances and that unless this was achieved no permanent mental change could be brought about in the patient. Since the analyst's efforts have in this way been directed upon the patient's resistance, analytic technique has attained a certainty and delicacy rivalling that of surgery. Consequently, everyone is strongly advised against undertaking psycho-analytic treatments without a strict training, and a physician who ventures upon them on the strength of his medical qualification is in no respect better than a layman.

[1923a, 3925]
Comparison between Psycho-Analysis and Hypnotic and Suggestive Methods. - Psycho-analytic procedure differs from all methods making use of suggestion, persuasion, etc., in that it does not seek to suppress by means of authority any mental phenomenon that may occur in the patient. It endeavours to trace the causation of the phenomenon and to remove it by bringing about a permanent modification in the conditions that led to it. In psycho-analysis the suggestive influence which is inevitably exercised by the physician is diverted on to the task assigned to the patient of overcoming his resistances, that is, of carrying forward the curative process. Any danger of falsifying the products of a patient's memory by suggestion can be avoided by prudent handling of the technique; but in general the arousing of resistances is a guarantee against the misleading effects of suggestive influence. It may be laid down that the aim of the treatment is to remove the patient's resistances and to pass his repressions in review and thus to bring about the most far-reaching unification and strengthening of his ego, to enable him to save the mental energy which he is expending upon internal conflicts, to make the best of him that his inherited capacities will allow and so to make him as efficient and as capable of enjoyment as is possible. The removal of the symptoms of the illness is not specifically aimed at, but is achieved, as it were, as a by-product if the analysis is properly carried through. The analyst respects the patient's individuality and does not seek to remould him in accordance with his own - that is, according to the physician's - personal ideals; he is glad to avoid giving advice and instead to arouse the patient's power of initiative.

In the further course of psycho-analytic work, however, even these distinctions have proved to be inadequate and, for practical purposes, insufficient. This has become clear in more ways than one; but the decisive instance is as follows. We have formed the idea that in each individual there is a coherent organization of mental processes; and we call this his ego. It is to this ego that consciousness is attached; the ego controls the approaches to motility - that is, to the discharge of excitations into the external world; it is the mental agency which supervises all its own constituent processes, and which goes to sleep at night, though even then it exercises the censorship on dreams. From this ego proceed the repressions, too, by means of which it is sought to exclude certain trends in the mind not merely from consciousness but also from other forms of effectiveness and activity. In analysis these trends which have been shut out stand in opposition to the ego, and the analysis is faced with the task of removing the resistances which the ego displays against concerning itself with the repressed. Now we find during analysis that, when we put certain tasks before the patient, he gets into difficulties; his associations fail when they should be coming near the repressed. We then tell him that he is dominated by a resistance; but he is quite unaware of the fact, and, even if he guesses from his unpleasurable feelings that a resistance is now at work in him, he does not know what it is or how to describe it. Since, however, there can be no question but that this resistance emanates from his ego and belongs to it, we find ourselves in an unforeseen situation. We have come upon something in the ego itself which is also unconscious, which behaves exactly like the repressed - that is, which produces powerful effects without itself being conscious and which requires special work before it can be made conscious. From the point of view of analytic practice, the consequence of this discovery is that we land in endless obscurities and difficulties if we keep to our habitual forms of expression and try, for instance, to derive neuroses from a conflict between the conscious and the unconscious. We shall have to substitute for this antithesis another, taken from our insight into the structural conditions of the mind - the antithesis between the coherent ego and the repressed which is split off from it.¹

¹[1923b, 3951]
The description we have given applies to the most extreme instances of this state of affairs, but in a lesser measure this factor has to be reckoned with in very many cases, perhaps in all comparatively severe cases of neurosis. In fact it may be precisely this element in the situation, the attitude of the ego ideal, that determines the severity of a neurotic illness. We shall not hesitate, therefore, to discuss rather more fully the way in which the sense of guilt expresses itself under different conditions.

[1923b, 3984]

Is it possible, then, that corroborative dreams are really the result of suggestion, that they are ‘obliging’ dreams? The patients who produce only corroborative dreams are the same patients in whom doubt plays the principal part in resistance. One makes no attempt at shouting down this doubt by means of one’s authority or at reducing it by arguments. It must persist until it is brought to an end in the further course of the analysis. The analyst, too, may himself retain a doubt of the same kind in some particular instances. What makes him certain in the end is precisely the complication of the problem before him, which is like the solution of a jig-saw puzzle. A coloured picture, pasted upon a thin sheet of wood and fitting exactly into a wooden frame, is cut into a large number of pieces of the most irregular and crooked shapes. If one succeeds in arranging the confused heap of fragments, each of which bears upon it an unintelligible piece of drawing, so that the picture acquires a meaning, so that there is no gap anywhere in the design and so that the whole fits into the frame - if all these conditions are fulfilled, then one knows that one has solved the puzzle and that there is no alternative solution.

[1923c, 4037]

If one practises dream-interpretation according to the sole justifiable technical procedure, one soon notices that success depends entirely upon the tension of resistance between the awakened ego and the repressed unconscious. Work under a ‘high pressure of resistance’ demands (as I have explained elsewhere) a different attitude on the part of the analyst from work under a low pressure. In analysis one has for long periods at a time to deal with strong resistances which are still unknown to one and which it will in any case be impossible to overcome so long as they remain unknown. It is therefore not to be wondered at that only a certain portion of a patient's dream-products can be translated and made use of, and, even at that, most often incompletely. Even if, owing to one's own experience, one is in a position to understand many dreams to the interpretation of which the dreamer has contributed little, one must always remember that the certainty of such interpretations remains in doubt and one hesitates to press one’s conjectures upon the patient.

