destiny. Medical research explains dreams as purely somatic phenomena, without meaning or
significance, and regards them as the reaction of a mental organ sunk in a state of sleep to
physical stimuli which partially awaken it. Psycho-analysis raises the status of dreams into that of
psychical acts possessing meaning and purpose, and having a place in the subject's mental life,
and thus disregards their strangeness, incoherence and absurdity. On this view somatic stimuli
merely play the part of material that is worked over in the course of the construction of the dream.
There is no half-way house between these two views of dreams. What argues against the
physiological hypothesis is its unfruitfulness, and what may be argued in favour of the psycho-
analytic one is the fact that it has translated and given a meaning to thousands of dreams and
has used them to throw light on the intimate details of the human mind.

The interpretation of dreams became a solace and a support to me in those arduous first years
of analysis, when I had to master the technique, clinical phenomena and therapy of the neuroses
all at the same time. At that period I was completely isolated and in the network of problems and
accumulation of difficulties I often dreaded losing my bearings and also my confidence. There
were often patients with whom an unaccountably long time elapsed before my hypothesis, that a
neurosis was bound to become intelligible through analysis, proved true; but these patients'
dreams, which might be regarded as analogues of their symptoms, almost always confirmed the
hypothesis.

It is by no means easy to arrive at general conclusions upon the value of correctly translated
dreams. If a conflict due to ambivalence is taking place in a patient, then the emergence in him of
a hostile thought certainly does not imply a permanent overcoming of his affectionate impulse -
that is to say, a resolution of the conflict: neither does any such implication follow from a dream
with a similarly hostile content. During a conflict such as this arising from ambivalence, there are
often two dreams every night, each of them representing an opposite attitude. In that case the
progress lies in the fact that a complete isolation of the two contrasted impulses has been
achieved and that each of them, with the help of its unconscious reinforcements, can be followed
and understood to its extreme limits. And if it sometimes happens that one of the two ambivalent
dreams has been forgotten, one must not be deceived into assuming that a decision has been
made in favour of the one side. The fact that one of the dreams has been forgotten shows, it is
ture, that for the moment one tendency is in the ascendant, but that is true only of the one day,
and may be changed. The next night may perhaps bring the opposite expression into the
foreground. The true state of the conflict can only be determined by taking into account all the
other indications, including those of waking life.
Critical voices will now be raised. It will be objected that, since it is not possible to interpret every dream that is dealt with, one should cease asserting more than one can establish and should be content to say that some dreams can be shown by interpretation to have a meaning but that as to the rest we are in ignorance. But the very fact that success in interpretation depends upon the resistance absolves the analyst from the necessity for such modesty. He may have the experience of a dream that was at first unintelligible becoming clear during the very same hour after some fortunate remark has got rid of one of the dreamer's resistances. A portion of the dream which the patient had hitherto forgotten may suddenly occur to him and may bring the key to the interpretation; or a new association may emerge which may throw light upon the darkness. It sometimes happens, too, that, after months or years of analytic labour, one returns to a dream which at the beginning of the treatment seemed meaningless and incomprehensible but which is now, in the light of knowledge obtained in the meantime, completely elucidated. And if one further takes into consideration the argument from the theory of dreams that the model dream-products of children invariably have a clear meaning and are easy to interpret, then it will be justifiable to assert that dreams are quite generally mental structures that are capable of interpretation, though the situation may not always allow of an interpretation being reached.

[1925i, 4046]

There were now a whole series of questions to be answered, among the most important of them being whether the formation of dreams had a motive, under what conditions it took place, by what methods the dream-thoughts (which are invariably full of sense) become converted into the dream (which is often senseless), and others besides. I attempted to solve all of these problems in *The Interpretation of Dreams*, which I published in the year 1900. I can only find space here for the briefest abstract of my investigation. When the latent dream-thoughts that are revealed by the analysis of a dream are examined, one of them is found to stand out from among the rest, which are intelligible and well known to the dreamer. These latter thoughts are residues of waking life (the day's residues, as they are called technically); but the isolated thought is found to be a wishful impulse, often of a very repellent kind, which is foreign to the waking life of the dreamer and is consequently disavowed by him with surprise or indignation. This impulse is the actual constructor of the dream: it provides the energy for its production and makes use of the day's residues as material. The dream which thus originates represents a situation of satisfaction for the impulse, it is the fulfilment of its wish. It would not be possible for this process to take place without being favoured by the presence of something in the nature of a state of sleep. The necessary mental precondition of sleep is the concentration of the ego upon the wish to sleep and the withdrawal of psychical energy from all the interests of life. Since at the same time all the paths of approach to motility are blocked, the ego is also able to reduce the expenditure by which at other times it maintains the repressions. The unconscious impulse makes use of this nocturnal relaxation of repression in order to push its way into consciousness with the dream. But the repressive resistance of the ego is not abolished in sleep but merely reduced. Some of it remains in the shape of a *censorship of dreams* and forbids the unconscious impulse to express itself in the forms which it would properly assume. In consequence of the severity of the censorship of dreams, the latent dream-thoughts are obliged to submit to being altered and softened so as to make the forbidden meaning of the dream unrecognizable. This is the explanation of *dream-distortion*, which accounts for the most striking characteristics of the manifest dream. We are therefore justified in asserting that a dream is the (disguised) fulfilment of a (repressed) wish. It will now be seen that dreams are constructed like a neurotic symptom: they are compromises between the demands of a repressed impulse and the resistance of a censoring force in the ego. Since they have a similar origin they are equally unintelligible and stand in equal need of interpretation.

[1925d, 4219]
I was able to show from a short story by W. Jensen called *Gradiva*, which has no particular merit in itself, that invented dreams can be interpreted in the same way as real ones and that the unconscious mechanisms familiar to us in the 'dream-work' are thus also operative in the processes of imaginative writing. My book on *Jokes and their Relation to the Unconscious* was a side-issue directly derived from *The Interpretation of Dreams*. The only friend of mine who was at that time interested in my work remarked to me that my interpretations of dreams often impressed him as being like jokes. In order to throw some light on this impression, I began to investigate jokes and found that their essence lay in the technical methods employed in them, and that these were the same as the means used in the 'dream-work' - that is to say, condensation, displacement, the representation of a thing by its opposite or by something very small, and so on. This led to an economic enquiry into the origin of the high degree of pleasure obtained from hearing a joke. And to this the answer was that it was due to the momentary suspension of the expenditure of energy upon maintaining repression, owing to the attraction exercised by the offer of a bonus of pleasure (*fore-pleasure*).

[LADIES AND GENTLEMEN, - If, after an interval of more than fifteen years, I have brought you together again to discuss with you what novelties, and what improvements it may be, the intervening time has introduced into psycho-analysis, it is right and fitting from more than one point of view that we should turn our attention first to the position of the theory of dreams. It occupies a special place in the history of psycho-analysis and marks a turning-point; it was with it that analysis took the step from being a psychotherapeutic procedure to being a depth-psychology. Since then, too, the theory of dreams has remained what is most characteristic and peculiar about the young science, something to which there is no counterpart in the rest of our knowledge, a stretch of new country, which has been reclaimed from popular beliefs and mysticism. The strangeness of the assertions it was obliged to put forward has made it play the part of a shibboleth, the use of which decided who could become a follower of psycho-analysis and to whom it remained forever incomprehensible. I myself found it a sheet-anchor during those difficult times when the unrecognized facts of the neuroses used to confuse my inexperienced judgement. Whenever I began to have doubts of the correctness of my wavering conclusions, the successful transformation of a senseless and muddled dream into a logical and intelligible mental process in the dreamer would renew my confidence of being on the right track.

[1925d, 4239]

LADIES AND GENTLEMEN, - If, after an interval of more than fifteen years, I have brought you together again to discuss with you what novelties, and what improvements it may be, the intervening time has introduced into psycho-analysis, it is right and fitting from more than one point of view that we should turn our attention first to the position of the theory of dreams. It occupies a special place in the history of psycho-analysis and marks a turning-point; it was with it that analysis took the step from being a psychotherapeutic procedure to being a depth-psychology. Since then, too, the theory of dreams has remained what is most characteristic and peculiar about the young science, something to which there is no counterpart in the rest of our knowledge, a stretch of new country, which has been reclaimed from popular beliefs and mysticism. The strangeness of the assertions it was obliged to put forward has made it play the part of a shibboleth, the use of which decided who could become a follower of psycho-analysis and to whom it remained forever incomprehensible. I myself found it a sheet-anchor during those difficult times when the unrecognized facts of the neuroses used to confuse my inexperienced judgement. Whenever I began to have doubts of the correctness of my wavering conclusions, the successful transformation of a senseless and muddled dream into a logical and intelligible mental process in the dreamer would renew my confidence of being on the right track.

[1933a, 4621]

Now, however, the difficulties of our task and the enigmas of our subject rise before our eyes. How do we propose to transform the dream into a normal communication and how do we explain the fact that some of the patient’s utterances have assumed a form that is unintelligible both to him and to us?

[1933a, 4623]

When they fell in with my instructions they told me their dreams, amongst other things, as though they were of the same kind as their other thoughts. This was a plain hint that I should assign as much importance to these dreams as to other, intelligible, phenomena. They, however, were *not* intelligible, but strange, confused, absurd: like dreams, in fact - which for that very reason, were condemned by science as random and senseless twitches of the organ of the mind. If my patients were right - and they seemed only to be repeating the ancient beliefs held by unscientific men for thousands of years - I was faced by the task of 'interpreting dreams' in a way that could stand up against scientific criticism.

[1932c, 4808]
To begin with, I naturally understood no more about my patients' dreams than the dreamers did themselves. But by applying to these dreams, and more particularly to my own dreams, the procedure which I had already used for the study of other abnormal psychological structures, I succeeded in answering most of the questions which could be raised by an interpretation of dreams. There were many such questions: What do we dream about? Why do we dream at all? What is the origin of all the strange characteristics which distinguish dreams from waking life? - and many more such questions besides. Some of the answers were easily given and turned out to confirm views that had already been put forward; but others involved completely new hypotheses with regard to the structure and functioning of the apparatus of the mind. People dream about the things that have engaged their minds during the waking day. People dream in order to allay impulses that seek to disturb sleep, and in order to be able to sleep on. But why was it possible for dreams to present such a strange appearance, so confusedly senseless, so obviously contrasted with the content of waking thought, in spite of being concerned with the same material? There could be no doubt that dreams were only a substitute for a rational process of thought and could be interpreted - that is to say, translated into a rational process. But what needed explaining was the fact of the distortion which the dream-work had carried out upon the rational and intelligible material.

[1932c, 4808]

We find our way to the understanding ('interpretation') of a dream by assuming that what we recollect as the dream after we have woken up is not the true dream-process but only a façade behind which that process lies concealed. Here we have our distinction between the manifest content of a dream and the latent dream-thoughts. The process which produces the former out of the latter is described as the dream-work. The study of the dream-work teaches us by an excellent example the way in which unconscious material from the id (originally unconscious and repressed unconscious alike) forces its way into the ego, becomes preconscious and, as a result of the ego's opposition, undergoes the changes which we know as dream-distortion. There are no features of a dream which cannot be explained in this way.

[1940a [1938], 4975]
In the pages that follow I shall bring forward proof that there is a psychological technique which makes it possible to interpret dreams, and that, if that procedure is employed, every dream reveals itself as a psychical structure which has a meaning and which can be inserted at an assignable point in the mental activities of waking life. I shall further endeavour to elucidate the processes to which the strangeness and obscurity of dreams are due and to deduce from those processes the nature of the psychical forces by whose concurrent or mutually opposing action dreams are generated. Having gone thus far, my description will break off, for it will have reached a point at which the problem of dreams merges into more comprehensive problems, the solution of which must be approached upon the basis of material of another kind.

My knowledge of that procedure was reached in the following manner. I have been engaged for many years (with a therapeutic aim in view) in unravelling certain psychopathological structures - hysterical phobias, obsessional ideas, and so on. I have been doing so, in fact, ever since I learnt from an important communication by Josef Breuer that as regards these structures (which are looked on as pathological symptoms) unravelling these coincides with removing them. (Cf. Breuer and Freud, 1895.) If a pathological idea of this sort can be traced back to the elements in the patient's mental life from which it originated, it simultaneously crumbles away and the patient is freed from it. Considering the impotence of our other therapeutic efforts and the puzzling nature of these disorders, I felt tempted to follow the path marked out by Breuer, in spite of every difficulty, till a complete explanation was reached. I shall have on another occasion to report at length upon the form finally taken by this procedure and the results of my labours. It was in the course of these psycho-analytic studies that I came upon dream-interpretation. My patients were pledged to communicate to me every idea or thought that occurred to them in connection with some particular subject; amongst other things they told me their dreams and so taught me that a dream can be inserted into the psychical chain that has to be traced backwards in the memory from a pathological idea. It was then only a short step to treating the dream itself as a symptom and to applying to dreams the method of interpretation that had been worked out for symptoms.

When, after passing through a narrow defile, we suddenly emerge upon a piece of high ground, where the path divides and the finest prospects open up on every side, we may pause for a moment and consider in which direction we shall first turn our steps. Such is the case with us, now that we have surmounted the first interpretation of a dream. We find ourselves in the full daylight of a sudden discovery. Dreams are not to be likened to the unregulated sounds that rise from a musical instrument struck by the blow of some external force instead of by a player's hand; they are not meaningless, they are not absurd; they do not imply that one portion of our store of ideas is asleep while another portion is beginning to wake. On the contrary, they are psychical phenomena of complete validity - fulfilments of wishes; they can be inserted into the chain of intelligible waking mental acts; they are constructed by a highly complicated activity of the mind.

But, having recognized that the dream was a process with a meaning, and that it can be inserted into the chain of the dreamer's psychical experiences, we may still wonder why it was that a dream occurred at all in such circumstances, when the most rapid possible awakening was called for. And here we shall observe that this dream, too, contained the fulfilment of a wish. The dead child behaved in the dream like a living one: he himself warned his father, came to his bed, and caught him by the arm, just as he had probably done on the occasion from the memory of which the first part of the child's words in the dream were derived. For the sake of the fulfilment of this wish the father prolonged his sleep by one moment. The dream was preferred to a waking reflection because it was able to show the child as once more alive. If the father had woken up first and then made the inference that led him to go into the next room, he would, as it were, have shortened his child's life by that moment of time.
In my Interpretation of Dreams, published in 1900, I showed that dreams in general can be interpreted, and that after the work of interpretation has been completed they can be replaced by perfectly correctly constructed thoughts which can be assigned a recognizable position in the chain of mental events. I wish to give an example in the following pages of the only practical application of which the art of interpreting dreams seems to admit. I have already mentioned in my book¹ how it was that I came upon the problem of dreams. The problem crossed my path as I was endeavouring to cure psychoneuroses by means of a particular psychotherapeutic method. For, among their other mental experiences, my patients told me their dreams, and these dreams seemed to call for insertion in the long thread of connections which spun itself out between a symptom of the disease and a pathogenic idea. At that time I learnt how to translate the language of dreams into the forms of expression of our own thought-language, which can be understood without further help. And I may add that this knowledge is essential for the psycho-analyst; for the dream is one of the roads along which consciousness can be reached by the psychical material which, on account of the opposition aroused by its content, has been cut off from consciousness and repressed, and has thus become pathogenic. The dream, in short, is one of the détours by which repression can be evaded; it is one of the principal means employed by what is known as the indirect method of representation in the mind. The following fragment from the history of the treatment of a hysterical girl is intended to show the way in which the interpretation of dreams plays a part in the work of analysis. It will at the same time give me a first opportunity of publishing at sufficient length to prevent further misunderstanding some of my views upon the psychical processes of hysteria and upon its organic determinants. I need no longer apologize on the score of length, since it is now agreed that the exacting demands which hysteria makes upon physician and investigator can be met only by the most sympathetic spirit of inquiry and not by an attitude of superiority and contempt. For,

[1905e, 1357]

At this point I shall interrupt my report of the analysis in order to compare this small piece of dream-interpretation with the general statements I have made upon the mechanism of the formation of dreams. I argued in my book, The Interpretation of Dreams (1900a), that every dream is a wish which is represented as fulfilled, that the representation acts as a takes disguise if the wish is a repressed one, belonging to the unconscious, and that except in the case of children's dreams only an unconscious wish or one which reaches down into the unconscious has the force necessary for the formation of a dream. I fancy my theory would have been more certain of general acceptance if I had contented myself with maintaining that every dream had a meaning, which could be discovered by means of a certain process of interpretation; and that when the interpretation had been completed the dream could be replaced by thoughts which would fall into place at an easily recognizable point in the waking mental life of the dreamer. I might then have gone on to say that the meaning of a dream turned out to be of as many different sorts as the processes of waking thought; that in one case it would be a fulfilled wish, in another a realized fear, or again a reflection persisting on into sleep, or an intention (as in the instance of Dora's dream), or a piece of creative thought during sleep, and so on. Such a theory would no doubt have proved attractive from its very simplicity, and it might have been supported by a great many examples of dreams that had been satisfactorily interpreted, as for instance by the one which has been analysed in these pages.

[1905e, 1404]
The application of a few of the rules of dream-interpretation to Hanold's first dream has thus resulted in making it intelligible to us in its main features and in inserting it into the nexus of the story. Surely, then, the author must have observed these rules in creating it? We might ask another question, too: why did the author introduce a dream at all to bring about the further development of the delusion? In my opinion it was an ingenious notion and once again true to reality. We have already heard that in real illnesses a delusion very often arises in connection with a dream, and, after what we have learnt about the nature of dreams, there is no need to see a fresh riddle in this fact. Dreams and delusions arise from the same source - from what is repressed. Dreams are, as one might say, the physiological delusions of normal people. Before what is repressed has become strong enough to break through into waking life as a delusion, it may easily have achieved a first success, under the more favourable conditions of the state of sleep, in the form of a dream with persisting effects. For during sleep, along with a general lowering of mental activity, there is a relaxation in the strength of the resistance with which the dominant psychical forces oppose what is repressed. It is this relaxation that makes the formation of dreams possible, and that is why dreams give us our best access to a knowledge of the unconscious part of the mind - except that, as a rule, with the re-establishment of the psychical cathexes of waking life, the dream once more takes to flight and the ground that had been won by the unconscious is evacuated once again.

[1907a, 1858]

In the further course of the story there is yet another dream, which may perhaps tempt us even more than the first to try to translate it and insert it into the train of events in the hero's mind. But we should save very little by diverging from the author's account and hurrying on immediately to this second dream; for no one who wishes to analyse some one else's dream can avoid turning his attention in the greatest detail to all the dreamer's experiences, both external and internal. It will probably be best, therefore, to keep close to the thread of the story and to intersperse it with our glosses as we proceed.

[1907a, 1859]

Obsessional ideas, as is well known, have an appearance of being either without motive or without meaning, just a dreams have. The first problem is how to give them a sense and a status in the subject's mental life, so as to make them comprehensible and even obvious. The problem of translating them may seem insoluble; but we must never let ourselves be misled by that illusion. The wildest and most eccentric obsessional ideas can be cleared up if they are investigated deeply enough. The solution is effected by bringing the obsessional ideas into temporal relationship with the patient's experiences, that is to say, by inquiring when a particular obsessional idea made its first appearance and in what external circumstances it is apt to recur. When, as so often happens, an obsessional idea has not succeeded in establishing itself permanently, the task of clearing it up is correspondingly simplified. We can easily convince ourselves that, when once the interconnections between an obsessional idea and the patient's experiences have been discovered, there will be no difficulty in obtaining access to whatever else may be puzzling or worth knowing in the pathological structure we are dealing with - its meaning, the mechanism of its origin, and its derivation from the preponderant motive forces of the patient's mind.

[1909d, 2147]
The latent thoughts of the dream differ in no respect from the products of our regular conscious activity; they deserve the name of foreconscious thoughts, and may indeed have been conscious at some moment of waking life. But by entering into connection with the unconscious tendencies during the night they have become assimilated to the latter, degraded as it were to the condition of unconscious thoughts, and subjected to the laws by which unconscious activity is governed. And here is the opportunity to learn what we could not have guessed from speculation, or from another source of empirical information - that the laws of unconscious activity differ widely from those of the conscious. We gather in detail what the peculiarities of the Unconscious are, and we may hope to learn still more about them by a profounder investigation of the processes of dream-formation.

I have said that animism is a system of thought, the first complete theory of the universe, and I shall now go on to draw certain conclusions from the psycho-analytic view of such systems. Every day of our lives our experience is in a position to show us the principal characteristics of a 'system'. We have dreams during the night and we have learnt how to interpret them during the day. Dreams may, without contradicting their nature, appear confused and disconnected. But they may, on the contrary, simulate the orderly impressions of a real experience, they may make one event follow from another and make one portion of their content refer to another. Such a result can be more or less successfully achieved; but it scarcely ever succeeds so completely as to leave no absurdity, no rift in its texture, visible. When we come to submit a dream to interpretation, we find that the erratic and irregular arrangement of its constituent parts is quite unimportant from the point of view of our understanding it. The essential elements in a dream are the dream-thoughts, and these have meaning, connection and order. But their order is quite other than that remembered by us as present in the manifest dream. In the latter the connection between the dream-thoughts has been abandoned and may either remain completely lost or be replaced by the new connection exhibited in the manifest content. The elements of the dream, apart from their being condensed, are almost invariably arranged in a new order more or less independent of their earlier arrangement. Finally, it must be added that whatever the original material of the dream-thoughts has been turned into by the dream-work is then subjected to a further influence. This is what is known as 'secondary revision', and its purpose is evidently to get rid of the disconnectedness and unintelligibility produced by the dream-work and replace it by a new 'meaning'. But this new meaning, arrived at by secondary revision, is no longer the meaning of the dream-thoughts.
There are a large number of phenomena related to facial and other expressive movements and to speech, as well as many processes of thought (both in normal and sick people), which have hitherto escaped the notice of psychology because they have been regarded as no more than the results of organic disorder or of some abnormal failure in function of the mental apparatus. What I have in mind are ‘parapraxes’ (slips of the tongue or pen, forgetfulness, etc.), haphazard actions and dreams in normal people, and convulsive attacks, deliria, visions, and obsessive ideas or acts in neurotic subjects. These phenomena (in so far as they were not entirely neglected, as was the case with the parapraxes) were relegated to pathology and an attempt was made to find 'physiological' explanations of them, though these were invariably unsatisfactory. Psycho-analysis, on the contrary, has been able to show that all these things can be explained by means of hypotheses of a purely psychological nature and can be fitted into the chain of psychical events already known to us. Thus on the one hand psycho-analysis has narrowed the region subject to the physiological point of view and on the other hand has brought a large section of pathology into the sphere of psychology. In this instance the normal phenomena provide the more convincing evidence. Psycho-analysis cannot be accused of having applied to normal cases findings arrived at from pathological material. The evidence in the latter and in the former was reached independently and shows that normal processes and what are described as pathological ones follow the same rules.

The explanation of parapraxes owes its theoretical value to the ease with which they can be solved and their frequency in normal people. But the success of psycho-analysis in explaining them is far surpassed in importance by a further achievement made by it, relating to another phenomenon of normal mental life. What I have in mind is the interpretation of dreams, which brought psycho-analysis for the first time into the conflict with official science which was to be its destiny. Medical research explains dreams as purely somatic phenomena, without meaning or significance, and regards them as the reaction of a mental organ sunk in a state of sleep to physical stimuli which partially awaken it. Psycho-analysis raises the status of dreams into that of psychical acts possessing meaning and purpose, and having a place in the subject's mental life, and thus disregards their strangeness, incoherence and absurdity. On this view somatic stimuli merely play the part of material that is worked over in the course of the construction of the dream. There is no half-way house between these two views of dreams. What argues against the physiological hypothesis is its unfruitfulness, and what may be argued in favour of the psychoanalytic one is the fact that it has translated and given a meaning to thousands of dreams and has used them to throw light on the intimate details of the human mind.

Thus neurotic symptoms have a sense, like parapraxes and dreams, and, like them, have a connection with the life of those who produce them. I should now like to make this important discovery plain to you by a few examples. I can indeed only assert, I cannot prove, that it is always and in every instance so. Anyone who looks for experiences himself, will find convincing evidence. But for certain reasons I shall choose these examples from cases not of hysteria but of another, highly remarkable neurosis which is fundamentally very much akin to it and about which I have a few introductory remarks to make.

[1913j, 2803]

[1913j, 2806]

[1916-1917, 3338]
LADIES AND GENTLEMEN, - If, after an interval of more than fifteen years, I have brought you together again to discuss with you what novelties, and what improvements it may be, the intervening time has introduced into psycho-analysis, it is right and fitting from more than one point of view that we should turn our attention first to the position of the theory of dreams. It occupies a special place in the history of psycho-analysis and marks a turning-point; it was with it that analysis took the step from being a psychotherapeutic procedure to being a depth-psychology. Since then, too, the theory of dreams has remained what is most characteristic and peculiar about the young science, something to which there is no counterpart in the rest of our knowledge, a stretch of new country, which has been reclaimed from popular beliefs and mysticism. The strangeness of the assertions it was obliged to put forward has made it play the part of a shibboleth, the use of which decided who could become a follower of psycho-analysis and to whom it remained forever incomprehensible. I myself found it a sheet-anchor during those difficult times when the unrecognized facts of the neuroses used to confuse my inexperienced judgement. Whenever I began to have doubts of the correctness of my wavering conclusions, the successful transformation of a senseless and muddled dream into a logical and intelligible mental process in the dreamer would renew my confidence of being on the right track.

Let us suppose, then, that someone - a patient in analysis, for instance - tells us one of his dreams. We shall assume that in this way he is making us one of the communications to which he has pledged himself by the fact of having started an analytic treatment. It is, to be sure, a communication made by inappropriate means, for dreams are not in themselves social utterances, not a means of giving information. Nor, indeed, do we understand what the dreamer was trying to say to us, and he himself is equally in the dark. And now we have to make a quick decision. On the one hand, the dream may be, as non-analytic doctors assure us, a sign that the dreamer has slept badly, that not every part of his brain has come to rest equally, that some areas of it, under the influence of unknown stimuli, endeavoured to go on working but were only able to do so in a very incomplete fashion. If that is the case, we shall be right to concern ourselves no further with the product of a nocturnal disturbance which has no psychical value: for what could we expect to derive from investigating it that would be of use for our purposes? Or on the other hand - but it is plain that we have from the first decided otherwise. We have - quite arbitrarily, it must be admitted - made the assumption, adopted as a postulate, that even this unintelligible dream must be a fully valid psychical act, with sense and worth, which we can use in analysis like any other communication. Only the outcome of our experiment can show whether we are right. If we succeed in turning the dream into an utterance of value of that kind, we shall evidently have a prospect of learning something new and of receiving communications of a sort which would otherwise be inaccessible to us.
In the pages that follow I shall bring forward proof that there is a psychological technique which makes it possible to interpret dreams, and that, if that procedure is employed, every dream reveals itself as a psychical structure which has a meaning and which can be inserted at an assignable point in the mental activities of waking life. I shall further endeavour to elucidate the processes to which the strangeness and obscurity of dreams are due and to deduce from those processes the nature of the psychical forces by whose concurrent or mutually opposing action dreams are generated. Having gone thus far, my description will break off, for it will have reached a point at which the problem of dreams merges into more comprehensive problems, the solution of which must be approached upon the basis of material of another kind.

Our scientific consideration of dreams starts off from the assumption that they are products of our own mental activity. Nevertheless the finished dream strikes us as something alien to us. We are so little obliged to acknowledge our responsibility for it that we are just as ready to say 'mir hat geträumt' ['I had a dream', literally 'a dream came to me'] as 'ich habe geträumt' ['I dreamt']. What is the origin of this feeling that dreams are extraneous to our minds? In view of our discussion upon the sources of dreams, we must conclude that the strangeness cannot be due to the material that finds its way into their content, since that material is for the most part common to dreaming and waking life. The question arises whether in dreams there may not be modifications in the processes of the mind which produce the impression we are discussing; and we shall therefore make an attempt at drawing a picture of the psychological attributes of dreams.

No one has emphasized more sharply the essential difference between dreaming and waking life or drawn more far-reaching conclusions from it than G. T. Fechner in a passage in his *Elemente der Psychophysik* (1889, 2, 520-1). In his opinion, 'neither the mere lowering of conscious mental life below the main threshold', nor the withdrawal of attention from the influences of the external world, are enough to explain the characteristics of dream-life as contrasted with waking life. He suspects, rather, that *the scene of action of dreams is different from that of waking ideational life*. 'If the scene of action of psychophysical activity were the same in sleeping and waking, dreams could, in my view, only be a prolongation at a lower degree of intensity of waking ideational life and, moreover, would necessarily be of the same material and form. But the facts are quite otherwise.'

It is not clear what Fechner had in mind in speaking of this change of location of mental activity; nor, so far as I know, has anyone else pursued the path indicated by his words. We may, I think, dismiss the possibility of giving the phrase an anatomical interpretation and supposing it to refer to physiological cerebral localization or even to the histological layers of the cerebral cortex. It may be, however, that the suggestion will eventually prove to be sagacious and fertile, if it can be applied to a *mental* apparatus built up of a number of agencies arranged in a series one behind the other.

We may, then, class together under the heading of 'involuntary ideas' the whole of the ideational material the emergence of which, alike in immoral and in absurd dreams, causes us so much bewilderment. There is, however, one important point of difference: involuntary ideas in the moral sphere contradict our usual attitude of mind, whereas the others merely strike us as strange. No step has yet been taken towards a deeper knowledge which would resolve this distinction.
When in the course of a piece of scientific work we come upon a problem which is difficult to solve, it is often a good plan to take up a second problem along with the original one - just as it is easier to crack two nuts together than each separately. Thus we are not only faced by the question 'How can distressing dreams and anxiety-dreams be wish-fulfilments?'; our reflections enable us to add a second question: 'Why is it that dreams with an indifferent content, which turn out to be wish-fulfilments, do not express their meaning undisguised?' Take, for instance, the dream which I treated at such length of Irma's injection. It was not by any means of a distressing nature and interpretation showed it as a striking example of the fulfilment of a wish. But why should it have needed any interpretation at all? Why did it not say what it meant straight out? At first sight the dream of Irma's injection gave no impression that it represented a wish of the dreamer's as fulfilled. My readers will have had no such impression; but neither did I myself before I carried out the analysis. Let us describe this behaviour of dreams, which stands in so much need of explanation, as 'the phenomenon of distortion in dreams'. Thus our second problem is: what is the origin of dream-distortion?

I then recalled that there was still a piece of the dream which the interpretation had not touched. After the idea had occurred to me that R. was my uncle, I had had a warm feeling of affection for him in the dream. Where did that feeling belong? I had naturally never had any feeling of affection for my Uncle Josef. I had been fond of my friend R. and had esteemed him for many years; but if I had gone up to him and expressed my sentiments in terms approaching the degree of affection I had felt in the dream, there could be no doubt that he would have been astonished. My affection for him struck me as ungenuine and exaggerated - like the judgement of his intellectual qualities which I had expressed by fusing his personality with my uncle's, though there the exaggeration had been in the opposite direction. But a new light began to dawn on me. The affection in the dream did not belong to the latent content, to the thoughts that lay behind the dream; it stood in contradiction to them and was calculated to conceal the true interpretation of the dream. And probably that was precisely its raison d'être. I recalled my resistance against embarking on the interpretation, how long I had put it off and how I had declared that the dream was sheer nonsense. My psycho-analytic treatments taught me how a repudiation of that kind was to be interpreted: it had no value as a judgement but was simply an expression of emotion. If my little daughter did not want an apple that was offered to her, she asserted that the apple tasted sour without having tasted it. And if my patients behaved like the child, I knew that they were concerned with an idea which they wanted to repress. The same was true of my dream. I did not want to interpret it, because the interpretation contained something that I was struggling against. When I had completed the interpretation I learnt what it was that I had been struggling against - namely, the assertion that R. was a simpleton. The affection that I felt for R. could not be derived from the latent dream-thoughts; but no doubt it originated from this struggle of mine. If my dream was distorted in this respect from its latent content - and distorted into its opposite - then the affection that was manifest in the dream served the purpose of this distortion. In other words, distortion was shown in this case to be deliberate and to be a means of dissimulation. My dream thoughts had contained a slander against R.; and, in order that I might not notice this, what appeared in the dream was the opposite, a feeling of affection for him.

[1900a, 633]
It seemed as though this might be a discovery of general validity. It is true that, as was shown by the instances quoted in Chapter III, there are some dreams which are undisguised fulfilments of wishes. But in cases where the wish-fulfilment is unrecognizable, where it has been disguised, there must have existed some inclination to put up a defence against the wish; and owing to this defence the wish was unable to express itself except in a distorted shape. I will try to seek a social parallel to this internal event in the mind. Where can we find a similar distortion of a psychical act in social life? Only where two persons are concerned, one of whom possesses a certain degree of power which the second is obliged to take into account. In such a case the second person will distort his psychical acts or, as we might put it, will dissimulate. The politeness which I practise every day is to a large extent dissimulation of this kind; and when I interpret my dreams for my readers I am obliged to adopt similar distortions. The poet complains of the need for these distortions in the words:
[1900a, 638]

The fact that the phenomena of censorship and of dream-distortion correspond down to their smallest details justifies us in presuming that they are similarly determined. We may therefore suppose that dreams are given their shape in individual human beings by the operation of two psychical forces (or we may describe them as currents or systems); and that one of these forces constructs the wish which is expressed by the dream, while the other exercises a censorship upon this dream-wish and, by the use of that censorship, forcibly brings about a distortion in the expression of the wish. It remains to enquire as to the nature of the power enjoyed by this second agency which enables it to exercise its censorship. When we bear in mind that the latent dream-thoughts are not conscious before an analysis has been carried out, whereas the manifest content of the dream is consciously remembered, it seems plausible to suppose that the privilege enjoyed by the second agency is that of permitting thoughts to enter consciousness. Nothing, it would seem, can reach consciousness from the first system without passing the second agency; and the second agency allows nothing to pass without exercising its rights and making such modifications as it thinks fit in the thought which is seeking admission to consciousness. Incidentally, this enables us to form a quite definite view of the 'essential nature' of consciousness: we see the process of a thing becoming conscious as a specific psychical act, distinct from and independent of the process of the formation of a presentation or idea; and we regard consciousness as a sense organ which perceives data that arise elsewhere. It can be demonstrated that these basic assumptions are absolutely indispensable to psychopathology. We must, however, postpone our further consideration of them to a later stage.
[1900a, 639]

These considerations may lead us to feel that the interpretation of dreams may enable us to draw conclusions as to the structure of our mental apparatus which we have hoped for in vain from philosophy. I do not propose, however, to follow this line of thought; but, having cleared up the matter of distortion in dreams, I shall go back to the problem from which we started. The question raised was how dreams with a distressing content can be resolved into wish-fulfilments. We now see that this is possible if dream-distortion has occurred and if the distressing content serves only to disguise something that is wished for. Bearing in mind our assumption of the existence of two psychical agencies, we can further say that distressing dreams do in fact contain something which is distressing to the second agency, but something which at the same time fulfils a wish on the part of the first agency. They are wishful dreams in so far as every dream arises from the first agency; the relation of the second agency towards dreams is of a defensive and not of a creative kind.¹ If we were to restrict ourselves to considering what the second agency contributes to dreams, we could never arrive at an understanding of them: all the conundrums which the authorities have observed in dreams would remain unsolved.
[1900a, 641]
In order to conceal her wish, she had evidently chosen a situation in which such wishes are usually suppressed, a situation in which one is so much filled with grief that one has no thought of love. Yet it is quite possible that even in the real situation of which the dream was an exact replica, beside the coffin of the elder boy whom she had loved still more, she may have been unable to suppress her tender feelings for the visitor who had been absent so long.

I hope that the foregoing examples will be enough (till the next objection is raised) to make it seem plausible that even dreams with a distressing content are to be construed as wish-fulfilments. Nor will anyone regard it as a chance coincidence that the interpretation of these dreams has brought us up each time against topics about which people are loth to speak or to think. The distressing feeling aroused by these dreams is no doubt identical with the repugnance which tends (usually with success) to restrain us from discussing or mentioning such topics, and which each of us has to overcome if we nevertheless find ourselves compelled to embark on them. But the unpleasurable feeling which thus recurs in dreams does not disprove the existence of a wish. Everyone has wishes that he would prefer not to disclose to other people, and wishes that he will not admit even to himself. On the other hand, we are justified in linking the unpleasurable character of all these dreams with the fact of dream-distortion. And we are justified in concluding that these dreams are distorted and the wish-fulfilment contained in them disguised to the point of being unrecognizable precisely owing to the repugnance felt for the topic of the dream or for the wish derived from it and to an intention to repress them. The distortion in the dream is thus shown in fact to be an act of the censorship. We shall be taking into account everything that has been brought to light by our analysis of unpleasurable dreams if we make the following modification in the formula in which we have sought to express the nature of dreams: a dream is a (disguised) fulfilment of a (suppressed or repressed) wish.¹

We have already seen (on p. 534) that a dream very seldom reproduces recollections in such a way that they constitute, without abbreviation or modification, the whole of its manifest content. Nevertheless there are some undoubted instances of this happening: and I can add a few more, relating, once more, to childhood scenes. One of my patients was presented in a dream with an almost undistorted reproduction of a sexual episode, which was at once recognizable as a true recollection. His memory of the event had, in fact, never been completely lost in waking life, though it had become greatly obscured, and its revival was a consequence of work previously done in analysis. At the age of twelve, the dreamer had gone to visit a school friend who was laid up in bed, when the latter, by what was probably an accidental movement, uncovered his body. At the sight of his friend's genitals, my patient had been overcome by some sort of compulsion and had uncovered himself too and caught hold of the other's penis. His friend looked at him with indignation and astonishment; where upon, overcome by embarrassment, he let go. This scene was repeated in a dream twenty-three years later, including all the details of his feelings at the time. It was modified, however, to this extent, that the dreamer assumed the passive instead of the active role, while the figure of his school-friend was replaced by someone belonging to his contemporary life.
I must also refrain from any detailed analysis of the two remaining episodes of the dream. I will merely pick out the elements leading to the two childhood scenes on whose account alone I embarked upon a discussion of this dream. It will rightly be suspected that what compels me to make this suppression is sexual material; but there is no need to rest content with this explanation. After all, there are many things which one has to keep secret from other people but of which one makes no secret to oneself; and the question here is not as to why I am obliged to conceal the solution but as to the motives for the internal censorship which hid the true content of the dream from myself. I must therefore explain that the analysis of these three episodes of the dream showed that they were impertinent boastings, the issue of an absurd megalomania which had long been suppressed in my waking life and a few of whose ramifications had even made their way into the dream's manifest content (e. g. 'I felt I was being very cunning'), and which incidentally accounted for my exuberant spirits during the evening before I had the dream. The boasting extended to all spheres; for instance, the mention of Graz went back to the slang phrase 'What's the price of Graz? ', which expresses the self-satisfaction of a person who feels extremely well-off. The first episode of the dream may also be included among the boastings by anyone who will bear in mind the great Rabelais' incomparable account of the life and deeds of Gargantua and his son Pantagruel.

[1900a, 696]

The core of a dream of exhibiting lies in the figure of the dreamer himself (not as he was as a child but as he appears at the present time) and his inadequate clothing (which emerges indistinctly, whether owing to superimposed layers of innumerable later memories of being in undress or as a result of the censorship). Added to these are the figures of the people in whose presence the dreamer feels ashamed. I know of no instance in which the actual spectators of the infantile scene of exhibiting have appeared in the dream; a dream is scarcely ever a simple memory. Curiously enough, the people upon whom our sexual interest was directed in childhood are omitted in all the reproductions which occur in dreams, in hysteria and in obsessional neurosis. It is only in paranoia that these spectators reappear and, though they remain invisible, their presence is inferred with fanatical conviction. What takes their place in dreams - 'a lot of strangers' who take no notice of the spectacle that is offered - is nothing more nor less than the wishful contrary of the single familiar individual before whom the dreamer exposed himself. Incidentally, 'a lot of strangers' frequently appear in dreams in many other connections, and they always stand as the wishful contrary of 'secrecy'. It is to be noticed that even in paranoia, where the original state of things is restored, this reversal into a contrary is observed. The subject feels that he is no longer alone, he has no doubt that he is being observed, but the observers are 'a lot of strangers' whose identity is left curiously vague.

[1900a, 724]
I once had an opportunity of making a detailed study of a young woman who passed through a variety of psychical conditions. Her illness began with a state of confusional excitement during which she displayed a quite special aversion to her mother, hitting and abusing her whenever she came near her bed, while at the same period she was docile and affectionate towards a sister who was many years her senior. This was followed by a state in which she was lucid but somewhat apathetic and suffered from badly disturbed sleep. It was during this phase that I began treating her and analysing her dreams. An immense number of these dreams were concerned, with a greater or less degree of disguise, with the death of her mother: at one time she would be attending an old woman's funeral, at another she and her sister would be sitting at table dressed in mourning. There could be no question as to the meaning of these dreams. As her condition improved still further, hysterical phobias developed. The most tormenting of these was a fear that something might have happened to her mother. She was obliged to hurry home, wherever she might be, to convince herself that her mother was still alive. This case, taken in conjunction with what I had learnt from other sources, was highly instructive: it exhibited, translated as it were into different languages, the various ways in which the psychical apparatus reacted to one and the same exciting idea. In the confusional state, in which, as I believe, the second psychical agency was overwhelmed by the normally suppressed first one, her unconscious hostility to her mother found a powerful motor expression. When the calmer condition set in, when the rebellion was suppressed and the domination of the censorship re-established, the only region left open in which her hostility could realize the wish for her mother's death was that of dreaming. When a normal state was still more firmly established, it led to the production of her exaggerated worry about her mother as a hysterical counter-reaction and defensive phenomenon. In view of this it is no longer hard to understand why hysterical girls are so often attached to their mothers with such exaggerated affection.

I cannot leave the subject of typical dreams of the death of loved relatives, without adding a few more words to throw light on their significance for the theory of dreams in general. In these dreams we find the highly unusual condition realized of a dream-thought formed by a repressed wish entirely eluding censorship and passing into the dream without modification. There must be special factors at work to make this event possible, and I believe that the occurrence of these dreams is facilitated by two such factors. Firstly, there is no wish that seems more remote from us than this one: 'we couldn't even dream' - so we believe - of wishing such a thing. For this reason the dream-censorship is not armed to meet such a monstrosity, just as Solon's penal code contained no punishment for parricide. Secondly, in this case the repressed and unsuspected wish is particularly often met half-way by a residue from the previous day in the form of a worry about the safety of the person concerned. This worry can only make its way into the dream by availing itself of the corresponding wish; while the wish can disguise itself behind the worry that has become active during the day. We may feel inclined to think that things are simpler than this and that one merely carries on during the night and in dreams with what one has been turning over in one's mind during the day; but if so we shall be leaving dreams of the death of people of whom the dreamer is fond completely in the air and without any connection with our explanation of dreams in general, and we shall thus be clinging quite unnecessarily to a riddle which is perfectly capable of solution.
Who can the unknown person have been whose sumptuous banquet of meat was the subject of the little boy's dream? His experiences during the dream-day must enlighten us on the subject. By doctor's orders he had been put on a milk diet for the past few days. On the evening of the dream-day he had been naughty, and as a punishment he had been sent to bed without his supper. He had been through this hunger-cure once before and had been very brave about it. He knew he would get nothing, but would not allow himself to show by so much as a single word that he was hungry. Education had already begun to have an effect on him: it found expression in this dream, which exhibits the beginning of dream-distortion. There can be no doubt that the person whose wishes were aimed at this lavish meal - a meat meal, too - was himself. But since he knew he was not allowed it, he did not venture to sit down to the meal himself, as hungry children do in dreams. (Cf. my little daughter Anna's dream of strawberries on p. 628.) The person who ate the meal remained anonymous.

The element in this dream which stood out most was the botanical monograph. This arose from the impressions of the dream day: I had in fact seen a monograph on the genus Cyclamen in the window of a book-shop. There was no mention of this genus in the content of the dream; all that was left in it was the monograph and its relation to botany. The 'botanical monograph' immediately revealed its connection with the work upon cocaine which I had once written. From 'cocaine' the chains of thought led on the one hand to the Festschrift and to certain events in a University laboratory, and on the other hand to my friend Dr. Königstein, the eye surgeon, who had had a share in the introduction of cocaine. The figure of Dr. Königstein further reminded me of the interrupted conversation which I had had with him the evening before and of my various reflections upon the payment for medical services among colleagues. This conversation was the actual currently active instigator of the dream; the monograph on the cyclamen was also a currently active impression, but one of an indifferent nature. As I perceived, the 'botanical monograph' in the dream turned out to be an 'intermediate common entity' between the two experiences of the previous day: it was taken over unaltered from the indifferent impression and was linked with the psychically significant event by copious associative connections.

Nor do I think we shall have any difficulty in recognizing the psychical force which manifests itself in the facts of dream-displacement. The consequence of the displacement is that the dream-content no longer resembles the core of the dream-thoughts and that the dream gives no more than a distortion of the dream-wish which exists in the unconscious. But we are already familiar with dream-distortion. We traced it back to the censorship which is exercised by one psychical agency in the mind over another. Dream-displacement is one of the chief methods by which that distortion is achieved. Is fecit cui profuit. We may assume, then, that dream-displacement comes about through the influence of the same censorship - that is, the censorship of endopsychic defence.¹

The question of the interplay of these factors - of displacement, condensation and overdetermination - in the construction of dreams, and the question which is a dominant factor and which a subordinate one - all of this we shall leave aside for later investigation. But we can state provisionally a second condition which must be satisfied by those elements of the dream-thoughts which make their way into the dream: they must escape the censorship imposed by resistance. And henceforward in interpreting dreams we shall take dream-displacement into account as an undeniable fact.
My attempts at building up dreams by synthesis from the dream-thoughts have taught me that the material which emerges in the course of interpretation is not all of the same value. One part of it is made up of the essential dream-thoughts - those, that is, which completely replace the dream, and which, if there were no censorship of dreams, would be sufficient in themselves to replace it. The other part of the material is usually to be regarded as of less importance. Nor is it possible to support the view that all the thoughts of this second kind had a share in the formation of the dream. On the contrary, there may be associations among them which relate to events that occurred after the dream, between the times of dreaming and interpreting. This part of the material includes all the connecting paths that led from the manifest dream-content to the latent dream-thoughts, as well as the intermediate and linking associations by means of which, in the course of the process of interpretation, we came to discover these connecting paths. [1900a, 782]

The possibility of creating composite structures stands foremost among the characteristics which so often lend dreams a fantastic appearance, for it introduces into the content of dreams elements which could never have been objects of actual perception. The psychical process of constructing composite images in dreams is evidently the same as when we imagine or portray a centaur or a dragon in waking life. The only difference is that what determines the production of the imaginary figure in waking life is the impression which the new structure itself is intended to make; whereas the formation of the composite structure in a dream is determined by a factor extraneous to its actual shape - namely the common element in the dream-thoughts. Composite structures in dreams can be formed in a great variety of ways. The most naive of these procedures merely represents the attributes of one thing to the accompaniment of a knowledge that they also belong to something else. A more painstaking technique combines the features of both objects into a new image and in so doing makes clever use of any similarities that the two objects may happen to possess in reality. The new structure may seem entirely absurd or may strike us as an imaginative success, according to the material and to the ingenuity with which it is put together. If the objects which are to be condensed into a single unity are much too incongruous, the dream-work is often content with creating a composite structure with a comparatively distinct nucleus, accompanied by a number of less distinct features. In that case the process of unification into a single image may be said to have failed. The two representations are superimposed and produce something in the nature of a contest between the two visual images. One might arrive at similar representations in a drawing, if one tried to illustrate the way in which a general concept is formed from a number of individual perceptual images. [1900a, 794]
This second species of displacement which occurs in dream-formation is not only of great theoretical interest but is also specially well calculated to explain the appearance of fantastic absurdity in which dreams are disguised. The direction taken by the displacement usually results in a colourless and abstract expression in the dream-thought being exchanged for a pictorial and concrete one. The advantage, and accordingly the purpose, of such a change jumps to the eyes. A thing that is pictorial is, from the point of view of a dream, a thing that is capable of being represented: it can be introduced into a situation in which abstract expressions offer the same kind of difficulties to representation in dreams as a political leading article in a newspaper would offer to an illustrator. But not only representability, but the interests of condensation and the censorship as well can be the gainers from this exchange. A dream-thought is unusable so long as it is expressed in an abstract form; but when once it has been transformed into pictorial language, contrasts and identifications of the kind which the dream-work requires, and which it creates if they are not already present, can be established more easily than before between the new form of expression and the remainder of the material underlying the dream. This is so because in every language concrete terms, in consequence of the history of their development, are richer in associations than conceptual ones. We may suppose that a good part of the intermediate work done during the formation of a dream, which seeks to reduce the dispersed dream-thoughts to the most succinct and unified expression possible, proceeds along the line of finding appropriate verbal transformations for the individual thoughts. Any one thought, whose form of expression may happen to be fixed for other reasons, will operate in a determinant and selective manner on the possible forms of expression allotted to the other thoughts, and it may do so, perhaps, from the very start - as is the case in writing a poem. If a poem is to be written in rhymes, the second line of a couplet is limited by two conditions: it must express an appropriate meaning, and the expression of that meaning must rhyme with the first line. No doubt the best poem will be one in which we fail to notice the intention of finding a rhyme, and in which the two thoughts have, by mutual influence, chosen from the very start a verbal expression which will allow a rhyme to emerge with only slight subsequent adjustment.

In a few instances a change of expression of this kind assists dream-condensation even more directly, by finding a form of words which owing to its ambiguity is able to give expression to more than one of the dream-thoughts. In this way the whole domain of verbal wit is put at the disposal of the dream-work. There is no need to be astonished at the part played by words in dream-formation. Words, since they are the nodal point of numerous ideas, may be regarded as predestined to ambiguity; and the neuroses (e.g. in framing obsessions and phobias), no less than dreams, make unashamed use of the advantages thus offered by words for purposes of condensation and disguise.¹ It is easy to show that dream-distortion too profits from displacement of expression. If one ambiguous word is used instead of two unambiguous ones the result is misleading; and if our everyday, sober method of expression is replaced by a pictorial one, our understanding is brought to a halt, particularly since a dream never tells us whether its elements are to be interpreted literally or in a figurative sense or whether they are to be connected with the material of the dream-thoughts directly or through the intermediary of some interpolated phraseology. In interpreting any dream-element it is in general doubtful
It would seem that the occurrence of sexual symbolism in dreams has already been experimentally confirmed by some work carried out by K. Schröter, on lines proposed by H. Swoboda. Subjects under deep hypnosis were given suggestions by Schröter, and these led to the production of dreams a large part of whose content was determined by the suggestions. If he gave a suggestion that the subject should dream of normal or abnormal sexual intercourse, the dream, in obeying the suggestion, would make use of symbols familiar to us from psycho-analysis in place of the sexual material. For instance, when a suggestion was made to a female subject that she should dream of having homosexual intercourse with a friend, the friend appeared in the dream carrying a shabby hand-bag with a label stuck on to it bearing the words 'Ladies only.' The woman who dreamt this was said never to have had any knowledge of symbolism in dreams or of their interpretation. Difficulties are, however, thrown in the way of our forming an opinion of the value of these interesting experiments by the unfortunate circumstance that Dr. Schröter committed suicide soon after making them. The only record of them is to be found in a preliminary communication published in the *Zentralblatt für Psychoanalyse* (Schrötter, 1912).

[1900a, 841]

Similar findings were published by Roffenstein in 1923. Some experiments made by Betlheim and Hartmann (1924) were of particular interest, since they made no use of hypnosis. These experimenters related anecdotes of a coarsely sexual character to patients suffering from Korsakoff's syndrome and observed the distortions which occurred when the anecdotes were reproduced by the patients in these confusional states. They found that the symbols familiar to us from the interpretation of dreams made their appearance (e.g. going upstairs, stabbing and shooting as symbols of copulation, and knives and cigarettes as symbols of the penis). The authors attached special importance to the appearance of the symbol of a staircase, for, as they justly observed, 'no conscious desire to distort could have arrived at a symbol of such a kind.'

[1900a, 841]

It will be observed that the meaning and context of the numbers have been altered to a far greater extent in this dream than in the former one. The processes of modification and distortion have gone further here; and this is to be explained by the dream-thoughts in this case having to overcome a specially high degree of endopsychic resistance before they could obtain representation. Nor should we overlook the fact that there was an element of absurdity in the dream, namely the *three* seats being taken by *two* people. I will anticipate my discussion of absurdity in dreams by pointing out that this absurd detail in the content of the dream was intended to represent the most strongly emphasized of the dream-thoughts, viz., 'it was absurd to marry so early.' The absurdity which had to find a place in the dream was ingeniously supplied by the number 3, which was itself derived from a quite immaterial point of distinction between the two people under comparison - the 3 months' difference between their ages. The reduction of the actual 150 florins to 1 florin 50 corresponded to the *low value* assigned by the dreamer to her husband (or treasure), in her suppressed thoughts.

[1900a, 870]
We should conclude from the preceding discussion that the insistence with which this dream exhibited its absurdities could only be taken as indicating the presence in the dream-thoughts of a particularly embittered and passionate polemic. We shall therefore be all the more astonished to observe that in this dream the polemic was carried on in the open and that my father was the explicit object of the ridicule. Openness of this kind seems to contradict our assumptions as regards the working of the censorship in connection with the dream-work. The position will become clearer, however, when it is realized that in this instance my father was merely put forward as a show figure, and that the dispute was really being carried on with someone else, who only appeared in the dream in a single allusion. Whereas normally a dream deals with rebellion against someone else, behind whom the dreamer’s father is concealed, the opposite was true here. My father was made into a man of straw, in order to screen someone else; and the dream was allowed to handle in this undisguised way a figure who was as a rule treated as sacred, because at the same time I knew with certainty that it was not he who was really meant. That this was so was shown by the exciting cause of the dream. For it occurred after I had heard that a senior colleague of mine, whose judgement was regarded as beyond criticism, had given voice to disapproval and surprise at the fact that the psycho-analytic treatment of one of my patients had already entered its fifth year. The first sentences of the dream alluded under a transparent disguise to the fact that for some time this colleague had taken over the duties which my father could no longer fulfil (‘fees due’, ‘maintenance in the hospital’), and that, when our relations began to be less friendly, I became involved in the same kind of emotional conflict which, when a misunderstanding arises between a father and son, is inevitably produced owing to the position occupied by the father and the assistance formerly given by him. The dream-thoughts protested bitterly against the reproach that I was not getting on faster - a reproach which, applying first to my treatment of the patient, extended later to other things. Did he know anyone, I thought, who could get on more quickly? Was he not aware that, apart from my methods of treatment, conditions of that kind are altogether incurable and last a life-time? What were four or five years in comparison with a whole life-time, especially considering that the patient’s existence had been so very much eased during the treatment?

[1900a, 884]
A great part of the impression of absurdity in this dream was brought about by running together sentences from different parts of the dream-thoughts without any transition. Thus the sentence ‘I went to him in the next room’, etc., dropped the subject with which the preceding sentences had been dealing and correctly reproduced the circumstances in which I informed my father of my having become engaged to be married without consulting him. This sentence was therefore reminding me of the admirable unselfishness displayed by the old man on that occasion, and contrasting it with the behaviour of someone else - of yet another person. It is to be observed that the dream was allowed to ridicule my father because in the dream-thoughts he was held up in unqualified admiration as a model to other people. It lies in the very nature of every censorship that of forbidden things it allows those which are untrue to be said rather than those which are true. The next sentence, to the effect that he recollected ‘having once got drunk and been locked up for it’, was no longer concerned with anything that related to my father in reality. Here the figure for whom he stood was no less a person than the great Meynert, in whose footsteps I had trodden with such deep veneration and whose behaviour towards me, after a short period of favour, had turned to undisguised hostility. The dream reminded me that he himself had told me that at one time in his youth he had indulged in the habit of making himself intoxicated with chloroform and that on account of it he had had to go into a home. It also reminded me of another incident with him shortly before his death. I had carried on an embittered controversy with him in writing, on the subject of male hysteria, the existence of which he denied. When I visited him during his fatal illness and asked after his condition, he spoke at some length about his state and ended with these words: ‘You know, I was always one of the clearest cases of male hysteria.’ He was thus admitting, to my satisfaction and astonishment, what he had for so long obstinately contested. But the reason why I was able in this scene of the dream to use my father as a screen for Meynert did not lie in any analogy that I had discovered between the two figures. The scene was a concise but entirely adequate representation of a conditional sentence in the dream-thoughts, which ran in full: ‘If only I had been the second generation, the son of a professor or Hofrat, I should certainly have got on faster.’ In the dream I made my father into a Hofrat and professor. -The most blatant and disturbing absurdity in the dream resides in its treatment of the date 1851, which seemed to me not to differ from 1856, just as though a difference of five years was of no significance whatever. But this last was precisely what the dream-thoughts sought to express. Four or five years was the length of time during which I enjoyed the support of the colleague whom I mentioned earlier in this analysis; but it was also the length of time during which I made my fiancée wait for our marriage; and it was also, by a chance coincidence which was eagerly exploited by the dream-thoughts, the length of time during which I made my patient of longest standing wait for a complete recovery. ‘What are five years?’ asked the dream-thoughts; ‘that’s no time at all, so far as I am concerned; it doesn’t count. I have time enough in front of me. And just as I succeeded in the end in that, though you would not believe it, so I shall achieve this, too.’ Apart from this, however, the number 51 by itself, without the number of the century, was determined in another, and indeed, in an opposite sense; and this, too, is why it appeared in the dream several times. 51 is the age which seems to be a particularly dangerous one to men; I have known colleagues who have died suddenly at that age, and amongst them one who, after long delays, had been appointed to a professorship only a few days before his death.

[1900a, 885]
In the case of a psychical complex which has come under the influence of the censorship imposed by resistance, the affects are the constituent which is least influenced and which alone can give us a pointer as to how we should fill in the missing thoughts. This is seen even more clearly in the psychoneuroses than in dreams. Their affects are always appropriate, at least in their quality though we must allow for their intensity being increased owing to displacements of neurotic attention. If a hysteric is surprised at having to be so frightened of something trivial or if a man suffering from obsessions is surprised at such distressing self-reproaches arising out of a mere nothing, they have both gone astray, because they regard the ideational content - the triviality or the mere nothing - as what is essential; and they put up an unsuccessful fight because they take this ideational content as the starting-point of their thought-activity. Psycho-analysis can put them upon the right path by recognizing the affect as being, on the contrary, justified and by seeking out the idea which belongs to it but has been repressed and replaced by a substitute. A necessary premise to all this is that the release of affect and the ideational content do not constitute the indissoluble organic unity as which we are in the habit of treating them, but that these two separate entities may be merely soldered together and can thus be detached from each other by analysis. Dream-interpretation shows that this is in fact the case.

[1900a, 905]

No complete theoretical explanation can here be given of this suppression of affect in the course of the dream-work. It would require to be preceded by a most painstaking investigation of the theory of affects and of the mechanism of repression. I will only permit myself a reference to two points. I am compelled - for other reasons - to picture the release of affects as a centrifugal process directed towards the interior of the body and analogous to the processes of motor and secretory innervation. Now just as in the state of sleep the sending out of motor impulses towards the external world appears to be suspended, so it may be that the centrifugal calling-up of affects by unconscious thinking may become more difficult during sleep. In that case the affective impulses occurring during the course of the dream-thoughts would from their very nature be weak impulses, and consequently those which found their was into the dream would be no less weak. On this view, then, the 'suppression of affect' would not in any way be the consequence of the dream-work but would result from the state of sleep. This may be true, but it cannot be the whole truth. We must also bear in mind that any relatively complex dream turns out to be a compromise produced by a conflict between psychical forces. For one thing, the thoughts constructing the wish are obliged to struggle against the opposition of a censoring agency; and for another thing, we have often seen that in unconscious thinking itself every train of thought is yoked with its contradictory opposite. Since all of these trains of thought are capable of carrying an affect, we shall by and large scarcely be wrong if we regard the suppression of affect as a consequence of the inhibition which these contraries exercise upon each other and which the censorship exercises upon the impulsions suppressed by it. The inhibition of affect, accordingly, must be considered as the second consequence of the censorship of dreams, just as dream-distortion is its first consequence.

[1900a, 911]
Let us next consider the two dreams in which an expression of satisfaction was transposed to the moment after waking. In the one case the reason given for the satisfaction was an expectation that I should now discover what was meant by 'I've dreamt of that before', while the satisfaction really referred to the birth of my first children. In the other case the ostensible reason was my conviction that something that had been 'prognosticated' was now coming true, while the real reference was similar to that in the former dream: it was the satisfaction with which I greeted the birth of my second son. Here the affects which dominated the dream-thoughts persisted in the dreams; but it is safe to say that in no dream can things be as simple as all that. If we go a little more deeply into the two analyses we find that this satisfaction which had escaped censorship had received an accession from another source. This other source had grounds for fearing the censorship, and its affect would undoubtedly have aroused opposition if it had not covered itself by the similar, legitimate affect of satisfaction, arising from the permissible source, and slipped in, as it were, under its wing.

[1900a, 920]

But what had become of the dream-censorship? Why had it not raised the most energetic objections against this blatantly egoistic train of thought? And why had it not transformed the satisfaction attached to that train of thought into severe unpleasure? The explanation was, I think, that other, unobjectionable, trains of thought in connection with the same people found simultaneous satisfaction and screened with their affect the affect which arose from the forbidden infantile source. In another stratum of my thoughts, during the ceremonial unveiling of the memorial, I had reflected thus: 'What a number of valued friends I have lost, some through death, some through a breach of our friendship! How fortunate that I have found a substitute for them and that I have gained one who means more to me than ever the others could, and that, at a time of life when new friendships cannot easily be formed, I shall never lose his!' My satisfaction at having found a substitute for these lost friends could be allowed to enter the dream without interference; but there slipped in, along with it, the hostile satisfaction derived from the infantile source. It is no doubt true that infantile affection served to reinforce my contemporary and justified affection. But infantile hatred, too, succeeded in getting itself represented.

[1900a, 926]

We can have no hesitation in deciding in favour of the second alternative. There can be no doubt that the censoring agency, whose influence we have so far only recognized in limitations and omissions in the dream-content, is also responsible for interpolations and additions in it. The interpolations are easy to recognize. They are often reported with hesitation, and introduced by an 'as though'; they are not in themselves particularly vivid and are always introduced at points at which they can serve as links between two portions of the dream-content or to bridge a gap between two parts of the dream. They are less easily retained in the memory than genuine derivatives of the material of the dream-thoughts; if the dream is to be forgotten they are the first part of it to disappear, and I have a strong suspicion that the common complaint of having dreamt a lot, but of having forgotten most of it and of having only retained fragments, is based upon the rapid disappearance precisely of these connecting thoughts. In a complete analysis these interpolations are sometimes betrayed by the fact that no material connected with them is to be found in the dream-thoughts. But careful examination leads me to regard this as the less frequent case; as a rule the connecting thoughts lead back nevertheless to material in the dream-thoughts, but to material which could have no claim to acceptance in the dream either on its own account or owing to its being over-determined. Only in extreme cases, it seems, does the psychical function in dream-formation which we are now considering proceed to make new creations. So long as possible, it employs anything appropriate that it can find in the material of the dream-thoughts.

[1900a, 929]
The function of 'secondary revision', which we have attributed to the fourth of the factors concerned in shaping the content of dreams, shows us in operation once more the activity which is able to find free vent in the creation of day-dreams without being inhibited by any other influences. We might put it simply by saying that this fourth factor of ours seeks to mould the material offered to it into something like a day-dream. If, however, a day-dream of this kind has already been formed within the nexus of the dream-thoughts, this fourth factor in the dream-work will prefer to take possession of the ready-made day-dream and seek to introduce it into the content of the dream. There are some dreams which consist merely in the repetition of a day-time phantasy which may perhaps have remained unconscious: such, for instance, as the boy's dream of driving in a war-chariot with the heroes of the Trojan War. In my 'Autodidasker' dream the second part at all events was a faithful reproduction of a daytime phantasy, innocent in itself, of a conversation with Professor N. In view of the complicated conditions which a dream has to satisfy when it comes into existence, it happens more frequently that the ready-made phantasy forms only a portion of the dream, or that only a portion of the phantasy forces its way into the dream. Thereafter, the phantasy is treated in general like any other portion of the latent material, though it often remains recognizable as an entity in the dream. There are often parts of my dreams which stand out as producing a different impression from the rest. They strike me as being, as it were, more fluent, more connected and at the same time more fleeting than other parts of the same dream. These, I know, are unconscious phantasies which have found their way into the fabric of the dream, but I have never succeeded in pinning down a phantasy of this kind. Apart from this, these phantasies, like any other component of the dream-thoughts, are compressed, condensed, superimposed on one another, and so on. There are, however, transitional cases, between the case in which they constitute the content (or at least the façade) of the dream unaltered and the extreme opposite in which they are represented in the content of the dream only by one of their elements or by a distant allusion. What happens to phantasies present in the dream-thoughts is evidently also determined by any advantages they may have to offer the requirements of the censorship and of the urge towards condensation.

We are ready to recognize the fact that Silberer's phenomena constitute a second contribution on the part of waking thought to the construction of dreams; though it is less regularly present and less significant than the first one, which has already been introduced under the name of 'secondary revision.' It has been shown that a part of the attention which operates during the day continues to be directed towards dreams during the state of sleep, that it keeps a check on them and criticizes them and reserves the power to interrupt them. It has seemed plausible to recognize in the mental agency which thus remains awake the censor to whom we have had to attribute such a powerful restricting influence upon the form taken by dreams. What Silberer's observations have added to this is the fact that in certain circumstances a species of self-observation plays a part in this and makes a contribution to the content of the dream. The probable relations of this self-observing agency, which may be particularly prominent in philosophical minds, to endopsychic perception, to delusions of observation, to conscience and to the censor of dreams can be more appropriately treated elsewhere.
I will now try to sum up this lengthy disquisition on the dream-work. We were faced by the question whether the mind employs the whole of its faculties without reserve in constructing dreams or only a functionally restricted fragment of them. Our investigations led us to reject entirely the form in which the question was framed as being inadequate to the circumstances. If, however, we had to reply to the question on the basis of the terms in which it was stated, we should be obliged to reply in the affirmative to both the alternatives, mutually exclusive though they appear to be. Two separate functions may be distinguished in mental activity during the construction of a dream: the production of the dream-thoughts, and their transformation into the content of the dream. The dream-thoughts are entirely rational and are constructed with an expenditure of all the psychical energy of which we are capable. They have their place among thought-processes that have not become conscious - processes from which, after some modification, our conscious thoughts, too, arise. However many interesting and puzzling questions the dream-thoughts may involve, such questions have, after all, no special relation to dreams and do not call for treatment among the problems of dreams.¹ On the other hand, the second function of mental activity during dream-construction, the transformation of the unconscious thoughts into the content of the dream, is peculiar to dream-life and characteristic of it. This dream-work proper diverges further from our picture of waking thought than has been supposed even by the most determined depreciator of psychical functioning during the formation of dreams. The dream-work is not simply more careless, more irrational, more forgetful and more incomplete than waking thought; it is completely different from it qualitatively and for that reason not immediately comparable with it. It does not think, calculate or judge in any way at all; it restricts itself to giving things a new form. It is exhaustively described by an enumeration of the conditions which it has to satisfy in producing its result. That product, the dream, has above all to evade the censorship, and with that end in view the dream-work makes use of a displacement of psychical intensities to the point of a transvaluation of all psychical values. The thoughts have to be reproduced exclusively or predominantly in the material of visual and acoustic memory-traces, and this necessity imposes upon the dream-work considerations of representability which it meets by carrying out fresh displacements. Greater intensities have probably to be produced than are available in the dream-thoughts at night, and this purpose is served by the extensive condensation which is carried out with the constituents of the dream-thoughts. Little attention is paid to the logical relations between the thoughts; those relations are ultimately given a disguised representation in certain formal characteristics of dreams. Any affect attached to the dream-thoughts undergoes less modification than their ideational content. Such affects are as a rule suppressed; when they are retained, they are detached from the ideas that properly belong to them, affects of a similar character being brought together. Only a single portion of the dream-work and one which operates to an irregular degree, the working over of the material by partly aroused waking thought, tallies to some extent with the view which other writers have sought to apply to the entire activity of dream-construction.

¹ [1900a, 944]

There can be no doubt what the peculiar feature is which attracts our interest to this brief dream. Hitherto we have been principally concerned with the secret meaning of dreams and the method of discovering it and with the means employed by the dream-work for concealing it. The problems of dream-interpretation have hitherto occupied the centre of the picture. And now we come upon a dream which raises no problem of interpretation and the meaning of which is obvious, but which, as we see, nevertheless retains the essential characteristics that differentiate dreams so strikingly from waking life and consequently call for explanation. It is only after we have disposed of everything that has to do with the work of interpretation that we can begin to realize the incompleteness of our psychology of dreams.

[1900a, 946]
The explanation is in our favour, though without putting the other writers in the wrong. In the light of our newly-won understanding of the origin of dreams the contradiction disappears completely. It is true that we distort dreams in attempting to reproduce them; here we find at work once more the process which we have described as the secondary (and often ill-conceived) revision of the dream by the agency which carries out normal thinking. But this distortion is itself no more than a part of the revision to which the dream-thoughts are regularly subjected as a result of the dream-censorship. The other writers have at this point noticed or suspected the part of dream-distortion which operates manifestly; we are less interested, since we know that a much more far-reaching process of distortion, though a less obvious one, has already developed the dream out of the hidden dream-thoughts. The only mistake made by previous writers has been in supposing that the modification of the dream in the course of being remembered and put into words is an arbitrary one and cannot be further resolved and that it is therefore calculated to give us a misleading picture of the dream. They have underestimated the extent to which psychical events are determined. There is nothing arbitrary about them. It can be shown quite generally that if an element is left undetermined by one train of thought, its determination is immediately effected by a second one. For instance, I may try to think of a number arbitrarily. But this is impossible: the number that occurs to me will be unambiguously and necessarily determined by thoughts of mine, though they may be remote from my immediate intention.¹ The modifications to which dreams are submitted under the editorship of waking life are just as little arbitrary. They are associatively linked to the material which they replace, and serve to show us the way to that material, which may in its turn be a substitute for something else.

Having now repelled the objections that have been raised against us, or having at least indicated where our defensive weapons lie, we must no longer postpone the task of setting about the psychological investigations for which we have so long been arming ourselves. Let us summarize the principal findings of our enquiry so far as it has gone. Dreams are psychical acts of as much significance as any others; their motive force is in every instance a wish seeking fulfilment; the fact of their not being recognizable as wishes and their many peculiarities and absurdities are due to the influence of the psychical censorship to which they have been subjected during the process of their formation; apart from the necessity of evading this censorship, other factors which have contributed to their formation are a necessity for the condensation of their psychical material, a regard for the possibility of its being represented in sensory images and - though not invariably - a demand that the structure of the dream shall have a rational and intelligible exterior. Each of these propositions opens a way to fresh psychological postulates and speculations; the mutual relations between the wish which is the dream's motive force and the four conditions to which the dream's formation is subject, as well as the interrelations between the latter, require to be investigated; and the place of dreams in the nexus of mental life has to be assigned.

We have already been led by wish-fulfilment itself to divide dreams into two groups. We have found some dreams which appeared openly as wish-fulfilments, and others in which the wish-fulfilment was unrecognized and often disguised by every possible means. In the latter we have perceived the dream censorship at work. We found the undistorted wishful dreams principally in children; though short, frankly wishful dreams seemed (and I lay emphasis upon this qualification) to occur in adults as well.
The unconscious wishful impulses clearly try to make themselves effective in daytime as well, and the fact of transference, as well as the psychoses, show us that they endeavour to force their way by way of the preconscious system into consciousness and to obtain control of the power of movement. Thus the censorship between the Ucs. and the Pcs., the assumption of whose existence is positively forced upon us by dreams, deserves to be recognized and respected as the watchman of our mental health. Must we not regard it, however, as an act of carelessness on the part of that watchman that it relaxes its activities during the night, allows the suppressed impulses in the Ucs. to find expression, and makes it possible for hallucinatory regression to occur once more? I think not. For even though this critical watchman goes to rest - and we have proof that its slumbers are not deep - it also shuts the door upon the power of movement. No matter what impulses from the normally inhibited Ucs. may prance upon the stage, we need feel no concern; they remain harmless, since they are unable to set in motion the motor apparatus by which alone they might modify the external world. The state of sleep guarantees the security of the citadel that must be guarded. The position is less harmless when what brings about the displacement of forces is not the nightly relaxation in the critical censorship’s output of force, but a pathological reduction in that force or a pathological intensification of the unconscious excitations while the preconscious is still cathected and the gateway to the power of movement stands open. When this is so, the watchman is overpowered, the unconscious excitations overwhelm the Pcs., and thence obtain control over our speech and actions; or they forcibly bring about hallucinatory regression and direct the course of the apparatus (which was not designed for their use) by virtue of the attraction exercised by perceptions on the distribution of our psychical energy. To this state of things we give the name of psychosis.

[1900a, 997]
The other members of this class of wish-fulfilments - hysterical symptoms, for instance - possess one essential characteristic, however, which I cannot discover in dreams. I have learnt from the researches which I have mentioned so often in the course of this work that in order to bring about the formation of a hysterical symptom both currents of our mind must converge. A symptom is not merely the expression of a realized unconscious wish; a wish from the preconscious which is fulfilled by the same symptom must also be present. So that the symptom will have of at least two determinants, one arising from each of the systems involved in the conflict. As in the case of dreams, there are no limits to the further determinants that may be present - to the 'overdetermination' of the symptoms. The determinant which does not arise from the Ucs. is invariably, so far as I know, a train of thought reacting against the unconscious wish - a self-punishment, for instance. I can therefore make the quite general assertion that a hysterical symptom develops only where the fulfilments of two opposing wishes, arising each from a different psychical system, are able to converge in a single expression. (Compare in this connection my most recent formulations on the origin of hysterical symptoms in my paper on hysterical phantasies and their relation to bisexuality.) Examples would serve very little purpose here, since nothing but an exhaustive elucidation of the complications involved could carry conviction. I will therefore leave my assertion to stand for itself and only quote an example in order to make the point clear, and not to carry conviction. In one of my women patients, then, hysterical vomiting turned out to be on the one hand the fulfilment of an unconscious phantasy dating from her puberty - of a wish, that is, that she might be continuously pregnant and have innumerable children, with a further wish, added later, that she might have them by as many men as possible. A powerful defensive impulse had sprung up against this unbridled wish. And, since the patient might lose her figure and her good looks as a result of her vomiting, and so might cease to be attractive to anyone, the symptom was acceptable to the punitive train of thought as well; and since it was permitted by both sides it could become a reality. This was the same method of treating a wish-fulfilment as was adopted by the Parthian queen towards the Roman triumvir Crassus. Believing that he had embarked on his expedition out of love of gold, she ordered molten gold to be poured down his throat when he was dead: 'Now', she said, 'you have what you wanted.' But all that we so far know about dreams is that they express the fulfilment of a wish from the unconscious; it seems as though the dominant, preconscious system acquiesces in this after insisting upon a certain number of distortions. Nor is it possible as a general rule to find a train of thought opposed to the dream-wish and, like its counterpart, realized in the dream. Only here and there in dream-analyses do we come upon signs of reactive creations, like, for instance, my affectionate feelings for my friend R. in the dream of my uncle (cf. p. 637 ff.). But we can find the missing ingredient from the preconscious elsewhere. Whereas the wish from the Ucs. is able to find expression in the dream after undergoing distortions of every kind, the dominant system withdraws into a wish to sleep, realizes that wish by bringing about the modifications which it is able to produce in the catheces within the psychical apparatus, and persists in that wish throughout the whole duration of sleep.¹

[1900a, 999]
The situation is this. Either residues of the previous day have been left over from the activity of waking life and it has not been possible to withdraw the whole cathectic of energy from them; or the activity of waking life during the course of the day has led to the stirring up of an unconscious wish; or these two events have happened to coincide. (We have already discussed the various possibilities in this connection.) The unconscious wish links itself up with the day's residues and effects a transference on to them; this may happen either in the course of the day or not until a state of sleep has been established. A wish now arises which has been transferred on to the recent material; or a recent wish, having been suppressed, gains fresh life by being reinforced from the unconscious. This wish seeks to force its way along the normal path taken by thought processes, though the Pcs. (to which, indeed, it in part belongs) to consciousness. But it comes up against the censorship, which is still functioning and to the influence of which it now submits. At this point it takes on the distortion for which the way has already been paved by the transference of the wish on to recent material. So far it is on the way to becoming an obsessive idea or a delusion or something of the kind - that is, a thought which has been intensified by transference and distorted in its expression by censorship. Its further advance is halted, however, by the sleeping state of the preconscious. (The probability is that that system has protected itself against the invasion by diminishing its own excitations.) The dream-process consequently enters on a regressive path, which lies open to it precisely owing to the peculiar nature of the state of sleep, and it is led along that path by the attraction exercised on it by groups of memories; some of these memories themselves exist only in the form of visual cathexes and not as translations into the terminology of the later systems. In the course of its regressive path the dream-process acquires the attribute of representability. (I shall deal later with the question of compression.) It has now completed the second portion of its zigzag journey. The first portion was a progressive one, leading from the unconscious scenes or phantasies to the preconscious; the second portion led from the frontier of the censorship back again to perceptions. But when the content of the dream process has become perceptual, by that fact it has, as it were, found a way of evading the obstacle put in its way by the censorship and the state of sleep in the Pcs. It succeeds in drawing attention to itself and in being noticed by consciousness.

[1900a, 1002]

It has already been pointed out by Dugas that Goblot would have to disregard many facts before he could assert his thesis generally. Dreams occur from which we do not awaken for instance, some in which we dream that we are dreaming. With our knowledge of the dream-work, we could not possibly agree that it only covers the period of awakening. It seems probable, on the contrary, that the first portion of the dream-work has already begun during the day, under the control of the preconscious. Its second portion - the modification imposed by the censorship, the attraction exercised by unconscious scenes, and the forcing of its way to perception - no doubt proceeds all through the night; and in this respect we may perhaps always be right when we express a feeling of having been dreaming all night long, though we cannot say what.

[1900a, 1004]

The view that dreams carry on the occupations and interests of waking life has been entirely confirmed by the discovery of the concealed dream-thoughts. These are only concerned with what seems important to us and interests us greatly. Dreams are never occupied with minor details. But we have also found reason for accepting the contrary view, that dreams pick up indifferent refuse left over from the previous day and that they cannot get control of any major day time interest until it has been to some extent withdrawn from waking activity. We have found that this holds good of the dream's content, which gives expression to the dream-thoughts in a form modified by distortion. For reasons connected with the mechanism of association, as we have seen, the dream-process finds it easier to get control of recent or indifferent ideational material which has not yet been requisitioned by waking thought-activity; and for reasons of censorship it transfers psychical intensity from what is important but objectionable on to what is indifferent.

[1900a, 1016]
We have thus been able to find a place in our structure for the most various and contradictory findings of earlier writers, thanks to the novelty of our theory of dreams, which combines them, as it were, into a higher unity. Some of those findings we have put to other uses, but we have wholly rejected only a few. Nevertheless our edifice is still uncompleted. Apart from the many perplexing questions in which we have become involved in making our way into the obscurities of psychology, we seem to be troubled by a fresh contradiction. On the one hand we have supposed that the dream-thoughts arise through entirely normal mental activity; but on the other hand we have discovered a number of quite abnormal processes of thought among the dream-thoughts, which extend into the dream-content, and which we then repeat in the course of our dream-interpretation. Everything that we have described as the 'dream-work' seems to depart so widely from what we recognize as rational thought-processes that the most severe strictures passed by earlier writers on the low level of psychical functioning in dreams must appear fully justified.

[1900a, 1019]

From this point onwards the train of thought undergoes a series of transformations which we can no longer recognize as normal psychical processes and which lead to a result that bewilders us - a psychopathological structure. I will enumerate these processes and classify them.

[1900a, 1022]

In the most favourable cases the generation of unpleasure ceases along with the withdrawal of cathexis from the transference thoughts in the Pcs.; and this outcome signifies that the intervention of the unpleasure principle has served a useful purpose. But it is another matter when the repressed unconscious wish receives an organic reinforcement, which it passes on to its transference thoughts; in that way it may place them in a position to make an attempt at forcing their way through with their excitation, even if they have lost their cathexis from the Pcs. There then follows a defensive struggle - for the Pcs. in turn reinforces its opposition to the repressed thoughts (i.e. produces an 'anticathexis') - and thereafter the transference thoughts, which are the vehicles of the unconscious wish, force their way through in some form of compromise which is reached by the production of a symptom. But from the moment at which the repressed thoughts are strongly cathected by the unconscious wishful impulse and, on the other hand, abandoned by the preconscious cathexis, they become subject to the primary psychical process and their one aim is motor discharge or, if the path is open, hallucinatory revival of the desired perceptual identity. We have already found empirically that the irrational processes we have described are only carried out with thoughts that are under repression. We can now see our way a little further into the whole position. The irrational processes which occur in the psychical apparatus are the primary ones. They appear wherever ideas are abandoned by the preconscious cathexis, are left to themselves and can become charged with the uninhibited energy from the unconscious which is striving to find an outlet. Some other observations lend support to the view that these processes which are described as irrational are not in fact falsifications of normal processes - intellectual errors - but are modes of activity of the psychical apparatus that have been freed from an inhibition. Thus we find that the transition from preconscious excitation to movement is governed by the same processes, and that the linking of preconscious ideas to words may easily exhibit the same displacements and confusions, which are then attributed to inattention. Evidence, finally, of the increase in activity which becomes necessary when these primary modes of functioning are inhibited is to be found in the fact that we produce a comic effect, that is, a surplus of energy which has to be discharged in laughter, if we allow these modes of thinking to force their way through into consciousness.

[1900a, 1032]
Here and elsewhere I have intentionally left gaps in the treatment of my theme because to fill them would on the one hand require too great an effort and on the other would involve my basing myself on material that is alien to the subject of dreams. For instance, I have omitted to state whether I attribute different meanings to the words 'suppressed' and 'repressed.' It should have been clear, however, that the latter lays more stress than the former upon the fact of attachment to the unconscious. Nor have I entered into the obvious problem of why the dream-thoughts are subjected to distortion by the censorship even in cases where they have abandoned the progressive path towards consciousness and have chosen the regressive one. And there are many similar omissions. What I was above all anxious to do was to create an impression of the problems to which a further analysis of the dream-work must lead and to give a hint of the other topics with which that further analysis would come into contact. It has not always been easy for me to decide the point at which to break off my pursuit of this line of exposition. There are special reasons, which may not be what my readers expect, why I have not given any exhaustive treatment to the part played in dreams by the world of sexual ideas and why I have avoided analysing dreams of obviously sexual content. Nothing could be further from my own views or from the theoretical opinions which I hold in neuropathology than to regard sexual life as something shameful, with which neither a physician nor a scientific research worker has any concern. Moreover, the moral indignation by which the translator of the *Oneirocritica* of Artemidorus of Daldis allowed himself to be led into withholding the chapter on sexual dreams from the knowledge of his readers strikes me as laughable. What governed my decision was simply my seeing that an explanation of sexual dreams would involve me deeply in the still unsolved problems of perversion and bisexuality; and I accordingly reserved this material for another occasion.