[1925i, 4045]

For the contradiction exists only as long as we keep our eyes fixed on the situation at the beginning of the neurosis, in which the ego, in the service of reality, sets about the repression of an instinctual impulse. This, however, is not yet the neurosis itself. The neurosis consists rather in the processes which provide a compensation for the portion of the id that has been damaged - that is to say, in the reaction against the repression and in the failure of the repression. The loosening of the relation to reality is a consequence of this second step in the formation of a neurosis, and it ought not to surprise us if a detailed examination shows that the loss of reality affects precisely that piece of reality as a result of whose demands the instinctual repression ensued.

[1924e, 4094]
A conflict between two groups of mental trends had to be looked on as the ground for repression and accordingly as the cause of every neurotic illness. And here experience taught us a new and surprising fact about the nature of the forces that were struggling against each other. Repression invariably proceeded from the sick person's conscious personality (his ego) and took its stand on aesthetic and ethical motives; the impulses that were subjected to repression were those of selfishness and cruelty, which can be summed up in general as evil, but above all sexual wishful impulses, often of the crudest and most forbidden kind. Thus the symptoms were a substitute for forbidden satisfactions and the illness seemed to correspond to an incomplete subjugation of the immoral side of human beings.

Thus the strongest resistances to psycho-analysis were not of an intellectual kind but arose from emotional sources. This explained their passionate character as well as their poverty in logic. The situation obeyed a simple formula: men in the mass behaved to psycho-analysis in precisely the same way as individual neurotics under treatment for their disorders. It is possible, however, by patient work to convince these latter individuals that everything happened as we maintained it did: we had not invented it ourselves but had arrived at it from a study of other neurotics covering a period of twenty or thirty years. The position was at once alarming and consoling: alarming because it was no small thing to have the whole human race as one's patient, and consoling because after all everything was taking place as the hypotheses of psycho-analysis declared that it was bound to.

The means which I first adopted for overcoming the patient's resistance, by insistence and encouragement, had been indispensable for the purpose of giving me a first general survey of what was to be expected. But in the long run it proved to be too much of a strain on both sides, and further, it seemed open to certain obvious criticisms. It therefore gave place to another method which was in one sense its opposite. Instead of urging the patient to say something upon some particular subject, I now asked him to abandon himself to a process of free association - that is, to say whatever came into his head, while ceasing to give any conscious direction to his thoughts. It was essential, however, that he should bind himself to report literally everything that occurred to his self-perception and not to give way to critical objections which sought to put certain associations on one side on the ground that they were not sufficiently important or that they were irrelevant or that they were altogether meaningless. There was no necessity to repeat explicitly the demand for candour on the patient's part in reporting his thoughts, for it was the precondition of the whole analytic treatment.
It may seem surprising that this method of free association, carried out subject to the observation of the fundamental rule of psycho-analysis, should have achieved what was expected of it, namely the bringing into consciousness of the repressed material which was held back by resistances. We must, however, bear in mind that free association is not really free. The patient remains under the influence of the analytic situation even though he is not directing his mental activities on to a particular subject. We shall be justified in assuming that nothing will occur to him that has not some reference to that situation. His resistance against reproducing the repressed material will now be expressed in two ways. Firstly it will be shown by critical objections; and it was to deal with these that the fundamental rule of psycho-analysis was invented. But if the patient observes that rule and so overcomes his reticences, the resistance will find another means of expression. It will so arrange it that the repressed material itself will never occur to the patient but only something which approximates to it in an allusive way; and the greater the resistance, the more remote from the actual idea that the analyst is in search of will be the substitutive association which the patient has to report. The analyst, who listens composedly but without any constrained effort to the stream of associations and who, from his experience, has a general notion of what to expect, can make use of the material brought to light by the patient according to two possibilities. If the resistance is slight he will be able from the patient's allusions to infer the unconscious material itself; or if the resistance is stronger he will be able to recognize its character from the associations, as they seem to become more remote from the topic in hand, and will explain it to the patient. Uncovering the resistance, however, is the first step towards overcoming it. Thus the work of analysis involves an art of interpretation, the successful handling of which may require tact and practice but which is not hard to acquire. But it is not only in the saving of labour that the method of free association has an advantage over the earlier method. It exposes the patient to the least possible amount of compulsion, it never allows of contact being lost with the actual current situation, it guarantees to a great extent that no factor in the structure of the neurosis will be overlooked and that nothing will be introduced into it by the expectations of the analyst. It is left to the patient in all essentials to determine the course of the analysis and the arrangement of the material; any systematic handling of particular symptoms or complexes thus becomes impossible. In complete contrast to what happened with hypnosis and with the urging method, interrelated material makes its appearance at different times and at different points in the treatment. To a spectator, therefore - though in fact there must be none - an analytic treatment would seem completely obscure.

It is perfectly true that psycho-analysis, like other psychotherapeutic methods, employs the instrument of suggestion (or transference). But the difference is this: that in analysis it is not allowed to play the decisive part in determining the therapeutic results. It is used instead to induce the patient to perform a piece of psychical work - the overcoming of his transference resistances - which involves a permanent alteration in his mental economy. The transference is made conscious to the patient by the analyst, and it is resolved by convincing him that in his transference-attitude he is re-experiencing emotional relations which had their origin in his earliest object-attachments during the repressed period of his childhood. In this way the transference is changed from the strongest weapon of the resistance into the best instrument of the analytic treatment. Nevertheless its handling remains the most difficult as well as the most important part of the technique of analysis.
In the Oedipus complex the libido was seen to be attached to the image of the parental figures. But earlier there was a period in which there were no such objects. There followed from this fact the concept (of fundamental importance for the libido theory) of a state in which the subject's libido filled his own ego and had that for its object. This state could be called \textit{narcissism} or self-love. A moment's reflection showed that this state never completely ceases. All through the subject's life his ego remains the great reservoir of his libido, from which object-cathexes are sent out and into which the libido can stream back again from the objects. Thus narcissistic libido is constantly being transformed into object-libido, and \textit{vice versa}. An excellent instance of the length to which this transformation can go is afforded by the state of being in love, whether in a sexual or sublimated manner, which goes so far as involving a sacrifice of the self. Whereas hitherto in considering the process of repression attention had only been paid to what was repressed, these ideas made it possible to form a correct estimate of the repressing forces too. It had been said that repression was set in action by the instincts of self-preservation operating in the ego (the 'ego-instincts') and that it was brought to bear upon the libidinal instincts. But since the instincts of self-preservation were now recognized as also being of a libidinal nature, as being narcissistic libido, the process of repression was seen to be a process occurring within the libido itself; narcissistic libido was opposed to object-libido, the interest of self-preservation was defending itself against the demands of object-love, and therefore against the demands of sexuality in the narrower sense as well.

[1925d, 4231]

Two impressions at once emerge from this brief survey of obsessional symptoms. The first is that a ceaseless struggle is being waged against the repressed, in which the repressing forces steadily lose ground; the second is that the ego and the super-ego have a specially large share in the formation of the symptoms.
[1926d, 4272]

The third, psychological, factor resides in a defect of our mental apparatus which has to do precisely with its differentiation into an id and an ego, and which is therefore also attributable ultimately to the influence of the external world. In view of the dangers of reality, the ego is obliged to guard against certain instinctual impulses in the id and to treat them as dangers. But it cannot protect itself from internal instinctual dangers as effectively as it can from some piece of reality that is not part of itself. Intimately bound up with the id as it is, it can only fend off an instinctual danger by restricting its own organization and by acquiescing in the formation of symptoms in exchange for having impaired the instinct. If the rejected instinct renews its attack, the ego is overtaken by all those difficulties which are known to us as neurotic ailments.
[1926d, 4309]
We showed on an earlier occasion that the resistance that has to be overcome in analysis proceeds from the ego, which clings to its anticathexes. It is hard for the ego to direct its attention to perceptions and ideas which it has up till now made a rule of avoiding, or to acknowledge as belonging to itself impulses that are the complete opposite of those which it knows as its own. Our fight against resistance in analysis is based upon this view of the facts. If the resistance is itself unconscious, as so often happens owing to its connection with the repressed material, we make it conscious. If it is conscious, or when it has become conscious, we bring forward logical arguments against it; we promise the ego rewards and advantages if it will give up its resistance. There can be no doubt or mistake about the existence of this resistance on the part of the ego. But we have to ask ourselves whether it covers the whole state of affairs in analysis. For we find that even after the ego has decided to relinquish its resistances it still has difficulty in undoing the repressions; and we have called the period of strenuous effort which follows after its praiseworthy decision, the phase of 'working-through'.

The dynamic factor which makes a working-through of this kind necessary and comprehensible is not far to seek. It must be that after the ego's resistance has been removed the power of the compulsion to repeat - the attraction exerted by the unconscious prototype upon the repressed instincual process - has still to be overcome. There is nothing to be said against describing this factor as the resistance of the unconscious. There is no need to be discouraged by these emendations. They are to be welcomed if they add something to our knowledge, and they are no disgrace to us so long as they enrich rather than invalidate our earlier views - by limiting some statement, perhaps, that was too general or by enlarging some idea that was too narrowly formulated.

[1926d, 4312]

It must not be supposed that these emendations provide us with a complete survey of all the kinds of resistance that are met with in analysis. Further investigation of the subject shows that the analyst has to combat no less than five kinds of resistance, emanating from three directions - the ego, the id and the super-ego. The ego is the source of three of these, each differing in its dynamic nature. The first of these three ego-resistances is the repression resistance, which we have already discussed above and about which there is least new to be added. Next there is the transference resistance, which is of the same nature but which has different and much clearer effects in analysis, since it succeeds in establishing a relation to the analytic situation or the analyst himself and thus re-animating a repression which should only have been recollected. The third resistance, though also an ego-resistance, is of quite a different nature. It proceeds from the gain from illness and is based upon an assimilation of the symptom into the ego. It represents an unwillingness to renounce any satisfaction or relief that has been obtained. The fourth variety, arising from the id, is the resistance which, as we have just seen, necessitates 'working-through'. The fifth, coming from the super-ego and the last to be discovered, is also the most obscure though not always the least powerful one. It seems to originate from the sense of guilt or the need for punishment; and it opposes every move towards success, including, therefore, the patient's own recovery through analysis.

[1926d, 4313]
Yes, we are only beginning to appreciate the significance of all these important circumstances. That is why my description was bound to turn out so obscure. But now I can proceed. We describe all the forces that oppose the work of recovery as the patient's 'resistances'. The gain from illness is one such resistance. The 'unconscious sense of guilt' represents the super-ego's resistance; it is the most powerful factor, and the one most dreaded by us. We meet with still other resistances during the treatment. If the ego during the early period has set up a repression out of fear, then the fear still persists and manifests itself as a resistance if the ego approaches the repressed material. And finally, as you can imagine, there are likely to be difficulties if an instinctual process which has been going along a particular path for whole decades is suddenly expected to take a new path that has just been made open for it. That might be called the id's resistance. The struggle against all these resistances is our main work during an analytic treatment; the task of making interpretations is nothing compared to it. But as a result of this struggle and of the overcoming of the resistances, the patient's ego is so much altered and strengthened that we can look forward calmly to his future behaviour when the treatment is over. On the other hand, you can understand now why we need such long treatments. The length of the path of development and the wealth of the material are not the decisive factors. It is more a question of whether the path is clear. An army can be held up for weeks on a stretch of country which in peace time an express train crosses in a couple of hours - if the army has to overcome the enemy's resistance there. Such battles call for time in mental life too. I am unfortunately obliged to tell you that every effort to hasten analytic treatment appreciably has hitherto failed. The best way of shortening it seems to be to carry it out according to the rules.