Now that the old antithesis between conscious life and dream life has been reduced to its proper proportions by the establishment of unconscious psychical reality, a number of dream-problems with which earlier writers were deeply concerned have lost their significance. Thus some of the activities whose successful performance in dreams excited astonishment are now no longer to be attributed to dreams but to unconscious thinking, which is active during the day no less than at night. If, as Scherner has said, dreams appear to engage in making symbolic representations of the body, we now know that those representations are the product of certain unconscious phantasies (deriving, probably, from sexual impulses) which find expression not only in dreams but also in hysterical phobias and other symptoms. If a dream carries on the activities of the day and completes them and even brings valuable fresh ideas to light, all we need do is to strip it of the dream disguise, which is the product of dream-work and the mark of assistance rendered by obscure forces from the depths of the mind (cf. the Devil in Tartini's sonata dream); the intellectual achievement is due to the same mental forces which produce every similar result during the daytime. We are probably inclined greatly to over-estimate the conscious character of intellectual and artistic production as well. Accounts given us by some of the most highly productive men, such as Goethe and Helmholtz, show rather that what is essential and new in their creations came to them without premeditation and as an almost ready-made whole. There is nothing strange if in other cases, where a concentration of every intellectual faculty was needed, conscious activity also contributed its share. But it is the much-abused privilege of conscious activity, wherever it plays a part, to conceal every other activity from our eyes.
But another achievement of the dream-work, tending as it does to produce incoherent dreams, is even more striking. If in any particular instance we compare the number of ideational elements or the space taken up in writing them down in the case of the dream and of the dream-thoughts to which the analysis leads us and of which traces are to be found in the dream itself, we shall be left in no doubt that the dream-work has carried out a work of compression or condensation on a large scale. It is impossible at first to form any judgement of the degree of this condensation; but the deeper we plunge into a dream-analysis the more impressive it seems. From every element in a dream's content associative threads branch out in two or more directions; every situation in a dream seems to be put together out of two or more impressions or experiences. For instance, I once had a dream of a sort of swimming-pool, in which the bathers were scattering in all directions; at one point on the edge of the pool someone was standing and bending towards one of the people bathing, as though to help her out of the water. The situation was put together from a memory of an experience I had had at puberty and from two paintings, one of which I had seen shortly before the dream. One was a picture from Schwind's series illustrating the legend of Mélusine, which showed the water-nymps surprised in their pool (cf. the scattering bathers in the dream); the other was a picture of the Deluge by an Italian Master; while the little experience remembered from my puberty was of having seen the instructor at a swimming-school helping a lady out of the water who had stopped in until after the time set aside for men bathers. - In the case of the example which I chose for interpretation, an analysis of the situation led me to a small series of recollections each of which contributed something to the content of the dream. In the first place, there was the episode from the time of my engagement of which I have already spoken. The pressure upon my hand under the table, which was a part of that episode, provided the dream with the detail 'under the table' - a detail which I had to add as an afterthought to my memory of the dream. In the episode itself there was of course no question of 'turning to me'; the analysis showed that this element was the fulfilment of a wish by presenting the opposite of an actual event, and that it related to my wife's behaviour at the table d'hôte. But behind this recent recollection there lay concealed an exactly similar and far more important scene from the time of our engagement, which estranged us for a whole day. The intimate laying of a hand on my knee belonged to a quite different context and was concerned with quite other people. This element in the dream was in turn the starting-point of two separate sets of memories - and so on.

The process of condensation further explains certain constituents of the content of dreams which are peculiar to them and are not found in waking ideation. What I have in mind are 'collective' and 'composite figures' and the strange 'composite structures', which are creations not unlike the composite animals invented by the folk-imagination of the Orient. The latter, however, have already assumed stereotyped shapes in our thought, whereas in dreams fresh composite forms are being perpetually constructed in an inexhaustible variety. We are all of us familiar with such structures from our own dreams.
First and foremost, when by means of analysis we have arrived at a knowledge of the dream-thoughts, we observe that the manifest dream-content deals with quite different material from the latent thoughts. This, to be sure, is no more than an appearance, which evaporates under closer examination, for we find ultimately that the whole of the dream-content is derived from the dream-thoughts, and that almost all the dream-thoughts are represented in the dream-content. Nevertheless, something of the distinction still remains. What stands out boldly and clearly in the dream as its essential content must, after analysis, be satisfied with playing an extremely subordinate role among the dream-thoughts; and what, on the evidence of our feelings, can claim to be the most prominent among the dream-thoughts is either not present at all as ideational material in the content of the dream or is only remotely alluded to in some obscure region of it. We may put it in this way: in the course of the dream-work the psychical intensity passes over from the thoughts and ideas to which it properly belongs on to others which in our judgement have no claim to any such emphasis. No other process contributes so much to concealing the meaning of a dream and to making the connection between the dream-content and the dream-thoughts unrecognizable. In the course of this process, which I shall describe as 'dream-displacement', the psychical intensity, significance or affective potentiality of the thoughts is, as we further find, transformed into sensory vividness. We assume as a matter of course that the most distinct element in the manifest content of a dream is the most important one; but in fact it is often an indistinct element which turns out to be the most direct derivative of the essential dream-thought.

What I have called dream-displacement might equally be described as 'a transvaluation of psychical values.' I shall not have given an exhaustive estimate of this phenomenon, however, unless I add that this work of displacement or transvaluation is performed to a very varying degree in different dreams. There are dreams which come about almost without any displacement. These are the ones which make sense and are intelligible, such, for instance, as those which we have recognized as undisguised wishful dreams. On the other hand, there are dreams in which not a single piece of the dream-thoughts has retained its own psychical value, or in which everything that is essential in the dream-thoughts has been replaced by something trivial. And we can find a complete series of transitional cases between these two extremes. The more obscure and confused a dream appears to be, the greater the share in its construction which may be attributed to the factor of displacement.

It is the process of displacement which is chiefly responsible for our being unable to discover or recognize the dream-thoughts in the dream-content, unless we understand the reason for their distortion. Nevertheless, the dream-thoughts are also submitted to another and milder sort of transformation, which leads to our discovering a new achievement on the part of the dream-work - one, however, which is easily intelligible. The dream-thoughts which we first come across as we proceed with our analysis often strike us by the unusual form in which they are expressed; they are not clothed in the prosaic language usually employed by our thoughts, but are on the contrary represented symbolically by means of similes and metaphors, in images resembling those of poetic speech. There is no difficulty in accounting for the constraint imposed upon the form in which the dream-thoughts are expressed. The manifest content of dreams consists for the most part in pictorial situations; and the dream-thoughts must accordingly be submitted in the first place to a treatment which will make them suitable for a representation of this kind. If we imagine ourselves faced by the problem of representing the arguments in a political leading article or the speeches of counsel before a court of law in a series of pictures, we shall easily understand the modifications which must necessarily be carried out by the dream-work owing to considerations of representability in the content of the dream.
The heart of the problem lies in displacement, which is by far the most striking of the special achievements of the dream-work. If we enter deeply into the subject, we come to realize that the essential determining condition of displacement is a purely psychological one: something in the nature of a motive. One comes upon its track if one takes into consideration certain experiences which one cannot escape in analysing dreams. In analysing my specimen dream I was obliged to break off my report of the dream-thoughts on p. 1059, because, as I confessed, there were some among them which I should prefer to conceal from strangers and which I could not communicate to other people without doing serious mischief in important directions. I added that nothing would be gained if I were to choose another dream instead of that particular one with a view to reporting its analysis: I should come upon dream-thoughts which required to be kept secret in the case of every dream with an obscure or confused content. If, however, I were to continue the analysis on my own account, without any reference to other people (whom, indeed, an experience so personal as my dream cannot possibly have been intended to reach), I should eventually arrive at thoughts which would surprise me, whose presence in me I was unaware of, which were not only alien but also disagreeable to me, and which I should therefore feel inclined to dispute energetically, although the chain of thoughts running through the analysis insisted upon them remorselessly. There is only one way of accounting for this state of affairs, which is of quite universal occurrence; and that is to suppose that these thoughts really were present in my mind, and in possession of a certain amount of psychical intensity or energy, but that they were in a peculiar psychological situation, as a consequence of which they could not become conscious to me. (I describe this particular condition as one of 'repression.') We cannot help concluding, then, that there is a causal connection between the obscurity of the dream-content and the state of repression (in admissibility to consciousness) of certain of the dream-thoughts, and that the dream had to be obscure so as not to betray the proscribed dream-thoughts. Thus we are led to the concept of a 'dream-distortion', which is the product of the dream-work and serves the purpose of dissimulation, that is, of disguise.

[1901a, 1085]

I will test this on the specimen dream which I chose for analysis, and enquire what the thought was which made its way into that dream in a distorted form, and which I should be inclined to repudiate if it were undistorted. I recall that my free cab-drive reminded me of my recent expensive drive with a member of my family, that the interpretation of the dream was 'I wish I might for once experience love that cost me nothing', and that a short time before the dream I had been obliged to spend a considerable sum of money on this same person's account. Bearing this context in mind, I cannot escape the conclusion that I regret having made that expenditure. Not until I have recognized this impulse does my wish in the dream for the love which would call for no expenditure acquire a meaning. Yet I can honestly say that when I decided to spend this sum of money I did not hesitate for a moment. My regret at having to do so - the contrary current of feeling - did not become conscious to me. Why it did not, is another and a far-reaching question, the answer to which is known to me but belongs in another connection.

[1901a, 1086]
Now that we have established the concept of repression and have brought dream-distortion into relation with repressed psychical material, we can express in general terms the principal finding to which we have been led by the analysis of dreams. In the case of dreams which are intelligible and have a meaning, we have found that they are undisguised wish-fulfilments; that is, that in their case the dream-situation represents as fulfilled a wish which is known to consciousness, which is left over from daytime life, and which is deservedly of interest. Analysis has taught us something entirely analogous in the case of obscure and confused dreams: once again the dream-situation represents a wish as fulfilled - a wish which invariably arises from the dream-thoughts, but one which is represented in an unrecognizable form and can only be explained when it has been traced back in analysis. The wish in such cases is either itself a repressed one and alien to consciousness, or it is intimately connected with repressed thoughts and is based upon them. Thus the formula for such dreams is as follows: they are disguised fulfilments of repressed wishes. It is interesting in this connection to observe that the popular belief that dreams always foretell the future is confirmed. Actually the future which the dream shows us is not the one which will occur but the one which we should like to occur. The popular mind is behaving here as it usually does: what it wishes, it believes.

Hitherto philosophers have had no occasion to concern themselves with a psychology of repression. We may therefore be permitted to make a first approach to this hitherto unknown topic by constructing a pictorial image of the course of events in dream-formation. It is true that the schematic picture we have arrived at - not only from the study of dreams - is a fairly complicated one; but we cannot manage with anything simpler. Our hypothesis is that in our mental apparatus there are two thought-constructing agencies, of which the second enjoys the privilege of having free access to consciousness for its products whereas the activity of the first is in itself unconscious and can only reach consciousness by way of the second. On the frontier between the two agencies, where the first passes over to the second, there is a censorship, which only allows what is agreeable to it to pass through and holds back everything else. According to our definition, then, what is rejected by the censorship is in a state of repression. Under certain conditions, of which the state of sleep is one, the relation between the strength of the two agencies is modified in such a way that what is repressed can no longer be held back. In the state of sleep this probably occurs owing to a relaxation of the censorship; when this happens it becomes possible for what has hitherto been repressed to make a path for itself to consciousness. Since, however, the censorship is never completely eliminated but merely reduced, the repressed material must submit to certain alterations which mitigate its offensive features. What becomes conscious in such cases is a compromise between the intentions of one agency and the demands of the other. Repression - relaxation of the censorship - the formation of a compromise, this is the fundamental pattern for the generation not only of dreams but of many other psychopathological structures; and in the latter cases too we may observe that the formation of compromises is accompanied by processes of condensation and displacement and by the employment of superficial associations, which we have become familiar with in the dream-work.

[1901a, 1087]
We have no reason to disguise the fact that in the hypothesis which we have set up in order to explain the dream-work a part is played by what might be described as a 'daemonic' element. We have gathered an impression that the formation of obscure dreams occurs as though one person who was dependent upon a second person had to make a remark which was bound to be disagreeable in the ears of this second one; and it is on the basis of this simile that we have arrived at the concepts of dream-distortion and censorship, and have endeavoured to translate our impression into a psychological theory which is no doubt crude but is at least lucid. Whatever it may be with which a further investigation of the subject may enable us to identify our first and second agencies, we may safely expect to find a confirmation of some correlate of our hypothesis that the second agency controls access to consciousness and can bar the first agency from such access.

[1901a, 1090]

When once we have recognized that the content of a dream is the representation of a fulfilled wish and that its obscurity is due to alterations in repressed material made by the censorship, we shall no longer have any difficulty in discovering the function of dreams. It is commonly said that sleep is disturbed by dreams; strangely enough, we are led to a contrary view and must regard dreams as the guardians of sleep.

[1901a, 1091]

No one who accepts the view that the censorship is the chief reason for dream-distortion will be surprised to learn from the results of dream-interpretation that most of the dreams of adults are traced back by analysis to erotic wishes. This assertion is not aimed at dreams with an undisguised sexual content, which are no doubt familiar to all dreamers from their own experience and are as a rule the only ones to be described as 'sexual dreams.' Even dreams of this latter kind offer enough surprises in their choice of the people whom they make into sexual objects, in their disregard of all the limitations which the dreamer imposes in his waking life upon his sexual desires, and by their many strange details, hinting at what are commonly known as 'perversions.' A great many other dreams, however, which show no sign of being erotic in their manifest content, are revealed by the work of interpretation in analysis as sexual wish-fulfillments; and, on the other hand, analysis proves that a great many of the thoughts left over from the activity of waking life as 'residues of the previous day' only find their way to representation in dreams through the assistance of repressed erotic wishes.

[1901a, 1094]

(G) A few words should be said to indicate at least in what direction this wider context lies. The mechanism of parapraxes and chance actions, as we have come to know it by our employment of analysis, can be seen to correspond in its most essential points with the mechanism of dream-formation which I have discussed in the chapter on the 'dream-work' in my Interpretation of Dreams. In both cases we find condensations and compromise-formations (contaminations). We have the same situation: by unfamiliar paths, and by the way of external associations, unconscious thoughts find expression as modifications of other thoughts. The incongruities, absurdities and errors of the dream-content, which result in the dream being scarcely recognized as the product of psychical activity, originate in the same way, though it is true with a freer use of the means at hand, as our common mistakes in everyday life. In both cases the appearance of an incorrect function is explained by the peculiar mutual interference between two or several correct functions.

[1901b, 1346]
At this point I shall interrupt my report of the analysis in order to compare this small piece of dream-interpretation with the general statements I have made upon the mechanism of the formation of dreams. I argued in my book, *The Interpretation of Dreams* (1900a), that every dream is a wish which is represented as fulfilled, that the representation acts as a disguise if the wish is a repressed one, belonging to the unconscious, and that except in the case of children's dreams only an unconscious wish or one which reaches down into the unconscious has the force necessary for the formation of a dream. I fancy my theory would have been more certain of general acceptance if I had contented myself with maintaining that every dream had a meaning, which could be discovered by means of a certain process of interpretation; and that when the interpretation had been completed the dream could be replaced by thoughts which would fall into place at an easily recognizable point in the waking mental life of the dreamer. I might then have gone on to say that the meaning of a dream turned out to be of as many different sorts as the processes of waking thought; that in one case it would be a fulfilled wish, in another a realized fear, or again a reflection persisting on into sleep, or an intention (as in the instance of Dora's dream), or a piece of creative thought during sleep, and so on. Such a theory would no doubt have proved attractive from its very simplicity, and it might have been supported by a great many examples of dreams that had been satisfactorily interpreted, as for instance by the one which has been analysed in these pages.

Can we feel sure that none of the possible techniques of jokes has escaped our investigation? Of course not. But a continued examination of fresh material can convince us that we have got to know the commonest and most important technical methods of the joke-work - at all events as much as is required for forming a judgement on the nature of that psychical process. So far we have not arrived at any such judgement; but on the other hand we are now in possession of an important indication of the direction from which we may expect to receive further light upon the problem. The interesting processes of condensation accompanied by the formation of a substitute, which we have recognized as the core of the technique of verbal jokes, point towards the formation of dreams, in the mechanism of which the same psychical processes have been discovered. This is equally true, however, of the techniques of conceptual jokes - displacement, faulty reasoning, absurdity, indirect representation, representation by the opposite - which re-appear one and all in the technique of the dream-work. Displacement is responsible for the puzzling appearance of dreams, which prevents our recognizing that they are a continuation of our waking life. The use of absurdity and nonsense in dreams has cost them the dignity of being regarded as psychical products and has led the authorities to suppose that a disintegration of the mental activities and a cessation of criticism, morality and logic are necessary conditions of the formation of dreams. Representation by the opposite is so common in dreams that even the popular books of dream-interpretation, which are on a completely wrong tack, are in the habit of taking it into account. Indirect representation - the replacement of a dream-thought by an allusion, by something small, a symbolism akin to analogy - is precisely what distinguishes the mode of expression of dreams from that of our waking life.¹ So far-reaching an agreement between the methods of the joke-work and those of the dream-work can scarcely be a matter of chance. To demonstrate this agreement in detail and to examine its basis will be one of our later tasks.

[1905c, 1686]
The dream-work, then - to which I return after this digression - submits the thought-material, which is brought forward in the optative mood, to a most strange revision. First, it takes the step from the optative to the present indicative; it replaces 'Oh! if only . . .' by 'It is'. The 'It is' is then given a hallucinatory representation; and this I have called the 'regression' in the dream-work - the path that leads from thoughts to perceptual images, or, to use the terminology of the still unknown topography of the mental apparatus (which is not to be taken anatomically), from the region of thought-structures to that of sensory perceptions. On this path, which is in the reverse direction to that taken by the course of development of mental complications, the dream-thoughts are given a pictorial character; and eventually a plastic situation is arrived at which is the core of the manifest 'dream-picture'. In order for it to be possible for the dream-thoughts to be represented in sensory form, their expression has to undergo far-reaching modifications. But while the thoughts are being changed back into sensory images still further alterations occur in them, some of which can be seen to be necessary while others are surprising. We can understand that, as a subsidiary result of regression, almost all the internal relations between the thoughts which linked them together will be lost in the manifest dream. The dream-work, as we might say, only undertakes to represent the raw material of the ideas and not the logical relations in which they stand to one another; or at all events it reserves the liberty to disregard the latter. On the other hand, there is another part of the dream-work which we cannot attribute to regression, to the change back into sensory images; and it is precisely this part which has an important bearing on our analogy with the formation of jokes. In the course of the dream-work the material of the dream-thoughts is subjected to a quite extraordinary compression or condensation. A starting point for it is provided by any common elements that may be present in the dream-thoughts, whether by chance or from the nature of their content. Since these are not as a rule sufficient for any considerable condensation, new artificial and transient common elements are created in the dream-work, and to this end there is actually a preference for the use of words the sound of which expresses different meanings. The newly-created common elements of condensation enter the manifest content of the dream as representatives of the dream-thoughts, so that an element in the dream corresponds to a nodal point or junction in the dream-thoughts, and, as compared with these latter, must quite generally be described as 'overdetermined'. The fact of condensation is the piece of the dream-work which can be most easily recognized; it is only necessary to compare the text of a dream as it is noted down with the record of the dream-thoughts arrived at by analysis in order to get a good impression of the extensiveness of dream-condensation.

Strange to say, it does. The sense is merely disguised in a particular way so that it is not immediately recognizable. Hanold learned in the dream that the girl he was looking for was living in a town and contemporaneously with him. Now this was true of Zoe Bertgang; only in the dream the town was not the German university town but Pompeii, and the time was not the present but the year 79 A.D. It is, as it were, a distortion by displacement: what we have is not Gradiva in the present but the dreamer transported into the past. Nevertheless, in this manner, the essential and new fact is stated: he is in the same place and time as the girl he is looking for. But whence come this displacement and disguise which were bound to deceive both us and the dreamer over the true meaning and content of the dream? Well, we already have the means at our disposal for giving a satisfactory answer to that question.
Let us recall all that we have heard about the nature and origin of the phantasies which are the precursors of delusions. They are substitutes for and derivatives of repressed memories which a resistance will not allow to enter consciousness unaltered, but which can purchase the possibility of becoming conscious by taking account, by means of changes and distortions, of the resistance's censorship. When this compromise has been accomplished, the memories have turned into the phantasies, which can easily be misunderstood by the conscious personality - that is, understood so as to fit in with the dominant psychical current. Now let us suppose that dream-images are what might be described as the creations of people's physiological delusions - the products of the compromise in the struggle between what is repressed and what is dominant which is probably present in every human being, including those who in the day-time are perfectly sound in mind. We shall then understand that dream-images have to be regarded as something distorted, behind which something else must be looked for, something not distorted, but in some sense objectionable, like Hanold's repressed memories behind his phantasies. We can give expression to the contrast which we have thus recognized, by distinguishing what the dreamer remembers when he wakes up as the manifest content of the dream from what constituted the basis of the dream before the distortion imposed by the censorship - namely, the latent dream-thoughts. Thus, interpreting a dream consists in translating the manifest content of the dream into the latent dream-thoughts, in undoing the distortion which the dream-thoughts have had to submit to from the censorship of the resistance. If we apply these notions to the dream we are concerned with, we shall find that its latent dream-thoughts can only have been: 'the girl you are looking for with the graceful gait is really living in this town with you.' But in that form the thought could not become conscious. It was obstructed by the fact that a phantasy had laid it down, as the result of an earlier compromise, that Gradiva was a Pompeian; consequently, if the real fact that she was living in the same place and at the same time was to be affirmed, there was no choice but to adopt the distortion: 'You are living at Pompeii at the time of Gradiva.' This then was the idea which was realized by the manifest content of the dream, and was represented as a present event actually being experienced.

[1907a, 1855]

It is only rarely that a dream represents, or, as we might say, 'stages', a single thought: there are usually a number of them, a tissue of thoughts. Another component of the content of Hanold's dream can be detached, the distortion of which can easily be got rid of, so that the latent idea represented by it can be detected. This is a piece of the dream to which once again it is possible to extend the assurance of reality with which the dream ended. In the dream Gradiva as she steps along is transformed into a marble sculpture. This is no more than an ingenious and poetical representation of the real event. Hanold had in fact transferred his interest from the living girl to the sculpture: the girl he loved had been transformed for him into a marble relief. The latent dream-thoughts, which were bound to remain unconscious, sought to change the sculpture back into the living girl; what they were saying to him accordingly was something like: 'After all, you're only interested in the statue of Gradiva because it reminds you of Zoe, who is living here and now.' But if this discovery could have become conscious, it would have meant the end of the delusion.

[1907a, 1856]

Are we to venture on an attempt at interpreting this dream too - that is, at replacing it by the latent thoughts from whose distortion it must have arisen? It is as senseless as only a dream can be expected to be; and this absurdity of dreams is the mainstay of the view which refuses to characterize dreams as completely valid psychical acts and maintains that they arise out of a purposeless excitation of the elements of the mind.

[1907a, 1867]
‘Somewhere in the sun Gradiva was sitting, catching lizards and speaking.’ What impression of the previous day finds an echo in this part of the dream? Undoubtedly the encounter with the elderly gentleman, the lizard-catcher, who was thus replaced in the dream by Gradiva. He sat or lay ‘on a sun-bathed slope’ and he, too, spoke to Hanold. Furthermore, Gradiva’s remarks in the dream were copied from this man’s remarks: viz. ‘The method prescribed by our colleague Eimer is a really good one; I have made use of it many times already with excellent results. Please keep quite still.’ Gradiva used much the same words in the dream, except that ‘our colleague Eimer’ was replaced by an unnamed ‘lady colleague’; moreover, the ‘many times’ in the zoologist’s speech was omitted in the dream and the order of the sentences was somewhat altered. It seems, therefore, that this experience of the previous day was transformed into the dream with the help of a few changes and distortions. Why this particular experience? And what is the meaning of the changes - the replacement of the elderly gentleman by Gradiva and the introduction of the enigmatic ‘lady colleague’?

[1907a, 1867]

But why was it necessary for this penetration of Zoe’s intentions to appear in the dream in the form of the old zoologist’s speech? the old gentleman’s skill in lizard-catching? Well, we can have no difficulty in answering that question. We guessed long ago that the lizard-catcher was none other than Bertgang, the professor of Zoology and Zoe’s father, who, incidentally, must have known Hanold too - which explains how he came to address him as an acquaintance. Let us assume, once again, that in his unconscious Hanold at once recognized the Professor. ‘He had a vague notion that he had already had a passing glimpse of the lizard hunter’s face, probably in one of the two hotels.’ This, then, is the explanation of the strange disguise under which the intention attributed to Zoe made its appearance: she was the lizard-catcher’s daughter and had acquired her skill from him.

[1907a, 1869]

The replacement of the lizard-catcher by Gradiva in the content of the dream is accordingly a representation of the relation between the two figures which was known to Hanold in his unconscious; the introduction of the ‘lady colleague’ instead of ‘our colleague Eimer’ allowed the dream to express Hanold’s realization that she was wooing a man. So far the dream welded together (‘condensed’, as we say) two experiences of the previous day into one situation, in order to bring to expression (in a very obscure way, it is true) two discoveries which were not allotted to become conscious. But we can go further, we can diminish the strangeness of the dream still more and we can demonstrate the influence of his other experiences of the previous day on the form taken by the manifest dream.

[1907a, 1870]
We would seem to have reached the end. But an attentive reader might remind us that at the beginning we threw out an assertion that dreams are wishes represented as fulfilled and that we gave no proof of this. Well, is our reply, what we have described in these pages might show how little justification there is for trying to cover the explanations we have to give of dreams with the single formula that dreams are wish-fulfilments. Nevertheless the assertion stands and can easily be proved too for the dreams in *Gradiva*. The latent dream-thoughts - we know now what is meant by them - may be of the most various kinds; in *Gradiva* they are 'days' residues', thoughts that have been left over unnoticed and undealt-with from the mental activities of waking life. But in order for a dream to develop out of them, the co-operation of a wish (usually an unconscious one) is required; this contributes the motive force for constructing the dream, while the day's residues provide the material. In Norbert Hanold's first dream two wishes competed with each other in making the dream; one of them was actually admissible to consciousness, while the other belonged to the unconscious and operated from out of repression. The first was a wish, understandable in any archaeologist, to have been present as an eye-witness at the catastrophe in the year 79 A.D. What sacrifice would an archaeologist think too great if this wish could be realized in any way other than in a dream! The other wish, the other constructor of the dream, was of an erotic nature: it might be crudely and also incompletely stated as a wish to be there when the girl he loved lay down to sleep. This was the wish the rejection of which caused the dream to become an anxiety-dream. The wishes that were the motive forces of the second dream are perhaps less conspicuous; but if we recall its translation we shall not hesitate to describe them too as erotic. The wish to be taken captive by the girl he loved, to fall in with her wishes and to be subjected to her - for so we may construe the wish behind the situation of the lizard-catching - was in fact of a passive, masochistic character. Next day the dreamer hit the girl, as though he was dominated by the contrary erotic current . . . But we must stop here, or we may really forget that Hanold and Gradiva are only creatures of their author's mind.

I cannot pass over the relation of phantasies to dreams. Our dreams at night are nothing else than phantasies like these, as we can demonstrate from the interpretation of dreams.¹ Language, in its unrivalled wisdom, long ago decided the question of the essential nature of dreams by giving the name of 'day-dreams' to the airy creations of phantasy. If the meaning of our dreams usually remains obscure to us in spite of this pointer, it is because of the circumstance that at night there also arise in us wishes of which we are ashamed; these we must conceal from ourselves, and they have consequently been repressed, pushed into the unconscious. Repressed wishes of this sort and their derivatives are only allowed to come to expression in a very distorted form. When scientific work had succeeded in elucidating this factor of dream-distortion, it was no longer difficult to recognize that night-dreams are wish-fulfilments in just the same way as day-dreams - the phantasies which we all know so well.

A common source and normal prototype of all these creations of phantasy is to be found in what are called the day-dreams of youth. These have already received some, though as yet insufficient, notice in the literature of the subject.¹ They occur with perhaps equal frequency in both sexes, though it seems that while in girls and women they are invariably of an erotic nature, in men they may be either erotic or ambitious. Nevertheless the importance of the erotic factor in men, too, should not be given a secondary rating; a closer investigation of a man's day-dreams generally shows that all his heroic exploits are carried out and all his successes achieved only in order to please a woman and to be preferred by her to other men.² These phantasies are satisfactions of wishes proceeding from deprivation and longing. They are justly called 'day-dreams', for they give us the key to an understanding of night-dreams - in which the nucleus of the dream-formation consists of nothing else than complicated day-time phantasies of this kind that have been distorted and are misunderstood by the conscious psychical agency.³
The same is true of the relation between the 'latent' dream-thoughts and the elements of the 'manifest' content of a dream. See the section of my Interpretation of Dreams which deals with the 'dream-work'. [1908a, 1936]

When one carries out the psycho-analysis of a hysterical woman patient whose complaint is manifested in attacks, one soon becomes convinced that these attacks are nothing else but phantasies translated into the motor sphere, projected on to motility and portrayed in pantomime. It is true that the phantasies are unconscious; but apart from this they are of the same nature as the phantasies which can be observed directly in day-dreams or which can be elicited by interpretation from dreams at night. Often a dream takes the place of an attack, and still more often it explains it, since the same phantasy finds a different expression in a dream and in an attack. We might expect then that by observing an attack we should be able to get to know the phantasy represented in it; but this is seldom possible. As a rule, owing to the influence of the censorship, the pantomimic portrayal of the phantasy has undergone distortions which are completely analogous to the hallucinatory distortions of a dream, so that both of them have, in the first resort, become unintelligible to the subject's own consciousness as well as to the observer's comprehension. A hysterical attack, therefore, needs to be subjected to the same interpretative revision as we employ for night-dreams. But not only are the forces from which the distortion proceeds and the purpose of the distortion the same as those we have come to know through the interpretation of dreams; the technique employed in the distortion is the same too. [1909a, 1981]

At about the same period Hans had a dream which was in striking contrast with the boldness he had shown towards his mother. It was the first dream of his that was made unrecognizable by distortion. His father's penetration, however, succeeded in clearing it up. [1909b, 2013]

What is officially described as an 'obsessional idea' exhibits, therefore, in its distortion from its original wording, traces of the primary defensive struggle. Its distortion enables it to persist, since conscious thought is thus compelled to misapprehend it, just as though it were a dream; for dreams also are a product of compromise and distortion, and are also misapprehended by waking thought. [1909d, 2175]
This misapprehension on the part of consciousness can be seen at work not only in reference to the obsessional ideas themselves, but also in reference to the products of the secondary defensive struggle, such, for instance, as the protective formulas. I can produce two good examples of this. Our patient used to employ as a defensive formula a rapidly pronounced ‘aber’ ['but'] accompanied by a gesture of repudiation. He told me on one occasion that this formula had become altered recently; he now no longer said ‘aber’ but ‘abér’. When he was asked to give the reason for this new departure, he declared that the mute ‘e’ of the second syllable gave him no sense of security against the intrusion, which he so much dreaded, of some foreign and contradictory element, and that he had therefore decided to accent the ‘e’. This explanation (an excellent sample of the obsessional neurotic style) was, however, clearly inadequate; the most that it could claim to be was a rationalization. The truth was that ‘abér’ was an approximation towards the similar-sounding ‘abwehr’ ['defence'], a term which he had learnt in the course of our theoretical discussions of psycho-analysis. He had thus put the treatment to an illegitimate and ‘delirious’ use in order to strengthen a defensive formula. Another time he told me about his principal magic word, which was an apotropaic against every evil; he had put it together out of the initial letters of the most powerfully beneficial of his prayers and had clapped on an ‘amen’ at the end of it. I cannot reproduce the word itself, for reasons which will become apparent immediately. For, when he told it me, I could not help noticing that the word was in fact an anagram of the name of his lady. Her name contained an ‘s’, and this he had put last, that is, immediately before the ‘amen’ at the end. We may say, therefore, that by this process he had brought his ‘Samen’ ['semen'] into contact with the woman he loved; in imagination, that is to say, he had masturbated with her. He himself, however, had never noticed this very obvious connection; his defensive forces had allowed themselves to be fooled by the repressed ones. This is also a good example of the rule that in time the thing which is meant to be warded off invariably finds its way into the very means which is being used for warding it off.

[1909d, 2175]

I have already asserted that obsessional thoughts have undergone a distortion similar to that undergone by dream-thoughts before they become the manifest content of a dream. The technique of this distortion may therefore be of interest to us, and there should be nothing to prevent our exhibiting its various modes by means of a series of obsessions which have been translated and made clear. But here again the conditions governing the publication of this case make it impossible for me to give more than a few specimens. Not all of the patient's obsessions were so complicated in their structure and so difficult to solve as the great rat idea. In some of the others a very simple technique was employed - namely, that of distortion by omission or ellipsis. This technique is pre-eminently applicable to jokes, but in our present case, too, it did useful work as a means of protecting things from being understood.

[1909d, 2176]
The first and most serious objection is that the content of adults' dreams is as a rule unintelligible and could not look more unlike the fulfilment of a wish. And here is the answer. Such dreams have been subjected to distortion; the psychical process underlying them might originally have been expressed in words quite differently. You must distinguish the manifest content of the dream, as you vaguely recollect it in the morning and laboriously (and, as it seems, arbitrarily) clothe it in words, and the latent dream-thoughts, which you must suppose were present in the unconscious. This distortion in dreams is the same process that you have already come to know in investigating the formation of hysterical symptoms. It indicates, too, that the same interplay of mental forces is at work in the formation of dreams as in that of symptoms. The manifest content of the dream is the distorted substitute for the unconscious dream-thoughts and this distortion is the work of the ego's forces of defence - of resistances. In waking life these resistances altogether prevent the repressed wishes of the unconscious from entering consciousness; and during the lowered state of sleep they are at least strong enough to oblige them to adopt a veil of disguise. Thereafter, the dreamer can no more understand the meaning of his dreams than the hysteric can understand the connection and significance of his symptoms.

Psycho-analysis, then, has demonstrated the following facts. All dreams have a meaning. Their strangeness is due to distortions that have been made in the expression of their meaning. Their absurdity is deliberate and expresses derision, ridicule and contradiction. Their incoherence is a matter of indifference for their interpretation. The dream as we remember it after waking is described by us as its 'manifest content'. In the process of interpreting this, we are led to the 'latent dream-thoughts', which lie hidden behind the manifest content and which are represented by it. These latent dream-thoughts are no longer strange, incoherent or absurd; they are completely valid constituents of our waking thought. We give the name of 'dream-work' to the process which transforms the latent dream-thoughts into the manifest content of the dream; it is this dream-work that brings about the distortion which makes the dream-thoughts unrecognizable in the content of the dream.

I need say little about the interpretation of dreams. It came as the first fruits of the technical innovation I had adopted when, following a dim presentiment, I decided to replace hypnosis by free association. My desire for knowledge had not at the start been directed towards understanding dreams. I do not know of any outside influence which drew my interest to them or inspired me with any helpful expectations. Before Breuer and I ceased to meet I only just had time to tell him in a single sentence that I now understood how to translate dreams. Since this was how the discovery came about, it followed that the symbolism in the language of dreams was almost the last thing to become accessible to me, for the dreamer's associations help very little towards understanding symbols. I have held fast to the habit of always studying things themselves before looking for information about them in books, and therefore I was able to establish the symbolism of dreams for myself before I was led to it by Scherner's work on the subject. It was only later that I came to appreciate to its full extent this mode of expression of dreams. This was partly through the influence of the works of Stekel, who at first did such very creditable work but afterwards went totally astray. The close connection between psycho-analytic dream-interpretation and the art of interpreting dreams as practised and held in such high esteem in antiquity only became clear to me much later. Later on I found the essential characteristic and most important part of my dream theory - the derivation of dream-distortion from an internal conflict, a kind of inner dishonesty - in a writer who was ignorant, it is true, of medicine, though not of philosophy, the famous engineer J. Popper, who published his Phantasien eines Realisten under the name of Lynkeus.

[1910a, 2222]

[1913j, 2807]

[1914d, 2888]
Perhaps you recognize, moreover, what it is that supports our hypotheses of the two systems, and their relation to each other and to consciousness? After all, the watchman between the unconscious and the preconscious is nothing else than the censorship, to which, as we found, the form taken by the manifest dream is subject. The day's residues, which we recognized as the instigators of the dream, were preconscious material which, at night-time and in the state of sleep, had been under the influence of unconscious and repressed wishful impulses; they had been able, in combination with those impulses and thanks to their energy, to construct the latent dream. Under the dominance of the unconscious system this material had been worked over (by condensation and displacement) in a manner which is unknown or only exceptionally permissible in normal mental life - that is, in the preconscious system. We came to regard this difference in their manner of operating as what characterizes the two systems; the relation which the preconscious has to consciousness was regarded by us merely as an indication of its belonging to one of the two systems. Dreams are not pathological phenomena; they can appear in any healthy person under the conditions of a state of sleep. Our hypothesis about the structure of the mental apparatus, which allows us to understand the formation alike of dreams and of neurotic symptoms, has an incontrovertible claim to being taken into account in regard to normal mental life as well.

[1916-1917, 3370]

The path to perversion branches off sharply from that to neurosis. If these regressions rouse no objection from the ego, no neurosis will come about either; and the libido will arrive at some real, even though no longer normal, satisfaction. But if the ego, which has under its control not only consciousness but also the approaches to motor innervation and accordingly to the realization of mental desires, does not agree with these regressions, conflict will follow. The libido is, as it were, cut off and must try to escape in some direction where, in accordance with the requirements of the pleasure principle, it can find a discharge for its cathexis of energy. It must withdraw from the ego. An escape of this kind is offered it by the fixations on the path of its development which it has now entered on regressively - fixations from which the ego had protected itself in the past by repressions. By cathecting these repressed positions as it flows backward, the libido has withdrawn from the ego and its laws, and has at the same time renounced all the education it has acquired under the ego's influence. It was docile so long as satisfaction beckoned to it; but under the double pressure of external and internal frustration it becomes refractory, and recalls earlier and better times. Such is the libido's fundamentally unchangeable character. The ideas to which it now transfers its energy as a cathexis belong to the system of the unconscious and are subject to the processes which are possible there, particularly to condensation and displacement. In this way conditions are established which completely resemble those in dream-construction. The dream proper, which has been completed in the unconscious and is the fulfillment of an unconscious wishful phantasy, is brought up against a portion of (pre)conscious activity which exercises the office of censorship and which, when it has been indemnified, permits the formation of the manifest dream as a compromise. In the same way, what represents the libido in the unconscious has to reckon with the power of the preconscious ego. The opposition which had been raised against it in the ego pursues it as an 'anticathexis' and compels it to choose a form of expression which can at the same time become an expression of the opposition itself. Thus the symptom emerges as a many-times-distorted derivative of the unconscious libidinal wish-fulfilment, an ingeniously chosen piece of ambiguity with two meanings in complete mutual contradiction. In this last respect, however, there is a distinction between the construction of a dream and of a symptom. For in dream-formation the preconscious purpose is merely concerned to preserve sleep, to allow nothing that would disturb it to make its way into consciousness; it does not insist upon calling out sharply 'No! on the contrary!' to the unconscious wishful impulse. It can afford to be more tolerant because the situation of someone sleeping is less perilous. The state of sleep in itself bars any outlet into reality.

[1916-1917, 3418]
I told you too that we hoped that the analysis of the narcissistic disorders would give us an insight into the way in which our ego is put together and built up out of different agencies. We have already made a start with this at one point. From the analysis of delusions of observation we have drawn the conclusion that there actually exists in the ego an agency which unceasingly observes, criticizes and compares, and in that way sets itself over against the other part of the ego. We believe, therefore, that the patient is betraying a truth to us which is not yet sufficiently appreciated when he complains that he is spied upon and observed at every step he takes and that every one of his thoughts is reported and criticized. His only mistake is in regarding this uncomfortable power as something alien to him and placing it outside himself. He senses an agency holding sway in his ego which measures his actual ego and each of its activities by an ideal ego that he has created for himself in the course of his development. We believe, too, that this creation was made with the intention of re-establishing the self-satisfaction which was attached to primary infantile narcissism but which since then has suffered so many disturbances and mortifications. We know the self-observing agency as the ego-censor, the conscience; it is this that exercises the dream-censorship during the night, from which the repressions of inadmissible wishful impulses proceed. When in delusions of observation it becomes split up, it reveals to us its origin from the influences of parents, educators and social environment - from an identification with some of these model figures.

[1916-1917, 3472]

I am not of opinion, however, that such scenes must necessarily be phantasies because they do not reappear in the shape of recollections. It seems to me absolutely equivalent to a recollection, if the memories are replaced (as in the present case) by dreams the analysis of which invariably leads back to the same scene and which reproduce every portion of its content in an inexhaustible variety of new shapes. Indeed, dreaming is another kind of remembering, though one that is subject to the conditions that rule at night and to the laws of dream-formation. It is this recurrence in dreams that I regard as the explanation of the fact that the patients themselves gradually acquire a profound conviction of the reality of these primal scenes, a conviction which is in no respect inferior to one based on recollection.¹

[1918b, 3538]

It will perhaps not be thought too rash to suppose that the impulses arising from the instincts do not belong to the type of bound nervous processes but of freely mobile processes which press towards discharge. The best part of what we know of these processes is derived from our study of the dream-work. We there discovered that the processes in the unconscious systems were fundamentally different from those in the preconscious (or conscious) systems. In the unconscious, cathexes can easily be completely transferred, displaced and condensed. Such treatment, however, could produce only invalid results if it were applied to preconscious material; and this accounts for the familiar peculiarities exhibited by manifest dreams after the preconscious residues of the preceding day have been worked over in accordance with the laws operating in the unconscious. I described the type of process found in the unconscious as the ‘primary’ psychical process, in contradistinction to the ‘secondary’ process which is the one obtaining in our normal waking life. Since all instinctual impulses have the unconscious systems as their point of impact, it is hardly an innovation to say that they obey the primary process. Again, it is easy to identify the primary psychical process with Breuer’s freely mobile cathexis and the secondary process with changes in his bound or tonic cathexis.¹ If so, it would be the task of the higher strata of the mental apparatus to bind the instinctual excitation reaching the primary process. A failure to effect this binding would provoke a disturbance analogous to a traumatic neurosis; and only after the binding has been accomplished would it be possible for the dominance of the pleasure principle (and of its modification, the reality principle) to proceed unhindered. Till then the other task of the mental apparatus, the task of mastering or binding excitations, would have precedence - not, indeed, in opposition to the pleasure principle, but independently of it and to some extent in disregard of it.

[1920g, 3737]
I can imagine that to point out the existence of lying dreams of this kind, 'obliging' dreams, will arouse a positive storm of helpless indignation in some readers who call themselves analysts. 'What!' they will exclaim, 'the unconscious, the real centre of our mental life, the part of us that is so much nearer the divine than our poor consciousness - it too can lie! Then how can we still build on the interpretations of analysis and the accuracy of our findings?' To which one must reply that the recognition of these lying dreams does not constitute any shattering novelty. I know, indeed, that the craving of mankind for mysticism is ineradicable, and that it makes ceaseless efforts to win back for mysticism the territory it has been deprived of by The Interpretation of Dreams, but surely in the case under consideration everything is simple enough. A dream is not the 'unconscious'; it is the form into which a thought left over from preconscious, or even from conscious, waking life, can, thanks to the favouring state of sleep, be recast. In the state of sleep this thought has been reinforced by unconscious wishful impulses and has thus experienced distortion through the dream-work, which is determined by the mechanisms prevailing in the unconscious. With our dreamer, the intention to mislead me, just as she did her father, certainly emanated from the preconscious, and may indeed have been conscious; it could come to expression by entering into connection with the unconscious wishful impulse to please her father (or father-substitute), and in this way it created a lying dream. The two intentions, to betray and to please her father, originated in the same complex; the former resulted from the repression of the latter, and the later one was brought back by the dream-work to the earlier one. There can therefore be no question of any devaluation of the unconscious, nor of a shattering of our confidence in the results of analysis.

[1920a, 3854]

The Dynamic Theory of Dream-Formation. The motive power for the formation of dreams is not provided by the latent dream-thoughts or day's residues, but by an unconscious impulse, repressed during the day, with which the day's residues have been able to establish contact and which contrives to make a wish-fulfilment for itself out of the material of the latent thoughts. Thus every dream is on the one hand the fulfilment of a wish on the part of the unconscious and on the other hand (in so far as it succeeds in guarding the state of sleep against being disturbed) the fulfilment of the normal wish to sleep which set the sleep going. If we disregard the unconscious contribution to the formation of the dream and limit the dream to its latent thoughts, it can represent anything with which waking life has been concerned - a reflection, a warning, an intention, a preparation for the immediate future or, once again, the satisfaction of an unfulfilled wish. The unrecognizability, strangeness and absurdity of the manifest dream are partly the result of the translation of the thoughts into a different, so to say archaic, method of expression, but partly the effect of a restrictive, critically disapproving agency in the mind which does not entirely cease to function during sleep. It is plausible to suppose that the 'dream-censorship', which we regard as being responsible in the first instance for the distortion of the dream-thoughts into the manifest dream, is an expression of the same mental forces which during the day-time had held back or repressed the unconscious wishful impulse.

[1923a, 3918]

What conclusions can one draw from a correctly translated dream? I have an impression that analytic practice has not always avoided errors and over-estimations on this point, partly owing to an exaggerated respect for the 'mysterious unconscious'. It is only too easy to forget that a dream is as a rule merely a thought like any other, made possible by a relaxation of the censorship and by unconscious reinforcement, and distorted by the operation of the censorship and by unconscious revision.

[1923c, 4033]
In my case, too, the originality of many of the new ideas employed by me in the interpretation of dreams and in psycho-analysis has evaporated in this way. I am ignorant of the source of only one of these ideas. It was no less than the key to my view of dreams and helped me to solve their riddles, so far as it has been possible to solve them hitherto. I started out from the strange, confused and senseless character of so many dreams, and hit upon the notion that dreams were bound to become like that because something was struggling for expression in them which was opposed by a resistance from other mental forces. In dreams hidden impulses were stirring which stood in contradiction to what might be called the dreamer's official ethical and aesthetic creed; the dreamer was thus ashamed of these impulses, turned away from them and refused to acknowledge them in day-time, and if during the night he could not withhold expression of some kind from them, he submitted them to a 'dream-distortion' which made the content of the dream appear confused and senseless. To the mental force in human beings which keeps watch on this internal contradiction and distorts the dream's primitive instinctual impulses in favour of conventional or of higher moral standards, I gave the name of 'dream-censorship'.

There were now a whole series of questions to be answered, among the most important of them being whether the formation of dreams had a motive, under what conditions it took place, by what methods the dream-thoughts (which are invariably full of sense) become converted into the dream (which is often senseless), and others besides. I attempted to solve all of these problems in *The Interpretation of Dreams*, which I published in the year 1900. I can only find space here for the briefest abstract of my investigation. When the latent dream-thoughts that are revealed by the analysis of a dream are examined, one of them is found to stand out from among the rest, which are intelligible and well known to the dreamer. These latter thoughts are residues of waking life (the day's residues, as they are called technically); but the isolated thought is found to be a wishful impulse, often of a very repellent kind, which is foreign to the waking life of the dreamer and is consequently disavowed by him with surprise or indignation. This impulse is the actual constructor of the dream: it provides the energy for its production and makes use of the day's residues as material. The dream which thus originates represents a situation of satisfaction for the impulse, it is the fulfilment of its wish. It would not be possible for this process to take place without being favoured by the presence of something in the nature of a state of sleep. The necessary mental precondition of sleep is the concentration of the ego upon the wish to sleep and the withdrawal of psychical energy from all the interests of life. Since at the same time all the paths of approach to motility are blocked, the ego is also able to reduce the expenditure by which at other times it maintains the repressions. The unconscious impulse makes use of this nocturnal relaxation of repression in order to push its way into consciousness with the dream. But the repressive resistance of the ego is not abolished in sleep but merely reduced. Some of it remains in the shape of a censorship of dreams and forbids the unconscious impulse to express itself in the forms which it would properly assume. In consequence of the severity of the censorship of dreams, the latent dream-thoughts are obliged to submit to being altered and softened so as to make the forbidden meaning of the dream unrecognizable. This is the explanation of dream-distortion, which accounts for the most striking characteristics of the manifest dream. We are therefore justified in asserting that a dream is the (disguised) fulfilment of a (repressed) wish. It will now be seen that dreams are constructed like a neurotic symptom: they are compromises between the demands of a repressed impulse and the resistance of a censoring force in the ego. Since they have a similar origin they are equally unintelligible and stand in equal need of interpretation.

[1923f, 4159]

[1925d, 4219]
There is no difficulty in discovering the general function of dreaming. It serves the purpose of fending off, by a kind of soothing action, external or internal stimuli which would tend to arouse the sleeper, and thus of securing sleep against interruption. External stimuli are fended off by being given a new interpretation and by being woven into some harmless situation; internal stimuli, caused by instinctual demands, are given free play by the sleeper and allowed to find satisfaction in the formation of dreams, so long as the latent dream-thoughts submit to the control of the censorship. But if they threaten to break free and the meaning of the dream becomes too plain, the sleeper cuts short the dream and wakes in a fright. (Dreams of this class are known as anxiety-dreams.) A similar failure in the function of dreaming occurs if an external stimulus becomes too strong to be fended off. (This is the class of arousal-dreams.) I have given the name of dream-work to the process which, with the co-operation of the censorship, converts the latent thoughts into the manifest content of the dream. It consists of a peculiar way of treating the preconscious material of thought, so that its component parts become condensed, its psychical emphasis becomes displaced, and the whole of it is translated into visual images or dramatized, and completed by a deceptive secondary revision. The dream-work is an excellent example of the processes occurring in the deeper, unconscious layers of the mind, which differ considerably from the familiar normal processes of thought. It also displays a number of archaic characteristics, such as the use of a symbolism (in this case of a predominantly sexual kind) which it has since also been possible to discover in other spheres of mental activity.

[1925d, 4220]

From all this we infer that the resistance which we come across in the work of interpreting dreams must also have had a share in their origin. We can actually distinguish between dreams that arose under a slight and under a high pressure of resistance. But this pressure varies as well from place to place within one and the same dream; it is responsible for the gaps, obscurities and confusions which may interrupt the continuity of even the finest of dreams.

[1933a, 4628]

But what is creating the resistance and against what is it aimed? Well, the resistance is the surest sign to us of a conflict. There must be a force here which is seeking to express something and another which is striving to prevent its expression. What comes about in consequence as a manifest dream may combine all the decisions into which this struggle between two trends has been condensed. At one point one of these forces may have succeeded in putting through what it wanted to say, while at another point it is the opposing agency which has managed to blot out the intended communication completely or to replace it by something that reveals not a trace of it. The commonest and most characteristic cases of dream-construction are those in which the conflict has ended in a compromise, so that the communicating agency has, it is true, been able to say what it wanted but not in the way it wanted - only in a softened down, distorted and unrecognized form. If, then, dreams do not give a faithful picture of the dream-thoughts and if the work of interpretation is required in order to bridge the gap between them, that is the outcome of the opposing, inhibiting and restricting agency which we have inferred from our perception of the resistance while we interpret dreams. So long as we studied dreams as isolated phenomena independent of the psychical structures akin to them, we named this agency the censor of dreams.

[1933a, 4628]
You have long been aware that this censorship is not an institution peculiar to dream-life. You know that the conflict between the two psychical agencies, which we - inaccurately - describe as the 'unconscious repressed' and the 'conscious', dominates our whole mental life and that the resistance against the interpretation of dreams, the sign of the dream-censorship, is nothing other than the resistance due to repression by which the two agencies are separated. You know too that the conflict between these two agencies may under certain conditions produce other psychical structures which, like dreams, are the outcome of compromises; and you will not expect me to repeat to you here everything that was contained in my introduction to the theory of the neuroses in order to demonstrate to you what we know of the determinants of the formation of such compromises. You have realized that the dream is a pathological product, the first member of the class which includes hysterical symptoms, obsessions and delusions, but that it is distinguished from the others by its transitoriness and by its occurrence under conditions which are part of normal life. For let us bear firmly in mind that, as was already pointed out by Aristotle, dream life is the way in which our mind works during the state of sleep. The state of sleep involves a turning-away from the real external world, and there we have the necessary condition for the development of a psychosis. The most careful study of the severe psychoses will not reveal to us a single feature that is more characteristic of those pathological conditions. In psychoses, however, the turning-away from reality is brought about in two kinds of way: either by the unconscious repressed becoming excessively strong so that it overwhelms the conscious, which is attached to reality, or because reality has become so intolerably distressing that the threatened ego throws itself into the arms of the unconscious instinctual forces in a desperate revolt. The harmless dream-psychosis is the result of a withdrawal from the external world which is consciously willed and only temporary, and it disappears when relations to the external world are resumed. During the isolation of the sleeping individual an alteration in the distribution of his psychical energy also sets in; a part of the expenditure on repression, which is normally required in order to hold the unconscious down, can be saved, for if the unconscious makes use of its relative liberation for active purposes, it finds its path to motility closed and the only path open to it is the harmless one leading to hallucinatory satisfaction. Now, therefore, a dream can be formed; but the fact of the dream-censorship shows that even during sleep enough of the resistance due to repression is retained.

[1933a, 4629]
In what follows I shall not be able to avoid a schematic method of exposition. Let us assume that in a particular case we have before us all the latent thoughts, charged with a greater or less amount of affect, by which the manifest dream has been replaced after its interpretation has been completed. We shall then be struck by one difference among these latent thoughts, and that difference will take us a long way. Almost all these dream-thoughts are recognized by the dreamer or acknowledged by him; he admits that he has thought this, now or at some other time, or that he might have thought it. There is only one single thought that he refuses to accept; it is strange to him or even perhaps repellent; he may possibly reject it with passionate feeling. It now becomes evident to us that the other thoughts are portions of a conscious, or, more accurately, a preconscious train of thinking. They might have been thought in waking life too, and indeed they were probably formed during the previous day. This one repudiated thought, however, or, properly speaking, this one impulse, is a child of night; it belongs to the dreamer's unconscious and on that account it is repudiated and rejected by him. It had to wait for the nightly relaxation of repression in order to arrive at any kind of expression. And in any case this expression is a weakened, distorted and disguised one; without our work of dream-interpretation we should not have found it. This unconscious impulse has to thank its link with the other, unobjectionable, dream-thoughts for the opportunity of slipping past the barrier of the censorship in an inconspicuous disguise. On the other hand, the preconscious dream-thoughts have to thank this same link for the power to occupy mental life during sleep as well. For there is no doubt about it: this unconscious impulse is the true creator of the dream; it is what produces the psychical energy for the dream's construction. Like any other instinctual impulse, it cannot strive for anything other than its own satisfaction; and our experience in interpreting dreams shows us too that that is the sense of all dreaming. In every dream an instinctual wish has to be represented as fulfilled. The shutting-off of mental life from reality at night and the regression to primitive mechanisms which this makes possible enable this wished-for instinctual satisfaction to be experienced in a hallucinatory manner as occurring in the present. As a result of this same regression, ideas are transformed in the dream into visual pictures: the latent dream-thoughts, that is to say, are dramatized and illustrated.

This piece of the dream-work gives us information about some of the most striking and peculiar features of dreams. I will repeat the course of events in dream-formation. As an introduction: the wish to sleep and intentional turning away from the external world. Next, two consequences of this for the mental apparatus: first, the possibility for older and more primitive methods of working to emerge in it - regression; secondly, the lowering of the resistance due to repression which weighs down upon the unconscious. As a result of this last factor the possibility arises for the formation of a dream and this is taken advantage of by the precipitating causes, the internal and external stimuli which have become active. The dream which originates in this way is already a compromise-structure. It has a double function; on the one hand it is ego-syntonic, since, by getting rid of the stimuli which are interfering with sleep, it serves the wish to sleep; on the other hand it allows a repressed instinctual impulse to obtain the satisfaction that is possible in these circumstances, in the form of the hallucinated fulfilment of a wish. The whole process of forming a dream which is permitted by the sleeping ego is, however, subject to the condition of the censorship, which is exercised by the residue of the repression still in operation. I cannot present the process more simply: it is not more simple. But I can proceed now with my description of the dream-work.
Let us go back once more to the latent dream-thoughts. Their most powerful element is the repressed instinctual impulse which has created in them an expression for itself on the basis of the presence of chance stimuli and by transference on to the day’s residues - though an expression that is toned down and disguised. Like every instinctual impulse, it too presses for satisfaction by action; but its path to motility is blocked by the physiological regulations implied in the state of sleep; it is compelled to take the backwards course in the direction of perception and to be content with a hallucinated satisfaction. The latent dream-thoughts are thus transformed into a collection of sensory images and visual scenes. It is as they travel on this course that what seems to us so novel and so strange occurs to them. All the linguistic instruments by which we express the subtler relations of thought - the conjunctions and prepositions, the changes in declension and conjugation - are dropped, because there are no means of representing them; just as in a primitive language without any grammar, only the raw material of thought is expressed and abstract terms are taken back to the concrete ones that are at their basis. What is left over after this may well appear disconnected. The copious employment of symbols, which have become alien to conscious thinking, for representing certain objects and processes is in harmony alike with the archaic regression in the mental apparatus and with the demands of the censorship. [1933a, 4632]

Still more remarkable is the other process - displacement or shifting of accent - which in conscious thinking we come across only as faulty reasoning or as means for a joke. The different ideas in the dream-thoughts are, indeed, not all of equal value; they are cathected with quotas of affect of varying magnitude and are correspondingly judged to be important and deserving of interest to a greater or less degree. In the dream-work these ideas are separated from the affects attaching to them. The affects are dealt with independently; they may be displaced on to something else, they may be retained, they may undergo alterations, or they may not appear in the dream at all. The importance of the ideas that have been stripped of their affect returns in the dream as sensory strength in the dream-pictures; but we observe that this accent has passed over from important elements to indifferent ones. Thus something that played only a minor part in the dream-thoughts seems to be pushed into the foreground in the dream as the main thing, while, on the contrary, what was the essence of the dream-thoughts finds only passing and indistinct representation in the dream. No other part of the dream-work is so much responsible for making the dream strange and incomprehensible to the dreamer. Displacement is the principal means used in the dream-distortion to which the dream-thoughts must submit under the influence of the censorship. [1933a, 4633]

The myth tells us that Prometheus the Titan, a culture-hero who was still a god¹ and who was perhaps originally himself a demiurge and a creator of men, brought fire to men, having stolen it from the gods, hidden in a hollow stick, a fennel-stalk. If we were interpreting a dream we should be inclined to regard such an object as a penis symbol, although the unusual stress laid on its hollowness might make us hesitate. But how can we bring this penis-tube into connection with the preservation of fire? There seems little chance of doing this, till we remember the procedure of reversal, of turning into the opposite, of inverting relationships, which is so common in dreams and which so often conceals their meaning from us. What a man harbours in his penis-tube is not fire. On the contrary, it is the means of quenching fire; it is the water of his stream of urine. This relationship between fire and water then connects up with a wealth of familiar analytic material. [1932a, 4782]
To begin with, I naturally understood no more about my patients' dreams than the dreamers did themselves. But by applying to these dreams, and more particularly to my own dreams, the procedure which I had already used for the study of other abnormal psychological structures, I succeeded in answering most of the questions which could be raised by an interpretation of dreams. There were many such questions: What do we dream about? Why do we dream at all? What is the origin of all the strange characteristics which distinguish dreams from waking life? - and many more such questions besides. Some of the answers were easily given and turned out to confirm views that had already been put forward; but others involved completely new hypotheses with regard to the structure and functioning of the apparatus of the mind. People dream about the things that have engaged their minds during the waking day. People dream in order to allay impulses that seek to disturb sleep, and in order to be able to sleep on. But why was it possible for dreams to present such a strange appearance, so confusedly senseless, so obviously contrasted with the content of waking thought, in spite of being concerned with the same material? There could be no doubt that dreams were only a substitute for a rational process of thought and could be interpreted - that is to say, translated into a rational process. But what needed explaining was the fact of the distortion which the dream-work had carried out upon the rational and intelligible material.

[1932c, 4808]
Dream-distortion was the profoundest and most difficult problem of dream life. And light was thrown on it by the following consideration, which placed dreams in a class along with other psychopathological formations and revealed them, as it were, as the normal psychoses of human beings. For our mind, that precious instrument by whose means we maintain ourselves in life, is no peacefully self-contained unity. It is rather to be compared with a modern State in which a mob, eager for enjoyment and destruction, has to be held down forcibly by a prudent superior class. The whole flux of our mental life and everything that finds expression in our thoughts are derivations and representatives of the multifarious instincts that are innate in our physical constitution. But these instincts are not all equally susceptible to direction and education, or equally ready to fall in with the demands of the external world and of human society. A number of them have retained their primitive, ungovernable nature; if we let them have their way, they would infallibly bring us to ruin. Consequently, learning by experience, we have developed organizations in our mind which, in the form of inhibitions, set themselves up against the direct manifestations of the instincts. Every impulse in the nature of a wish that arises from the sources of instinctual energy must submit itself to examination by the highest agencies of our mind, and, if it is not approved, is rejected and restrained from exercising any influence upon our movements - that is, from coming into execution. Often enough, indeed, such wishes are even forbidden to enter consciousness, which is habitually unaware even of the existence of these dangerous instinctual sources. We describe such impulses as being repressed from the point of view of consciousness, and as surviving only in the unconscious. If what is repressed contrives somehow to force its way into consciousness or into movement or into both, we are no longer normal: at that point the whole range of neurotic and psychotic symptoms arise. The maintenance of the necessary inhibitions and repressions imposes upon our mind a great expenditure of energy, from which it is glad to be relieved. A good opportunity for this seems to be offered at night by the state of sleep, since sleep involves a cessation of our motor functions. The situation seems safe, and the severity of our internal police-force may therefore be relaxed. It is not entirely withdrawn, since one cannot be certain: it may be that the unconscious never sleeps at all. And now the reduction of pressure upon the repressed unconscious produces its effect. Wishes arise from it which during sleep might find the entrance to consciousness open. If we were to know them we should be appalled, alike by their subject-matter, their unrestraint and indeed the mere possibility of their existence. This, however, occurs only seldom, and when it does we awake as speedily as possible, in a state of fear. But as a rule our consciousness does not experience the dream as it really was. It is true that the inhibitory forces (the dream censorship, as we may call them) are not completely awake, but neither are they wholly asleep. They have had an influence on the dream while it was struggling to find an expression in words and pictures, they have got rid of what was most objectionable, they have altered other parts of it till they are unrecognizable, they have severed real connections while introducing false ones, until the honest but brutal wishful phantasy which lay behind the dream has turned into the manifest dream as we remember it - more or less confused and almost always strange and incomprehensible. Thus the dream (or the distortion which characterizes it) is the expression of a compromise, the evidence of a conflict between the mutually incompatible impulses and strivings of our mental life. And do not let us forget that the same process, the same interplay of forces, which explains the dreams of a normal sleeper, gives us the key to understanding all the phenomena of neurosis and psychosis.

[1932c, 4809]
Now, if we leave psychological terminology out of account, this was the very same explanation of dream-distortion that I had arrived at from my study of dreams. Distortion was a compromise, something in its very nature disingenuous, the product of a conflict between thought and feeling, or, as I had put it, between what is conscious and what is repressed. Where a conflict of this kind was not present and repression was unnecessary, dreams could not be strange or senseless. The man who dreamed in a way no different from that in which he thought while awake was granted by Popper the very condition of internal harmony which, as a social reformer, he aimed at producing in the body politic. And if Science informs us that such a man, wholly without evil and falseness and devoid of all repressions, does not exist and could not survive, yet we may guess that, so far as an approximation to this ideal is possible, it had found its realization in the person of Popper himself.

[1932c, 4810]

The laws that govern the passage of events in the unconscious, which come to light in this manner, are remarkable enough and suffice to explain most of what seems strange to us about dreams. Above all there is a striking tendency to condensation, an inclination to form fresh unities out of elements which in our waking thought we should certainly have kept separate. As a consequence of this, a single element of the manifest dream often stands for a whole number of latent dream-thoughts as though it were a combined allusion to all of them; and in general the compass of the manifest dream is extraordinarily small in comparison with the wealth of material from which it has sprung. Another peculiarity of the dream-work, not entirely independent of the former one, is the ease with which psychical intensities (cathexes) are displaced from one element to another, so that it often happens that an element which was of little importance in the dream-thoughts appears as the clearest and accordingly most important feature of the manifest dream, and, vice versa, that essential elements of the dream-thoughts are represented in the manifest dream only by slight allusions. Moreover, as a rule the existence of quite insignificant points in common between two elements is enough to allow the dream-work to replace one by the other in all further operations. It will easily be imagined how greatly these mechanisms of condensation and displacement can increase the difficulty of interpreting a dream and of revealing the relations between the manifest dream and the latent dream-thoughts. From the evidence of the existence of these two tendencies to condensation and displacement our theory infers that in the unconscious id the energy is in a freely mobile state and that the id sets more store by the possibility of discharging quantities of excitation than by any other consideration;¹ and our theory makes use of these two peculiarities in defining the character of the primary process we have attributed to the id.

[1940a [1938], 4978]
From the unconscious, in fact. My supposition is that a conscious wish can only become a dream-instigator if it succeeds in awakening an unconscious wish with the same tenor and in obtaining reinforcement from it. From indications derived from the psycho-analysis of the neuroses, I consider that these unconscious wishes are always on the alert, ready at any time to find their way to expression when an opportunity arises for allying themselves with an impulse from the conscious and for transferring their own great intensity on to the latter's lesser one.¹ It will then appear as though the conscious wish alone had been realized in the dream; only some small peculiarity in the dream's configuration will serve as a finger-post to put us on the track of the powerful ally from the unconscious. These wishes in our unconscious, ever on the alert and, so to say, immortal, remind one of the legendary Titans, weighed down since primaeval ages by the massive bulk of the mountains which were once hurled upon them by the victorious gods and which are still shaken from time to time by the convulsion of their limbs. But these wishes, held under repression, are themselves of infantile origin, as we are taught by psychological research into the neuroses. I would propose, therefore, to set aside the assertion made just now, that the place of origin of dream-wishes is a matter of indifference and replace it by another one to the following effect: a wish which is represented in a dream must be an infantile one. In the case of adults it originates from the Ucs., in the case of children, where there is as yet no division or censorship between the Ucs. and the Pcs., or where that division is only gradually being set up, it is an unfulfilled, unrepressed wish from waking life. I am aware that this assertion cannot be proved to hold universally; but it can be proved to hold frequently, even in unsuspected cases, and it cannot be contradicted as a general proposition.

[1900a, 985]

It is worth while pausing in order to convince oneself from pathological cases how sensitive a human mind becomes in states of repression to any approach by what has been repressed, and how even trivial similarities suffice for the repressed to emerge behind the repressing force and take effect by means of it. I once had under medical treatment a young man - he was still almost a boy - who, after he had first unwillingly become acquainted with the processes of sex, had taken flight from every sexual desire that arose in him. For that purpose he made use of various methods of repression-: he intensified his zeal in learning, exaggerated his dependence on his mother, and in general assumed a childish character. I will not here enter into the manner in which his repressed sexuality broke through once more precisely in his relation to his mother; but I will describe a rarer and stranger instance of how another of his bulwarks collapsed on an occasion which could scarcely be regarded as sufficient. Mathematics enjoys the greatest reputation as a diversion from sexuality. This had been the very advice to which Jean Jacques Rousseau was obliged to listen from a lady who was dissatisfied with him: 'Lascia le donne e studia la matematica!'¹ So too our fugitive threw himself with special eagerness into the mathematics and geometry which he was taught at school, till suddenly one day his powers of comprehension were paralysed in the face of some apparently innocent problems. It was possible to establish two of these problems: 'Two bodies come together, one with a speed of . . . etc.' and 'On a cylinder, the diameter of whose surface is $m$, describe a cone . . . etc.' Other people would certainly not have regarded these as very striking allusions to sexual events; but he felt that he had been betrayed by mathematics as well, and took flight from it too.

[1907a, 1838]
Thus in the very first products of Hanold's delusional phantasies and actions we already find a double set of determinants, a derivation from two different sources. One of these is the one that was manifest to Hanold himself, the other is the one which is revealed to us when we examine his mental processes. One of them, looked at from Hanold's point of view, was conscious to him, the other was completely unconscious to him. One of them was derived wholly from the circle of ideas of the science of archaeology, the other arose from the repressed childhood memories that had become active in him and from the emotional instincts attached to them. One might be described as lying on the surface and covering the other, which was, as it were, concealed behind it. The scientific motivation might be said to serve as a pretext for the unconscious erotic one, and science had put itself completely at the service of the delusion. It should not be forgotten, however, that the unconscious determinants could not effect anything that did not simultaneously satisfy the conscious, scientific ones. The symptoms of a delusion - phantasies and actions alike - are in fact the products of compromise between the two mental currents, and in a compromise account is taken of the demands of each of the two parties to it; but each side must also renounce a part of what it wanted to achieve. Where a compromise comes about it must have been preceded by a struggle - in this case it was the conflict we have assumed between suppressed erotism and the forces that were keeping it in repression. In the formation of a delusion this struggle is in fact unending. Assault and resistance are renewed after the construction of each compromise, which is never, so to speak, entirely satisfying. Our author too is aware of this, and that is why he makes a peculiar unrest dominate this stage of his hero's disorder, as a precursor and guarantee of further developments.

[1907a, 1850]

The taboo of virginity and something of its motivation has been depicted most powerfully of all in a well-known dramatic character, that of Judith in Hebbel's tragedy *Judith und Holofernes*. Judith is one of those women whose virginity is protected by a taboo. Her first husband was paralysed on the bridal night by a mysterious anxiety, and never again dared to touch her, 'My beauty is like belladonna,' she says. 'Enjoyment of it brings madness and death.' When the Assyrian general is besieging her city, she conceives the plan of seducing him by her beauty and of destroying him, thus employing a patriotic motive to conceal a sexual one. After she has been deflowered by this powerful man, who boasts of his strength and ruthlessness, she finds the strength in her fury to strike off his head, and thus becomes the liberator of her people. Beheading is well known to us as a symbolic substitute for castrating; Judith is accordingly the woman who castrates the man who has deflowered her, which was just the wish of the newly-married woman expressed in the dream I reported. It is clear that Hebbel has intentionally sexualized the patriotic narrative from the Apocrypha of the Old Testament, for there Judith is able to boast after her return that she has not been defiled, nor is there in the Biblical text any mention of her uncanny wedding night. But probably, with the fine perception of a poet, he sensed the ancient motive, which had been lost in the tendentious narrative, and has merely restored its earlier content to the material.

[1918a, 2362]
In what follows I shall not be able to avoid a schematic method of exposition. Let us assume that in a particular case we have before us all the latent thoughts, charged with a greater or less amount of affect, by which the manifest dream has been replaced after its interpretation has been completed. We shall then be struck by one difference among these latent thoughts, and that difference will take us a long way. Almost all these dream-thoughts are recognized by the dreamer or acknowledged by him; he admits that he has thought this, now or at some other time, or that he might have thought it. There is only one single thought that he refuses to accept; it is strange to him or even perhaps repellent; he may possibly reject it with passionate feeling. It now becomes evident to us that the other thoughts are portions of a conscious, or, more accurately, a preconscious train of thinking. They might have been thought in waking life too, and indeed they were probably formed during the previous day. This one repudiated thought, however, or, properly speaking, this one impulse, is a child of night; it belongs to the dreamer's unconscious and on that account it is repudiated and rejected by him. It had to wait for the nightly relaxation of repression in order to arrive at any kind of expression. And in any case this expression is a weakened, distorted and disguised one; without our work of dream-interpretation we should not have found it. This unconscious impulse has to thank its link with the other, unobjectionable, dream-thoughts for the opportunity of slipping past the barrier of the censorship in an inconspicuous disguise. On the other hand, the preconscious dream-thoughts have to thank this same link for the power to occupy mental life during sleep as well. For there is no doubt about it: this unconscious impulse is the true creator of the dream; it is what produces the psychical energy for the dream's construction. Like any other instinctual impulse, it cannot strive for anything other than its own satisfaction; and our experience in interpreting dreams shows us too that that is the sense of all dreaming. In every dream an instinctual wish has to be represented as fulfilled. The shutting-off of mental life from reality at night and the regression to primitive mechanisms which this makes possible enable this wished-for instinctual satisfaction to be experienced in a hallucinatory manner as occurring in the present. As a result of this same regression, ideas are transformed in the dream into visual pictures: the latent dream-thoughts, that is to say, are dramatized and illustrated. [1933a, 4631]
We have already been led by wish-fulfilment itself to divide dreams into two groups. We have found some dreams which appeared openly as wish-fulfilments, and others in which the wish-fulfilment was unrecognizable and often disguised by every possible means. In the latter we have perceived the dream censorship at work. We found the undistorted wishful dreams principally in children; though short, frankly wishful dreams seemed (and I lay emphasis upon this qualification) to occur in adults as well.

[1900a, 983]

The analysis of dreams led further: it was brought to public notice by the present writer as early as in 1900 in *The Interpretation of Dreams*. This showed that dreams are constructed in just the same way as neurotic symptoms. Like them, they may appear strange and senseless; but, if we examine them by a technique which differs little from the free association used in psycho-analysis, we are led from their manifest content to a secret meaning, to the latent dream-thoughts. This latent meaning is always a wishful impulse which is represented as fulfilled at the moment of the dream. But, except in young children and under the pressure of imperative physical needs, this secret wish can never be expressed recognizably. It has first to submit to a distortion, which is the work of restrictive, censoring forces in the dreamer’s ego. In this way the manifest dream, as it is remembered in waking life, comes about. It is distorted, to the pitch of being unrecognizable, by concessions made to the dream-censorship; but it can be revealed once more by analysis as an expression of a situation of satisfaction or as the fulfilment of a wish. It is a compromise between two conflicting groups of mental trends, just as we have found to be the case with hysterical symptoms. The formula which, at bottom, best meets the essence of the dream is this: a dream is a (disguised) fulfilment of a (repressed) wish. The study of the process which transforms the latent dream-wish into the manifest content of the dream - a process known as the ‘dream-work’ - has taught us the best part of what we know of unconscious mental life.

[1924f, 4109]
The wish-fulfilment can be detected equally easily in some other dreams which I have collected from normal people. A friend of mine, who knows my theory of dreams and has told his wife of it, said to me one day: 'My wife has asked me to tell you that she had a dream yesterday that she was having her period. You can guess what that means.' I could indeed guess it. The fact that this young married woman dreamt that she was having her period meant that she had missed her period. I could well believe that she would have been glad to go on enjoying her freedom a little longer before shouldering the burden of motherhood. It was a neat way of announcing her first pregnancy. Another friend of mine wrote and told me that, not long before, his wife had dreamt that she had noticed some milk stains on the front of her vest. This too was an announcement of pregnancy, but not of a first one. The young mother was wishing that she might have more nourishment to give her second child than she had had for her first. [1900a, 625]

These examples will perhaps be enough to show that dreams which can only be understood as fulfilments of wishes and which bear their meaning upon their faces without disguise are to be found under the most frequent and various conditions. They are mostly short and simple dreams, which afford a pleasant contrast to the confused and exuberant compositions that have in the main attracted the attention of the authorities. Nevertheless, it will repay us to pause for a moment over these simple dreams. We may expect to find the very simplest forms of dreams in children, since there can be no doubt that their psychical productions are less complicated than those of adults. Child psychology, in my opinion, is destined to perform the same useful services for adult psychology that the investigation of the structure or development of the lower animals has performed for research into the structure of the higher classes of animals. Few deliberate efforts have hitherto been made to make use of child psychology for this purpose. [1900a, 625]

It seemed as though this might be a discovery of general validity. It is true that, as was shown by the instances quoted in Chapter III, there are some dreams which are undisguised fulfilments of wishes. But in cases where the wish-fulfilment is unrecognizable, where it has been disguised, there must have existed some inclination to put up a defence against the wish; and owing to this defence the wish was unable to express itself except in a distorted shape. I will try to seek a social parallel to this internal event in the mind. Where can we find a similar distortion of a psychical act in social life? Only where two persons are concerned, one of whom possesses a certain degree of power which the second is obliged to take into account. In such a case the second person will distort his psychical acts or, as we might put it, will dissimulate. The politeness which I practise every day is to a large extent dissimulation of this kind; and when I interpret my dreams for my readers I am obliged to adopt similar distortions. The poet complains of the need for these distortions in the words: [1900a, 638]

We have already been led by wish-fulfilment itself to divide dreams into two groups. We have found some dreams which appeared openly as wish-fulfilments, and others in which the wish-fulfilment was unrecognizable and often disguised by every possible means. In the latter we have perceived the dream censorship at work. We found the undistorted wishful dreams principally in children; though short, frankly wishful dreams seemed (and I lay emphasis upon this qualification) to occur in adults as well. [1900a, 983]
But you must not blame the dream itself on account of its evil content. Do not forget that it performs the innocent and indeed useful function of preserving sleep from disturbance. This wickedness is not part of the essential nature of dreams. Indeed you know too that there are dreams which can be recognized as the satisfaction of justified wishes and of pressing bodily needs. These, it is true, have no dream-distortion; but they have no need of it, for they can fulfil their function without insulting the ethical and aesthetic purposes of the ego. Bear in mind, too, that dream-distortion is proportionate to two factors. On the one hand it becomes greater the worse the wish that has to be censored; but on the other hand it also becomes greater the more severe the demands of the censorship at the moment. Thus a strictly brought-up and prudish young girl, with a relentless censorship, will distort dream-impulses which we doctors, for instance, would have to regard as permissible, harmless, libidinal wishes, and on which in ten years' time the dreamer herself will make the same judgement.

[1916-1917, 3238]

The analysis of dreams led further: it was brought to public notice by the present writer as early as in 1900 in *The Interpretation of Dreams*. This showed that dreams are constructed in just the same way as neurotic symptoms. Like them, they may appear strange and senseless; but, if we examine them by a technique which differs little from the free association used in psycho-analysis, we are led from their manifest content to a secret meaning, to the latent dream-thoughts. This latent meaning is always a wishful impulse which is represented as fulfilled at the moment of the dream. But, except in young children and under the pressure of imperative physical needs, this secret wish can never be expressed recognizably. It has first to submit to a distortion, which is the work of restrictive, censoring forces in the dreamer's ego. In this way the manifest dream, as it is remembered in waking life, comes about. It is distorted, to the pitch of being unrecognizable, by concessions made to the dream-censorship; but it can be revealed once more by analysis as an expression of a situation of satisfaction or as the fulfilment of a wish. It is a compromise between two conflicting groups of mental trends, just as we have found to be the case with hysterical symptoms. The formula which, at bottom, best meets the essence of the dream is this: a dream is a (disguised) fulfilment of a (repressed) wish. The study of the process which transforms the latent dream-wish into the manifest content of the dream - a process known as the 'dream-work' - has taught us the best part of what we know of unconscious mental life.

[1924f, 4109]
We have explained that the unconscious instinctual impulse of the dream connects itself with a residue of the day, with some interest of waking life which has not been disposed of; it thus gives the dream which it constructs a double value for the work of analysis. For on the one hand a dream that has been analysed reveals itself as the fulfilment of a repressed wish; but on the other hand it may be a continuation of some preconscious activity of the day before and may contain every kind of subject-matter and give expression to an intention, a warning, a reflection, or once more to the fulfilment of a wish. Analysis exploits the dream in both directions, as a means of obtaining knowledge alike of the patient's conscious and of his unconscious processes. It also profits from the fact that dreams have access to the forgotten material of childhood, and so it happens that infantile amnesia is for the most part overcome in connection with the interpretation of dreams. In this respect dreams achieve a part of what was previously the task of hypnotism. On the other hand, I have never maintained the assertion which has so often been ascribed to me that dream-interpretation shows that all dreams have a sexual content or are derived from sexual motive forces. It is easy to see that hunger, thirst, or the need to excrete, can produce dreams of satisfaction just as well as any repressed sexual or egoistic impulse. The case of young children affords us a convenient test of the validity of our theory of dreams. In them the various psychical systems are not yet sharply divided and the repressions have not yet grown deep, so that we often come upon dreams which are nothing more than undisguised fulfilments of wishful impulses left over from waking life. Under the influence of imperative needs, adults may also produce dreams of this infantile type.¹

[1925d, 4221]
It is easy to prove that dreams often reveal themselves without any disguise as fulfilments of wishes; so that it may seem surprising that the language of dreams was not understood long ago. For instance, there is a dream that I can produce in myself as often as I like - experimentally, as it were. If I eat anchovies or olives or any other highly salted food in the evening, I develop thirst during the night which wakes me up. But my waking is preceded by a dream; and this always has the same content, namely, that I am drinking. I dream I am swallowing down water in great gulps, and it has the delicious taste that nothing can equal but a cool drink when one is parched with thirst. Then I wake up and have to have a real drink. This simple dream is occasioned by the thirst which I become aware of when I wake. The thirst gives rise to a wish to drink, and the dream shows me that wish fulfilled. In doing so it is performing a function - which it was easy to divine. I am a good sleeper and not accustomed to be woken by any physical need. If I can succeed in appeasing my thirst by *dreaming* that I am drinking, then I need not wake up in order to quench it. This, then, is a dream of convenience. Dreaming has taken the place of action, as it often does elsewhere in life. Unluckily my need for water to quench my thirst cannot be satisfied by a dream in the same way as my thirst for revenge against my friend Otto and Dr. M.; but the good intention is there in both cases. Not long ago this same dream of mine showed some modification. I had felt thirsty even before I fell asleep, and I had emptied a glass of water that stood on the table beside my bed. A few hours later during the night I had a fresh attack of thirst, and this had inconvenient results. In order to provide myself with some water I should have had to get up and fetch the glass standing on the table by my wife's bed. I therefore had an appropriate dream that my wife was giving me a drink out of a vase; this vase was an Etruscan cinerary urn which I had brought back from a journey to Italy and had since given away. But the water in it tasted so salty (evidently because of the ashes in the urn) that I woke up. It will be noticed how conveniently everything was arranged in this dream. Since its only purpose was to fulfil a wish, it could be completely egoistical. A love of comfort and convenience is not really compatible with consideration for other people. The introduction of the cinerary urn was probably yet another wish-fulfilment. I was sorry that the vase was no longer in my possession - just as the glass of water on my wife's table was out of my reach. The urn with its ashes fitted in, too, with the salty taste in my mouth which had now grown stronger and which I knew was bound to wake me.¹

[1900a, 623]

These examples will perhaps be enough to show that dreams which can only be understood as fulfilments of wishes and which bear their meaning upon their faces without disguise are to be found under the most frequent and various conditions. They are mostly short and simple dreams, which afford a pleasant contrast to the confused and exuberant compositions that have in the main attracted the attention of the authorities. Nevertheless, it will repay us to pause for a moment over these simple dreams. We may expect to find the very simplest forms of dreams in children, since there can be no doubt that their psychical productions are less complicated than those of adults. Child psychology, in my opinion, is destined to perform the same useful services for adult psychology that the investigation of the structure or development of the lower animals has performed for research into the structure of the higher classes of animals. Few deliberate efforts have hitherto been made to make use of child psychology for this purpose. [1900a, 625]

The dreams of young children are frequently pure wish-fulfilments and are in that case quite uninteresting compared with the dreams of adults. They raise no problems for solution; but on the other hand they are of inestimable importance in proving that, in their essential nature, dreams represent fulfilments of wishes. I have been able to collect a few instances of such dreams from material provided by my own children. [1900a, 626]
Here is an equally straightforward dream, provoked by the beauty of the scenery at Aussee in another of my daughters, who was at that time three and a quarter. She had crossed the lake for the first time, and the crossing had been too short for her: when we reached the landing-stage she had not wanted to leave the boat and had wept bitterly. Next morning she said: 'Last night I went on the lake.' Let us hope that her dream-crossing had been of a more satisfying length.