The therapeutic influence of psycho-analysis depends on the replacement of unconscious mental acts by conscious ones and is effective within the limits of that factor. The replacement is effected by overcoming internal resistances in the patient's mind. The future will probably attribute far greater importance to psycho-analysis as the science of the unconscious than as a therapeutic procedure.
Now, however, another problem awaits us - at the opposite end of the ego, as we might put it. It is presented to us by an observation during the work of analysis, an observation which is actually a very old one. As not infrequently happens, it has taken a long time to come to the point of appreciating its importance. The whole theory of psycho-analysis is, as you know, in fact built up on the perception of the resistance offered to us by the patient when we attempt to make his unconscious conscious to him. The objective sign of this resistance is that his associations fail or depart widely from the topic that is being dealt with. He may also recognize the resistance subjectively by the fact that he has distressing feelings when he approaches the topic. But this last sign may also be absent. We then say to the patient that we infer from his behaviour that he is now in a state of resistance; and he replies that he knows nothing of that, and is only aware that his associations have become more difficult. It turns out that we were right; but in that case his resistance was unconscious too, just as unconscious as the repressed, at the lifting of which we were working. We should long ago have asked the question: from what part of his mind does an unconscious resistance like this arise? The beginner in psycho-analysis will be ready at once with the answer: it is, of course, the resistance of the unconscious. An ambiguous and unserviceable answer! If it means that the resistance arises from the repressed, we must rejoin: certainly not! We must rather attribute to the repressed a strong upward drive, an impulsion to break through into consciousness. The resistance can only be a manifestation of the ego, which originally put the repression into force and now wishes to maintain it. That, moreover, is the view we always took. Since we have come to assume a special agency in the ego, the super-ego, which represents demands of a restrictive and rejecting character, we may say that repression is the work of this super-ego and that it is carried out either by itself or by the ego in obedience to its orders. If then we are met by the case of the resistance in analysis not being conscious to the patient, this means either that in quite important situations the super-ego and the ego can operate unconsciously, or - and this would be still more important - that portions of both of them, the ego and the super-ego themselves, are unconscious. In both cases we have to reckon with the disagreeable discovery that on the one hand (super-) ego and conscious and on the other hand repressed and unconscious are far from coinciding.

[1933a, 4677]
With the mention of resistance we have reached the second and more important part of our task. We have already learnt that the ego protects itself against the invasion of undesired elements from the unconscious and repressed id by means of anticathexes, which must remain intact if it is to function normally. The more hard-pressed the ego feels, the more convulsively it clings (as though in a fright) to these anticathexes, in order to protect what remains of itself from further irruptions. But this defensive purpose does not by any means accord with the aims of our treatment. What we desire, on the contrary, is that the ego, emboldened by the certainty of our help, shall dare to take the offensive in order to reconquer what has been lost. And it is here that we become aware of the strength of these anticathexes in the form of resistances to our work. The ego draws back in alarm from such undertakings, which seem dangerous and threaten unpleasure; it must be constantly encouraged and soothed if it is not to fail us. This resistance, which persists throughout the whole treatment and is renewed at every fresh piece of work, is known, not quite correctly, as the resistance due to repression. We shall find that it is not the only one that faces us. It is interesting to notice that in this situation the party-divisions are to some extent reversed: for the ego struggles against our instigation, while the unconscious, which is ordinarily our opponent, comes to our help, since it has a natural 'upward drive' and desires nothing better than to press forward across its settled frontiers into the ego and so to consciousness. The struggle which develops, if we gain our end and can induce the ego to overcome its resistances, is carried through under our direction and with our assistance. Its outcome is a matter of indifference: whether it results in the ego accepting, after a fresh examination, an instinctual demand which it has hitherto rejected, or whether it dismisses it once more, this time for good and all. In either case a permanent danger has been disposed of, the compass of the ego has been extended and a wasteful expenditure of energy has been made unnecessary.

[1940a [1938], 4988]

The overcoming of resistances is the part of our work that requires the most time and the greatest trouble. It is worth while, however, for it brings about an advantageous alteration of the ego which will be maintained independently of the outcome of the transference and will hold good in life. We have also worked simultaneously at getting rid of the alteration of the ego which had been brought about under the influence of the unconscious; for whenever we have been able to detect any of its derivatives in the ego we have pointed out their illegitimate origin and have instigated the ego to reject them. It will be remembered that it was one of the necessary preconditions of our pact of assistance that any such alteration of the ego due to the intrusion of unconscious elements should not have gone beyond a certain amount.

[1940a [1938], 4989]
Let us once more glance over the situation which we have reached in our attempt at bringing help to the patient's neurotic ego. That ego is no longer able to fulfil the task set it by the external world (including human society). Not all of its experiences are at its disposal, a large proportion of its store of memories have escaped it. Its activity is inhibited by strict prohibitions from the super-ego, its energy is consumed in vain attempts at fending off the demands of the id. Beyond this, as a result of continuous irruptions by the id, its organization is impaired, it is no longer capable of any proper synthesis, it is torn by mutually opposed urges, by unsettled conflicts and by unsolved doubts. To start with, we get the patient's thus weakened ego to take part in the purely intellectual work of interpretation, which aims at provisionally filling the gaps in his mental assets, and to transfer to us the authority of his super-ego; we encourage it to take up the struggle over each individual demand made by the id and to conquer the resistances which arise in connection with it. At the same time we restore order in the ego by detecting the material and urges which have forced their way in from the unconscious, and expose them to criticism by tracing them back to their origin. We serve the patient in various functions, as an authority and a substitute for his parents, as a teacher and educator; and we have done the best for him if, as analysts, we raise the mental processes in his ego to a normal level, transform what has become unconscious and repressed into preconscious material and thus return it once more to the possession of his ego. On the patient's side a few rational factors work in our favour, such as the need for recovery which has its motive in his sufferings, and the intellectual interest that we may awaken in him in the theories and revelations of psychoanalysis; but of far greater force is the positive transference with which he meets us. Fighting against us, on the other hand, are the negative transference, the ego's resistance due to repression (that is, its unpleasure at having to lay itself open to the hard work imposed on it), the sense of guilt arising from its relation to the super-ego and the need to be ill due to deep-going changes in the economics of his instincts. The share taken by the last two factors decides whether the case is to be regarded as slight or severe. Apart from these, a few other factors may be discerned as having a favourable or unfavourable bearing. A certain psychical inertia, a sluggishness of the libido, which is unwilling to abandon its fixations cannot be welcome to us; the patient's capacity for sublimating his instincts plays a large part and so does his capacity for rising above the crude life of the instincts; so, too, does the relative power of his intellectual functions.

We must first of all decide what is meant by the ambiguous phrase 'the end of an analysis'. From a practical standpoint it is easy to answer. An analysis is ended when the analyst and the patient cease to meet each other for the analytic session. This happens when two conditions have been approximately fulfilled: first, that the patient shall no longer be suffering from his symptoms and shall have overcome his anxieties and his inhibitions; and secondly, that the analyst shall judge that so much repressed material has been made conscious, so much that was unintelligible has been explained, and so much internal resistance conquered, that there is no need to fear a repetition of the pathological processes concerned. If one is prevented by external difficulties from reaching this goal, it is better to speak of an incomplete analysis rather than of an unfinished one.

[1940a [1938], 4990]

[1937c, 5017]
If, however, the recognition of resistance has become so important, we should do well to find room for a cautious doubt whether we have not been too light-heartedly assuming resistances. Perhaps there really are cases of neurosis in which associations fail for other reasons, perhaps the arguments against our hypotheses really deserve to have their content examined, and perhaps we are doing patients an injustice in so conveniently setting aside their intellectual criticisms as resistance. But, Gentlemen, we did not arrive at this judgement lightly. We have had occasion to observe all these critical patients at the moment of the emergence of a resistance and after its disappearance. For resistance is constantly altering its intensity during the course of a treatment; it always increases when we are approaching a new topic, it is at its most intense while we are at the climax of dealing with that topic, and it dies away when the topic has been disposed of. Nor do we ever, unless we have been guilty of special clumsiness in our technique, have to meet the full amount of resistance of which a patient is capable. We have therefore been able to convince ourselves that on countless occasions in the course of his analysis the same man will abandon his critical attitude and then take it up again. If we are on the point of bringing a specially distressing piece of unconscious material to his consciousness, he is extremely critical; he may previously have understood and accepted a great deal, but now it is just as though those acquisitions have been swept away; in his efforts for opposition at any price, he may offer a complete picture of someone who is an emotional imbecile. But if we succeed in helping him to overcome this new resistance, he recovers his insight and understanding. Thus his critical faculty is not an independent function, to be respected as such, it is the tool of his emotional attitudes and is directed by his resistance. If there is something he does not like, he can put up a shrewd fight against it and appear highly critical; but if something suits his book, he can, on the contrary, show himself most credulous. Perhaps none of us are very different; a man who is being analysed only reveals this dependence of the intellect upon emotional life so clearly because in analysis we are putting such great pressure on him.

[1916-1917, 3367]
The therapeutic effect depends on making conscious what is repressed, in the widest sense of the word, in the id. We prepare the way for this making conscious by interpretations and constructions, but we have interpreted only for ourselves not for the patient so long as the ego holds on to its earlier defences and does not give up its resistances. Now these resistances, although they belong to the ego, are nevertheless unconscious and in some sense separated off within the ego. The analyst recognizes them more easily than he does the hidden material in the id. One might suppose that it would be sufficient to treat them like portions of the id and, by making them conscious, bring them into connection with the rest of the ego. In this way, we should suppose, one half of the task of analysis would be accomplished; we should not reckon on meeting with a resistance against the uncovering of resistances. But what happens is this. During the work on the resistances the ego withdraws - with a greater or less degree of seriousness - from the agreement on which the analytic situation is founded. The ego ceases to support our efforts at uncovering the id; it opposes them, disobeys the fundamental rule of analysis, and allows no further derivatives of the repressed to emerge. We cannot expect the patient to have a strong conviction of the curative power of analysis. He may have brought along with him a certain amount of confidence in his analyst, which will be strengthened to an effective point by the factors of the positive transference which will be aroused in him. Under the influence of the unpleasurable impulses which he feels as a result of the fresh activation of his defensive conflicts, negative transferences may now gain the upper hand and completely annul the analytic situation. The patient now regards the analyst as no more than a stranger who is making disagreeable demands on him, and he behaves towards him exactly like a child who does not like the stranger and does not believe anything he says. If the analyst tries to explain to the patient one of the distortions made by him for the purposes of defence, and to correct it, he finds him uncomprehending and inaccessible to sound arguments. Thus we see that there is a resistance against the uncovering of resistances, and the defensive mechanisms really do deserve the name which we gave them originally, before they had been more closely examined. They are resistances not only to the making conscious of contents of the id, but also to the analysis as a whole, and thus to recovery.