[1900a, 628]

³ [Footnote added 1911:] The fact should be mentioned that children soon begin to have more complicated and less transparent dreams, and that, on the other hand, adults in certain circumstances often have dreams of a similarly simple, infantile character. The wealth of unexpected material that may occur in the dreams of children of four or five is shown by examples in my 'Analysis of a Phobia in a Five-Year-Old Boy' (1909b) and in Jung (1910a). - [Added 1914:] For analytical interpretations of children's dreams see also von Hug-Heilmuth (1911 and 1913), Putnam (1912), van Raalte (1912), Spielrein (1913) and Tausk (1913). Children's dreams are also reported by Bianchieri (1912), Busemann (1909 and 1910), Doglia and Bianchieri (1910-11) and, in particular, Wiggam (1909), who laid stress on their trend towards wish-fulfilment. - [Added 1911:] On the other hand, dreams of an infantile type seem to occur in adults with special frequency when they find themselves in unusual external circumstances. Thus Otto Nordenskjöld (1904, 1, 336 f.) writes as follows of the members of his expedition while they were wintering in the Antarctic: 'The direction taken by our innermost thoughts was very clearly shown by our dreams, which were never more vivid or numerous than at this time. Even those of us who otherwise dreamt but rarely had long stories to tell in the morning when we exchanged our latest experiences in this world of the imagination. They were all concerned with the outside world which was now so remote from us, though they were often adapted to our actual circumstances. One of my companions had a particularly characteristic dream of being back in his school class-room, where it was his task to skin miniature seals which had been specially prepared for instructional purposes. Eating and drinking, however, were the pivot round which our dreams most often revolved. One of us, who had a special gift for attending large luncheon parties during the night, was proud if he was able to report in the morning that he had "got though a three-course dinner". Another of us dreamt of tobacco, of whole mountains of tobacco; while a third dreamt of a ship in full sail coming in across open water. Yet another dream is worth repeating. The postman brought round the mail and gave a long explanation of why we had had to wait so long for it: he had delivered it at the wrong address and had only succeeded in recovering it with great difficulty. We dreamt, of course, of still more impossible things. But there was a most striking lack of imaginativeness shown by almost all the dreams that I dreamt myself or heard described. It would certainly be of great psychological interest if all these dreams could be recorded. And it will easily be understood how much we longed for sleep, since it could offer each one of us everything that he most eagerly desired.' - [Added 1914:] According to Du Prel (1865, 231), 'Mungo Park, when he was almost dying of thirst on one of his African journeys, dreamt unceasingly of the well-watered valleys and meadows of his home. Similarly, Baron Trenck suffering torments of hunger while he was a prisoner in the fortress at Magdeburg, dreamt of being surrounded by sumptuous meals; and George Back, who took part in Franklin's first expedition, when he was almost dying of starvation as a result of his fearful privations, dreamt constantly and regularly of copious meals.'

[1900a, 629]
'There is nothing new,' I shall be told, 'in the idea that some dreams are to be regarded as wish-fulfilments; the authorities noticed that fact long ago. Cf. Radestock (1879, 137 f.), Volkelt (1875, 110 f.), Purkinje (1846, 456), Tissié (1898, 70), Simon (1888, 42, on the hunger dreams of Baron Trenck while he was a prisoner), and a passage in Griesinger (1845, 89).¹ But to assert that there are no dreams other than wish-fulfilment dreams is only one more unjustifiable generalization, though fortunately one which it is easy to disprove. After all, plenty of dreams occur which contain the most distressing subject matter but never a sign of any wish-fulfilment. Eduard von Hartmann, the philosopher of pessimism, is probably furthest removed from the wish-fulfilment theory. In his *Philosophie des Unbewussten* (1890, 2, 344) he writes: "When it comes to dreams, we find all the annoyances of waking life carried over into the state of sleep; the only thing we do not find is what can to some extent reconcile an educated man to life - scientific and artistic enjoyment. . . ." But even less disgruntled observers have insisted that pain and unpleasure are more common in dreams than pleasure: for instance, Scholz (1893, 57), Volkelt (1875, 80), and others. Indeed two ladies, Florence Hallam and Sarah Weed (1896, 499), have actually given statistical expression, based on a study of their own dreams, to the preponderance of unpleasure in dreaming. They find that 57.2 per cent of dreams are "disagreeable" and only 28.6 percent positively "pleasant". And apart from these dreams, which carry over into sleep the various distressing emotions of life, there are anxiety-dreams, in which that most dreadful of all unpleasurable feelings holds us in its grasp till we awaken. And the commonest victims of these anxiety-dreams are precisely children,² whose dreams you have described as undisguised wish-fulfilments.'

[1900a, 631]

If this sentence is taken in the sense in which it was intended, it merely shows the unconscientious manner in which critics are accustomed to perform their functions, and the readiness with which opponents overlook the clearest statements if they do not give scope to their aggressive inclinations. For only a few pages earlier I had mentioned the variety of the wishes whose fulfilments are to be found in children's dreams (wishes to take part in an excursion or a sail on a lake, or to make up for a missed meal, and so on); and in other passages I had discussed dreams of hunger, dreams stimulated by thirst or by excretory needs, and dreams of mere convenience. Even Rank himself made no absolute assertion. The words he used were 'also as a rule erotic wishes', and what he said can be amply confirmed in the dreams of most adults.

[1900a, 653]

We have already been led by wish-fulfilment itself to divide dreams into two groups. We have found some dreams which appeared openly as wish-fulfilments, and others in which the wish-fulfilment was unrecognizable and often disguised by every possible means. In the latter we have perceived the dream censorship at work. We found the undistorted wishful dreams principally in children; though short, frankly wishful dreams seemed (and I lay emphasis upon this qualification) to occur in adults as well.

[1900a, 983]
If we cast our minds over the dreams that are at our disposal for answering this question, we shall at once be reminded that we must add a fourth source of dream-wishes, namely the current wishful impulses that arise during the night (e.g. those stimulated by thirst or sexual needs). In the next place, we shall form the opinion that the place of origin of a dream-wish probably has no influence on its capacity for instigating dreams. I may recall the little girl's dream which prolonged a trip on the lake that had been interrupted during the day and the other children's dreams which I have recorded. They were explained as being due to unfulfilled, but unsuppressed, wishes from the previous day. Instances of a wish that has been suppressed in the daytime finding its way out in a dream are exceedingly numerous. I will add a further very simple example of this class. The dreamer was a lady who was rather fond of making fun of people and one of whose friends, a woman younger than herself, had just become engaged. All day long she had been asked by her acquaintances whether she knew the young man and what she thought of him. She had replied with nothing but praises, with which she had silenced her real judgement; for she would have liked to tell the truth - that he was a 'Dutzendmensch' [literally a 'dozen man', a very commonplace sort of person - people like him are turned out by the dozen]. She dreamt that night that she was asked the same question, and replied with the formula: 'In the case of repeat orders it is sufficient to quote the number.' We have learnt, lastly, from numerous analyses that wherever a dream has undergone distortion the wish has arisen from the unconscious and was one which could not be perceived during the day. Thus it seems at first glance as though all wishes are of equal importance and equal power in dreams.

I cannot offer any proof here that the truth is nevertheless otherwise; but I may say that I am strongly inclined to suppose that dream-wishes are more strictly determined. It is true that children's dreams prove beyond a doubt that a wish that has not been dealt with during the day can act as a dream-instigator. But it must not be forgotten that it is a child's wish, a wishful impulse of the strength proper to children. I think it is highly doubtful whether in the case of an adult a wish that has not been fulfilled during the day would be strong enough to produce a dream. It seems to me, on the contrary, that, with the progressive control exercised upon our instinctual life by our thought-activity, we are more and more inclined to renounce as unprofitable the formation or retention of such intense wishes as children know. It is possible that there are individual differences in this respect, and that some people retain an infantile type of mental process longer than others, just as there are similar differences in regard to the diminution of visual imagery, which is so vivid in early years. But in general, I think, a wish that has been left over unfulfilled from the previous day is insufficient to produce a dream in the case of an adult. I readily admit that a wishful impulse originating in the conscious will contribute to the instigation of a dream, but it will probably not do more than that. The dream would not materialize if the preconscious wish did not succeed in finding reinforcement from elsewhere.

The contrast between the manifest and latent content of dreams is clearly of significance only for dreams of the second and more particularly of the third category. It is there that we are faced by riddles which only disappear after we have replaced the manifest dream by the latent thoughts behind it; and it was on a specimen of the last category - a confused and unintelligible dream - that the analysis which I have just recorded was carried out. Contrary to our expectation, however, we came up against motives which prevented us from becoming fully acquainted with the latent dream-thoughts. A repetition of similar experiences may lead us to suspect that there is an intimate and regular relation between the unintelligible and confused nature of dreams and the difficulty of reporting the thoughts behind them. Before enquiring into the nature of this relation, we may with advantage turn our attention to the more easily intelligible dreams of the first category, in which the manifest and latent content coincide, and there appears to be a consequent saving in dream-work.
Moreover, an examination of these dreams offers advantages from another standpoint. For children's dreams are of that kind - significant and not puzzling. Here, incidentally, we have a further argument against tracing the origin of dreams to dissociated cerebral activity during sleep. For why should a reduction in psychical functioning of this kind be a characteristic of the state of sleep in the case of adults but not in that of children? On the other hand, we shall be fully justified in expecting that an explanation of psychical processes in children, in whom they may well be greatly simplified, may turn out to be an indispensable prelude to the investigation of the psychology of adults.

I will therefore record a few instances of dreams which I have collected from children. A little girl nineteen months old had been kept without food all day because she had had an attack of vomiting in the morning; her nurse declared that she had been upset by eating strawberries. During the night after this day of starvation she was heard saying her own name in her sleep and adding: 'Strawberries, wild strawberries, omblet, pudding!' She was thus dreaming of eating a meal, and she laid special stress in her menu on the particular delicacy of which, as she had reason to expect, she would only be allowed scanty quantities in the near future. - A little boy of twenty-two months had a similar dream of a feast which he had been denied. The day before, he had been obliged to present his uncle with a gift of a basket of fresh cherries, of which he himself, of course, had only been allowed to taste a single sample. He awoke with this cheerful news: 'Hermann eaten all the chewies!' - One day a girl of three and a quarter made a trip across a lake. The voyage was evidently not long enough for her, for she cried when she had to get off the boat. Next morning she reported that during the night she had been for a trip on the lake: she had been continuing her interrupted voyage. - A boy of five and a quarter showed signs of dissatisfaction in the course of a walk in the neighbourhood of the Dachstein. Each time a new mountain came into view he asked if it was the Dachstein and finally refused to visit a waterfall with the rest of the company. His behaviour was attributed to fatigue; but it found a better explanation when next morning he reported that he had dreamt that he climbed up the Dachstein. He had evidently had the idea that the expedition would end in a climb up the Dachstein, and had become depressed when the promised mountain never came in view. He made up in his dream for what the previous day had failed to give him. - A six-year-old girl had an exactly similar dream. In the course of a walk her father had stopped short of their intended goal as the hour was getting late. On their way back she had noticed a signpost bearing the name of another landmark; and her father had promised to take her there as well another time. Next morning she met her father with the news that she had dreamt that she had been with her to both places.

The common element in all these children's dreams is obvious. All of them fulfilled wishes which were active during the day but had remained unfulfilled. The dreams were simple and undisguised wish-fulfilments.

Here is another child's dream, which, though at first sight it is not quite easy to understand, is also nothing more than a wish-fulfilment. A little girl not quite four years old had been brought to town from the country because she was suffering from an attack of poliomyelitis. She spent the night with an aunt who had no children, and was put to sleep in a large bed - much too large for her, of course. Next morning she said she had had a dream that the bed had been far too small for her, and that there has been no room for her in it. It is easy to recognize this dream as a wishful dream if we remember that children very often express a wish 'to be big.' The size of the bed was a disagreeable reminder of her smallness to the would-be big child; she therefore corrected the unwelcome relation in her dream, and grew so big that even the large bed was too small for her.
Even when the content of children's dreams becomes complicated and subtle, there is never any difficulty in recognizing them as wish-fulfilments. An eight-year-old boy had a dream that he was driving in a chariot with Achilles and that Diomede was the charioteer. It was shown that the day before he had been deep in a book of legends about the Greek heroes; and it was easy to see that he had taken the heroes as his models and was sorry not to be living in their days. [1901a, 1063]

This small collection throws a direct light on a further characteristic of children's dreams: their connection with daytime life. The wishes which are fulfilled in them are carried over from daytime and as a rule from the day before, and in waking life they have been accompanied by intense emotion. Nothing unimportant or indifferent, or nothing which would strike a child as such, finds its way into the content of their dreams. [1901a, 1063]

But before taking leave of infantile dreams with their undisguised wish-fulfilments, I must not omit to mention one principal feature of dreams, which has long been evident and which emerges particularly clearly precisely in this group. Every one of these dreams can be replaced by an optative clause: 'Oh, if only the trip on the lake had lasted longer!' - 'If only I were already washed and dressed!' - 'If only I could have kept the cherries instead of giving them to Uncle!' But dreams give us more than such optative clauses. They show us the wish as already fulfilled; they represent its fulfilment as real and present; and the material employed in dream-representation consists principally, though not exclusively, of situations and of sensory images, mostly of a visual character. Thus, even in this infantile group, a species of transformation, which deserves to be described as dream-work, is not completely absent: *a thought expressed in the optative has been replaced by a representation in the present tense.* [1901a, 1065]

Now that we have established the concept of repression and have brought dream-distortion into relation with repressed psychical material, we can express in general terms the principal finding to which we have been led by the analysis of dreams. In the case of dreams which are intelligible and have a meaning, we have found that they are undisguised wish-fulfilments; that is, that in their case the dream-situation represents as fulfilled a wish which is known to consciousness, which is left over from daytime life, and which is deservedly of interest. Analysis has taught us something entirely analogous in the case of obscure and confused dreams: once again the dream-situation represents a wish as fulfilled - a wish which invariably arises from the dream-thoughts, but one which is represented in an unrecognizable form and can only be explained when it has been traced back in analysis. The wish in such cases is either itself a repressed one and alien to consciousness, or it is intimately connected with repressed thoughts and is based upon them. Thus the formula for such dreams is as follows: *they are disguised fulfilments of repressed wishes.* It is interesting in this connection to observe that the popular belief that dreams always foretell the future is confirmed. Actually the future which the dream shows us is not the one which will occur but the one which we should like to occur. The popular mind is behaving here as it usually does: what it wishes, it believes. [1901a, 1087]
In the case of children's dreams there should be no difficulty in accepting this statement. The state of sleep or the psychical modification involved in sleep, whatever that may be, is brought about by a resolve to sleep which is either imposed upon the child or is reached on the basis of sensations of fatigue; and it is only made possible by the withholding of stimuli which might suggest to the psychical apparatus aims other than that of sleeping. The means by which external stimuli can be kept off are familiar to us; but what are the means available for controlling internal mental stimuli which set themselves against falling asleep? Let us observe a mother putting her child to sleep. The child gives vent to an unceasing stream of desires: he wants one more kiss, he wants to go on playing. His mother satisfies some of these desires, but uses her authority to postpone others of them to the next day. It is clear that any wishes or needs that may arise have an inhibiting effect upon falling asleep. We all know the amusing story told by Balduin Groller of the bad little boy who woke up in the middle of the night and shouted across the night nursery: 'I want the rhino!' A better behaved child, instead of shouting, would have dreamt that he was playing with the rhino. Since a dream that shows a wish as fulfilled is believed during sleep, it does away with the wish and makes sleep possible. It cannot be disputed that dream-images are believed in this way, for they are clothed in the psychical appearance of perceptions, and children have not yet acquired the later faculty of distinguishing hallucinations or phantasies from reality.

At this point I shall interrupt my report of the analysis in order to compare this small piece of dream-interpretation with the general statements I have made upon the mechanism of the formation of dreams. I argued in my book, *The Interpretation of Dreams* (1900a), that every dream is a wish which is represented as fulfilled, that the representation acts as a takes disguise if the wish is a repressed one, belonging to the unconscious, and that except in the case of children's dreams only an unconscious wish or one which reaches down into the unconscious has the force necessary for the formation of a dream. I fancy my theory would have been more certain of general acceptance if I had contented myself with maintaining that every dream had a meaning, which could be discovered by means of a certain process of interpretation; and that when the interpretation had been completed the dream could be replaced by thoughts which would fall into place at an easily recognizable point in the waking mental life of the dreamer. I might then have gone on to say that the meaning of a dream turned out to be of as many different sorts as the processes of waking thought; that in one case it would be a fulfilled wish, in another a realized fear, or again a reflection persisting on into sleep, or an intention (as in the instance of Dora's dream), or a piece of creative thought during sleep, and so on. Such a theory would no doubt have proved attractive from its very simplicity, and it might have been supported by a great many examples of dreams that had been satisfactorily interpreted, as for instance by the one which has been analysed in these pages.
The achievements of the dream-work can, however, be described as follows. A tissue of thoughts, usually a very complicated one, which has been built up during the day and has not been completely dealt with - 'a day's residue' - continues during the night to retain the quota of energy - the 'interest' - claimed by it, and threatens to disturb sleep. This 'day's residue' is transformed by the dream-work into a dream and made innocuous to sleep. In order to provide a fulcrum for the dream-work, the 'day's residue' must be capable of constructing a wish - which is not a very hard condition to fulfil. The wish arising from the dream-thoughts forms the preliminary stage and later the core of the dream. Experience derived from analyses - and not the theory of dreams - informs us that in children any wish left over from waking life is sufficient to call up a dream, which emerges as connected and ingenious but usually short, and which is easily recognized as a 'wish-fulfilment'. In the case of adults it seems to be a generally binding condition that the wish which creates the dream shall be one that is alien to conscious thinking - a repressed wish - or will possibly at least have reinforcements that are unknown to consciousness. Without assuming the existence of the unconscious in the sense explained above, I should not be able to develop the theory of dreams further or to interpret the material met with in dream-analyses. The action of this unconscious wish upon the consciously rational material of the dream-thoughts produces the dream. While this happens, the dream is, as it were, dragged down into the unconscious, or, more precisely, is submitted to a treatment such as is met with at the level of unconscious thought-processes and is characteristic of that level. Hitherto it is only from the results of the 'dream-work' that we are in fact acquainted with the characteristics of unconscious thinking and its differences from thinking that is capable of becoming conscious - 'preconscious' thinking.

[1905c, 1746]

In the first place, not all dreams are alien to the dreamer, incomprehensible and confused. If you inspect the dreams of very young children, from eighteen months upwards, you will find them perfectly simple and easy to explain. Small children always dream of the fulfilment of wishes that were aroused in them the day before but not satisfied. You will need no interpretative art in order to find this simple solution; all you need do is to enquire into the child's experiences on the previous day (the 'dream-day'). Certainly the most satisfactory solution of the riddle of dreams would be to find that adults' dreams too were like those of children - fulfiments of wishful impulses that had come to them on the dream-day. And such in fact is the case. The difficulties in the way of this solution can be overcome step by step if dreams are analysed more closely.

[1910a, 2221]

You can convince yourself that there are such things as latent dream-thoughts and that the relation between them and the manifest content of the dream is really as I have described it, if you carry out an analysis of dreams, the technique of which is the same as that of psycho-analysis. You entirely disregard the apparent connections between the elements in the manifest dream and collect the ideas that occur to you in connection with each separate element of the dream by free association according to the psycho-analytic rule of procedure. From this material you arrive at the latent dream-thoughts, just as you arrived at the patient's hidden complexes from his associations to his symptoms and memories. The latent dream-thoughts which have been reached in this way will at once show you how completely justified we have been in tracing back adults' dreams to children's dreams. The true meaning of the dream, which has now taken the place of its manifest content, is always clearly intelligible; it has its starting-point in experiences of the previous day, and proves to be a fulfilment of unsatisfied wishes. The manifest dream, which you know from your memory when you wake up, can therefore only be described as a disguised fulfilment of repressed wishes.

[1910a, 2222]
LADIES AND GENTLEMEN, - I am under the impression that we have advanced too quickly. Let us go back a little. Before we made our last attempt at overcoming the difficulty of distortion in dreams by the help of our technique, we were saying that our best plan would be to get round the difficulty by keeping to dreams in which there was no distortion or only a very little - if such dreams exist. This will once more mean a divergence from the historical development of our discoveries; for actually it was only after the technique of interpretation had been consistently applied and distorted dreams had been completely analysed that the existence of dreams that are free from distortion came to our notice.

[1916-1917, 3221]

The dreams we are in search of occur in children. They are short, clear, coherent, easy to understand and unambiguous; but they are nevertheless undoubtedly dreams. You must not suppose, however, that all children's dreams are of this kind. Dream-distortion sets in very early in childhood, and dreams dreamt by children of between five and eight have been reported which bear all the characteristics of later ones. But if you limit yourselves to ages between the beginning of observable mental activity and the fourth or fifth year, you will come upon a number of dreams which possess the characteristics that can be described as 'infantile' and you will find a few of the same kind in later years of childhood. Indeed, under certain conditions even adults have dreams which are quite similar to the typically infantile ones.

[1916-1917, 3221]

From these children's dreams we can draw conclusions with great ease and certainty on the essential nature of dreams in general, and we can hope that those conclusions will prove decisive and universally valid.

[1916-1917, 3221]

(1) No analysis, no application of any technique is necessary in order to understand these dreams. There is no need to question a child who tells us his dream. One has, however, to add a piece of information to it from the events of the child's life. There is invariably some experience of the previous day which explains the dream to us. The dream is the reaction of the child's mental life in his sleep to this experience of the previous day.

[1916-1917, 3221]

(2) As we can see, these children's dreams are not senseless. They are intelligible, completely valid mental acts. You will recall what I told you of the medical view of dreams and of the analogy with unmusical fingers wandering over the keys of a piano. You cannot fail to observe how sharply these children's dreams contradict this view. It would really be too strange if children could perform complete mental functions in their sleep while adults were content under the same conditions with reactions which were no more than 'twitchings'. Moreover, we have every reason to think that children's sleep is sounder and deeper.

[1916-1917, 3222]

(3) These dreams are without any dream-distortion, and therefore call for no interpretative activity. Here the manifest and the latent dream coincide. Thus dream-distortion is not part of the essential nature of dreams. I expect this will be a weight off your minds. But when we examine these dreams more closely, we shall recognize a small piece of dream-distortion even in them, a certain distinction between the manifest content of the dream and the latent dream-thoughts.

[1916-1917, 3223]
(4) A child's dream is a reaction to an experience of the previous day, which has left behind it a regret, a longing, a wish that has not been dealt with. The dream produces a direct, undisguised fulfilment of that wish. Let us recall now our discussions on the part played by somatic stimuli from outside and from within as disturbers of sleep and instigators of dreams. In that connection we came to know some quite undoubted facts, but by their means we were only able to explain a small number of dreams. In these children's dreams, however, there is nothing that points to the operation of somatic stimuli of that kind; we could not be mistaken in this, for the dreams are completely intelligible and easy to grasp. But this does not mean that we need abandon the stimulus aetiology of dreams. We can only ask how it has happened that from the first we have forgotten that besides somatic stimuli there are mental stimuli that disturb sleep. We know, after all, that it is excitations of this kind that are chiefly responsible for disturbing the sleep of an adult by preventing him from establishing the mood required for falling asleep - the withdrawing of interest from the world. He does not want to interrupt his life but would rather continue his work on the things he is concerned with, and for that reason he does not fall asleep. In the case of children, therefore, the stimulus that disturbs sleep is a mental one - the wish that has not been dealt with - and it is to this that they react with the dream.

[1916-1917, 3223]

(6) What instigates a dream is a wish, and the fulfilment of that wish is the content of the dream - this is one of the chief characteristics of dreams. The other, equally constant one, is that a dream does not simply give expression to a thought, but represents the wish-fulfilled as a hallucinatory experience. 'I should like to go on the lake' is the wish that instigates the dream. The content of the dream itself is: 'I am going on the lake.' Thus even in these simple children's dreams a difference remains between the latent and the manifest dream, there is a distortion of the latent dream-thought: the transformation of a thought into an experience. In the process of interpreting a dream this alteration must first be undone. If this turns out to be the most universal characteristic of dreams, the fragment of dream which I reported to you earlier 'I saw my brother in a box [Kasten]' is not to be translated 'my brother is restricting himself [schnärkt sich ein]' but 'I should like my brother to restrict himself: my brother must restrict himself.' Of the two general characteristics of dreams which I have here brought forward, the second clearly has more prospect of being accepted without contradiction than the first. It is only by means of far-reaching investigations that we shall be able to establish the fact that what instigates dreams must always be a wish and cannot be a worry or an intention or a reproach; but this will not affect the other characteristic - that the dream does not simply reproduce this stimulus, but removes it, gets rid of it, deals with it, by means of a kind of experience.

[1916-1917, 3224]

But consider what a large amount of light has been thrown on things by our examination of children's dreams, and with scarcely any effort: the functions of dreams as the guardians of sleep; their origin from two concurrent purposes, one of which, the desire for sleep, remains constant, while the other strives to satisfy a psychical stimulus; proof that dreams are psychical acts with a sense; their two chief characteristics - wish-fulfilment and hallucinatory experience. And in discovering all this we were almost able to forget that we were engaged on psychoanalysis. Apart from its connection with parapraxes, our work has carried no specific mark. Any psychologist, knowing nothing of the postulates of psycho-analysis, might have been able to give this explanation of children's dreams. Why have they not done so?

[1916-1917, 3226]
In any case, there is yet another class of dreams which are undistorted and, like children’s dreams, can easily be recognized as wish-fulfilments. These are the dreams which all through life are called up by imperative bodily needs - hunger, thirst, sexual need - that is, they are wish-fulfilments as reactions to internal somatic stimuli. Thus I have a note of a dream dreamt by a little girl of nineteen months, which consisted of a menu, to which her own name was attached: 'Anna F., stawbiewwies, wild stawbiewwies, omblet, pudden!' This was a reaction to a day without food, owing to a digestive upset, which had actually been traced back to the fruit which appeared twice in the dream. The little girl's grandmother - their combined ages came to seventy years - was simultaneously obliged to go without food for a whole day on account of a disturbance due to a floating kidney. She dreamt the same night that she had been 'asked out' and had been served with the most appetizing delicacies.

In all dreams other than children's dreams and those of an infantile type our path is, as I have said, obstructed by dream distortion. We cannot tell, to begin with, whether these other dreams too are wish-fulfilments as we suspect, we cannot guess from their manifest content to what psychical stimulus they owe their origin, and we cannot prove that they too are endeavouring to get rid of that stimulus or in some way deal with it. They must be interpreted - that is, translated -, their distortion must be undone, and their manifest content replaced by their latent one, before we can form a judgement as to whether what we have found in infantile dreams can claim to be valid for all dreams.

LADIES AND GENTLEMEN, - The study of the dreams of children has taught us the origin, the essential nature and the function of dreams. Dreams are things which get rid of (psychical) stimuli disturbing to sleep, by the method of hallucinatory satisfaction. We have, however, only been able to explain one group of the dreams of adults - those which we have described as dreams of an infantile type. What the facts are about the others we cannot yet say, but we do not understand them. We have arrived at a provisional finding, however, whose importance we must not under-estimate. Whenever a dream has been completely intelligible to us, it has turned out to be the hallucinated fulfilment of a wish. This coincidence cannot be a chance one nor a matter of indifference.

I hope you will never again confuse these two things with each other. If you reach that point, you will probably have gone further in understanding dreams than most readers of my Interpretation of Dreams. And let me remind you once again that the work which transforms the latent dream into the manifest one is called the dream-work. The work which proceeds in the contrary direction, which endeavours to arrive at the latent dream from the manifest one, is our work of interpretation. This work of interpretation seeks to undo the dream-work. The dreams of infantile type which we recognize as obvious fulfilments of wishes have nevertheless experienced some amount of dream-work - they have been transformed from a wish into an actual experience and also, as a rule, from thoughts into visual images. In their case there is no need for interpretation but only for undoing these two transformations. The additional dream-work that occurs in other dreams is called 'dream-distortion', and this has to be undone by our work of interpretation.
LADIES AND GENTLEMEN, - Shall I remind you once more of the ground we have covered so far? Of how, when we began applying our technique, we came up against the distortion in dreams, of how we thought we would begin by evading it and obtained our first decisive information on the essential nature of dreams from the dreams of children? Of how, after that, armed with what we had learnt from that enquiry, we made a direct assault on dream-distortion and, as I hope, overcame it step by step? We are bound to admit, however, that the things we have discovered by the one path and by the other do not entirely correspond. It will be our task to piece the two sets of findings together and reconcile them with each other.

[1916-1917, 3301]

It will not be difficult for us now to reach a still better understanding of anxiety-dreams. We will bring up one more observation and then make up our minds to adopt a hypothesis in favour of which there is much to be said. The observation is that anxiety-dreams often have a content entirely devoid of distortion, a content which has, so to speak, evaded the censorship. An anxiety-dream is often the undisguised fulfilment of a wish - not, of course, of an acceptable wish, but of a repudiated one. The generation of anxiety has taken the place of the censorship. Whereas we can say of an infantile dream that it is the open fulfilment of a permitted wish, and of an ordinary distorted dream that it is the disguised fulfilment of a repressed wish, the only formula which fits an anxiety-dream is that it is the open fulfilment of a repressed wish. The anxiety is a sign that the repressed wish has shown itself stronger than the censorship, that it has put through, or is on the point of putting through, its wish-fulfilment in spite of the censorship. We perceive that what is for it a wish-fulfilment can only be for us, who are on the side of the censorship, an occasion for distressing feelings and for fending the wish off. The anxiety that emerges in the dream is, if you like, anxiety at the strength of these wishes which are normally held down. Why this fending-off appears in the form of anxiety cannot be discovered from the study of dreams alone; anxiety must clearly be studied elsewhere.

[1916-1917, 3305]

On another occasion an association which suddenly occurred to him carried us another step forward in our understanding of the dream: 'The tree was a Christmas-tree.' He now knew that he had dreamt the dream shortly before Christmas and in expectation of it. Since Christmas Day was also his birthday, it now became possible to establish with certainty the date of the dream and of the change in him which proceeded from it. It was immediately before his fourth birthday. He had gone to sleep, then, in tense expectation of the day which ought to bring him a double quantity of presents. We know that in such circumstances a child may easily anticipate the fulfilment of his wishes. So it was already Christmas in his dream; the content of the dream showed him his Christmas box, the presents which were to be his were hanging on the tree. But instead of presents they had turned into - wolves, and the dream ended by his being overcome by fear of being eaten by the wolf (probably his father), and by his flying for refuge to his nurse. Our knowledge of his sexual development before the dream makes it possible for us to fill in the gaps in the dream and to explain the transformation of his satisfaction into anxiety. Of the wishes concerned in the formation of the dream the most powerful must have been the wish for the sexual satisfaction which he was at that time longing to obtain from his father. The strength of this wish made it possible to revive a long-forgotten trace in his memory of a scene which was able to show him what sexual satisfaction from his father was like; and the result was terror, horror of the fulfilment of the wish, the repression of the impulse which had manifested itself by means of the wish, and consequently a flight from his father to his less dangerous nurse.

[1918b, 3526]
Critical voices will now be raised. It will be objected that, since it is not possible to interpret every dream that is dealt with, one should cease asserting more than one can establish and should be content to say that some dreams can be shown by interpretation to have a meaning but that as to the rest we are in ignorance. But the very fact that success in interpretation depends upon the resistance absolves the analyst from the necessity for such modesty. He may have the experience of a dream that was at first unintelligible becoming clear during the very same hour after some fortunate remark has got rid of one of the dreamer's resistances. A portion of the dream which the patient had hitherto forgotten may suddenly occur to him and may bring the key to the interpretation; or a new association may emerge which may throw light upon the darkness. It sometimes happens, too, that, after months or years of analytic labour, one returns to a dream which at the beginning of the treatment seemed meaningless and incomprehensible but which is now, in the light of knowledge obtained in the meantime, completely elucidated. And if one further takes into consideration the argument from the theory of dreams that the model dream-products of children invariably have a clear meaning and are easy to interpret, then it will be justifiable to assert that dreams are quite generally mental structures that are capable of interpretation, though the situation may not always allow of an interpretation being reached.

[1925i, 4046]

The analysis of dreams led further: it was brought to public notice by the present writer as early as in 1900 in *The Interpretation of Dreams*. This showed that dreams are constructed in just the same way as neurotic symptoms. Like them, they may appear strange and senseless; but, if we examine them by a technique which differs little from the free association used in psycho-analysis, we are led from their manifest content to a secret meaning, to the latent dream-thoughts. This latent meaning is always a wishful impulse which is represented as fulfilled at the moment of the dream. But, except in young children and under the pressure of imperative physical needs, this secret wish can never be expressed recognizably. It has first to submit to a distortion, which is the work of restrictive, censoring forces in the dreamer's ego. In this way the manifest dream, as it is remembered in waking life, comes about. It is distorted, to the pitch of being unrecognizable, by concessions made to the dream-censorship; but it can be revealed once more by analysis as an expression of a situation of satisfaction or as the fulfilment of a wish. It is a compromise between two conflicting groups of mental trends, just as we have found to be the case with hysterical symptoms. The formula which, at bottom, best meets the essence of the dream is this: a dream is a (disguised) fulfilment of a (repressed) wish. The study of the process which transforms the latent dream-wish into the manifest content of the dream - a process known as the 'dream-work' - has taught us the best part of what we know of unconscious mental life.

[1924f, 4109]
We have explained that the unconscious instinctual impulse of the dream connects itself with a residue of the day, with some interest of waking life which has not been disposed of; it thus gives the dream which it constructs a double value for the work of analysis. For on the one hand a dream that has been analysed reveals itself as the fulfilment of a repressed wish; but on the other hand it may be a continuation of some preconscious activity of the day before and may contain every kind of subject-matter and give expression to an intention, a warning, a reflection, or once more to the fulfilment of a wish. Analysis exploits the dream in both directions, as a means of obtaining knowledge alike of the patient's conscious and of his unconscious processes. It also profits from the fact that dreams have access to the forgotten material of childhood, and so it happens that infantile amnesia is for the most part overcome in connection with the interpretation of dreams. In this respect dreams achieve a part of what was previously the task of hypnotism. On the other hand, I have never maintained the assertion which has so often been ascribed to me that dream-interpretation shows that all dreams have a sexual content or are derived from sexual motive forces. It is easy to see that hunger, thirst, or the need to excrete, can produce dreams of satisfaction just as well as any repressed sexual or egoistic impulse. The case of young children affords us a convenient test of the validity of our theory of dreams. In them the various psychical systems are not yet sharply divided and the repressions have not yet grown deep, so that we often come upon dreams which are nothing more than undisguised fulfilments of wishful impulses left over from waking life. Under the influence of imperative needs, adults may also produce dreams of this infantile type.¹

¹[1925d, 4221]
From the unconscious, in fact. My supposition is that a conscious wish can only become a
dream-instigator if it succeeds in awakening an unconscious wish with the same tenor and in
obtaining reinforcement from it. From indications derived from the psycho-analysis of the
neuroses, I consider that these unconscious wishes are always on the alert, ready at any time
to find their way to expression when an opportunity arises for allying themselves with an
impulse from the conscious and for transferring their own great intensity on to the latter's lesser
one.¹ It will then appear as though the conscious wish alone had been realized in the dream;
only some small peculiarity in the dream's configuration will serve as a finger-post to put us on
the track of the powerful ally from the unconscious. These wishes in our unconscious, ever on
the alert and, so to say, immortal, remind one of the legendary Titans, weighed down since
primaeval ages by the massive bulk of the mountains which were once hurled upon them by the
victorious gods and which are still shaken from time to time by the convulsion of their limbs. But
these wishes, held under repression, are themselves of infantile origin, as we are taught by
psychological research into the neuroses. I would propose, therefore, to set aside the assertion
made just now, that the place of origin of dream-wishes is a matter of indifference and replace it
by another one to the following effect: a wish which is represented in a dream must be an
infantile one. In the case of adults it originates from the Ucs., in the case of children, where
there is as yet no division or censorship between the Ucs. and the Pcs., or where that division is
only gradually being set up, it is an unfulfilled, unrepressed wish from waking life. I am aware
that this assertion cannot be proved to hold universally; but it can be proved to hold frequently,
even in unsuspected cases, and it cannot be contradicted as a general proposition.
[1900a, 985]
The fact should be mentioned that children soon begin to have more complicated and less transparent dreams, and that, on the other hand, adults in certain circumstances often have dreams of a similarly simple, infantile character. The wealth of unexpected material that may occur in the dreams of children of four or five is shown by examples in my 'Analysis of a Phobia in a Five-Year-Old Boy' (1909b) and in Jung (1910a). - 

For analytical interpretations of children's dreams see also von Hug-Hellmuth (1911 and 1913), Putnam (1912), van Raalte (1912), Spielrein (1913) and Tausk (1913). Children's dreams are also reported by Bianchieri (1912), Busemann (1909 and 1910), Doglia and Bianchieri (1910-11) and, in particular, Wiggam (1909), who laid stress on their trend towards wish-fulfilment. - 

On the other hand, dreams of an infantile type seem to occur in adults with special frequency when they find themselves in unusual external circumstances. Thus Otto Nordenskjöld (1904, 1, 336 f.) writes as follows of the members of his expedition while they were wintering in the Antarctic: 'The direction taken by our innermost thoughts was very clearly shown by our dreams, which were never more vivid or numerous than at this time. Even those of us who otherwise dreamt but rarely had long stories to tell in the morning when we exchanged our latest experiences in this world of the imagination. They were all concerned with the outside world which was now so remote from us, though they were often adapted to our actual circumstances. One of my companions had a particularly characteristic dream of being back in his school class-room, where it was his task to skin miniature seals which had been specially prepared for instructional purposes. Eating and drinking, however, were the pivot round which our dreams most often revolved. One of us, who had a special gift for attending large luncheon parties during the night, was proud if he was able to report in the morning that he had "got though a three-course dinner". Another of us dreamt of tobacco, of whole mountains of tobacco; while a third dreamt of a ship in full sail coming in across open water. Yet another dream is worth repeating. The postman brought round the mail and gave a long explanation of why we had had to wait so long for it: he had delivered it at the wrong address and had only succeeded in recovering it with great difficulty. We dreamt, of course, of still more impossible things. But there was a most striking lack of imaginativeness shown by almost all the dreams that I dreamt myself or heard described. It would certainly be of great psychological interest if all these dreams could be recorded. And it will easily be understood how much we longed for sleep, since it could offer each one of us everything that he most eagerly desired.' - 

According to Du Prel (1885, 231), 'Mungo Park, when he was almost dying of thirst on one of his African journeys, dreamt unceasingly of the well-watered valleys and meadows of his home. Similarly, Baron Trenck suffering torments of hunger while he was a prisoner in the fortress at Magdeburg, dreamt of being surrounded by sumptuous meals; and George Back, who took part in Franklin's first expedition, when he was almost dying of starvation as a result of his fearful privations, dreamt constantly and regularly of copious meals.'

It by no means rarely happens that in the course of a comparatively long, complicated and on the whole confused dream one particularly clear portion stands out, which contains an unmistakable wish-fulfilment, but which is bound up with some other, unintelligible material. But in the case of adults, anyone with some experience in analysing their dreams will find to his surprise that even those dreams which have an appearance of being transparently clear are seldom as simple as those of children, and that behind the obvious wish-fulfilment some other meaning may lie concealed.
It would indeed be a simple and satisfactory solution of the riddle of dreams if the work of analysis were to enable us to trace even the meaningless and confused dreams of adults back to the infantile type of fulfillment of an intensely felt wish of the previous day. There can be no doubt, however, that appearances do not speak in favour of such an expectation. Dreams are usually full of the most indifferent and strangest material, and there is no sign in their content of the fulfillment of any wish.

[1901a, 1064]

Adults have learnt to make this distinction; they have also grasped the uselessness of wishing, and after lengthy practice know how to postpone their desires until they can find satisfaction by the long and roundabout path of altering the external world. In their case, accordingly, wish-fulfilments along the short psychical path are rare in sleep too; it is even possible, indeed, that they never occur at all, and that anything that may seem to us to be constructed on the pattern of a child's dream in fact requires a far more complicated solution. On the other hand, in the case of adults - and this no doubt applies without exception to everyone in full possession of his senses - a differentiation has occurred in the psychical material, which was not present in children. A psychical agency has come into being, which, taught by experience of life, exercises a dominating and inhibiting influence upon mental impulses and maintains that influence with jealous severity, and which, owing to its relation to consciousness and to voluntary movement, is armed with the strongest instruments of psychical power. A portion of the impulses of childhood has been suppressed by this agency as being useless to life, and any thought-material derived from those impulses is in a state of repression.

[1901a, 1092]

At about the same period Hans had a dream which was in striking contrast with the boldness he had shown towards his mother. It was the first dream of his that was made unrecognizable by distortion. His father's penetration, however, succeeded in clearing it up.

[1909b, 2013]

We found from both sources that the dream-work consists essentially in the transformation of thoughts into a hallucinatory experience. How this can happen is sufficiently mysterious; but it is a problem of general psychology with which we are not properly concerned here. We learnt from children's dreams that it is the intention of the dream-work to get rid of a mental stimulus, which is disturbing sleep, by means of the fulfilment of a wish. We were unable to say anything similar of distorted dreams till we found out how to interpret them. But it was from the first our expectation that we should be able to regard distorted dreams in the same light as those of children. The first confirmation of this expectation was brought to us by the discovery that in point of fact all dreams are children's dreams, that they work with the same infantile material, with the mental impulses and mechanisms of childhood. Now that we believe we have overcome dream-distortion, we must go on to enquire whether the view of dreams as the fulfilment of wishes is also valid of distorted dreams.

[1916-1917, 3301]
Discussions upon the exciting causes of dreams occupy a very large space in the literature of the subject. The problem could obviously only arise after dreams had become a subject of biological investigation. The ancients, who believed that dreams were inspired by the gods, had no need to look around for their stimulus: dreams emanated from the will of divine or daemonic powers and their content arose from the knowledge or purpose of those powers. Science was immediately faced by the question of whether the stimulus to dreaming was always the same or whether there could be many kinds of such stimuli; and this involved the consideration of whether the explanation of the causation of dreams fell within the province of psychology or rather of physiology. Most authorities seem to agree in assuming that the causes that disturb sleep - that is, the sources of dreaming - may be of many kinds and that somatic stimuli and mental excitations alike may come to act as instigators of dreams. Opinions differ widely, however, in the preference they show for one or the other source of dreams and in the order of importance which they assign to them as factors in the production of dreams.

Any complete enumeration of the sources of dreams leads to a recognition of four kinds of source; and these have also been used for the classification of dreams themselves. They are: (1) external (objective) sensory excitations; (2) internal (subjective) sensory excitations; (3) internal (organic) somatic stimuli; and (4) purely psychical sources of stimulation.

The younger Strümpell, the son of the philosopher whose book on dreams has already given us several hints upon their problems, published a well-known account of his observations upon one of his patients who was afflicted with general anaesthesia of the surface of his body and paralysis of several of his higher sense organs. If the few of this man's sensory channels which remained open to the external world were closed, he would fall asleep. Now when we ourselves wish to go to sleep we are in the habit of trying to produce a situation similar to that of Strümpell's experiment. We close our most important sensory channels, our eyes, and try to protect the other senses from all stimuli or from any modification of the stimuli acting on them. We then fall asleep, even though our plan is never completely realized. We cannot keep stimuli completely away from our sense organs nor can we completely suspend the excitability of our sense organs. The fact that a fairly powerful stimulus will awaken us at any time is evidence that 'even in sleep the soul is in constant contact with the extracorporeal world'. The sensory stimuli that reach us during sleep may very well become sources of dreams.

When we were dealing with the relations of dreams to waking life and with the material of dreams, we found that the most ancient and the most recent students of dreams were united in believing that men dream of what they do during the daytime and of what interests them while they are awake. Such an interest, carried over from waking life into sleep, would not only be a mental bond, a link between dreams and life, but would also provide us with a further source of dreams and one not to be despised. Indeed, taken in conjunction with the interests that develop during sleep - the stimuli that impinge on the sleeper - it might be enough to explain the origin of all dream-images. But we have also heard the opposite asserted, namely that dreams withdraw the sleeper from the interests of daytime and that, as a rule, we only start dreaming of the things that have most struck us during the day, after they have lost the spice of actuality in waking life. Thus at every step we take in our analysis of dream-life we come to feel that it is impossible to make generalizations without covering ourselves by such qualifying phrases as 'frequently', 'as a rule' or 'in most cases', and without being prepared to admit the validity of exceptions.
If it were a fact that waking interests, along with internal and external stimuli during sleep, sufficed to exhaust the aetiology of dreams, we ought to be in a position to give a satisfactory account of the origin of every element of a dream: the riddle of the sources of dreams would be solved, and it would only remain to define the share taken respectively by psychical and somatic stimuli in any particular dream. Actually no such complete explanation of a dream has ever yet been achieved, and anyone who has attempted it has found portions (and usually very numerous portions) of the dream regarding whose origin he could find nothing to say. Daytime interests are clearly not such far-reaching psychical sources of dreams as might have been expected from the categorical assertions that everyone continues to carry on his daily business in his dreams. [1900a, 551]

Those writers who, like that eminent philosopher Wundt, take up a middle position do not fail to remark that in most dreams somatic stimuli and the psychical instigators (whether unknown or recognized as daytime interests) work in co-operation. [1900a, 552]

We shall find later that the enigma of the formation of dreams can be solved by the revelation of an unsuspected psychical source of stimulation. Meanwhile we shall feel no surprise at the over-estimation of the part played in forming dreams by stimuli which do not arise from mental life. Not only are they easy to discover and even open to experimental confirmation; but the somatic view of the origin of dreams is completely in line with the prevailing trend of thought in psychiatry to-day. It is true that the dominance of the brain over the organism is asserted with apparent confidence. Nevertheless, anything that might indicate that mental life is in any way independent of demonstrable organic changes or that its manifestations are in any way spontaneous alarms the modern psychiatrist, as though a recognition of such things would inevitably bring back the days of the Philosophy of Nature, and of the metaphysical view of the nature of mind. The suspicions of the psychiatrists have put the mind, as it were, under tutelage, and they now insist that none of its impulses shall be allowed to suggest that it has any means of its own. This behaviour of theirs only shows how little trust they really have in the validity of a causal connection between the somatic and the mental. Even when investigation shows that the primary exciting cause of a phenomenon is psychical, deeper research will one day trace the path further and discover an organic basis for the mental event. But if at the moment we cannot see beyond the mental, that is no reason for denying its existence. [1900a, 552]

There can be no doubt that the psychical achievements of dreams received readier and warmer recognition during the intellectual period which has now been left behind, when the human mind was dominated by philosophy and not by the exact natural sciences. Pronouncements such as that by Schubert (1814, 20 f.) that dreams are a liberation of the spirit from the power of external nature, a freeing of the soul from the bonds of the senses, and similar remarks by the younger Fichte (1864, 1, 143 f.)¹ and others, all of which represent dreams as an elevation of mental life to a higher level, seem to us now to be scarcely intelligible; today they are repeated only by mystics and pietists.² The introduction of the scientific mode of thought has brought along with it a reaction in the estimation of dreams. Medical writers in especial tend to regard psychical activity in dreams as trivial and valueless; while philosophers and non-professional observers - amateur psychologists - whose contributions to this particular subject are not to be despised, have (in closer alignment with popular feeling) retained a belief in the psychical value of dreams. Anyone who is inclined to take a low view of psychical functioning in dreams will naturally prefer to assign their source to somatic stimulation; whereas those who believe that the dreaming mind retains the greater part of its waking capacities have of course no reason for denying that the stimulus to dreaming can arise within the dreaming mind itself. [1900a, 571]
But Robert's theory is diametrically opposed to the ruling one in its estimate of the nature of the sources of dreams. According to the latter, there would be no dreaming at all if the mind were not being constantly wakened by external and internal sensory stimuli. But in Robert's view the impulsion to dreaming arises in the mind itself - in the fact of its becoming overloaded and requiring relief; and he concludes with perfect logic that causes derived from somatic conditions play a subordinate part as determinants of dreams, and that such causes would be quite incapable of provoking dreams in a mind in which there was no material for the construction of dreams derived from waking consciousness. The only qualification he makes is to admit that the phantasy-images arising in dreams out of the depths of the mind may be affected by nervous stimuli. (Ibid., 48.) After all, therefore, Robert does not regard dreams as so completely dependent upon somatic events. Nevertheless, in his view dreams are not psychical processes, they have no place among the psychical processes of waking life; they are somatic processes occurring every night in the apparatus that is concerned with mental activity, and they have as their function the task of protecting that apparatus from excessive tension - or, to change the metaphor - of acting as scavengers of the mind.

Nevertheless we must not be in a hurry to take leave of Robert's ideas without further consideration. We have still not explained the fact that one of the indifferent impressions of waking life, one, moreover, dating from the day preceding the dream, invariably contributes towards the dream's content. The connections between this impression and the true source of the dream in the unconscious are not always there ready-made; as we have seen, they may only be established retrospectively, in the course of the dream-work, with a view, as it were, to making the intended displacement feasible. There must therefore be some compelling force in the direction of establishing connections precisely with a recent, though indifferent, impression; and the latter must possess some attribute which makes it especially suitable for this purpose. For if that were not so, it would be just as easy for the dream-thoughts to displace their emphasis on to an unimportant component in their own circle of ideas.

It will further be observed, if we consider these four possible cases, that a psychical element which is significant but not recent (e.g. a train of thought or a memory) can be replaced, for the purpose of forming a dream, by an element which is recent but indifferent, provided only that two conditions are fulfilled: (1) the content of the dream must be connected with a recent experience, and (2) the instigator of the dream must remain a psychically significant process. Only in one case - case (a) - are both of these conditions fulfilled by one and the same impression. It is to be noticed, moreover, that indifferent impressions which are capable of being used for constructing a dream so long as they are recent lose that capacity as soon as they are a day (or at the most a few days) older. From this we must conclude that the freshness of an impression gives it some kind of psychical value for purposes of dream-construction equivalent in some way to the value of emotionally coloured memories or trains of thought. The basis of the value which thus attaches to recent impressions in connection with the construction of dreams will only become evident in the course of our subsequent psychological discussions.
An important contribution to the part played by recent material in the construction of dreams has been made by Pötzl (1917) in a paper which carries a wealth of implications. In a series of experiments Pötzl required the subjects to make a drawing of what they had consciously noted of a picture exposed to their view in a tachistoscope. He then turned his attention to the dreams dreamt by the subjects during the following night and required them once more to make drawings of appropriate portions of these dreams. It was shown unmistakeably that those details of the exposed picture which had not been noted by the subject provided material for the construction of the dream, whereas those details which had been consciously perceived and recorded in the drawing made after the exposure did not recur in the manifest content of the dream. The material that was taken over by the dream-work was modified by it for the purposes of dream-construction in its familiar ‘arbitrary’ (or, more properly, ‘autocratic’) manner. The questions raised by Pötzl’s experiment go far beyond the sphere of dream-interpretation as dealt with in the present volume. In passing, it is worth remarking on the contrast between this new method of studying the formation of dreams experimentally and the earlier, crude technique for introducing into the dream stimuli which interrupted the subject’s sleep.

The reader will rightly conclude from the foregoing arguments that I am asserting that there are no indifferent dream-instigators - and consequently no 'innocent' dreams. Those are, in the strictest and most absolute sense, my opinions - if I leave on one side the dreams of children and perhaps brief reactions in dreams to sensations felt during the night. Apart from this, what we dream is either manifestly recognizable as psychically significant, or it is distorted and cannot be judged till the dream has been interpreted, after which it will once more be found to be significant. Dreams are never concerned with trivialities; we do not allow our sleep to be disturbed by trifles.¹ The apparently innocent dreams turn out to be quite the reverse when we take the trouble to analyse them. They are, if I may say so, wolves in sheep's clothing. Since this is another point upon which I may expect to be contradicted, and since I am glad of an opportunity of showing dream-distortion at work, I will select a number of 'innocent' dreams from my records and submit them to analysis.

It has often been proposed to separate off ‘dreams due to nervous stimulation’ from other forms of dreams as a sub-species that has been thoroughly investigated. Thus Spitta divides dreams into 'dreams due to nervous stimulation' and 'dreams due to association'. This solution was, however, bound to remain unsatisfactory so long as it was impossible to demonstrate the link between the somatic sources of a dream and its ideational content. Thus, in addition to the first objection - the insufficient frequency of external sources of stimulation - there was a second one - the insufficient explanation of dreams afforded by such sources. We have a right to expect the supporters of this theory to give us explanations of two points; first, why it is that the external stimulus of a dream is not perceived in its true character but is invariably misunderstood (Cf. the alarm-clock dreams on p. 541 f.); and secondly, why it is that the reaction of the perceiving mind to these misunderstood stimuli should lead to results of such unpredictable variety.
We have already taken the first step in this direction by advancing the thesis (see p. 666 f.) that the dream-work is under the necessity of combining into a unity all instigations to dreaming which are active simultaneously. We found that, when two or more experiences capable of creating an impression are left over from the previous day, the wishes derived from them are combined in a single dream, and similarly that the psychically significant impressions and the indifferent experiences from the previous day are brought together in the dream-material, provided always that it is possible to set up communicating ideas between them. Thus a dream appears to be a reaction to everything that is simultaneously present in the sleeping mind as currently active material. So far as we have hitherto analysed the material of dreams, we have seen it as a collection of psychical residues and memory-traces, to which (on account of the preference shown for recent and infantile material) we have been led to attribute a hitherto indefinable quality of being 'currently active'. We can foresee, then, without any great difficulty, what will happen if fresh material in the form of sensations is added during sleep to these currently active memories. It is once again owing to the fact of their being currently active that these sensory excitations are of importance for the dream; they are united with the other currently active psychical material to furnish what is used for the construction of the dream. To put it another way, stimuli arising during sleep are worked up into a wish-fulfilment the other constituents of which are the familiar psychical 'day's residues'. This combination need not occur; as I have already pointed out, there is more than one way of reacting to a somatic stimulus during sleep. When it does occur, it means that it has been possible to find ideational material to serve as the content of the dream of such a sort as to be able to represent both kinds of source of the dream - the somatic and the psychical.

[1900a, 707]

When external nervous stimuli and internal somatic stimuli are intense enough to force psychical attention to themselves, then - provided that their outcome is dreaming and not waking up - they serve as a fixed point for the formation of a dream, a nucleus in its material; a wish-fulfilment is then looked for that shall correspond to this nucleus, just as (see above) intermediate ideas are looked for between two psychical dream stimuli. To that extent it is true that in a number of dreams the content of the dream is dictated by the somatic element. In this extreme instance it may even happen that a wish which is not actually a currently active one is called up for the sake of constructing a dream. A dream, however, has no alternative but to represent a wish in the situation of having been fulfilled; it is, as it were, faced with the problem of looking for a wish which can be represented as fulfilled by the currently active sensation. If this immediate material is of a painful or distressing kind, that does not necessarily mean that it cannot be used for the construction of a dream. The mind has wishes at its disposal whose fulfilment produces unpleasure. This seems self-contradictory; but it becomes intelligible when we take into account the presence of two psychical agencies and a censorship between them.

[1900a, 714]
I should, of course, not draw such far-reaching conclusions if only a single dream-analysis was at my disposal. If experience shows me, however, that by uncritically pursuing the associations arising from any dream I can arrive at a similar train of thoughts, among the elements of which the constituents of the dream re-appear and which are interconnected in a rational and intelligible manner, then it will be safe to disregard the slight possibility that the connections observed in a first experiment might be due to chance. I think I am justified, therefore, in adopting a terminology which will crystallize our new discovery. In order to contrast the dream as it is retained in my memory with the relevant material discovered by analysing it, I shall speak of the former as the 'manifest content of the dream' and the latter - without, in the first instance, making any further distinction - as the 'latent content of the dream.' I am now faced by two new problems which have not hitherto been formulated. (1) What is the psychical process which has transformed the latent content of the dream into the manifest one which is known to me from my memory? (2) What are the motive or motives which have necessitated this transformation? I shall describe the process which transforms the latent into the manifest content of dreams as the 'dream-work.' The counterpart to this activity - one which brings about a transformation in the opposite direction - is already known to us as the work of analysis. The remaining problems arising out of dreams - questions as to the instigators of dreams, as to the origin of their material, as to their possible meaning, as to the possible function of dreaming, and as to the reasons for dreams being forgotten - all these problems will be discussed by me on the basis, not of the manifest, but of the newly discovered latent dream-content. Since I attribute all the contradictory and incorrect views upon dream-life which appear in the literature of the subject to ignorance of the latent content of dreams as revealed by analysis, I shall be at the greatest pains henceforward to avoid confusing the manifest dream with the latent dream-thoughts.

[1901a, 1059]

If we undo dream-displacement by means of analysis, we obtain what seems to be completely trustworthy information on two much-disputed problems concerning dreams: as to their instigators and as to their connection with waking life. There are dreams which immediately reveal their derivation from events of the day; there are others in which no trace of any such derivation is to be discovered. If we seek the help of analysis, we find that every dream without any possible exception goes back to an impression of the past few days, or, it is probably more correct to say, of the day immediately preceding the dream, of the 'dream-day.' The impression which plays the part of dream-instigator may be such an important one that we feel no surprise at being concerned with it in the daytime, and in that case we rightly speak of the dream as carrying on with the significant interests of our waking life. As a rule, however, if a connection is to be found in the content of the dream with any impression of the previous day, that impression is so trivial, insignificant and unmemorable, that it is only with difficulty that we ourselves can recall it. And in such cases the content of the dream itself, even if it is connected and intelligible, seems to be concerned with the most indifferent trivialities, which would be unworthy of our interest if we were awake. A good deal of the contempt in which dreams are held is due to the preference thus shown in their content for what is indifferent and trivial.

[1901a, 1071]
Analysis does away with the misleading appearance upon which this derogatory judgement is
founded. If the content of a dream puts forward some indifferent impression as being its
instigator, analysis invariably brings to light a significant experience, and one by which the
dreamer has good reason to be stirred. This experience has been replaced by the indifferent
one, with which it is connected by copious associative links. Where the content of the dream
treats of insignificant and uninteresting ideational material, analysis uncovers the numerous
associative paths connecting these trivialities with things that are of the highest psychical
importance in the dreamer's estimation. If what makes their way into the content of dreams are
impressions and material which are indifferent and trivial rather than justifiably stirring and
interesting, that is only the effect of the process of displacement. If we answer our questions
about dream-instigators and the connection between dreaming and daily affairs on the basis of
the new insight we have gained from replacing the manifest by the latent content of dreams, we
arrive at these conclusions: dreams are never concerned with things with which we should not
think it worth while to be concerned during the day, and trivialities which do no affect us during
the day are unable to pursue us in our sleep.
[1901a, 1072]

What was the dream-instigator in the specimen that we have chosen for analysis? It was the
definitely insignificant event of my friend giving me a drive in a cab free of cost. The situation in
the dream at the table d'hôte contained an allusion to this insignificant precipitating cause, for in
my conversation I had compared the taximeter cab with a table d'hôte. But I can also point to
the important experience which was represented by this trivial one. A few days earlier I had paid
out a considerable sum of money on behalf of a member of my family of whom I am fond. No
wonder, said the dream-thoughts, if this person were to feel grateful to me: love of that sort
would not be 'free of cost.' Love that is free of cost, however, stood in the forefront of the dream-
thoughts. The fact that not long before I had had several cab-drives with the relative in question,
made it possible for the cab-drive with my friend to remind me of my connections with this other
person.
[1901a, 1072]

The indifferent impression which becomes a dream-instigator owing to associations of this
kind is subject to a further condition which does not apply to the true source of the dream: it
must always be a recent impression, derived from the dream-day.
[1901a, 1073]

In the case of children's dreams there should be no difficulty in accepting this statement. The
state of sleep or the psychical modification involved in sleep, whatever that may be, is brought
about by a resolve to sleep which is either imposed upon the child or is reached on the basis of
sensations of fatigue; and it is only made possible by the withholding of stimuli which might
suggest to the psychical apparatus aims other than that of sleeping. The means by which
external stimuli can be kept off are familiar to us; but what are the means available for
controlling internal mental stimuli which set themselves against falling asleep? Let us observe a
mother putting her child to sleep. The child gives vent to an unceasing stream of desires: he
wants one more kiss, he wants to go on playing. His mother satisfies some of these desires, but
uses her authority to postpone others of them to the next day. It is clear that any wishes or
needs that may arise have an inhibiting effect upon falling asleep. We all know the amusing
story told by Balduin Groller of the bad little boy who woke up in the middle of the night and
shouted across the night nursery: 'I want the rhino!' A better behaved child, instead of shouting,
would have dreamt that he was playing with the rhino. Since a dream that shows a wish as
fulfilled is believed during sleep, it does away with the wish and makes sleep possible. It cannot
be disputed that dream-images are believed in this way, for they are clothed in the psychical
appearance of perceptions, and children have not yet acquired the later faculty of distinguishing
hallucinations or phantasies from reality.
[1901a, 1091]
I have made one or two observations in my *Interpretation of Dreams* on the relation between the waking thoughts which are continued into sleep (the 'day's residues') and the unconscious wish which forms the dream. I will quote them here as they stand, for I have nothing to add to them, and the analysis of this dream of Dora's proves afresh that the facts are as I have supposed: 'I am ready to admit that there is a whole class of dreams the *instigation* to which arises principally or even exclusively from the residues of daytime life; and I think that even my wish that I might at long last become a Professor Extraordinarius¹ might have allowed me to sleep through the night in peace if my worry over my friend's health had not still persisted from the previous day. But the worry alone could not have made a dream. The *motive force* which the dream required had to be provided by a wish; it was the business of the worry to get hold of a wish to act as the motive force of the dream.

[1905e, 1423]

In what way, however, can a case arise in which the intention to sleep meets with an interruption? The interruption may proceed from an internal excitation or from an external stimulus. Let us first consider the more obscure and more interesting case of interruption from within. Observation shows that dreams are instigated by residues from the previous day - thought-cathexes which have not submitted to the general withdrawal of cathexes, but have retained in spite of it a certain amount of libidinal or other interest. Thus the narcissism of sleep has from the outset had to admit an exception at this point, and it is here that the formation of dreams takes its start. In analysis we make the acquaintance of these 'day's residues' in the shape of latent dream-thoughts; and, both by reason of their nature and of the whole situation, we must regard them as preconscious ideas, as belonging to the system *Pcs*.

[1917d, 3029]

Let us notice, however, one peculiarity of dream-life which comes to light in this study of the effects of stimuli. Dreams do not simply reproduce the stimulus; they work it over, they make allusions to it, they include it in some context, they replace it by something else. This is a side of the dream-work which is bound to interest us since it may perhaps bring us nearer to the essence of dreams. When a person constructs something as a result of a stimulus, the stimulus need not on that account exhaust the whole of the work. Shakespeare's *Macbeth*, for instance, was a *pièce d'occasion* composed to celebrate the accession of the king who first united the crowns of the three kingdoms. But does this immediate historical occasion cover the content of the tragedy? Does it explain its greatnesses and its enigmas? It may be that the external and internal stimuli, too, impinging on the sleeper, are only the *instigators* of the dream and will accordingly betray nothing to us of its essence.

[1916-1917, 3196]

The second thing that is common to dreams, their psychical peculiarity, is on the one hand hard to grasp and on the other offers us no starting-point for further enquiry. We experience things in dreams as a rule in visual forms. Can the stimuli throw any light on this? Is what we experience in fact the stimulus? But, if so, why is the experience visual, while it is only in the rarest cases that optical stimulation has instigated the dream? Or if we dream spoken words, can it be shown that during sleep a conversation, or some noise resembling one made its way into our ears? I venture to dismiss that possibility decisively.

[1916-1917, 3196]
I think that, like me, you must be tired of pursuing enquiries like those we have so far been making. All one's interest in a problem is evidently insufficient unless one knows as well of a path of approach that will lead to its solution. We have not yet found such a path. Experimental psychology has brought us nothing but some very valuable information on the significance of stimuli as instigators to dreaming. We have nothing to expect from philosophy except that it will once again haughtily point out to us the intellectual inferiority of the object of our study. Nor have we any wish to borrow anything from the occult sciences. History and popular opinion tell us that dreams have a sense and a meaning: that they look into the future - which is hard to accept and certainly incapable of proof. So our first effort leaves us completely at a loss. [1916-1917, 3197]

(4) A child's dream is a reaction to an experience of the previous day, which has left behind it a regret, a longing, a wish that has not been dealt with. *The dream produces a direct, undisguised fulfilment of that wish.* Let us recall now our discussions on the part played by somatic stimuli from outside and from within as disturbers of sleep and instigators of dreams. In that connection we came to know some quite undoubted facts, but by their means we were only able to explain a small number of dreams. In these children's dreams, however, there is nothing that points to the operation of somatic stimuli of that kind; we could not be mistaken in this, for the dreams are completely intelligible and easy to grasp. But this does not mean that we need abandon the stimulus aetiology of dreams. We can only ask how it has happened that from the first we have forgotten that besides somatic stimuli there are *mental* stimuli that disturb sleep. We know, after all, that it is excitations of this kind that are chiefly responsible for disturbing the sleep of an adult by preventing him from establishing the mood required for falling asleep - the withdrawing of interest from the world. He does not want to interrupt his life but would rather continue his work on the things he is concerned with, and for that reason he does not fall asleep. In the case of children, therefore, the stimulus that disturbs sleep is a mental one - the wish that has not been dealt with - and it is to this that they react with the dream. [1916-1917, 3223]

Here we are presented with a means of answering the question of whether dreams have a function too, whether they are entrusted with any useful achievement. The condition of rest free from stimulus, which the state of sleep wishes to establish, is threatened from three directions: in a relatively accidental manner by external stimuli during sleep, and by interests of the previous day which cannot be broken off, and in an unavoidable manner by unsated repressed instinctual impulses which are on the watch for an opportunity of finding expression. In consequence of the diminishing of repressions at night there would be a risk that the rest afforded by sleep would be interrupted whenever an instigation from outside or from inside succeeded in linking up with an unconscious instinctual source. The process of dreaming allows the product of a collaboration of this kind to find an outlet in a harmless hallucinatory experience and in that way assures a continuation of sleep. The fact that a dream occasionally awakens the sleeper, to the accompaniment of a generation of anxiety, is no contradiction of this function but rather, perhaps, a signal that the watchman regards the situation as too dangerous and no longer feels able to control it. And very often then, while we are still asleep, a consolation occurs to us which seeks to prevent our waking up: 'But after all it's only a dream!' [1933a, 4630]
This piece of the dream-work gives us information about some of the most striking and peculiar features of dreams. I will repeat the course of events in dream-formation. As an introduction: the wish to sleep and intentional turning away from the external world. Next, two consequences of this for the mental apparatus: first, the possibility for older and more primitive methods of working to emerge in it - regression; secondly, the lowering of the resistance due to repression which weighs down upon the unconscious. As a result of this last factor the possibility arises for the formation of a dream and this is taken advantage of by the precipitating causes, the internal and external stimuli which have become active. The dream which originates in this way is already a compromise-structure. It has a double function; on the one hand it is ego-syntonic, since, by getting rid of the stimuli which are interfering with sleep, it serves the wish to sleep; on the other hand it allows a repressed instinctual impulse to obtain the satisfaction that is possible in these circumstances, in the form of the hallucinated fulfilment of a wish. The whole process of forming a dream which is permitted by the sleeping ego is, however, subject to the condition of the censorship, which is exercised by the residue of the repression still in operation. I cannot present the process more simply: it is not more simple. But I can proceed now with my description of the dream-work.

[1933a, 4632]

It is best to begin by pointing out that the formation of a dream can be provoked in two different ways. Either, on the one hand, an instinctual impulse which is ordinarily suppressed (an unconscious wish) finds enough strength during sleep to make itself felt by the ego, or, on the other hand, an urge left over from waking life, a preconscious train of thought with all the conflicting impulses attached to it, finds reinforcement during sleep from an unconscious element. In short, dreams may arise either from the id or from the ego. The mechanism of dream-formation is in both cases the same and so also is the necessary dynamic precondition. The ego gives evidence of its original derivation from the id by occasionally ceasing its functions and allowing a reversion to an earlier state of things. This is logically brought about by its breaking off its relations with the external world and withdrawing its cathexes from the sense organs. We are justified in saying that there arises at birth an instinct to return to the intra-uterine life that has been abandoned - an instinct to sleep. Sleep is a return of this kind to the womb. Since the waking ego governs motility, that function is paralysed in sleep, and accordingly a good part of the inhibitions imposed on the unconscious id become superfluous. The withdrawal or reduction of these 'anticathexes' thus allows the id what is now a harmless amount of liberty.

[1940a [1938], 4976]
It remains for us to give a dynamic explanation of why the sleeping ego takes on the task of the dream-work at all. The explanation is fortunately easy to find. With the help of the unconscious, every dream that is in process of formation makes a demand upon the ego - for the satisfaction of an instinct, if the dream originates from the id; for the solution of a conflict, the removal of a doubt or the forming of an intention, if the dream originates from a residue of preconscious activity in waking life. The sleeping ego, however, is focused on the wish to maintain sleep; it feels this demand as a disturbance and seeks to get rid of the disturbance. The ego succeeds in doing this by what appears to be an act of compliance: it meets the demand with what is in the circumstances a harmless fulfillment of a wish and so gets rid of it.

This replacement of the demand by the fulfillment of a wish remains the essential function of the dream-work. It may perhaps be worth while to illustrate this by three simple examples - a hunger dream, a dream of convenience and a dream prompted by sexual desire. A need for food makes itself felt in a dreamer during his sleep: he has a dream of a delicious meal and sleeps on. The choice, of course, was open to him either of waking up and eating something or of continuing his sleep. He decided in favour of the latter and satisfied his hunger by means of the dream - for the time being, at all events, for if his hunger had persisted he would have had to wake up nevertheless. Here is the second example. A sleeper had to wake up so as to be in time for his work at the hospital. But he slept on, and had a dream that he was already at the hospital - but as a patient, who has no need to get up. Or again, a desire becomes active during the night for the enjoyment of a forbidden sexual object, the wife of a friend of the sleeper. He has a dream of sexual intercourse - not, indeed, with this person but with someone else of the same name to whom he is in fact indifferent; or his struggle against the desire may find expression in his mistress remaining altogether anonymous.

[1940a [1938], 4980]
We shall find later that the enigma of the formation of dreams can be solved by the revelation of an unsuspected psychical source of stimulation. Meanwhile we shall feel no surprise at the over-estimation of the part played in forming dreams by stimuli which do not arise from mental life. Not only are they easy to discover and even open to experimental confirmation; but the somatic view of the origin of dreams is completely in line with the prevailing trend of thought in psychiatry to-day. It is true that the dominance of the brain over the organism is asserted with apparent confidence. Nevertheless, anything that might indicate that mental life is in any way independent of demonstrable organic changes or that its manifestations are in any way spontaneous alarms the modern psychiatrist, as though a recognition of such things would inevitably bring back the days of the Philosophy of Nature, and of the metaphysical view of the nature of mind. The suspicions of the psychiatrists have put the mind, as it were, under tutelage, and they now insist that none of its impulses shall be allowed to suggest that it has any means of its own. This behaviour of theirs only shows how little trust they really have in the validity of a causal connection between the somatic and the mental. Even when investigation shows that the primary exciting cause of a phenomenon is psychical, deeper research will one day trace the path further and discover an organic basis for the mental event. But if at the moment we cannot see beyond the mental, that is no reason for denying its existence.

[1900a, 552]
I am prepared to leave room at this point for the operation of a number of special factors which can lend a varying importance to external stimuli in relation to dreams. As I picture it, a combination of individual factors, physiological and accidental, produced by the circumstances of the moment, is what determines how a person shall behave in particular cases of comparatively intense objective stimulation during sleep. The habitual or accidental depth of his sleep, taken in conjunction with the intensity of the stimulus, will make it possible in one case for him to suppress the stimulus so that his sleep is not interrupted and in another case will compel him to wake up or will encourage an attempt to overcome the stimulus by weaving it into a dream. In accordance with these various possible combinations, external objective stimuli will find expression in dreams with greater or less frequency in one person than in another. In my own case, since I am an excellent sleeper and obstinately refuse to allow anything to disturb my sleep, it very rarely happens that external causes of excitation find their way into my dreams; whereas psychical motives obviously cause me to dream very easily. In fact I have only noted a single dream in which an objective and painful source of stimulus is recognizable; and it will be most instructive to examine the effect which the external stimulus produced in this particular dream.

There is no need to give up this theory entirely on that account. Moreover it is capable of extension. It is obviously a matter of indifference what it is that disturbs sleep or instigates the mind to dream. If it cannot invariably be a sensory stimulus coming from outside, there may instead be what is called a somatic stimulus, arising from the internal organs. This is a very plausible notion and agrees with the most popular view of the origin of dreams: 'dreams come from indigestion,' people often say. Here too unluckily we must often suspect that there are cases when a somatic stimulus which has impinged on a sleeper during the night is no longer manifest after waking and can therefore not be proved to have occurred. But we shall not overlook the number of clear experiences which support the origin of dreams from somatic stimuli. In general, there can be no doubt that the condition of the internal organs can influence dreams. The relation of the content of some dreams to an over full bladder or to a state of excitation of the genital organs is too plain to be mistaken. These clear cases lead to others in which the content of the dreams give rise to a justifiable suspicion that there has been an impact from somatic stimuli because there is something in the content which can be regarded as a working over, a representation or an interpretation of such stimuli. Scherner (1861), who made researches into dreams, argued particularly strongly in favour of the derivation of dreams from organic stimuli and brought forward some good examples of it. For instance, in one dream he saw 'two rows of pretty boys with fair hair and delicatecomplexions facing one another in pugnacious array, making an onset and attacking one another, and then drawing back and taking up their old position again, and then starting the whole business once more.' His interpretation of these two rows of boys as teeth is plausible in itself and seems fully confirmed when we learn that after this scene the dreamer 'pulled a long tooth out of his jaw.' Similarly, the interpretation of 'long, narrow, winding passages' as derived from an intestinal stimulus seems valid, and confirms the assertion by Scherner that dreams seek above all to represent the organ that sends out the stimulus by objects resembling it.

Thus we must be prepared to admit that internal stimuli can play the same part in dreams as external ones. Any estimate of their importance is unfortunately open to the same objections. In a large number of cases an interpretation pointing to a somatic stimulus is uncertain or unprovable. Not all dreams, but only a certain number of them give rise to a suspicion that internal organic stimuli had a share in their origin. And lastly, internal somatic stimuli are as little able as external sensory stimuli to explain more of a dream than what corresponds in it to a direct reaction to the stimulus. Where the rest of the dream comes from remains obscure.
Let us notice, however, one peculiarity of dream-life which comes to light in this study of the effects of stimuli. Dreams do not simply reproduce the stimulus; they work it over, they make allusions to it, they include it in some context, they replace it by something else. This is a side of the dream-work which is bound to interest us since it may perhaps bring us nearer to the essence of dreams. When a person constructs something as a result of a stimulus, the stimulus need not on that account exhaust the whole of the work. Shakespeare's *Macbeth*, for instance, was a *pièce d'occasion* composed to celebrate the accession of the king who first united the crowns of the three kingdoms. But does this immediate historical occasion cover the content of the tragedy? Does it explain its greatnesses and its enigmas? It may be that the external and internal stimuli, too, impinging on the sleeper, are only the *instigators* of the dream and will accordingly betray nothing to us of its essence.

[1916-1917, 3196]

(4) A child's dream is a reaction to an experience of the previous day, which has left behind it a regret, a longing, a wish that has not been dealt with. The dream produces a direct, undisguised fulfilment of that wish. Let us recall now our discussions on the part played by somatic stimuli from outside and from within as disturbers of sleep and instigators of dreams. In that connection we came to know some quite undoubted facts, but by their means we were only able to explain a small number of dreams. In these children's dreams, however, there is nothing that points to the operation of somatic stimuli of that kind; we could not be mistaken in this, for the dreams are completely intelligible and easy to grasp. But this does not mean that we need abandon the stimulus aetiology of dreams. We can only ask how it has happened that from the first we have forgotten that besides somatic stimuli there are mental stimuli that disturb sleep. We know, after all, that it is excitations of this kind that are chiefly responsible for disturbing the sleep of an adult by preventing him from establishing the mood required for falling asleep - the withdrawing of interest from the world. He does not want to interrupt his life but would rather continue his work on the things he is concerned with, and for that reason he does not fall asleep. In the case of children, therefore, the stimulus that disturbs sleep is a mental one - the wish that has not been dealt with - and it is to this that they react with the dream.

[1916-1917, 3223]

If you prefer to assume that a telepathic message about the daughter's confinement reached the sleeper, further questions arise of the relation of a message such as this to a dream and of its influence on the formation of dreams. The answer is not far to seek and is quite unambiguous. A telepathic message will be treated as a portion of the material that goes to the formation of a dream, like any other external or internal stimulus, like a disturbing noise in the street or an insistent organic sensation in the sleeper's own body. In our example it is evident how the message, with the help of a lurking repressed wish, became remodelled into a wish-fulfilment; it is unfortunately less easy to show that it combined with other material that had become active at the same time and was blended into a dream. Telepathic messages - if we are justified in recognizing their existence - can thus make no alteration in the process of forming a dream; telepathy has nothing to do with the nature of dreams. And in order to avoid the impression that I am trying to conceal a vague notion behind abstract and fine-sounding words, I am willing to repeat: the essential nature of dreams consists in the peculiar process of 'dream-work' which, with the help of an unconscious wish, carries the preconscious thoughts (day's residues) over into the manifest content of the dream. The problem of telepathy concerns dreams as little as does the problem of anxiety.

[1922a, 3887]
There is no difficulty in discovering the general function of dreaming. It serves the purpose of fending off, by a kind of soothing action, external or internal stimuli which would tend to arouse the sleeper, and thus of securing sleep against interruption. External stimuli are fended off by being given a new interpretation and by being woven into some harmless situation; internal stimuli, caused by instinctual demands, are given free play by the sleeper and allowed to find satisfaction in the formation of dreams, so long as the latent dream-thoughts submit to the control of the censorship. But if they threaten to break free and the meaning of the dream becomes too plain, the sleeper cuts short the dream and wakes in a fright. (Dreams of this class are known as anxiety-dreams.) A similar failure in the function of dreaming occurs if an external stimulus becomes too strong to be fended off. (This is the class of arousal-dreams.) I have given the name of dream-work to the process which, with the co-operation of the censorship, converts the latent thoughts into the manifest content of the dream. It consists of a peculiar way of treating the preconscious material of thought, so that its component parts become condensed, its psychical emphasis becomes displaced, and the whole of it is translated into visual images or dramatized, and completed by a deceptive secondary revision. The dream-work is an excellent example of the processes occurring in the deeper, unconscious layers of the mind, which differ considerably from the familiar normal processes of thought. It also displays a number of archaic characteristics, such as the use of a symbolism (in this case of a predominantly sexual kind) which it has since also been possible to discover in other spheres of mental activity.

[1925d, 4220]

Here we are presented with a means of answering the question of whether dreams have a function too, whether they are entrusted with any useful achievement. The condition of rest free from stimulus, which the state of sleep wishes to establish, is threatened from three directions: in a relatively accidental manner by external stimuli during sleep, and by interests of the previous day which cannot be broken off, and in an unavoidable manner by unsated repressed instinctual impulses which are on the watch for an opportunity of finding expression. In consequence of the diminishing of repressions at night there would be a risk that the rest afforded by sleep would be interrupted whenever an instigation from outside or from inside succeeded in linking up with an unconscious instinctual source. The process of dreaming allows the product of a collaboration of this kind to find an outlet in a harmless hallucinatory experience and in that way assures a continuation of sleep. The fact that a dream occasionally awakens the sleeper, to the accompaniment of a generation of anxiety, is no contradiction of this function but rather, perhaps, a signal that the watchman regards the situation as too dangerous and no longer feels able to control it. And very often then, while we are still asleep, a consolation occurs to us which seeks to prevent our waking up: 'But after all it's only a dream!'

[1933a, 4630]
Now there are a great number of such stimuli, ranging from the unavoidable ones which the state of sleep itself necessarily involves or must tolerate from time to time, to the accidental, rousing stimuli which may or do put an end to sleep. A bright light may force its way into our eyes, or a noise may make itself heard, or some strong-smelling substance may stimulate the mucous membrane of our nose. By unintentional movements during our sleep we may uncover some part of our body and expose it to sensations of chill, or by a change in posture we may ourselves bring about sensations of pressure or contact. We may be stung by a gnat, or some small mishap during the night may impinge upon several of our senses at once. Attentive observers have collected a whole series of dreams in which there has been such a far-reaching correspondence between a stimulus noticed on waking and a portion of the content of the dream that it has been possible to identify the stimulus as the source of the dream.

I will quote from Jessen (1855, 527 f.) a collection of dreams of this kind which may be traced back to objective, and more or less accidental, sensory stimulation.

"Every noise that is indistinctly perceived arouses corresponding dream-images. A peal of thunder will set us in the midst of a battle; the crowing of a cock may turn into a man’s cry of terror; the creaking of a door may produce a dream of burglars. If our bed-clothes fall off in the night, we may dream, perhaps, of walking about naked or of falling into water. If we are lying cross-wise in bed and push our feet over the edge, we may dream that we are standing on the brink of a frightful precipice or that we are falling over a cliff. If our head happens to get under the pillow, we dream of being beneath a huge overhanging rock which is on the point of burying us under its weight. Accumulations of semen lead to lascivious dreams, local pains produce ideas of being ill-treated, attacked or injured. . . ."

The argument based on the similarity between the stimulus and the content of the dream gains in strength if it is possible deliberately to convey a sensory stimulus to the sleeper and produce in him a dream corresponding to that stimulus. According to Macnish (loc. cit.), quoted by Jessen (1855, 529), experiments of this sort had already been made by Girou de Buzareingues. ‘He left his knee uncovered and dreamt that he was travelling at night in a mail coach. He remarks upon this that travellers will no doubt be aware how cold one’s knees become at night in a coach. Another time he left his head uncovered at the back and dreamt that he was taking part in a religious ceremony in the open air. It must be explained that in the country in which he lived it was the custom always to keep the head covered except in circumstances such as these.’

Examples of this kind leave an impression that of all the sources of dreams the best confirmed are objective sensory stimuli during sleep. Moreover they are the only sources whatever taken into account by laymen. If an educated man, who is unacquainted with the literature of dreams, is asked how dreams arise, he will infallibly answer with a reference to some instance he has come across in which a dream was explained by an objective sensory stimulus discovered after waking. Scientific enquiry, however, cannot stop there. It finds an occasion for further questions in the observed fact that the stimulus which impinges on the senses during sleep does not appear in the dream in its real shape but is replaced by another image in some way related to it. But the relation connecting the stimulus of the dream to the dream which is its result is, to quote Maury’s words (1854, 72), ‘une affinité quelconque, mais qui n’est pas unique et exclusive.’ Let us consider in this connection three of Hildebrandt’s alarm-clock dreams (1875, 37 f.). The question they raise is why the same stimulus should have provoked three such different dreams and why it should have provoked these rather than any other.
The question of why the mind mistakes the nature of objective sensory stimuli in dreams receives almost the same answer from Strümpell (1877) as from Wundt (1874): the mind receives stimuli that reach it during sleep under conditions favourable to the formation of illusions. A sense impression is recognized by us and correctly interpreted - that is, it is placed in the group of memories to which, in accordance with all our previous experiences, it belongs - provided the impression is sufficiently strong, clear and lasting and provided we have sufficient time at our disposal for considering the matter. If these conditions are not fulfilled, we mistake the object which is the source of the impression: we form an illusion about it. 'If someone goes for a walk in the open country and has an indeterminate perception of a distant object, he may at first believe it to be a horse.' On a closer view he may be led to interpret it as a cow lying down, and the image may finally resolve itself definitely into a group of people sitting on the ground. The impressions received by the mind from external stimuli during sleep are of a similarly indeterminate nature; and on their basis the mind forms illusions, since a greater or smaller number of mnemic images are aroused by the impression and it is through them that it acquires its psychological value. From *which* of the many groups of memories concerned the related images shall be aroused and *which* of the possible associative connections shall accordingly be put into action - these questions too, on Strümpell's theory, are indeterminable and are, as it were, left open to the arbitrary decision of the mind.