[1937c, 5034]
The therapeutic effect depends on making conscious what is repressed, in the widest sense of the word, in the id. We prepare the way for this making conscious by interpretations and constructions, but we have interpreted only for ourselves not for the patient so long as the ego holds on to its earlier defences and does not give up its resistances. Now these resistances, although they belong to the ego, are nevertheless unconscious and in some sense separated off within the ego. The analyst recognizes them more easily than he does the hidden material in the id. One might suppose that it would be sufficient to treat them like portions of the id and, by making them conscious, bring them into connection with the rest of the ego. In this way, we should suppose, one half of the task of analysis would be accomplished; we should not reckon on meeting with a resistance against the uncovering of resistances. But what happens is this. During the work on the resistances the ego withdraws - with a greater or less degree of seriousness - from the agreement on which the analytic situation is founded. The ego ceases to support our efforts at uncovering the id; it opposes them, disobeys the fundamental rule of analysis, and allows no further derivatives of the repressed to emerge. We cannot expect the patient to have a strong conviction of the curative power of analysis. He may have brought along with him a certain amount of confidence in his analyst, which will be strengthened to an effective point by the factors of the positive transference which will be aroused in him. Under the influence of the unpleasurable impulses which he feels as a result of the fresh activation of his defensive conflicts, negative transferences may now gain the upper hand and completely annul the analytic situation. The patient now regards the analyst as no more than a stranger who is making disagreeable demands on him, and he behaves towards him exactly like a child who does not like the stranger and does not believe anything he says. If the analyst tries to explain to the patient one of the distortions made by him for the purposes of defence, and to correct it, he finds him uncomprehending and inaccessible to sound arguments. Thus we see that there is a resistance against the uncovering of resistances, and the defensive mechanisms really do deserve the name which we gave them originally, before they had been more closely examined. They are resistances not only to the making conscious of contents of the id, but also to the analysis as a whole, and thus to recovery.

[1937c, 5034]
I myself had adopted another way of speeding up an analytic treatment even before the war. At that time I had taken on the case of a young Russian, a man spoilt by wealth, who had come to Vienna in a state of complete helplessness, accompanied by a private doctor and an attendant.¹ In the course of a few years it was possible to give him back a large amount of his independence, to awaken his interest in life and to adjust his relations to the people most important to him. But there progress came to a stop. We advanced no further in clearing up the neurosis of his childhood, on which his later illness was based, and it was obvious that the patient found his present position highly comfortable and had no wish to take any step forward which would bring him nearer to the end of his treatment. It was a case of the treatment inhibiting itself: it was in danger of failing as a result of its - partial - success. In this predicament I resorted to the heroic measure of fixing a time limit for the analysis. At the beginning of a year's work I informed the patient that the coming year was to be the last one of his treatment, no matter what he achieved in the time still left to him. At first he did not believe me, but once he was convinced that I was in deadly earnest, the desired change set in. His resistances shrank up, and in these last months of his treatment he was able to reproduce all the memories and to discover all the connections which seemed necessary for understanding his early neurosis and mastering his present one. When he left me in the midsummer of 1914, with as little suspicion as the rest of us of what lay so shortly ahead, I believed that his cure was radical and permanent.

¹ [1937c, 5015]

The effect brought about in the ego by the defences can rightly be described as an 'alteration of the ego' if by that we understand a deviation from the fiction of a normal ego which would guarantee unshakable loyalty to the work of analysis. It is easy, then, to accept the fact, shown by daily experience, that the outcome of an analytic treatment depends essentially on the strength and on the depth of root of these resistances that bring about an alteration of the ego. Once again we are confronted with the importance of the quantitative factor, and once again we are reminded that analysis can only draw upon definite and limited amounts of energy which have to be measured against the hostile forces. And it seems as if victory is in fact as a rule on the side of the big battalions.

[1937c, 5034]
Perhaps I may give you a more vivid picture of repression and of its necessary relation to resistance, by a rough analogy derived from our actual situation at the present moment. Let us suppose that in this lecture-room and among this audience, whose exemplary quiet and attentiveness I cannot sufficiently commend, there is nevertheless someone who is causing a disturbance and whose ill-mannered laughter, chattering and shuffling with his feet are distracting my attention from my task. I have to announce that I cannot proceed with my lecture; and thereupon three or four of you who are strong men stand up and, after a short struggle, put the interrupter outside the door. So now he is 'repressed', and I can continue my lecture. But in order that the interruption shall not be repeated, in case the individual who has been expelled should try to enter the room once more, the gentlemen who have put my will into effect place their chairs up against the door and thus establish a 'resistance' after the repression has been accomplished. If you will now translate the two localities concerned into psychical terms as the 'conscious' and the 'unconscious', you will have before you a fairly good picture of the process of repression.

[1910a, 2213]

In the first place, then, when we undertake to restore a patient to health, to relieve him of the symptoms of his illness, he meets us with a violent and tenacious resistance, which persists throughout the whole length of the treatment. This is such a strange fact that we cannot expect it to find much credence. It is best to say nothing about it to the patient's relatives, for they invariably regard it as an excuse on our part for the length or failure of our treatment. The patient, too, produces all the phenomena of this resistance without recognizing it as such, and if we can induce him to take our view of it and to reckon with its existence, that already counts as a great success. Only think of it! The patient, who is suffering so much from his symptoms and is causing those about him to share his sufferings, who is ready to undertake so many sacrifices in time, money, effort and self-discipline in order to be freed from those symptoms we are to believe that this same patient puts up a struggle in the interest of his illness against the person who is helping him. How improbable such an assertion must sound! Yet it is true; and when its improbability is pointed out to us, we need only reply that it is not without analogies. A man who has gone to the dentist because of an unbearable toothache will nevertheless try to hold the dentist back when he approaches the sick tooth with a pair of forceps.