[1900a, 542]

At this point we are faced with a choice between two alternatives. We may admit it as a fact that it is impossible to follow the laws governing the formation of dreams any further; and we may accordingly refrain from enquiring whether there may not be other determinants governing the interpretation put by the dreamer upon the illusion called up by the sense-impression. Or, on the other hand, we may have a suspicion that the sensory stimulus which impinges on the sleeper plays only a modest part in generating his dream and that other factors determine the choice of the mnemic images which are to be aroused in him. In fact, if we examine Maury's experimentally produced dreams (which I have related in such detail for this very reason), we shall be tempted to say that the experiment in fact accounts for the origin of only one element of the dreams; the rest of their content seems too self-contained, too definite in its details, to be explicable solely by the necessity for fitting in with the element experimentally introduced from outside. Indeed, one begins to have doubts about the illusion theory and about the power of objective impressions to give a shape to dreams when one finds that those impressions are sometimes subjected in dreams to the most peculiar and far-fetched interpretations. Thus Simon (1888) tells us of a dream in which he saw some gigantic figures seated at table and clearly heard the frightful snapping noise made by their jaws coming together as they chewed. When he awoke he heard the beat of a horse's hooves galloping past his window. The noise made by the horse's hooves may have suggested ideas from a group of memories connected with *Gulliver's Travels* - the giants of Brobdingnag and the virtuous Houyhnhnms - if I may venture on an interpretation without the dreamer's assistance. Is it not probable, then, that the choice of such an unusual group of memories as these was facilitated by motives other than the objective stimulus alone!*

[1900a, 542]
In spite of any objections to the contrary, it has to be admitted that the part played by objective sensory excitations during sleep in provoking dreams remains indisputable. And if such stimuli may appear, from their nature and frequency, insufficient to explain every dream-image, we shall be encouraged to seek for other sources of dreams analogous to them in their operation. I cannot say when the idea first cropped up of taking internal (subjective) excitations of the sense organs into account alongside of the external sensory stimuli. It is, however, the case that this is done, more or less explicitly, in all the more recent discussions of the aetiology of dreams. 'An essential part is also played, I believe', writes Wundt (1874, 657), 'in the production of the illusions that occur in dreams by the subjective visual and auditory sensations which are familiar to us in the waking state as the formless areas of luminosity which become visible to us when our field of vision is darkened, as ringing or buzzing in the ears, and so on. Especially important among these are the subjective excitations of the retina. It is in this way that is to be explained the remarkable tendency of dreams to conjure up before the eyes similar or identical objects in large numbers. We see before us innumerable birds or butterflies or fishes or coloured beads or flowers, etc. Here the luminous dust in the darkened field of vision has taken on a fantastic shape, and the numerous specks of which it consists are incorporated into the dream as an equal number of separate images; and these, on account of their mobility, are regarded as moving objects. -This is no doubt also the basis of the great fondness shown by dreams for animal figures of every sort; for the immense variety of such forms can adjust itself easily to the particular form assumed by the subjective luminous images.'

A more recent observer of hypnagogic hallucinations, G. Trumbull Ladd (1892), has followed the same lines as Müller and Maury. After some practice he succeeded in being able to wake himself suddenly without opening his eyes, from two to five minutes after gradually falling asleep. He thus had an opportunity of comparing the retinal sensations which were just disappearing with the dream-images persisting in his memory. He declares that it was possible in every case to recognize an internal relation between the two, for the luminous points and lines of the idioretinal light provided, as it were, an outline drawing or diagram of the figures mentally perceived in the dream. For instance, an arrangement of the luminous points in the retina in parallel lines corresponded to a dream in which he had been seeing, clearly spread out in front of him, some lines of print which he was engaged in reading. Or, to use his own words, 'the clearly printed page which I was reading in my dream faded away into an object that appeared to my waking consciousness like a section of an actual page of print when seen through an oval hole in a piece of paper at too great a distance to distinguish more than an occasional fragment of a word, and even that dimly.' Ladd is of opinion (though he does not underestimate the part played in the phenomenon by central factors) that scarcely a single visual dream, occurs without the participation of material provided by intraocular retinal excitation. This applies especially to dreams occurring soon after falling asleep in a dark room, while the source of stimulus for dreams occurring in the morning shortly before waking is the objective light which penetrates the eyes in a room that is growing light. The changing, perpetually shifting character of the excitation of the idioretinal light corresponds precisely to the constantly moving succession of images shown us by our dreams. No one who attaches importance to these observations of Ladd's will underestimate the part played in dreams by these subjective sources of stimulation, for, as we know, visual images constitute the principal component of our dreams. The contributions from the other senses, except for that of hearing, are intermittent and of less importance.

[1900a, 544]
When we were dealing with the relations of dreams to waking life and with the material of dreams, we found that the most ancient and the most recent students of dreams were united in believing that men dream of what they do during the daytime and of what interests them while they are awake. Such an interest, carried over from waking life into sleep, would not only be a mental bond, a link between dreams and life, but would also provide us with a further source of dreams and one not to be despised. Indeed, taken in conjunction with the interests that develop during sleep - the stimuli that impinge on the sleeper - it might be enough to explain the origin of all dream-images. But we have also heard the opposite asserted, namely that dreams withdraw the sleeper from the interests of daytime and that, as a rule, we only start dreaming of the things that have most struck us during the day, after they have lost the spice of actuality in waking life. Thus at every step we take in our analysis of dream-life we come to feel that it is impossible to make generalizations without covering ourselves by such qualifying phrases as 'frequently', 'as a rule' or 'in most cases', and without being prepared to admit the validity of exceptions.

I have already discussed at length in the opening chapter (Section C) the part assigned by scientific writers to somatic sources of stimulation in the formation of dreams; so that here I need only recall the results of that enquiry. We found that three different kinds of somatic sources of stimulation were distinguished: objective sensory stimuli arising from external objects, internal states of excitation of the sense organs having only a subjective basis, and somatic stimuli derived from the interior of the body. We noticed moreover that the authorities were inclined to push into the background, or to exclude entirely, any possible psychical sources of dreams, as compared with these somatic stimuli (cf. p. 552). In our examination of the claims made on behalf of somatic sources of stimulation we arrived at the following conclusions. The significance of objective excitations of the sense organs (consisting partly of chance stimuli during sleep and partly of excitations such as cannot fail to impinge even upon a sleeping mind) is established from numerous observations and has been experimentally confirmed (cf. p. 538). The part played by subjective sensory excitations seems to be demonstrated by the recurrence in dreams of hypnagogic sensory images (cf. p. 543 f.). And lastly it appears that, though it is impossible to prove that the images and ideas occurring in our dreams can be traced back to internal somatic stimuli to the extent to which this has been asserted to be the case, nevertheless this origin finds support in the universally recognized influence exercised upon our dreams by states of excitation in our digestive, urinary and sexual organs.

However secure the supporters of this theory might feel in its factual basis - especially as far as accidental and external nervous stimuli are concerned, since these can be traced in the content of dreams without any trouble at all - not one of them could fail to perceive that it is impossible to attribute the wealth of ideational material in dreams to external nervous stimuli alone. Miss Mary Whiton Calkins (1893, 312) examined her own and another person's dreams for six weeks with this question in mind. She found that in only 13.2 per cent and 6.7 per cent of them respectively was it possible to trace the element of external sense-perception; while only two cases in the collection were derivable from organic sensations. Here we have statistical confirmation of what I had been led to suspect from a hasty survey of my own experiences.
I am prepared to leave room at this point for the operation of a number of special factors which can lend a varying importance to external stimuli in relation to dreams. As I picture it, a combination of individual factors, physiological and accidental, produced by the circumstances of the moment, is what determines how a person shall behave in particular cases of comparatively intense objective stimulation during sleep. The habitual or accidental depth of his sleep, taken in conjunction with the intensity of the stimulus, will make it possible in one case for him to suppress the stimulus so that his sleep is not interrupted and in another case will compel him to wake up or will encourage an attempt to overcome the stimulus by weaving it into a dream. In accordance with these various possible combinations, external objective stimuli will find expression in dreams with greater or less frequency in one person than in another. In my own case, since I am an excellent sleeper and obstinately refuse to allow anything to disturb my sleep, it very rarely happens that external causes of excitation find their way into my dreams; whereas psychical motives obviously cause me to dream very easily. In fact I have only noted a single dream in which an objective and painful source of stimulus is recognizable; and it will be most instructive to examine the effect which the external stimulus produced in this particular dream.

[1900a, 708]

Let us compare this dream of the first Napoleon (who, incidentally, was an extremely sound sleeper) with that of the sleepy student who was roused by his landlady and told that it was time to go to the hospital, and who proceeded to dream that he was in bed at the hospital and then slept on, under the pretext that as he was already in the hospital there was no need for him to get up and go there. This latter dream was clearly a dream of convenience. The dreamer admitted his motive for dreaming without any disguise; but at the same time he gave away one of the secrets of dreaming in general. All dreams are in a sense dreams of convenience: they serve the purpose of prolonging sleep instead of waking up. Dreams are the GUARDIANS of sleep and not its disturbers. We shall have occasion elsewhere to justify this view of them in relation to awakening factors of a psychical kind; but we are already in a position to show that it is applicable to the part played by objective external stimuli. Either the mind pays no attention at all to occasions for sensation during sleep - if it is able to do this despite the intensity of the stimuli and the significance which it knows attaches to them; or it makes use of a dream in order to deny the stimuli; or, thirdly, if it is obliged to recognize them, it seeks for an interpretation of them which will make the currently active sensation into a component part of a situation which is wished for and which is consistent with sleeping. The currently active sensation is woven into a dream in order to rob it of reality. Napoleon could sleep on - with a conviction that what was trying to disturb him was only a dream-memory of the thunder of the guns at Arcole.¹

[1900a, 712]
Among the dreams collected by Justine Tobowolska in her dissertation on the apparent passage of time in dreams, the most informative seems to me to be the one reported by Macario (1857) as having been dreamt by a dramatic author, Casimir Bonjour. One evening Bonjour wanted to attend the first performance of one of his pieces; but he was so fatigued that as he was sitting behind the scenes he dozed off just at the moment the curtain went up. During his sleep he went through the whole five acts of the play, and observed all the various signs of emotion shown by the audience during the different scenes. At the end of the performance he was delighted to hear his name being shouted with the liveliest demonstrations of applause. Suddenly he woke up. He could not believe either his eyes or his ears, for the performance had not gone beyond the first few lines of the first scene; he could not have been asleep for longer than two minutes. It is surely not too rash to suppose in the case of this dream that the dreamer's going through all five acts of the play and observing the attitude of the public to different passages in it need not have arisen from any fresh production of material during his sleep, but may have reproduced a piece of phantasy-activity (in the sense I have described) which had already been completed. Tobowolska, like other writers, emphasizes the fact that dreams with an accelerated passage of ideas have the common characteristic of seeming specially coherent, quite unlike other dreams, and that the recollection of them is summary far more than detailed. This would indeed be a characteristic which ready-made phantasies of this kind, touched upon by the dream-work, would be bound to possess, though this is a conclusion which the writers in question fail to draw. I do not assert, however, that all arousal dreams admit of this explanation, or that the problem of the accelerated passage of ideas in dreams can be entirely dismissed in this fashion.

[1900a, 936]

This determined wish on the part of the preconscious to sleep exercises a generally facilitating effect on the formation of dreams. Let me recall the dream dreamt by the man who was led to infer from the glare of light coming out of the next room that his child's body might be on fire. The father drew this inference in a dream instead of allowing himself to be woken up by the glare; and we have suggested that one of the psychical forces responsible for this result was a wish which prolonged by that one moment the life of the child whom he pictured in the dream. Other wishes, originating from the repressed, probably escape us, since we are unable to analyse the dream. But we may assume that a further motive force in the production of the dream was the father's need to sleep; his sleep, like the child's life, was prolonged by one moment by the dream. 'Let the dream go on' - such was his motive - 'or I shall have to wake up.' In every other dream, just as in this one, the wish to sleep lends its support to the unconscious wish. On p. 624 f. I described some dreams which appeared openly as dreams of convenience. But in fact all dreams can claim a right to the same description. The operation of the wish to continue sleeping is most easily to be seen in arousal dreams, which modify external sensory stimuli in such a way as to make them compatible with a continuance of sleep; they weave them into a dream in order to deprive them of any possibility of acting as reminders of the external world. That same wish must, however, play an equal part in allowing the occurrence of all other dreams, though it may only be from within that they threaten to shake the subject out of his sleep. In some cases, when a dream carries things too far, the Ucs. says to consciousness: 'Never mind! go on sleeping! after all it's only a dream!' But this describes in general the attitude of our dominant mental activity towards dreams, though it may not be openly expressed. I am driven to conclude that throughout our whole sleeping state we know just as certainly that we are dreaming as we know that we are sleeping. We must not pay too much attention to the counter-argument that our consciousness is never brought to bear on the latter piece of knowledge and that it is only brought to bear on the former on particular occasions when the censorship feels that it has, as it were, been taken off its guard.

[1900a, 1000]
It has naturally not occurred to us to throw any doubt on the significance, which has been experimentally demonstrated, of external sensory stimuli during sleep; but we have shown that such material stands in the same relation to the dream-wish as do the residues of thought left over from day time activity. Nor have we seen any reason to dispute the view that dreams interpret objective sensory stimuli just as illusions do; but we have found the motive which provides the reason for that interpretation, a reason which has been left unspecified by other writers. Interpretation is carried out in such a way that the object perceived shall not interrupt sleep and shall be usable for purposes of wish-fulfilment. As regards subjective states of excitation in the sense organs during sleep, the occurrence of which seems to have been proved by Trumbull Ladd, it is true that we have not accepted them as a particular source of dreams; but we have been able to explain them as resulting from the regressive revival of memories that are in operation behind the dream.

[1900a, 1016]

The function of the dream as a guardian of sleep becomes particularly evident when an external stimulus impinges upon the senses of a sleeper. It is generally recognized that sensory stimuli arising during sleep influence the content of dreams; this can be proved experimentally and is among the few certain (but, incidentally, greatly overvalued) findings of medical investigation into dreams. But this finding involves a puzzle which has hitherto proved insoluble. For the sensory stimulus which the experimenter causes to impinge upon the sleeper is not correctly recognized in the dream; it is subjected to one of an indefinite number of possible interpretations, the choice being apparently left to an arbitrary psychical determination. But there is, of course, no such thing as arbitrary determination in the mind. There are several ways in which a sleeper may react to an external sensory stimulus. He may wake up or he may succeed in continuing his sleep in spite of it. In the latter case he may make use of a dream in order to get rid of the external stimulus, and here again there is more than one method open to him. For instance, he may get rid of the stimulus by dreaming that he is in a situation which is absolutely incompatible with the stimulus. Such was the line taken by a sleeper who was subject to disturbance by a painful abscess on the perineum. He dreamt that he was riding on a horse, making use of the poultice that was intended to mitigate his pain as a saddle, and in this way he avoided being disturbed. Or, as happens more frequently, the external stimulus is given an interpretation which brings it into the context of a repressed wish which is at the moment awaiting fulfilment; in this way the external stimulus is robbed of its reality and is treated as though it were a portion of the psychical material. Thus someone dreamt that he had written a comedy with a particular plot; it was produced in a theatre, the first act was over, and there were thunders of applause; the clapping was terrific. . . . The dreamer must have succeeded in prolonging his sleep till after the interference had ceased; for when he woke up he no longer heard the noise, but rightly concluded that someone must have been beating a carpet or mattress. Every dream which occurs immediately before the sleeper is woken by a loud noise has made an attempt at explaining away the arousing stimulus by providing another explanation of it and has thus sought to prolong sleep, even if only for a moment.

[1901a, 1093]
Norbert Hanold's delusion, as I was saying, was carried a step further by a dream which occurred in the middle of his efforts to discover a gait like Gradiva's in the streets of the town where he lived. It is easy to give the content of this dream in brief. The dreamer found himself in Pompeii on the day on which that unhappy city was destroyed, and experienced its horrors without being in danger himself; he suddenly saw Gradiva stepping along there, and understood all at once, as though it was something quite natural, that since she was a Pompeian, she was living in her native town, and 'without his having suspected it, living as his contemporary'. He was seized with fear on her account and gave a warning cry, whereupon she turned her face towards him for a moment. But she proceeded on her way without paying any attention to him, lay down on the steps of the Temple of Apollo, and was buried in the rain of ashes after her face had lost its colour, as though it were turning into white marble, until it had become just like a piece of sculpture. As he was waking up, he interpreted the noises of a big city penetrating into his bedroom as the cries for help of the despairing inhabitants of Pompeii and the thunder of the wildly agitated sea. The feeling that what he had dreamt had really happened to him would not leave him for some time after he had awoken, and a conviction that Gradiva had lived in Pompeii and had perished there on the fatal day was left over with him by the dream as a fresh starting-point for his delusion.

I can well imagine that at this point a reader may exclaim: 'The dream is quite easily explained - it is a simple anxiety dream, occasioned by the noises of the city, which were misinterpreted into the destruction of Pompeii by the archaeologist, whose mind was occupied with his Pompeian girl.' In view of the low opinion generally prevailing of the performances of dreams, all that is usually asked from an explanation of one is that some external stimulus shall be found that more or less coincides with a piece of the dream's content. This external stimulus to dreaming would be supplied by the noise which woke the sleeper; and with this, interest in the dream would be exhausted. If only we had some reason for supposing that the town was noisier than usual that morning! If only, for instance, the author had not omitted to tell us that Hanold, against his usual practice, had slept that night with his windows open! What a pity the author did not take the trouble to do that! And if only anxiety-dreams were as simple as that! But no, interest in the dream is not so easily exhausted.

There is nothing essential for the construction of a dream in a link with an external sensory stimulus. A sleeper can disregard a stimulus of this kind from the external world, or he can allow himself to be awakened by it without constructing a dream, or, as happened here, he can weave it into his dream if that suits him for some other reason; and there are numerous dreams of which it is impossible to show that their content was determined in this way by a stimulus impinging on the sleeper's senses. No, we must try another path.
When we were dealing with the relations of dreams to waking life and with the material of dreams, we found that the most ancient and the most recent students of dreams were united in believing that men dream of what they do during the daytime and of what interests them while they are awake. Such an interest, carried over from waking life into sleep, would not only be a mental bond, a link between dreams and life, but would also provide us with a further source of dreams and one not to be despised. Indeed, taken in conjunction with the interests that develop during sleep - the stimuli that impinge on the sleeper - it might be enough to explain the origin of all dream-images. But we have also heard the opposite asserted, namely that dreams withdraw the sleeper from the interests of daytime and that, as a rule, we only start dreaming of the things that have most struck us during the day, after they have lost the spice of actuality in waking life. Thus at every step we take in our analysis of dream-life we come to feel that it is impossible to make generalizations without covering ourselves by such qualifying phrases as 'frequently', 'as a rule' or 'in most cases', and without being prepared to admit the validity of exceptions.

No other psychical sources of dreams are known. So it comes about that all the explanations of dreams given in the literature of the subject - with the possible exception of Scherner's, which will be dealt with later - leave a great gap when it comes to assigning an origin for the ideational images which constitute the most characteristic material of dreams. In this embarrassing situation, a majority of the writers on the subject have tended to reduce to a minimum the part played by psychical factors in instigating dreams, since those factors are so hard to come at. It is true that they divide dreams into two main classes - those 'due to nervous stimulation' and those 'due to association', of which the latter have their source exclusively in reproduction (cf. Wundt, 1874, 657 f.). Nevertheless they cannot escape a doubt whether any dream can take place without being given an impetus by some somatic stimulus' (Volkelt, 1875, 127). It is difficult even to give a description of purely associative dreams. 'In associative dreams proper, there can be no question of any such solid core. Even the very centre of the dream is only loosely put together. The ideational processes, which in any dream are unguided by reason or common sense, are here no longer even held together by my relatively important somatic or mental excitations, and are thus abandoned to their own kaleidoscopic changes and to their own jumbled confusion.' (Ibid., 118.) Wundt (1874, 656-7), too, seeks to minimize the psychical factor in the instigation of dreams. He declares that there seems to be no justification for regarding the phantasms of dreams as pure hallucinations; most dream-images are probably in fact illusions, since they arise from faint sense-impressions, which never cease during sleep. Weygandt (1893, 17) has adopted this same view and made its application general. He asserts of all dream-images 'that their primary causes are sensory stimuli and that only later do reproductive associations become attached to them'. Tissié (1898, 183) goes even further in putting a limit to the psychical sources of stimulation: 'Les rêves d'origine absolument psychique n'existent pas'; and (ibid., 6) 'les pensées de nos rêves nous viennent du dehors. . . .' ¹

The two scenes of micturition from my childhood were in any case closely linked to the topic of megalomania; but their emergence while I was travelling to Aussee was further assisted by the chance circumstance that there was no lavatory attached to my compartment and that I had reason to anticipate the predicament which in fact arose in the morning. I awoke with the sensations of a physical need. One might, I think, be inclined to suppose that these sensations were the actual provoking agent of the dream; but I would prefer to take another view, namely that the desire to micturate was only called up by the dream-thoughts. It is quite unusual for me to be disturbed in my sleep by physical needs of any kind, especially at the hour at which I awoke on this occasion - a quarter to three in the morning. And I may meet a further objection by remarking that upon other journeys under more comfortable conditions I have scarcely ever felt a need to micturate when I have woken up early. But in any case it will do no harm to leave the point unresolved.

¹ [1900a, 551]
The inadequacy of the theory of the somatic stimulation of dreams can be demonstrated in other ways. Observation shows that external stimuli do not necessarily compel me to dream, even though such stimuli appear in the content of my dream when and if I do dream. Supposing, let us say, that I am subjected to a tactile stimulus while I am asleep. A variety of different reactions are then open to me. I may disregard it, and when I wake up I may find, for instance, that my leg is uncovered or that there is some pressure on my arm; pathology provides very numerous instances in which various powerfully exciting sensory and motor stimuli can remain without effect during sleep. Or again, I may be aware of the sensation in my sleep - I may be aware of it, as one might say, 'through' my sleep -(which is what happens as a rule in the case of painful stimuli) but without my weaving the pain into a dream. And thirdly, I may react to the stimulus by waking up so as to get rid of it.¹ It is only as a fourth possibility that the nervous stimulus may cause me to dream. Yet the other possibilities are realized at least as frequently as this last one of constructing a dream. And this could not happen unless the motive for dreaming lay elsewhere than in somatic sources of stimulation.

[1900a, 704]

I am prepared to leave room at this point for the operation of a number of special factors which can lend a varying importance to external stimuli in relation to dreams. As I picture it, a combination of individual factors, physiological and accidental, produced by the circumstances of the moment, is what determines how a person shall behave in particular cases of comparatively intense objective stimulation during sleep. The habitual or accidental depth of his sleep, taken in conjunction with the intensity of the stimulus, will make it possible in one case for him to suppress the stimulus so that his sleep is not interrupted and in another case will compel him to wake up or will encourage an attempt to overcome the stimulus by weaving it into a dream. In accordance with these various possible combinations, external objective stimuli will find expression in dreams with greater or less frequency in one person than in another. In my own case, since I am an excellent sleeper and obstinately refuse to allow anything to disturb my sleep, it very rarely happens that external causes of excitation find their way into my dreams; whereas psychical motives obviously cause me to dream very easily. In fact I have only noted a single dream in which an objective and painful source of stimulus is recognizable; and it will be most instructive to examine the effect which the external stimulus produced in this particular dream.

[1900a, 708]

In the assessment of the significance of dreams three lines of thought can be distinguished. One of these, which echoes, as it were, the ancient overvaluation of dreams, is expressed in the writings of certain philosophers. They consider that the basis of dream-life is a peculiar state of mental activity, and even go so far as to acclaim that state as an elevation to a higher level. For instance, Schubert declares that dreams are a liberation of the spirit from the power of external nature, and a freeing of the soul from the bonds of the senses. Other thinkers, without going so far as this, insist nevertheless that dreams arise essentially from mental impulses and represent manifestations of mental forces which have been prevented from expanding freely during the daytime. (Cf. the 'dream imagination' of Scherner and Volkelt.) A large number of observers agree in attributing to dream-life a capacity for superior functioning in certain departments at least (e.g. in memory).

[1901a, 1051]
Let us notice, however, one peculiarity of dream-life which comes to light in this study of the effects of stimuli. Dreams do not simply reproduce the stimulus; they work it over, they make allusions to it, they include it in some context, they replace it by something else. This is a side of the dream-work which is bound to interest us since it may perhaps bring us nearer to the essence of dreams. When a person constructs something as a result of a stimulus, the stimulus need not on that account exhaust the whole of the work. Shakespeare's *Macbeth*, for instance, was a *pièce d'occasion* composed to celebrate the accession of the king who first united the crowns of the three kingdoms. But does this immediate historical occasion cover the content of the tragedy? Does it explain its greatnesses and its enigmas? It may be that the external and internal stimuli, too, impinging on the sleeper, are only the *instigators* of the dream and will accordingly betray nothing to us of its essence.

[1916-1917, 3196]

If you prefer to assume that a telepathic message about the daughter's confinement reached the sleeper, further questions arise of the relation of a message such as this to a dream and of its influence on the formation of dreams. The answer is not far to seek and is quite unambiguous. A telepathic message will be treated as a portion of the material that goes to the formation of a dream, like any other external or internal stimulus, like a disturbing noise in the street or an insistent organic sensation in the sleeper's own body. In our example it is evident how the message, with the help of a lurking repressed wish, became remodelled into a wish-fulfilment; it is unfortunately less easy to show that it combined with other material that had become active at the same time and was blended into a dream. Telepathic messages - if we are justified in recognizing their existence - can thus make no alteration in the process of forming a dream; telepathy has nothing to do with the nature of dreams. And in order to avoid the impression that I am trying to conceal a vague notion behind abstract and fine-sounding words, I am willing to repeat: the essential nature of dreams consists in the peculiar process of 'dream-work' which, with the help of an unconscious wish, carries the preconscious thoughts (day's residues) over into the manifest content of the dream. The problem of telepathy concerns dreams as little as does the problem of anxiety.

[1922a, 3887]

There is no difficulty in discovering the general function of dreaming. It serves the purpose of fending off, by a kind of soothing action, external or internal stimuli which would tend to arouse the sleeper, and thus of securing sleep against interruption. External stimuli are fended off by being given a new interpretation and by being woven into some harmless situation; internal stimuli, caused by instinctual demands, are given free play by the sleeper and allowed to find satisfaction in the formation of dreams, so long as the latent dream-thoughts submit to the control of the censorship. But if they threaten to break free and the meaning of the dream becomes too plain, the sleeper cuts short the dream and wakes in a fright. (Dreams of this class are known as *anxiety-dreams*.) A similar failure in the function of dreaming occurs if an external stimulus becomes too strong to be fended off. (This is the class of *arousal-dreams.*) I have given the name of *dream-work* to the process which, with the co-operation of the censorship, converts the latent thoughts into the manifest content of the dream. It consists of a peculiar way of treating the preconscious material of thought, so that its component parts become *condensed*, its psychical emphasis becomes *displaced*, and the whole of it is translated into visual images or *dramatized*, and completed by a deceptive *secondary revision*. The dream-work is an excellent example of the processes occurring in the deeper, unconscious layers of the mind, which differ considerably from the familiar normal processes of thought. It also displays a number of archaic characteristics, such as the use of a symbolism (in this case of a predominantly sexual kind) which it has since also been possible to discover in other spheres of mental activity.

[1925d, 4220]
It is best to begin by pointing out that the formation of a dream can be provoked in two different ways. Either, on the one hand, an instinctual impulse which is ordinarily suppressed (an unconscious wish) finds enough strength during sleep to make itself felt by the ego, or, on the other hand, an urge left over from waking life, a preconscious train of thought with all the conflicting impulses attached to it, finds reinforcement during sleep from an unconscious element. In short, dreams may arise either from the id or from the ego. The mechanism of dream-formation is in both cases the same and so also is the necessary dynamic precondition. The ego gives evidence of its original derivation from the id by occasionally ceasing its functions and allowing a reversion to an earlier state of things. This is logically brought about by its breaking off its relations with the external world and withdrawing its cathexes from the sense organs. We are justified in saying that there arises at birth an instinct to return to the intra-uterine life that has been abandoned - an instinct to sleep. Sleep is a return of this kind to the womb. Since the waking ego governs motility, that function is paralysed in sleep, and accordingly a good part of the inhibitions imposed on the unconscious id become superfluous. The withdrawal or reduction of these 'anticathexes' thus allows the id what is now a harmless amount of liberty.

[1940a [1938], 4976]
Since we are now engaged in looking for sources of dreams inside the organism instead of outside it, we must bear in mind that almost all our internal organs, though they give us scarcely any news of their working so long as they are in a healthy state, become a source of what are mainly distressing sensations when they are in what we describe as states of excitation, or during illnesses. These sensations must be equated with the sensory or painful stimuli reaching us from the outside. The experience of ages is reflected in - to take an example - Strümpell's remarks on the subject (1877, 107): 'During sleep the mind attains a far deeper and wider sensory consciousness of somatic events than during the waking state. It is obliged to receive and be affected by impressions of stimuli from parts of the body and from changes in the body of which it knows nothing when awake.' So early a writer as Aristotle regarded it as quite possible that the beginnings of an illness might make themselves felt in dreams before anything could be noticed of it in waking life, owing to the magnifying effect produced upon impressions by dreams. (See above, p. 518.) Medical writers, too, who were certainly far from believing in the prophetic power of dreams, have not disputed their significance as premonitors of illness. (Cf. Simon, 1888, 31, and many earlier writers.)¹

Pronounced disorders of the internal organs obviously act as instigators of dreams in a whole number of cases. The frequency of anxiety-dreams in diseases of the heart and lungs is generally recognized. Indeed, this side of dream-life is placed in the foreground by so many authorities that I am content with a mere reference to the literature: Radestock, Spitta, Maury, Simon (1888), Tissié. Tissié is even of the opinion that the particular organ affected gives a characteristic impress to the content of the dream. Thus the dreams of those suffering from diseases of the heart are usually short and come to a terrifying end at the moment of waking; their content almost always includes a situation involving a horrible death. Sufferers from diseases of the lungs dream of suffocation, crowding and fleeing, and are remarkably subject to the familiar nightmare. (It may be remarked, incidentally, that Börner (1855) has succeeded in provoking the latter experimentally by lying on his face or covering the respiratory apertures.) In the case of digestive disorders dreams contain ideas connected with enjoyment of food or disgust. Finally, the influence of sexual excitement on the content of dreams can be adequately appreciated by everyone from his own experience and provides the theory that dreams are instigated by organic stimuli with its most powerful support.

No one, moreover, who goes through the literature of the subject can fail to notice that some writers, such as Maury and Weygandt (1893), were led to the study of dream problems by the effect of their own illnesses upon the content of their dreams.

Nevertheless, though these facts are established beyond a doubt, their importance for the study of the sources of dreams is not so great as might have been hoped. Dreams are phenomena which occur in healthy people - perhaps in everyone, perhaps every night - and it is obvious that organic illness cannot be counted among its indispensable conditions. And what we are concerned with is not the origin of certain special dreams but the source that instigates the ordinary dreams of normal people.
We have here reached the theory of the origin of dreams which is preferred by all the medical authorities. The obscurity in which the centre of our being (the 'moi splanchnique', as Tissié calls it) is veiled from our knowledge and the obscurity surrounding the origin of dreams tally too well not to be brought into relation to each other. The line of thought which regards vegetative organic sensation as the constructor of dreams has, moreover, a particular attraction for medical men since it allows of a single aetiology for dreams and mental diseases, whose manifestations have so much in common; for coenaesthetic changes and stimuli arising from the internal organs are also held largely responsible for the origin of the psychoses. It is not surprising, therefore, that the origin of the theory of somatic stimulation may be traced back to more than one independent source.

The line of argument developed by the philosopher Schopenhauer in 1851 has had a decisive influence on a number of writers. Our picture of the universe, in his view, is arrived at by our intellect taking the impressions that impinge on it from outside and remoulding them into the forms of time, space and causality. During the daytime the stimuli from the interior of the organism, from the sympathetic nervous system, exercise at the most an unconscious effect upon our mood. But at night, when we are no longer deafened by the impressions of the day, those which arise from within are able to attract attention just as at night we can hear the murmuring of a brook which is drowned by daytime noise. But how is the intellect to react to these stimuli otherwise than by carrying out its own peculiar function on them? The stimuli are accordingly remodelled into forms occupying space and time and obeying the rules of causality, and thus dreams arise. Scherner (1861) and after him Volkelt (1875) endeavoured subsequently to investigate in more detail the relation between somatic stimuli and dream-images, but I shall postpone my consideration of these attempts till we reach the section dealing with the various theories about dreams.

Krauss, the psychiatrist, in an investigation carried through with remarkable consistency, traces the origin alike of dreams and of deliria and delusions to the same factor, namely to organically determined sensations. It is scarcely possible to think of any part of the organism which might not be the starting-point of a dream or of a delusion. Organically determined sensations 'may be divided into two classes: (1) those constituting the general mood (coenaesthesia) and (2) the specific sensations immanent in the principal systems of the vegetative organism. Of these latter five groups are to be distinguished: (a) muscular, (b) respiratory, (c) gastric, (d) sexual and (e) peripheral sensations.' Krauss supposes that the process by which dream-images arise on the basis of somatic stimuli is as follows. The sensation that has been aroused evokes a cognate image, in accordance with some law of association. It combines with the image into an organic structure, to which, however, consciousness reacts abnormally. For it pays no attention to the sensation, but directs the whole of it to the accompanying images - which explains why the true facts were for so long misunderstood. Krauss has a special term for describing this process: the 'trans-substantiation' of sensations into dream-images.

The influence of organic somatic stimuli upon the formation of dreams is almost universally accepted to-day; but the question of the laws that govern the relation between them is answered in very various ways, and often by obscure pronouncements. On the basis of the theory of somatic stimulation, dream-interpretation is thus faced with the special problem of tracing back the content of a dream to the organic stimuli which caused it; and, if the rules for interpretation laid down by Scherner (1861) are not accepted, one is often faced with the awkward fact that the only thing that reveals the existence of the organic stimulus is precisely the content of the dream itself.
Simon (1888, 34 f.) has attempted to deduce some of the rules governing the way in which organic stimuli determine the resultant dreams by comparing a series of similar dreams. He asserts that if an organic apparatus which normally plays a part in the expression of an emotion is brought by some extraneous cause during sleep into the state of excitation which is usually produced by the emotion, then a dream will arise which will contain images appropriate to the emotion in question. Another rule lays it down that if during sleep an organ is in a state of activity, excitation or disturbance, the dream will produce images related to the performance of the function which is discharged by the organ concerned. Mourly Vold (1896) has set out to prove experimentally in one particular field the effect on the production of dreams which is asserted by the theory of somatic stimulation. His experiment consisted in altering the position of a sleeper's limbs and comparing the resultant dreams with the alterations made. He states his findings as follows:

[1900a, 550]

When we were dealing with the relations of dreams to waking life and with the material of dreams, we found that the most ancient and the most recent students of dreams were united in believing that men dream of what they do during the daytime and of what interests them while they are awake. Such an interest, carried over from waking life into sleep, would not only be a mental bond, a link between dreams and life, but would also provide us with a further source of dreams and one not to be despised. Indeed, taken in conjunction with the interests that develop during sleep - the stimuli that impinge on the sleeper - it might be enough to explain the origin of all dream-images. But we have also heard the opposite asserted, namely that dreams withdraw the sleeper from the interests of daytime and that, as a rule, we only start dreaming of the things that have most struck us during the day, after they have lost the spice of actuality in waking life. Thus at every step we take in our analysis of dream-life we come to feel that it is impossible to make generalizations without covering ourselves by such qualifying phrases as ‘frequently’, ‘as a rule’ or ‘in most cases’, and without being prepared to admit the validity of exceptions.

[1900a, 551]

We shall find later that the enigma of the formation of dreams can be solved by the revelation of an unsuspected psychical source of stimulation. Meanwhile we shall feel no surprise at the over-estimation of the part played in forming dreams by stimuli which do not arise from mental life. Not only are they easy to discover and even open to experimental confirmation; but the somatic view of the origin of dreams is completely in line with the prevailing trend of thought in psychiatry to-day. It is true that the dominance of the brain over the organism is asserted with apparent confidence. Nevertheless, anything that might indicate that mental life is in any way independent of demonstrable organic changes or that its manifestations are in any way spontaneous alarms the modern psychiatrist, as though a recognition of such things would inevitably bring back the days of the Philosophy of Nature, and of the metaphysical view of the nature of mind. The suspicions of the psychiatrists have put the mind, as it were, under tutelage, and they now insist that none of its impulses shall be allowed to suggest that it has any means of its own. This behaviour of theirs only shows how little trust they really have in the validity of a causal connection between the somatic and the mental. Even when investigation shows that the primary exciting cause of a phenomenon is psychical, deeper research will one day trace the path further and discover an organic basis for the mental event. But if at the moment we cannot see beyond the mental, that is no reason for denying its existence.

[1900a, 552]
The material with which dream-imagination accomplishes its artistic work is principally, according to Scherner, provided by the organic somatic stimuli which are so obscure during the daytime. (See above, p. 544 ff.) Thus the excessively fantastic hypothesis put forward by Scherner and the perhaps unduly sober doctrines of Wundt and other physiologists, which are poles asunder in other respects, are entirely at one in regard to their theory of the sources and instigators of dreams. According to the physiological view, however, the mental reaction to the internal somatic stimuli is exhausted with the provoking of certain ideas appropriate to the stimuli; these ideas give rise to others along associative lines and at this point the course of psychical events in dreams seems to be at an end. According to Scherner, on the other hand, the somatic stimuli do no more than provide the mind with material of which it can make use for its imaginative purposes. The formation of dreams only begins, in Scherner's eyes, at the point which the other writers regard as its end.

What dream-imagination does to the somatic stimuli cannot, of course, be regarded as serving any useful purpose. It plays about with them and pictures the organic sources, from which the stimuli of the dream in question have arisen, in some kind of plastic symbolism. Scherner is of the opinion - though here Volkelt and others refuse to follow him - that dream imagination has one particular favourite way of representing the organism as a whole: namely as a house. Fortunately, however, it does not seem to be restricted to this one method of representation. On the other hand, it may make use of a whole row of houses to indicate a single organ; for instance, a very long street of houses may represent a stimulus from the intestines. Again, separate portions of a house may stand for separate portions of the body; thus, in a dream caused by a headache, the head may be represented by the ceiling of a room covered with disgusting, toad-like spiders.

[1900a, 591]
It is easy to prove that dreams often reveal themselves without any disguise as fulfilsments of wishes; so that it may seem surprising that the language of dreams was not understood long ago. For instance, there is a dream that I can produce in myself as often as I like - experimentally, as it were. If I eat anchovies or olives or any other highly salted food in the evening, I develop thirst during the night which wakes me up. But my waking is preceded by a dream; and this always has the same content, namely, that I am drinking. I dream I am swallowing down water in great gulps, and it has the delicious taste that nothing can equal but a cool drink when one is parched with thirst. Then I wake up and have to have a real drink. This simple dream is occasioned by the thirst which I become aware of when I wake. The thirst gives rise to a wish to drink, and the dream shows me that wish fulfilled. In doing so it is performing a function - which it was easy to divine. I am a good sleeper and not accustomed to be woken by any physical need. If I can succeed in appeasing my thirst by dreaming that I am drinking, then I need not wake up in order to quench it. This, then, is a dream of convenience. Dreaming has taken the place of action, as it often does elsewhere in life. Unluckily my need for water to quench my thirst cannot be satisfied by a dream in the same way as my thirst for revenge against my friend Otto and Dr. M.; but the good intention is there in both cases. Not long ago this same dream of mine showed some modification. I had felt thirsty even before I fell asleep, and I had emptied a glass of water that stood on the table beside my bed. A few hours later during the night I had a fresh attack of thirst, and this had inconvenient results. In order to provide myself with some water I should have had to get up and fetch the glass standing on the table by my wife's bed. I therefore had an appropriate dream that my wife was giving me a drink out of a vase; this vase was an Etruscan cinerary urn which I had brought back from a journey to Italy and had since given away. But the water in it tasted so salty (evidently because of the ashes in the urn) that I woke up. It will be noticed how conveniently everything was arranged in this dream. Since its only purpose was to fulfil a wish, it could be completely egoistical. A love of comfort and convenience is not really compatible with consideration for other people. The introduction of the cinerary urn was probably yet another wish-fulfilment. I was sorry that the vase was no longer in my possession - just as the glass of water on my wife's table was out of my reach. The urn with its ashes fitted in, too, with the salty taste in my mouth which had now grown stronger and which I knew was bound to wake me.¹

[1900a, 623]
The fact should be mentioned that children soon begin to have more complicated and less transparent dreams, and that, on the other hand, adults in certain circumstances often have dreams of a similarly simple, infantile character. The wealth of unexpected material that may occur in the dreams of children of four or five is shown by examples in my 'Analysis of a Phobia in a Five-Year-Old Boy' (1909b) and in Jung (1910a). - For analytical interpretations of children's dreams see also von Hug-Hellmuth (1911 and 1913), Putnam (1912), van Raalte (1912), Spielrein (1913) and Tausk (1913). Children's dreams are also reported by Bianchieri (1912), Busemann (1909 and 1910), Doglia and Bianchieri (1910-11) and, in particular, Wiggam (1909), who laid stress on their trend towards wish-fulfilment. - On the other hand, dreams of an infantile type seem to occur in adults with special frequency when they find themselves in unusual external circumstances. Thus Otto Nordenskjöld (1904, 1, 336 f.) writes as follows of the members of his expedition while they were wintering in the Antarctic: 'The direction taken by our innermost thoughts was very clearly shown by our dreams, which were never more vivid or numerous than at this time. Even those of us who otherwise dreamt but rarely had long stories to tell in the morning when we exchanged our latest experiences in this world of the imagination. They were all concerned with the outside world which was now so remote from us, though they were often adapted to our actual circumstances. One of my companions had a particularly characteristic dream of being back in his school class-room, where it was his task to skin miniature seals which had been specially prepared for instructional purposes. Eating and drinking, however, were the pivot round which our dreams most often revolved. One of us, who had a special gift for attending large luncheon parties during the night, was proud if he was able to report in the morning that he had "got though a three-course dinner". Another of us dreamt of tobacco, of whole mountains of tobacco; while a third dreamt of a ship in full sail coming in across open water. Yet another dream is worth repeating. The postman brought round the mail and gave a long explanation of why we had had to wait so long for it: he had delivered it at the wrong address and had only succeeded in recovering it with great difficulty. We dreamt, of course, of still more impossible things. But there was a most striking lack of imaginativeness shown by almost all the dreams that I dreamt myself or heard described. It would certainly be of great psychological interest if all these dreams could be recorded. And it will easily be understood how much we longed for sleep, since it could offer each one of us everything that he most eagerly desired.' - According to Du Prel (1885, 231), 'Mungo Park, when he was almost dying of thirst on one of his African journeys, dreamt unceasingly of the well-watered valleys and meadows of his home. Similarly, Baron Trenck suffering torments of hunger while he was a prisoner in the fortress at Magdeburg, dreamt of being surrounded by sumptuous meals; and George Back, who took part in Franklin's first expedition, when he was almost dying of starvation as a result of his fearful privations, dreamt constantly and regularly of copious meals.'

If this sentence is taken in the sense in which it was intended, it merely shows the unconscientious manner in which critics are accustomed to perform their functions, and the readiness with which opponents overlook the clearest statements if they do not give scope to their aggressive inclinations. For only a few pages earlier I had mentioned the variety of the wishes whose fulfilments are to be found in children's dreams (wishes to take part in an excursion or a sail on a lake, or to make up for a missed meal, and so on); and in other passages I had discussed dreams of hunger, dreams stimulated by thirst or by excretory needs, and dreams of mere convenience. Even Rank himself made no absolute assertion. The words he used were 'also as a rule erotic wishes', and what he said can be amply confirmed in the dreams of most adults.
I have already discussed at length in the opening chapter (Section C) the part assigned by scientific writers to somatic sources of stimulation in the formation of dreams; so that here I need only recall the results of that enquiry. We found that three different kinds of somatic sources of stimulation were distinguished: objective sensory stimuli arising from external objects, internal states of excitation of the sense organs having only a subjective basis, and somatic stimuli derived from the interior of the body. We noticed moreover that the authorities were inclined to push into the background, or to exclude entirely, any possible psychical sources of dreams, as compared with these somatic stimuli (cf. p. 552). In our examination of the claims made on behalf of somatic sources of stimulation we arrived at the following conclusions. The significance of objective excitations of the sense organs (consisting partly of chance stimuli during sleep and partly of excitations such as cannot fail to impinge even upon a sleeping mind) is established from numerous observations and has been experimentally confirmed (cf. p. 538). The part played by subjective sensory excitations seems to be demonstrated by the recurrence in dreams of hypnagogic sensory images (cf. p. 543 f.). And lastly it appears that, though it is impossible to prove that the images and ideas occurring in our dreams can be traced back to internal somatic stimuli to the extent to which this has been asserted to be the case, nevertheless this origin finds support in the universally recognized influence exercised upon our dreams by states of excitation in our digestive, urinary and sexual organs.

This is an appropriate point at which to return to a topic that was broken off in an earlier chapter (p. 716): the problem of the part played in the formation of dreams by organic stimuli which disturb sleep. Dreams which come about under their influence openly exhibit not only the usual tendency to wish-fulfilment and to serving the end of convenience, but very often a perfectly transparent symbolism as well; for it not infrequently happens that a stimulus awakens a dreamer after a vain attempt has been made to deal with it in a dream under a symbolic disguise. This applies to dreams of emission or orgasm as well as to those provoked by a need to micturate or defaecate. 'The peculiar nature of emission dreams not only puts us in a position to reveal directly certain sexual symbols which are already known as being typical, but which have nevertheless been violently disputed; it also enables us to convince ourselves that some apparently innocent situations in dreams are no more than a symbolic prelude to crudely sexual scenes. The latter are as a rule represented undisguisedly in the relatively rare emission dreams, whereas they culminate often enough in anxiety dreams, which have the same result of awakening the sleeper.'

The symbolism of dreams with a urinary stimulus is especially transparent and has been recognized from the earliest times. The view was already expressed by Hippocrates that dreams of fountains and springs indicate a disorder of the bladder (Havelock Ellis). Scherner studied the multiplicity of the symbolism of urinary stimuli and asserted that 'any urinary stimulus of considerable strength invariably passes over into stimulation of the sexual regions and symbolic representations of them. . . . Dreams with a urinary stimulus are often at the same time representatives of sexual dreams.'

Otto Rank, whose discussion in his paper on the stratification of symbols in arousal dreams I am here following, has made it seem highly probable that a great number of dreams with a urinary stimulus have in fact been caused by a sexual stimulus which has made a first attempt to find satisfaction regressively in the infantile form of urethral erotism. Those cases are particularly instructive in which the urinary stimulus thus set up leads to awakening and emptying the bladder, but in which the dream is nevertheless continued and the need then expressed in undisguisedly erotic imagery.
If we cast our minds over the dreams that are at our disposal for answering this question, we shall at once be reminded that we must add a fourth source of dream-wishes, namely the current wishful impulses that arise during the night (e.g. those stimulated by thirst or sexual needs). In the next place, we shall form the opinion that the place of origin of a dream-wish probably has no influence on its capacity for instigating dreams. I may recall the little girl's dream which prolonged a trip on the lake that had been interrupted during the day and the other children's dreams which I have recorded. They were explained as being due to unfulfilled, but unsuppressed, wishes from the previous day. Instances of a wish that has been suppressed in the daytime finding its way out in a dream are exceedingly numerous. I will add a further very simple example of this class. The dreamer was a lady who was rather fond of making fun of people and one of whose friends, a woman younger than herself, had just become engaged. All day long she had been asked by her acquaintances whether she knew the young man and what she thought of him. She had replied with nothing but praises, with which she had silenced her real judgement; for she would have liked to tell the truth - that he was a 'Dutzendmensch' [literally a 'dozen man', a very commonplace sort of person - people like him are turned out by the dozen]. She dreamt that night that she was asked the same question, and replied with the formula: 'In the case of repeat orders it is sufficient to quote the number.'

We have learnt, lastly, from numerous analyses that wherever a dream has undergone distortion the wish has arisen from the unconscious and was one which could not be perceived during the day. Thus it seems at a first glance as though all wishes are of equal importance and equal power in dreams.

Internal organic sensations, which have commonly been taken as a cardinal point in explanations of dreaming, have retained a place, though a humbler one, in our theory. Such sensations - sensations of falling, for instance, or floating, or being inhibited - provide a material which is accessible at any time and of which the dream-work makes use, whenever it has need of it, for expressing the dream-thoughts.

Numerous examples of dreams of this infantile type can be found occurring in adults as well, though, as I have said, they are usually brief in content. Thus a number of people regularly respond to a stimulus of thirst during the night with dreams of drinking, which thus endeavour to get rid of the stimulus and enable sleep to continue. In some people 'dreams of convenience' of this kind often occur before waking, when the necessity for getting up presents itself. They dream that they are already up and at the washing-stand, or that they are already at the school or office where they are due at some particular time. During the night before a journey we not infrequently dream of having arrived at our destination; so too, before a visit to the theatre or a party, a dream will often anticipate the pleasure that lies ahead - out of impatience, as it were. In other dreams the wish-fulfilment is expressed a stage more indirectly: some connection or implication must be established - that is, the work of interpretation must be begun - before the wish-fulfilment can be recognized. A man told me, for instance, that his young wife had had a dream that her period had started. I reflected that if this young woman had missed her period she must have known that she was faced with a pregnancy. Thus when she reported her dream she was announcing her pregnancy, and the meaning of the dream was to represent as fulfilled her wish that the pregnancy might be postponed for a while. Under unusual or extreme conditions dreams of this infantile character are particularly common. Thus the leader of a polar expedition has recorded that the members of his expedition, while they were wintering in the ice-field and living on a monotonous diet and short rations, regularly dreamt like children of large meals, of mountains of tobacco, and of being back at home.
The so-called 'day's residues' can act as disturbers of sleep and constructors of dreams; they are affectively cathected thought-processes from the dream-day, which have resisted the general lowering through sleep. These day's residues are uncovered by tracing back the manifest dream to the latent dream-thoughts; they constitute portions of the latter and are thus among the activities of waking life - whether conscious or unconscious - which have been able to persist into the period of sleep. In accordance with the multiplicity of thought-processes in the conscious and preconscious, these day's residues have the most numerous and varied meanings: they may be wishes or fears that have not been disposed of, or intentions, reflections, warnings, attempts at adaptation to current tasks, and so on. To this extent the classification of dreams that is under consideration seems to be justified by the content which is uncovered by interpretation. These day's residues, however, are not the dream itself: they lack the main essential of a dream. Of themselves they are not able to construct a dream. They are, strictly speaking, only the psychical material for the dream-work, just as sensory and somatic stimuli, whether accidental or produced under experimental conditions, constitute the somatic material for the dream-work. To attribute to them the main part in the construction of dreams is simply to repeat at a new point the pre-analytic error which explained dreams by referring them to bad digestion or to pressure on the skin. Scientific errors, indeed, are tenacious of life, and even when they have been refuted are ready to creep in again under new disguises.

[1913a, 2590]

The explanation of parapraxes owes its theoretical value to the ease with which they can be solved and their frequency in normal people. But the success of psycho-analysis in explaining them is far surpassed in importance by a further achievement made by it, relating to another phenomenon of normal mental life. What I have in mind is the interpretation of dreams, which brought psycho-analysis for the first time into the conflict with official science which was to be its destiny. Medical research explains dreams as purely somatic phenomena, without meaning or significance, and regards them as the reaction of a mental organ sunk in a state of sleep to physical stimuli which partially awaken it. Psycho-analysis raises the status of dreams into that of psychical acts possessing meaning and purpose, and having a place in the subject's mental life, and thus disregards their strangeness, incoherence and absurdity. On this view somatic stimuli merely play the part of material that is worked over in the course of the construction of the dream. There is no half-way house between these two views of dreams. What argues against the physiological hypothesis is its unfruitfulness, and what may be argued in favour of the psycho-analytic one is the fact that it has translated and given a meaning to thousands of dreams and has used them to throw light on the intimate details of the human mind.

[1913j, 2806]

In what way, however, can a case arise in which the intention to sleep meets with an interruption? The interruption may proceed from an internal excitation or from an external stimulus. Let us first consider the more obscure and more interesting case of interruption from within. Observation shows that dreams are instigated by residues from the previous day - thought-cathexes which have not submitted to the general withdrawal of cathexes, but have retained in spite of it a certain amount of libidinal or other interest. Thus the narcissism of sleep has from the outset had to admit an exception at this point, and it is here that the formation of dreams takes its start. In analysis we make the acquaintance of these 'day's residues' in the shape of latent dream-thoughts; and, both by reason of their nature and of the whole situation, we must regard them as preconscious ideas, as belonging to the system Pcs.

[1917d, 3029]
There is no need to give up this theory entirely on that account. Moreover it is capable of extension. It is obviously a matter of indifference what it is that disturbs sleep or instigates the mind to dream. If it cannot invariably be a sensory stimulus coming from outside, there may instead be what is called a somatic stimulus, arising from the internal organs. This is a very plausible notion and agrees with the most popular view of the origin of dreams: 'dreams come from indigestion,' people often say. Here too unluckily we must often suspect that there are cases when a somatic stimulus which has impinged on a sleeper during the night is no longer manifest after waking and can therefore not be proved to have occurred. But we shall not overlook the number of clear experiences which support the origin of dreams from somatic stimuli. In general, there can be no doubt that the condition of the internal organs can influence dreams. The relation of the content of some dreams to an over full bladder or to a state of excitation of the genital organs is too plain to be mistaken. These clear cases lead to others in which the content of the dreams give rise to a justifiable suspicion that there has been an impact from somatic stimuli because there is something in the content which can be regarded as a working over, a representation or an interpretation of such stimuli. Scherner (1861), who made researches into dreams, argued particularly strongly in favour of the derivation of dreams from organic stimuli and brought forward some good examples of it. For instance, in one dream he saw 'two rows of pretty boys with fair hair and delicate complexions facing one another in pugnacious array, making an onset and attacking one another, and then drawing back and taking up their old position again, and then starting the whole business once more.' His interpretation of these two rows of boys as teeth is plausible in itself and seems fully confirmed when we learn that after this scene the dreamer 'pulled a long tooth out of his jaw.' Similarly, the interpretation of 'long, narrow, winding passages' as derived from an intestinal stimulus seems valid, and confirms the assertion by Scherner that dreams seek above all to represent the organ that sends out the stimulus by objects resembling it.

Thus we must be prepared to admit that internal stimuli can play the same part in dreams as external ones. Any estimate of their importance is unfortunately open to the same objections. In a large number of cases an interpretation pointing to a somatic stimulus is uncertain or unprovable. Not all dreams, but only a certain number of them give rise to a suspicion that internal organic stimuli had a share in their origin. And lastly, internal somatic stimuli are as little able as external sensory stimuli to explain more of a dream than what corresponds in it to a direct reaction to the stimulus. Where the rest of the dream comes from remains obscure.

(4) A child's dream is a reaction to an experience of the previous day, which has left behind it a regret, a longing, a wish that has not been dealt with. The dream produces a direct, undisguised fulfillment of that wish. Let us recall now our discussions on the part played by somatic stimuli from outside and from within as disturbers of sleep and instigators of dreams. In that connection we came to know some quite undoubted facts, but by their means we were only able to explain a small number of dreams. In these children's dreams, however, there is nothing that points to the operation of somatic stimuli of that kind; we could not be mistaken in this, for the dreams are completely intelligible and easy to grasp. But this does not mean that we need abandon the stimulus aetiology of dreams. We can only ask how it has happened that from the first we have forgotten that besides somatic stimuli there are mental stimuli that disturb sleep. We know, after all, that it is excitations of this kind that are chiefly responsible for disturbing the sleep of an adult by preventing him from establishing the mood required for falling asleep - the withdrawing of interest from the world. He does not want to interrupt his life but would rather continue his work on the things he is concerned with, and for that reason he does not fall asleep. In the case of children, therefore, the stimulus that disturbs sleep is a mental one - the wish that has not been dealt with - and it is to this that they react with the dream.
In any case, there is yet another class of dreams which are undistorted and, like children's dreams, can easily be recognized as wish-fulfilments. These are the dreams which all through life are called up by imperative bodily needs - hunger, thirst, sexual need - that is, they are wish-fulfilments as reactions to internal somatic stimuli. Thus I have a note of a dream dreamt by a little girl of nineteen months, which consisted of a menu, to which her own name was attached: 'Anna F., stawbewwies, wild stawbewwies, omblet, pudden.' This was a reaction to a day without food, owing to a digestive upset, which had actually been traced back to the fruit which appeared twice in the dream. The little girl's grandmother - their combined ages came to seventy years - was simultaneously obliged to go without food for a whole day on account of a disturbance due to a floating kidney. She dreamt the same night that she had been 'asked out' and had been served with the most appetizing delicacies.

Observations on prisoners who have been compelled to starve, and on people who have been subjected to privations on travels and explorations, teach us that under these conditions the satisfaction of their needs is regularly dreamt of. Thus Otto Nordenskjöld (1904, 1, 336 f.) writes as follows of the members of his expedition while they were wintering in the Antarctic: 'The direction taken by our innermost thoughts was very clearly shown by our dreams, which were never more vivid or numerous than at this time. Even those of us who otherwise dreamt but rarely had long stories to tell in the morning when we exchanged our latest experiences in this world of the imagination. They were all concerned with the outside world which was now so remote from us, though they were often adapted to our actual circumstances. . . . Eating and drinking, however, were the pivot round which our dreams most often revolved. One of us, who had a special gift for attending large luncheon parties during the night, was proud if he was able to report in the morning that he had "got through a three-course dinner". Another of us dreamt of tobacco, of whole mountains of tobacco; while a third dreamt of a ship in full sail coming in across open water. Yet another dream is worth repeating. The postman brought round the mail and gave a long explanation of why we had had to wait so long for it: he had delivered it at the wrong address and had only succeeded in recovering it with great difficulty. We dreamt, of course, of still more impossible things. But there was a most striking lack of imaginativeness shown by almost all the dreams I dreamt myself or heard described. It would certainly be of great psychological interest if all these dreams could be recorded. And it will easily be understood how much we longed for sleep, since it could offer each one of us everything that he most eagerly desired.' So too, according to Du Prel, 'Mungo Park, when he was almost dying of thirst on one of his African journeys, dreamt unceasingly of the well-watered valleys and meadows of his home. Similarly, Baron Trenck, suffering torments of hunger while he was a prisoner in the fortress at Magdeburg, dreamt of being surrounded by sumptuous meals; and George Back, who took part in Franklin's first expedition, when he was almost dying of starvation as a result of his fearful privations, dreamt constantly and regularly of copious meals.'

Anyone who has eaten some highly-spiced dish at dinner and develops a thirst during the night is very likely to dream that he is drinking. It is of course impossible to get rid of a fairly strong need for food or drink by means of a dream. One wakes up from a dream of this sort still feeling thirsty, and has to have a drink of real water. The effect produced by the dream is in this instance trivial from the practical point of view; but it is none the less clear that it was produced with the aim of protecting one's sleep against a stimulus that was urging one to wake up and take action. When the need is of less intensity dreams of satisfaction often help one to get over it.
In the same way, dreams create satisfactions under the influence of sexual stimuli, but these show peculiarities which deserve mention. Since it is characteristic of the sexual instinct to be a degree less dependent on its object than hunger and thirst, the satisfaction in dreams of emission can be a real one; and in consequence of certain difficulties (which I shall have to mention later) in its relation to its object, it happens with special frequency that the real satisfaction is nevertheless attached to a dream-content which is obscure or distorted. This characteristic of dreams of emission (as Otto Rank has pointed out) makes them particularly favourable subjects for the study of dream-distortion. Furthermore, all adult dreams arising from bodily needs usually contain, in addition to the satisfaction, other material which is derived from purely psychical sources of stimulation and requires interpretation before it can be understood. 
[1916-1917, 3229]

Moreover I do not mean to assert that the wish-fulfilment dreams of adults which are constructed on infantile lines only appear as reactions to the imperative needs that I have mentioned. We are acquainted as well with short, clear dreams of this sort which, under the influence of some dominant situation, arise out of what are unquestionably psychical sources of stimulation. There are, for instance, dreams of impatience: if someone has made preparations for a journey, for a theatrical performance that is important to him, for going to a lecture or paying a visit, he may dream of a premature fulfilment of his expectation; he may, during the night before the event, see himself arrived at his destination, present at the theatre, in conversation with the person he is going to visit. Or there are what are justly known as dreams of convenience, in which a person who would like to sleep longer dreams that he is already up and is washing, or is already at school, whereas he is really still sleeping and would rather get up in a dream than in reality. The wish to sleep, which we have recognized as regularly playing a part in the construction of dreams, comes into the open in these dreams and reveals itself in them as the essential dream-constructor. There is good reason for ranking the need to sleep alongside of the other great bodily needs. 
[1916-1917, 3229]

I feel sure that you have heard some time or other that it is asserted by psycho-analysis that every dream has a sexual meaning. Well, you yourselves are in a position to form a judgement of the incorrectness of this reproach. You have become acquainted with wishful dreams dealing with the satisfaction of the most obvious needs - hunger and thirst and the longing for freedom - with dreams of convenience and of impatience, and also with purely covetous and egoistic dreams. But at the same time you should bear in mind, as one of the results of psycho-analytic research, that greatly distorted dreams give expression mainly (though, again, not exclusively) to sexual wishes. 
[1916-1917, 3283]
The analysis of dreams led further: it was brought to public notice by the present writer as early as in 1900 in *The Interpretation of Dreams*. This showed that dreams are constructed in just the same way as neurotic symptoms. Like them, they may appear strange and senseless; but, if we examine them by a technique which differs little from the free association used in psycho-analysis, we are led from their manifest content to a secret meaning, to the latent dream-thoughts. This latent meaning is always a wishful impulse which is represented as fulfilled at the moment of the dream. But, except in young children and under the pressure of imperative physical needs, this secret wish can never be expressed recognizably. It has first to submit to a distortion, which is the work of restrictive, censoring forces in the dreamer's ego. In this way the manifest dream, as it is remembered in waking life, comes about. It is distorted, to the pitch of being unrecognizable, by concessions made to the dream-censorship; but it can be revealed once more by analysis as an expression of a situation of satisfaction or as the fulfillment of a wish. It is a compromise between two conflicting groups of mental trends, just as we have found to be the case with hysterical symptoms. The formula which, at bottom, best meets the essence of the dream is this: a dream is a (disguised) fulfilment of a (repressed) wish. The study of the process which transforms the latent dream-wish into the manifest content of the dream - a process known as the 'dream-work' - has taught us the best part of what we know of unconscious mental life.

We have explained that the unconscious instinctual impulse of the dream connects itself with a residue of the day, with some interest of waking life which has not been disposed of; it thus gives the dream which it constructs a double value for the work of analysis. For on the one hand a dream that has been analysed reveals itself as the fulfilment of a repressed wish; but on the other hand it may be a continuation of some preconscious activity of the day before and may contain every kind of subject-matter and give expression to an intention, a warning, a reflection, or once more to the fulfilment of a wish. Analysis exploits the dream in both directions, as a means of obtaining knowledge alike of the patient's conscious and of his unconscious processes. It also profits from the fact that dreams have access to the forgotten material of childhood, and so it happens that infantile amnesia is for the most part overcome in connection with the interpretation of dreams. In this respect dreams achieve a part of what was previously the task of hypnotism. On the other hand, I have never maintained the assertion which has so often been ascribed to me that dream-interpretation shows that all dreams have a sexual content or are derived from sexual motive forces. It is easy to see that hunger, thirst, or the need to excrete, can produce dreams of satisfaction just as well as any repressed sexual or egoistic impulse. The case of young children affords us a convenient test of the validity of our theory of dreams. In them the various psychical systems are not yet sharply divided and the repressions have not yet grown deep, so that we often come upon dreams which are nothing more than undisguised fulfilments of wishful impulses left over from waking life. Under the influence of imperative needs, adults may also produce dreams of this infantile type.¹

¹[1925d, 4221]
It remains for us to give a dynamic explanation of why the sleeping ego takes on the task of the dream-work at all. The explanation is fortunately easy to find. With the help of the unconscious, every dream that is in process of formation makes a demand upon the ego - for the satisfaction of an instinct, if the dream originates from the id; for the solution of a conflict, the removal of a doubt or the forming of an intention, if the dream originates from a residue of preconscious activity in waking life. The sleeping ego, however, is focused on the wish to maintain sleep; it feels this demand as a disturbance and seeks to get rid of the disturbance. The ego succeeds in doing this by what appears to be an act of compliance: it meets the demand with what is in the circumstances a harmless fulfilment of a wish and so gets rid of it. This replacement of the demand by the fulfilment of a wish remains the essential function of the dream-work. It may perhaps be worth while to illustrate this by three simple examples - a hunger dream, a dream of convenience and a dream prompted by sexual desire. A need for food makes itself felt in a dreamer during his sleep: he has a dream of a delicious meal and sleeps on. The choice, of course, was open to him either of waking up and eating something or of continuing his sleep. He decided in favour of the latter and satisfied his hunger by means of the dream - for the time being, at all events, for if his hunger had persisted he would have had to wake up nevertheless. Here is the second example. A sleeper had to wake up so as to be in time for his work at the hospital. But he slept on, and had a dream that he was already at the hospital - but as a patient, who has no need to get up. Or again, a desire becomes active during the night for the enjoyment of a forbidden sexual object, the wife of a friend of the sleeper. He has a dream of sexual intercourse - not, indeed, with this person but with someone else of the same name to whom he is in fact indifferent; or his struggle against the desire may find expression in his mistress remaining altogether anonymous.

[1940a [1938], 4980]
In spite of any objections to the contrary, it has to be admitted that the part played by objective sensory excitation during sleep in provoking dreams remains indisputable. And if such stimuli may appear, from their nature and frequency, insufficient to explain every dream-image, we shall be encouraged to seek for other sources of dreams analogous to them in their operation. I cannot say when the idea first cropped up of taking internal (subjective) excitations of the sense organs into account alongside of the external sensory stimuli. It is, however, the case that this is done, more or less explicitly, in all the more recent discussions of the aetiology of dreams. 'An essential part is also played, I believe', writes Wundt (1874, 657), 'in the production of the illusions that occur in dreams by the subjective visual and auditory sensations which are familiar to us in the waking state as the formless areas of luminosity which become visible to us when our field of vision is darkened, as ringing or buzzing in the ears, and so on. Especially important among these are the subjective excitations of the retina. It is in this way that is to be explained the remarkable tendency of dreams to conjure up before the eyes similar or identical objects in large numbers. We see before us innumerable birds or butterflies or fishes or coloured beads or flowers, etc. Here the luminous dust in the darkened field of vision has taken on a fantastic shape, and the numerous specks of which it consists are incorporated into the dream as an equal number of separate images; and these, on account of their mobility, are regarded as moving objects. -This is no doubt also the basis of the great fondness shown by dreams for animal figures of every sort; for the immense variety of such forms can adjust itself easily to the particular form assumed by the subjective luminous images.'

As sources of dream-images, subjective sensory excitation have the obvious advantage of not being dependent, like objective ones, upon external chance. They are ready to hand, as one might say, whenever they are needed as an explanation. But they are at a disadvantage compared with objective sensory stimuli in that the part they play in instigating a dream is scarcely or not at all open to confirmation, as is the case with objective stimuli, by observation and experiment. The chief evidence in favour of the power of subjective sensory excitations to instigate dreams is provided by what are known as 'hypnagogic hallucinations', or, to use Johannes Müller's term (1826), 'imaginative visual phenomena'. These are images, often very vivid and rapidly changing, which are apt to appear - quite habitually, in some people - during the period of falling asleep; and they may also persist for a time after the eyes have been opened. Maury, who was subject to them in a high degree, has made an exhaustive examination of them and maintains (as did Müller before him) their connection and indeed their identity with dream-images. In order to produce them, he says (Maury, 1878, 59 f.), a certain amount of mental passivity, a relaxation of the strain of attention, is necessary. It is enough, however, to fall into a lethargic state of this kind for no more than a second (provided that one has the necessary predisposition) in order to have a hypnagogic hallucination. After this one may perhaps wake up again and the process may be repeated several times until one finally falls asleep. Maury found that if he then woke up once more after not too long an interval, he was able to detect in his dream the same images that had floated before his eyes as hypnagogic hallucinations before he fell asleep. (Ibid., 134 f.) This was the case on one occasion with a number of grotesque figures with distorted faces and strange coiffures which pestered him with extreme pertinacity while he was going to sleep and which he remembered having dreamt about after he woke. Another time, when he was suffering from hunger owing to having put himself on a light diet, he had a hypnagogic vision of a plate and a hand armed with a fork which was helping itself to some of the food from the plate. In the dream which followed he was sitting at a well spread table and heard the noise made by the diners with their forks. Yet another time, when he went to sleep with his eyes in an irritated and painful state, he had a hypnagogic hallucination of some microscopically small signs which he could only decipher one by one with the greatest difficulty; he was woken from his sleep an hour later and remembered a dream in which here was an open book printed in very small type which he was reading painfully.

[1900a, 543]
Auditory hallucinations of words, names, and so on can also occur hypnagogically in the same way as visual images, and may then be repeated in a dream - just as an overture announces the principal themes which are to be heard in the opera that is to follow.

A more recent observer of hypnagogic hallucinations, G. Trumbull Ladd (1892), has followed the same lines as Müller and Maury. After some practice he succeeded in being able to wake himself suddenly without opening his eyes, from two to five minutes after gradually falling asleep. He thus had an opportunity of comparing the retinal sensations which were just disappearing with the dream-images persisting in his memory. He declares that it was possible in every case to recognize an internal relation between the two, for the luminous points and lines of the idioretinal light provided, as it were, an outline drawing or diagram of the figures mentally perceived in the dream. For instance, an arrangement of the luminous points in the retina in parallel lines corresponded to a dream in which he had been seeing, clearly spread out in front of him, some lines of print which he was engaged in reading. Or, to use his own words, 'the clearly printed page which I was reading in my dream faded away into an object that appeared to my waking consciousness like a section of an actual page of print when seen through an oval hole in a piece of paper at too great a distance to distinguish more than an occasional fragment of a word, and even that dimly.' Ladd is of opinion (though he does not underestimate the part played in the phenomenon by central factors) that scarcely a single visual dream, occurs without the participation of material provided by intraocular retinal excitation. This applies especially to dreams occurring soon after falling asleep in a dark room, while the source of stimulus for dreams occurring in the morning shortly before waking is the objective light which penetrates the eyes in a room that is growing light. The changing, perpetually shifting character of the excitation of the idioretinal light corresponds precisely to the constantly moving succession of images shown us by our dreams. No one who attaches importance to these observations of Ladd's will underestimate the part played in dreams by these subjective sources of stimulation, for, as we know, visual images constitute the principal component of our dreams. The contributions from the other senses, except for that of hearing, are intermittent and of less importance.

This dream was a reaction to a digestive disturbance that day, which made me consider whether I should go to one of my colleagues to have a dietary prescribed for me. My reason for choosing Oser for that purpose, who had died in the course of the summer, went back to the death of another University teacher whom I greatly admired, which had occurred shortly before (on October 1st). When had Oser died? and when had I heard of his death? According to a paragraph in the papers he had died on August 22nd. I had been in Holland at that time and had my Vienna newspaper sent on to me regularly; so that I must have read of his death on August 24th or 25th. But here the interval no longer corresponds to either period. It amounts to $7 + 30 + 2 = 39$ days or possibly 40 days. I could not recall having spoken or thought of Oser in the meantime.
I have already discussed at length in the opening chapter (Section C) the part assigned by scientific writers to somatic sources of stimulation in the formation of dreams; so that here I need only recall the results of that enquiry. We found that three different kinds of somatic sources of stimulation were distinguished: objective sensory stimuli arising from external objects, internal states of excitation of the sense organs having only a subjective basis, and somatic stimuli derived from the interior of the body. We noticed moreover that the authorities were inclined to push into the background, or to exclude entirely, any possible psychical sources of dreams, as compared with these somatic stimuli (cf. p. 552). In our examination of the claims made on behalf of somatic sources of stimulation we arrived at the following conclusions. The significance of objective excitations of the sense organs (consisting partly of chance stimuli during sleep and partly of excitations such as cannot fail to impinge even upon a sleeping mind) is established from numerous observations and has been experimentally confirmed (cf. p. 538). The part played by subjective sensory excitations seems to be demonstrated by the recurrence in dreams of hypnagogic sensory images (cf. p. 543 f.). And lastly it appears that, though it is impossible to prove that the images and ideas occurring in our dreams can be traced back to internal somatic stimuli to the extent to which this has been asserted to be the case, nevertheless this origin finds support in the universally recognized influence exercised upon our dreams by states of excitation in our digestive, urinary and sexual organs.

[1900a, 700]

However secure the supporters of this theory might feel in its factual basis - especially as far as accidental and external nervous stimuli are concerned, since these can be traced in the content of dreams without any trouble at all - not one of them could fail to perceive that it is impossible to attribute the wealth of ideational material in dreams to external nervous stimuli alone. Miss Mary Whiton Calkins (1893, 312) examined her own and another person's dreams for six weeks with this question in mind. She found that in only 13.2 per cent and 6.7 per cent of them respectively was it possible to trace the element of external sense-perception; while only two cases in the collection were derivable from organic sensations. Here we have statistical confirmation of what I had been led to suspect from a hasty survey of my own experiences. [1900a, 701]
This indication of the way in which infantile scenes (or their reproductions as phantasies) function in a sense as models for the content of dreams, removes the necessity for one of the hypotheses put forward by Scherner and his followers in regard to internal sources of stimulation. Scherner supposes that, when dreams exhibit particularly vivid or particularly copious visual elements, there is present a state of 'visual stimulation', that is, of internal excitation in the organ of vision. We need not dispute this hypothesis, but can content ourselves with assuming that this state of excitation applies merely to the psychical perceptual system of the visual organ; we may, however, further point out that the state of excitation has been set up by a memory, that it is a revival of a visual excitation which was originally an immediate one. I cannot produce any good example from my own experience of an infantile memory producing this kind of result. My dreams are in general less rich in sensory elements than I am led to suppose is the case in other people. But in the case of my most vivid and beautiful dream of the last few years I was easily able to trace back the hallucinatory clarity of the dream's content to the sensory qualities of recent or fairly recent impressions. On p. 907 ff. I recorded a dream in which the deep blue colour of the water, the brown of the smoke coming from the ship's funnels, and the dark brown and red of the buildings left behind a profound impression on me. This dream, if any, should be traceable, to a visual stimulus. What was it that had brought my visual organ into this state of stimulation? A recent impression, which attached itself to a number of earlier ones. The colours which I saw were in the first instance those of a box of toy bricks with which, on the day before the dream, my children had put up a fine building and shown it off for my admiration. The big bricks were of the same dark red and the small ones were of the same blue and brown. This was associated with colour impressions from my last travels in Italy: the beautiful blue of the Isonzo and the lagoons and the brown of the Carso. The beauty of the colours in the dream was only a repetition of something seen in my memory.

[1900a, 979]

It has naturally not occurred to us to throw any doubt on the significance, which has been experimentally demonstrated, of external sensory stimuli during sleep; but we have shown that such material stands in the same relation to the dream-wish as do the residues of thought left over from day time activity. Nor have we seen any reason to dispute the view that dreams interpret objective sensory stimuli just as illusions do; but we have found the motive which provides the reason for that interpretation, a reason which has been left unspecified by other writers. Interpretation is carried out in such a way that the object perceived shall not interrupt sleep and shall be usable for purposes of wish-fulfilment. As regards subjective states of excitation in the sense organs during sleep, the occurrence of which seems to have been proved by Trumbull Ladd, it is true that we have not accepted them as a particular source of dreams; but we have been able to explain them as resulting from the regressive revival of memories that are in operation behind the dream.

[1900a, 1016]
(4) A child's dream is a reaction to an experience of the previous day, which has left behind it a regret, a longing, a wish that has not been dealt with. The dream produces a direct, undisguised fulfilment of that wish. Let us recall now our discussions on the part played by somatic stimuli from outside and from within as disturbers of sleep and instigators of dreams. In that connection we came to know some quite undoubted facts, but by their means we were only able to explain a small number of dreams. In these children's dreams, however, there is nothing that points to the operation of somatic stimuli of that kind; we could not be mistaken in this, for the dreams are completely intelligible and easy to grasp. But this does not mean that we need abandon the stimulus aetiology of dreams. We can only ask how it has happened that from the first we have forgotten that besides somatic stimuli there are mental stimuli that disturb sleep. We know, after all, that it is excitations of this kind that are chiefly responsible for disturbing the sleep of an adult by preventing him from establishing the mood required for falling asleep - the withdrawing of interest from the world. He does not want to interrupt his life but would rather continue his work on the things he is concerned with, and for that reason he does not fall asleep. In the case of children, therefore, the stimulus that disturbs sleep is a mental one - the wish that has not been dealt with - and it is to this that they react with the dream.

[1916-1917, 3223]

(7) On the basis of these characteristics of dreams, we can return once more to a comparison between a dream and a parapraxis. In the latter we distinguished between a disturbing purpose and a disturbed one, and the parapraxis was a compromise between them. A dream can be fitted into the same pattern. The disturbed purpose can only be that of sleeping. We may replace the disturbing one by the psychical stimulus, or let us say by the wish which presses to be dealt with, since we have not learnt so far of any other psychical stimulus that disturbs sleep. Here the dream, too, is the result of a compromise. One sleeps, but one nevertheless experiences the removing of a wish; one satisfies a wish, but at the same time one continues to sleep. Both purposes are partly achieved and partly abandoned.

[1916-1917, 3225]

Moreover I do not mean to assert that the wish-fulfilment dreams of adults which are constructed on infantile lines only appear as reactions to the imperative needs that I have mentioned. We are acquainted as well with short, clear dreams of this sort which, under the influence of some dominant situation, arise out of what are unquestionably psychical sources of stimulation. There are, for instance, dreams of impatience: if someone has made preparations for a journey, for a theatrical performance that is important to him, for going to a lecture or paying a visit, he may dream of a premature fulfilment of his expectation; he may, during the night before the event, see himself arrived at his destination, present at the theatre, in conversation with the person he is going to visit. Or there are what are justly known as dreams of convenience, in which a person who would like to sleep longer dreams that he is already up and is washing, or is already at school, whereas he is really still sleeping and would rather get up in a dream than in reality. The wish to sleep, which we have recognized as regularly playing a part in the construction of dreams, comes into the open in these dreams and reveals itself in them as the essential dream-structor. There is good reason for ranking the need to sleep alongside of the other great bodily needs.

[1916-1917, 3229]
In all dreams other than children's dreams and those of an infantile type our path is, as I have said, obstructed by dream distortion. We cannot tell, to begin with, whether these other dreams too are wish-fulfilments as we suspect, we cannot guess from their manifest content to what psychical stimulus they owe their origin, and we cannot prove that they too are endeavouring to get rid of that stimulus or in some way deal with it. They must be interpreted - that is, translated -, their distortion must be undone, and their manifest content replaced by their latent one, before we can form a judgement as to whether what we have found in infantile dreams can claim to be valid for all dreams.

[1916-1917, 3231]

Here we are presented with a means of answering the question of whether dreams have a function too, whether they are entrusted with any useful achievement. The condition of rest free from stimulus, which the state of sleep wishes to establish, is threatened from three directions: in a relatively accidental manner by external stimuli during sleep, and by interests of the previous day which cannot be broken off, and in an unavoidable manner by unsated repressed instinctual impulses which are on the watch for an opportunity of finding expression. In consequence of the diminishing of repressions at night there would be a risk that the rest afforded by sleep would be interrupted whenever an instigation from outside or from inside succeeded in linking up with an unconscious instinctual source. The process of dreaming allows the product of a collaboration of this kind to find an outlet in a harmless hallucinatory experience and in that way assures a continuation of sleep. The fact that a dream occasionally awakens the sleeper, to the accompaniment of a generation of anxiety, is no contradiction of this function but rather, perhaps, a signal that the watchman regards the situation as too dangerous and no longer feels able to control it. And very often then, while we are still asleep, a consolation occurs to us which seeks to prevent our waking up: 'But after all it's only a dream!'

[1933a, 4630]
The fact was that I could not forget the hint which seemed to be conveyed by the ambiguous words already noticed - *that it might be necessary to leave the room; that an accident might happen in the night*. Added to this was the fact that the elucidation of the dream seemed to me incomplete so long as a particular requirement remained unsatisfied; for, though I do not wish to insist that this requirement is a universal one, I have a predilection for discovering a means of satisfying it. A regularly formed dream stands, as it were, upon two legs, one of which is in contact with the main and current exciting cause, and the other with some momentous event in the years of childhood. The dream sets up a connection between those two factors - the event during childhood and the event of the present day - and it endeavours to re-shape the present on the model of the remote past. For the wish which creates the dream always springs from the period of childhood; and it is continually trying to summon childhood back into reality and to correct the present day by the measure of childhood. I believed that I could already clearly detect those elements of Dora's dream which could be pieced together into an allusion to an event in childhood.

[1905e, 1408]
When we were dealing with the relations of dreams to waking life and with the material of dreams, we found that the most ancient and the most recent students of dreams were united in believing that men dream of what they do during the daytime and of what interests them while they are awake. Such an interest, carried over from waking life into sleep, would not only be a mental bond, a link between dreams and life, but would also provide us with a further source of dreams and one not to be despised. Indeed, taken in conjunction with the interests that develop during sleep - the stimuli that impinge on the sleeper - it might be enough to explain the origin of all dream-images. But we have also heard the opposite asserted, namely that dreams withdraw the sleeper from the interests of daytime and that, as a rule, we only start dreaming of the things that have most struck us during the day, after they have lost the spice of actuality in waking life. Thus at every step we take in our analysis of dream-life we come to feel that it is impossible to make generalizations without covering ourselves by such qualifying phrases as ‘frequently’, ‘as a rule’ or ‘in most cases’, and without being prepared to admit the validity of exceptions.

If it were a fact that waking interests, along with internal and external stimuli during sleep, sufficed to exhaust the aetiology of dreams, we ought to be in a position to give a satisfactory account of the origin of every element of a dream: the riddle of the sources of dreams would be solved, and it would only remain to define the share taken respectively by psychical and somatic stimuli in any particular dream. Actually no such complete explanation of a dream has ever yet been achieved, and anyone who has attempted it has found portions (and usually very numerous portions) of the dream regarding whose origin he could find nothing to say. Daytime interests are clearly not such far-reaching psychical sources of dreams as might have been expected from the categorical assertions that everyone continues to carry on his daily business in his dreams.