[1916-1917, 3362]

Thus the course of this treatment illustrates a maxim whose truth has long been appreciated in the technique of analysis. The length of the road over which an analysis must travel with the patient, and the quantity of material which must be mastered on the way, are of no importance in comparison with the resistance which is met with in the course of the work, and are only of importance at all in so far as they are necessarily proportional to the resistance. The situation is the same as when to-day an enemy army needs weeks and months to make its way across a stretch of country which in times of peace was traversed by an express train in a few hours and which only a short time before had been passed over by the defending army in a few days.

[1918b, 3507]
Yes, we are only beginning to appreciate the significance of all these important circumstances. That is why my description was bound to turn out so obscure. But now I can proceed. We describe all the forces that oppose the work of recovery as the patient's 'resistances'. The gain from illness is one such resistance. The 'unconscious sense of guilt' represents the super-ego's resistance; it is the most powerful factor, and the one most dreaded by us. We meet with still other resistances during the treatment. If the ego during the early period has set up a repression out of fear, then the fear still persists and manifests itself as a resistance if the ego approaches the repressed material. And finally, as you can imagine, there are likely to be difficulties if an instinctual process which has been going along a particular path for whole decades is suddenly expected to take a new path that has just been made open for it. That might be called the id's resistance. The struggle against all these resistances is our main work during an analytic treatment; the task of making interpretations is nothing compared to it. But as a result of this struggle and of the overcoming of the resistances, the patient's ego is so much altered and strengthened that we can look forward calmly to his future behaviour when the treatment is over. On the other hand, you can understand now why we need such long treatments. The length of the path of development and the wealth of the material are not the decisive factors. It is more a question of whether the path is clear. An army can be held up for weeks on a stretch of country which in peace time an express train crosses in a couple of hours - if the army has to overcome the enemy's resistance there. Such battles call for time in mental life too. I am unfortunately obliged to tell you that every effort to hasten analytic treatment appreciably has hitherto failed. The best way of shortening it seems to be to carry it out according to the rules.

[1926e, 4366]
Various qualifications are required of anyone who is to be beneficially affected by psycho-analysis. To begin with, he must be capable of a psychically normal condition; during periods of confusion or melancholic depression nothing can be accomplished even in cases of hysteria. Furthermore, a certain measure of natural intelligence and ethical development are to be required of him; if the physician has to deal with a worthless character, he soon loses the interest which makes it possible for him to enter profoundly into the patient's mental life. Deep-rooted malformations of character, traits of an actually degenerate constitution, show themselves during treatment as sources of a resistance that can scarcely be overcome. In this respect the constitution of the patient sets a general limit to the curative effect of psychotherapy. If the patient's age is in the neighbourhood of the fifties the conditions for psycho-analysis become unfavourable. The mass of psychical material is then no longer manageable; the time required for recovery is too long; and the ability to undo psychical processes begins to grow weaker.

In his attitude towards his father and mother Hans confirms in the most concrete and uncompromising manner what I have said in my Interpretation of Dreams and in my Three Essays with regard to the sexual relations of a child to his parents. Hans really was a little Oedipus who wanted to have his father 'out of the way', to get rid of him, so that he might be alone with his beautiful mother and sleep with her. This wish had originated during his summer holidays, when the alternating presence and absence of his father had drawn Hans's attention to the condition upon which depended the intimacy with his mother which he longed for. At that time the form taken by the wish had been merely that his father should 'go away'; and at a later stage it became possible for his fear of being bitten by a white horse to attach itself directly on to this form of the wish, owing to a chance impression which he received at the moment of some one else's departure. But subsequently (probably not until they had moved back to Vienna, where his father's absences were no longer to be reckoned on) the wish had taken the form that his father should be permanently away - that he should be 'dead'. The fear which sprang from this death-wish against his father, and which may thus be said to have had a normal motive, formed the chief obstacle to the analysis until it was removed during the conversation in my consulting-room.¹

¹ Even in analyses in which the physician and the patient are strangers, fear of the father plays one of the most important parts as a resistance against the reproduction of the unconscious pathogenic material. Resistances are sometimes in the nature of 'motifs'. But sometimes, as in the present instance, one piece of the unconscious material is capable from its actual content of operating as an inhibition against the reproduction of another piece.

LADIES AND GENTLEMEN, - With the discovery of infantile sexuality and the tracing back of neurotic symptoms to erotic instinctual components we have arrived at some unexpected formulas concerning the nature and purposes of neurotic illnesses. We see that human beings fall ill when, as a result of external obstacles or of an internal lack of adaptation, the satisfaction of their erotic needs in reality frustrated. We see that they then take flight into illness in order that by its help they may find a satisfaction to take the place of what has been frustrated. We recognize that the pathological symptoms constitute a portion of the subject's sexual activity or even the whole of his sexual life, and we find that the withdrawal from reality is the main purpose of the illness but also the main damage caused by it. We suspect that our patients' resistance to recovery is no simple one, but compounded of several motives. Not only does the patient's ego rebel against giving up the repressions by means of which it has risen above its original disposition, but the sexual instincts are unwilling to renounce their substitutive satisfaction so long as it is uncertain whether reality will offer them anything better.

(b) I will hasten on to the innovations in the field of technique, where indeed nearly everything still awaits final settlement, and much is only now beginning to become clear. There are now two aims in psycho-analytic technique: to save the physician effort and to give the patient the most unrestricted access to his unconscious. As you know, our technique has undergone a fundamental transformation. At the time of the cathartic treatment what we aimed at was the elucidation of the symptoms; we then turned away from the symptoms and devoted ourselves instead to uncovering the 'complexes', to use a word which Jung has made indispensable; now, however, our work is aimed directly at finding out and overcoming the 'resistances', and we can justifiably rely on the complexes coming to light without difficulty as soon as the resistances have been recognized and removed. Some of you have since felt a need to be able to make a survey of these resistances and classify them. I will ask you to examine your material and see whether you can confirm the generalized statement that in male patients the most important resistances in the treatment seem to be derived from the father-complex and to express themselves in fear of the father, in defiance of the father and in disbelief of the father.

[1910d, 2309]

There would be nothing more to discuss or worry about in this behaviour of transference, if it were not that two points remain unexplained about it which are of particular interest to psycho-analysis. Firstly, we do not understand why transference is so much more intense with neurotic subjects in analysis than it is with other such people who are not being analysed; and secondly, it remains a puzzle why in analysis transference emerges as the most powerful resistance to the treatment, whereas outside analysis it must be regarded as the vehicle of cure and the condition of success. For our experience has shown us - and the fact can be confirmed as often as we please - that if a patient's free associations fail¹ the stoppage can invariably be removed by an assurance that he is being dominated at the moment by an association which is concerned with the doctor himself or with something connected with him. As soon as this explanation is given, the stoppage is removed, or the situation is changed from one in which the associations fail into one in which they are being kept back. At first sight it appears to be an immense disadvantage in psycho-analysis as a method that what is elsewhere the strongest factor towards success is changed in it into the most powerful medium of resistance. If, however, we examine the situation more closely, we can at least clear away the first of our two problems. It is not a fact that transference emerges with greater intensity and lack of restraint during psycho-analysis than outside it. In institutions in which nerve patients are treated non-analytically, we can observe transference occurring with the greatest intensity and in the most unworthy forms, extending to nothing less than mental bondage, and moreover showing the plainest erotic colouring. Gabriele Reuter, with her sharp powers of observation, described this at a time when there was no such thing as psycho-analysis, in a remarkable book which betrays in every respect the clearest insight into the nature and genesis of neuroses.² These characteristics of transference are therefore to be attributed not to psycho-analysis but to neurosis itself.

[1912b, 2458]
Our second problem - the problem of why transference appears in psycho-analysis as resistance - has been left for the moment untouched; and we must now approach it more closely. Let us picture the psychological situation during the treatment. An invariable and indispensable precondition of every onset of a psychoneurosis is the process to which Jung has given the appropriate name of 'introversion'.¹ That is to say: the portion of libido which is capable of becoming conscious and is directed towards reality is diminished, and the portion which is directed away from reality and is unconscious, and which, though it may still feed the subject's phantasies, nevertheless belongs to the unconscious, is proportionately increased. The libido (whether wholly or in part) has entered on a regressive course and has revived the subject's infantile imagos.² The analytic treatment now proceeds to follow it; it seeks to track down the libido, to make it accessible to consciousness and, in the end, serviceable for reality. Where the investigations of analysis come upon the libido withdrawn into its hiding-place, a struggle is bound to break out; all the forces which have caused the libido to regress will rise up as 'resistances' against the work of analysis, in order to conserve the new state of things. For if the libido's introversion or regression had not been justified by a particular relation between the subject and the external world - stated in the most general terms, by the frustration of satisfaction - and if it had not for the moment even become expedient, it could never have taken place at all. But the resistances from this source are not the only ones or indeed the most powerful. The libido at the disposal of the subject's personality had always been under the influence of the attraction of his unconscious complexes (or more correctly, of the portions of those complexes belonging to the unconscious), and it entered on a regressive course because the attraction of reality had diminished. In order to liberate it, this attraction of the unconscious has to be overcome; that is, the repression of the unconscious instincts and of their productions, which has meanwhile been set up in the subject, must be removed. This is responsible for by far the largest part of the resistance, which so often causes the illness to persist even after the turning away from reality has lost its temporary justification. The analysis has to struggle against the resistances from both these sources. The resistance accompanies the treatment step by step. Every single association, every act of the person under treatment must reckon with the resistance and represents a compromise between the forces that are striving towards recovery and the opposing ones which I have described.

¹ This, however, should not lead us to conclude in general that the element selected for transference-resistance is of peculiar pathogenic importance. If in the course of a battle there is a particularly embittered struggle over the possession of some little church or some individual farm, there is no need to suppose that the church is a national shrine perhaps, or that the house shelters the army's pay-chest. The value to the object may be a purely tactical one and may perhaps emerge only in this one battle.

² The question then arises whether the advantage gained by the patient would not to some extent counterbalance the sacrifice made by the physician. I may venture to form a judgement about this, since for ten years or so I set aside one hour a day, and sometimes two, for gratuitous treatments, because I wanted, in order to find my way about in the neuroses, to work in the face of as little resistance as possible. The advantages I sought by this means were not forthcoming. Free treatment enormously increases some of a neurotic's resistances - in young women, for instance, the temptation which is inherent in their transference-relation, and in young men, their opposition to an obligation to feel grateful, an opposition which arises from their father-complex and which presents one of the most troublesome hindrances to the acceptance of medical help. The absence of the regulating effect offered by the payment of a fee to the doctor makes itself very painfully felt; the whole relationship is removed from the real world, and the patient is deprived of a strong motive for endeavouring to bring the treatment to an end.