This dream has one advantage over many others. It was immediately clear what events of the previous day provided its starting-point. My preamble makes that plain. The news which Otto had given me of Irma's condition and the case history which I had been engaged in writing till far into the night continued to occupy my mental activity even after I was asleep. Nevertheless, no one who had only read the preamble and the content of the dream itself could have the slightest notion of what the dream meant. I myself had no notion. I was astonished at the symptoms of which Irma complained to me in the dream, since they were not the same as those for which I had treated her. I smiled at the senseless idea of an injection of propionic acid and at Dr. M.'s consoling reflections. Towards its end the dream seemed to me to be more obscure and compressed than it was at the beginning. In order to discover the meaning of all this it was necessary to undertake a detailed analysis.
I have now completed the interpretation of the dream.¹ While I was carrying it out I had some difficulty in keeping at bay all the ideas which were bound to be provoked by a comparison between the content of the dream and the concealed thoughts lying behind it. And in the meantime the 'meaning' of the dream was borne in upon me. I became aware of an intention which was carried into effect by the dream and which must have been my motive for dreaming it. The dream fulfilled certain wishes which were started in me by the events of the previous evening (the news given me by Otto and my writing out of the case history). The conclusion of the dream, that is to say, was that I was not responsible for the persistence of Irma's pains, but that Otto was. Otto had in fact annoyed me by his remarks about Irma's incomplete cure, and the dream gave me my revenge by throwing the reproach back on to him. The dream acquitted me of the responsibility for Irma's condition by showing that it was due to other factors - it produced a whole series of reasons. The dream represented a particular state of affairs as I should have wished it to be. Thus its content was the fulfilment of a wish and its motive was a wish.

[1900a, 618]

A similar dream of another woman patient had a different explanation. When she was young she had been remarkable for her ready wit and cheerful disposition; and these characteristics were still to be seen, at all events in the ideas that occurred to her during the treatment. In the course of a longish dream, this lady imagined that she saw her only fifteen-year-old daughter lying dead 'in a case.' She had half a mind to use the scene as an objection to the wish-fulfilment theory, though she herself suspected that the detail of the 'case' must point the way to another view of the dream.¹ In the course of the analysis she recalled that at a party the evening before there had been some talk about the English word 'box' and the various ways in which it could be translated into German - such as 'Schachtel', 'Loge', 'Kasten', 'Ohrfeige', and so on. Other portions of the same dream enabled us to discover further that she had guessed that the English 'box' was related to the German 'Büchse', and that she had then been plagued by a recollection that 'Büchse' is used as a vulgar term for the female genitals. If some allowance was made for the limits of her knowledge of topographical anatomy, it might be presumed, therefore, that the child lying in the case meant an embryo in the womb. After being enlightened up to this point, she no longer denied that the dream-picture corresponded to a wish of hers. Like so many young married women, she had been far from pleased when she became pregnant; and more than once she had allowed herself to wish that the child in her womb might die. Indeed, in a fit of rage after a violent scene with her husband, she had beaten with her fists on her body so as to hit the child inside it. Thus the dead child was in fact the fulfilment of a wish, but of a wish that had been put aside fifteen years earlier. It is scarcely to be wondered at if a wish that was fulfilled after such a long delay was not recognized. Too much had changed in the interval.

[1900a, 649]

If I examine my own experience on the subject of the origin of the elements included in the content of dreams, I must begin with an assertion that in every dream it is possible to find a point of contact with the experiences of the previous day. This view is confirmed by every dream that I look into, whether my own or anyone else's. Bearing this fact in mind, I am able, on occasion, to begin a dream's interpretation by looking for the event of the previous day which set it in motion; in many instances, indeed, this is the easiest method. In the two dreams which I have analysed in detail in my last chapters (the dream of Irma's injection and the dream of my uncle with a yellow beard) the connection with the previous day is so obvious as to require no further comment. But in order to show the regularity with which such a connection can be traced, I will go through the records of my own dreams and give some instances. I shall only quote enough of the dream to indicate the source we are looking for:

[1900a, 656]
When had I last seen a portrait of Savonarola? My travel-diary proved that I had been in Florence on September 4th and 5th. While I was there I thought I would show my travelling companion the medallion bearing the fanatical monk's features, let into the pavement of the Piazza della Signoria, which marks the place where he was burned. I pointed it out to him, I believe, on the morning of the 3rd. Between this impression and its reappearance in the dream 27 + 1 days elapsed - Fliess's 'female period'. Unluckily for the conclusiveness of this example, however, I must add that on the actual 'dream-day' I had a visit (for the first time since my return) from a capable but gloomy-looking medical colleague of mine whom I had many years before nick-named 'Rabbi Savonarola'. He introduced a patient to me who was suffering from the effects of an accident to the Pontebba express, in which I myself had travelled a week earlier, and my thoughts were thus led back to my recent visit to Italy. The appearance in the content of the dream of the outstanding element 'Savonarola' is thus accounted for by my colleague's visit on the dream-day; and the interval of 28 days is deprived of its significance.

Unfortunately, when we go into the interpretation of this dream in greater detail, we once again find that the coincidence loses some of its conclusiveness. The exciting cause of the dream was the news I received on the dream-day that the clinic, in whose lecture room I was able by courtesy to deliver my lectures, was shortly to be removed to another locality. I took it for granted that its new situation would be very out of the way and told myself that in that case I might just as well not have a lecture room at my disposal at all. From that point my thoughts must have gone back to the beginning of my career as University Lecturer when I in fact had no lecture room and when my efforts to get hold of one met with little response from the powerfully placed Hofrats and Professors. In those circumstances I had gone to L., who at that time held the office of Dean of the Faculty and who I believed was friendly disposed to me, to complain of my troubles. He promised to help me, but I heard nothing more from him. In the dream he was Archimedes, giving me a που σὺ ψηλά [footing] and himself leading me to the new locality. Anyone who is an adept at interpretation will guess that the dream-thoughts were not exactly free from ideas of vengeance and self-importance. It seems clear, in any case, that without this exciting cause Archimedes would scarcely have found his way into my dream that night; nor am I convinced that the powerful and still recent impression made on me by the statue in Syracuse might not have produced its effect after some different interval of time.

I believe, then, that the instigating agent of every dream is to be found among the experiences which one has not yet 'slept on'. Thus the relations of a dream's content to impressions of the most recent past (with the single exception of the day immediately preceding the night of the dream) differ in no respect from its relations to impressions dating from any remoter period. Dreams can select their material from any part of the dreamer's life, provided only that there is a train of thought linking the experience of the dream-day (the 'recent' impressions) with the earlier ones.

My thoughts then went on to the occasion when I had last been reminded of this business of the cocaine. It had been a few days earlier, when I had been looking at a copy of a Festschrift in which grateful pupils had celebrated the jubilee of their teacher and laboratory director. Among the laboratory's claims to distinction which were enumerated in this book I had seen a mention of the fact that Koller had made his discovery there of the anaesthetic properties of cocaine. I then suddenly perceived that my dream was connected with an event of the previous evening. I had walked home precisely with Dr. Königstein and had got into conversation with him about a matter which never fails to excite my feelings whenever it is raised. While I was talking to him in the entrance-hall, Professor Gärtner and his wife had joined us; and I could not help congratulating them both on their blooming looks. But Professor Gärtner was one of the authors of the Festschrift I have just mentioned, and may well have reminded me of it. Moreover, the Frau L., whose disappointment on her birthday I described earlier, was mentioned - though only, it is true, in another connection - in my conversation with Dr. Königstein.
For reasons with which we are not concerned, I shall not pursue the interpretation of this dream any further, but will merely indicate the direction in which it lay. In the course of the work of analysis I was reminded of my conversation with Dr. Königstein, and I was brought to it from more than one direction. When I take into account the topics touched upon in that conversation, the meaning of the dream becomes intelligible to me. All the trains of thought starting from the dream - the thoughts about my wife's and my own favourite flowers, about cocaine, about the awkwardness of medical treatment among colleagues, about my preference for studying monographs and about my neglect of certain branches of science such as botany - all of these trains of thought, when they were further pursued, led ultimately to one or other of the many ramifications of my conversation with Dr. Königstein. Once again the dream, like the one we first analysed - the dream of Irma's injection - turns out to have been in the nature of a self-justification, a plea on behalf of my own rights. Indeed, it carried the subject that was raised in the earlier dream a stage further and discussed it with reference to fresh material that had arisen in the interval between the two dreams. Even the apparently indifferent form in which the dream was couched turns out to have had significance. What it meant was: 'After all, I'm the man who wrote the valuable and memorable paper (on cocaine),' just as in the earlier dream I had said on my behalf: 'I'm a conscientious and hard-working student.' In both cases what I was insisting was: 'I may allow myself to do this.' There is, however, no need for me to carry the interpretation of the dream any further, since my only purpose in reporting it was to illustrate by an example the relation between the content of a dream and the experience of the previous day which provoked it. So long as I was aware only of the dream's manifest content, it appeared to be related only to a single event of the dream-day. But when the analysis was carried out, a second source of the dream emerged in another experience of the same day. The first of these two impressions with which the dream was connected was an indifferent one, a subsidiary circumstance: I had seen a book in a shop-window whose title attracted my attention for a moment but whose subject-matter could scarcely be of interest to me. The second experience had a high degree of psychical importance: I had had a good hour's lively conversation with my friend the eye-surgeon; in the course of it I had given him some information which was bound to affect both of us closely, and I had had memories stirred up in me which had drawn my attention to a great variety of internal stresses in my own mind. Moreover, the conversation had been interrupted before its conclusion because we had been joined by acquaintances.

[1900a, 661]
The following observations may help us towards clearing up this point. If in the course of a single day we have two or more experiences suitable for provoking a dream, the dream will make a combined reference to them as a single whole; *it is under a necessity to combine them into a unity*. Here is an instance. One afternoon during the summer I entered a railway compartment in which I found two acquaintances who were strangers to each other. One of them was an eminent medical colleague and the other was a member of a distinguished family with which I had professional relations. I introduced the two gentlemen to each other, but all through the long journey they conducted their conversation with me as a go-between, so that I presently found myself discussing various topics alternately, first with the one and then with the other. I asked my doctor friend to use his influence on behalf of a common acquaintance of ours who was just starting a medical practice. The doctor replied that he was convinced of the young man's capacity, but that his homely appearance would make it hard for him to make his way in families of the better class; to which I replied that that was the very reason why he needed influential assistance. Turning to my other fellow-traveller, I enquired after the health of his aunt - the mother of one of my patients - who was lying seriously ill at the time. During the night following the journey I had a dream that the young friend on whose behalf I had pleaded was sitting in a fashionable drawing-room in a select company composed of all the distinguished and wealthy people of my acquaintance and, with the easy bearing of a man of the world, was delivering a funeral oration on the old lady (who was already dead so far as my dream was concerned), the aunt of my second fellow-traveller. (I must confess that I had not been on good terms with that lady.) Thus my dream had, once again, worked out connections between the two sets of impressions of the previous day and had combined them into a single situation.

The dream's connection with the previous day was quite straightforward. She had actually gone to the market too late and had got nothing. The situation seemed to shape itself into the phrase *Die Flieschbank war schon geschloossen*. I pulled myself up: was not that, or rather its opposite, a vulgar description of a certain sort of slovenliness in a man's dress? However, the dreamer herself did not use the phrase; she may perhaps have avoided using it. Let us endeavour, then, to arrive at an interpretation of the details of the dream.

Yet again the occasion for the dream was a real event. The day before she had actually put a candle into a candlestick, though it did not break. Some transparent symbolism was being used in this dream. A candle is an object which can excite the female genitals; and, if it is broken, so that it cannot stand up properly, it means that the man is impotent. (*It was not her fault.*) But could a carefully brought-up young woman, who had been screened from the impact of anything ugly, have known that a candle might be put to such a use? As it happened, she was able to indicate how it was that she obtained this piece of knowledge. Once when they were in a rowing boat on the Rhine, another boat had passed them with some students in it. They were in high spirits and were singing, or rather shouting, a song:
The element in this dream which stood out most was the botanical monograph. This arose from the impressions of the dream day: I had in fact seen a monograph on the genus Cyclamen in the window of a book-shop. There was no mention of this genus in the content of the dream; all that was left in it was the monograph and its relation to botany. The 'botanical monograph' immediately revealed its connection with the work upon cocaine which I had once written. From 'cocaine' the chains of thought led on the one hand to the Festschrift and to certain events in a University laboratory, and on the other hand to my friend Dr. Königstein, the eye surgeon, who had had a share in the introduction of cocaine. The figure of Dr. Königstein further reminded me of the interrupted conversation which I had had with him the evening before and of my various reflections upon the payment for medical services among colleagues. This conversation was the actual currently active instigator of the dream; the monograph on the cyclamen was also a currently active impression, but one of an indifferent nature. As I perceived, the 'botanical monograph' in the dream turned out to be an 'intermediate common entity' between the two experiences of the previous day: it was taken over unaltered from the indifferent impression and was linked with the psychically significant event by copious associative connections.

[1900a, 755]

ANALYSIS. - Her husband was temporarily away from home, and her fourteen-year-old daughter was sleeping in the bed beside her. The evening before, the girl had drawn her attention to a moth which had fallen into her tumbler of water; but she had not taken it out and felt sorry for the poor creature next morning. The book she had been reading during the evening had told how some boys had thrown a cat into boiling water, and had described the animal's convulsions. These were the two precipitating causes of the dream - in themselves indifferent. She then pursued the subject of cruelty to animals further. Some years before, while they were spending the summer at a particular place, her daughter had been very cruel to animals. She was collecting butterflies and asked the patient for some arsenic to kill them with. On one occasion a moth with a pin through its body had gone on flying about the room for a long time; another time some caterpillars which the child was keeping to turn into chrysalises starved to death. At a still more tender age the same child used to tear the wings off beetles and butterflies. But to-day she would be horrified at all these cruel actions she had grown so kind-hearted.

[1900a, 762]

The evening before the dream she had been rummaging among some old letters and had read some of them - some serious and some comic - aloud to her children. There had been a most amusing letter from a piano-teacher who had courted her when she was a girl, and another from an admirer of noble birth.¹

[1900a, 763]

It will be seen that the indifferent exciting cause of the dream only covers one element of it. That episode only obtained any importance from the fact that the dreamer put it in the same series as an earlier experience which, though equally indifferent in itself, was given a substitutive meaning by his imagination. When he was a boy, living with his father, he had upset a glass of water over the floor while he was half-asleep. The flex of the house-telephone had been soaked through and its continuous ringing had disturbed his father's sleep. Since the continuous ringing corresponded to getting wet, the 'detached rings' were used to represent drops falling. The word 'tutelrein' could be analysed in three directions, and led in that way to three of the subjects represented in the dream-thoughts. 'Tutel' is a legal term for 'guardianship' ['tutelage']. 'Tutel' (or possibly 'Tuttel') is also a vulgar term for a woman's breast. The remaining portion of the word, 'rein' ['clean'], combined with the first part of 'Zimmertelegraph' ['house-telephone'], forms 'zimmerrein' ['house-trained'] - which is closely connected with making the floor wet, and, in addition, sounded very much like the name of a member of the dreamer's family.¹

[1900a, 770]
In a confused dream of my own of some length, whose central point seemed to be a sea voyage, it appeared that the next stopping place was called 'Hearsing' and the next after that 'Fliess.' This last word was the name of my friend, who has often been the goal of my travels. 'Hearsing' was a compound. One part of it was derived from the names of places on the suburban railway near Vienna, which so often end in 'ing': Hietzing, Liesing, Mödling (Medelitz, 'meae deliciae', was its old name - that is 'meine Freud' ['my delight']). The other part was derived from the English word 'hearsay.' This suggested slander and established the dream's connection with its indifferent instigator of the previous day: a poem in the periodical Fliegende Blätter about a slanderous dwarf called 'Sagter Hatergesagt' ['He-says Says-he']. If the syllable 'ing' were to be added to the name 'Fliess' we should get 'Vlissingen', which was in fact the stopping-place on the sea voyage made by my brother whenever he visited us from England. But the English name for Vlissingen is 'Flushing', which in English means 'blushing' and reminded me of the patients I have treated for ereutophobia, and also of a recent paper on that neurosis by Bechterew which had caused me some annoyance.

[1900a, 771]

¹ In the complete analysis there was a reference to an event in my childhood, reached by the following chain of association. 'Der Mohr hat seine Schuldigkeit getan, der Mohr kann gehen.' ['The Moor has done his duty, the Moor can go.'] Then came a facetious conundrum: 'How old was the Moor when he had done his duty?' - 'One year old, because then he could go ['gehen' - both 'to go' and 'to walk']. (It appears that I came into the world with such a tangle of black hair that my young mother declared I was a little Moor.) - My not being able to find my hat was an occurrence from waking life which was used in more than one sense. Our housemaid, who was a genius at putting things away, had hidden it. - The end of this dream also concealed a rejection of some melancholy thoughts about death: 'I am far from having done my duty, so I must not go yet.' - Birth and death were dealt with in it, just as they had been in the dream of Goethe and the paralytic patient, which I had dreamt a short time before. (See pp. 797, 886 ff.)

[1900a, 806]

We may next ask where the wishes that come true in dreams originate. What contrasting possibilities or what alternatives have we in mind in raising this question? It is the contrast, I think, between the consciously perceived life of daytime and a psychical activity which has remained unconscious and of which we can only become aware at night. I can distinguish three possible origins for such a wish. (1) It may have been aroused during the day and for external reasons may not have been satisfied; in that case an acknowledged wish which has not been dealt with is left over for the night. (2) It may have arisen during the day but been repudiated; in that case what is left over is a wish which has not been dealt with but has been suppressed. (3) It may have no connection with daytime life and be one of those wishes which only emerge from the suppressed part of the mind and become active in us at night. If we turn again to our schematic picture of the psychical apparatus, we shall localize wishes of the first kind in the system Pcs.; we shall suppose that wishes of the second kind have been driven out of the system Pcs. into the Ucs., where, if at all, they continue to exist; and we shall conclude that wishful impulses of the third kind are altogether incapable of passing beyond the system Ucs. The question then arises whether wishes derived from these different sources are of equal importance for dreams and have equal power to instigate them.

[1900a, 983]
I cannot offer any proof here that the truth is nevertheless otherwise; but I may say that I am strongly inclined to suppose that dream-wishes are more strictly determined. It is true that children's dreams prove beyond a doubt that a wish that has not been dealt with during the day can act as a dream-instigator. But it must not be forgotten that it is a child's wish, a wishful impulse of the strength proper to children. I think it is highly doubtful whether in the case of an adult a wish that has not been fulfilled during the day would be strong enough to produce a dream. It seems to me, on the contrary, that, with the progressive control exercised upon our instinctual life by our thought-activity, we are more and more inclined to renounce as unprofitable the formation or retention of such intense wishes as children know. It is possible that there are individual differences in this respect, and that some people retain an infantile type of mental process longer than others, just as there are similar differences in regard to the diminution of visual imagery, which is so vivid in early years. But in general, I think, a wish that has been left over unfulfilled from the previous day is insufficient to produce a dream in the case of an adult. I readily admit that a wishful impulse originating in the conscious will contribute to the instigation of a dream, but it will probably not do more than that. The dream would not materialize if the preconscious wish did not succeed in finding reinforcement from elsewhere. [1900a, 984]

In my view, therefore, wishful impulses left over from conscious waking life must be relegated to a secondary position in respect to the formation of dreams. I cannot allow that, as contributors to the content of dreams, they play any other part than by the material of sensations which become currently active during sleep. (See pp. 707-708.) I shall follow the same line of thought in now turning to consider those psychical instigations to dreaming, left over from waking life, which are other than wishes. When we decide to go to sleep, we may succeed in temporarily bringing to an end the cathexes of energy attaching to our waking thoughts. Anyone who can do this easily is a good sleeper; the first Napoleon seems to have been a model of this class. But we do not always succeed in doing so, nor do we always succeed completely. Unsolved problems, tormenting worries, overwhelming impressions - all these carry thought-activity over into sleep and sustain mental processes in the system that we have named the preconscious. If we wish to classify the thought-impulses which persist in sleep, we may divide them into the following groups: (1) what has not been carried to a conclusion during the day owing to some chance hindrance; (2) what has not been dealt with owing to the insufficiency of our intellectual power - what is unsolved; (3) what has been rejected and suppressed during the daytime. To these we must add (4) a powerful group consisting of what has been set in action in our Ucs. by the activity of the preconscious in the course of the day; and finally (5) the group of daytime impressions which are indifferent and have for that reason not been dealt with. [1900a, 986]
There is no need to underestimate the importance of the psychical intensities which are introduced into the state of sleep by these residues of daytime life, and particularly of those in the group of unsolved problems. It is certain that these excitations continue to struggle for expression during the night; and we may assume with equal certainty that the state of sleep makes it impossible for the excitatory process to be pursued in the habitual manner in the preconscious and brought to an end by becoming conscious. In so far as our thought-processes are able to become conscious in the normal way at night, we are simply not asleep. I am unable to say what modification in the system $Pcs.$ is brought about by the state of sleep;¹ but there can be no doubt that the psychological characteristics of sleep are to be looked for essentially in modifications in the cathexis of this particular system - a system that is also in control of access to the power of movement, which is paralysed during sleep. On the other hand, nothing in the psychology of dreams gives me reason to suppose that sleep produces any modifications other than secondary ones in the state of things prevailing in the $Ucs.$ No other course, then, lies open to excitations occurring at night in the $Pcs.$ than that followed by wishful excitations arising from the $Ucs.$; the preconscious excitations must find reinforcement from the $Ucs.$ and must accompany the unconscious excitations along their circuitous paths. But what is the relation of the preconscious residues of the previous day to dreams? There is no doubt that they find their way into dreams in great quantity, and that they make use of the content of dreams in order to penetrate into consciousness even during the night. Indeed they occasionally dominate the content of a dream and force it to carry on the activity of daytime. It is certain, too, that the day's residues may be of any other character just as easily as wishes; but it is highly instructive in this connection, and of positively decisive importance for the theory of wish-fulfilment, to observe the condition to which they must submit in order to be received into a dream.

¹[1900a, 987]

I will report a dream of my own in order to illustrate what I have just said, and in particular the way in which the dream-work deals with a residue of distressing anticipations from the previous day.

¶[1900a, 991]

I am now in a position to give a precise account of the part played in dreams by the unconscious wish. I am ready to admit that there is a whole class of dreams the instigation to which arises principally or even exclusively from the residues of daytime life; and I think that even my wish that I might at long last become a Professor Extraordinarius might have allowed me to sleep through the night in peace if my worry over my friend's health had not still persisted from the previous day. But the worry alone could not have made a dream. The motive force which the dream required had to be provided by a wish; it was the business of the worry to get hold of a wish to act as the motive force of the dream.

¶[1900a, 992]
Though the preceding considerations have reduced the importance of the part played by the
day's residues in dreams, it is worth while devoting a little more attention to them. It must be that
they are essential ingredients in the formation of dreams, since experience has revealed the
surprising fact that in the content of every dream some link with a recent daytime impression -
often of the most insignificant sort - is to be detected. We have not hitherto been able to explain
the necessity for this addition to the mixture that constitutes a dream (see p. 669). And it is only
possible to do so if we bear firmly in mind the part played by the unconscious wish and then
seek for information from the psychology of the neuroses. We learn from the latter that an
unconscious idea is as such quite incapable of entering the preconscious and that it can only
exercise any effect there by establishing a connection with an idea which already belongs to the
preconscious, by transferring its intensity on to it and by getting itself 'covered' by it. Here we
have the fact of 'transference', which provides an explanation of so many striking phenomena in
the mental life of neurotics. The preconscious idea, which thus acquires an undeserved degree
of intensity may either be left unaltered by the transference, or it may have a modification forced
upon it, derived from the content of the idea which effects the transference. I hope I may be
forgiven for drawing analogies from everyday life, but I am tempted to say that the position of a
repressed idea resembles that of an American dentist in this country: he is not allowed to set up
in practice unless he can make use of a legally qualified medical practitioner to serve as a
stalking-horse and to act as a 'cover' in the eyes of the law. And just as it is not exactly the
physicians with the largest practices who form alliances of this kind with dentists, so in the same
way preconscious or conscious ideas which have already attracted a sufficient amount of the
attention that is operating in the preconscious will not be the ones to be chosen to act as covers
for a repressed idea. The unconscious prefers to weave its connections round preconscious
impressions and ideas which are either indifferent and have thus had no attention paid to them,
or have been rejected and have thus had attention promptly withdrawn from them. It is a familiar
article in the doctrine of association, and one that is entirely confirmed by experience, that an
idea which is bound by a very intimate tie in one direction, tends, as it were, to repel whole
groups of new ties. I once attempted to base a theory of hysterical paralyses on this proposition.
[1900a, 993]

I have only one thing more to add about the day's residues. There can be no doubt that it is
they that are the true disturbers of sleep and not dreams, which, on the contrary are concerned
to guard it. I shall return to this point later.
[1900a, 994]

We have so far been studying dream-wishes: we have traced them from their origin in the
region of the Ucs. and have analysed their relations to the day's residues, which in their turn
may either be wishes or psychical impulses of some other kind or simply recent impressions. In
this way we have allowed room for every claim that may be raised by any of the multifarious
waking thought-activities on behalf of the importance of the part played by them in the process
of constructing dreams. It is not impossible, even, that our account may have provided an
explanation of the extreme cases in which a dream, pursuing the activities of daytime, arrives at
a happy solution of some unsolved problem of waking life. All we need is an example of this
kind, so that we might analyse it and trace the source of the infantile or repressed wishes whose
help has been enlisted and has reinforced the efforts of preconscious activity with such
success. But all this has not brought us a step nearer to solving the riddle of why it is that the
unconscious has nothing else to offer during sleep but the motive force for the fulfilment of a
wish. The answer to this question must throw light upon the psychical nature of wishes, and I
propose to give the answer by reference to our schematic picture of the psychical apparatus.
[1900a, 994]
The situation is this. Either residues of the previous day have been left over from the activity of waking life and it has not been possible to withdraw the whole cathexis of energy from them; or the activity of waking life during the course of the day has led to the stirring up of an unconscious wish; or these two events have happened to coincide. (We have already discussed the various possibilities in this connection.) The unconscious wish links itself up with the day’s residues and effects a transference on to them; this may happen either in the course of the day or not until a state of sleep has been established. A wish now arises which has been transferred on to the recent material; or a recent wish, having been suppressed, gains fresh life by being reinforced from the unconscious. This wish seeks to force its way along the normal path taken by thought processes, though the Pcs. (to which, indeed, it in part belongs) to consciousness. But it comes up against the censorship, which is still functioning and to the influence of which it now submits. At this point it takes on the distortion for which the way has already been paved by the transference of the wish on to recent material. So far it is on the way to becoming an obsessive idea or a delusion or something of the kind - that is, a thought which has been intensified by transference and distorted in its expression by censorship. Its further advance is halted, however, by the sleeping state of the preconscious. (The probability is that that system has protected itself against the invasion by diminishing its own excitations.) The dream-process consequently enters on a regressive path, which lies open to it precisely owing to the peculiar nature of the state of sleep, and it is led along that path by the attraction exercised on it by groups of memories; some of these memories themselves exist only in the form of visual cathexes and not as translations into the terminology of the later systems. In the course of its regressive path the dream-process acquires the attribute of representability. (I shall deal later with the question of compression.) It has now completed the second portion of its zigzag journey. The first portion was a progressive one, leading from the unconscious scenes or phantasies to the preconscious; the second portion led from the frontier of the censorship back again to perceptions. But when the content of the dream process has become perceptual, by that fact it has, as it were, found a way of evading the obstacle put in its way by the censorship and the state of sleep in the Pcs. It succeeds in drawing attention to itself and in being noticed by consciousness.

[1900a, 1002]

The view that dreams carry on the occupations and interests of waking life has been entirely confirmed by the discovery of the concealed dream-thoughts. These are only concerned with what seems important to us and interests us greatly. Dreams are never occupied with minor details. But we have also found reason for accepting the contrary view, that dreams pick up indifferent refuse left over from the previous day and that they cannot get control of any major day time interest until it has been to some extent withdrawn from waking activity. We have found that this holds good of the dream’s content, which gives expression to the dream-thoughts in a form modified by distortion. For reasons connected with the mechanism of association, as we have seen, the dream-process finds it easier to get control of recent or indifferent ideational material which has not yet been requisitioned by waking thought-activity; and for reasons of censorship it transfers psychical intensity from what is important but objectionable on to what is indifferent.

[1900a, 1016]
Now that the old antithesis between conscious life and dream life has been reduced to its proper proportions by the establishment of unconscious psychical reality, a number of dream-problems with which earlier writers were deeply concerned have lost their significance. Thus some of the activities whose successful performance in dreams excited astonishment are now no longer to be attributed to dreams but to unconscious thinking, which is active during the day no less than at night. If, as Scherner has said, dreams appear to engage in making symbolic representations of the body, we now know that those representations are the product of certain unconscious phantasies (deriving, probably, from sexual impulses) which find expression not only in dreams but also in hysterical phobias and other symptoms. If a dream carries on the activities of the day and completes them and even brings valuable fresh ideas to light, all we need do is to strip it of the dream disguise, which is the product of dream-work and the mark of assistance rendered by obscure forces from the depths of the mind (cf. the Devil in Tartini's sonata dream); the intellectual achievement is due to the same mental forces which produce every similar result during the daytime. We are probably inclined greatly to over-estimate the conscious character of intellectual and artistic production as well. Accounts given us by some of the most highly productive men, such as Goethe and Helmholtz, show rather that what is essential and new in their creations came to them without premeditation and as an almost ready-made whole. There is nothing strange if in other cases, where a concentration of every intellectual faculty was needed, conscious activity also contributed its share. But it is the much-abused privilege of conscious activity, wherever it plays a part, to conceal every other activity from our eyes.

Two other things are already clear. The content of the dream is very much shorter than the thoughts for which I regard it as a substitute; and analysis has revealed that the instigator of the dream was an unimportant event of the evening before I dreamt it.

This small collection throws a direct light on a further characteristic of children's dreams: their connection with daytime life. The wishes which are fulfilled in them are carried over from daytime and as a rule from the day before, and in waking life they have been accompanied by intense emotion. Nothing unimportant or indifferent, or nothing which would strike a child as such, finds its way into the content of their dreams.

Analysis does away with the misleading appearance upon which this derogatory judgement is founded. If the content of a dream puts forward some indifferent impression as being its instigator, analysis invariably brings to light a significant experience, and one by which the dreamer has good reason to be stirred. This experience has been replaced by the indifferent one, with which it is connected by copious associative links. Where the content of the dream treats of insignificant and uninteresting ideational material, analysis uncovers the numerous associative paths connecting these trivialities with things that are of the highest psychical importance in the dreamer's estimation. If what makes their way into the content of dreams are impressions and material which are indifferent and trivial rather than justifiably stirring and interesting, that is only the effect of the process of displacement. If we answer our questions about dream-instigators and the connection between dreaming and daily affairs on the basis of the new insight we have gained from replacing the manifest by the latent content of dreams, we arrive at these conclusions: dreams are never concerned with things with which we should not think it worth while to be concerned during the day, and trivialities which do no affect us during the day are unable to pursue us in our sleep.
The indifferent impression which becomes a dream-instigator owing to associations of this kind is subject to a further condition which does not apply to the true source of the dream: it must always be a recent impression, derived from the dream-day.

(III) A lady who, though she was still young, had been married for a number of years, received news that an acquaintance of hers, Fräulein Elise L., who was almost exactly her contemporary, had become engaged. This was the precipitating cause of the following dream:

A girl had a dream of seeing her sister's only surviving child lying dead in the same surroundings in which a few years earlier she had in fact seen the dead body of her sister's first child. She felt no pain over this; but she naturally rejected the idea that this situation represented any wish of hers. Nor was there any need to suppose this. It had been beside the first child's coffin, however, that, years before, she had seen and spoken to the man she was in love with; if the second child died, she would no doubt meet the man again in her sister's house. She longed for such a meeting, but fought against the feeling. On the dream-day she had bought a ticket for a lecture which was to be given by this same man, to whom she was still devoted. Her dream was a simple dream of impatience of the kind that often occurs before journeys, visits to the theatre, and similar enjoyments that lie ahead. But in order to disguise this longing from her, the situation was displaced on to an event of a kind most unsuitable for producing a feeling of enjoyment, though it had in fact done so in the past. It is to be observed that the emotional behaviour in the dream was appropriate to the real content which lay in the background and not to what was pushed into the foreground. The dream-situation anticipated the meeting she had so long desired; it offered no basis for any painful feelings.

Her first reply was that she did not know, but after a while she added: 'Yes. I think it was after the scene.'

I have made one or two observations in my *Interpretation of Dreams* on the relation between the waking thoughts which are continued into sleep (the 'day's residues') and the unconscious wish which forms the dream. I will quote them here as they stand, for I have nothing to add to them, and the analysis of this dream of Dora's proves afresh that the facts are as I have supposed: 'I am ready to admit that there is a whole class of dreams the instigation to which arises principally or even exclusively from the residues of daytime life; and I think that even my wish that I might at long last become a Professor Extraordinarius' might have allowed me to sleep through the night in peace if my worry over my friend's health had not still persisted from the previous day. But the worry alone could not have made a dream. The motive force which the dream required had to be provided by a wish; it was the business of the worry to get hold of a wish to act as the motive force of the dream.
'The position may be explained by an analogy. A daytime thought may very well play the part of \textit{entrepreneur} for a dream; but the \textit{entrepreneur}, who, as people say, has the idea and the initiative to carry it out, can do nothing without capital; he needs a \textit{capitalist} who can afford the outlay, and the capitalist who provides the psychical outlay for the dream is invariably and indisputably, whatever may be the thoughts of the previous day, a \textit{wish from the unconscious}.'

[1905e, 1423]

The wandering about in a strange town was overdetermined. It led back to one of the exciting causes from the day before. A young cousin of Dora's had come to stay with them for the holidays, and Dora had had to show him round Vienna. This cause was, it is true, a matter of complete indifference to her. But her cousin's visit reminded her of her own first brief visit to Dresden. On that occasion she had been a stranger and had wandered about, not failing, of course, to visit the famous picture gallery. Another cousin of hers, who was with them and knew Dresden, had wanted to act as a guide and take her round the gallery. \textit{But she declined and went alone}, and stopped in front of the pictures that appealed to her. She remained \textit{two hours} in front of the Sistine Madonna, rapt in silent admiration. When I asked her what had pleased her so much about the picture she could find no clear answer to make. At last she said: 'The Madonna.'

[1905e, 1432]

\textit{She asked quite a hundred times}. . . . This led to another exciting cause of the dream, and this time to one that was less indifferent. On the previous evening they had had company, and afterwards her father had asked her to fetch him the brandy: he could not get to sleep unless he had taken some brandy. She had asked her mother for the key of the sideboard; but the latter had been deep in conversation, and had not answered her, until Dora had exclaimed with the exaggeration of impatience: 'I've asked you a hundred times already where the key is.' As a matter of fact, she had of course only repeated the question about \textit{five times}.

[1905e, 1433]

Dora went on to say that during this same family gathering some one had toasted her father and had expressed the hope that he might continue to enjoy the best of health for many years to come, etc. At this a strange quiver passed over her father's tired face, and she had understood what thoughts he was having to keep down. Poor sick man! who could tell what span of life was still to be his?

[1905e, 1433]

So here we were back again at the scene by the lake and at the problems connected with it. I asked Dora to describe the scene to me in detail. At first she produced little that was new. Herr K.'s exordium had been somewhat serious; but she had not let him finish what he had to say. No sooner had she grasped the purport of his words than she had slapped him in the face and hurried away. I enquired what his actual words had been. Dora could only remember one of his pleas: 'You know I get nothing out of my wife.' In order to avoid meeting him again she had wanted to get back to L-- on foot, by walking round the lake, and \textit{she had asked a man whom she met how far it was}. On his replying that it was \textit{Two and a half hours}, she had given up her intention and had after all gone back to the boat, which left soon afterwards. Herr K. had been there too and had come up to her and begged her to forgive him and not to mention the incident. But she had made no reply. - Yes. The wood in the dream had been just like the wood by the shore of the lake, the wood in which the scene she had just described once more had taken place. But she had seen precisely the same thick wood the day before, in a picture at the Secessionist exhibition. In the background of the picture there were \textit{nymphs}.

[1905e, 1434]
The phantasies of the pubertal period have as their starting-point the infantile sexual researches that were abandoned in childhood. No doubt, too, they are also present before the end of the latency period. They may persist wholly, or to a great extent, unconsciously and for that reason it is often impossible to date them accurately. They are of great importance in the origin of many symptoms, since they precisely constitute preliminary stages of these symptoms and thus lay down the forms in which the repressed libidinal components find satisfaction. In the same way, they are the prototypes of the nocturnal phantasies which become conscious as dreams. Dreams are often nothing more than revivals of pubertal phantasies of this kind under the influence of, and in relation to, some stimulus left over from the waking life of the previous day (the 'day's residues'). Some among the sexual phantasies of the pubertal period are especially prominent, and are distinguished by their very general occurrence and by being to a great extent independent of individual experience. Such are the adolescent's phantasies of overhearing his parents in sexual intercourse, of having been seduced at an early age by someone he loves and of having been threatened with castration; such, too, are his phantasies of being in the womb, and even of experiences there, and the so-called 'Family Romance', in which he reacts to the difference between his attitude towards his parents now and in his childhood. The close relations existing between these phantasies and myths has been demonstrated in the case of the last instance by Otto Rank (1909).

Can we feel sure that none of the possible techniques of jokes has escaped our investigation? Of course not. But a continued examination of fresh material can convince us that we have got to know the commonest and most important technical methods of the joke-work - at all events as much as is required for forming a judgement on the nature of that psychical process. So far we have not arrived at any such judgement; but on the other hand we are now in possession of an important indication of the direction from which we may expect to receive further light upon the problem. The interesting processes of condensation accompanied by the formation of a substitute, which we have recognized as the core of the technique of verbal jokes, point towards the formation of dreams, in the mechanism of which the same psychical processes have been discovered. This is equally true, however, of the techniques of conceptual jokes - displacement, faulty reasoning, absurdity, indirect representation, representation by the opposite - which reappear one and all in the technique of the dream-work. Displacement is responsible for the puzzling appearance of dreams, which prevents our recognizing that they are a continuation of our waking life. The use of absurdity and nonsense in dreams has cost them the dignity of being regarded as psychical products and has led the authorities to suppose that a disintegration of the mental activities and a cessation of criticism, morality and logic are necessary conditions of the formation of dreams. Representation by the opposite is so common in dreams that even the popular books of dream-interpretation, which are on a completely wrong tack, are in the habit of taking it into account. Indirect representation - the replacement of a dream-thought by an allusion, by something small, a symbolism akin to analogy - is precisely what distinguishes the mode of expression of dreams from that of our waking life.¹ So far-reaching an agreement between the methods of the joke-work and those of the dream-work can scarcely be a matter of chance. To demonstrate this agreement in detail and to examine its basis will be one of our later tasks.

The following forces may be recognized as having a share in the formation of dreams: the wish to sleep, the cathexis of energy that still remains in the day's residues after it has been lowered by the state of sleep, the psychical energy of the dream-constructing unconscious wish and the opposing force of the 'censorship', which dominates daytime life and is not completely lifted during sleep. The task of dream-formation is above all to overcome the inhibition from the censorship; and it is precisely this task which is solved by the displacements of psychical energy within the material of the dream-thoughts.
But after all, what we really intended to do originally was only to investigate two or three dreams that are to be found here and there in *Gradiva* with the help of certain analytic methods. How has it come about, then, that we have been led into dissecting the whole story and examining the mental processes in the two chief characters? This has not in fact been an unnecessary piece of work; it was an essential preliminary. It is equally the case that when we try to understand the real dreams of a real person we have to concern ourselves intensively with his character and his career, and we must get to know not only his experiences shortly before the dream but also those dating far back into the past. It is even my view that we are still not free to turn to our proper task, but that we must linger a little more over the story itself and carry out some further preliminary work.

[1907a, 1842]

One of these rules is to the effect that a dream is invariably related to the events of the day before the dream. Our author seems to be wishing to show that he has followed this rule, for he attaches the dream immediately to Hanold's 'pedestrian researches'. Now these had no meaning other than a search for Gradiva, whose characteristic gait he was trying to recognize. So the dream ought to have contained an indication of where Gradiva was to be found. And it does so, by showing her in Pompeii; but that is no novelty to us.

[1907a, 1854]

'Somewhere in the sun Gradiva was sitting, catching lizards and speaking.' What impression of the previous day finds an echo in this part of the dream? Undoubtedly the encounter with the elderly gentleman, the lizard-catcher, who was thus replaced in the dream by Gradiva. He sat or lay 'on a sun-bathed slope' and he, too, spoke to Hanold. Furthermore, Gradiva's remarks in the dream were copied from this man's remarks: viz. 'The method prescribed by our colleague Eimer is a really good one; I have made use of it many times already with excellent results. Please keep quite still.' Gradiva used much the same words in the dream, except that 'our colleague Eimer' was replaced by an unnamed 'lady colleague'; moreover, the 'many times' in the zoologist's speech was omitted in the dream and the order of the sentences was somewhat altered. It seems, therefore, that this experience of the previous day was transformed into the dream with the help of a few changes and distortions. Why this particular experience? And what is the meaning of the changes - the replacement of the elderly gentleman by Gradiva and the introduction of the enigmatic 'lady colleague'?

[1907a, 1867]
We would seem to have reached the end. But an attentive reader might remind us that at the beginning we threw out an assertion that dreams are wishes represented as fulfilled and that we gave no proof of this. Well, in our reply, what we have described in these pages might show how little justification there is for trying to cover the explanations we have to give of dreams with the single formula that dreams are wish-fulfilments. Nevertheless the assertion stands and can easily be proved too for the dreams in *Gradiva*. The latent dream-thoughts - we know now what is meant by them - may be of the most various kinds; in *Gradiva* they are 'days' residues', thoughts that have been left over unnoticed and undealt-with from the mental activities of waking life. But in order for a dream to develop out of them, the co-operation of a wish (usually an unconscious one) is required; this contributes the motive force for constructing the dream, while the day's residues provide the material. In Norbert Hanold's first dream two wishes competed with each other in making the dream; one of them was actually admissible to consciousness, while the other belonged to the unconscious and operated from out of repression. The first was a wish, understandable in any archaeologist, to have been present as an eye-witness at the catastrophe in the year 79 A.D. What sacrifice would an archaeologist think too great if this wish could be realized in any way other than in a dream! The other wish, the other constructor of the dream, was of an erotic nature: it might be crudely and also incompletely stated as a wish to be there when the girl he loved lay down to sleep. This was the wish the rejection of which caused the dream to become an anxiety-dream. The wishes that were the motive forces of the second dream are perhaps less conspicuous; but if we recall its translation we shall not hesitate to describe them too as erotic. The wish to be taken captive by the girl he loved, to fall in with her wishes and to be subjected to her - for so we may construe the wish behind the situation of the lizard-catching - was in fact of a passive, masochistic character. Next day the dreamer hit the girl, as though he was dominated by the contrary erotic current . . . But we must stop here, or we may really forget that Hanold and Gradiva are only creatures of their author's mind.

[1907a, 1884]

The so-called 'day's residues' can act as disturbers of sleep and constructors of dreams; they are affectively cathected thought-processes from the dream-day, which have resisted the general lowering through sleep. These day's residues are uncovered by tracing back the manifest dream to the latent dream-thoughts; they constitute portions of the latter and are thus among the activities of waking life - whether conscious or unconscious - which have been able to persist into the period of sleep. In accordance with the multiplicity of thought-processes in the conscious and preconscious, these day's residues have the most numerous and varied meanings: they may be wishes or fears that have not been disposed of, or intentions, reflections, warnings, attempts at adaptation to current tasks, and so on. To this extent the classification of dreams that is under consideration seems to be justified by the content which is uncovered by interpretation. These day's residues, however, are not the dream itself: they lack the main essential of a dream. Of themselves they are not able to construct a dream. They are, strictly speaking, only the psychical material for the dream-work, just as sensory and somatic stimuli, whether accidental or produced under experimental conditions, constitute the somatic material for the dream-work. To attribute to them the main part in the construction of dreams is simply to repeat at a new point the pre-analytic error which explained dreams by referring them to bad digestion or to pressure on the skin. Scientific errors, indeed, are tenacious of life, and even when they have been refuted are ready to creep in again under new disguises.

[1913a, 2590]
The present state of our knowledge leads us to conclude that the essential factor in the construction of dreams is an unconscious wish - as a rule an infantile wish, now repressed - which can come to expression in this somatic or psychical material (in the day's residues too, therefore) and can thus supply these with a force which enables them to press their way through to consciousness even during the suspension of thought at night. The dream is in every case a fulfilment of this unconscious wish, whatever else it may contain - warning, reflection, admission, or any other part of the rich content of preconscious waking life that has persisted undetected into the night. It is this unconscious wish that gives the dream-work its peculiar character as an unconscious revision of preconscious material. A psycho-analyst can characterize as dreams only the products of the dream-work: in spite of the fact that the latent dream-thoughts are only arrived at from the interpretation of the dream, he cannot reckon them as part of the dream, but only as part of preconscious reflection. (Secondary revision by the conscious agency is here reckoned as part of the dream-work. Even if one were to separate it, this would not involve any alteration in our conception. We should then have to say: dreams in the analytic sense comprise the dream-work proper together with the secondary revision of its products.) The conclusion to be drawn from these considerations is that one cannot put the wish-fulfilling character of dreams on a par with their character as warnings, admissions, attempts at solution, etc., without denying the concept of a psychological dimension of depth - that is to say, without denying the standpoint of psycho-analysis.

[1913a, 2591]

In what way, however, can a case arise in which the intention to sleep meets with an interruption? The interruption may proceed from an internal excitation or from an external stimulus. Let us first consider the more obscure and more interesting case of interruption from within. Observation shows that dreams are instigated by residues from the previous day - thought-cathexes which have not submitted to the general withdrawal of cathexes, but have retained in spite of it a certain amount of libidinal or other interest. Thus the narcissism of sleep has from the outset had to admit an exception at this point, and it is here that the formation of dreams takes its start. In analysis we make the acquaintance of these 'day's residues' in the shape of latent dream-thoughts; and, both by reason of their nature and of the whole situation, we must regard them as preconscious ideas, as belonging to the system Pcs.

[1917d, 3029]

We cannot proceed any further in explaining the formation of dreams till we have overcome certain difficulties. The narcissism of the state of sleep implies a withdrawal of cathexis from all ideas of objects, from both the unconscious and the preconscious portions of those ideas. If, then, certain day's residues have retained their cathexis, we hesitate to suppose that they have acquired at night so much energy as to compel notice on the part of consciousness; we should be more inclined to suppose that the cathexis they have retained is far weaker than that which they possessed during the day. Here analysis saves us further speculation, for it shows that these day's residues must receive a reinforcement which has its source in unconscious instinctual impulses if they are to figure as constructors of dreams. This hypothesis presents no immediate difficulties, for we have every reason to suppose that in sleep the censorship between the Pcs. and the Ucs. is greatly reduced, so that communication between the two systems is made easier.

[1917d, 3029]
The possibility mentioned above - that some of the preconscious thoughts of the day may also prove resistant and retain a part of their cathexis - must be recognized as a second breach in narcissism. At bottom, the two cases may be identical. The resistance of the day's residues may originate in a link with unconscious impulses which is already in existence during waking life; or the process may be somewhat less simple, and the day's residues which have not been wholly emptied of cathexis may establish a connection with the repressed material only after the state of sleep has set in, thanks to the easing of communication between the Pcs. and the Ucs. In both cases there follows the same decisive step in dream-formation: the preconscious dream-wish is formed, which gives expression to the unconscious impulse in the material of the preconscious day's residues. This dream-wish must be sharply distinguished from the day's residues; it need not have existed in waking life and it may already display the irrational character possessed by everything that is unconscious when we translate it into the conscious. Again, the dream-wish must not be confused with the wishful impulses which may have been present, though they certainly need not necessarily be present, amongst the preconscious (latent) dream-thoughts. If, however, there were any such preconscious wishes, the dream-wish associates itself with them, as a most effective reinforcement of them.

[1917d, 3031]

We have already in The Interpretation of Dreams described the way in which the regression of the preconscious day's residues takes place in dream-formation. In this process thoughts are transformed into images, mainly of a visual sort; that is to say, word-presentations are taken back to the thing-presentations which correspond to them, as if, in general, the process were dominated by considerations of representability. When regression has been completed, a number of cathexes are left over in the system Ucs. - cathexes of memories of things. The primary psychical process is brought to bear on these memories, till, by condensation of them and displacement between their respective cathexes, it has shaped the manifest dream-content. Only where the word-presentations occurring in the day's residues are recent and current residues of perceptions, and not the expression of thoughts, are they themselves treated like thing-presentations, and subjected to the influence of condensation and displacement. Hence the rule laid down in The Interpretation of Dreams, and since confirmed beyond all doubt, that words and speeches in the dream-content are not freshly formed, but are modelled on speeches from the day preceding the dream (or on some other recent impressions, such as something that has been read). It is very noteworthy how little the dream-work keeps to the word-presentations; it is always ready to exchange one word for another till it finds the expression which is most handy for plastic representation.¹

[1917d, 3033]
You are correct on all your minor points. A dream differs from a slip of the tongue, among other things, in the multiplicity of its elements. Our technique must take this into account. I therefore suggest to you that we should divide the dream into its elements and start a separate enquiry into each element; if we do this, the analogy with a slip of the tongue is re-established. You are also right in thinking that when the dreamer is questioned about the separate elements of the dream he may reply that nothing occurs to him. There are some instances in which we let this reply pass, and you will later hear which these are; strangely enough, they are instances in which definite ideas may occur to us ourselves. But in general if the dreamer asserts that nothing occurs to him we contradict him; we bring urgent pressure to bear on him, we insist that something must occur to him - and we turn out to be right. He will produce an idea - some idea, it is a matter of indifference to us which. He will give us certain pieces of information, which may be described as 'historical', with particular ease. He may say: 'That's something that happened yesterday' (as was the case in our two 'matter-of-fact' dreams), or: 'That reminds me of something that happened a short time ago' - and we shall discover in this way that dreams are connected with impressions of the last day or two much more often than we thought to begin with. And finally he will also recall, starting from the dream, events from further back and even perhaps from the far distant past.

[1916-1917, 3203]

The first thing the dreamer reported to us was that the precipitating cause of the dream was touched on in its manifest content. Her husband had in fact told her that Elise L., who was approximately her contemporary, had just become engaged. The dream was a reaction to this information. We know already that it is easy in the case of many dreams to point to a precipitating cause like this from the previous day, and that the dreamer is often able to trace this for us without any difficulty. The dreamer in the present case put similar information at our disposal for other elements of the manifest dream as well. - Where did the detail come from about one side of the stalls being empty? It was an allusion to a real event of the previous week. She had planned to go to a particular play and had therefore bought her tickets early - so early that she had had to pay a booking fee. When they got to the theatre it turned out that her anxiety was quite uncalled-for, since one side of the stalls was almost empty. It would have been early enough if she had bought the tickets on the actual day of the performance. Her husband had kept on teasing her for having been in too much of a hurry. - What was the origin of the 1 florin 50 kreuzers? It arose in quite another connection, which had nothing to do with the former one but also alluded to some information from the previous day. Her sister-in-law had been given a present of 150 florins by her husband and had been in a great hurry - the silly goose - to rush off to the jewellers' and exchange the money for a piece of jewellery. - Where did the 'three' come from? She could think of nothing in connection with that, unless we counted the idea that her newly-engaged friend, Elise L., was only three months her junior, though she herself had been a married woman for nearly ten years. - And the absurd notion of taking three tickets for only two people? She had nothing to say to that, and refused to report any further ideas or information.

[1916-1917, 3218]

(1) No analysis, no application of any technique is necessary in order to understand these dreams. There is no need to question a child who tells us his dream. One has, however, to add a piece of information to it from the events of the child's life. There is invariably some experience of the previous day which explains the dream to us. The dream is the reaction of the child's mental life in his sleep to this experience of the previous day.

[1916-1917, 3221]
Symbolism is perhaps the most remarkable chapter of the theory of dreams. In the first place, since symbols are stable translations, they realize to some extent the ideal of the ancient as well as of the popular interpretation of dreams, from which, with our technique, we had departed widely. They allow us in certain circumstances to interpret a dream without questioning the dreamer, who indeed would in any case have nothing to tell, us about the symbol. If we are acquainted with the ordinary dream-symbols, and in addition with the dreamer's personality, the circumstances in which he lives and the impressions which preceded the occurrence of the dream, we are often in a position to interpret a dream straightaway - to translate it at sight, as it were. A piece of virtuosity of this kind flatters the dream-interpreter and impresses the dreamer; it forms an agreeable contrast to the laborious work of questioning the dreamer. But do not allow yourselves to be led astray by this. It is not our business to perform acts of virtuosity. Interpretation based on a knowledge of symbols is not a technique which can replace or compete with the associative one. It forms a supplement to the latter and yields results which are only of use when introduced into it. And as regards acquaintance with the dreamer's psychical situation, you must bear in mind that the dreams of people you know well are not the only ones you have to analyse, that you are not as a rule familiar with the events of the previous day, which were the instigators of the dream, but that the associations of the person you are analysing will provide you precisely with a knowledge of what we call the psychical situation.

As the outcome of our whole enquiry, let us grasp two discoveries, though they only signify the beginning of fresh enigmas and fresh doubts. First, the regression of the dream-work is not only a formal but also a material one. It not only translates our thoughts into a primitive form of expression; but it also revives the characteristics of our primitive mental life - the old dominance of the ego, the initial impulses of our sexual life, and even, indeed, our old intellectual endowment, if symbolic connections may be regarded as such. And secondly, all this, which is old and infantile and was once dominant and alone dominant, must to-day be ascribed to the unconscious, our ideas of which are now becoming altered and extended. 'Unconscious' is no longer the name of what is latent at the moment; the unconscious is a particular realm of the mind with its own wishful impulses, its own mode of expression and its peculiar mental mechanisms which are not in force elsewhere. But the latent dream-thoughts which we have discovered by interpreting dreams do not belong to this realm; they are on the contrary thoughts just as we might have thought them in waking life. Nevertheless, they are unconscious. How, then, is this contradiction to be solved? We begin to suspect that a distinction is to be drawn here. Something which is derived from our conscious life and shares its characteristics - we call it 'the day's residues' - combines with something else coming from the realm of the unconscious in order to construct a dream. The dream-work is accomplished between these two components. The influence exercised upon the day's residues by the addition of the unconscious is no doubt among the determinants of regression. This is the deepest insight that we can reach here into the essential nature of dreams - until we have investigated further regions of the mind. But the time will soon have come to provide another name for the unconscious character of the latent dream-thoughts in order to distinguish it from the unconscious which comes from the realm of the infantile.
(4) One day the objective value of research into dreams seemed to be put in question by an
observation that patients under analytic treatment arrange the content of their dreams in
accordance with the favourite theories of their physicians some dreaming predominantly of
sexual instinctual impulses, others of the struggle for power and yet others even of rebirth
(Stekel). The weight of this observation was, however, diminished by the reflection that human
beings had dreams before there was any psycho-analytic treatment which could give those
dreams a direction, and that people who are now under treatment used also to dream during the
period before the treatment started. What was true about this novelty could soon be seen to be
self-evident and of no relevance to the theory of dreams. The day's residues which instigate
dreams are left over from powerful interests in waking life. When the remarks made by the
physician and the hints he gives become of significance to the patient, they enter the circle of
the day's residues and can provide psychical stimuli for the construction of dreams like any
other emotionally coloured interests of the previous day which have not been dealt with, and
they then operate like somatic stimuli which impinge on the sleeper during his sleep. The trains
of thought set going by the physician can, like these other instigators of dreams, appear in the
manifest content of a dream or be discovered in its latent content. Indeed, we know that a
dream can be experimentally produced, or, to put it more correctly, a part of the dream material
can be introduced into the dream. In producing these effects on his patients, an analyst is thus
playing a part no different from an experimenter who, like Mourly Vold, gives particular postures
to the limbs of the subjects of his experiments.

Perhaps you recognize, moreover, what it is that supports our hypotheses of the two systems,
and their relation to each other and to consciousness? After all, the watchman between the
unconscious and the preconscious is nothing else than the censorship, to which, as we found,
the form taken by the manifest dream is subject. The day's residues, which we recognized as
the instigators of the dream, were preconscious material which, at night-time and in the state of
sleep, had been under the influence of unconscious and repressed wishful impulses; they had
been able, in combination with those impulses and thanks to their energy, to construct the latent
dream. Under the dominance of the unconscious system this material had been worked over
(by condensation and displacement) in a manner which is unknown or only exceptionally
permissible in normal mental life - that is, in the preconscious system. We came to regard this
difference in their manner of operating as what characterizes the two systems; the relation
which the preconscious has to consciousness was regarded by us merely as an indication of its
belonging to one of the two systems. Dreams are not pathological phenomena; they can appear
in any healthy person under the conditions of a state of sleep. Our hypothesis about the
structure of the mental apparatus, which allows us to understand the formation alike of dreams
and of neurotic symptoms, has an incontrovertible claim to being taken into account in regard to
normal mental life as well.

My second remark is a supplement to the theory of dreams. We cannot explain the origin of
dreams unless we adopt the hypothesis that the repressed unconscious has achieved some
degree of independence of the ego, so that it does not acquiesce in the wish to sleep and
retains its cathexes even when all the object-cathexes depending on the ego have been
withdrawn in order to encourage sleep. Only if that is so can we understand how the
unconscious can make use of the lifting or reduction of the censorship which occurs at night,
and can succeed in obtaining control over the day's residues so as to construct a forbidden
dream-wish out of their material. On the other hand, it may be that these day's residues have to
thank an already existing connection with the repressed unconscious for some of their
resistance to the withdrawal of libido commanded by the wish to sleep. We will, then, insert this
dynamically important feature into our view of the formation of dreams by way of supplement.
The manifestations of a compulsion to repeat (which we have described as occurring in the 
early activities of infantile mental life as well as among the events of psycho-analytic treatment) 
exhibit to a high degree an instinctual character and, when they act in opposition to the pleasure 
principle, give the appearance of some 'daemonic' force at work. In the case of children's play 
we seemed to see that children repeat unpleasurable experiences for the additional reason that 
they can master a powerful impression far more thoroughly by being active than they could by 
merely experiencing it passively. Each fresh repetition seems to strengthen the mastery they 
are in search of. Nor can children have their \textit{pleasurable} experiences repeated often enough, 
and they are inexorable in their insistence that the repetition shall be an identical one. This 
character trait disappears later on. If a joke is heard for a second time it produces almost no 
effect; a theatrical production never creates so great an impression the second time as the first; 
indeed, it is hardly possible to persuade an adult who has very much enjoyed reading a book to 
re-read it immediately. Novelty is always the condition of enjoyment. But children will never tire 
of asking an adult to repeat a game that he has shown them or played with them, till he is too 
exhausted to go on. And if a child has been told a nice story, he will insist on hearing it over and 
over again rather than a new one; and he will remorselessly stipulate that the repetition shall be 
an identical one and will correct any alterations of which the narrator may be guilty - though they 
may actually have been made in the hope of gaining fresh approval. None of this contradicts the 
pleasure principle; repetition, the re-experiencing of something identical, is clearly in itself a 
source of pleasure. In the case of a person in analysis, on the contrary, the compulsion to 
repeat the events of his childhood in the transference evidently disregards the pleasure principle 
every way. The patient behaves in a purely infantile fashion and thus shows us that the 
repressed memory-traces of his primaeval experiences are not present in him in a bound state 
and are indeed in a sense incapable of obeying the secondary process. It is to this fact of not 
being bound, moreover, that they owe their capacity for forming, in conjunction with the residues 
of the previous day, a wishful phantasy that emerges in a dream. This same compulsion to 
repeat frequently meets us as an obstacle to our treatment when at the end of an analysis we 
try to induce the patient to detach himself completely from his physician. It may be presumed, 
too, that when people unfamiliar with analysis feel an obscure fear - a dread of rousing 
something that, so they feel, is better left sleeping - what they are afraid of at bottom is the 
emergence of this compulsion with its hint of possession by some 'daemonic' power. 
[1920g, 3738]

¹ In the interpretation of dreams, to which, indeed, we owe our best knowledge of unconscious mental 
life, we follow a technical rule of disregarding doubt and uncertainty in the narrative of the dream, and of 
treating every element of the manifest dream as being quite certain. We attribute doubt and uncertainty to 
the influence of the censorship to which the dream-work is subjected, and we assume that the primary 
dream-thoughts are not acquainted with doubt and uncertainty as critical processes. They may of course 
be present, like anything else, as part of the content of the day's residues which lead to the dream. 
[1921c, 3773]
I can imagine that to point out the existence of lying dreams of this kind, 'obliging' dreams, will arouse a positive storm of helpless indignation in some readers who call themselves analysts. 'What!' they will exclaim, 'the unconscious, the real centre of our mental life, the part of us that is so much nearer the divine than our poor consciousness - it too can lie! Then how can we still build on the interpretations of analysis and the accuracy of our findings?' To which one must reply that the recognition of these lying dreams does not constitute any shattering novelty. I know, indeed, that the craving of mankind for mysticism is ineradicable, and that it makes ceaseless efforts to win back for mysticism the territory it has been deprived of by *The Interpretation of Dreams*, but surely in the case under consideration everything is simple enough. A dream is not the 'unconscious'; it is the form into which a thought left over from preconscious, or even from conscious, waking life, can, thanks to the favouring state of sleep, be recast. In the state of sleep this thought has been reinforced by unconscious wishful impulses and has thus experienced distortion through the dream-work, which is determined by the mechanisms prevailing in the unconscious. With our dreamer, the intention to mislead me, just as she did her father, certainly emanated from the preconscious, and may indeed have been conscious; it could come to expression by entering into connection with the unconscious wishful impulse to please her father (or father-substitute), and in this way it created a lying dream. The two intentions, to betray and to please her father, originated in the same complex; the former resulted from the repression of the latter, and the later one was brought back by the dream-work to the earlier one. There can therefore be no question of any devaluation of the unconscious, nor of a shattering of our confidence in the results of analysis.
[1920a, 3854]

If you prefer to assume that a telepathic message about the daughter's confinement reached the sleeper, further questions arise of the relation of a message such as this to a dream and of its influence on the formation of dreams. The answer is not far to seek and is quite unambiguous. A telepathic message will be treated as a portion of the material that goes to the formation of a dream, like any other external or internal stimulus, like a disturbing noise in the street or an insistent organic sensation in the sleeper's own body. In our example it is evident how the message, with the help of a lurking repressed wish, became remodelled into a wish-fulfilment; it is unfortunately less easy to show that it combined with other material that had become active at the same time and was blended into a dream. Telepathic messages - if we are justified in recognizing their existence - can thus make no alteration in the process of forming a dream; telepathy has nothing to do with the nature of dreams. And in order to avoid the impression that I am trying to conceal a vague notion behind abstract and fine-sounding words, I am willing to repeat: the essential nature of dreams consists in the peculiar process of 'dream-work' which, with the help of an unconscious wish, carries the preconscious thoughts (day's residues) over into the manifest content of the dream. The problem of telepathy concerns dreams as little as does the problem of anxiety.
[1922a, 3887]
I am hoping that you will grant this, but that you will raise the objection that there are, nevertheless, other telepathic dreams in which there is no difference between the event and the dream, and in which there is nothing else to be found but an undistorted reproduction of the event. I have no knowledge of such dreams from my own experience, but I know they have often been reported. If we assume that we have such an undisguised and unadulterated telepathic dream to deal with, another question arises. Ought we to call such a telepathic experience a 'dream' at all? You will certainly do so as long as you keep to popular usage, in which everything that takes place in mental life during sleep is called a dream. You, too, perhaps say, 'I tossed about in my dream', and still less are you conscious of anything incorrect when you say, 'I shed tears in my dream' or 'I felt apprehensive in my dream'. But you will no doubt notice that in all these cases you are using 'dream' and 'sleep' and 'state of being asleep' interchangeably, as if there were no distinction between them. I think it would be in the interests of scientific accuracy to keep 'dream' and 'state of sleep' more distinctly separate. Why should we provide a counterpart to the confusion evoked by Maeder who, by refusing to distinguish between the dream-work and the latent dream-thoughts, has discovered a new function for dreams? Supposing, then, that we are brought face to face with a pure telepathic 'dream', let us rather call it instead a telepathic experience in a state of sleep. A dream without condensation, distortion, dramatization, above all, without wish-fulfilment, surely does not deserve the name. You will remind me that, if so, there are other mental products in sleep to which the right to be called 'dreams' would have to be refused. Actual experiences of the day are sometimes simply repeated in sleep; reproductions of traumatic scenes in 'dreams' have led us only lately to revise the theory of dreams. There are dreams which are to be distinguished from the usual type by certain special qualities, which are, properly speaking, nothing but night-phantasies, not having undergone additions or alterations of any kind and being in all other ways similar to the familiar day-dreams. It would be awkward, no doubt, to exclude these structures from the domain of 'dreams'. But still they all come from within, are products of our mental life, whereas the very conception of the purely telepathic dream lies in its being a perception of something external, in relation to which the mind remains passive and receptive.

[1922a, 3887]

We also describe the latent dream-thoughts, on account of their connection with waking life, as 'residues of the day'. By the operation of the dream-work (to which it would be quite incorrect to ascribe any 'creative' character) the latent dream thoughts are condensed in a remarkable way, are distorted by the displacement of psychical intensities and are arranged with a view to being represented in visual pictures; and, besides all this, before the manifest dream is arrived at, they are submitted to a process of secondary revision which seeks to give the new product something in the nature of sense and coherence. Strictly speaking, this last process does not form a part of the dream-work.

[1923a, 3918]
The Dynamic Theory of Dream-Formation. The motive power for the formation of dreams is not provided by the latent dream-thoughts or day's residues, but by an unconscious impulse, repressed during the day, with which the day's residues have been able to establish contact and which contrives to make a wish-fulfilment for itself out of the material of the latent thoughts. Thus every dream is on the one hand the fulfilment of a wish on the part of the unconscious and on the other hand (in so far as it succeeds in guarding the state of sleep against being disturbed) the fulfilment of the normal wish to sleep which set the sleep going. If we disregard the unconscious contribution to the formation of the dream and limit the dream to its latent thoughts, it can represent anything with which waking life has been concerned - a reflection, a warning, an intention, a preparation for the immediate future or, once again, the satisfaction of an unfulfilled wish. The unrecognizability, strangeness and absurdity of the manifest dream are partly the result of the translation of the thoughts into a different, so to say archaic, method of expression, but partly the effect of a restrictive, critically disapproving agency in the mind which does not entirely cease to function during sleep. It is plausible to suppose that the ‘dream-censorship’, which we regard as being responsible in the first instance for the distortion of the dream-thoughts into the manifest dream, is an expression of the same mental forces which during the day-time had held back or repressed the unconscious wishful impulse.

Or one can (b) start the work of interpretation from some one particular element of the dream which one picks out from the middle of it. For instance, one can choose the most striking piece of it, or the piece which shows the greatest clarity or sensory intensity; or, again, one can start off from some spoken words in the dream, in the expectation that they will lead to the recollection of some spoken words in waking life.

Or one can (c) begin by entirely disregarding the manifest content and instead ask the dreamer what events of the previous day are associated in his mind with the dream he has just described.

It is possible to distinguish between dreams from above and dreams from below, provided the distinction is not made too sharply. Dreams from below are those which are provoked by the strength of an unconscious (repressed) wish which has found a means of being represented in some of the day's residues. They may be regarded as inroads of the repressed into waking life. Dreams from above correspond to thoughts or intentions of the day before which have contrived during the night to obtain reinforcement from repressed material that is debarred from the ego. When this is so, analysis as a rule disregards this unconscious ally and succeeds in inserting the latent dream-thoughts into the texture of waking thought. This distinction calls for no modification in the theory of dreams.

The fact that the manifest content of dreams is influenced by the analytic treatment stands in no need of proof. It follows from our knowledge that dreams take their start from waking life and work over material derived from it. Occurrences during analytic treatment are of course among the impressions of waking life and soon become some of the most powerful of these. So it is not to be wondered at that patients should dream of things which the analyst has discussed with them and of which he has aroused expectations in them. At least it is no more to be wondered at than what is implied in the familiar fact of ‘experimental’ dreams.
But from here our interest proceeds to the question whether the latent dream-thoughts that have to be arrived at by interpretation can also be influenced or suggested by the analyst. And to this the answer must once more be that they obviously can be. For a portion of these latent dream-thoughts correspond to preconscious thought-formation, perfectly capable of being conscious, with which the dreamer might quite well have reacted to the physician's remarks in his waking state too - whether the patient's reactions were in harmony with those remarks or in opposition to them. In fact, if we replace the dream by the dream-thoughts which it contains, the question of how far one can suggest dreams coincides with the more general question of how far a patient in analysis is accessible to suggestion.

[1923c, 4035]

In spite of the caution which is prescribed by the importance, novelty and obscurity of the subject, I feel that I should not be justified in holding back any longer these considerations upon the problem of telepathy. All of this has only this much to do with dreams: if there are such things as telepathic messages, the possibility cannot be dismissed of their reaching someone during sleep and coming to his knowledge in a dream. Indeed, on the analogy of other perceptual and intellectual material, the further possibility arises that telepathic messages received in the course of the day may only be dealt with during a dream of the following night. There would then be nothing contradictory in the material that has been telepathically communicated being modified and transformed in the dream like any other material. It would be satisfactory if with the help of psycho-analysis we could obtain further and better authenticated knowledge of telepathy.

[1925i, 4055]
There were now a whole series of questions to be answered, among the most important of them being whether the formation of dreams had a motive, under what conditions it took place, by what methods the dream-thoughts (which are invariably full of sense) become converted into the dream (which is often senseless), and others besides. I attempted to solve all of these problems in *The Interpretation of Dreams*, which I published in the year 1900. I can only find space here for the briefest abstract of my investigation. When the latent dream-thoughts that are revealed by the analysis of a dream are examined, one of them is found to stand out from among the rest, which are intelligible and well known to the dreamer. These latter thoughts are residues of waking life (the *day's residues*, as they are called technically); but the isolated thought is found to be a wishful impulse, often of a very repellent kind, which is foreign to the waking life of the dreamer and is consequently disavowed by him with surprise or indignation. This impulse is the actual constructor of the dream: it provides the energy for its production and makes use of the day's residues as material. The dream which thus originates represents a situation of satisfaction for the impulse, it is the fulfilment of its wish. It would not be possible for this process to take place without being favoured by the presence of something in the nature of a state of sleep. The necessary mental precondition of sleep is the concentration of the ego upon the wish to sleep and the withdrawal of psychical energy from all the interests of life. Since at the same time all the paths of approach to motility are blocked, the ego is also able to reduce the expenditure by which at other times it maintains the repressions. The unconscious impulse makes use of this nocturnal relaxation of repression in order to push its way into consciousness with the dream. But the repressive resistance of the ego is not abolished in sleep but merely reduced. Some of it remains in the shape of a *censorship of dreams* and forbids the unconscious impulse to express itself in the forms which it would properly assume. In consequence of the severity of the censorship of dreams, the latent dream-thoughts are obliged to submit to being altered and softened so as to make the forbidden meaning of the dream unrecognizable. This is the explanation of *dream-distortion*, which accounts for the most striking characteristics of the manifest dream. We are therefore justified in asserting that a *dream is the (disguised) fulfilment of a (repressed) wish*. It will now be seen that dreams are constructed like a neurotic symptom: they are compromises between the demands of a repressed impulse and the resistance of a censoring force in the ego. Since they have a similar origin they are equally unintelligible and stand in equal need of interpretation.

[1925d, 4219]

We have explained that the unconscious instinctual impulse of the dream connects itself with a residue of the day, with some interest of waking life which has not been disposed of; it thus gives the dream which it constructs a double value for the work of analysis. For on the one hand a dream that has been analysed reveals itself as the fulfilment of a repressed wish; but on the other hand it may be a continuation of some preconscious activity of the day before and may contain every kind of subject-matter and give expression to an intention, a warning, a reflection, or once more to the fulfilment of a wish. Analysis exploits the dream in both directions, as a means of obtaining knowledge alike of the patient's conscious and of his unconscious processes. It also profits from the fact that dreams have access to the forgotten material of childhood, and so it happens that infantile amnesia is for the most part overcome in connection with the interpretation of dreams. In this respect dreams achieve a part of what was previously the task of hypnotism. On the other hand, I have never maintained the assertion which has so often been ascribed to me that dream-interpretation shows that all dreams have a sexual content or are derived from sexual motive forces. The case of young children affords us a convenient test of the validity of our theory of dreams. In them the various psychical systems are not yet sharply divided and the repressions have not yet grown deep, so that we often come upon dreams which are nothing more than undisguised fulfilments of wishful impulses left over from waking life. Under the influence of imperative needs, adults may also produce dreams of this infantile type.¹

[1925d, 4221]
Our philosopher’s dreams are what are known as 'dreams from above' ("Träume von oben"). That is to say, they are formulations of ideas which could have been created just as well in a waking state as during the state of sleep, and which have derived their content only in certain parts from mental states at a comparatively deep level. That is why these dreams offer for the most part a content which has an abstract, poetic or symbolic form.

That is a curious technique, is it not? - not the usual way of dealing with a communication or utterance. And no doubt you guess that behind this procedure there are assumptions which have not yet been expressly stated. But let us proceed. In what order are we to get the patient to take up the portions of his dream? There are various possibilities open to us. We can simply follow the chronological order in which they appeared in the account of the dream. That is what may be called the strictest, classical method. Or we can direct the dreamer to begin by looking out for the ‘day’s residues’ in the dream; for experience has taught us that almost every dream includes the remains of a memory or an allusion to some event (or often to several events) of the day before the dream, and, if we follow these connections, we often arrive with one blow at the transition from the apparently far remote dream-world to the real life of the patient. Or, again, we may tell him to start with those elements of the dream’s content which strike him by their special clarity and sensory strength; for we know that he will find it particularly easy to get associations to these. It makes no difference by which of these methods we approach the associations we are in search of.

And next, we obtain these associations. What they bring us is of the most various kinds: memories from the day before, the ‘dream-day’, and from times long past, reflections, discussions, with arguments for and against, confessions and enquiries. Some of them the patient pours out; when he comes to others he is held up for a time. Most of them show a clear connection to some element of the dream; no wonder, since those elements were their starting-point. But it also sometimes happens that the patient introduces them with these words: ‘This seems to me to have nothing at all to do with the dream, but I tell it you because it occurs to me.’

Here we are presented with a means of answering the question of whether dreams have a function too, whether they are entrusted with any useful achievement. The condition of rest free from stimulus, which the state of sleep wishes to establish, is threatened from three directions: in a relatively accidental manner by external stimuli during sleep, and by interests of the previous day which cannot be broken off, and in an unavoidable manner by unsated repressed instinctual impulses which are on the watch for an opportunity of finding expression. In consequence of the diminishing of repressions at night there would be a risk that the rest afforded by sleep would be interrupted whenever an instigation from outside or from inside succeeded in linking up with an unconscious instinctual source. The process of dreaming allows the product of a collaboration of this kind to find an outlet in a harmless hallucinatory experience and in that way assures a continuation of sleep. The fact that a dream occasionally awakens the sleeper, to the accompaniment of a generation of anxiety, is no contradiction of this function but rather, perhaps, a signal that the watchman regards the situation as too dangerous and no longer feels able to control it. And very often then, while we are still asleep, a consolation occurs to us which seeks to prevent our waking up: ‘But after all it’s only a dream!’
After these influences have been brought to bear upon the dream-thoughts the dream is almost complete. A further, somewhat variable, factor also comes into play - known as 'secondary revision' - after the dream has been presented before consciousness as an object of perception. At that point we treat it as we are in general accustomed to treat the contents of our perception: we fill in gaps and introduce connections, and in doing so are often guilty of gross misunderstandings. But this activity, which might be described as a rationalizing one and which at best provides the dream with a smooth façade that cannot fit its true content, may also be omitted or only be expressed to a very modest degree - in which case the dream will display all its rents and cracks openly. It must not be forgotten, on the other hand, that the dream-work does not always operate with equal energy either; it often restricts itself to certain portions of the dream-thoughts only and others of them are allowed to appear in the dream unaltered. In such cases an impression is given of the dream having carried out the most delicate and complex intellectual operations, of its having speculated, made jokes, arrived at decisions and solved problems, whereas all this is a product of our normal mental activity, may have been performed equally well during the day before the dream as during the night, has nothing to do with the dream-work and brings nothing to light that is characteristic of dreams. Nor is it superfluous to insist once more on the contrast within the dream-thoughts themselves between the unconscious instinctual impulse and the day's residues. While the latter exhibit all the multiplicity of our mental acts, the former, which becomes the motive force proper of the forming of the dream, finds its outlet invariably in the fulfilment of a wish.

Actually I have little to tell you - only a modest fact. I will also at once reduce your expectations still further by saying that at bottom dreams have little to do with telepathy. Telepathy does not throw any fresh light on the nature of dreams nor do dreams give any direct evidence of the reality of telepathy. Moreover the phenomenon of telepathy is by no means bound up with dreams; it can occur as well during the waking state. The only reason for discussing the relation between dreams and telepathy is that the state of sleep seems particularly suited for receiving telepathic messages. In such cases one has what is called a telepathic dream and, when it is analysed, one forms a conviction that the telepathic news has played the same part as any other portion of the day's residues and that it has been changed in the same way by the dream-work and made to serve its purpose.

It is best to begin by pointing out that the formation of a dream can be provoked in two different ways. Either, on the one hand, an instinctual impulse which is ordinarily suppressed (an unconscious wish) finds enough strength during sleep to make itself felt by the ego, or, on the other hand, an urge left over from waking life, a preconscious train of thought with all the conflicting impulses attached to it, finds reinforcement during sleep from an unconscious element. In short, dreams may arise either from the id or from the ego. The mechanism of dream-formation is in both cases the same and so also is the necessary dynamic precondition. The ego gives evidence of its original derivation from the id by occasionally ceasing its functions and allowing a reversion to an earlier state of things. This is logically brought about by its breaking off its relations with the external world and withdrawing its cathexes from the sense organs. We are justified in saying that there arises at birth an instinct to return to the intra-uterine life that has been abandoned - an instinct to sleep. Sleep is a return of this kind to the womb. Since the waking ego governs motility, that function is paralysed in sleep, and accordingly a good part of the inhibitions imposed on the unconscious id become superfluous. The withdrawal or reduction of these 'anticathexes' thus allows the id what is now a harmless amount of liberty.

[1940a [1938], 4976]
But what makes dreams so invaluable in giving us insight is the circumstance that, when the unconscious material makes its way into the ego, it brings its own modes of working along with it. This means that the preconscious thoughts in which the unconscious material has found its expression are handled in the course of the dream-work as though they were unconscious portions of the id; and, in the case of the alternative method of dream-formation, the preconscious thoughts which have obtained reinforcement from an unconscious instinctual impulse are brought down to the unconscious state. It is only in this way that we learn the laws which govern the passage of events in the unconscious and the respects in which they differ from the rules that are familiar to us in waking thought. Thus the dream-work is essentially an instance of the unconscious working-over of preconscious thought-processes. To take an analogy from history: invading conquerors govern a conquered country, not according to the judicial system which they find in force there, but according to their own. It is, however, an unmistakable fact that the outcome of the dream-work is a compromise. The ego-organization is not yet paralysed, and its influence is to be seen in the distortion imposed on the unconscious material and in what are often very ineffective attempts at giving the total result a form not too unacceptable to the ego (secondary revision). In our analogy this would be an expression of the continued resistance of the defeated people.

It remains for us to give a dynamic explanation of why the sleeping ego takes on the task of the dream-work at all. The explanation is fortunately easy to find. With the help of the unconscious, every dream that is in process of formation makes a demand upon the ego - for the satisfaction of an instinct, if the dream originates from the id; for the solution of a conflict, the removal of a doubt or the forming of an intention, if the dream originates from a residue of preconscious activity in waking life. The sleeping ego, however, is focused on the wish to maintain sleep; it feels this demand as a disturbance and seeks to get rid of the disturbance. The ego succeeds in doing this by what appears to be an act of compliance: it meets the demand with what is in the circumstances a harmless fulfilment of a wish and so gets rid of it. This replacement of the demand by the fulfilment of a wish remains the essential function of the dream-work. It may perhaps be worth while to illustrate this by three simple examples - a hunger dream, a dream of convenience and a dream prompted by sexual desire. A need for food makes itself felt in a dreamer during his sleep: he has a dream of a delicious meal and sleeps on. The choice, of course, was open to him either of waking up and eating something or of continuing his sleep. He decided in favour of the latter and satisfied his hunger by means of the dream - for the time being, at all events, for if his hunger had persisted he would have had to wake up nevertheless. Here is the second example. A sleeper had to wake up so as to be in time for his work at the hospital. But he slept on, and had a dream that he was already at the hospital - but as a patient, who has no need to get up. Or again, a desire becomes active during the night for the enjoyment of a forbidden sexual object, the wife of a friend of the sleeper. He has a dream of sexual intercourse - not, indeed, with this person but with someone else of the same name to whom he is in fact indifferent; or his struggle against the desire may find expression in his mistress remaining altogether anonymous.

[1940a [1938], 4977]
Naturally, every case is not so simple. Especially in dreams which have originated from undealt-with residues of the previous day, and which have only obtained an unconscious reinforcement during the state of sleep, it is often no easy task to uncover the unconscious motive force and its wish-fulfilment; but we may assume that it is always there. The thesis that dreams are the fulfilments of wishes will easily arouse scepticism when it is remembered how many dreams have an actually distressing content or even wake the dreamer in anxiety, quite apart from the numerous dreams without any definite feeling-tone. But the objection based on anxiety dreams cannot be sustained against analysis. It must not be forgotten that dreams are invariably the product of a conflict, that they are a kind of compromise-structure. Something that is a satisfaction for the unconscious id may for that very reason be a cause of anxiety for the ego.

[1940a [1938], 4980]
In my view, therefore, wishful impulses left over from conscious waking life must be relegated to a secondary position in respect to the formation of dreams. I cannot allow that, as contributors to the content of dreams, they play any other part than by the material of sensations which become currently active during sleep. (See pp. 707-708.) I shall follow the same line of thought in now turning to consider those psychical instigations to dreaming, left over from waking life, which are other than wishes. When we decide to go to sleep, we may succeed in temporarily bringing to an end the cathexes of energy attaching to our waking thoughts. Anyone who can do this easily is a good sleeper; the first Napoleon seems to have been a model of this class. But we do not always succeed in doing so, nor do we always succeed completely. Unsolved problems, tormenting worries, overwhelming impressions - all these carry thought-activity over into sleep and sustain mental processes in the system that we have named the preconscious. If we wish to classify the thought-impulses which persist in sleep, we may divide them into the following groups: (1) what has not been carried to a conclusion during the day owing to some chance hindrance; (2) what has not been dealt with owing to the insufficiency of our intellectual power - what is unsolved; (3) what has been rejected and suppressed during the daytime. To these we must add (4) a powerful group consisting of what has been set in action in our Ucs. by the activity of the preconscious in the course of the day; and finally (5) the group of daytime impressions which are indifferent and have for that reason not been dealt with.

[1900a, 986]

There is no need to underestimate the importance of the psychical intensities which are introduced into the state of sleep by these residues of daytime life, and particularly of those in the group of unsolved problems. It is certain that these excitations continue to struggle for expression during the night; and we may assume with equal certainty that the state of sleep makes it impossible for the excitatory process to be pursued in the habitual manner in the preconscious and brought to an end by becoming conscious. In so far as our thought-processes are able to become conscious in the normal way at night, we are simply not asleep. I am unable to say what modification in the system Pcs. is brought about by the state of sleep;¹ but there can be no doubt that the psychological characteristics of sleep are to be looked for essentially in modifications in the cathexis of this particular system - a system that is also in control of access to the power of movement, which is paralysed during sleep. On the other hand, nothing in the psychology of dreams gives me reason to suppose that sleep produces any modifications other than secondary ones in the state of things prevailing in the Ucs. No other course, then, lies open to excitations occurring at night in the Pcs. than that followed by wishful excitations arising from the Ucs.; the preconscious excitations must find reinforcement from the Ucs. and must accompany the unconscious excitations along their circuitous paths. But what is the relation of the preconscious residues of the previous day to dreams? There is no doubt that they find their way into dreams in great quantity, and that they make use of the content of dreams in order to penetrate into consciousness even during the night. Indeed they occasionally dominate the content of a dream and force it to carry on the activity of daytime. It is certain, too, that the day's residues may be of any other character just as easily as wishes; but it is highly instructive in this connection, and of positively decisive importance for the theory of wish-fulfilment, to observe the condition to which they must submit in order to be received into a dream.

[1900a, 987]
Let us take one of the dreams I have already recorded - for instance, the one in which my friend Otto appeared with the signs of Graves' disease. (See p. 746 ff.) I had been worried during the previous day by Otto's looks; and, like everything else concerned with him, this worry affected me closely. And it pursued me, as I may assume, into my sleep. I was probably anxious to discover what could be wrong with him. This worry found expression during the night in the dream I have described, the content of which was in the first place nonsensical and in the second place was in no respect the fulfilment of a wish. I then began to investigate the origin of this inappropriate expression of the worry I had felt during the day, and by means of analysis I found a connection through the fact of my having identified my friend with a certain Baron L. and myself with Professor R. There was only one explanation of my having been obliged to choose this particular substitute for my daytime thought. I must have been prepared at all times in my Ucs. to identify myself with Professor R., since by means of that identification one of the immortal wishes of childhood - the megalomaniac wish - was fulfilled. Ugly thoughts hostile to my friend, which were certain to be repudiated during the day, had seized the opportunity of slipping through with the wish and getting themselves represented in the dream; but my daytime worry had also found some sort of expression in the content of the dream by means of a substitute. The daytime thought, which was not in itself a wish but on the contrary a worry, was obliged to find a connection in some way or other with an infantile wish which was now unconscious and suppressed, and which would enable it - suitably decocted, it is true - to 'originate' in consciousness. The more dominating was the worry, the more far-fetched a link could be established; there was no necessity for there being any connection whatever between the content of the wish and that of the worry, and in fact no such connection existed in our example.

[1900a, 988]

I will report a dream of my own in order to illustrate what I have just said, and in particular the way in which the dream-work deals with a residue of distressing anticipations from the previous day.

[1900a, 991]
Once again it is impossible for me to present a complete analysis. I must restrict myself to bringing out a few salient points. Distressing anticipations from the previous day were what gave rise to the dream: we had once more been without news of our son at the front for over a week. It is easy to see that the content of the dream expressed a conviction that he had been wounded or killed. Energetic efforts were clearly being made at the beginning of the dream to replace the distressing thoughts by their contrary. I had some highly agreeable news to communicate - something about money being sent . . . distinction . . . distribution. (The sum of money was derived from an agreeable occurrence in my medical practice; it was an attempt at a complete diversion from the topic.) But these efforts failed. My wife suspected something dreadful and refused to listen to me. The disguises were too thin and references to what it was sought to repress pierced through them everywhere. If my son had been killed, his fellow-officers would send back his belongings and I should have to distribute what he left among his brothers and sisters and other people. A 'distinction' is often awarded to an officer who has fallen in battle. Thus the dream set about giving direct expression to what it had first sought to deny, though the inclination towards wish-fulfilment was still shown at work in the distortions. (The change of locality during the dream is no doubt to be understood as what Silberer has described as 'threshold symbolism'. We cannot tell, it is true, what it was that provided the dream with the motive force for thus giving expression to my distressing thoughts. My son did not appear as someone 'falling' but as someone 'climbing.' He had in fact been a keen mountaineer. He was not in uniform but in sports clothes; this meant that the place of the accident that I now feared had been taken by an earlier, sporting one; for he had had a fall during a skiing expedition and broken his thigh. The way in which he was dressed, on the other hand, which made him look like a seal, at once recalled someone younger - our funny little grandson; while the grey hair reminded me of the latter's father, our son-in-law, who had been hard hit by the war. What could this mean? . . . but I have said enough of it. - The locality in a store-closet and the cupboard from which he wanted to take something ('on which he wanted to put something' in the dream) - these allusions reminded me unmistakably of an accident of my own which I had brought on myself when I was between two and three years old. I had climbed up on to a stool in the store-closet to get something nice that was lying on a cupboard or table. The stool had tipped over and its corner had struck me behind my lower jaw; I might easily, I reflected, have knocked out all my teeth. The recollection was accompanied by an admonitory thought: 'that serves you right'; and this seemed as though it was a hostile impulse aimed at the gallant soldier. Deeper analysis at last enabled me to discover what the concealed impulse was which might have found satisfaction in the dreaded accident to my son: it was the envy which is felt for the young by those who have grown old, but which they believe they have completely stifled. And there can be no question that it was precisely the strength of the painful emotion which would have arisen if such a misfortune had really happened that caused that emotion to seek out a repressed wish-fulfilment of this kind in order to find some consolation.

[1900a, 991]

The view that dreams carry on the occupations and interests of waking life has been entirely confirmed by the discovery of the concealed dream-thoughts. These are only concerned with what seems important to us and interests us greatly. Dreams are never occupied with minor details. But we have also found reason for accepting the contrary view, that dreams pick up indifferent refuse left over from the previous day and that they cannot get control of any major day time interest until it has been to some extent withdrawn from waking activity. We have found that this holds good of the dream's content, which gives expression to the dream-thoughts in a form modified by distortion. For reasons connected with the mechanism of association, as we have seen, the dream-process finds it easier to get control of recent or indifferent ideational material which has not yet been requisitioned by waking thought-activity; and for reasons of censorship it transfers psychical intensity from what is important but objectionable on to what is indifferent.

[1900a, 1016]
The dream from the analysis of which we have derived this information corresponded, as we have seen, to an intention which Dora carried with her into her sleep. It was therefore repeated each night until the intention had been carried out; and it reappeared years later when an occasion arose for forming an analogous intention. The intention might have been consciously expressed in some such words as these: 'I must fly from this house, for I see that my virginity is threatened here; I shall go away with my father, and I shall take precautions not to be surprised while I am dressing in the morning.' These thoughts were clearly expressed in the dream; they formed part of a mental current which had achieved consciousness and a dominating position in waking life. Behind them can be discerned obscure traces of a train of thought which formed part of a contrary current and had consequently been suppressed. This other train of thought culminated in the temptation to yield to the man, out of gratitude for the love and tenderness he had shown her during the last few years, and it may perhaps have revived the memory of the only kiss she had so far had from him. But according to the theory which I developed in my Interpretation of Dreams such elements as these are not enough for the formation of a dream. On that theory a dream is not an intention represented as having been carried out, but a wish represented as having been fulfilled, and, moreover, in most cases a wish dating from childhood. It is our business now to discover whether this principle may not be contradicted by the present dream. [1905e, 1421]

But we have gone a long way ahead. It is not a question yet of establishing whether the meaning of a dream can always be rendered by a fulfilled wish, or whether it may not just as often stand for an anxious expectation, an intention, a reflection, and so on. On the contrary, the question that first arises is whether dreams have a meaning at all, whether they ought to be assessed as mental events. Science answers 'no': it explains dreaming as a purely physiological process, behind which, accordingly, there is no need to look for sense, meaning or purpose. Somatic stimuli, so it says, play upon the mental instrument during sleep and thus bring to consciousness now one idea and now another, robbed of all mental content: dreams are comparable only to twitchings, not to expressive movements, of the mind. [1907a, 1813]

It is possible to distinguish between dreams from above and dreams from below, provided the distinction is not made too sharply. Dreams from below are those which are provoked by the strength of an unconscious (repressed) wish which has found a means of being represented in some of the day's residues. They may be regarded as inroads of the repressed into waking life. Dreams from above correspond to thoughts or intentions of the day before which have contrived during the night to obtain reinforcement from repressed material that is debarred from the ego. When this is so, analysis as a rule disregards this unconscious ally and succeeds in inserting the latent dream-thoughts into the texture of waking thought. This distinction calls for no modification in the theory of dreams. [1923c, 4032]
It is best to begin by pointing out that the formation of a dream can be provoked in two different ways. Either, on the one hand, an instinctual impulse which is ordinarily suppressed (an unconscious wish) finds enough strength during sleep to make itself felt by the ego, or, on the other hand, an urge left over from waking life, a preconscious train of thought with all the conflicting impulses attached to it, finds reinforcement during sleep from an unconscious element. In short, dreams may arise either from the id or from the ego. The mechanism of dream-formation is in both cases the same and so also is the necessary dynamic precondition. The ego gives evidence of its original derivation from the id by occasionally ceasing its functions and allowing a reversion to an earlier state of things. This is logically brought about by its breaking off its relations with the external world and withdrawing its cathexes from the sense organs. We are justified in saying that there arises at birth an instinct to return to the intra-uterine life that has been abandoned - an instinct to sleep. Sleep is a return of this kind to the womb. Since the waking ego governs motility, that function is paralysed in sleep, and accordingly a good part of the inhibitions imposed on the unconscious id become superfluous. The withdrawal or reduction of these 'anticathexes' thus allows the id what is now a harmless amount of liberty.

[1940a [1938], 4976]

It remains for us to give a dynamic explanation of why the sleeping ego takes on the task of the dream-work at all. The explanation is fortunately easy to find. With the help of the unconscious, every dream that is in process of formation makes a demand upon the ego - for the satisfaction of an instinct, if the dream originates from the id; for the solution of a conflict, the removal of a doubt or the forming of an intention, if the dream originates from a residue of preconscious activity in waking life. The sleeping ego, however, is focused on the wish to maintain sleep; it feels this demand as a disturbance and seeks to get rid of the disturbance. The ego succeeds in doing this by what appears to be an act of compliance: it meets the demand with what is in the circumstances a harmless fulfilment of a wish and so gets rid of it. This replacement of the demand by the fulfilment of a wish remains the essential function of the dream-work. It may perhaps be worth while to illustrate this by three simple examples - a hunger dream, a dream of convenience and a dream prompted by sexual desire. A need for food makes itself felt in a dreamer during his sleep: he has a dream of a delicious meal and sleeps on. The choice, of course, was open to him either of waking up and eating something or of continuing his sleep. He decided in favour of the latter and satisfied his hunger by means of the dream - for the time being, at all events, for if his hunger had persisted he would have had to wake up nevertheless. Here is the second example. A sleeper had to wake up so as to be in time for his work at the hospital. But he slept on, and had a dream that he was already at the hospital - but as a patient, who has no need to get up. Or again, a desire becomes active during the night for the enjoyment of a forbidden sexual object, the wife of a friend of the sleeper. He has a dream of sexual intercourse - not, indeed, with this person but with someone else of the same name to whom he is in fact indifferent; or his struggle against the desire may find expression in his mistress remaining altogether anonymous.

[1940a [1938], 4980]
Naturally, every case is not so simple. Especially in dreams which have originated from undealt-with residues of the previous day, and which have only obtained an unconscious reinforcement during the state of sleep, it is often no easy task to uncover the unconscious motive force and its wish-fulfilment; but we may assume that it is always there. The thesis that dreams are the fulfilments of wishes will easily arouse scepticism when it is remembered how many dreams have an actually distressing content or even wake the dreamer in anxiety, quite apart from the numerous dreams without any definite feeling-tone. But the objection based on anxiety dreams cannot be sustained against analysis. It must not be forgotten that dreams are invariably the product of a conflict, that they are a kind of compromise-structure. Something that is a satisfaction for the unconscious id may for that very reason be a cause of anxiety for the ego.

[1940a [1938], 4980]
I believe, then, that the instigating agent of every dream is to be found among the experiences which one has not yet 'slept on'. Thus the relations of a dream's content to impressions of the most recent past (with the single exception of the day immediately preceding the night of the dream) differ in no respect from its relations to impressions dating from any remoter period. Dreams can select their material from any part of the dreamer's life, provided only that there is a train of thought linking the experience of the dream-day (the 'recent' impressions) with the earlier ones.

[1900a, 657]

I will now proceed to the question of whether the instigating source of a dream, revealed by analysis, must invariably be a recent (and significant) event or whether an internal experience, that is, the recollection of a psychically important event - a train of thought - can assume the role of a dream-instigator. The answer, based upon a large number of analyses, is most definitely in favour of the latter alternative. A dream can be instigated by an internal process which has, as it were, become a recent event, owing to thought-activity during the previous day. This seems to be the appropriate moment for tabulating the different conditions to which we find that the sources of dreams are subject. The source of a dream may be either -

[1900a, 667]
(III) A lady who, though she was still young, had been married for a number of years, received
news that an acquaintance of hers, Fräulein Elise L., who was almost exactly her contemporary,
had become engaged. This was the precipitating cause of the following dream:
[1901a, 1083]

Careful questioning established that there was no evidence of her having had any recollection
of the dream on the morning after she dreamt it - that is, until after her walk and the meeting.
She could produce no objection to an account of what happened which robbed the episode of
anything miraculous and left nothing but an interesting psychological problem. She was walking
along the street in question one morning and met her old family doctor in front of a particular
shop, and thereupon, on seeing him, she felt convinced that she had dreamt the night before of
having this meeting at that precise spot. Analysis was then able to show with great probability
how she arrived at this sense of conviction, which, according to general rules, cannot fairly be
denied a certain right to be considered authentic. A meeting at a particular place, which has
been expected beforehand, amounts in fact to a rendezvous. The old family doctor awakened
her memory of former days, when meetings with a third person, also a friend of the doctor, had
played a very important part in her life. Since then she had continued her relations with that
gentleman and had waited for him in vain on the day before the dream was supposed to have
taken place. If I were able to report the circumstances of the case in greater detail it would be
easy for me to show that her illusion, when she saw her friend of former days, of having had a
prophetic dream was equivalent to some such remark as this; 'Ah! doctor - you remind me now
of past times when I never had to wait in vain for N. if we'd arranged a meeting.'
[1901b, 1332]

Her first reply was that she did not know, but after a while she added: 'Yes. I think it was after
the scene.'
[1905e, 1403]

We have explained that the unconscious instinctual impulse of the dream connects itself with
a residue of the day, with some interest of waking life which has not been disposed of; it thus
gives the dream which it constructs a double value for the work of analysis. For on the one hand
a dream that has been analysed reveals itself as the fulfilment of a repressed wish; but on the
other hand it may be a continuation of some preconscious activity of the day before and may
contain every kind of subject-matter and give expression to an intention, a warning, a reflection,
or once more to the fulfilment of a wish. Analysis exploits the dream in both directions, as a
means of obtaining knowledge alike of the patient's conscious and of his unconscious
processes. It also profits from the fact that dreams have access to the forgotten material of
childhood, and so it happens that infantile amnesia is for the most part overcome in connection
with the interpretation of dreams. In this respect dreams achieve a part of what was previously
the task of hypnotism. On the other hand, I have never maintained the assertion which has so
often been ascribed to me that dream-interpretation shows that all dreams have a sexual
content or are derived from sexual motive forces. It is easy to see that hunger, thirst, or the
need to excrete, can produce dreams of satisfaction just as well as any repressed sexual or
egoistic impulse. The case of young children affords us a convenient test of the validity of our
theory of dreams. In them the various psychical systems are not yet sharply divided and the
repressions have not yet grown deep, so that we often come upon dreams which are nothing
more than undisguised fulfilments of wishful impulses left over from waking life. Under the
influence of imperative needs, adults may also produce dreams of this infantile type.¹
[1925d, 4221]
(c) In the field of the development of character we are bound to meet with the same instinctual forces which we have found at work in the neuroses. But a sharp theoretical distinction between the two is necessitated by the single fact that the failure of repression and the return of the repressed - which are peculiar to the mechanism of neurosis - are absent in the formation of character. In the latter, repression either does not come into action or smoothly achieves its aim of replacing the repressed by reaction-formations and sublimations. Hence the processes of the formation of character are more obscure and less accessible to analysis than neurotic ones.

[1913i, 2629]

(6) What instigates a dream is a wish, and the fulfilment of that wish is the content of the dream - this is one of the chief characteristics of dreams. The other, equally constant one, is that a dream does not simply give expression to a thought, but represents the wish-fulfilled as a hallucinatory experience. 'I should like to go on the lake' is the wish that instigates the dream. The content of the dream itself is: 'I am going on the lake.' Thus even in these simple children's dreams a difference remains between the latent and the manifest dream, there is a distortion of the latent dream-thought: the transformation of a thought into an experience. In the process of interpreting a dream this alteration must first be undone. If this turns out to be the most universal characteristic of dreams, the fragment of dream which I reported to you earlier 'I saw my brother in a box [Kasten]' is not to be translated 'my brother is restricting himself [schnärkt sich ein]' but 'I should like my brother to restrict himself: my brother must restrict himself.' Of the two general characteristics of dreams which I have here brought forward, the second clearly has more prospect of being accepted without contradiction than the first. It is only by means of far-reaching investigations that we shall be able to establish the fact that what instigates dreams must always be a wish and cannot be a worry or an intention or a reproach; but this will not affect the other characteristic - that the dream does not simply reproduce this stimulus, but removes it, gets rid of it, deals with it, by means of a kind of experience.

[1916-1917, 3224]

(7) On the basis of these characteristics of dreams, we can return once more to a comparison between a dream and a parapraxis. In the latter we distinguished between a disturbing purpose and a disturbed one, and the parapraxis was a compromise between them. A dream can be fitted into the same pattern. The disturbed purpose can only be that of sleeping. We may replace the disturbing one by the psychical stimulus, or let us say by the wish which presses to be dealt with, since we have not learnt so far of any other psychical stimulus that disturbs sleep. Here the dream, too, is the result of a compromise. One sleeps, but one nevertheless experiences the removing of a wish; one satisfies a wish, but at the same time one continues to sleep. Both purposes are partly achieved and partly abandoned.

[1916-1917, 3225]

If dreams of the infantile kind were the only ones, the problem would be solved and our task finished, and that without our questioning the dreamer or bringing in the unconscious or resorting to free association. This is evidently where a continuation of our task lies ahead. We have already found repeatedly that characteristics which were claimed as being of general validity have turned out to apply only to a particular sort and number of dreams. The question for us is therefore whether the general characteristics we inferred from children's dreams have a firmer footing, whether they also hold good of dreams which are not transparently clear and whose manifest content gives no sign of being connected with a wish left over from the previous day. It is our view that these other dreams have undergone a far-reaching distortion and for that reason cannot be judged at a first glance. We suspect too that to explain this distortion we shall need the psycho-analytic technique which we have been able to do without in the understanding we have just gained of children's dreams.

[1916-1917, 3227]
It is often possible to influence dreamers as to what they shall dream about, but never as to what they shall dream. The mechanism of the dream-work and the unconscious dream wish are exempt from any outside influence. In considering dreams with a somatic stimulus, we have already found that the characteristic nature and independence of dream-life are shown in the reaction with which dreams respond to the somatic or mental stimuli that are brought to bear. The thesis which we have been discussing, and which seeks to throw doubt on the objectivity of research into dreams, is thus once again based on a confusion - this time between the dream and the dream-material.

[1916-1917, 3323]

My second remark is a supplement to the theory of dreams. We cannot explain the origin of dreams unless we adopt the hypothesis that the repressed unconscious has achieved some degree of independence of the ego, so that it does not acquiesce in the wish to sleep and retains its cathexes even when all the object-cathexes depending on the ego have been withdrawn in order to encourage sleep. Only if that is so can we understand how the unconscious can make use of the lifting or reduction of the censorship which occurs at night, and can succeed in obtaining control over the day's residues so as to construct a forbidden dream-wish out of their material. On the other hand, it may be that these day's residues have to thank an already existing connection with the repressed unconscious for some of their resistance to the withdrawal of libido commanded by the wish to sleep. We will, then, insert this dynamically important feature into our view of the formation of dreams by way of supplement.

[1916-1917, 3464]

The dream ended in a state of anxiety, from which he did not recover until he had his Nanya with him. He fled, therefore, from his father to her. His anxiety was a repudiation of the wish for sexual satisfaction from his father - the trend which had put the dream into his head. The form taken by the anxiety, the fear of 'being eaten by the wolf', was only the (as we shall hear, regressive) transposition of the wish to be copulated with by his father, that is, to be given sexual satisfaction in the same way as his mother. His last sexual aim, the passive attitude towards his father, succumbed to repression, and fear of his father appeared in its place in the shape of the wolf phobia.

[1918b, 3534]

This would seem to be the place, then, at which to admit for the first time an exception to the proposition that dreams are fulfilments of wishes. Anxiety dreams, as I have shown repeatedly and in detail, offer no such exception. Nor do 'punishment dreams', for they merely replace the forbidden wish-fulfilment by the appropriate punishment for it; that is to say, they fulfil the wish of the sense of guilt which is the reaction to the repudiated impulse. But it is impossible to classify as wish-fulfilments the dreams we have been discussing which occur in traumatic neuroses, or the dreams during psycho-analyses which bring to memory the psychical traumas of childhood. They arise, rather, in obedience to the compulsion to repeat, though it is true that in analysis that compulsion is supported by the wish (which is encouraged by 'suggestion') to conjure up what has been forgotten and repressed. Thus it would seem that the function of dreams, which consists in setting aside any motives that might interrupt sleep, by fulfilling the wishes of the disturbing impulses, is not their original function. It would not be possible for them to perform that function until the whole of mental life had accepted the dominance of the pleasure principle. If there is a 'beyond the pleasure principle', it is only consistent to grant that there was also a time before the purpose of dreams was the fulfilment of wishes. This would imply no denial of their later function. But if once this general rule has been broken, a further question arises. May not dreams which, with a view to the psychical binding of traumatic impressions, obey the compulsion to repeat - may not such dreams occur outside analysis as well? And the reply can only be a decided affirmative.

[1920g, 3735]
And now I have reached the point I wish to put before you. We have endeavoured to maintain the strictest impartiality and have allowed two conceptions of the dream to rank as equally probable and equally unproved. According to the first the dream is a reaction to a telepathic message: 'your daughter has just brought twins into the world.' According to the second an unconscious process of thought underlies the dream, which may be reproduced somewhat as follows: 'To-day is the day the confinement should take place if the young people in Berlin are really out in their reckoning by a month, as I suspect. And if my (first) wife were still alive, she certainly would not be content with one grandchild. To please her there would have to be at least twins!' If this second view is right, no new problems arise. It is simply a dream like any other. The (preconscious) dream-thoughts as outlined above are reinforced by the (unconscious) wish that no other than the daughter should be the dreamer's second wife, and thus the manifest dream as described to us arises. [1922a, 3886]

After these influences have been brought to bear upon the dream-thoughts the dream is almost complete. A further, somewhat variable, factor also comes into play - known as 'secondary revision' - after the dream has been presented before consciousness as an object of perception. At that point we treat it as we are in general accustomed to treat the contents of our perception: we fill in gaps and introduce connections, and in doing so are often guilty of gross misunderstandings. But this activity, which might be described as a rationalizing one and which at best provides the dream with a smooth façade that cannot fit its true content, may also be omitted or only be expressed to a very modest degree - in which case the dream will display all its rents and cracks openly. It must not be forgotten, on the other hand, that the dream-work does not always operate with equal energy either; it often restricts itself to certain portions of the dream-thoughts only and others of them are allowed to appear in the dream unaltered. In such cases an impression is given of the dream having carried out the most delicate and complex intellectual operations, of its having speculated, made jokes, arrived at decisions and solved problems, whereas all this is a product of our normal mental activity, may have been performed equally well during the day before the dream as during the night, has nothing to do with the dream-work and brings nothing to light that is characteristic of dreams. Nor is it superfluous to insist once more on the contrast within the dream-thoughts themselves between the unconscious instinctual impulse and the day's residues. While the latter exhibit all the multiplicity of our mental acts, the former, which becomes the motive force proper of the forming of the dream, finds its outlet invariably in the fulfilment of a wish. [1933a, 4634]

It is best to begin by pointing out that the formation of a dream can be provoked in two different ways. Either, on the one hand, an instinctual impulse which is ordinarily suppressed (an unconscious wish) finds enough strength during sleep to make itself felt by the ego, or, on the other hand, an urge left over from waking life, a preconscious train of thought with all the conflicting impulses attached to it, finds reinforcement during sleep from an unconscious element. In short, dreams may arise either from the id or from the ego. The mechanism of dream-formation is in both cases the same and so also is the necessary dynamic precondition. The ego gives evidence of its original derivation from the id by occasionally ceasing its functions and allowing a reversion to an earlier state of things. This is logically brought about by its breaking off its relations with the external world and withdrawing its cathexes from the sense organs. We are justified in saying that there arises at birth an instinct to return to the intra-uterine life that has been abandoned - an instinct to sleep. Sleep is a return of this kind to the womb. Since the waking ego governs motility, that function is paralysed in sleep, and accordingly a good part of the inhibitions imposed on the unconscious id become superfluous. The withdrawal or reduction of these 'anticathexes' thus allows the id what is now a harmless amount of liberty. [1940a [1938], 4976]
It remains for us to give a dynamic explanation of why the sleeping ego takes on the task of the dream-work at all. The explanation is fortunately easy to find. With the help of the unconscious, every dream that is in process of formation makes a demand upon the ego - for the satisfaction of an instinct, if the dream originates from the id; for the solution of a conflict, the removal of a doubt or the forming of an intention, if the dream originates from a residue of preconscious activity in waking life. The sleeping ego, however, is focused on the wish to maintain sleep; it feels this demand as a disturbance and seeks to get rid of the disturbance. The ego succeeds in doing this by what appears to be an act of compliance: it meets the demand with what is in the circumstances a harmless fulfilment of a wish and so gets rid of it. This replacement of the demand by the fulfilment of a wish remains the essential function of the dream-work. It may perhaps be worth while to illustrate this by three simple examples - a hunger dream, a dream of convenience and a dream prompted by sexual desire. A need for food makes itself felt in a dreamer during his sleep: he has a dream of a delicious meal and sleeps on. The choice, of course, was open to him either of waking up and eating something or of continuing his sleep. He decided in favour of the latter and satisfied his hunger by means of the dream - for the time being, at all events, for if his hunger had persisted he would have had to wake up nevertheless. Here is the second example. A sleeper had to wake up so as to be in time for his work at the hospital. But he slept on, and had a dream that he was already at the hospital - but as a patient, who has no need to get up. Or again, a desire becomes active during the night for the enjoyment of a forbidden sexual object, the wife of a friend of the sleeper. He has a dream of sexual intercourse - not, indeed, with this person but with someone else of the same name to whom he is in fact indifferent; or his struggle against the desire may find expression in his mistress remaining altogether anonymous. [1940a [1938], 4980]
We may next ask where the wishes that come true in dreams originate. What contrasting possibilities or what alternatives have we in mind in raising this question? It is the contrast, I think, between the consciously perceived life of daytime and a psychical activity which has remained unconscious and of which we can only become aware at night. I can distinguish three possible origins for such a wish. (1) It may have been aroused during the day and for external reasons may not have been satisfied; in that case an acknowledged wish which has not been dealt with is left over for the night. (2) It may have arisen during the day but been repudiated; in that case what is left over is a wish which has not been dealt with but has been suppressed. (3) It may have no connection with daytime life and be one of those wishes which only emerge from the suppressed part of the mind and become active in us at night. If we turn again to our schematic picture of the psychical apparatus, we shall localize wishes of the first kind in the system \( Pcs \); we shall suppose that wishes of the second kind have been driven out of the system \( Pcs \) into the \( Ucs \), where, if at all, they continue to exist; and we shall conclude that wishful impulses of the third kind are altogether incapable of passing beyond the system \( Ucs \).

The question then arises whether wishes derived from these different sources are of equal importance for dreams and have equal power to instigate them.

[1900a, 983]

If we cast our minds over the dreams that are at our disposal for answering this question, we shall at once be reminded that we must add a fourth source of dream-wishes, namely the current wishful impulses that arise during the night (e.g. those stimulated by thirst or sexual needs). In the next place, we shall form the opinion that the place of origin of a dream-wish probably has no influence on its capacity for instigating dreams. I may recall the little girl's dream which prolonged a trip on the lake that had been interrupted during the day and the other children's dreams which I have recorded. They were explained as being due to unfulfilled, but unsuppressed, wishes from the previous day. Instances of a wish that has been suppressed in the daytime finding its way out in a dream are exceedingly numerous. I will add a further very simple example of this class. The dreamer was a lady who was rather fond of making fun of people and one of whose friends, a woman younger than herself, had just become engaged. All day long she had been asked by her acquaintances whether she knew the young man and what she thought of him. She had replied with nothing but praises, with which she had silenced her real judgement; for she would have liked to tell the truth - that he was a 'Dutzendmensch' [literally a 'dozen man', a very commonplace sort of person - people like him are turned out by the dozen]. She dreamt that night that she was asked the same question, and replied with the formula: 'In the case of repeat orders it is sufficient to quote the number.' We have learnt, lastly, from numerous analyses that wherever a dream has undergone distortion the wish has arisen from the unconscious and was one which could not be perceived during the day. Thus it seems at a first glance as though all wishes are of equal importance and equal power in dreams.

[1900a, 984]
I cannot offer any proof here that the truth is nevertheless otherwise; but I may say that I am strongly inclined to suppose that dream-wishes are more strictly determined. It is true that children's dreams prove beyond a doubt that a wish that has not been dealt with during the day can act as a dream-instigator. But it must not be forgotten that it is a child's wish, a wishful impulse of the strength proper to children. I think it is highly doubtful whether in the case of an adult a wish that has not been fulfilled during the day would be strong enough to produce a dream. It seems to me, on the contrary, that, with the progressive control exercised upon our instinctual life by our thought-activity, we are more and more inclined to renounce as unprofitable the formation or retention of such intense wishes as children know. It is possible that there are individual differences in this respect, and that some people retain an infantile type of mental process longer than others, just as there are similar differences in regard to the diminution of visual imagery, which is so vivid in early years. But in general, I think, a wish that has been left over unfulfilled from the previous day is insufficient to produce a dream in the case of an adult. I readily admit that a wishful impulse originating in the conscious will contribute to the instigation of a dream, but it will probably not do more than that. The dream would not materialize if the preconscious wish did not succeed in finding reinforcement from elsewhere.

The situation is this. Either residues of the previous day have been left over from the activity of waking life and it has not been possible to withdraw the whole cathexis of energy from them; or the activity of waking life during the course of the day has led to the stirring up of an unconscious wish; or these two events have happened to coincide. (We have already discussed the various possibilities in this connection.) The unconscious wish links itself up with the day's residues and effects a transference on to them; this may happen either in the course of the day or not until a state of sleep has been established. A wish now arises which has been transferred on to the recent material; or a recent wish, having been suppressed, gains fresh life by being reinforced from the unconscious. This wish seeks to force its way along the normal path taken by thought processes, though the Pcs. (to which, indeed, it in part belongs) to consciousness. But it comes up against the censorship, which is still functioning and to the influence of which it now submits. At this point it takes on the distortion for which the way has already been paved by the transference of the wish on to recent material. So far it is on the way to becoming an obsessive idea or a delusion or something of the kind - that is, a thought which has been intensified by transference and distorted in its expression by censorship. Its further advance is halted, however, by the sleeping state of the preconscious. (The probability is that that system has protected itself against the invasion by diminishing its own excitations.) The dream-process consequently enters on a regressive path, which lies open to it precisely owing to the peculiar nature of the state of sleep, and it is led along that path by the attraction exercised on it by groups of memories; some of these memories themselves exist only in the form of visual cathexes and not as translations into the terminology of the later systems. In the course of its regressive path the dream-process acquires the attribute of representability. (I shall deal later with the question of compression.) It has now completed the second portion of its zigzag journey. The first portion was a progressive one, leading from the unconscious scenes or phantasies to the preconscious; the second portion led from the frontier of the censorship back again to perceptions. But when the content of the dream process has become perceptual, by that fact it has, as it were, found a way of evading the obstacle put in its way by the censorship and the state of sleep in the Pcs. It succeeds in drawing attention to itself and in being noticed by consciousness.
The purposes against which the dream-censorship is directed must be described in the first instance from the point of view of that agency itself. If so, one can only say that they are invariably of a reprehensible nature, repulsive from the ethical, aesthetic and social point of view - matters of which one does not venture to think at all or thinks only with disgust. These wishes, which are censored and given a distorted expression in dreams, are first and foremost manifestations of an unbridled and ruthless egoism. And, to be sure, the dreamer's own ego appears in every dream and plays the chief part in it, even if it knows quite well how to hide itself so far as the manifest content goes. This 'sacro egoismo' of dreams is certainly not unrelated to the attitude we adopt when we sleep, which consists in our withdrawing our interest from the whole external world.

[1916-1917, 3237]

The ego, freed from all ethical bonds, also finds itself at one with all the demands of sexual desire, even those which have long been condemned by our aesthetic upbringing and those which contradict all the requirements of moral restraint. The desire for pleasure - the 'libido', as we call it - chooses its objects without inhibition, and by preference, indeed, the forbidden ones: not only other men's wives, but above all incestuous objects, objects sanctified by the common agreement of mankind, a man's mother and sister, a woman's father and brother. (The dream of our fifty-year-old lady, too, was incestuous; her libido was unmistakably directed to her son.) Lusts which we think of as remote from human nature show themselves strong enough to provoke dreams. Hatred, too, rages without restraint. Wishes for revenge and death directed against those who are nearest and dearest in waking life, against the dreamer's parents, brothers and sisters, husband or wife, and his own children are nothing unusual. These censored wishes appear to rise up out of a positive Hell; after they have been interpreted when we are awake, no censorship of them seems to us too severe.

[1916-1917, 3237]

Yes, indeed! Both simpler and more satisfactory - but not necessarily on that account more correct. Let us give ourselves time: the matter is not yet ripe for judgement. And first we can further strengthen the criticism of our dream-interpretations. The fact that the findings from them are so disagreeable and repellent need not, perhaps, carry very great weight. A stronger argument is that the dreamers to whom we are led to attribute such wishful purposes by the interpretation of their dreams reject them most emphatically and for good reasons. 'What?' says one of them, 'you want to convince me from this dream that I regret the money I have spent on my sister's dowry and my brother's education? But that cannot be so. I work entirely for my brothers and sisters; I have no other interest in life but to fulfil my duties to them, which, as the eldest of the family, I promised our departed mother I would do.' Or a woman dreamer would say: 'You think I wish my husband was dead? That is a shocking piece of nonsense! It is not only that we are most happily married - you would probably not believe me if I said that - but his death would rob me of everything I possess in the world.' Or another man would answer us: 'You say that I have sensual desires for my sister? That is ridiculous! She means nothing at all to me. We are on bad terms with each other and I have not exchanged a word with her for years.' We might still take it lightly, perhaps, if these dreamers neither confirmed nor denied the purposes we attribute to them; we might say that these were just things they did not know about themselves. But when they feel in themselves the precise contrary of the wish we have interpreted to them and when they are able to prove to us by the lives they lead that they are dominated by this contrary wish, it must surely take us aback. Has not the time come to throw aside the whole work we have done on dream-interpretation as something which its findings have reduced ad absurdum?

[1916-1917, 3239]
I feel sure that you have heard some time or other that it is asserted by psycho-analysis that every dream has a sexual meaning. Well, you yourselves are in a position to form a judgement of the incorrectness of this reproach. You have become acquainted with wishful dreams dealing with the satisfaction of the most obvious needs - hunger and thirst and the longing for freedom - with dreams of convenience and of impatience, and also with purely covetous and egoistic dreams. But at the same time you should bear in mind, as one of the results of psycho-analytic research, that greatly distorted dreams give expression mainly (though, again, not exclusively) to sexual wishes.

This same piece of information can be further applied to another of the riddles we have come up against. You recall the amazement which was caused by our discovery that what instigates dreams are actively evil and extravagantly sexual wishes, which have made the censorship and distortion of dreams necessary. When we have interpreted a dream of this sort to the dreamer and if, to take the most favourable case, he does not actually attack the interpretation, he nevertheless regularly raises the question of where these wishes come from, since they feel alien to him and their opposite is what he is conscious of. We need have no hesitation in pointing out their origin. These evil wishful impulses arise from the past, and often from a past that is not very remote. It can be shown that there was a time when they were familiar and conscious, even if they are no longer so to-day. A woman, whose dream meant that she would like to see her only daughter, now seventeen years old, dead before her eyes, found under our guidance that she had indeed at one time harboured this death wish. The child was the fruit of an unhappy marriage which was soon dissolved. Once, while she still bore her daughter in her womb, in a fit of rage after a violent scene with her husband she had beaten with her fists on her body in order to kill the child inside it. How many mothers, who love their children tenderly, perhaps over-tenderly, to-day, conceived them unwillingly and wished at that time that the living thing within them might not develop further! They may even have expressed that wish in various, fortunately harmless, actions. Thus their death-wish against someone they love, which is later so mysterious, originates from the earliest days of their relationship to that person.

What we have already learnt from our study of the mental life of children will lead us to expect to find a similar explanation of the other group of forbidden dream-wishes - the excessive sexual impulses. We are thus encouraged to make a study of the development of children's sexual life and from many sources we arrive at what follows.
A short time ago we submitted a series of dreams to interpretation, but we left wish-fulfilment completely out of account. I feel sure that you must have repeatedly been driven to ask yourselves: 'But where is the wish-fulfilment, which is supposed to be the aim of the dream-work?' The question is an important one, for it has become the question raised by our lay critics. Human beings, as you know, have an instinctive tendency to fend off intellectual novelties. One of the ways in which this tendency is manifested is by immediately reducing the novelty to the smallest proportions, by compressing it if possible into a single catch-word. 'Wish-fulfilment' has become the catch word for the new theory of dreams. The layman asks: 'Where is the wish-fulfilment?' And instantly, having heard that dreams are supposed to be wish-fulfilments, and in the very act of asking the question, he answers it with a rejection. He immediately thinks of countless experiences of his own with dreams, in which the dream has been accompanied by feelings ranging from the unpleasurable to severe anxiety, so that the assertion made by the psycho-analytic theory of dreams seems to him most improbable. We have no difficulty in replying that in distorted dreams the wish-fulfilment cannot be obvious but must be looked for, so that it cannot be pointed out until the dream has been interpreted. We know too that the wishes in these distorted dreams are forbidden ones - rejected by the censorship - whose existence was precisely the cause of the dream's distortion, the reason for the intervention of the dream censorship. But it is difficult to make the lay critic understand that before a dream has been interpreted one cannot enquire about the fulfilment of its wish. He will keep on forgetting this. His rejection of the theory of wish-fulfilment is actually nothing other than a consequence of the dream-censorship, a substitute for the rejection of the censored dream-wishes and an effluence from it.

In this connection it strikes us that we are still quite ignorant of why it is that these evil, repudiated wishes become active precisely at night and disturb us during our sleep. The answer is almost bound to lie in some hypothesis going back to the nature of the state of sleep. In daytime the heavy weight of censorship rests on them and as a rule makes it impossible for them to manifest themselves in any activity. At night this censorship, like all the other interests of mental life, is probably withdrawn, or at least greatly reduced, in favour of the single wish to sleep. It is this lowering of the censorship at night that the forbidden wishes have to thank for being able to become active once more. There are some neurotic patients who are unable to sleep and who admit to us that their insomnia was originally intentional. They did not dare to sleep because they were afraid of their dreams - afraid, that is, of the results of the weakening of the censorship. You will easily see, however, that in spite of this the withdrawal of the censorship implies no gross carelessness. The state of sleep paralyses our motive powers. If our evil intentions begin to stir, they can, after all, do nothing more than precisely cause a dream, which is harmless from the practical point of view. It is this soothing consideration that is the basis of the highly sensible remark made by the sleeper-made at night, it is true, but not forming part of dream-life: 'After all it's only a dream. So let us leave it to take its course, and let us sleep on.'
On the whole, therefore, I have made no concession to your objection to the theory of wish-fulfilment. It is our duty, however, to be able to indicate the wish-fulfilment in any distorted dream we may come across, and we shall certainly not evade the task. Let us go back to the dream we have already interpreted of the three bad theatre-tickets for 1 florin 50, from which we have already learnt so much. I hope you still recollect it. A lady, whose husband had told her during the day that her friend Elise, who was only three months her junior, had become engaged, dreamt that she was at the theatre with her husband. One side of the stalls was almost empty. Her husband said to her that Elise and her fiancé had wanted to go to the theatre too but had not been able to, since they had only got bad seats - three for 1 florin 50. She thought it would not really have done any harm if they had. We found that the dream-thoughts related to her anger at having married so early and to her dissatisfaction with her husband. We may be curious to discover how these gloomy thoughts were transformed into the fulfilment of a wish and where any trace of it is to be found in the manifest content of the dream. We already know that the element 'too early, in a hurry' was eliminated from the dream by the censorship. The empty stalls were an allusion to it. The mysterious 'three for 1 florin 50' now becomes more intelligible to us with the help of the symbolism with which we have meanwhile become acquainted. The '3' really means a man and the manifest element is easy to translate: buying a husband with her dowry. ('I could have got one ten times better with my dowry.') 'Marrying' is clearly replaced by 'going to the theatre'. 'Taking the theatre tickets too early' is, indeed, an immediate substitute for 'marrying too early'. This substitution is, however, the work of a wish-fulfilment. Our dreamer was not always so dissatisfied with her early marriage as she was on the day when she received the news of her friend's engagement. She had been proud of it at one time and regarded herself as at an advantage over her friend. Simple-minded girls, after becoming engaged, are reputed often to express their joy that they will soon be able to go to the theatre, to all the plays which have hitherto been prohibited, and will be allowed to see everything. The pleasure in looking, or curiosity, which is revealed in this was no doubt originally a sexual desire to look, directed towards sexual happenings and especially on to the girls' parents, and hence it became a powerful motive for urging them to an early marriage. In this way a visit to the theatre became an obvious substitute, by way of allusion, for being married. Thus the dreamer, in her present anger at her early marriage, harked back to the time at which early marriage was the fulfilment of a wish because it satisfied her scopophilia, and, under the lead of this old wishful impulse, she replaced marriage by going to the theatre.

[1916-1917, 3308]
Let us once again take up the dream we have already so often returned to: the dream of the three theatre-tickets for 1 florin 50. (I can assure you that I originally chose out this example without any special purpose in view.) You know the latent dream thoughts: anger at having been in such a hurry to get married which arose when she heard the news that her friend had only just become engaged, putting a low value on her husband and the idea that she might have got a better one if only she had waited. We already know the wish which made a dream out of these thoughts: it was the desire to look, to be able to go to the theatre, most probably an offshoot of her old curiosity to discover at long last what really happens when one is married. This curiosity is, as we know, regularly directed by children towards their parents' sexual life,: it is an infantile curiosity, and, so far as it still persists later, an instinctual impulse with roots reaching back into infancy. But the news the dreamer had received during the day gave no occasion for awakening this desire to look, but only for awakening anger and regret. This wishful impulse was not in the first instance connected with the latent dream-thoughts; and we were able to include the outcome of the dream-interpretation in the analysis without taking any account of that impulse. But the anger in itself was not capable of creating a dream. A dream could not arise out of the thoughts that 'it was absurd to marry so early' until they had awakened the old wish to see at long last what happens in marriage. This wish then gave the dream-content its form by replacing marriage by going to the theatre, and the form was that of an earlier wish-fulfilment: 'There! now I may go to the theatre and look at everything that's forbidden, and you mayn't! I'm married and you must wait!' In this way the dreamer's present situation was transformed into its opposite, an old triumph was put in the place of her recent defeat. And, incidentally, a satisfaction of her scopophilia was mixed with a satisfaction of her egoistic competitive sense. This satisfaction then determined the manifest content of the dream, in which the position actually was that she was sitting in the theatre while her friend could not gain admission to it. The portions of the content of the dream behind which the latent dream-thoughts still lay concealed were superimposed on this situation of satisfaction as a misplaced and unintelligible modification of it. The dream's interpretation had to disregard everything that served to represent the wish-fulfilment and to re-establish the distressing latent dream-thoughts from these obscure remaining hints.

[1916-1917, 3312]
If we recognize that the links between a latent dream-element and its manifest substitute can be of the most out-of-the-way and peculiar nature, sometimes appearing comic and sometimes resembling a joke, we are basing ourselves on copious experience of examples which, as a rule, we have not solved ourselves. It is often impossible to give such interpretations on our own account: no sensible person could guess at the connection. The dreamer gives us the translation either all at once by a direct association - he is able to, since it was he who produced the substitute - or else he brings up so much material that the solution no longer calls for any particular acumen, but presents itself, so to speak, as a matter of course. If the dreamer fails to assist in one or other of these two ways, the manifest element in question will for ever remain unintelligible to us. I will, if I may, give you an example which occurred to me recently. One of my women patients lost her father in the course of the treatment. Since then she has taken every opportunity of bringing him to life in her dreams. In one of these her father appeared (in a particular connection of no further relevance) and said: 'It's a quarter past eleven, it's half-past eleven, it's a quarter to twelve.' By way of interpretation of this oddity all that occurred to her was that her father liked his grown-up children to appear punctually at the family meals. No doubt this was connected with the dream-element, but it threw no light on its origin. There was a suspicion, based on the immediate situation in the treatment, that a carefully suppressed critical revolt against her beloved and honoured father played some part in the dream. In the further course of her associations, apparently remote from the dream, she told how the day before there had been a lot of talk about psychology in her presence, and a relative of hers had remarked: 'The *Urmensch* [primal man] survives in all of us.' This seemed to provide us with the explanation. It had given her an excellent opportunity of bringing her dead father to life once again. She made him in the dream into an 'Uhrmensch' ['clock-man'] by making him announce the quarter hours at midday.

But there is something else that I cannot pass by. The reminder of dreams given to us by the mother and wife of Oedipus must not be allowed to remain fruitless. Do you recall the outcome of our dream-analyses - how the wishes that construct dreams are so often of a perverse or incestuous nature or reveal an unsuspected hostility to those who are nearest and dearest to the dreamer? At that time we gave no explanation of the origin of these evil impulses. Now you can find it for yourselves. They are allocations of the libido and object-cathexes which date from early infancy and have long since been abandoned as far as conscious life is concerned, but which prove still to be present at night-time and to be capable of functioning in a certain sense. Since, however, everyone, and not only neurotics, experiences these perverse, incestuous and murderous dreams, we may conclude that people who are normal to-day have passed along a path of development that has led through the perversions and object-cathexes of the Oedipus complex, that that is the path of normal development and that neurotics merely exhibit to us in a magnified and coarsened form what the analysis of dreams reveals to us in healthy people as well. And this is one of the reasons why I dealt with the study of dreams before that of neurotic symptoms.

But our interest in the genesis of these *manifestly* immoral dreams is greatly reduced when we find from analysis that the majority of dreams - innocent dreams, dreams without affect and anxiety-dreams - are revealed, when the distortions of the censorship have been undone, as the fulfillments of immoral - egoistic, sadistic, perverse or incestuous - wishful impulses. As in the world of waking life, these masked criminals are far commoner than those with their vizors raised. The straightforward dream of sexual relations with one's mother, which Jocasta alludes to in the *Oedipus Rex*, is a rarity in comparison with all the multiplicity of dreams which psycho-analysis must interpret in the same sense.
I have dealt so exhaustively in these pages with this characteristic of dreams, which indeed
provides the motive for their distortion, that I can pass at once from this topic to the problem that
lies before us: Must one assume responsibility for the content of one's dreams? For the sake of
completeness, it should, however, be added that dreams do not always offer immoral wish-
fulfilments, but often energetic reactions against them in the form of 'punishment dreams'. In
other words, the dream-censorship cannot only express itself in distortions and the generation
of anxiety, but can go so far as to blot out the immoral subject-matter completely and replace it
by something else that serves as an atonement, though it allows one to see what lies behind.
But the problem of responsibility for the immoral content of dreams no longer exists for us as it
formerly did for writers who knew nothing of latent dream-thoughts and the repressed part of our
mental life. Obviously one must hold oneself responsible for the evil impulses of one's dreams.
What else is one to do with them? Unless the content of the dream (rightly understood) is
inspired by alien spirits, it is a part of my own being. If I seek to classify the impulses that are
present in me according to social standards into good and bad, I must assume responsibility for
both sorts; and if, in defence, I say that what is unknown, unconscious and repressed in me is
not my 'ego', then I shall not be basing my position upon psycho-analysis, I shall not have
accepted its conclusions - and I shall perhaps be taught better by the criticisms of my fellow-
men, by the disturbances in my actions and the confusion of my feelings. I shall perhaps learn
that what I am disavowing not only 'is' in me but sometimes 'acts' from out of me as well.
[1925i, 4050]

There were now a whole series of questions to be answered, among the most important of
them being whether the formation of dreams had a motive, under what conditions it took place,
by what methods the dream-thoughts (which are invariably full of sense) become converted into
the dream (which is often senseless), and others besides. I attempted to solve all of these
problems in *The Interpretation of Dreams*, which I published in the year 1900. I can only find
space here for the briefest abstract of my investigation. When the latent dream-thoughts that
are revealed by the analysis of a dream are examined, one of them is found to stand out from
among the rest, which are intelligible and well known to the dreamer. These latter thoughts are
residues of waking life (the *day's residues*, as they are called technically); but the isolated
thought is found to be a wishful impulse, often of a very repellent kind, which is foreign to the
waking life of the dreamer and is consequently disavowed by him with surprise or indignation.
This impulse is the actual constructor of the dream: it provides the energy for its production and
makes use of the day's residues as material. The dream which thus originates represents a
situation of satisfaction for the impulse, it is the fulfilment of its wish. It would not be possible for
this process to take place without being favoured by the presence of something in the nature of
a state of sleep. The necessary mental precondition of sleep is the concentration of the ego
upon the wish to sleep and the withdrawal of psychical energy from all the interests of life. Since
at the same time all the paths of approach to motility are blocked, the ego is also able to reduce
the expenditure by which at other times it maintains the repressions. The unconscious impulse
makes use of this nocturnal relaxation of repression in order to push its way into consciousness
with the dream. But the repressive resistance of the ego is not abolished in sleep but merely
reduced. Some of it remains in the shape of a *censorship of dreams* and forbids the
unconscious impulse to express itself in the forms which it would properly assume. In
consequence of the severity of the censorship of dreams, the latent dream-thoughts are obliged
to submit to being altered and softened so as to make the forbidden meaning of the dream
unrecognizable. This is the explanation of *dream-distortion*, which accounts for the most striking
characteristics of the manifest dream. We are therefore justified in asserting that a dream is the
*(disguised) fulfilment of a (repressed) wish*. It will now be seen that dreams are constructed like
a neurotic symptom: they are compromises between the demands of a repressed impulse and
the resistance of a censoring force in the ego. Since they have a similar origin they are equally
unintelligible and stand in equal need of interpretation.
[1925d, 4219]
In another instance it became apparent that, though the wish which instigated the dream was a present-day one, it had received a powerful reinforcement from memories that stretched far back into childhood. What I have in mind is a series of dreams which are based upon a longing to visit Rome. For a long time to come, no doubt, I shall have to continue to satisfy that longing in my dreams: for at the season of the year when it is possible for me to travel, residence in Rome must be avoided for reasons of health.¹ For instance, I dreamt once that I was looking out of a railway-carriage window at the Tiber and the Ponte Sant' Angelo. The train began to move off, and it occurred to me that I had not so much as set foot in the city. The view that I had seen in my dream was taken from a well-known engraving which I had caught sight of for a moment the day before in the sitting-room of one of my patients. Another time someone led me to the top of a hill and showed me Rome half-shrouded in mist; it was so far away that I was surprised at my view of it being so clear. There was more in the content of this dream than I feel prepared to detail; but the theme of 'the promised land seen from afar' was obvious in it. The town which I saw in this way for the first time, shrouded in mist, was - Lübeck, and the prototype of the hill was - at Gleichenberg. In a third dream I had at last got to Rome, as the dream itself informed me; but I was disappointed to find that the scenery was far from being of an urban character. There was a narrow stream of dark water; on one side of it were black cliffs and on the other meadows with big white flowers. I noticed a Herr Zucker (whom I knew slightly) and determined to ask him the way to the city. I was clearly making a vain attempt to see in my dream a city which I had never seen in my waking life. Breaking up the landscape in the dream into its elements, I found that the white flowers took me to Ravenna, which I have visited and which, for a time at least, superseded Rome as capital of Italy. In the marshes round Ravenna we found the loveliest water-lilies growing in black water. Because we had had such difficulty in picking them out of the water, the dream made them grow in meadows like the narcissi at our own Aussee. The dark cliff, so close to the water, reminded me vividly of the valley of the Tepl near Karlsbad. ‘Karlsbad’ enabled me to explain the curious detail of my having asked Herr Zucker the way. The material out of which the dream was woven included at this point two of those facetious Jewish anecdotes which contain so much profound and often bitter worldly wisdom and which we so greatly enjoy quoting in our talk and letters. Here is the first one: the 'constitution' story. An impecunious Jew had stowed himself away without a ticket in the fast train to Karlsbad. He was caught, and each time tickets were inspected he was taken out of the train and treated more and more severely. At one of the stations on his via dolorosa he met an acquaintance, who asked him where he was travelling to. 'To Karlsbad', was his reply, 'if my constitution can stand it.' My memory then passed on to another story: of a Jew who could not speak French and had been recommended when he was in Paris to ask the way to the rue Richelieu. Paris itself had for many long years been another goal of my longings; and the blissful feelings with which I first set foot on its pavement seemed to me a guarantee that others of my wishes would be fulfilled as well. 'Asking the way', moreover, was a direct allusion to Rome, since it is well known that all roads lead there. Again, the name Zucker was once more an allusion to Karlsbad; for we are in the habit of prescribing treatment there for anyone suffering from the constitutional complaint of diabetes. The instigation to this dream had been a proposal made by my friend in Berlin that we should meet in Prague at Easter. What we were going to discuss there would have included something with a further connection with 'sugar' and 'diabetes'.

¹[1900a, 679]
I cannot leave the subject of typical dreams of the death of loved relatives, without adding a few more words to throw light on their significance for the theory of dreams in general. In these dreams we find the highly unusual condition realized of a dream-thought formed by a repressed wish entirely eluding censorship and passing into the dream without modification. There must be special factors at work to make this event possible, and I believe that the occurrence of these dreams is facilitated by two such factors. Firstly, there is no wish that seems more remote from us than this one: 'we couldn't even dream' - so we believe - of wishing such a thing. For this reason the dream-censorship is not armed to meet such a monstrosity, just as Solon's penal code contained no punishment for parricide. Secondly, in this case the repressed and unsuspected wish is particularly often met half-way by a residue from the previous day in the form of a worry about the safety of the person concerned. This worry can only make its way into the dream by availing itself of the corresponding wish; while the wish can disguise itself behind the worry that has become active during the day. We may feel inclined to think that things are simpler than this and that one merely carries on during the night and in dreams with what one has been turning over in one's mind during the day; but if so we shall be leaving dreams of the death of people of whom the dreamer is fond completely in the air and without any connection with our explanation of dreams in general, and we shall thus be clinging quite unnecessarily to a riddle which is perfectly capable of solution.

[1900a, 744]

It is also instructive to consider the relation of these dreams to anxiety-dreams. In the dreams we have been discussing, a repressed wish has found a means of evading censorship - and the distortion which censorship involves. The invariable concomitant is that painful feelings are experienced in the dream. In just the same way anxiety-dreams only occur if the censorship has been wholly or partly overpowered; and, on the other hand, the overpowering of the censorship is facilitated if anxiety has already been produced as an immediate sensation arising from somatic sources. We can thus plainly see the purpose for which the censorship exercises its office and brings about the distortion of dreams: it does so in order to prevent the generation of anxiety or other forms of distressing affect.

[1900a, 744]
In this series of dreams dreamt by an author who had been a journeyman tailor in his youth, it is hard to recognize the dominance of wish-fulfilment. All the dreamer's enjoyment lay in his day-time existence, whereas in his dreams he was still haunted by the shadow of an unhappy life from which he had at last escaped. Some dreams of my own of a similar kind have enabled me to throw a little light on the subject. As a young doctor I worked for a long time at the Chemical Institute without ever becoming proficient in the skills which that science demands; and for that reason in my waking life I have never liked thinking of this barren and indeed humiliating episode in my apprenticeship. On the other hand I have a regularly recurring dream of working in the laboratory, of carrying out analyses and of having various experiences there. These dreams are disagreeable in the same way as examination dreams and they are never very distinct. While I was interpreting one of them, my attention was eventually attracted by the word 'analysis', which gave me a key to their understanding. Since those days I have become an 'analyst', and I now carry out analyses which are very highly spoken of, though it is true that they are 'psycho-analyses'. It was now clear to me: if I have grown proud of carrying out analyses of that kind in my daytime life and feel inclined to boast to myself of how successful I have become, my dreams remind me during the night of those other, unsuccessful analyses of which I have no reason to feel proud. They are the punishment dreams of a parvenu, like the dreams of the journeyman tailor who had grown into a famous author. But how does it become possible for a dream, in the conflict between a parvenu's pride and his self-criticism, to side with the latter, and choose as its content a sensible warning instead of an unlawful wish-fulfilment? As I have already said, the answer to this question raises difficulties. We may conclude that the foundation of the dream was formed in the first instance by an exaggeratedly ambitious phantasy, but that humiliating thoughts that poured cold water on the phantasy found their way into the dream instead. It may be remembered that there are masochistic impulses in the mind, which may be responsible for a reversal such as this. I should have no objection to this class of dreams being distinguished from 'wish-fulfilment dreams' under the name of 'punishment dreams'. I should not regard this as implying any qualification of the theory of dreams which I have hitherto put forward; it would be no more than a linguistic expedient for meeting the difficulties of those who find it strange that opposites should converge. But a closer examination of some of these dreams brings something more to light. In an indistinct part of the background of one of my laboratory dreams I was of an age which placed me precisely in the gloomiest and most unsuccessful year of my medical career. I was still without a post and had no idea how I could earn my living; but at the same time I suddenly discovered that I had a choice open to me between several women whom I might marry! So I was once more young, and, more than everything, she was once more young - the woman who had shared all these difficult years with me. The unconscious instigator of the dream was thus revealed as one of the constantly gnawing wishes of a man who is growing older. The conflict raging in other levels of the mind between vanity and self-criticism had, it is true, determined the content of the dream; but it was only the more deeply-rooted wish for youth that had made it possible for that conflict to appear as a dream. Even when we are awake we sometimes say to ourselves: 'Things are going very well to-day and times were hard in the old days; all the same, it was lovely then - I was still young.'
Analysis is able to demonstrate that these unpleasurable dreams are wish-fulfillments no less than the rest. An unconscious and repressed wish, whose fulfilment the dreamer's ego could not fail to experience as something distressing, has seized the opportunity offered to it by the persisting cathexis of the distressing residues of the previous day; it has lent them its support and by that means rendered them capable of entering a dream. But whereas in Group A the unconscious wish coincided with the conscious one, in Group B the gulf between the unconscious and the conscious (between the repressed and the ego) is revealed and the situation in the fairy tale of the three wishes which were granted by the fairy to the husband and wife is realized. (See below, p. 1009 f. n.) The satisfaction at the fulfilment of the repressed wish may turn out to be so great that it counterbalances the distressing feelings attaching to the day's residues; in that case the feeling-tone of the dream is indifferent, in spite of its being on the one hand the fulfilment of a wish and on the other the fulfilment of a fear. Or it may happen that the sleeping ego takes a still larger share in the construction of the dream, that it reacts to the satisfying of the repressed wish with violent indignation and itself puts an end to the dream with an outburst of anxiety. Thus there is no difficulty in seeing that unpleasurable dreams and anxiety-dreams are just as much wish-fulfilments in the sense of our theory as are straightforward dreams of satisfaction.

I am now in a position to give a precise account of the part played in dreams by the unconscious wish. I am ready to admit that there is a whole class of dreams the instigation to which arises principally or even exclusively from the residues of daytime life; and I think that even my wish that I might at long last become a Professor Extraordinarius might have allowed me to sleep through the night in peace if my worry over my friend's health had not still persisted from the previous day. But the worry alone could not have made a dream. The motive force which the dream required had to be provided by a wish; it was the business of the worry to get hold of a wish to act as the motive force of the dream.
Though the preceding considerations have reduced the importance of the part played by the day's residues in dreams, it is worth while devoting a little more attention to them. It must be that they are essential ingredients in the formation of dreams, since experience has revealed the surprising fact that in the content of every dream some link with a recent daytime impression - often of the most insignificant sort - is to be detected. We have not hitherto been able to explain the necessity for this addition to the mixture that constitutes a dream (see p. 669). And it is only possible to do so if we bear firmly in mind the part played by the unconscious wish and then seek for information from the psychology of the neuroses. We learn from the latter that an unconscious idea is as such quite incapable of entering the preconscious and that it can only exercise any effect there by establishing a connection with an idea which already belongs to the preconscious, by transferring its intensity on to it and by getting itself 'covered' by it. Here we have the fact of 'transference', which provides an explanation of so many striking phenomena in the mental life of neurotics. The preconscious idea, which thus acquires an undeserved degree of intensity may either be left unaltered by the transference, or it may have a modification forced upon it, derived from the content of the idea which effects the transference. I hope I may be forgiven for drawing analogies from everyday life, but I am tempted to say that the position of a repressed idea resembles that of an American dentist in this country: he is not allowed to set up in practice unless he can make use of a legally qualified medical practitioner to serve as a stalking-horse and to act as a 'cover' in the eyes of the law. And just as it is not exactly the physicians with the largest practices who form alliances of this kind with dentists, so in the same way preconscious or conscious ideas which have already attracted a sufficient amount of the attention that is operating in the preconscious will not be the ones to be chosen to act as covers for a repressed idea. The unconscious prefers to weave its connections round preconscious impressions and ideas which are either indifferent and have thus had no attention paid to them, or have been rejected and have thus had attention promptly withdrawn from them. It is a familiar article in the doctrine of association, and one that is entirely confirmed by experience, that an idea which is bound by a very intimate tie in one direction, tends, as it were, to repel whole groups of new ties. I once attempted to base a theory of hysterical paralyses on this proposition.

We have so far been studying dream-wishes: we have traced them from their origin in the region of the Ucs. and have analysed their relations to the day's residues, which in their turn may either be wishes or psychical impulses of some other kind or simply recent impressions. In this way we have allowed room for every claim that may be raised by any of the multifarious waking thought-activities on behalf of the importance of the part played by them in the process of constructing dreams. It is not impossible, even, that our account may have provided an explanation of the extreme cases in which a dream, pursuing the activities of daytime, arrives at a happy solution of some unsolved problem of waking life. All we need is an example of this kind, so that we might analyse it and trace the source of the infantile or repressed wishes whose help has been enlisted and has reinforced the efforts of preconscious activity with such success. But all this has not brought us a step nearer to solving the riddle of why it is that the unconscious has nothing else to offer during sleep but the motive force for the fulfilment of a wish. The answer to this question must throw light upon the psychical nature of wishes, and I propose to give the answer by reference to our schematic picture of the psychical apparatus.

[1900a, 993]
We are now well on the way to proceeding further with the erection of the psychological scaffold, which we stopped at the point at which we introduced the two systems Ucs. and Pcs. But there are reasons for continuing a little with our consideration of wishes as the sole psychical motive force for the construction of dreams. We have accepted the idea that the reason why dreams are invariably wish-fulfilments is that they are products of the system Ucs., whose activity knows no other aim than the fulfilment of wishes and which has at its command no other forces than wishful impulses. If we insist, for even a moment longer, upon our right to base such far-reaching psychological speculations upon the interpretation of dreams, we are in duty found to prove that those speculations have enabled us to insert dreams into a nexus which can include other psychical structures as well. If such a thing as a system Ucs. exists (or something analogous to it for the purposes of our discussion), dreams cannot be its only manifestation; every dream may be a wish-fulfilment, but apart from dreams there must be other forms of abnormal wish-fulfilments. And it is a fact that the theory governing all psychoneurotic symptoms culminates in a single proposition, which asserts that they too are to be regarded as fulfilments of unconscious wishes.¹ Our explanation makes the dream only the first member of a class which is of the greatest significance to psychiatrists and an understanding of which implies the solution of the purely psychological side of the problem of psychiatry.²

[1900a, 998]

The situation is this. Either residues of the previous day have been left over from the activity of waking life and it has not been possible to withdraw the whole cathexis of energy from them; or the activity of waking life during the course of the day has led to the stirring up of an unconscious wish; or these two events have happened to coincide. (We have already discussed the various possibilities in this connection.) The unconscious wish links itself up with the day’s residues and effects a transference on to them; this may happen either in the course of the day or not until a state of sleep has been established. A wish now arises which has been transferred on to the recent material; or a recent wish, having been suppressed, gains fresh life by being reinforced from the unconscious. This wish seeks to force its way along the normal path taken by thought processes, though the Pcs. (to which, indeed, it in part belongs) to consciousness. But it comes up against the censorship, which is still functioning and to the influence of which it now submits. At this point it takes on the distortion for which the way has already been paved by the transference of the wish on to recent material. So far it is on the way to becoming an obsessive idea or a delusion or something of the kind - that is, a thought which has been intensified by transference and distorted in its expression by censorship. Its further advance is halted, however, by the sleeping state of the preconscious. (The probability is that that system has protected itself against the invasion by diminishing its own excitations.) The dream-process consequently enters on a regressive path, which lies open to it precisely owing to the peculiar nature of the state of sleep, and it is led along that path by the attraction exercised on it by groups of memories; some of these memories themselves exist only in the form of visual cathexes and not as translations into the terminology of the later systems. In the course of its regressive path the dream-process acquires the attribute of representability. (I shall deal later with the question of compression.) It has now completed the second portion of its zigzag journey. The first portion was a progressive one, leading from the unconscious scenes or phantasies to the preconscious; the second portion led from the frontier of the censorship back again to perceptions. But when the content of the dream process has become perceptual, by that fact it has, as it were, found a way of evading the obstacle put in its way by the censorship and the state of sleep in the Pcs. It succeeds in drawing attention to itself and in being noticed by consciousness.

[1900a, 1002]
Greater theoretical interest, however, attaches to the dreams which have the power to rouse us in the middle of our sleep. Bearing in mind the expediency which is everywhere else the rule, we may ask why a dream, that is, an unconscious wish, is given the power to interfere with sleep, that is, with the fulfilment of the preconscious wish. The explanation no doubt lies in relations of energy of which we have no knowledge. If we possessed such knowledge, we should probably find that allowing the dream to take its course and expending a certain amount of more or less detached attention on it is an economy of energy compared with holding the unconscious as tightly under control at night as in the daytime. Experience shows that dreaming is compatible with sleeping, even if it interrupts sleep several times during the night. One wakes up for an instant and then falls asleep again at once. It is like brushing away a fly in one's sleep: a case of *ad hoc* awakening. If one falls asleep again, the interruption has been disposed of. As is shown by such familiar examples as the sleep of a nursing mother or wet nurse, the fulfilment of the wish to sleep is quite compatible with maintaining a certain expenditure of attention in some particular direction.

At this point an objection arises, which is based on a better knowledge of unconscious processes. I myself have asserted that unconscious wishes are always active. But in spite of this they seem not to be strong enough to make themselves perceptible during the day. If, however, while a state of sleep prevails, an unconscious wish has shown itself strong enough to construct a dream and arouse the preconscious with it, why should this strength fail after the dream has been brought to knowledge? Should not the dream continue to recur perpetually, precisely as the vexatious fly keeps on coming back after it has been driven away? What right have we to assert that dreams get rid of the disturbance of sleep?

We have no difference of opinion over the functions that are to be assigned to dreams. The view that dreams act as a safety valve to the mind and that, in the words of Robert, all kinds of harmful things are made harmless by being presented in a dream - not only does this view coincide exactly with our theory of the double wish-fulfilment brought about by dreams, but the way in which it is phrased is more intelligible to us than to Robert himself. The view that the mind has free play in its functioning in dreams is represented in our theory by the fact of the preconscious activity allowing dreams to take their course. Such phrases as 'the return of the mind in dreams to an embryonic point of view' or the words used by Havelock Ellis to describe dreams - 'an archaic world of vast emotions and imperfect thoughts' - strike us as happy anticipations of our own assertions that primitive modes of activity which are suppressed during the day are concerned in the construction of dreams. We have been able to accept entirely as our own what Sully has written: 'Our dreams are a means of conserving these successive personalities. When asleep we go back to the old ways of looking at things and of feeling about them, to impulses and activities which long ago dominated us'. For us no less than for Delage what has been 'suppressed' has become 'the motive force of dreams.'

We accordingly borrow the following thesis from the theory of hysteria: *a normal train of thought is only submitted to abnormal psychical treatment of the sort we have been describing if an unconscious wish, derived from infancy and in a state of repression has been transferred on to it*. In accordance with this thesis we have constructed our theory of dreams on the assumption that the dream-wish which provides the motive power invariably originates from the unconscious - an assumption which, as I myself am ready to admit, cannot be proved to hold generally, though neither can it be disproved. But in order to explain what is meant by 'repression', a term with which we have already made play so many times, it is necessary to proceed a stage further with our psychological scaffolding.
The theory of the psychoneuroses asserts as an indisputable and invariable fact that only sexual wishful impulses from infancy, which have undergone repression (i.e. a transformation of their affect) during the developmental period of childhood, are capable of being revived during later developmental periods (whether as a result of the subject's sexual constitution, which is derived from an initial bisexuality, or as a result of unfavourable influences acting upon the course of his sexual life) and are thus able to furnish the motive force for the formation of psychoneurotic symptoms of every kind. It is only by reference to these sexual forces that we can close the gaps that are still patent in the theory of repression. I will leave it an open question whether these sexual and infantile factors are equally required in the theory of dreams: I will leave that theory incomplete at this point, since I have already gone a step beyond what can be demonstrated in assuming that dream-wishes are invariably derived from the unconscious.¹ Nor do I propose to enquire further into the nature of the distinction between the play of psychical forces in the formation of dreams and in that of hysterical symptoms: we are still without a sufficiently accurate knowledge of one of the two objects of the comparison. [1900a, 1033]

Between the scene in which her wish had been fulfilled and the time of the dream more than twenty-five years elapsed. In the meantime Frau B. had become the widow of a second husband who left her with a child and a fortune. The old lady's affection was still centred on Dr. K., who was now her adviser and the administrator of her estate and whom she saw frequently. Let us suppose that during the few days before the dream she had been expecting a visit from him, but that this had not taken place - he was no longer so pressing as he used to be. She may then have quite well had a nostalgic dream one night which took her back to the old days. Her dream was probably of a rendez-vous at the time of her love affair, and the chain of her dream-thoughts carried her back to the occasion when, without any pre-arrangement, he had come in at the very moment at which she had been longing for him. She probably had dreams of this kind quite often now; they were a part of the belated punishment with which a woman pays for her youthful cruelty. But such dreams - derivatives of a suppressed current of thought, filled with memories of rendez-vous of which, since her second marriage, she no longer liked to think - such dreams were put aside on waking. And that was what happened to our ostensibly prophetic dream. She then went out, and in the Kärntnerstrasse, at a spot which was in itself indifferent, she met her old family doctor, Dr. K. It was a very long time since she had seen him. He was intimately associated with the excitements of that happy-unhappy time. He too had been a helper, and we may suppose that he had been used in her thoughts, and perhaps in her dreams as well, as a screen figure behind which she concealed the better-loved figure of the other Dr. K. This meeting now revived her recollection of the dream. She must have thought: ‘Yes, I had a dream last night of my rendez-vous with Dr. K.’ But this recollection had to undergo the distortion which the dream escaped only because it had been completely forgotten. She inserted the indifferent K. (who had reminded her of the dream) in place of the beloved K. The content of the dream - the rendez-vous - was transferred to a belief that she had dreamt of that particular spot, for a rendez-vous consists in two people coming to the same spot at the same time. And if she then had an impression that a dream had been fulfilled, she was only giving effect in that way to her memory of the scene in which she had longed in her misery for him to come and her longing had at once been fulfilled. [1900a, 1048]
The dream from the analysis of which we have derived this information corresponded, as we have seen, to an intention which Dora carried with her into her sleep. It was therefore repeated each night until the intention had been carried out; and it reappeared years later when an occasion arose for forming an analogous intention. The intention might have been consciously expressed in some such words as these: 'I must fly from this house, for I see that my virginity is threatened here; I shall go away with my father, and I shall take precautions not to be surprised while I am dressing in the morning.' These thoughts were clearly expressed in the dream; they formed part of a mental current which had achieved consciousness and a dominating position in waking life. Behind them can be discerned obscure traces of a train of thought which formed part of a contrary current and had consequently been suppressed. This other train of thought culminated in the temptation to yield to the man, out of gratitude for the love and tenderness he had shown her during the last few years, and it may perhaps have revived the memory of the only kiss she had so far had from him. But according to the theory which I developed in my Interpretation of Dreams such elements as these are not enough for the formation of a dream. On that theory a dream is not an intention represented as having been carried out, but a wish represented as having been fulfilled, and, moreover, in most cases a wish dating from childhood. It is our business now to discover whether this principle may not be contradicted by the present dream.
[1905e, 1421]

I have made one or two observations in my Interpretation of Dreams on the relation between the waking thoughts which are continued into sleep (the 'day's residues') and the unconscious wish which forms the dream. I will quote them here as they stand, for I have nothing to add to them, and the analysis of this dream of Dora's proves afresh that the facts are as I have supposed: 'I am ready to admit that there is a whole class of dreams the instigation to which arises principally or even exclusively from the residues of daytime life; and I think that even my wish that I might at long last become a Professor Extraordinarius¹ might have allowed me to sleep through the night in peace if my worry over my friend's health had not still persisted from the previous day. But the worry alone could not have made a dream. The motive force which the dream required had to be provided by a wish; it was the business of the worry to get hold of a wish to act as the motive force of the dream.
[1905e, 1423]

'The position may be explained by an analogy. A daytime thought may very well play the part of entrepreneur for a dream; but the entrepreneur, who, as people say, has the idea and the initiative to carry it out, can do nothing without capital; he needs a capitalist who can afford the outlay, and the capitalist who provides the psychical outlay for the dream is invariably and indisputably, whatever may be the thoughts of the previous day, a wish from the unconscious.'
[1905e, 1423]
We would seem to have reached the end. But an attentive reader might remind us that at the beginning we threw out an assertion that dreams are wishes represented as fulfilled and that we gave no proof of this. Well, is our reply, what we have described in these pages might show how little justification there is for trying to cover the explanations we have to give of dreams with the single formula that dreams are wish-fulfilments. Nevertheless the assertion stands and can easily be proved too for the dreams in *Gradiva*. The latent dream-thoughts - we know now what is meant by them - may be of the most various kinds; in *Gradiva* they are 'days' residues', thoughts that have been left over unnoticed and undealt-with from the mental activities of waking life. But in order for a dream to develop out of them, the co-operation of a wish (usually an unconscious one) is required; this contributes the motive force for constructing the dream, while the day's residues provide the material. In Norbert Hanold's first dream two wishes competed with each other in making the dream; one of them was actually admissible to consciousness, while the other belonged to the unconscious and operated from out of repression. The first was a wish, understandable in any archaeologist, to have been present as an eye-witness at the catastrophe in the year 79 A.D. What sacrifice would an archaeologist think too great if this wish could be realized in any way other than in a dream! The other wish, the other constructor of the dream, was of an erotic nature: it might be crudely and also incompletely stated as a wish to be there when the girl he loved lay down to sleep. This was the wish the rejection of which caused the dream to become an anxiety-dream. The wishes that were the motive forces of the second dream are perhaps less conspicuous; but if we recall its translation we shall not hesitate to describe them too as erotic. The wish to be taken captive by the girl he loved, to fall in with her wishes and to be subjected to her - for so we may construe the wish behind the situation of the lizard-catching - was in fact of a passive, masochistic character. Next day the dreamer hit the girl, as though he was dominated by the contrary erotic current . . . But we must stop here, or we may really forget that Hanold and Gradiva are only creatures of their author's mind.

[1907a, 1884]

We cannot proceed any further in explaining the formation of dreams till we have overcome certain difficulties. The narcissism of the state of sleep implies a withdrawal of cathexis from all ideas of objects, from both the unconscious and the preconscious portions of those ideas. If, then, certain day's residues have retained their cathexis, we hesitate to suppose that they have acquired at night so much energy as to compel notice on the part of consciousness; we should be more inclined to suppose that the cathexis they have retained is far weaker than that which they possessed during the day. Here analysis saves us further speculation, for it shows that these day's residues must receive a reinforcement which has its source in unconscious instinctual impulses if they are to figure as constructors of dreams. This hypothesis presents no immediate difficulties, for we have every reason to suppose that in sleep the censorship between the Pcs. and the Ucs. is greatly reduced, so that communication between the two systems is made easier.

[1917d, 3029]
We have now to consider the further vicissitudes undergone by this wishful impulse, which in its essence represents an unconscious instinctual demand and which has been formed in the *Pcs.* as a dream-wish (a wish-fulfilling phantasy). Reflection tells us that this wishful impulse may be dealt with along three different paths. It may follow the path that would be normal in waking life, by pressing from the *Pcs.* to consciousness; or it may bypass the *Cs.* and find direct motor discharge; or it may take the unexpected path which observation enables us in fact to trace. In the first case, it would become a *delusion* having as content the fulfilment of the wish; but in the state of sleep this never happens. With our scanty knowledge of the metapsychological conditions of mental processes, we may perhaps take this fact as a hint that a complete emptying of a system renders it little susceptible to instigation. The second case, that of direct motor discharge, should be excluded by the same principle; for access to motility normally lies yet another step beyond the censorship of consciousness. But we do meet with exceptional instances in which this happens, in the form of somnambulism. We do not know what conditions make this possible, or why it does not happen more often. What actually happens in dream-formation is a very remarkable and quite unforeseen turn of events. The process, begun in the *Pcs.* and reinforced by the *Ucs.*, pursues a backward course, through the *Ucs.* to perception, which is pressing upon consciousness. This *regression* is the third phase of dream-formation. For the sake of clarity, we will repeat the two earlier ones: the reinforcement of the *Pcs.* by the *Ucs.*, and the setting up of the dream-wish.

[1917d, 3032]

This same piece of information can be further applied to another of the riddles we have come up against. You recall the amazement which was caused by our discovery that what instigates dreams are actively evil and extravagantly sexual wishes, which have made the censorship and distortion of dreams necessary. When we have interpreted a dream of this sort to the dreamer and if, to take the most favourable case, he does not actually attack the interpretation, he nevertheless regularly raises the question of where these wishes come from, since they feel alien to him and their opposite is what he is conscious of. We need have no hesitation in pointing out their origin. These evil wishful impulses arise from the past, and often from a past that is not very remote. It can be shown that there was a time when they were familiar and conscious, even if they are no longer so to-day. A woman, whose dream meant that she would like to see her only daughter, now seventeen years old, dead before her eyes, found under our guidance that she had indeed at one time harboured this death wish. The child was the fruit of an unhappy marriage which was soon dissolved. Once, while she still bore her daughter in her womb, in a fit of rage after a violent scene with her husband she had beaten with her fists on her body in order to kill the child inside it. How many mothers, who love their children tenderly, perhaps over-tenderly, to-day, conceived them unwillingly and wished at that time that the living thing within them might not develop further! They may even have expressed that wish in various, fortunately harmless, actions. Thus their death-wish against someone they love, which is later so mysterious, originates from the earliest days of their relationship to that person.

[1916-1917, 3291]
Perhaps you recognize, moreover, what it is that supports our hypotheses of the two systems, and their relation to each other and to consciousness? After all, the watchman between the unconscious and the preconscious is nothing else than the censorship, to which, as we found, the form taken by the manifest dream is subject. The day's residues, which we recognized as the instigators of the dream, were preconscious material which, at night-time and in the state of sleep, had been under the influence of unconscious and repressed wishful impulses; they had been able, in combination with those impulses and thanks to their energy, to construct the latent dream. Under the dominance of the unconscious system this material had been worked over (by condensation and displacement) in a manner which is unknown or only exceptionally permissible in normal mental life - that is, in the preconscious system. We came to regard this difference in their manner of operating as what characterizes the two systems; the relation which the preconscious has to consciousness was regarded by us merely as an indication of its belonging to one of the two systems. Dreams are not pathological phenomena; they can appear in any healthy person under the conditions of a state of sleep. Our hypothesis about the structure of the mental apparatus, which allows us to understand the formation alike of dreams and of neurotic symptoms, has an incontrovertible claim to being taken into account in regard to normal mental life as well.

[1916-1917, 3370]

My second remark is a supplement to the theory of dreams. We cannot explain the origin of dreams unless we adopt the hypothesis that the repressed unconscious has achieved some degree of independence of the ego, so that it does not acquiesce in the wish to sleep and retains its cathexes even when all the object-cathexes depending on the ego have been withdrawn in order to encourage sleep. Only if that is so can we understand how the unconscious can make use of the lifting or reduction of the censorship which occurs at night, and can succeed in obtaining control over the day's residues so as to construct a forbidden dream-wish out of their material. On the other hand, it may be that these day's residues have to thank an already existing connection with the repressed unconscious for some of their resistance to the withdrawal of libido commanded by the wish to sleep. We will, then, insert this dynamically important feature into our view of the formation of dreams by way of supplement.

[1916-1917, 3464]

From the standpoint of the libido theory, too, we may say a last word on dreams. A neurotic's dreams help us, like his parapraxes and his free associations to them, to discover the sense of his symptoms and to reveal the way in which his libido is allocated. They show us, in the form of a wish-fulfilment, what wishful impulses have been subjected to repression and to what objects the libido withdrawn from the ego has become attached. For this reason the interpretation of dreams plays a large part in a psycho-analytic treatment, and in some cases it is over long periods the most important instrument of our work. We already know that the state of sleep in itself leads to a certain relaxation of the repressions. A repressed impulse, owing to this reduction in the pressure weighing down upon it, becomes able to express itself far more clearly in a dream than it can be allowed to be expressed by a symptom during the day. The study of dreams therefore becomes the most convenient means of access to a knowledge of the repressed unconscious, of which the libido withdrawn from the ego forms a part.

[1916-1917, 3496]
For a time psycho-analysis seemed fated to merge into psychology without being able to show why the psychology of the sick differed from that of the normal. In the course of its advance, however, it came up against the problem of dreams, which are abnormal products of the mind created by normal men under regularly recurrent physiological conditions. When psycho-analysis had solved the problem of dreams, it had discovered in unconscious psychical processes the common ground in which the highest and the lowest of mental impulses have their roots and from which spring the most normal as well as the most morbid and erratic of mental productions. The new picture of the workings of the mind began to grow ever clearer and more complete. It was a picture of obscure instinctual forces organic in origin, strivings towards inborn aims, and, above them, of an agency comprising more highly organized mental structures - acquisitions of human evolution made under the impact of human history -, an agency which has taken over portions of the instinctual impulses, has developed them further or has even directed them towards higher aims, but which in any case binds them firmly and manipulates their energy to suit its own purposes. This higher organization, however, which is known to us as the ego, has rejected another portion of these same elementary instinctual impulses as being unserviceable because they cannot be fitted into the organic unity of the individual or because they rebel against the individual's cultural aims. The ego is not in a position to exterminate these unsubdued mental powers, but it turns its back on them, lets them remain at the lowest psychological level, defends itself from their demands by the energetic erection of protective and antithetical barriers or seeks to come to terms with them by means of substitutive satisfactions. These instincts which have fallen victim to repression - untamed and indestructible, yet inhibited from any kind of activity - together with their primitive mental representatives, constitute the mental underworld, the nucleus of the true unconscious, and are at every moment ready to assert their demands and, by hook or by crook, to force their way forward to satisfaction. To this is due the instability of the proud superstructure of the mind, the emergence at night of the proscribed and repressed material in the form of dreams, and the tendency to fall ill with neuroses and psychoses as soon as the balance of power between the ego and the repressed shifts to the disadvantage of the ego.¹

In this place I shall only follow up one of the consequences which seem possible from this point of view, thus resuming the discussion of a problem which I was obliged to leave unsolved elsewhere.¹ Each of the mental differentiations that we have become acquainted with represents a fresh aggravation of the difficulties of mental functioning, increases its instability, and may become the starting-point for its breakdown, that is, for the onset of a disease. Thus, by being born we have made the step from an absolutely self-sufficient narcissism to the perception of a changing external world and the beginnings of the discovery of objects. And with this is associated the fact that we cannot endure the new state of things for long, that we periodically revert from it, in our sleep, to our former condition of absence of stimulation and avoidance of objects. It is true, however, that in this we are following a hint from the external world, which, by means of the periodical change of day and night, temporarily withdraws the greater part of the stimuli that affect us. The second example of such a step, pathologically more important, is subject to no such qualification. In the course of development we have effected a separation of our mental existence into a coherent ego and into an unconscious and repressed portion which is left outside it; and we know that the stability of this new acquisition is exposed to constant shocks. In dreams and in neuroses what is thus excluded knocks for admission at the gates, guarded though they are by resistances; and in our waking health we make use of special artifices for allowing what is repressed to circumvent the resistances and for receiving it temporarily into our ego to the increase of our pleasure. Jokes and humour, and to some extent the comic in general, may be regarded in this light. Everyone acquainted with the psychology of the neuroses will think of similar examples of less importance; but I hasten on to the application I have in view.

[1919g, 3703]

[1921c, 3821]
I can imagine that to point out the existence of lying dreams of this kind, 'obliging' dreams, will arouse a positive storm of helpless indignation in some readers who call themselves analysts. 'What!' they will exclaim, 'the unconscious, the real centre of our mental life, the part of us that is so much nearer the divine than our poor consciousness - it too can lie! Then how can we still build on the interpretations of analysis and the accuracy of our findings?' To which one must reply that the recognition of these lying dreams does not constitute any shattering novelty. I know, indeed, that the craving of mankind for mysticism is ineradicable, and that it makes ceaseless efforts to win back for mysticism the territory it has been deprived of by The Interpretation of Dreams, but surely in the case under consideration everything is simple enough. A dream is not the 'unconscious'; it is the form into which a thought left over from preconscious, or even from conscious, waking life, can, thanks to the favouring state of sleep, be recast. In the state of sleep this thought has been reinforced by unconscious wishful impulses and has thus experienced distortion through the dream-work, which is determined by the mechanisms prevailing in the unconscious. With our dreamer, the intention to mislead me, just as she did her father, certainly emanated from the preconscious, and may indeed have been conscious; it could come to expression by entering into connection with the unconscious wishful impulse to please her father (or father-substitute), and in this way it created a lying dream. The two intentions, to betray and to please her father, originated in the same complex; the former resulted from the repression of the latter, and the later one was brought back by the dream-work to the earlier one. There can therefore be no question of any devaluation of the unconscious, nor of a shattering of our confidence in the results of analysis.

And now I have reached the point I wish to put before you. We have endeavoured to maintain the strictest impartiality and have allowed two conceptions of the dream to rank as equally probable and equally unproved. According to the first the dream is a reaction to a telepathic message: 'your daughter has just brought twins into the world.' According to the second an unconscious process of thought underlies the dream, which may be reproduced somewhat as follows: 'To-day is the day the confinement should take place if the young people in Berlin are really out in their reckoning by a month, as I suspect. And if my (first) wife were still alive, she certainly would not be content with one grandchild. To please her there would have to be at least twins!' If this second view is right, no new problems arise. It is simply a dream like any other. The (preconscious) dream-thoughts as outlined above are reinforced by the (unconscious) wish that no other than the daughter should be the dreamer's second wife, and thus the manifest dream as described to us arises.

If you prefer to assume that a telepathic message about the daughter's confinement reached the sleeper, further questions arise of the relation of a message such as this to a dream and of its influence on the formation of dreams. The answer is not far to seek and is quite unambiguous. A telepathic message will be treated as a portion of the material that goes to the formation of a dream, like any other external or internal stimulus, like a disturbing noise in the street or an insistent organic sensation in the sleeper's own body. In our example it is evident how the message, with the help of a lurking repressed wish, became remodelled into a wish-fulfilment; it is unfortunately less easy to show that it combined with other material that had become active at the same time and was blended into a dream. Telepathic messages - if we are justified in recognizing their existence - can thus make no alteration in the process of forming a dream; telepathy has nothing to do with the nature of dreams. And in order to avoid the impression that I am trying to conceal a vague notion behind abstract and fine-sounding words, I am willing to repeat: the essential nature of dreams consists in the peculiar process of 'dream-work' which, with the help of an unconscious wish, carries the preconscious thoughts (day's residues) over into the manifest content of the dream. The problem of telepathy concerns dreams as little as does the problem of anxiety.
There remains one element of the apparently intimate connection between telepathy and dreams which is not affected by any of these considerations: namely, the incontestable fact that sleep creates favourable conditions for telepathy. Sleep is not, it is true, indispensable to the occurrence of telepathic processes - whether they originate in messages or in unconscious activity. If you are not already aware of this, you will learn it from the instance given by our second correspondent, of the young man's message which came between nine and ten in the morning. We must add, however, that no one has a right to take exception to telepathic occurrences if the event and the intimation (or message) do not exactly coincide in astronomical time. It is perfectly conceivable that a telepathic message might arrive contemporaneously with the event and yet only penetrate to consciousness the following night during sleep (or even in waking life only after a while, during some pause in the activity of the mind). We are, as you know, of opinion that dream-formation itself does not necessarily wait for the onset of sleep before it begins. Often the latent dream-thoughts may have been being got ready during the whole day, till at night they find the contact with the unconscious wish that shapes them into a dream. But if the phenomenon of telepathy is only an activity of the unconscious mind, then, of course, no fresh problem lies before us. The laws of unconscious mental life may then be taken for granted as applying to telepathy.

[1922a, 3897]

It is possible to distinguish between dreams from above and dreams from below, provided the distinction is not made too sharply. Dreams from below are those which are provoked by the strength of an unconscious (repressed) wish which has found a means of being represented in some of the day's residues. They may be regarded as inroads of the repressed into waking life. Dreams from above correspond to thoughts or intentions of the day before which have contrived during the night to obtain reinforcement from repressed material that is debarred from the ego. When this is so, analysis as a rule disregards this unconscious ally and succeeds in inserting the latent dream-thoughts into the texture of waking thought. This distinction calls for no modification in the theory of dreams.

[1923c, 4032]

We have explained that the unconscious instinctual impulse of the dream connects itself with a residue of the day, with some interest of waking life which has not been disposed of; it thus gives the dream which it constructs a double value for the work of analysis. For on the one hand a dream that has been analysed reveals itself as the fulfilment of a repressed wish; but on the other hand it may be a continuation of some preconscious activity of the day before and may contain every kind of subject-matter and give expression to an intention, a warning, a reflection, or once more to the fulfilment of a wish. Analysis exploits the dream in both directions, as a means of obtaining knowledge alike of the patient's conscious and of his unconscious processes. It also profits from the fact that dreams have access to the forgotten material of childhood, and so it happens that infantile amnesia is for the most part overcome in connection with the interpretation of dreams. In this respect dreams achieve a part of what was previously the task of hypnotism. On the other hand, I have never maintained the assertion which has so often been ascribed to me that dream-interpretation shows that all dreams have a sexual content or are derived from sexual motive forces. It is easy to see that hunger, thirst, or the need to excrete, can produce dreams of satisfaction just as well as any repressed sexual or egoistic impulse. The case of young children affords us a convenient test of the validity of our theory of dreams. In them the various psychical systems are not yet sharply divided and the repressions have not yet grown deep, so that we often come upon dreams which are nothing more than undisguised fulfilments of wishful impulses left over from waking life. Under the influence of imperative needs, adults may also produce dreams of this infantile type.¹

[1925d, 4221]
Here we are presented with a means of answering the question of whether dreams have a function too, whether they are entrusted with any useful achievement. The condition of rest free from stimulus, which the state of sleep wishes to establish, is threatened from three directions: in a relatively accidental manner by external stimuli during sleep, and by interests of the previous day which cannot be broken off, and in an unavoidable manner by unsated repressed instinctual impulses which are on the watch for an opportunity of finding expression. In consequence of the diminishing of repressions at night there would be a risk that the rest afforded by sleep would be interrupted whenever an instigation from outside or from inside succeeded in linking up with an unconscious instinctual source. The process of dreaming allows the product of a collaboration of this kind to find an outlet in a harmless hallucinatory experience and in that way assures a continuation of sleep. The fact that a dream occasionally awakens the sleeper, to the accompaniment of a generation of anxiety, is no contradiction of this function but rather, perhaps, a signal that the watchman regards the situation as too dangerous and no longer feels able to control it. And very often then, while we are still asleep, a consolation occurs to us which seeks to prevent our waking up: 'But after all it's only a dream!'

[1933a, 4630]

In what follows I shall not be able to avoid a schematic method of exposition. Let us assume that in a particular case we have before us all the latent thoughts, charged with a greater or less amount of affect, by which the manifest dream has been replaced after its interpretation has been completed. We shall then be struck by one difference among these latent thoughts, and that difference will take us a long way. Almost all these dream-thoughts are recognized by the dreamer or acknowledged by him; he admits that he has thought this, now or at some other time, or that he might have thought it. There is only one single thought that he refuses to accept; it is strange to him or even perhaps repellent; he may possibly reject it with passionate feeling. It now becomes evident to us that the other thoughts are portions of a conscious, or, more accurately, a preconscious train of thinking. They might have been thought in waking life too, and indeed they were probably formed during the previous day. This one repudiated thought, however, or, properly speaking, this one impulse, is a child of night; it belongs to the dreamer's unconscious and on that account it is repudiated and rejected by him. It had to wait for the nightly relaxation of repression in order to arrive at any kind of expression. And in any case this expression is a weakened, distorted and disguised one; without our work of dream-interpretation we should not have found it. This unconscious impulse has to thank its link with the other, unobjectionable, dream-thoughts for the opportunity of slipping past the barrier of the censorship in an inconspicuous disguise. On the other hand, the preconscious dream-thoughts have to thank this same link for the power to occupy mental life during sleep as well. For there is no doubt about it: this unconscious impulse is the true creator of the dream; it is what produces the psychical energy for the dream's construction. Like any other instinctual impulse, it cannot strive for anything other than its own satisfaction; and our experience in interpreting dreams shows us too that that is the sense of all dreaming. In every dream an instinctual wish has to be represented as fulfilled. The shutting-off of mental life from reality at night and the regression to primitive mechanisms which this makes possible enable this wished-for instinctual satisfaction to be experienced in a hallucinatory manner as occurring in the present. As a result of this same regression, ideas are transformed in the dream into visual pictures: the latent dream-thoughts, that is to say, are dramatized and illustrated.

[1933a, 4631]
This piece of the dream-work gives us information about some of the most striking and peculiar features of dreams. I will repeat the course of events in dream-formation. As an introduction: the wish to sleep and intentional turning away from the external world. Next, two consequences of this for the mental apparatus: first, the possibility for older and more primitive methods of working to emerge in it - regression; secondly, the lowering of the resistance due to repression which weighs down upon the unconscious. As a result of this last factor the possibility arises for the formation of a dream and this is taken advantage of by the precipitating causes, the internal and external stimuli which have become active. The dream which originates in this way is already a compromise-structure. It has a double function; on the one hand it is ego-syntonic, since, by getting rid of the stimuli which are interfering with sleep, it serves the wish to sleep; on the other hand it allows a repressed instinctual impulse to obtain the satisfaction that is possible in these circumstances, in the form of the hallucinated fulfilment of a wish. The whole process of forming a dream which is permitted by the sleeping ego is, however, subject to the condition of the censorship, which is exercised by the residue of the repression still in operation. I cannot present the process more simply: it is not more simple. But I can proceed now with my description of the dream-work.

[1933a, 4632]

Let us go back once more to the latent dream-thoughts. Their most powerful element is the repressed instinctual impulse which has created in them an expression for itself on the basis of the presence of chance stimuli and by transference on to the day's residues - though an expression that is toned down and disguised. Like every instinctual impulse, it too presses for satisfaction by action; but its path to motility is blocked by the physiological regulations implied in the state of sleep; it is compelled to take the backwards course in the direction of perception and to be content with a hallucinated satisfaction. The latent dream-thoughts are thus transformed into a collection of sensory images and visual scenes. It is as they travel on this course that what seems to us so novel and so strange occurs to them. All the linguistic instruments by which we express the subtler relations of thought - the conjunctions and prepositions, the changes in declension and conjugation - are dropped, because there are no means of representing them; just as in a primitive language without any grammar, only the raw material of thought is expressed and abstract terms are taken back to the concrete ones that are at their basis. What is left over after this may well appear disconnected. The copious employment of symbols, which have become alien to conscious thinking, for representing certain objects and processes is in harmony alike with the archaic regression in the mental apparatus and with the demands of the censorship.

[1933a, 4632]
After these influences have been brought to bear upon the dream-thoughts the dream is almost complete. A further, somewhat variable, factor also comes into play - known as 'secondary revision' - after the dream has been presented before consciousness as an object of perception. At that point we treat it as we are in general accustomed to treat the contents of our perception: we fill in gaps and introduce connections, and in doing so are often guilty of gross misunderstandings. But this activity, which might be described as a rationalizing one and which at best provides the dream with a smooth façade that cannot fit its true content, may also be omitted or only be expressed to a very modest degree - in which case the dream will display all its rents and cracks openly. It must not be forgotten, on the other hand, that the dream-work does not always operate with equal energy either; it often restricts itself to certain portions of the dream-thoughts only and others of them are allowed to appear in the dream unaltered. In such cases an impression is given of the dream having carried out the most delicate and complex intellectual operations, of its having speculated, made jokes, arrived at decisions and solved problems, whereas all this is a product of our normal mental activity, may have been performed equally well during the day before the dream as during the night, has nothing to do with the dream-work and brings nothing to light that is characteristic of dreams. Nor is it superfluous to insist once more on the contrast within the dream-thoughts themselves between the unconscious instinctual impulse and the day's residues. While the latter exhibit all the multiplicity of our mental acts, the former, which becomes the motive force proper of the forming of the dream, finds its outlet invariably in the fulfilment of a wish.

[1933a, 4634]

It is best to begin by pointing out that the formation of a dream can be provoked in two different ways. Either, on the one hand, an instinctual impulse which is ordinarily suppressed (an unconscious wish) finds enough strength during sleep to make itself felt by the ego, or, on the other hand, an urge left over from waking life, a preconscious train of thought with all the conflicting impulses attached to it, finds reinforcement during sleep from an unconscious element. In short, dreams may arise either from the id or from the ego. The mechanism of dream-formation is in both cases the same and so also is the necessary dynamic precondition. The ego gives evidence of its original derivation from the id by occasionally ceasing its functions and allowing a reversion to an earlier state of things. This is logically brought about by its breaking off its relations with the external world and withdrawing its cathexes from the sense organs. We are justified in saying that there arises at birth an instinct to return to the intra-uterine life that has been abandoned - an instinct to sleep. Sleep is a return of this kind to the womb. Since the waking ego governs motility, that function is paralysed in sleep, and accordingly a good part of the inhibitions imposed on the unconscious id become superfluous. The withdrawal or reduction of these 'anticathexes' thus allows the id what is now a harmless amount of liberty.

[1940a [1938], 4976]
We shall find later that the enigma of the formation of dreams can be solved by the revelation of an unsuspected psychical source of stimulation. Meanwhile we shall feel no surprise at the over-estimation of the part played in forming dreams by stimuli which do not arise from mental life. Not only are they easy to discover and even open to experimental confirmation; but the somatic view of the origin of dreams is completely in line with the prevailing trend of thought in psychiatry to-day. It is true that the dominance of the brain over the organism is asserted with apparent confidence. Nevertheless, anything that might indicate that mental life is in any way independent of demonstrable organic changes or that its manifestations are in any way spontaneous alarms the modern psychiatrist, as though a recognition of such things would inevitably bring back the days of the Philosophy of Nature, and of the metaphysical view of the nature of mind. The suspicions of the psychiatrists have put the mind, as it were, under tutelage, and they now insist that none of its impulses shall be allowed to suggest that it has any means of its own. This behaviour of theirs only shows how little trust they really have in the validity of a causal connection between the somatic and the mental. Even when investigation shows that the primary exciting cause of a phenomenon is psychical, deeper research will one day trace the path further and discover an organic basis for the mental event. But if at the moment we cannot see beyond the mental, that is no reason for denying its existence.

In which of these systems, then, are we to locate the impetus to the construction of dreams? For simplicity's sake, in the system $Ucs$. It is true that in the course of our future discussion we shall learn that this is not entirely accurate, and that the process of forming dreams is obliged to attach itself to dream-thoughts belonging to the preconscious system. But when we consider the dream-wish, we shall find that the motive force for producing dreams is supplied by the $Ucs$; and owing to this latter factor we shall take the unconscious system as the starting-point of dream-formation. Like all other thought structures, this dream-instigator will make an effort to advance into the $Pcs.$ and from there to obtain access to consciousness.

We may next ask where the wishes that come true in dreams originate. What contrasting possibilities or what alternatives have we in mind in raising this question? It is the contrast, I think, between the consciously perceived life of daytime and a psychical activity which has remained unconscious and of which we can only become aware at night. I can distinguish three possible origins for such a wish. (1) It may have been aroused during the day and for external reasons may not have been satisfied; in that case an acknowledged wish which has not been dealt with is left over for the night. (2) It may have arisen during the day but been repudiated; in that case what is left over is a wish which has not been dealt with but has been suppressed. (3) It may have no connection with daytime life and be one of those wishes which only emerge from the suppressed part of the mind and become active in us at night. If we turn again to our schematic picture of the psychical apparatus, we shall localize wishes of the first kind in the system $Pcs.$; we shall suppose that wishes of the second kind have been driven out of the system $Pcs.$ into the $Ucs.$, where, if at all, they continue to exist; and we shall conclude that wishful impulses of the third kind are altogether incapable of passing beyond the system $Ucs$. The question then arises whether wishes derived from these different sources are of equal importance for dreams and have equal power to instigate them.
From the unconscious, in fact. *My supposition is that a conscious wish can only become a dream-instigator if it succeeds in awakening an unconscious wish with the same tenor and in obtaining reinforcement from it.* From indications derived from the psycho-analysis of the neuroses, I consider that these unconscious wishes are always on the alert, ready at any time to find their way to expression when an opportunity arises for allying themselves with an impulse from the conscious and for transferring their own great intensity on to the latter’s lesser one.¹ It will then appear as though the conscious wish alone had been realized in the dream; only some small peculiarity in the dream’s configuration will serve as a finger-post to put us on the track of the powerful ally from the unconscious. These wishes in our unconscious, ever on the alert and, so to say, immortal, remind one of the legendary Titans, weighed down since primaeval ages by the massive bulk of the mountains which were once hurled upon them by the victorious gods and which are still shaken from time to time by the convulsion of their limbs. But these wishes, held under repression, are themselves of infantile origin, as we are taught by psychological research into the neuroses. I would propose, therefore, to set aside the assertion made just now, that the place of origin of dream-wishes is a matter of indifference and replace it by another one to the following effect: *a wish which is represented in a dream must be an infantile one.* In the case of adults it originates from the Ucs, in the case of children, where there is as yet no division or censorship between the Ucs and the Pcs, or where that division is only gradually being set up, it is an unfulfilled, unpressed wish from waking life. I am aware that this assertion cannot be proved to hold universally; but it can be proved to hold frequently, even in unsuspected cases, and it cannot be contradicted as a general proposition.

[1900a, 985]

We are now well on the way to proceeding further with the erection of the psychological scaffolding, which we stopped at the point at which we introduced the two systems Ucs and Pcs. But there are reasons for continuing a little with our consideration of wishes as the sole psychical motive force for the construction of dreams. We have accepted the idea that the reason why dreams are invariably wish-fulfilments is that they are products of the system Ucs, whose activity knows no other aim than the fulfilment of wishes and which has at its command no other forces than wishful impulses. If we insist, for even a moment longer, upon our right to base such far-reaching psychological speculations upon the interpretation of dreams, we are in duty found to prove that those speculations have enabled us to insert dreams into a nexus which can include other psychical structures as well. If such a thing as a system Ucs exists (or something analogous to it for the purposes of our discussion), dreams cannot be its only manifestation; every dream may be a wish-fulfilment, but apart from dreams there must be other forms of abnormal wish-fulfilments. And it is a fact that the theory governing all psychoneurotic symptoms culminates in a single proposition, which asserts that *they too are to be regarded as fulfilments of unconscious wishes.*¹ Our explanation makes the dream only the first member of a class which is of the greatest significance to psychiatrists and an understanding of which implies the solution of the purely psychological side of the problem of psychiatry.²

[1900a, 998]
I will test this on the specimen dream which I chose for analysis, and enquire what the thought was which made its way into that dream in a distorted form, and which I should be inclined to repudiate if it were undistorted. I recall that my free cab-drive reminded me of my recent expensive drive with a member of my family, that the interpretation of the dream was 'I wish I might for once experience love that cost me nothing', and that a short time before the dream I had been obliged to spend a considerable sum of money on this same person's account. Bearing this context in mind, I cannot escape the conclusion that I regret having made that expenditure. Not until I have recognized this impulse does my wish in the dream for the love which would call for no expenditure acquire a meaning. Yet I can honestly say that when I decided to spend this sum of money I did not hesitate for a moment. My regret at having to do so - the contrary current of feeling - did not become conscious to me. Why it did not, is another and a far-reaching question, the answer to which is known to me but belongs in another connection.

[1901a, 1086]

Now that we have established the concept of repression and have brought dream-distortion into relation with repressed psychical material, we can express in general terms the principal finding to which we have been led by the analysis of dreams. In the case of dreams which are intelligible and have a meaning, we have found that they are undisguised wish-fulfilments; that is, that in their case the dream-situation represents as fulfilled a wish which is known to consciousness, which is left over from daytime life, and which is deservedly of interest. Analysis has taught us something entirely analogous in the case of obscure and confused dreams: once again the dream-situation represents a wish as fulfilled - a wish which invariably arises from the dream-thoughts, but one which is represented in an unrecognizable form and can only be explained when it has been traced back in analysis. The wish in such cases is either itself a repressed one and alien to consciousness, or it is intimately connected with repressed thoughts and is based upon them. Thus the formula for such dreams is as follows: they are disguised fulfilments of repressed wishes. It is interesting in this connection to observe that the popular belief that dreams always foretell the future is confirmed. Actually the future which the dream shows us is not the one which will occur but the one which we should like to occur. The popular mind is behaving here as it usually does: what it wishes, it believes.

[1907a, 1858]
We would seem to have reached the end. But an attentive reader might remind us that at the beginning we threw out an assertion that dreams are wishes represented as fulfilled and that we gave no proof of this. Well, is our reply, what we have described in these pages might show how little justification there is for trying to cover the explanations we have to give of dreams with the single formula that dreams are wish-fulfillments. Nevertheless the assertion stands and can easily be proved too for the dreams in *Gradiva*. The latent dream-thoughts - we know now what is meant by them - may be of the most various kinds; in *Gradiva* they are 'days' residues', thoughts that have been left over unnoticed and undealt-with from the mental activities of waking life. But in order for a dream to develop out of them, the co-operation of a wish (usually an unconscious one) is required; this contributes the motive force for constructing the dream, while the day's residues provide the material. In Norbert Hanold's first dream two wishes competed with each other in making the dream; one of them was actually admissible to consciousness, while the other belonged to the unconscious and operated from out of repression. The first was a wish, understandable in any archaeologist, to have been present as an eye-witness at the catastrophe in the year 79 A.D. What sacrifice would an archaeologist think too great if this wish could be realized in any way other than in a dream! The other wish, the other constructor of the dream, was of an erotic nature: it might be cruelly and also incompletely stated as a wish to be there when the girl he loved lay down to sleep. This was the wish the rejection of which caused the dream to become an anxiety-dream. The wishes that were the motive forces of the second dream are perhaps less conspicuous; but if we recall its translation we shall not hesitate to describe them too as erotic. The wish to be taken captive by the girl he loved, to fall in with her wishes and to be subjected to her - for so we may construe the wish behind the situation of the lizard-catching - was in fact of a passive, masochistic character. Next day the dreamer hit the girl, as though he was dominated by the contrary erotic current . . . But we must stop here, or we may really forget that Hanold and Gradiva are only creatures of their author's mind.

The present state of our knowledge leads us to conclude that the essential factor in the construction of dreams is an unconscious wish - as a rule an infantile wish, now repressed - which can come to expression in this somatic or psychical material (in the day's residues too, therefore) and can thus supply these with a force which enables them to press their way through to consciousness even during the suspension of thought at night. The dream is in every case a fulfilment of *this* unconscious wish, whatever else it may contain - warning, reflection, admission, or any other part of the rich content of preconscious waking life that has persisted undealt-with into the night. It is *this* unconscious wish that gives the dream-work its peculiar character as an unconscious revision of preconscious material. A psycho-analyst can characterize as dreams only the products of the dream-work: in spite of the fact that the latent dream-thoughts are only arrived at from the interpretation of the dream, he cannot reckon them as part of the dream, but only as part of preconscious reflection. (Secondary revision by the conscious agency is here reckoned as part of the dream-work. Even if one were to separate it, this would not involve any alteration in our conception. We should then have to say: dreams in the analytic sense comprise the dream-work proper together with the secondary revision of its products.) The conclusion to be drawn from these considerations is that one cannot put the wish-fulfilling character of dreams on a par with their character as warnings, admissions, attempts at solution, etc., without denying the concept of a psychical dimension of depth - that is to say, without denying the standpoint of psycho-analysis.
The only essential thing about dreams is the dream-work that has influenced the thought-material. We have no right to ignore it in our theory, even though we may disregard it in certain practical situations. Analytic observation shows further that the dream-work never restricts itself to translating these thoughts into the archaic or regressive mode of expression that is familiar to you. In addition, it regularly takes possession of something else, which is not part of the latent thoughts of the previous day, but which is the true motive force for the construction of the dream. This indispensable addition is the equally unconscious wish for the fulfilment of which the content of the dream is given its new form. A dream may thus be any sort of thing in so far as you are only taking into account the thoughts it represents - a warning, an intention, a preparation, and so on; but it is always also the fulfilment of an unconscious wish and, if you are considering it as a product of the dream-work, it is only that. A dream is therefore never simply an intention, or a warning, but always an intention, etc., translated into the archaic mode of thought by the help of an unconscious wish and transformed to fulfil that wish. The one characteristic, the wish-fulfilment, is the invariable one; the other may vary. It may for its part once more be a wish, in which case the dream will, with the help of an unconscious wish, represent as fulfilled a latent wish of the previous day.

Let us once again take up the dream we have already so often returned to: the dream of the three theatre-tickets for 1 florin 50. (I can assure you that I originally chose out this example without any special purpose in view.) You know the latent dream thoughts: anger at having been in such a hurry to get married which arose when she heard the news that her friend had only just become engaged, putting a low value on her husband and the idea that she might have got a better one if only she had waited. We already know the wish which made a dream out of these thoughts: it was the desire to look, to be able to go to the theatre, most probably an offshoot of her old curiosity to discover at long last what really happens when one is married. This curiosity is, as we know, regularly directed by children towards their parents' sexual life,: it is an infantile curiosity, and, so far as it still persists later, an instinctual impulse with roots reaching back into infancy. But the news the dreamer had received during the day gave no occasion for awakening this desire to look, but only for awakening anger and regret. This wishful impulse was not in the first instance connected with the latent dream-thoughts; and we were able to include the outcome of the dream-interpretation in the analysis without taking any account of that impulse. But the anger in itself was not capable of creating a dream. A dream could not arise out of the thoughts that 'it was absurd to marry so early' until they had awakened the old wish to see at long last what happens in marriage. This wish then gave the dream-content its form by replacing marriage by going to the theatre, and the form was that of an earlier wish-fulfilment: 'There! now I may go to the theatre and look at everything that's forbidden, and you mayn't! I'm married and you must wait!' In this way the dreamer's present situation was transformed into its opposite, an old triumph was put in the place of her recent defeat. And, incidentally, a satisfaction of her scopophilia was mixed with a satisfaction of her egoistic competitive sense. This satisfaction then determined the manifest content of the dream, in which the position actually was that she was sitting in the theatre while her friend could not gain admission to it. The portions of the content of the dream behind which the latent dream-thoughts still lay concealed were superimposed on this situation of satisfaction as a misplaced and unintelligible modification of it. The dream's interpretation had to disregard everything that served to represent the wish-fulfilment and to re-establish the distressing latent dream-thoughts from these obscure remaining hints.

[1916-1917, 3311]

[1916-1917, 3312]
The fresh consideration I wish to bring before you is to draw your attention to the latent dream-thoughts which have now been put in the foreground. I beg you not to forget that in the first place they are unconscious to the dreamer, and secondly that they are completely rational and coherent so that they can be understood as natural reactions to the precipitating cause of the dream, and thirdly that they can be the equivalent of any mental impulse or intellectual operation. I shall now describe these thoughts more strictly than before as the 'day's residues', whether the dreamer confesses to them or not. I shall now distinguish between the day's residues and the latent dream-thoughts, and, in conformity with our earlier usage, I shall designate as latent dream-thoughts everything we learn in interpreting the dream, whereas the day's residues are only a portion of the latent dream-thoughts. Our view is then that something is added to the day's residues, something that was also part of the unconscious, a powerful but repressed wishful impulse; and it is this alone that makes the construction of the dream possible. The influence of this wishful impulse on the day's residues creates the further portion of the latent dream-thoughts - that which need no longer appear rational and intelligible as being derived from waking life.

I have made use of an analogy for the relation of the day's residues to the unconscious wish, and I can only repeat it here. In every undertaking there must be a capitalist who covers the required outlay and an entrepreneur who has the idea and knows how to carry it out. In the construction of dreams, the part of the capitalist is always played by the unconscious wish alone; it provides the psychical energy for the construction of the dream. The entrepreneur is the day's residues, which decide how this outlay is to be employed. It is possible, of course, for the capitalist himself to have the idea and the expert knowledge or for the entrepreneur himself to possess capital. This simplifies the practical situation but makes its theoretical understanding more difficult. In economics the same person is constantly divided into his two aspects of capitalist and entrepreneur and this restores the fundamental situation on which our analogy was based. In dream-construction the same variations occur and I will leave them for you to follow out.

We cannot advance any further here, for you have probably long been disturbed by a doubt which deserves to be given a hearing. 'Are the day's residues,' you will ask, 'really unconscious in the same sense as the unconscious wish which must be added to them in order to make them capable of producing a dream?' Your suspicion is correct. This is the salient point of the whole business. They are not unconscious in the same sense. The dream-wish belongs to a different unconscious - to the one which we have already recognized as being of infantile origin and equipped with peculiar mechanisms. It would be highly opportune to distinguish these two kinds of unconscious by different names. But we would prefer to wait till we have become familiar with the field of phenomena of the neuroses. People consider a single unconscious as something fantastic. What will they say when we confess that we cannot make shift without two of them?
Perhaps you recognize, moreover, what it is that supports our hypotheses of the two systems, and their relation to each other and to consciousness? After all, the watchman between the unconscious and the preconscious is nothing else than the *censorship*, to which, as we found, the form taken by the manifest dream is subject. The day's residues, which we recognized as the instigators of the dream, were preconscious material which, at night-time and in the state of sleep, had been under the influence of unconscious and repressed wishful impulses; they had been able, in combination with those impulses and thanks to their energy, to construct the latent dream. Under the dominance of the unconscious system this material had been worked over (by condensation and displacement) in a manner which is unknown or only exceptionally permissible in normal mental life - that is, in the preconscious system. We came to regard this difference in their manner of operating as what characterizes the two systems; the relation which the preconscious has to consciousness was regarded by us merely as an indication of its belonging to one of the two systems. Dreams are not pathological phenomena; they can appear in any healthy person under the conditions of a state of sleep. Our hypothesis about the structure of the mental apparatus, which allows us to understand the formation alike of dreams and of neurotic symptoms, has an incontrovertible claim to being taken into account in regard to normal mental life as well.

[1916-1917, 3370]

My second remark is a supplement to the theory of dreams. We cannot explain the origin of dreams unless we adopt the hypothesis that the repressed unconscious has achieved some degree of independence of the ego, so that it does not acquiesce in the wish to sleep and retains its cathexes even when all the object-cathexes depending on the ego have been withdrawn in order to encourage sleep. Only if that is so can we understand how the unconscious can make use of the lifting or reduction of the censorship which occurs at night, and can succeed in obtaining control over the day's residues so as to construct a forbidden dream-wish out of their material. On the other hand, it may be that these day's residues have to thank an already existing connection with the repressed unconscious for some of their resistance to the withdrawal of libido commanded by the wish to sleep. We will, then, insert this dynamically important feature into our view of the formation of dreams by way of supplement.

[1916-1917, 3464]

The wishes which act as motive forces in this dream are obvious. First there are the superficial wishes of the day, that Christmas with its presents may already be here (a dream of impatience) and accompanying these is the deeper wish, now permanently present, for sexual satisfaction from the dreamer's father. This is immediately replaced by the wish to see once more what was then so fascinating. The mental process then proceeds on its way. Starting from the fulfilment of this last wish with the conjuring up of the primal scene, it passes on to what has now become inevitable - the repudiation of that wish and its repression.

[1918b, 3532]
The Dynamic Theory of Dream-Formation. The motive power for the formation of dreams is not provided by the latent dream-thoughts or day's residues, but by an unconscious impulse, repressed during the day, with which the day's residues have been able to establish contact and which contrives to make a wish-fulfilment for itself out of the material of the latent thoughts. Thus every dream is on the one hand the fulfilment of a wish on the part of the unconscious and on the other hand (in so far as it succeeds in guarding the state of sleep against being disturbed) the fulfilment of the normal wish to sleep which set the sleep going. If we disregard the unconscious contribution to the formation of the dream and limit the dream to its latent thoughts, it can represent anything with which waking life has been concerned - a reflection, a warning, an intention, a preparation for the immediate future or, once again, the satisfaction of an unfulfilled wish. The unrecognizability, strangeness and absurdity of the manifest dream are partly the result of the translation of the thoughts into a different, so to say archaic, method of expression, but partly the effect of a restrictive, critically disapproving agency in the mind which does not entirely cease to function during sleep. It is plausible to suppose that the 'dream-censorship', which we regard as being responsible in the first instance for the distortion of the dream-thoughts into the manifest dream, is an expression of the same mental forces which during the day-time had held back or repressed the unconscious wishful impulse.

[1923a, 3918]

It is possible to distinguish between dreams from above and dreams from below, provided the distinction is not made too sharply. Dreams from below are those which are provoked by the strength of an unconscious (repressed) wish which has found a means of being represented in some of the day's residues. They may be regarded as inroads of the repressed into waking life. Dreams from above correspond to thoughts or intentions of the day before which have contrived during the night to obtain reinforcement from repressed material that is debarred from the ego. When this is so, analysis as a rule disregards this unconscious ally and succeeds in inserting the latent dream-thoughts into the texture of waking thought. This distinction calls for no modification in the theory of dreams.

[1923c, 4032]
There were now a whole series of questions to be answered, among the most important of them being whether the formation of dreams had a motive, under what conditions it took place, by what methods the dream-thoughts (which are invariably full of sense) become converted into the dream (which is often senseless), and others besides. I attempted to solve all of these problems in *The Interpretation of Dreams*, which I published in the year 1900. I can only find space here for the briefest abstract of my investigation. When the latent dream-thoughts that are revealed by the analysis of a dream are examined, one of them is found to stand out from among the rest, which are intelligible and well known to the dreamer. These latter thoughts are residues of waking life (the *day's residues*, as they are called technically); but the isolated thought is found to be a wishful impulse, often of a very repellent kind, which is foreign to the waking life of the dreamer and is consequently disavowed by him with surprise or indignation. This impulse is the actual constructor of the dream: it provides the energy for its production and makes use of the day's residues as material. The dream which thus originates represents a situation of satisfaction for the impulse, it is the fulfilment of its wish. It would not be possible for this process to take place without being favoured by the presence of something in the nature of a state of sleep. The necessary mental precondition of sleep is the concentration of the ego upon the wish to sleep and the withdrawal of psychical energy from all the interests of life. Since at the same time all the paths of approach to motility are blocked, the ego is also able to reduce the expenditure by which at other times it maintains the repressions. The unconscious impulse makes use of this nocturnal relaxation of repression in order to push its way into consciousness with the dream. But the repressive resistance of the ego is not abolished in sleep but merely reduced. Some of it remains in the shape of a *censorship of dreams* and forbids the unconscious impulse to express itself in the forms which it would properly assume. In consequence of the severity of the censorship of dreams, the latent dream-thoughts are obliged to submit to being altered and softened so as to make the forbidden meaning of the dream unrecognizable. This is the explanation of *dream-distortion*, which accounts for the most striking characteristics of the manifest dream. We are therefore justified in asserting that a dream is the (disguised) fulfilment of a (repressed) wish. It will now be seen that dreams are constructed like a neurotic symptom: they are compromises between the demands of a repressed impulse and the resistance of a censoring force in the ego. Since they have a similar origin they are equally unintelligible and stand in equal need of interpretation.

We have explained that the unconscious instinctual impulse of the dream connects itself with a residue of the day, with some interest of waking life which has not been disposed of; it thus gives the dream which it constructs a double value for the work of analysis. For on the one hand a dream that has been analysed reveals itself as the fulfilment of a repressed wish; but on the other hand it may be a continuation of some preconscious activity of the day before and may contain every kind of subject-matter and give expression to an intention, a warning, a reflection, or once more to the fulfilment of a wish. Analysis exploits the dream in both directions, as a means of obtaining knowledge alike of the patient's conscious and of his unconscious processes. It also profits from the fact that dreams have access to the forgotten material of childhood, and so it happens that infantile amnesia is for the most part overcome in connection with the interpretation of dreams. In this respect dreams achieve a part of what was previously the task of hypnotism. On the other hand, I have never maintained the assertion which has so often been ascribed to me that dream-interpretation shows that all dreams have a sexual content or are derived from sexual motive forces. The case of young children affords us a convenient test of the validity of our theory of dreams. In them the various psychical systems are not yet sharply divided and the repressions have not yet grown deep, so that we often come upon dreams which are nothing more than undisguised fulfilments of wishful impulses left over from waking life. Under the influence of imperative needs, adults may also produce dreams of this infantile type.
In what follows I shall not be able to avoid a schematic method of exposition. Let us assume that in a particular case we have before us all the latent thoughts, charged with a greater or less amount of affect, by which the manifest dream has been replaced after its interpretation has been completed. We shall then be struck by one difference among these latent thoughts, and that difference will take us a long way. Almost all these dream-thoughts are recognized by the dreamer or acknowledged by him; he admits that he has thought this, now or at some other time, or that he might have thought it. There is only one single thought that he refuses to accept; it is strange to him or even perhaps repellent; he may possibly reject it with passionate feeling. It now becomes evident to us that the other thoughts are portions of a conscious, or, more accurately, a preconscious train of thinking. They might have been thought in waking life too, and indeed they were probably formed during the previous day. This one repudiated thought, however, or, properly speaking, this one impulse, is a child of night; it belongs to the dreamer’s unconscious and on that account it is repudiated and rejected by him. It had to wait for the nightly relaxation of repression in order to arrive at any kind of expression. And in any case this expression is a weakened, distorted and disguised one; without our work of dream-interpretation we should not have found it. This unconscious impulse has to thank its link with the other, unobjectionable, dream-thoughts for the opportunity of slipping past the barrier of the censorship in an inconspicuous disguise. On the other hand, the preconscious dream-thoughts have to thank this same link for the power to occupy mental life during sleep as well. For there is no doubt about it: this unconscious impulse is the true creator of the dream; it is what produces the psychical energy for the dream's construction. Like any other instinctual impulse, it cannot strive for anything other than its own satisfaction; and our experience in interpreting dreams shows us too that that is the sense of all dreaming. In every dream an instinctual wish has to be represented as fulfilled. The shutting-off of mental life from reality at night and the regression to primitive mechanisms which this makes possible enable this wished-for instinctual satisfaction to be experienced in a hallucinatory manner as occurring in the present. As a result of this same regression, ideas are transformed in the dream into visual pictures: the latent dream-thoughts, that is to say, are dramatized and illustrated.

[1933a, 4631]

After these influences have been brought to bear upon the dream-thoughts the dream is almost complete. A further, somewhat variable, factor also comes into play - known as 'secondary revision' - after the dream has been presented before consciousness as an object of perception. At that point we treat it as we are in general accustomed to treat the contents of our perception: we fill in gaps and introduce connections, and in doing so are often guilty of gross misunderstandings. But this activity, which might be described as a rationalizing one and which at best provides the dream with a smooth façade that cannot fit its true content, may also be omitted or only be expressed to a very modest degree - in which case the dream will display all its rents and cracks openly. It must not be forgotten, on the other hand, that the dream-work does not always operate with equal energy either; it often restricts itself to certain portions of the dream-thoughts only and others of them are allowed to appear in the dream unaltered. In such cases an impression is given of the dream having carried out the most delicate and complex intellectual operations, of its having speculated, made jokes, arrived at decisions and solved problems, whereas all this is a product of our normal mental activity, may have been performed equally well during the day before the dream as during the night, has nothing to do with the dream-work and brings nothing to light that is characteristic of dreams. Nor is it superfluous to insist once more on the contrast within the dream-thoughts themselves between the unconscious instinctual impulse and the day's residues. While the latter exhibit all the multiplicity of our mental acts, the former, which becomes the motive force proper of the forming of the dream, finds its outlet invariably in the fulfillment of a wish.

[1933a, 4634]
It is best to begin by pointing out that the formation of a dream can be provoked in two different ways. Either, on the one hand, an instinctual impulse which is ordinarily suppressed (an unconscious wish) finds enough strength during sleep to make itself felt by the ego, or, on the other hand, an urge left over from waking life, a preconscious train of thought with all the conflicting impulses attached to it, finds reinforcement during sleep from an unconscious element. In short, dreams may arise either from the id or from the ego. The mechanism of dream-formation is in both cases the same and so also is the necessary dynamic precondition. The ego gives evidence of its original derivation from the id by occasionally ceasing its functions and allowing a reversion to an earlier state of things. This is logically brought about by its breaking off its relations with the external world and withdrawing its cathexes from the sense organs. We are justified in saying that there arises at birth an instinct to return to the intra-uterine life that has been abandoned - an instinct to sleep. Sleep is a return of this kind to the womb. Since the waking ego governs motility, that function is paralysed in sleep, and accordingly a good part of the inhibitions imposed on the unconscious id become superfluous. The withdrawal or reduction of these 'anticathexes' thus allows the id what is now a harmless amount of liberty.

[1940a [1938], 4976]

Naturally, every case is not so simple. Especially in dreams which have originated from undealt-with residues of the previous day, and which have only obtained an unconscious reinforcement during the state of sleep, it is often no easy task to uncover the unconscious motive force and its wish-fulfilment; but we may assume that it is always there. The thesis that dreams are the fulfilments of wishes will easily arouse scepticism when it is remembered how many dreams have an actually distressing content or even wake the dreamer in anxiety, quite apart from the numerous dreams without any definite feeling-tone. But the objection based on anxiety dreams cannot be sustained against analysis. It must not be forgotten that dreams are invariably the product of a conflict, that they are a kind of compromise-structure. Something that is a satisfaction for the unconscious id may for that very reason be a cause of anxiety for the ego.

[1940a [1938], 4980]
No one who accepts the view that the censorship is the chief reason for dream-distortion will be surprised to learn from the results of dream-interpretation that most of the dreams of adults are traced back by analysis to erotic wishes. This assertion is not aimed at dreams with an undisguised sexual content, which are no doubt familiar to all dreamers from their own experience and are as a rule the only ones to be described as ‘sexual dreams.’ Even dreams of this latter kind offer enough surprises in their choice of the people whom they make into sexual objects, in their disregard of all the limitations which the dreamer imposes in his waking life upon his sexual desires, and by their many strange details, hinting at what are commonly known as ‘perversions.’ A great many other dreams, however, which show no sign of being erotic in their manifest content, are revealed by the work of interpretation in analysis as sexual wish-fulfilments; and, on the other hand, analysis proves that a great many of the thoughts left over from the activity of waking life as ‘residues of the previous day’ only find their way to representation in dreams through the assistance of repressed erotic wishes.

We shall unquestionably be met at this point by an opinion which denies that the case presented by the author possesses any such general interest and disputes the existence of any problem requiring solution. Hanold, it will be said, had no alternative but to abandon his delusion, after its subject, the supposed ‘Gradiva’ herself, had shown him that all his hypotheses were incorrect and after she had given him the most natural explanations of everything puzzling - for instance, of how it was that she had known his name. This would be the logical end of the matter; but since the girl had incidentally revealed her love to him, the author, no doubt to the satisfaction of his female readers, arranged that his story, a not uninteresting one otherwise, should have the usual happy ending in marriage. It would have been more consistent and equally possible, the argument will proceed, if the young scientist, after his error had been pointed out, had taken his leave of the lady with polite thanks and given as the reason for refusing her love the fact that he was able to feel an intense interest in antique women made of bronze or marble, and in their originals if they were accessible to contact, but that he did not know what to do with contemporary girls of flesh and blood. The author, in short, had quite arbitrarily tacked a love story on to his archaeological phantasy.

[1901a, 1094]

[1907a, 1880]
We would seem to have reached the end. But an attentive reader might remind us that at the beginning we threw out an assertion that dreams are wishes represented as fulfilled and that we gave no proof of this. Well, is our reply, what we have described in these pages might show how little justification there is for trying to cover the explanations we have to give of dreams with the single formula that dreams are wish-fulfilments. Nevertheless the assertion stands and can easily be proved too for the dreams in *Gradiva*. The latent dream-thoughts - we know now what is meant by them - may be of the most various kinds; in *Gradiva* they are 'days' residues', thoughts that have been left over unnoticed and undealt-with from the mental activities of waking life. But in order for a dream to develop out of them, the co-operation of a wish (usually an unconscious one) is required; this contributes the motive force for constructing the dream, while the day's residues provide the material. In Norbert Hanold's first dream two wishes competed with each other in making the dream; one of them was actually admissible to consciousness, while the other belonged to the unconscious and operated from out of repression. The first was a wish, understandable in any archaeologist, to have been present as an eye-witness at the catastrophe in the year 79 A.D. What sacrifice would an archaeologist think too great if this wish could be realized in any way other than in a dream! The other wish, the other constructor of the dream, was of an erotic nature: it might be crudely and also incompletely stated as a wish to be there when the girl he loved lay down to sleep. This was the wish the rejection of which caused the dream to become an anxiety-dream. The wishes that were the motive forces of the second dream are perhaps less conspicuous; but if we recall its translation we shall not hesitate to describe them too as erotic. The wish to be taken captive by the girl he loved, to fall in with her wishes and to be subjected to her - for so we may construe the wish behind the situation of the lizard-catching - was in fact of a passive, masochistic character. Next day the dreamer hit the girl, as though he was dominated by the contrary erotic current . . . But we must stop here, or we may really forget that Hanold and Gradiva are only creatures of their author's mind.

[1907a, 1884]

The ego, freed from all ethical bonds, also finds itself at one with all the demands of sexual desire, even those which have long been condemned by our aesthetic upbringing and those which contradict all the requirements of moral restraint. The desire for pleasure - the 'libido', as we call it - chooses its objects without inhibition, and by preference, indeed, the forbidden ones: not only other men's wives, but above all incestuous objects, objects sanctified by the common agreement of mankind, a man's mother and sister, a woman's father and brother. (The dream of our fifty-year-old lady, too, was incestuous; her libido was unmistakably directed to her son.) Lusts which we think of as remote from human nature show themselves strong enough to provoke dreams. Hatred, too, rages without restraint. Wishes for revenge and death directed against those who are nearest and dearest in waking life, against the dreamer's parents, brothers and sisters, husband or wife, and his own children are nothing unusual. These censored wishes appear to rise up out of a positive Hell; after they have been interpreted when we are awake, no censorship of them seems to us too severe.

[1916-1917, 3283]

I feel sure that you have heard some time or other that it is asserted by psycho-analysis that every dream has a sexual meaning. Well, you yourselves are in a position to form a judgement of the incorrectness of this reproach. You have become acquainted with wishful dreams dealing with the satisfaction of the most obvious needs - hunger and thirst and the longing for freedom - with dreams of convenience and of impatience, and also with purely covetous and egoistic dreams. But at the same time you should bear in mind, as one of the results of psycho-analytic research, that greatly distorted dreams give expression mainly (though, again, not exclusively) to sexual wishes.

[1916-1917, 3283]
What we have already learnt from our study of the mental life of children will lead us to expect to find a similar explanation of the other group of forbidden dream-wishes - the excessive sexual impulses. We are thus encouraged to make a study of the development of children's sexual life and from many sources we arrive at what follows.
[1916-1917, 3296]

But there is something else that I cannot pass by. The reminder of dreams given to us by the mother and wife of Oedipus must not be allowed to remain fruitless. Do you recall the outcome of our dream-analyses - how the wishes that construct dreams are so often of a perverse or incestuous nature or reveal an unsuspected hostility to those who are nearest and dearest to the dreamer? At that time we gave no explanation of the origin of these evil impulses. Now you can find it for yourselves. They are allocations of the libido and object-cathexes which date from early infancy and have long since been abandoned as far as conscious life is concerned, but which prove still to be present at night-time and to be capable of functioning in a certain sense. Since, however, everyone, and not only neurotics, experiences these perverse, incestuous and murderous dreams, we may conclude that people who are normal to-day have passed along a path of development that has led through the perversions and object-cathexes of the Oedipus complex, that that is the path of normal development and that neurotics merely exhibit to us in a magnified and coarsened form what the analysis of dreams reveals to us in healthy people as well. And this is one of the reasons why I dealt with the study of dreams before that of neurotic symptoms.
[1916-1917, 3402]

The wishes which act as motive forces in this dream are obvious. First there are the superficial wishes of the day, that Christmas with its presents may already be here (a dream of impatience) and accompanying these is the deeper wish, now permanently present, for sexual satisfaction from the dreamer's father. This is immediately replaced by the wish to see once more what was then so fascinating. The mental process then proceeds on its way. Starting from the fulfilment of this last wish with the conjuring up of the primal scene, it passes on to what has now become inevitable - the repudiation of that wish and its repression.
[1918b, 3532]

The dream ended in a state of anxiety, from which he did not recover until he had his Nanya with him. He fled, therefore, from his father to her. His anxiety was a repudiation of the wish for sexual satisfaction from his father - the trend which had put the dream into his head. The form taken by the anxiety, the fear of 'being eaten by the wolf', was only the (as we shall hear, regressive) transposition of the wish to be copulated with by his father, that is, to be given sexual satisfaction in the same way as his mother. His last sexual aim, the passive attitude towards his father, succumbed to repression, and fear of his father appeared in its place in the shape of the wolf phobia.
[1918b, 3534]
It remains for us to give a dynamic explanation of why the sleeping ego takes on the task of the dream-work at all. The explanation is fortunately easy to find. With the help of the unconscious, every dream that is in process of formation makes a demand upon the ego - for the satisfaction of an instinct, if the dream originates from the id; for the solution of a conflict, the removal of a doubt or the forming of an intention, if the dream originates from a residue of preconscious activity in waking life. The sleeping ego, however, is focused on the wish to maintain sleep; it feels this demand as a disturbance and seeks to get rid of the disturbance. The ego succeeds in doing this by what appears to be an act of compliance: it meets the demand with what is in the circumstances a harmless fulfilment of a wish and so gets rid of it. This replacement of the demand by the fulfilment of a wish remains the essential function of the dream-work. It may perhaps be worth while to illustrate this by three simple examples - a hunger dream, a dream of convenience and a dream prompted by sexual desire. A need for food makes itself felt in a dreamer during his sleep: he has a dream of a delicious meal and sleeps on. The choice, of course, was open to him either of waking up and eating something or of continuing his sleep. He decided in favour of the latter and satisfied his hunger by means of the dream - for the time being, at all events, for if his hunger had persisted he would have had to wake up nevertheless. Here is the second example. A sleeper had to wake up so as to be in time for his work at the hospital. But he slept on, and had a dream that he was already at the hospital - but as a patient, who has no need to get up. Or again, a desire becomes active during the night for the enjoyment of a forbidden sexual object, the wife of a friend of the sleeper. He has a dream of sexual intercourse - not, indeed, with this person but with someone else of the same name to whom he is in fact indifferent; or his struggle against the desire may find expression in his mistress remaining altogether anonymous.

[1940a [1938], 4980]
No one who accepts the view that the censorship is the chief reason for dream-distortion will be surprised to learn from the results of dream-interpretation that most of the dreams of adults are traced back by analysis to erotic wishes. This assertion is not aimed at dreams with an undisguised sexual content, which are no doubt familiar to all dreamers from their own experience and are as a rule the only ones to be described as ‘sexual dreams.’ Even dreams of this latter kind offer enough surprises in their choice of the people whom they make into sexual objects, in their disregard of all the limitations which the dreamer imposes in his waking life upon his sexual desires, and by their many strange details, hinting at what are commonly known as ‘perversions.’ A great many other dreams, however, which show no sign of being erotic in their manifest content, are revealed by the work of interpretation in analysis as sexual wish-fulfilments; and, on the other hand, analysis proves that a great many of the thoughts left over from the activity of waking life as ‘residues of the previous day’ only find their way to representation in dreams through the assistance of repressed erotic wishes.

¹ I will add a few remarks on the structure of this dream, though it is not possible to understand it thoroughly enough to allow of a synthesis being attempted. A prominent piece of the dream is to be seen in the phantasy of revenge against her father, which stands out like a façade in front of the rest. (She had gone away from home by her own choice; her father was ill, and then dead. . . Then she went home; all the others were already at the cemetery. She went to her room, not the least sadly, and calmly began reading the encyclopaedia.) This part of the material also contained two allusions to her other act of revenge, which she had actually carried out, when she let her parents discover a farewell letter from her. (The letter - from her mother, in the dream and the mention of the funeral of the aunt who had always been her model.) Behind this phantasy lie concealed her thoughts of revenge against Herr K., for which she found an outlet in her behaviour to me. (The maidservant, the invitation, the wood, the two and a half hours - all these came from material connected with the events at L--.) Her recollection of the governess, and of the latter's exchange of letters with her parents, is related, no less than her farewell letter, to the letter in the dream allowing her to come home. Her refusal to let herself be accompanied and her decision to go alone may perhaps be translated into these words: ‘Since you have treated me like a servant, I shall take no more notice of you, I shall go my own way by myself, and not marry.’ - Screened by these thoughts of revenge, glimpses can be caught in other places of material derived from tender phantasies based upon the love for Herr K. which still persisted unconsciously in Dora. (‘I would have waited for you till I could be your wife’ - defloration - childbirth.) - Finally, we can see the action of the fourth and most deeply buried group of thoughts - those relating to her love for Frau K. - in the fact that the phantasy of defloration is represented from the man's point of view (her identification of herself with her admirer who lived abroad) and in the fact that in two places there are the clearest allusions to ambiguous speeches (‘Does Herr -- live here?’) and to that source of her sexual knowledge which had not been oral (the encyclopaedia). - Cruel and sadistic tendencies find satisfaction in this dream.
We would seem to have reached the end. But an attentive reader might remind us that at the beginning we threw out an assertion that dreams are wishes represented as fulfilled and that we gave no proof of this. Well, is our reply, what we have described in these pages might show how little justification there is for trying to cover the explanations we have to give of dreams with the single formula that dreams are wish-fulfilments. Nevertheless the assertion stands and can easily be proved too for the dreams in *Gradiva*. The latent dream-thoughts - we know now what is meant by them - may be of the most various kinds; in *Gradiva* they are 'days' residues', thoughts that have been left over unnoticed and undealt-with from the mental activities of waking life. But in order for a dream to develop out of them, the co-operation of a wish (usually an unconscious one) is required; this contributes the motive force for constructing the dream, while the day's residues provide the material. In Norbert Hanold's first dream two wishes competed with each other in making the dream; one of them was actually admissible to consciousness, while the other belonged to the unconscious and operated from out of repression. The first was a wish, understandable in any archaeologist, to have been present as an eye-witness at the catastrophe in the year 79 A.D. What sacrifice would an archaeologist think too great if this wish could be realized in any way other than in a dream! The other wish, the other constructor of the dream, was of an erotic nature: it might be crudely and also incompletely stated as a wish to be there when the girl he loved lay down to sleep. This was the wish the rejection of which caused the dream to become an anxiety-dream. The wishes that were the motive forces of the second dream are perhaps less conspicuous; but if we recall its translation we shall not hesitate to describe them too as erotic. The wish to be taken captive by the girl he loved, to fall in with her wishes and to be subjected to her - for so we may construe the wish behind the situation of the lizard-catching - was in fact of a passive, masochistic character. Next day the dreamer hit the girl, as though he was dominated by the contrary erotic current . . . But we must stop here, or we may really forget that Hanold and Gradiva are only creatures of their author's mind.

[1907a, 1884]

The ego, freed from all ethical bonds, also finds itself at one with all the demands of sexual desire, even those which have long been condemned by our aesthetic upbringing and those which contradict all the requirements of moral restraint. The desire for pleasure - the 'libido', as we call it - chooses its objects without inhibition, and by preference, indeed, the forbidden ones: not only other men's wives, but above all incestuous objects, objects sanctified by the common agreement of mankind, a man's mother and sister, a woman's father and brother. (The dream of our fifty-year-old lady, too, was incestuous; her libido was unmistakably directed to her son.) Lusts which we think of as remote from human nature show themselves strong enough to provoke dreams. Hatred, too, rages without restraint. Wishes for revenge and death directed against those who are nearest and dearest in waking life, against the dreamer's parents, brothers and sisters, husband or wife, and his own children are nothing unusual. These censored wishes appear to rise up out of a positive Hell; after they have been interpreted when we are awake, no censorship of them seems to us too severe.

[1916-1917, 3237]
First and foremost, it is an untenable error to deny that children have a sexual life and to suppose that sexuality only begins at puberty with the maturation of the genitals. On the contrary, from the very first children have a copious sexual life, which differs at many points from what is later regarded as normal. What in adult life is described as 'perverse' differs from the normal in these respects: first, by disregarding the barrier of species (the gulf between men and animals), secondly, by overstepping the barrier against disgust, thirdly that against incest (the prohibition against seeking sexual satisfaction from near blood-relations), fourthly that against members of one's own sex and fifthly the transferring of the part played by the genitals to other organs and areas of the body. None of these barriers existed from the beginning; they were only gradually erected in the course of development and education. Small children are free from them. They recognize no frightful gulf between human beings and animals; the arrogance with which men separate themselves from animals does not emerge until later. To begin with, children exhibit no disgust at excreta but acquire this slowly under the pressure of education; they attach no special importance to the distinction between the sexes, but attribute the same conformation of the genitals to both; they direct their first sexual lusts and their curiosity to those who are nearest and for other reasons dearest to them - parents, brothers and sisters, or nurses; and finally, they show (what later on breaks through once again at the climax of a love-relation) that they expect to derive pleasure not only from their sexual organs, but that many other parts of the body lay claim to the same sensitivity, afford them analogous feelings of pleasure and can accordingly play the part of genitals. Children may thus be described as 'polymorphously perverse', and if these impulses only show traces of activity, that is because on the one hand they are of less intensity compared with those in later life and on the other hand all a child's sexual manifestations are at once energetically suppressed by education. This suppression is, as it were, extended into theory; for adults endeavour to overlook one portion of the sexual manifestations of children and to disguise another portion by misinterpreting its sexual nature, so that they can then disavow the whole of them. It is often the very same people who in the nursery are furious with any sexual naughtinesses of children and afterwards at their writing-tables defend the sexual purity of the same children. When children are left to themselves, or under the influence of seduction, they often bring about quite considerable achievements in the way of perverse sexual activity. Adults are of course right not to take this too seriously and to regard it as 'childishness', or 'playfulness', for children are not to be condemned as fully capable or fully responsible either before the judgement-seat of morals or before the law; but nonetheless these things exist. They have their importance both as indications of a child's innate constitution and as causes and encouragements of later developments in him; they give us information on the sexual life of children and so on human sexual life in general. If, therefore, we once more find all these perverse wishful impulses behind our distorted dreams, that only means that in this field too dreams have taken a step backwards into the state of infancy.

[1916-1917, 3297]
Among these forbidden wishes special emphasis deserves to be further laid on the incestuous ones - that is, on those aiming at sexual intercourse with parents and brothers and sisters. You know what horror is felt, or at least professed, in human society at such intercourse, and what stress is laid on the prohibitions directed against it. Tremendous efforts have been made to explain this horror of incest. Some people have supposed that breeding considerations on the part of Nature have found psychical representation in this prohibition, since inbreeding would impair racial characters. Others have maintained that, as a result of living together from early childhood onwards, sexual desire has been diverted from the people in question. In both these cases, it may be remarked, an avoidance of incest would be secured automatically, and it would not be clear why such severe prohibitions were called for, which would point rather to the presence of a strong desire for it. Psycho-analytic researches have shown unmistakably that the choice of an incestuous love-object is, on the contrary, the first and invariable one, and that it is not until later that resistance to it sets in; it is no doubt impossible to trace back this resistance to individual psychology.
[1916-1917, 3298]

But there is something else that I cannot pass by. The reminder of dreams given to us by the mother and wife of Oedipus must not be allowed to remain fruitless. Do you recall the outcome of our dream-analyses - how the wishes that construct dreams are so often of a perverse or incestuous nature or reveal an unsuspected hostility to those who are nearest and dearest to the dreamer? At that time we gave no explanation of the origin of these evil impulses. Now you can find it for yourselves. They are allocations of the libido and object-cathexes which date from early infancy and have long since been abandoned as far as conscious life is concerned, but which prove still to be present at night-time and to be capable of functioning in a certain sense. Since, however, everyone, and not only neurotics, experiences these perverse, incestuous and murderous dreams, we may conclude that people who are normal to-day have passed along a path of development that has led through the perversions and object-cathexes of the Oedipus complex, that that is the path of normal development and that neurotics merely exhibit to us in a magnified and coarsened form what the analysis of dreams reveals to us in healthy people as well. And this is one of the reasons why I dealt with the study of dreams before that of neurotic symptoms.
[1916-1917, 3402]

But our interest in the genesis of these manifestly immoral dreams is greatly reduced when we find from analysis that the majority of dreams - innocent dreams, dreams without affect and anxiety-dreams - are revealed, when the distortions of the censorship have been undone, as the fulfillments of immoral - egoistic, sadistic, perverse or incestuous - wishful impulses. As in the world of waking life, these masked criminals are far commoner than those with their visors raised. The straightforward dream of sexual relations with one's mother, which Jocasta alludes to in the Oedipus Rex, is a rarity in comparison with all the multiplicity of dreams which psycho-analysis must interpret in the same sense.
[1925i, 4049]
I have asserted above that dreams have no means of expressing the relation of a contradiction, a contrary or a 'no'. I shall now proceed to give a first denial of this assertion. One class of cases which can be comprised under the heading of 'contraries' are, as we have seen, simply represented by identification - cases, that is, in which the idea of an exchange or substitution can be brought into connection with the contrast. I have given a number of instances of this. Another class of contraries in the dream-thoughts, falling into a category which may be described as 'contrariwise' or 'just the reverse', find their way into dreams in the following remarkable fashion, which almost deserves to be described as a joke. The 'just the reverse' is not itself represented in the dream-content, but reveals its presence in the material through the fact that some piece of the dream-content, which has already been constructed and happens (for some other reason) to be adjacent to it, is - as it were by an afterthought - turned round the other way. The process is more easily illustrated than described. In the interesting 'Up and Down' dream (p. 759 ff.) the representation of the climbing in the dream was the reverse of what it was in its prototype in the dream-thoughts - that is, in the introductory scene from Daudet's Sappho: in the dream the climbing was difficult at first but easier later, while in the Daudet scene it was easy at first but more and more difficult later. Further, the 'up above' and 'down below' in the dreamer's relation to his brother were represented the other way round in the dream. This pointed to the presence of a reversed or contrary relation between two pieces of the material in the dream-thoughts; and we found it in the dreamer's childhood phantasy of being carried by his wet-nurse, which was the reverse of the situation in the novel, where the hero was carrying his mistress. So too in my dream of Goethe's attack on Herr M. (see below, p. 886 ff.) there is a similar 'just the reverse' which has to be put straight before the dream can be successfully interpreted. In the dream Goethe made an attack on a young man, Herr M.; in the real situation contained in the dream-thoughts a man of importance, my friend, had been attacked by an unknown young writer. In the dream I based a calculation on the date of Goethe's death; in reality the calculation had been made from the year of the paralytic patient's birth. The thought which turned out to be the decisive one in the dream-thoughts was a contradiction of the idea that Goethe should be treated as though he were a lunatic. 'Just the reverse', said the dream, 'if you don't understand the book, it's you that are feeble-minded, and not the author.' I think, moreover, that all these dreams of turning things round the other way include a reference to the contemptuous implications of the idea of 'turning one's back on something.' (E.g. the dreamer's turning round in relation to his brother in the Sappho dream.) It is remarkable to observe, moreover, how frequently reversal is employed precisely in dreams arising from repressed homosexual impulses.

[1900a, 796]

The dream ended in a state of anxiety, from which he did not recover until he had his Nanya with him. He fled, therefore, from his father to her. His anxiety was a repudiation of the wish for sexual satisfaction from his father - the trend which had put the dream into his head. The form taken by the anxiety, the fear of 'being eaten by the wolf', was only the (as we shall hear, regressive) transposition of the wish to be copulated with by his father, that is, to be given sexual satisfaction in the same way as his mother. His last sexual aim, the passive attitude towards his father, succumbed to repression, and fear of his father appeared in its place in the shape of the wolf phobia.

[1918b, 3534]
I have already discussed a dream which taught us that the wishes which are represented in dreams as fulfilled are not always present-day wishes. They may also be wishes of the past which have been abandoned, overlaid and repressed, and to which we have to attribute some sort of continued existence only because of their re-emergence in a dream. They are not dead in our sense of the word but only like the shades in the Odyssey, which awoke to some sort of life as soon as they had tasted blood. In the dream of the dead child in the 'case' (p. 154) what was involved was a wish which had been an immediate one fifteen years earlier and was frankly admitted as having existed at that time. I may add - and this may not be without its bearing upon the theory of dreams - that even behind this wish there lay a memory from the dreamer's earliest childhood. When she was a small child - the exact date could not be fixed with certainty - she had heard that her mother had fallen into a deep depression during the pregnancy of which she had been the fruit and had passionately wished that the child she was bearing might die. When the dreamer herself was grown-up and pregnant, she merely followed her mother's example.
[1900a, 728]
There is no theoretical necessity why this should be so; but to explain the fact it may be pointed out that no other group of instincts has been submitted to such far-reaching suppression by the demands of cultural education, while at the same time the sexual instincts are also the ones which, in most people, find it easiest to escape from the control of the highest mental agencies. Since we have become acquainted with infantile sexuality: which is often so unobtrusive in its manifestations and is always overlooked and misunderstood, we are justified in saying that almost every civilized man retains the infantile forms of sexual life in some respect or other. We can thus understand how it is that repressed infantile sexual wishes provide the most frequent and strongest motive-forces for the construction of dreams.¹
[1901a, 1094]

What we have already learnt from our study of the mental life of children will lead us to expect to find a similar explanation of the other group of forbidden dream-wishes - the excessive sexual impulses. We are thus encouraged to make a study of the development of children's sexual life and from many sources we arrive at what follows.
[1916-1917, 3296]
First and foremost, it is an untenable error to deny that children have a sexual life and to suppose that sexuality only begins at puberty with the maturation of the genitals. On the contrary, from the very first children have a copious sexual life, which differs at many points from what is later regarded as normal. What in adult life is described as ‘perverse’ differs from the normal in these respects: first, by disregarding the barrier of species (the gulf between men and animals), secondly, by overstepping the barrier against disgust, thirdly that against incest (the prohibition against seeking sexual satisfaction from near blood-relations), fourthly that against members of one’s own sex and fifthly the transferring of the part played by the genitals to other organs and areas of the body. None of these barriers existed from the beginning; they were only gradually erected in the course of development and education. Small children are free from them. They recognize no frightful gulf between human beings and animals; the arrogance with which men separate themselves from animals does not emerge until later. To begin with, children exhibit no disgust at excreta but acquire this slowly under the pressure of education; they attach no special importance to the distinction between the sexes, but attribute the same conformation of the genitals to both; they direct their first sexual lusts and their curiosity to those who are nearest and for other reasons dearest to them - parents, brothers and sisters, or nurses; and finally, they show (what later on breaks through once again at the climax of a love-relation) that they expect to derive pleasure not only from their sexual organs, but that many other parts of the body lay claim to the same sensitivity, afford them analogous feelings of pleasure and can accordingly play the part of genitals. Children may thus be described as 'polymorphously perverse', and if these impulses only show traces of activity, that is because on the one hand they are of less intensity compared with those in later life and on the other hand all a child's sexual manifestations are at once energetically suppressed by education. This suppression is, as it were, extended into theory; for adults endeavour to overlook one portion of the sexual manifestations of children and to disguise another portion by misinterpreting its sexual nature, so that they can then disavow the whole of them. It is often the very same people who in the nursery are furious with any sexual naughtinesses of children and afterwards at their writing-tables defend the sexual purity of the same children. When children are left to themselves, or under the influence of seduction, they often bring about quite considerable achievements in the way of perverse sexual activity. Adults are of course right not to take this too seriously and to regard it as 'childishness', or 'playfulness', for children are not to be condemned as fully capable or fully responsible either before the judgement-seat of morals or before the law; but nonetheless these things exist. They have their importance both as indications of a child's innate constitution and as causes and encouragements of later developments in him; they give us information on the sexual life of children and so on human sexual life in general. If, therefore, we once more find all these perverse wishful impulses behind our distorted dreams, that only means that in this field too dreams have taken a step backwards into the state of infancy.

[1916-1917, 3297]
Among these forbidden wishes special emphasis deserves to be further laid on the incestuous ones - that is, on those aiming at sexual intercourse with parents and brothers and sisters. You know what horror is felt, or at least professed, in human society at such intercourse, and what stress is laid on the prohibitions directed against it. Tremendous efforts have been made to explain this horror of incest. Some people have supposed that breeding considerations on the part of Nature have found psychical representation in this prohibition, since inbreeding would impair racial characters. Others have maintained that, as a result of living together from early childhood onwards, sexual desire has been diverted from the people in question. In both these cases, it may be remarked, an avoidance of incest would be secured automatically, and it would not be clear why such severe prohibitions were called for, which would point rather to the presence of a strong desire for it. Psycho-analytic researches have shown unmistakably that the choice of an incestuous love-object is, on the contrary, the first and invariable one, and that it is not until later that resistance to it sets in; it is no doubt impossible to trace back this resistance to *individual* psychology.

[1916-1917, 3298]

The dream ended in a state of anxiety, from which he did not recover until he had his Nanya with him. He fled, therefore, from his father to her. His anxiety was a repudiation of the wish for sexual satisfaction from his father - the trend which had put the dream into his head. The form taken by the anxiety, the fear of 'being eaten by the wolf', was only the (as we shall hear, regressive) transposition of the wish to be copulated with by his father, that is, to be given sexual satisfaction in the same way as his mother. His last sexual aim, the passive attitude towards his father, succumbed to repression, and fear of his father appeared in its place in the shape of the wolf phobia.

[1918b, 3534]
In the case of another group of dreams, analysis shows us that the actual wish which instigated the dream, and the fulfilment of which is represented by the dream, is derived from childhood; so that, to our surprise, we find the child and the child's impulses still living on in the dream. 
[1900a, 677]

There is, however, another inference following from these last dream-analyses to which I will draw attention at once. Dreams frequently seem to have more than one meaning. Not only, as our examples have shown, may they include several wish-fulfilments one alongside the other; but a succession of meanings or wish-fulfilments may be superimposed on one another, the bottom one being the fulfilment of a wish dating from earliest childhood. And here again the question arises whether it might not be more correct to assert that this occurs 'invariably' rather than 'frequently.'¹ 
[1900a, 699]

The deepest and eternal nature of man, upon whose evocation in his hearers the poet is accustomed to rely, lies in those impulses of the mind which have their roots in a childhood that has since become prehistoric. Suppressed and forbidden wishes from childhood break through in the dream behind the exile's unobjectionable wishes which are capable of entering consciousness; and that is why the dream which finds concrete expression in the legend of Nausicāä ends as a rule as an anxiety-dream. 
[1900a, 725]

From the unconscious, in fact. My supposition is that a conscious wish can only become a dream-instigator if it succeeds in awakening an unconscious wish with the same tenor and in obtaining reinforcement from it. From indications derived from the psycho-analysis of the neuroses, I consider that these unconscious wishes are always on the alert, ready at any time to find their way to expression when an opportunity arises for allying themselves with an impulse from the conscious and for transferring their own great intensity on to the latter's lesser one.¹ It will then appear as though the conscious wish alone had been realized in the dream; only some small peculiarity in the dream's configuration will serve as a finger-post to put us on the track of the powerful ally from the unconscious. These wishes in our unconscious, ever on the alert and, so to say, immortal, remind one of the legendary Titans, weighed down since primaeval ages by the massive bulk of the mountains which were once hurled upon them by the victorious gods and which are still shaken from time to time by the convulsion of their limbs. But these wishes, held under repression, are themselves of infantile origin, as we are taught by psychological research into the neuroses. I would propose, therefore, to set aside the assertion made just now, that the place of origin of dream-wishes is a matter of indifference and replace it by another one to the following effect: a wish which is represented in a dream must be an infantile one. In the case of adults it originates from the Ucs., in the case of children, where there is as yet no division or censorship between the Ucs. and the Pcs., or where that division is only gradually being set up, it is an unfulfilled, unrepressed wish from waking life. I am aware that this assertion cannot be proved to hold universally; but it can be proved to hold frequently, even in unsuspected cases, and it cannot be contradicted as a general proposition. 
[1900a, 985]

¹ They share this character of indestructibility with all other mental acts which are truly unconscious, i.e. which belong to the system Ucs. only. These are paths which have been laid down once and for all, which never fall into disuse and which, whenever an unconscious excitation re-cathects them, are always ready to conduct the excitatory process to discharge. If I may use a simile, they are only capable of annihilation in the same sense as the ghosts in the underworld of the Odyssey - ghosts which awoke to new life as soon as they tasted blood. Processes which are dependent on the preconscious system are destructible in quite another sense. The psychotherapy of the neuroses is based on this distinction. 
[1900a, 985]
We have so far been studying dream-wishes: we have traced them from their origin in the region of the *Ucs* and have analysed their relations to the day's residues, which in their turn may either be wishes or psychical impulses of some other kind or simply recent impressions. In this way we have allowed room for every claim that may be raised by any of the multifarious waking thought-activities on behalf of the importance of the part played by them in the process of constructing dreams. It is not impossible, even, that our account may have provided an explanation of the extreme cases in which a dream, pursuing the activities of daytime, arrives at a happy solution of some unsolved problem of waking life. All we need is an example of this kind, so that we might analyse it and trace the source of the infantile or repressed wishes whose help has been enlisted and has reinforced the efforts of preconscious activity with such success. But all this has not brought us a step nearer to solving the riddle of why it is that the unconscious has nothing else to offer during sleep but the motive force for the fulfilment of a wish. The answer to this question must throw light upon the psychical nature of wishes, and I propose to give the answer by reference to our schematic picture of the psychical apparatus.

The fact that dreams are hypermnesic and have access to material from childhood has become one of the corner-stones of our teaching. Our theory of dreams regards wishes originating in infancy as the indispensable motive force for the formation of dreams.

We accordingly borrow the following thesis from the theory of hysteria: *a normal train of thought is only submitted to abnormal psychical treatment of the sort we have been describing if an unconscious wish, derived from infancy and in a state of repression has been transferred on to it.* In accordance with this thesis we have constructed our theory of dreams on the assumption that the dream-wish which provides the motive power invariably originates from the unconscious - an assumption which, as I myself am ready to admit, cannot be proved to hold generally, though neither can it be disproved. But in order to explain what is meant by 'repression', a term with which we have already made play so many times, it is necessary to proceed a stage further with our psychological scaffolding.

Among these wishful impulses derived from infancy, which can neither be destroyed nor inhibited, there are some whose fulfilment would be a contradiction of the purposive ideas of secondary thinking. The fulfilment of these wishes would no longer generate an affect of pleasure but of unpleasure; and it is precisely this transformation of affect which constitutes the essence of what we term 'repression'. The problem of repression lies in the question of how it is and owing to what motive forces that this transformation occurs; but it is a problem that we need only touch upon here. It is enough for us to be clear that a transformation of this kind does occur in the course of development - we have only to recall the way in which disgust emerges in childhood after having been absent to begin with - and that it is related to the activity of the secondary system. The memories on the basis of which the unconscious wish brings about the release of affect were never accessible to the *Pcs.*, and consequently the release of the affect attaching to those memories cannot be inhibited either. It is for the very reason of this generation of affect that these ideas are now inaccessible even by way of the preconscious thoughts on to which they have transferred their wishful force. On the contrary, the unpleasure principle takes control and causes the *Pcs.* to turn away from the transference thoughts. They are left to themselves - 'repressed' - and thus it is that the presence of a store of infantile memories, which has from the first been held back from the *Pcs.*, becomes a *sine qua non* for repression.
And the value of dreams for giving us knowledge of the future? There is of course no question of that. It would be truer to say instead that they give us knowledge of the past. For dreams are derived from the past in every sense. Nevertheless the ancient belief that dreams foretell the future is not wholly devoid of truth. By picturing our wishes as fulfilled, dreams are after all leading us into the future. But this future, which the dreamer pictures as the present, has been moulded by his indestructible wish into a perfect likeness of the past.
[1900a, 1045]

It would be a mistake, however, to suppose that these dream-facades are nothing other than mistaken and somewhat arbitrary revisions of the dream-content by the conscious agency of our mental life. In the erection of a dream-façade use is not infrequently made of wishful phantasies which are present in the dream-thoughts in a pre-constructed form, and are of the same character as the appropriately named ‘day-dreams’ familiar to us in waking life. The wishful phantasies revealed by analysis in night-dreams often turn out to be repetitions or modified versions of scenes from infancy; thus in some cases the façade of the dream directly reveals the dream’s actual nucleus, distorted by an admixture of other material.
[1901a, 1081]

There is no theoretical necessity why this should be so; but to explain the fact it may be pointed out that no other group of instincts has been submitted to such far-reaching suppression by the demands of cultural education, while at the same time the sexual instincts are also the ones which, in most people, find it easiest to escape from the control of the highest mental agencies. Since we have become acquainted with infantile sexuality: which is often so unobtrusive in its manifestations and is always overlooked and misunderstood, we are justified in saying that almost every civilized man retains the infantile forms of sexual life in some respect or other. We can thus understand how it is that repressed infantile sexual wishes provide the most frequent and strongest motive-forces for the construction of dreams.¹
[1901a, 1094]

The fact was that I could not forget the hint which seemed to be conveyed by the ambiguous words already noticed - that it might be necessary to leave the room; that an accident might happen in the night. Added to this was the fact that the elucidation of the dream seemed to me incomplete so long as a particular requirement remained unsatisfied; for, though I do not wish to insist that this requirement is a universal one, I have a predilection for discovering a means of satisfying it. A regularly formed dream stands, as it were, upon two legs, one of which is in contact with the main and current exciting cause, and the other with some momentous event in the years of childhood. The dream sets up a connection between those two factors - the event during childhood and the event of the present day - and it endeavours to re-shape the present on the model of the remote past. For the wish which creates the dream always springs from the period of childhood; and it is continually trying to summon childhood back into reality and to correct the present day by the measure of childhood. I believed that I could already clearly detect those elements of Dora’s dream which could be pieced together into an allusion to an event in childhood.
[1905e, 1408]
The dream from the analysis of which we have derived this information corresponded, as we have seen, to an intention which Dora carried with her into her sleep. It was therefore repeated each night until the intention had been carried out; and it reappeared years later when an occasion arose for forming an analogous intention. The intention might have been consciously expressed in some such words as these: 'I must fly from this house, for I see that my virginity is threatened here; I shall go away with my father, and I shall take precautions not to be surprised while I am dressing in the morning.' These thoughts were clearly expressed in the dream; they formed part of a mental current which had achieved consciousness and a dominating position in waking life. Behind them can be discerned obscure traces of a train of thought which formed part of a contrary current and had consequently been suppressed. This other train of thought culminated in the temptation to yield to the man, out of gratitude for the love and tenderness he had shown her during the last few years, and it may perhaps have revived the memory of the only kiss she had so far had from him. But according to the theory which I developed in my Interpretation of Dreams such elements as these are not enough for the formation of a dream. On that theory a dream is not an intention represented as having been carried out, but a wish represented as having been fulfilled, and, moreover, in most cases a wish dating from childhood. It is our business now to discover whether this principle may not be contradicted by the present dream.

The dream does in fact contain infantile material, though it is impossible at a first glance to discover any connections between that material and Dora's intention of flying from Herr K.'s house and the temptation of his presence. Why should a recollection have emerged of her bed-wetting when she was a child and of the trouble her father used to take to teach the child clean habits? We may answer this by saying that it was only by the help of this train of thought that it was possible to suppress the other thoughts which were so intensely occupied with the temptation to yield or that it was possible to secure the dominance of the intention which had been formed of combating those other thoughts. The child decided to fly with her father; in reality she fled to her father because she was afraid of the man who was pursuing her; she summoned up an infantile affection for her father so that it might protect her against her present affection for a stranger. Her father was himself partly responsible for her present danger, for he had handed her over to this strange man in the interests of his own love-affair. And how much better it had been when that same father of hers had loved no one more than her, and had exerted all his strength to save her from the dangers that had then threatened her! The infantile, and now unconscious, wish to put her father in the strange man's place had the potency necessary for the formation of a dream. If there were a past situation similar to a present one, and differing from it only in being concerned with one instead of with the other of the two persons mentioned in the wish, that situation would become the main one in the dream. But there had been such a situation. Her father had once stood beside her bed, just as Herr K. had the day before, and had woken her up, with a kiss perhaps, as Herr K. may have meant to do. Thus her intention of flying from the house was not in itself capable of producing a dream; but it became so by being associated with another intention which was founded upon infantile wishes. The wish to replace Herr K. by her father provided the necessary motive power for the dream. Let me recall the interpretation I was led to adopt of Dora's reinforced train of thought about her father's relations with Frau K. My interpretation was that she had at that point summoned up an infantile affection for her father so as to be able to keep her repressed love for Herr K. in its state of repression. This same sudden revulsion in the patient's mental life was reflected in the dream.

[1905e, 1421]

[1905e, 1422]
According to the necessary conditions of dream-formation the imagined situation must be chosen so as to reproduce a situation in infancy. A special triumph is achieved if a recent situation, perhaps even the very situation which is the exciting cause of the dream, can be transformed into an infantile one. This has actually been achieved in the present case, by a purely chance disposition of the material. Just as Herr K. had stood beside her sofa and woken her up, so her father had often done in her childhood. The whole trend of her thoughts could be most aptly symbolized by her substitution of her father for Herr K. in that situation.

Nevertheless, we feel a need to modify Spencer's notion, in part to give a more definite form to the ideas contained in it and in part to change them. We should say that laughter arises if a quota of psychical energy which has earlier been used for the cathexis of particular psychical paths has become unusable, so that it can find free discharge. We are well aware what 'evil looks' we are inviting with such a hypothesis; but we will venture to quote in our defence an apposite sentence from Lipps's book *Komik und Humor* (1898, 71), from which illumination is to be derived on more subjects than that of the comic and humour: 'Finally, specific psychological problems always lead fairly deep into psychology, so that at bottom no psychological problem can be treated in isolation.' The concepts of 'psychical energy' and 'discharge' and the treatment of psychical energy as a quantity have become habitual in my thoughts since I began to arrange the facts of psychopathology philosophically; and already in my *Interpretation of Dreams* (1900a) I tried (in the same sense as Lipps) to establish the fact that what are 'really psychically effective' are psychical processes which are unconscious in themselves, not the contents of consciousness.¹ It is only when I speak of the 'cathexis of psychical paths' that I seem to depart from the analogies commonly used by Lipps. My experiences of the displaceability of psychical energy along certain paths of association, and of the almost indestructible persistence of the traces of psychical processes, have in fact suggested to me an attempt at picturing the unknown in some such way. To avoid misunderstanding, I must add that I am making no attempt to proclaim that the cells and nerve fibres, or the systems of neurones which are taking their place to-day, are these psychical paths, even though it would have to be possible in some manner which cannot yet be indicated to represent such paths by organic elements of the nervous system.

Let me now proceed with my account of our findings. In another set of cases psycho-analytic investigation traces the symptoms back, it is true, not to sexual experiences but to commonplace traumatic ones. But this distinction loses its significance owing to another circumstance. For the work of analysis required for the thorough explanation and complete recovery of a case never comes to a stop at events that occurred at the time of the onset of the illness, but invariably goes back to the patient's puberty and early childhood; and it is only there that it comes upon the impressions and events which determined the later onset of the illness. It is only experiences in childhood that explain susceptibility to later traumas and it is only by uncovering these almost invariably forgotten memory-traces and by making them conscious that we acquire the power to get rid of the symptoms. And here we reach the same conclusion as in our investigation of dreams: the imperishable, repressed wishful impulses of childhood have alone provided the power for the construction of symptoms, and without them the reaction to later traumas would have taken a normal course. But these powerful wishful impulses of childhood may without exception be described as sexual.

¹ [1905c, 1735]

² [1910a, 2228]
But the distinction between foreconscious and unconscious activity, and the recognition of the barrier which keeps them asunder, is not the last or the most important result of the psychoanalytic investigation of psychical life. There is one psychical product to be met with in the most normal persons, which yet presents a very striking analogy to the wildest productions of insanity, and was no more intelligible to philosophers than insanity itself. I refer to dreams. Psycho-analysis is founded upon the analysis of dreams; the interpretation of dreams is the most complete piece of work the young science has done up to the present. One of the most common types of dream-formation may be described as follows: a train of thoughts has been aroused by the working of the mind in the daytime, and retained some of its activity, escaping from the general inhibition of interests which introduces sleep and constitutes the psychical preparation for sleeping. During the night this train of thoughts succeeds in finding connections with one of the unconscious tendencies present ever since his childhood in the mind of the dreamer, but ordinarily repressed and excluded from his conscious life. By the borrowed force of this unconscious help, the thoughts, the residue of the day's work,¹ now become active again, and emerge into consciousness in the shape of the dream. Now three things have happened:

[1912g, 2582]

Another and far more surprising discovery has been that, in spite of all the later development that occurs in the adult, none of the infantile mental formations perish. All the wishes, instinctual impulses, modes of reaction and attitudes of childhood are still demonstrably present in maturity and in appropriate circumstances can emerge once more. They are not destroyed but merely overlaid - to use the spatial mode of description which psycho-analytic psychology has been obliged to adopt. Thus it is part of the nature of the mental past that, unlike the historic past, it is not absorbed by its derivatives; it persists (whether actually or only potentially) alongside what has proceeded from it. The proof of this assertion lies in the fact that the dreams of normal people revive their childhood characters every night and reduce their whole mental life to an infantile level. This same return to psychical infantilism ('regression') appears in the neuroses and psychoses, whose peculiarities may to a great extent be described as psychical archaisms. The strength in which the residues of infancy are still present in the mind shows us the amount of disposition to illness; that disposition may accordingly be regarded as an expression of an inhibition in development. The part of a person's psychical material which has remained infantile and has been repressed as being unserviceable constitutes the core of his unconscious. And we believe we can follow in our patients' life-histories the way in which this unconscious, held back as it is by the forces of repression, lies in wait for a chance to become active and makes use of its opportunities if the later and higher psychical structures fail to master the difficulties of real life.

[1913j, 2820]

But there is something else that I cannot pass by. The reminder of dreams given to us by the mother and wife of Oedipus must not be allowed to remain fruitless. Do you recall the outcome of our dream-analyses - how the wishes that construct dreams are so often of a perverse or incestuous nature or reveal an unsuspected hostility to those who are nearest and dearest to the dreamer? At that time we gave no explanation of the origin of these evil impulses. Now you can find it for yourselves. They are allocations of the libido and object-cathexes which date from early infancy and have long since been abandoned as far as conscious life is concerned, but which prove still to be present at night-time and to be capable of functioning in a certain sense. Since, however, everyone, and not only neurotics, experiences these perverse, incestuous and murderous dreams, we may conclude that people who are normal to-day have passed along a path of development that has led through the perversions and object-cathexes of the Oedipus complex, that that is the path of normal development and that neurotics merely exhibit to us in a magnified and coarsened form what the analysis of dreams reveals to us in healthy people as well. And this is one of the reasons why I dealt with the study of dreams before that of neurotic symptoms.

[1916-1917, 3402]
The aetiology common to the onset of a psychoneurosis and of a psychosis always remains the same. It consists in a frustration, a non-fulfilment of one of those childhood wishes which are for ever undefeated and which are so deeply rooted in our phylogenetically determined organization. This frustration is in the last resort always an external one; but in the individual case it may proceed from the internal agency (in the super-ego) which has taken over the representation of the demands of reality. The pathogenic effect depends on whether, in a conflictual tension of this kind, the ego remains true to its dependence on the external world and attempts to silence the id, or whether it lets itself be overcome by the id and thus torn away from reality. A complication is introduced into this apparently simple situation, however, by the existence of the super-ego, which, though a link that is not yet clear to us, unites in itself influences coming from the id as well as from the external world, and is to some extent an ideal model of what the whole endeavour of the ego is aiming at - a reconciliation between its various dependent relationships. The attitude of the super-ego should be taken into account - which has not hitherto been done - in every form of psychical illness. We may provisionally assume that there must also be illnesses which are based on a conflict between the ego and the super-ego. Analysis gives us a right to suppose that melancholia is a typical example of this group; and we would set aside the name of 'narcissistic psychoneuroses' for disorders of that kind. Nor will it clash with our impressions if we find reasons for separating states like melancholia from the other psychoses. We now see that we have been able to make our simple genetic formula more complete, without dropping it. Transference neuroses correspond to a conflict between the ego and the id; narcissistic neuroses, to a conflict between the ego and the super-ego; and psychoses, to one between the ego and the external world. It is true that we cannot tell at once whether we have really gained any new knowledge by this, or have only enriched our store of formulas; but I think that this possible application of the proposed differentiation of the mental apparatus into an ego, a super-ego and an id cannot fail to give us courage to keep that hypothesis steadily in view.

[1924b, 4067]

We meet with the second of these facts almost every day in the course of our analytic work; and it does not imply such an important objection as the other does. One of the tasks of psycho-analysis, as you know, is to lift the veil of amnesia which hides the earliest years of childhood and to bring to conscious memory the manifestations of early infantile sexual life which are contained in them. Now these first sexual experiences of a child are linked to painful impressions of anxiety, prohibition, disappointment and punishment. We can understand their having been repressed; but, that being so, we cannot understand how it is that they have such free access to dream-life, that they provide the pattern for so many dream-phantasies and that dreams are filled with reproductions of these scenes from childhood and with allusions to them. It must be admitted that their unpleasurable character and the dream-work's wish-fulfilling purpose seem far from mutually compatible. But it may be that in this case we are magnifying the difficulty. After all, these same infantile experiences have attached to them all the imperishable, unfulfilled instinctual wishes which throughout life provide the energy for the construction of dreams, and to which we may no doubt credit the possibility, in their mighty uprush, of forcing to the surface, along with the rest, the material of distressing events. And on the other hand the manner and form in which this material is reproduced shows unmistakably the efforts of the dream-work directed to denying the unpleasure by means of distortion and to transforming disappointment into attainment.

[1933a, 4641]
When I began analysing this dream, I thought quite unexpectedly of the first novel I ever read (when I was thirteen, perhaps); as a matter of fact I began at the end of the first volume. I have never known the name of the novel or of its author; but I have a vivid memory of its ending. The hero went mad and kept calling out the names of the three women who had brought the greatest happiness and sorrow into his life. One of these names was Pélagie. I still had no notion what this recollection was going to lead to in the analysis. In connection with the three women I thought of the three Fates who spin the destiny of man, and I knew that one of the three women - the inn-hostess in the dream - was the mother who gives life, and furthermore (as in my own case) gives the living creature its first nourishment. Love and hunger, I reflected, meet at a woman's breast. A young man who was a great admirer of feminine beauty was talking once - so the story went - of the good-looking wet-nurse who had suckled him when he was a baby: 'I'm sorry', he remarked, 'that I didn't make a better use of my opportunity.' I was in the habit of quoting this anecdote to explain the factor of 'deferred action' in the mechanism of the psychoneuroses. - One of the Fates, then, was rubbing the palms of her hands together as though she was making dumplings: a queer occupation for a Fate, and one that cried out for an explanation. This was provided by another and earlier memory of my childhood. When I was six years old and was given my first lessons by my mother, I was expected to believe that we were all made of earth and must therefore return to earth. This did not suit me and I expressed doubts of the doctrine. My mother thereupon rubbed the palms of her hands together - just as she did in making dumplings, except that there was no dough between them - and showed me the blackish scales of epidermis produced by the friction as a proof that we were made of earth. My astonishment at this ocular demonstration knew no bounds and I acquiesced in the belief which I was later to hear expressed in the words: 'Du bist der Natur einen Tod schuldig.' ['Thou owest Nature a death.'] So they really were Fates that I found in the kitchen when I went into it - as I had so often done in my childhood when I was hungry, while my mother, standing by the fire, had admonished me that I must wait till dinner was ready. - And now for the dumplings - the Knödel! One at least of my teachers at the University - and precisely the one to whom I owe my histological knowledge (for instance of the epidermis) - would infallibly be reminded by the name Knödl of a person against whom he had been obliged to take legal action for plagiarizing his writings. The idea of plagiarizing - of appropriating whatever one can, even though it belongs to someone else - clearly led on to the second part of the dream, in which I was treated as though I were the thief who had for some time carried on his business of stealing overcoats in the lecture-rooms. I had written down the word 'plagiarizing', without thinking about it, because it occurred to me; but now I noticed that it could form a bridge [Brücke] between different pieces of the dream's manifest content. A chain of associations (Pélagie - plagiarizing - plagiostomes² or sharks [Haifische] - a fish's swimming-bladder [Fischblase]) connected the old novel with the case of Knödli and with the overcoats, which clearly referred to implements used in sexual technique. (Cf. Maury's alliterative dreams.) No doubt it was a very far-fetched and senseless chain of thought; but I could never have constructed it in waking life unless it had already been constructed by the dream-work. And, as though the need to set up forced connections regarded nothing as sacred, the honoured name of Brücke (cf. the verbal bridge above) reminded me of the Institute in which I spent the happiest hours of my student life, free from all other desires - [1900a, 688]
We have already taken the first step in this direction by advancing the thesis (see p. 666 f.) that the dream-work is under the necessity of combining into a unity all instigations to dreaming which are active simultaneously. We found that, when two or more experiences capable of creating an impression are left over from the previous day, the wishes derived from them are combined in a single dream, and similarly that the psychically significant impressions and the indifferent experiences from the previous day are brought together in the dream-material, provided always that it is possible to set up communicating ideas between them. Thus a dream appears to be a reaction to everything that is simultaneously present in the sleeping mind as currently active material. So far as we have hitherto analysed the material of dreams, we have seen it as a collection of psychical residues and memory-traces, to which (on account of the preference shown for recent and infantile material) we have been led to attribute a hitherto indefinable quality of being 'currently active'. We can foresee, then, without any great difficulty, what will happen if fresh material in the form of sensations is added during sleep to these currently active memories. It is once again owing to the fact of their being currently active that these sensory excitations are of importance for the dream; they are united with the other currently active psychical material to furnish what is used for the construction of the dream. To put it another way, stimuli arising during sleep are worked up into a wish-fulfilment the other constituents of which are the familiar psychical 'day's residues'. This combination need not occur; as I have already pointed out, there is more than one way of reacting to a somatic stimulus during sleep. When it does occur, it means that it has been possible to find ideational material to serve as the content of the dream of such a sort as to be able to represent both kinds of source of the dream - the somatic and the psychical.

[1900a, 707]

Every attempt that has hitherto been made to solve the problem of dreams has dealt directly with their manifest content as it is presented in our memory. All such attempts have endeavoured to arrive at an interpretation of dreams from their manifest content or (if no interpretation was attempted) to form a judgement as to their nature on the basis of that same manifest content. We are alone in taking something else into account. We have introduced a new class of psychical material between the manifest content of dreams and the conclusions of our enquiry: namely, their latent content, or (as we say) the 'dream-thoughts', arrived at by means of our procedure. It is from these dream-thoughts and not from a dream's manifest content that we disentangle its meaning. We are thus presented with a new task which had no previous existence: the task, that is, of investigating the relations between the manifest content of dreams and the latent dream-thoughts, and of tracing out the processes by which the latter have been changed into the former.

[1900a, 751]
Indeed, when we look into the matter more closely, we must recognize the fact that the
dream-work is doing nothing original in making substitutions of this kind. In order to gain its
ends - in this case the possibility of a representation hampered by censorship - it merely follows
the paths which it finds already laid down in the unconscious; and it gives preference to those
transformations of the repressed material which can also become conscious in the form of jokes
or allusions and of which the phantasies of neurotic patients are so full. At this point we
suddenly reach an understanding of Scherner's dream interpretations, whose essential
correctness I have defended elsewhere. The imagination's pre-occupation with the subject's
own body is by no means peculiar to dreams or characteristic only of them. My analyses have
shown me that it is habitually present in the unconscious thoughts of neurotics, and that it is
derived from sexual curiosity, which, in growing youths or girls, is directed to the genitals of the
other sex, and to those of their own as well. Nor, as Scherner and Volkelt have rightly insisted,
is a house the only circle of ideas employed for symbolizing the body; and this is equally true of
dreams and of the unconscious phantasies of neurosis. It is true that I know patients who have
retained an architectural symbolism for the body and the genitals. (Sexual interest ranges far
beyond the sphere of the external genitalia.) For these patients pillars and columns represent
the legs (as they do in the Song of Solomon), every gateway stands for one of the bodily orifices
(a 'hole'), every water-pipe is a reminder of the urinary apparatus, and so on. But the circle of
ideas centring round plant-life or the kitchen may just as readily be chosen to conceal sexual
images.' In the former case the way has been well prepared by linguistic usage, itself the
precipitate of imaginative similes reaching back to remote antiquity: e.g. the Lord's vineyard, the
seed, and the maiden's garden in the Song of Solomon. The ugliest as well as the most intimate
details of sexual life may be thought and dreamt of in seemingly innocent allusions to activities
in the kitchen; and the symptoms of hysteria could never be interpreted if we forgot that sexual
symbolism can find its best hiding-place behind what is commonplace and inconspicuous.
There is a valid sexual meaning behind the neurotic child's intolerance of blood or raw meat, or
his nausea at the sight of eggs or macaroni, and behind the enormous exaggeration in neurotics
of the natural human dread of snakes. Wherever neuroses make use of such disguises they are
following paths along which all humanity passed in the earliest periods of civilization - paths of
whose continued existence today, under the thinnest of veils, evidence is to be found in
linguistic usages, superstitions and customs.
[1900a, 815]
The localities in the dream were brought together from several trips of mine to the Adriatic (to Miramare, Duino, Venice and Aquileia). A short but enjoyable Easter trip which I had made to Aquileia with my brother a few weeks before the dream was still fresh in my memory. The dream also contained allusions to the maritime war between America and Spain and to anxieties to which it had given rise about the fate of my relatives in America. At two points in the dream affects were in question. At one point an affect that was to be anticipated was absent: attention was expressly drawn to the fact that the Governor's death made no impression on me. At another point, when I thought I saw the warship, I was frightened and felt all the sensations of fright in my sleep. In this well-constructed dream the affects were distributed in such a way that any striking contradiction was avoided. There was no reason why I should be frightened at the death of the Governor and it was quite reasonable that as Commandant of the Castle I should be frightened at the sight of the warship. The analysis showed, however, that Herr P. was only a substitute for my own self. (In the dream I was the substitute for him.) I was the Governor who suddenly died. The dream-thoughts dealt with the future of my family after my premature death. This was the only distressing one among the dream-thoughts; and it must have been from it that the fright was detached and brought into connection in the dream with the sight of the warship. On the other hand, the analysis showed that the region of the dream-thoughts from which the warship was taken was filled with the most cheerful recollections. It was a year earlier, in Venice, and we were standing one magically beautiful day at the windows of our room on the Riva degli Schiavoni and were looking across the blue lagoon on which that day there was more movement than usual. English ships were expected and were to be given a ceremonial reception. Suddenly my wife cried out gaily as a child: 'Here comes the English warship!' In the dream I was frightened at these same words. (We see once again that speeches in a dream are derived from speeches in real life; I shall show shortly that the element 'English' in my wife's exclamation did not elude the dream-work either.) Here, then, in the process of changing the dream-thoughts into the manifest dream-content, I have transformed cheerfulness into fear, and I need only hint that this transformation was itself giving expression to a portion of the latent dream-content. This example proves, however, that the dream-work is at liberty to detach an affect from its connections in the dream-thoughts and introduce it at any other point it chooses in the manifest dream.

Like dreams, they are wish-fulfilments; like dreams, they are based to a great extent on impressions of infantile experiences; like dreams, they benefit by a certain degree of relaxation of censorship. If we examine their structure, we shall perceive the way in which the wishful purpose that is at work in their production has mixed up the material of which they are built, has rearranged it and has formed it into a new whole. They stand in much the same relation to the childhood memories from which they are derived as do some of the Baroque palaces of Rome to the ancient ruins whose pavements and columns have provided the material for the more recent structures.
I will now try to sum up this lengthy disquisition on the dream-work. We were faced by the question whether the mind employs the whole of its faculties without reserve in constructing dreams or only a functionally restricted fragment of them. Our investigations led us to reject entirely the form in which the question was framed as being inadequate to the circumstances. If, however, we had to reply to the question on the basis of the terms in which it was stated, we should be obliged to reply in the affirmative to both the alternatives, mutually exclusive though they appear to be. Two separate functions may be distinguished in mental activity during the construction of a dream: the production of the dream-thoughts, and their transformation into the content of the dream. The dream-thoughts are entirely rational and are constructed with an expenditure of all the psychical energy of which we are capable. They have their place among thought-processes that have not become conscious - processes from which, after some modification, our conscious thoughts, too, arise. However many interesting and puzzling questions the dream-thoughts may involve, such questions have, after all, no special relation to dreams and do not call for treatment among the problems of dreams.¹ On the other hand, the second function of mental activity during dream-construction, the transformation of the unconscious thoughts into the content of the dream, is peculiar to dream-life and characteristic of it. This dream-work proper diverges further from our picture of waking thought than has been supposed even by the most determined depreciator of psychical functioning during the formation of dreams. The dream-work is not simply more careless, more irrational, more forgetful and more incomplete than waking thought; it is completely different from it qualitatively and for that reason not immediately comparable with it. It does not think, calculate or judge in any way at all; it restricts itself to giving things a new form. It is exhaustively described by an enumeration of the conditions which it has to satisfy in producing its result. That product, the dream, has above all to evade the censorship, and with that end in view the dream-work makes use of a displacement of psychical intensities to the point of a transvaluation of all psychical values. The thoughts have to be reproduced exclusively or predominantly in the material of visual and acoustic memory-traces, and this necessity imposes upon the dream-work considerations of representability which it meets by carrying out fresh displacements. Greater intensities have probably to be produced than are available in the dream-thoughts at night, and this purpose is served by the extensive condensation which is carried out with the constituents of the dream-thoughts. Little attention is paid to the logical relations between the thoughts; those relations are ultimately given a disguised representation in certain formal characteristics of dreams. Any affect attached to the dream-thoughts undergoes less modification than their ideational content. Such affects are as a rule suppressed; when they are retained, they are detached from the ideas that properly belong to them, affects of a similar character being brought together. Only a single portion of the dream-work and one which operates to an irregular degree, the working over of the material by partly aroused waking thought, tallies to some extent with the view which other writers have sought to apply to the entire activity of dream-construction.

[1900a, 944]
Footnote added 1925: I used at one time to find it extraordinarily difficult to accustom readers to the distinction between the manifest content of dreams and the latent dream-thoughts. Again and again arguments and objections would be brought up based upon some uninterpreted dream in the form in which it had been retained in the memory, and the need to interpret it would be ignored. But now that analysts at least have become reconciled to replacing the manifest dream by the meaning revealed by its interpretation, many of them have become guilty of falling into another confusion which they cling to with equal obstinacy. They seek to find the essence of dreams in their latent content and in so doing they overlook the distinction between the latent dream-thoughts and the dream-work. At bottom, dreams are nothing other than a particular form of thinking, made possible by the conditions of the state of sleep. It is the dream-work which creates that form, and it alone is the essence of dreaming - the explanation of its peculiar nature. I say this in order to make it possible to assess the value of the notorious 'prospective purpose' of dreams. The fact that dreams concern themselves with attempts at solving the problems by which our mental life is faced is no more strange than that our conscious waking life should do so; beyond this it merely tells us that that activity can also be carried on in the preconscious - and this we already knew.

[1900a, 944]

Self-corrections in dreams, which seem so marvellous to some writers, need not occupy our attention. I will indicate instead the recollection which served as the model for my verbal error in this dream. When I was nineteen years old I visited England for the first time and spent a whole day on the shore of the Irish Sea. I naturally revelled in the opportunity of collecting the marine animals left behind by the tide and I was occupied with a starfish - the words 'Hollthurn' and 'holothurians [sea-slugs]' occurred at the beginning of the dream - when a charming little girl came up to me and said: 'Is it a starfish? Is it alive?' 'Yes', I replied, 'he is alive', and at once, embarrassed at my mistake, repeated the sentence correctly ['It is alive']. The dream replaced the verbal error which I then made by another into which a German is equally liable to fall. 'Das Buch ist von Schiller' should be translated not with a 'from' but with a 'by.' After all that we have heard of the purposes of the dream-work and its reckless choice of methods for attaining them, we shall not be surprised to hear that it effected this replacement because of the magnificent piece of condensation that was made possible by the identity of sound of the English 'from' and the German adjective 'fromm' ['pious']. But how did my blameless memory of the sea-shore come to be in the dream? It served as the most innocent possible example of my using a word indicating gender or sex in the wrong place - of my bringing in sex (the word 'he') where it did not belong. This, incidentally, was one of the keys to the solution of the dream. No one who has heard, furthermore, the origin attributed to the title of Clerk-Maxwell's 'Matter and Motion' will have any difficulty in filling in the gaps: Molière's 'Le Malade Imaginaire' - 'La matière est-elle laudable?' - A motion of the bowels.

[1900a, 954]
On the other hand, I cannot confirm the opinion, first stated by Silberer, that all dreams (or many dreams, or certain classes of dreams) require two different interpretations, which are even stated to bear a fixed relation to each other. One of these interpretations, which Silberer calls the 'psycho-analytic' one, is said to give the dream some meaning or other, usually of an infantile-sexual kind: the other and more important interpretation, to which he gives the name of 'anagogic', is said to reveal the more serious thoughts, often of profound import, which the dream-work has taken as its material. Silberer has not given evidence in support of this opinion by reporting a series of dreams analysed in the two directions. And I must object that the alleged fact is non-existent. In spite of what he says, the majority of dreams require no 'over-interpretation' and, more particularly, are insusceptible to an anagogic interpretation. As in the case of many other theories put forward in recent years, it is impossible to overlook the fact that Silberer's views are influenced to some extent by a purpose which seeks to disguise the fundamental circumstances in which dreams are formed and to divert interest from their instinctual roots. In a certain number of cases I have been able to confirm Silberer's statements. Analysis showed that in such cases the dream-work found itself faced with the problem of transforming into a dream a series of highly abstract thoughts from waking life which were incapable of being given any direct representation. It endeavoured to solve the problem by getting hold of another group of intellectual material, somewhat loosely related (often in a manner which might be described as 'allegorical') to the abstract thoughts, and at the same time capable of being represented with fewer difficulties. The abstract interpretation of a dream that has arisen in this way is given by the dreamer without any difficulty; the correct interpretation of the material that has been interpolated must be looked for by the technical methods which are now familiar to us.

How, then, are we to explain this characteristic peculiarity of the dream-work, or, to put the question more modestly, how are we to find a place for it in the nexus of psychical processes?

It may perhaps be useful to continue our examination of the same question by considering how a dream behaves when the dream-thoughts present it with material which is the complete reverse of a wish-fulfilment - well-justified worries, painful reflections, distressing realizations. The many possible outcome can be classed under the two following groups. (A) The dream-work may succeed in replacing all the distressing ideas by contrary ones and in suppressing the unpleasurable affects attaching to them. The result will be a straightforward dream of satisfaction, a palpable 'wish-fulfilment', about which there seems no more to be said. (B) The distressing ideas may make their way, more or less modified but none the less quite recognizable, into the manifest content of the dream. This is the case which raises doubts as to the validity of the wish theory of dreams and needs further investigation. Dreams of this sort with a distressing content may either be experienced with indifference, or they may be accompanied by the whole of the distressing affect which their ideational content seems to justify, or they may even lead to the development of anxiety and to awakening.
We have thus been able to find a place in our structure for the most various and contradictory findings of earlier writers, thanks to the novelty of our theory of dreams, which combines them, as it were, into a higher unity. Some of those findings we have put to other uses, but we have wholly rejected only a few. Nevertheless our edifice is still uncompleted. Apart from the many perplexing questions in which we have become involved in making our way into the obscurities of psychology, we seem to be troubled by a fresh contradiction. On the one hand we have supposed that the dream-thoughts arise through entirely normal mental activity; but on the other hand we have discovered a number of quite abnormal processes of thought among the dream-thoughts, which extend into the dream-content, and which we then repeat in the course of our dream-interpretation. Everything that we have described as the ‘dream-work’ seems to depart so widely from what we recognize as rational thought-processes that the most severe strictures passed by earlier writers on the low level of psychical functioning in dreams must appear fully justified.

[1900a, 1019]

Thus we are driven to conclude that two fundamentally different kinds of psychical process are concerned in the formation of dreams. One of these produces perfectly rational dream-thoughts, of no less validity than normal thinking; while the other treats these thoughts in a manner which is in the highest degree bewildering and irrational. We have already in Chapter VI segregated this second psychical process as being the dream-work proper. What light have we now to throw upon its origin?

[1900a, 1024]

At the point which I have now reached, I am led to regard the dream as a sort of substitute for the thought-processes, full of meaning and emotion, at which I arrived after the completion of the analysis. We do not yet know the nature of the process which has caused the dream to be generated from these thoughts, but we can see that it is wrong to regard it as purely physical and without psychical meaning, as a process which has arisen from the isolated activity of separate groups of brain cells aroused from sleep.
I should, of course, not draw such far-reaching conclusions if only a single dream-analysis was at my disposal. If experience shows me, however, that by uncritically pursuing the associations arising from any dream I can arrive at a similar train of thoughts, among the elements of which the constituents of the dream re-appear and which are interconnected in a rational and intelligible manner, then it will be safe to disregard the slight possibility that the connections observed in a first experiment might be due to chance. I think I am justified, therefore, in adopting a terminology which will crystallize our new discovery. In order to contrast the dream as it is retained in my memory with the relevant material discovered by analysing it, I shall speak of the former as the 'manifest content of the dream' and the latter - without, in the first instance, making any further distinction - as the 'latent content of the dream.' I am now faced by two new problems which have not hitherto been formulated. (1) What is the psychical process which has transformed the latent content of the dream into the manifest one which is known to me from my memory? (2) What are the motive or motives which have necessitated this transformation? I shall describe the process which transforms the latent into the manifest content of dreams as the 'dream-work.' The counterpart to this activity - one which brings about a transformation in the opposite direction - is already known to us as the work of analysis. The remaining problems arising out of dreams - questions as to the instigators of dreams, as to the origin of their material, as to their possible meaning, as to the possible function of dreaming, and as to the reasons for dreams being forgotten - all these problems will be discussed by me on the basis, not of the manifest, but of the newly discovered latent dream-content. Since I attribute all the contradictory and incorrect views upon dream-life which appear in the literature of the subject to ignorance of the latent content of dreams as revealed by analysis, I shall be at the greatest pains henceforward to avoid confusing the manifest dream with the latent dream-thoughts.

[1901a, 1059]

The transformation of the latent dream-thoughts into the manifest dream-content deserves all our attention, since it is the first instance known to us of psychical material being changed over from one mode of expression to another, from a mode of expression which is immediately intelligible to us to another which we can only come to understand with the help of guidance and effort, though it too must be recognized as a function of our mental activity.

[1901a, 1060]

But before taking leave of infantile dreams with their undisguised wish-fulfilments, I must not omit to mention one principal feature of dreams, which has long been evident and which emerges particularly clearly precisely in this group. Every one of these dreams can be replaced by an optative clause: 'Oh, if only the trip on the lake had lasted longer!' - 'If only I were already washed and dressed!' - 'If only I could have kept the cherries instead of giving them to Uncle!' But dreams give us more than such optative clauses. They show us the wish as already fulfilled; they represent its fulfilment as real and present; and the material employed in dream-representation consists principally, though not exclusively, of situations and of sensory images, mostly of a visual character. Thus, even in this infantile group, a species of transformation, which deserves to be described as dream-work, is not completely absent: a thought expressed in the optative has been replaced by a representation in the present tense.

[1901a, 1065]
But another achievement of the dream-work, tending as it does to produce incoherent dreams, is even more striking. If in any particular instance we compare the number of ideational elements or the space taken up in writing them down in the case of the dream and of the dream-thoughts to which the analysis leads us and of which traces are to be found in the dream itself, we shall be left in no doubt that the dream-work has carried out a work of compression or condensation on a large scale. It is impossible at first to form any judgement of the degree of this condensation; but the deeper we plunge into a dream-analysis the more impressive it seems. From every element in a dream's content associative threads branch out in two or more directions; every situation in a dream seems to be put together out of two or more impressions or experiences. For instance, I once had a dream of a sort of swimming-pool, in which the bathers were scattering in all directions; at one point on the edge of the pool someone was standing and bending towards one of the people bathing, as though to help her out of the water. The situation was put together from a memory of an experience I had had at puberty and from two paintings, one of which I had seen shortly before the dream. One was a picture from Schwind's series illustrating the legend of Mélusine, which showed the water-nymphs surprised in their pool (cf. the scattering bathers in the dream); the other was a picture of the Deluge by an Italian Master; while the little experience remembered from my puberty was of having seen the instructor at a swimming-school helping a lady out of the water who had stopped in until after the time set aside for men bathers. -In the case of the example which I chose for interpretation, an analysis of the situation led me to a small series of recollections each of which contributed something to the content of the dream. In the first place, there was the episode from the time of my engagement of which I have already spoken. The pressure upon my hand under the table, which was a part of that episode, provided the dream with the detail 'under the table' - a detail which I had to add as an afterthought to my memory of the dream. In the episode itself there was of course no question of 'turning to me'; the analysis showed that this element was the fulfilment of a wish by presenting the opposite of an actual event, and that it related to my wife's behaviour at the table d'hôte. But behind this recent recollection there lay concealed an exactly similar and far more important scene from the time of our engagement, which estranged us for a whole day. The intimate laying of a hand on my knee belonged to a quite different context and was concerned with quite other people. This element in the dream was in turn the starting-point of two separate sets of memories - and so on.

[1901a, 1066]

The dream-work exhibits no activities other than the four that have already been mentioned. If we keep to the definition of 'dream-work' as the process of transforming the dream-thoughts into the dream-content, it follows that the dream-work is not creative, that it develops no phantasies of its own, that it makes no judgements and draws no conclusions; it has no functions whatever other than condensation and displacement of the material and its modification into pictorial form, to which must be added as a variable factor the final bit of interpretative revision. It is true that we find various things in the dream-content which we should be inclined to regard as a product of some other and higher intellectual function; but in every case analysis shows convincingly that these intellectual operations have already been performed in the dream-thoughts and have only been TAKEN OVER by the dream-content. A conclusion drawn in a dream is nothing other than the repetition of a conclusion in the dream-thoughts; if the conclusion is taken over into the dream unmodified, it will appear impeccable; if the dream-work has displaced it on to some other material, it will appear nonsensical. A calculation in the dream-content signifies nothing more than that there is a calculation in the dream-thoughts; but while the latter is always rational, a dream-calculation may produce the wildest results if its factors are condensed or if its mathematical operations are displaced on to other material. Not even the speeches that occur in the dream-content are original compositions; they turn out to be a hotchpotch of speeches made, heard or read, which have been revived in the dream-thoughts and whose wording is exactly reproduced, while their origin is entirely disregarded and their meaning is violently changed.

[1901a, 1082]
Having been made acquainted with the dream-work by the foregoing discussion, we shall no
doubt be inclined to pronounce it a quite peculiar psychical process, the like of which, so far as
we are aware, does not exist elsewhere. It is as though we were carrying over on to the dream-
work all the astonishment which used formerly to be aroused in us by its product, the dream. In
fact, however, the dream-work is only the first to be discovered of a whole series of psychical
processes, responsible for of hysterical symptoms, of phobias, obsessions and delusions.
Condensation and, above all, displacement are invariable characteristics of these other
processes as well. Modification into a pictorial form, on the other hand, remains a peculiarity of
the dream-work. If this explanation places dreams in a single series alongside the structures
produced by psychical illness, this makes it all the more important for us to discover the
essential determining conditions of such processes as those of dream-formation. We shall
probably be surprised to hear that neither the state of sleep nor illness is among these
indispensable conditions. A whole number of the phenomena of the everyday life of healthy
people - such as forgetting, slips of the tongue, bungled actions and a particular class of errors -
owe their origin to a psychical mechanism analogous to that of dreams and of the other
members of the series.
[1901a, 1084]

We have no reason to disguise the fact that in the hypothesis which we have set up in order to
explain the dream-work a part is played by what might be described as a ‘daemonic’ element.
We have gathered an impression that the formation of obscure dreams occurs as though one
person who was dependent upon a second person had to make a remark which was bound to
be disagreeable in the ears of this second one; and it is on the basis of this simile that we have
arrived at the concepts of dream-distortion and censorship, and have endeavoured to translate
our impression into a psychological theory which is no doubt crude but is at least lucid.
Whatever it may be with which a further investigation of the subject may enable us to identify
our first and second agencies, we may safely expect to find a confirmation of some correlate of
our hypothesis that the second agency controls access to consciousness and can bar the first
agency from such access.
[1901a, 1090]

I lay no claim to having thrown light in these pages upon all the problems of dreams, nor to
having dealt in a convincing way with those that I have discussed. Anyone who is interested in
the whole extent of the literature of dreams may be referred to a work by Sante de Sanctis (I
sogni, 1899); and anyone who wishes to hear more detailed arguments in favour of the view of
dreams which I myself have put forward should turn to my volume The Interpretation of Dreams,
1900. It only remains for me now to indicate the direction in which my exposition of the subject
of the dream-work calls for pursuit.
[1901a, 1098]

I have laid it down as the task of dream-interpretation to replace the dream by the latent
dream-thoughts, that is, to unravel what the dream-work has woven. In so doing I have raised a
number of new psychological problems dealing with the mechanism of this dream-work itself, as
well as with the nature and conditions of what is described as repression; on the other hand I
have asserted the existence of the dream-thoughts - a copious store of psychical structures of
the highest order, which is characterized by all the signs of normal intellectual functioning, but is
nevertheless withdrawn from consciousness till it emerges in distorted form in the dream-
content. I cannot but assume that thoughts of this kind are present in everyone, since almost
everyone, including the most normal people, is capable of dreaming. The unconscious material
of the dream-thoughts and its relation to consciousness and to repression raise further
questions of significance to psychology, the answers to which must no doubt be postponed until
analysis has clarified the origin of other psychopathological structures, such as hysterical
symptoms and obsessional ideas.
[1901a, 1098]
Now in my Interpretation of Dreams (1900a) I have demonstrated the part played by the work of condensation in forming what is called the manifest dream-content out of the latent dream-thoughts. A similarity of any sort between two elements of the unconscious material - a similarity between the things themselves or between their verbal presentations - is taken as an opportunity for creating a third, which is a composite or compromise idea. In the dream-content this third element represents both its components; and it is as a consequence of its originating in this way that it so frequently has various contradictory characteristics. The formation of substitutions and contaminations which occurs in slips of the tongue is accordingly a beginning of the work of condensation which we find taking a most vigorous share in the construction of dreams. [1901b, 1149]

I add a few remarks which may help towards the synthesis of this dream. The dream-work began on the afternoon of the day after the scene in the wood, after Dora had noticed that she was no longer able to lock the door of her room. She then said to herself: 'I am threatened by a serious danger here,' and formed her intention of not stopping on in the house alone but of going off with her father. This intention became capable of forming a dream, because it succeeded in finding a continuation in the unconscious. What corresponded to it there was her summoning up her infantile love for her father as a protection against the present temptation. The change which thus took place in her became fixed and brought her into the attitude shown by her supervalent train of thought - jealousy of Frau K. on her father's account, as though she herself were in love with him. There was a conflict within her between a temptation to yield to the man's proposal and a composite force rebelling against that feeling. This latter force was made up of motives of respectability and good sense, of hostile feelings caused by the governess's disclosures (jealousy and wounded pride, as we shall see later), and of a neurotic element, namely, the tendency to a repudiation of sexuality which was already present in her and was based on her childhood history. Her love for her father, which she summoned up to protect her against the temptation, had its origin in this same childhood history. [1905e, 1424]
Are processes similar to those which we have described here as the technique of jokes known already in any other field of mental events? They are - in a single field, and an apparently very remote one. In 1900 I published a book which, as its title (*The Interpretation of Dreams*) indicates, attempted to throw light on what is puzzling in dreams and to establish them as derivatives of our normal mental functioning. I found occasion there to contrast the manifest, and often strange, content of the dream with the latent, but perfectly logical, dream-thoughts from which the dream is derived; and I entered into an investigation of the processes which make the dream out of the latent dream-thoughts, as well as of the psychical forces which are involved in that transformation. To the totality of these transforming processes I gave the name of the 'dream-work'; and I have described as a part of this dream-work a process of condensation which shows the greatest similarity to the one found in the technique of jokes - which, like it, leads to abbreviation, and creates substitute-formations of the same character. Everyone will be familiar, from a recollection of his own dreams, with the composite structures both of people and of things which emerge in dreams. Indeed, dreams even construct them out of words, and they can then be dissected in analysis. (For instance, 'Autodidasker' = 'Autodidakt' + 'Lasker'.) On other occasions - much more often, in fact - what the work of condensation in dreams produces is not composite structures but pictures which exactly resemble one thing or one person except for an addition or alteration derived from another source - modifications, that is, just like those in Herr N.'s jokes. We cannot doubt that in both cases we are faced by the same psychical process, which we may recognize from its identical results. Such a far-reaching analogy between the technique of jokes and the dream-work will undoubtedly increase our interest in the former and raise an expectation in us that a comparison between jokes and dreams may help to throw light on jokes. But we will refrain from entering upon this task, for we must reflect that so far we have investigated the technique of only a very small number of jokes, so that we cannot tell whether the analogy by which we are proposing to be guided will in fact hold good. We will therefore turn away from the comparison with dreams and go back to the technique of jokes, though at this point we shall, as it were, be leaving a loose end to our enquiry, which at some later stage we may perhaps pick up once more.

A comparison of the recollected manifest content of the dream with the latent dream-thoughts thus discovered gives rise to the concept of the 'dream-work'. The dream-work is the name for the whole sum of transforming processes which have converted the dream-thoughts into the manifest dream. The surprise with which we formerly regarded the dream now attaches to the dream-work.

[1905c, 1634]

[1905c, 1745]
The achievements of the dream-work can, however, be described as follows. A tissue of thoughts, usually a very complicated one, which has been built up during the day and has not been completely dealt with - 'a day's residue' - continues during the night to retain the quota of energy - the 'interest' claimed by it, and threatens to disturb sleep. This 'day's residue' is transformed by the dream-work into a dream and made innocuous to sleep. In order to provide a fulcrum for the dream-work, the 'day's residue' must be capable of constructing a wish - which is not a very hard condition to fulfil. The wish arising from the dream-thoughts forms the preliminary stage and later the core of the dream. Experience derived from analyses - and not the theory of dreams - informs us that in children any wish left over from waking life is sufficient to call up a dream, which emerges as connected and ingenious but usually short, and which is easily recognized as a 'wish-fulfilment'. In the case of adults it seems to be a generally binding condition that the wish which creates the dream shall be one that is alien to conscious thinking - a repressed wish - or will possibly at least have reinforcements that are unknown to consciousness. Without assuming the existence of the unconscious in the sense explained above, I should not be able to develop the theory of dreams further or to interpret the material met with in dream-analyses. The action of this unconscious wish upon the consciously rational material of the dream-thoughts produces the dream. While this happens, the dream is, as it were, dragged down into the unconscious, or, more precisely, is submitted to a treatment such as is met with at the level of unconscious thought-processes and is characteristic of that level. Hitherto it is only from the results of the 'dream-work' that we are in fact acquainted with the characteristics of unconscious thinking and its differences from thinking that is capable of becoming conscious - 'preconscious' thinking.

[1905c, 1746]
The dream-work, then - to which I return after this digression - submits the thought-material, which is brought forward in the optative mood, to a most strange revision. First, it takes the step from the optative to the present indicative; it replaces 'Oh! if only . . .' by 'It is'. The 'It is' is then given a hallucinatory representation; and this I have called the 'regression' in the dream-work - the path that leads from thoughts to perceptual images, or, to use the terminology of the still unknown topography of the mental apparatus (which is not to be taken anatomically), from the region of thought-structures to that of sensory perceptions. On this path, which is in the reverse direction to that taken by the course of development of mental complications, the dream-thoughts are given a pictorial character; and eventually a plastic situation is arrived at which is the core of the manifest 'dream-picture'. In order for it to be possible for the dream-thoughts to be represented in sensory form, their expression has to undergo far-reaching modifications. But while the thoughts are being changed back into sensory images still further alterations occur in them, some of which can be seen to be necessary while others are surprising. We can understand that, as a subsidiary result of regression, almost all the internal relations between the thoughts which linked them together will be lost in the manifest dream. The dream-work, as we might say, only undertakes to represent the raw material of the ideas and not the logical relations in which they stand to one another; or at all events it reserves the liberty to disregard the latter. On the other hand, there is another part of the dream-work which we cannot attribute to regression, to the change back into sensory images; and it is precisely this part which has an important bearing on our analogy with the formation of jokes. In the course of the dream-work the material of the dream-thoughts is subjected to a quite extraordinary compression or condensation. A starting point for it is provided by any common elements that may be present in the dream-thoughts, whether by chance or from the nature of their content. Since these are not as a rule sufficient for any considerable condensation, new artificial and transient common elements are created in the dream-work, and to this end there is actually a preference for the use of words the sound of which expresses different meanings. The newly-created common elements of condensation enter the manifest content of the dream as representatives of the dream-thoughts, so that an element in the dream corresponds to a nodal point or junction in the dream-thoughts, and, as compared with these latter, must quite generally be described as 'overdetermined'. The fact of condensation is the piece of the dream-work which can be most easily recognized; it is only necessary to compare the text of a dream as it is noted down with the record of the dream-thoughts arrived at by analysis in order to get a good impression of the extensiveness of dream-condensation.

[1905c, 1748]

And now for the final question, whose answer we have already evaded more than once. Our views on repression, on the genesis of delusions and allied disorders, on the formation and solution of dreams, on the part played by erotic life, and on the method by which such disorders are cured, are far from being the common property of science, let alone the assured possession of educated people. If the insight which has enabled the author to construct his 'phantasy' in such a way that we have been able to dissect it like a real case history is in the nature of knowledge, we should be curious to learn what were the sources of that knowledge. One of our circle - the one who, as I said at the beginning, was interested in the dreams in Gradiva and their possible interpretation - approached the author with the direct question whether he knew anything of such scientific theories as these. The author replied, as was to be expected, in the negative, and, indeed, somewhat brusquely. His imagination, he said, had inspired Gradiva, and he had enjoyed it; if there was anyone whom it did not please, let him simply leave it alone. He had no suspicion of how greatly it had in fact pleased his readers.

[1907a, 1882]
You can also obtain a view, by a kind of synthetic work, of the process which has brought about the distortion of the unconscious dream-thoughts into the manifest content of the dream. We call this process the 'dream-work'. It deserves our closest theoretical interest, since we are able to study in it, as nowhere else, what unsuspected psychical processes can occur in the unconscious, or rather, to put it more accurately, between two separate psychical systems like the conscious and unconscious. Among these freshly discovered psychical processes those of condensation and displacement are especially noticeable. The dream-work is a special case of the effects produced by two different mental groupings on each other - that is, of the consequences of mental splitting; and it seems identical in all essentials with the process of distortion which transforms the repressed complexes into symptoms where there is unsuccessful repression.

[1910a, 2223]

Every analyst is in the position of the superior dream-interpreter, whom we have been imagining, in regard to the very first dreams that his patients bring, before they have learnt anything of the technique of translating dreams. These initial dreams may be described as unsophisticated: they betray a great deal to the listener, like the dreams of so-called healthy people. The question then arises whether the analyst is at once to translate to the patient all that he himself reads from them. This, however, is not the place for answering this question, for it evidently forms part of a wider one: at what stage in the treatment and how rapidly should the analyst introduce the patient to the knowledge of what lies veiled in his mind? The more the patient has learnt of the practice of dream-interpretation, the more obscure do his later dreams as a rule become. All the knowledge acquired about dreams serves also to put the dream-constructing process on its guard.

[1911e, 2453]

In the 'scientific' works about dreams, which in spite of their repudiation of dream-interpretation have received a new stimulus from psycho-analysis, one constantly finds that scrupulous care is most unnecessarily attached to the accurate preservation of the text of the dream. This is supposed to need protection from distortions and attritions in the hours immediately after waking. Some psycho-analysts, even, in giving the patient instructions to write down every dream immediately upon waking, seem not to rely consistently enough upon their knowledge of the conditions of dream-formation. In therapeutic work this rule is superfluous; and patients are glad to make use of it to disturb their sleep and to display great zeal where it can serve no useful purpose. For even if the text of a dream is in this way laboriously rescued from oblivion, it is easy enough to convince oneself that nothing has been achieved for the patient. Associations will not come to the text, and the result is the same as if the dream had not been preserved. No doubt the doctor has acquired some knowledge which he would not have done otherwise. But it is not the same thing whether the analyst knows something or the patient knows it; the importance of this distinction for the technique of psycho-analysis will be more fully considered elsewhere.

[1911e, 2453]
Psycho-analysis, then, has demonstrated the following facts. All dreams have a meaning. Their strangeness is due to distortions that have been made in the expression of their meaning. Their absurdity is deliberate and expresses derision, ridicule and contradiction. Their incoherence is a matter of indifference for their interpretation. The dream as we remember it after waking is described by us as its 'manifest content'. In the process of interpreting this, we are led to the 'latent dream-thoughts', which lie hidden behind the manifest content and which are represented by it. These latent dream-thoughts are no longer strange, incoherent or absurd; they are completely valid constituents of our waking thought. We give the name of 'dream-work' to the process which transforms the latent dream-thoughts into the manifest content of the dream; it is this dream-work that brings about the distortion which makes the dream-thoughts unrecognizable in the content of the dream.

The dream-work is a psychological process the like of which has hitherto been unknown to psychology. It has claims upon our interest in two main directions. In the first place, it brings to our notice novel processes such as 'condensation' (of ideas) and 'displacement' (of psychical emphasis from one idea to another), processes which we have never come across at all in our waking life, or only as the basis of what are known as 'errors in thought'. In the second place, it enables us to detect the operation in the mind of a play of forces which was concealed from our conscious perception. We find that there is a 'censorship', a testing agency, at work in us, which decides whether an idea cropping up in the mind shall be allowed to reach consciousness, and which, so far as lies within its power, ruthlessly excludes anything that might produce or revive unpleasure. And it will be recalled at this point that in our analysis of parapraxes we found traces of this same intention to avoid unpleasure in remembering things and of similar conflicts between mental impulses.

A study of the dream-work forces on us irresistibly a view of mental life which appears to decide the most controversial problems of psychology. The dream-work compels us to assume the existence of an unconscious psychical activity which is more comprehensive and more important than the familiar activity that is linked with consciousness. (I shall have some more to say on this point when I come to discuss the philosophical interest of psycho-analysis.) It enables us to dissect the psychical apparatus into a number of different agencies or systems, and shows us that in the system of unconscious mental activity processes operate which are of quite another kind from those perceived in consciousness.

The dream-work has only one function - namely to maintain sleep. 'Dreams are the guardians of sleep.' The dream-thoughts themselves may serve the purposes of the most various mental functions. The dream-work accomplishes its task by representing a wish that arises from the dream-thoughts as fulfilled in a hallucinatory fashion.
Let us notice, however, one peculiarity of dream-life which comes to light in this study of the effects of stimuli. Dreams do not simply reproduce the stimulus; they work it over, they make allusions to it, they include it in some context, they replace it by something else. This is a side of the dream-work which is bound to interest us since it may perhaps bring us nearer to the essence of dreams. When a person constructs something as a result of a stimulus, the stimulus need not on that account exhaust the whole of the work. Shakespeare's *Macbeth*, for instance, was a *pièce d'occasion* composed to celebrate the accession of the king who first united the crowns of the three kingdoms. But does this immediate historical occasion cover the content of the tragedy? Does it explain its greatnesses and its enigmas? It may be that the external and internal stimuli, too, impinging on the sleeper, are only the *instigators* of the dream and will accordingly betray nothing to us of its essence.

[1916-1917, 3196]

Dream-distortion is what makes a dream seem strange and unintelligible to us. We want to know a number of things about it: firstly, where it comes from - its dynamics -, secondly, what it does and, lastly, how it does it. We can also say that dream distortion is carried out by the dream-work; and we want to describe the dream-work and trace it back to the forces operating in it.

[1916-1917, 3232]

I hope you will never again confuse these two things with each other. If you reach that point, you will probably have gone further in understanding dreams than most readers of my *Interpretation of Dreams*. And let me remind you once again that the work which transforms the latent dream into the manifest one is called the *dream-work*. The work which proceeds in the contrary direction, which endeavours to arrive at the latent dream from the manifest one, is our *work of interpretation*. This work of interpretation seeks to undo the dream-work. The dreams of infantile type which we recognize as obvious fulfilments of wishes have nevertheless experienced some amount of dream-work - they have been transformed from a wish into an actual experience and also, as a rule, from thoughts into visual images. In their case there is no need for interpretation but only for undoing these two transformations. The additional dream-work that occurs in other dreams is called 'dream-distortion', and this has to be undone by our work of interpretation.

[1916-1917, 3262]

Having compared the interpretations of numerous dreams, I am in a position to give you a summary description of what the dream-work does with the material of the latent dream-thoughts. I beg you, however, not to try to understand too much. of what I tell you. It will be a piece of description which should be listened to with quiet attention.

[1916-1917, 3263]

LADIES AND GENTLEMEN, - Let us start out once more from the conclusion we arrived at that the dream-work, under the influence of the dream-censorship, transposes the latent dream-thoughts into a different mode of expression. The latent thoughts do not differ from our familiar conscious thoughts of waking life. The new mode of expression is incomprehensible to us owing to many of its features. We have said that it harks back to states of our intellectual development which have long since been superseded - to picture-language, to symbolic connections, to conditions, perhaps, which existed before our thought-language had developed. We have on that account described the mode of expression of the dream-work as *archaic* or *regressive*. 

[1916-1917, 3289]
We found from both sources that the dream-work consists essentially in the transformation of thoughts into a hallucinatory experience. How this can happen is sufficiently mysterious; but it is a problem of general psychology with which we are not properly concerned here. We learnt from children's dreams that it is the intention of the dream-work to get rid of a mental stimulus, which is disturbing sleep, by means of the fulfilment of a wish. We were unable to say anything similar of distorted dreams till we found out how to interpret them. But it was from the first our expectation that we should be able to regard distorted dreams in the same light as those of children. The first confirmation of this expectation was brought to us by the discovery that in point of fact all dreams are children's dreams, that they work with the same infantile material, with the mental impulses and mechanisms of childhood. Now that we believe we have overcome dream-distortion, we must go on to enquire whether the view of dreams as the fulfilment of wishes is also valid of distorted dreams.

[1916-1917, 3301]

A short time ago we submitted a series of dreams to interpretation, but we left wish-fulfilment completely out of account. I feel sure that you must have repeatedly been driven to ask yourselves: 'But where is the wish-fulfilment, which is supposed to be the aim of the dream-work?' The question is an important one, for it has become the question raised by our lay critics. Human beings, as you know, have an instinctive tendency to fend off intellectual novelties. One of the ways in which this tendency is manifested is by immediately reducing the novelty to the smallest proportions, by compressing it if possible into a single catch-word. 'Wish-fulfilment' has become the catch word for the new theory of dreams. The layman asks: 'Where is the wish-fulfilment?' And instantly, having heard that dreams are supposed to be wish-fulfilments, and in the very act of asking the question, he answers it with a rejection. He immediately thinks of countless experiences of his own with dreams, in which the dream has been accompanied by feelings ranging from the unpleasurable to severe anxiety, so that the assertion made by the psycho-analytic theory of dreams seems to him most improbable. We have no difficulty in replying that in distorted dreams the wish-fulfilment cannot be obvious but must be looked for, so that it cannot be pointed out until the dream has been interpreted. We know too that the wishes in these distorted dreams are forbidden ones - rejected by the censorship - whose existence was precisely the cause of the dream's distortion, the reason for the intervention of the dream censorship. But it is difficult to make the lay critic understand that before a dream has been interpreted one cannot enquire about the fulfilment of its wish. He will keep on forgetting this. His rejection of the theory of wish-fulfilment is actually nothing other than a consequence of the dream-censorship, a substitute for the rejection of the censored dream-wishes and an effluence from it.

[1916-1917, 3302]
Firstly, it may be that the dream-work has not completely succeeded in creating a wish-fulfilment; so that a portion of the distressing affect in the dream-thoughts has been left over in the manifest dream. In that case analysis would have to show that these dream-thoughts were far more distressing than the dream-constructed out of them. That much can always be proved. If so, we must admit that the dream-work has not achieved its aim any more than the dream of drinking, formed in response to the stimulus of thirst, succeeded in quenching the thirst. The dreamer remains thirsty and has to wake up in order to drink. Nevertheless it was a genuine dream, and had lost nothing of a dream's essential nature. We can only say: 'Ut desint vires, tamen est laudanda voluntas.'¹ The intention, at least, which can clearly be recognized, remains praiseworthy. Such instances of failure are no rare event. This is helped by that fact that it is so much harder for the dream-work to alter the sense of a dream's affects than of its content; affects are some times highly resistant. What then happens is that the dream-work transforms the distressing content of the dream-thoughts into the fulfilment of a wish, while the distressing affect persists unaltered. In dreams of this kind the affect is quite inappropriate to the content, and our critics can say that dreams are so far from being wish-fulfilments that even one with a harmless content can be felt as distressing. We can answer this foolish remark by pointing out that it is precisely in dreams like this that the wish-fulfilling purpose of the dream-work appears most clearly, because in isolation. The error arises because those who are unfamiliar with the neuroses picture the link between content and affect as too intimate and therefore cannot imagine the content being altered without a simultaneous alteration of the expression of affect attached to it.

[1916-1917, 3303]

I do it because I will not allow a foolish misunderstanding to pass which may rob us of the fruit of our efforts with dreams - a misunderstanding which confuses the dream with the latent dream-thoughts, and asserts of the former something that applies solely to the latter. For it is quite correct to say that a dream can represent and be replaced by everything you have just enumerated - an intention, a warning, a reflection, a preparation, an attempt at solving a problem, and so on. But if you look properly, you will see that all this only applies to the latent dream-thoughts, which have been transformed into the dream. You learn from interpretations of dreams that people's unconscious thinking is concerned with these intentions, preparations, reflections, and so on, out of which the dream-work then makes the dreams. If at the moment you are not interested in the dream-work, but are greatly interested in people's unconscious thought-activity, you then eliminate the dream-work and say of the dream what is in practice quite correct that it corresponds to a warning, an intention, and so on. what often happens in psycho-analytic activity is that our efforts are chiefly directed only to doing away with the dream-form and inserting in the context instead of it the latent thoughts out of which the dream was made.

[1916-1917, 3310]

But to go back, you are only correct so long as you are clearly aware that you have used an abbreviated form of expression and so long as you do not believe that the multiplicity you have been describing is to be related to the essential nature of dreams. When you speak of a 'dream', you must mean either the manifest dream - that is, the product of the dream-work or, at most, the dream-work itself as well - that is, the psychical process which forms the manifest dream out of the latent dream-thoughts. Any other use of the word is a confusion of ideas and can only lead to mischief. If you are making statements about the latent thoughts behind the dream, do so directly and do not obscure the problem of dreams by the loose manner in which you speak. The latent dream-thoughts are the material which the dream-work transforms into the manifest dream. Why should you want to confuse the material with the activity which forms it? If you do, what advantage have you over those who only knew the product of the activity and could not explain where it came from or how it was made?

[1916-1917, 3310]
The only essential thing about dreams is the dream-work that has influenced the thought-material. We have no right to ignore it in our theory, even though we may disregard it in certain practical situations. Analytic observation shows further that the dream-work never restricts itself to translating these thoughts into the archaic or regressive mode of expression that is familiar to you. In addition, it regularly takes possession of something else, which is not part of the latent thoughts of the previous day, but which is the true motive force for the construction of the dream. This indispensable addition is the equally unconscious wish for the fulfilment of which the content of the dream is given its new form. A dream may thus be any sort of thing in so far as you are only taking into account the thoughts it represents - a warning, an intention, a preparation, and so on; but it is always also the fulfilment of an unconscious wish and, if you are considering it as a product of the dream-work, it is only that. A dream is therefore never simply an intention, or a warning, but always an intention, etc., translated into the archaic mode of thought by the help of an unconscious wish and transformed to fulfil that wish. The one characteristic, the wish-fulfilment, is the invariable one; the other may vary. It may for its part once more be a wish, in which case the dream will, with the help of an unconscious wish, represent as fulfilled a latent wish of the previous day.

Let us recall that we have said that the dream-work makes a translation of the dream-thoughts into a primitive mode of expression similar to picture-writing. All such primitive systems of expression, however, are characterized by indefiniteness and ambiguity of this sort, without justifying us in casting doubts on their serviceability. The coalescence of contraries in the dream-work is, as you know, analogous to the so-called 'antithetical meaning of primal words' in the most ancient languages. Indeed, Abel (1884), the philologist to whom we owe this line of thought, implores us not to suppose that communications made by one person to another with the help of such ambivalent words were on that account ambiguous. On the contrary, intonation and gesture must have made it quite certain in the context of the speech which of the two contraries the speaker intended to convey. In writing, where gesture is absent, its place was taken by an additional pictograph which was not intended to be spoken - for instance by a picture of a little man, limply squatting or stiffly erect, according to whether the ambiguous hieroglyph 'ken' was to mean 'weak' or 'strong'. In this way, in spite of the ambiguity of the sounds and signs, misunderstanding was avoided.

If you prefer to assume that a telepathic message about the daughter's confinement reached the sleeper, further questions arise of the relation of a message such as this to a dream and of its influence on the formation of dreams. The answer is not far to seek and is quite unambiguous. A telepathic message will be treated as a portion of the material that goes to the formation of a dream, like any other external or internal stimulus, like a disturbing noise in the street or an insistent organic sensation in the sleeper's own body. In our example it is evident how the message, with the help of a lurking repressed wish, became remodelled into a wish-fulfilment; it is unfortunately less easy to show that it combined with other material that had become active at the same time and was blended into a dream. Telepathic messages - if we are justified in recognizing their existence - can thus make no alteration in the process of forming a dream; telepathy has nothing to do with the nature of dreams. And in order to avoid the impression that I am trying to conceal a vague notion behind abstract and fine-sounding words, I am willing to repeat: the essential nature of dreams consists in the peculiar process of 'dream-work' which, with the help of an unconscious wish, carries the preconscious thoughts (day's residues) over into the manifest content of the dream. The problem of telepathy concerns dreams as little as does the problem of anxiety.
The Interpretation of Dreams. - A new approach to the depths of mental life was opened when the technique of free association was applied to dreams, whether one's own or those of patients in analysis. In fact, the greater and better part of what we know of the processes in the unconscious levels of the mind is derived from the interpretation of dreams. Psycho-analysis has restored to dreams the importance which was generally ascribed to them in ancient times, but it treats them differently. It does not rely upon the cleverness of the dream-interpreter but for the most part hands the task over to the dreamer himself by asking him for his associations to the separate elements of the dream. By pursuing these associations further we obtain knowledge of thoughts which coincide entirely with the dream but which can be recognized - up to a certain point - as genuine and completely intelligible portions of waking mental activity. Thus the recollected dream emerges as the manifest dream content, in contrast to the latent dream-thoughts discovered by interpretation. The process which has transformed the latter into the former, that is to say into 'the dream', and which is undone by the work of interpretation, may be called the 'dream-work'.

We also describe the latent dream-thoughts, on account of their connection with waking life, as 'residues of the day'. By the operation of the dream-work (to which it would be quite incorrect to ascribe any 'creative' character) the latent dream thoughts are condensed in a remarkable way, are distorted by the displacement of psychical intensities and are arranged with a view to being represented in visual pictures; and, besides all this, before the manifest dream is arrived at, they are submitted to a process of secondary revision which seeks to give the new product something in the nature of sense and coherence. Strictly speaking, this last process does not form a part of the dream-work.

On the mechanism of dream-formation itself, on the dream-work in the strict sense of the word, one never exercises any influence: of that one may be quite sure.

The analysis of dreams led further: it was brought to public notice by the present writer as early as in 1900 in The Interpretation of Dreams. This showed that dreams are constructed in just the same way as neurotic symptoms. Like them, they may appear strange and senseless; but, if we examine them by a technique which differs little from the free association used in psycho-analysis, we are led from their manifest content to a secret meaning, to the latent dream-thoughts. This latent meaning is always a wishful impulse which is represented as fulfilled at the moment of the dream. But, except in young children and under the pressure of imperative physical needs, this secret wish can never be expressed recognizably. It has first to submit to a distortion, which is the work of restrictive, censoring forces in the dreamer's ego. In this way the manifest dream, as it is remembered in waking life, comes about. It is distorted, to the pitch of being unrecognizable, by concessions made to the dream-censorship; but it can be revealed once more by analysis as an expression of a situation of satisfaction or as the fulfilment of a wish. It is a compromise between two conflicting groups of mental trends, just as we have found to be the case with hysterical symptoms. The formula which, at bottom, best meets the essence of the dream is this: a dream is a (disguised) fulfilment of a (repressed) wish. The study of the process which transforms the latent dream-wish into the manifest content of the dream - a process known as the 'dream-work' - has taught us the best part of what we know of unconscious mental life.
There were now a whole series of questions to be answered, among the most important of them being whether the formation of dreams had a motive, under what conditions it took place, by what methods the dream-thoughts (which are invariably full of sense) become converted into the dream (which is often senseless), and others besides. I attempted to solve all of these problems in *The Interpretation of Dreams*, which I published in the year 1900. I can only find space here for the briefest abstract of my investigation. When the latent dream-thoughts that are revealed by the analysis of a dream are examined, one of them is found to stand out from among the rest, which are intelligible and well known to the dreamer. These latter thoughts are residues of waking life (the day's residues, as they are called technically); but the isolated thought is found to be a wishful impulse, often of a very repellent kind, which is foreign to the waking life of the dreamer and is consequently disavowed by him with surprise or indignation. This impulse is the actual constructor of the dream: it provides the energy for its production and makes use of the day's residues as material. The dream which thus originates represents a situation of satisfaction for the impulse, it is the fulfilment of its wish. It would not be possible for this process to take place without being favoured by the presence of something in the nature of a state of sleep. The necessary mental precondition of sleep is the concentration of the ego upon the wish to sleep and the withdrawal of psychical energy from all the interests of life. Since at the same time all the paths of approach to motility are blocked, the ego is also able to reduce the expenditure by which at other times it maintains the repressions. The unconscious impulse makes use of this nocturnal relaxation of repression in order to push its way into consciousness with the dream. But the repressive resistance of the ego is not abolished in sleep but merely reduced. Some of it remains in the shape of a censorship of dreams and forbids the unconscious impulse to express itself in the forms which it would properly assume. In consequence of the severity of the censorship of dreams, the latent dream-thoughts are obliged to submit to being altered and softened so as to make the forbidden meaning of the dream unrecognizable. This is the explanation of dream-distortion, which accounts for the most striking characteristics of the manifest dream. We are therefore justified in asserting that a dream is the (disguised) fulfilment of a (repressed) wish. It will now be seen that dreams are constructed like a neurotic symptom: they are compromises between the demands of a repressed impulse and the resistance of a censoring force in the ego. Since they have a similar origin they are equally unintelligible and stand in equal need of interpretation.

There is no difficulty in discovering the general function of dreaming. It serves the purpose of fending off, by a kind of soothing action, external or internal stimuli which would tend to arouse the sleeper, and thus of securing sleep against interruption. External stimuli are fended off by being given a new interpretation and by being woven into some harmless situation; internal stimuli, caused by instinctual demands, are given free play by the sleeper and allowed to find satisfaction in the formation of dreams, so long as the latent dream-thoughts submit to the control of the censorship. But if they threaten to break free and the meaning of the dream becomes too plain, the sleeper cuts short the dream and wakes in a fright. (Dreams of this class are known as anxiety-dreams.) A similar failure in the function of dreaming occurs if an external stimulus becomes too strong to be fended off. (This is the class of arousal-dreams.) I have given the name of dream-work to the process which, with the co-operation of the censorship, converts the latent thoughts into the manifest content of the dream. It consists of a peculiar way of treating the preconscious material of thought, so that its component parts become condensed, its psychical emphasis becomes displaced, and the whole of it is translated into visual images or dramatized, and completed by a deceptive secondary revision. The dream-work is an excellent example of the processes occurring in the deeper, unconscious layers of the mind, which differ considerably from the familiar normal processes of thought. It also displays a number of archaic characteristics, such as the use of a symbolism (in this case of a predominantly sexual kind) which it has since also been possible to discover in other spheres of mental activity.
Let us look through the volumes of the *Internationale Zeitschrift für (ärztliche) Psychoanalyse*, in which, since 1913, the authoritative writings in our field of work have been brought together. In the earlier volumes you will find a recurrent sectional heading 'On Dream-Interpretation', containing numerous contributions on various points in the theory of dreams. But the further you go the rarer do these contributions become, and finally the sectional heading disappears completely. The analysts behave as though they had no more to say about dreams, as though there was nothing more to be added to the theory of dreams. But if you ask how much of dream-interpretation has been accepted by outsiders - by the many psychiatrists and psychotherapists who warm their pot of soup at our fire (incidentally without being very grateful for our hospitality), by what are described as educated people, who are in the habit of assimilating the more striking findings of science, by the literary men and by the public at large - the reply gives little cause for satisfaction. A few formulas have become generally familiar, among them some that we have never put forward - such as the thesis that all dreams are of a sexual nature - but really important things like the fundamental distinction between the manifest content of dreams and the latent dream-thoughts, the realization that the wish-fulfilling function of dreams is not contradicted by anxiety-dreams, the impossibility of interpreting a dream unless one has the dreamer's associations to it at one's disposal, and, above all, the discovery that what is essential in dreams is the process of the dream-work - all this still seems about as foreign to general awareness as it was thirty years ago. I am in a position to say this, since in the course of that period I have received innumerable letters whose writers present their dreams for interpretation or ask for information about the nature of dreams and who declare that they have read my *Interpretation of Dreams*, though in every sentence they betray their lack of understanding of our theory of dreams. But all this shall not deter us from once more giving a connected account of what we know about dreams. You will recall that last time we devoted a whole number of lectures to showing how we came to understand this hitherto unexplained mental phenomenon.

[1933a, 4622]

As you see, Ladies and Gentlemen, this time I am taking the path not of a genetic but of a dogmatic exposition. Our first step is to establish our new attitude to the problem of dreams by introducing two new concepts and names. What has been called the dream we shall describe as the text of the dream or the *manifest* dream, and what we are looking for, what we suspect, so to say, of lying behind the dream, we shall describe as the *latent* dream-thoughts. Having done this, we can express our two tasks as follows. We have to transform the manifest dream into the latent one, and to explain how, in the dreamer's mind, the latter has become the former. The first portion is a *practical* task, for which dream-interpretation is responsible; it calls for a technique. The second portion is a *theoretical* task, whose business it is to explain the hypothetical dream-work; and it can only be a theory. Both of them, the technique of dream-interpretation and the theory of the dream-work, have to be newly created.

[1933a, 4623]

This was what I wanted to say to you, Ladies and Gentlemen, about dream-interpretation, whose task it is to lead the way from the manifest dream to the latent dream-thoughts. When this has been achieved, interest in a dream, so far as practical analysis is concerned, is for the most part at an end. We add the communication we have received in the form of a dream to the rest of the patient's communications and proceed with the analysis. We, however, have an interest in dwelling a little longer on the dream. We are tempted to study the process by which the latent dream-thoughts were transformed into the manifest dream. We call this the 'dream-work'. As you will recall, I described it in such detail in my earlier lectures that I can restrict my present survey to the most concise summary.

[1933a, 4630]
The process of the dream-work, then, is something entirely new and strange, nothing resembling which was known before. It has given us our first glimpse of the processes which take place in the unconscious system and has shown us that they are quite other than what we know from our conscious thinking and are bound to appear to the latter preposterous and incorrect. The importance of this finding was then increased by the discovery that in the construction of neurotic symptoms the same mechanisms (we do not venture to say 'processes of thought') are operative as those which have transformed the latent dream-thoughts into the manifest dream.

After these influences have been brought to bear upon the dream-thoughts the dream is almost complete. A further, somewhat variable, factor also comes into play - known as 'secondary revision' - after the dream has been presented before consciousness as an object of perception. At that point we treat it as we are in general accustomed to treat the contents of our perception: we fill in gaps and introduce connections, and in doing so are often guilty of gross misunderstandings. But this activity, which might be described as a rationalizing one and which at best provides the dream with a smooth façade that cannot fit its true content, may also be omitted or only be expressed to a very modest degree - in which case the dream will display all its rents and cracks openly. It must not be forgotten, on the other hand, that the dream-work does not always operate with equal energy either; it often restricts itself to certain portions of the dream-thoughts only and others of them are allowed to appear in the dream unaltered. In such cases an impression is given of the dream having carried out the most delicate and complex intellectual operations, of its having speculated, made jokes, arrived at decisions and solved problems, whereas all this is a product of our normal mental activity, may have been performed equally well during the day before the dream as during the night, has nothing to do with the dream-work and brings nothing to light that is characteristic of dreams. Nor is it superfluous to insist once more on the contrast within the dream-thoughts themselves between the unconscious instinctual impulse and the day's residues. While the latter exhibit all the multiplicity of our mental acts, the former, which becomes the motive force proper of the forming of the dream, finds its outlet invariably in the fulfilment of a wish.

In a very interesting series of experiments, Herbert Silberer has shown that one can catch the dream-work red-handed, as it were, in the act of turning abstract thoughts into visual pictures. If he tried to force himself to do intellectual work while he was in a state of fatigue and drowsiness, the thought would often vanish and be replaced by a vision, which was obviously a substitute for it.
We meet with the second of these facts almost every day in the course of our analytic work; and it does not imply such an important objection as the other does. One of the tasks of psycho-analysis, as you know, is to lift the veil of amnesia which hides the earliest years of childhood and to bring to conscious memory the manifestations of early infantile sexual life which are contained in them. Now these first sexual experiences of a child are linked to painful impressions of anxiety, prohibition, disappointment and punishment. We can understand their having been repressed; but, that being so, we cannot understand how it is that they have such free access to dream-life, that they provide the pattern for so many dream-phantasies and that dreams are filled with reproductions of these scenes from childhood and with allusions to them. It must be admitted that their unpleasurable character and the dream-work's wish-fulfilling purpose seem far from mutually compatible. But it may be that in this case we are magnifying the difficulty. After all, these same infantile experiences have attached to them all the imperishable, unfulfilled instinctual wishes which throughout life provide the energy for the construction of dreams, and to which we may no doubt credit the possibility, in their mighty uprush, of forcing to the surface, along with the rest, the material of distressing events. And on the other hand the manner and form in which this material is reproduced shows unmistakably the efforts of the dream-work directed to denying the unpleasure by means of distortion and to transforming disappointment into attainment.

[1933a, 4641]

With the traumatic neuroses things are different. In their case the dreams regularly end in the generation of anxiety. We should not, I think, be afraid to admit that here the function of the dream has failed. I will not invoke the saying that the exception proves the rule: its wisdom seems to me most questionable. But no doubt the exception does not overturn the rule. If, for the sake of studying it, we isolate one particular psychical function, such as dreaming, from the psychical machinery as a whole, we make it possible to discover the laws that are peculiar to it; but when we insert it once more into the general context we must be prepared to discover that these findings are obscured or impaired by collision with other forces. We say that a dream is the fulfilment of a wish; but if you want to take these latter objections into account, you can say nevertheless that a dream is an attempt at the fulfilment of a wish. No one who can properly appreciate the dynamics of the mind will suppose that you have said anything different by this. In certain circumstances a dream is only able to put its intention into effect very incompletely, or must abandon it entirely. Unconscious fixation to a trauma seems to be foremost among these obstacles to the function of dreaming. While the sleeper is obliged to dream, because the relaxation of repression at night allows the upward pressure of the traumatic fixation to become active, there is a failure in the functioning of his dream-work, which would like to transform the memory-traces of the traumatic event into the fulfilment of a wish. In these circumstances it will happen that one cannot sleep, that one gives up sleep from dread of the failure of the function of dreaming. Traumatic neuroses are here offering us an extreme case; but we must admit that childhood experiences, too, are of a traumatic nature, and we need not be surprised if comparatively trivial interferences with the function of dreams may arise under other conditions as well.

[1933a, 4642]
To begin with, I naturally understood no more about my patients' dreams than the dreamers did themselves. But by applying to these dreams, and more particularly to my own dreams, the procedure which I had already used for the study of other abnormal psychological structures, I succeeded in answering most of the questions which could be raised by an interpretation of dreams. There were many such questions: What do we dream about? Why do we dream at all? What is the origin of all the strange characteristics which distinguish dreams from waking life? - and many more such questions besides. Some of the answers were easily given and turned out to confirm views that had already been put forward; but others involved completely new hypotheses with regard to the structure and functioning of the apparatus of the mind. People dream about the things that have engaged their minds during the waking day. People dream in order to allay impulses that seek to disturb sleep, and in order to be able to sleep on. But why was it possible for dreams to present such a strange appearance, so confusedly senseless, so obviously contrasted with the content of waking thought, in spite of being concerned with the same material? There could be no doubt that dreams were only a substitute for a rational process of thought and could be interpreted - that is to say, translated into a rational process. But what needed explaining was the fact of the distortion which the dream-work had carried out upon the rational and intelligible material.

[1932c, 4808]

We find our way to the understanding ('interpretation') of a dream by assuming that what we recollect as the dream after we have woken up is not the true dream-process but only a façade behind which that process lies concealed. Here we have our distinction between the manifest content of a dream and the latent dream-thoughts. The process which produces the former out of the latter is described as the dream-work. The study of the dream-work teaches us by an excellent example the way in which unconscious material from the id (originally unconscious and repressed unconscious alike) forces its way into the ego, becomes preconscious and, as a result of the ego's opposition, undergoes the changes which we know as dream-distortion. There are no features of a dream which cannot be explained in this way.

[1940a [1938], 4975]

But what makes dreams so invaluable in giving us insight is the circumstance that, when the unconscious material makes its way into the ego, it brings its own modes of working along with it. This means that the preconscious thoughts in which the unconscious material has found its expression are handled in the course of the dream-work as though they were unconscious portions of the id; and, in the case of the alternative method of dream-formation, the preconscious thoughts which have obtained reinforcement from an unconscious instinctual impulse are brought down to the unconscious state. It is only in this way that we learn the laws which govern the passage of events in the unconscious and the respects in which they differ from the rules that are familiar to us in waking thought. Thus the dream-work is essentially an instance of the unconscious working-over of preconscious thought-processes. To take an analogy from history: invading conquerors govern a conquered country, not according to the judicial system which they find in force there, but according to their own. It is, however, an unmistakable fact that the outcome of the dream-work is a compromise. The ego-organization is not yet paralysed, and its influence is to be seen in the distortion imposed on the unconscious material and in what are often very ineffective attempts at giving the total result a form not too unacceptable to the ego (secondary revision). In our analogy this would be an expression of the continued resistance of the defeated people.

[1940a [1938], 4977]
It remains for us to give a dynamic explanation of why the sleeping ego takes on the task of the dream-work at all. The explanation is fortunately easy to find. With the help of the unconscious, every dream that is in process of formation makes a demand upon the ego - for the satisfaction of an instinct, if the dream originates from the id; for the solution of a conflict, the removal of a doubt or the forming of an intention, if the dream originates from a residue of preconscious activity in waking life. The sleeping ego, however, is focused on the wish to maintain sleep; it feels this demand as a disturbance and seeks to get rid of the disturbance. The ego succeeds in doing this by what appears to be an act of compliance: it meets the demand with what is in the circumstances a harmless fulfilment of a wish and so gets rid of it. This replacement of the demand by the fulfilment of a wish remains the essential function of the dream-work. It may perhaps be worth while to illustrate this by three simple examples - a hunger dream, a dream of convenience and a dream prompted by sexual desire. A need for food makes itself felt in a dreamer during his sleep: he has a dream of a delicious meal and sleeps on. The choice, of course, was open to him either of waking up and eating something or of continuing his sleep. He decided in favour of the latter and satisfied his hunger by means of the dream - for the time being, at all events, for if his hunger had persisted he would have had to wake up nevertheless. Here is the second example. A sleeper had to wake up so as to be in time for his work at the hospital. But he slept on, and had a dream that he was already at the hospital - but as a patient, who has no need to get up. Or again, a desire becomes active during the night for the enjoyment of a forbidden sexual object, the wife of a friend of the sleeper. He has a dream of sexual intercourse - not, indeed, with this person but with someone else of the same name to whom he is in fact indifferent; or his struggle against the desire may find expression in his mistress remaining altogether anonymous. [1940a [1938], 4980]
The fact that the phenomena of censorship and of dream-distortion correspond down to their smallest details justifies us in presuming that they are similarly determined. We may therefore suppose that dreams are given their shape in individual human beings by the operation of two psychical forces (or we may describe them as currents or systems); and that one of these forces constructs the wish which is expressed by the dream, while the other exercises a censorship upon this dream-wish and, by the use of that censorship, forcibly brings about a distortion in the expression of the wish. It remains to enquire as to the nature of the power enjoyed by this second agency which enables it to exercise its censorship. When we bear in mind that the latent dream-thoughts are not conscious before an analysis has been carried out, whereas the manifest content of the dream is consciously remembered, it seems plausible to suppose that the privilege enjoyed by the second agency is that of permitting thoughts to enter consciousness. Nothing, it would seem, can reach consciousness from the first system without passing the second agency; and the second agency allows nothing to pass without exercising its rights and making such modifications as it thinks fit in the thought which is seeking admission to consciousness. Incidentally, this enables us to form a quite definite view of the 'essential nature' of consciousness: we see the process of a thing becoming conscious as a specific psychical act, distinct from and independent of the process of the formation of a presentation or idea; and we regard consciousness as a sense organ which perceives data that arise elsewhere. It can be demonstrated that these basic assumptions are absolutely indispensable to psychopathology. We must, however, postpone our further consideration of them to a later stage.

[1900a, 639]

¹ [Footnote added 1911:] In an interesting paper, Silberer (1910) has tried to show from this part of my dream that the dream-work can succeed in reproducing not only the latent dream-thoughts but also the psychical processes that take place during the formation of dreams. (This is what he terms 'the functional phenomenon'.) [Added 1914.] But he is, I think, overlooking the fact that 'the psychical processes that take place during the formation of dreams' were, like the rest, part of the material of my thoughts. In this boastful dream I was evidently proud of having discovered those processes.

[1900a, 695]

In the process of transforming the latent thoughts into the manifest content of a dream we have found two factors at work: dream-condensation and dream-displacement. As we continue our investigation we shall, in addition to these, come across two further determinants which exercise an undoubted influence on the choice of the material which is to find access to the dream.

[1900a, 781]

The different portions of this complicated structure stand, of course, in the most manifold logical relations to one another. They can represent foreground and background, digressions and illustrations, conditions, chains of evidence and counter-arguments. When the whole mass of these dream-thoughts is brought under the pressure of the dream-work, and its elements are turned about, broken into fragments and jammed together - almost like pack-ice - the question arises of what happens to the logical connections which have hitherto formed its framework. What representation do dreams provide for 'if', 'because', 'just as', 'although', 'either-or', and all the other conjunctions without which we cannot understand sentences or speeches?

[1900a, 782]
We have been occupied so far with investigating the means by which dreams represent the
relations between the dream-thoughts. In the course of this investigation, however, we have
more than once touched upon the further topic of the general nature of the modifications which
the material of the dream-thoughts undergoes for the purpose of the formation of a dream. We
have learnt that that material, stripped to a large extent of its relations, is submitted to a process
of compression, while at the same time displacements of intensity between its elements
necessarily bring about a psychical transvaluation of the material. The displacements we have
hitherto considered turned out to consist in the replacing of some one particular idea by another
in some way closely associated with it, and they were used to facilitate condensation in so far
as, by their means, instead of two elements, a single common element intermediate between
them found its way into the dream. We have not yet referred to any other sort of displacement.
Analyses show us, however, that another sort exists and that it reveals itself in a change in the
verbal expression of the thoughts concerned. In both cases there is a displacement along a
chain of associations; but a process of such a kind can occur in various psychical spheres, and
the outcome of the displacement may in one case be that one element is replaced by another,
while the outcome in another case may be that a single element has its verbal form replaced by
another.
[1900a, 808]

The nature of the dream-work and the way in which it plays about with its material, the dream-
thoughts, are instructively shown when we come to consider numbers and calculations that
occur in dreams. Moreover, numbers in dreams are regarded superstitiously as being especially
significant in regard to the future. I shall therefore select a few instances of this kind from my
collection.
[1900a, 869]

My next task is to show that the dream-work consists in nothing more than a combination of
the three factors I have mentioned - and of a fourth which I have still to mention; that it carries
out no other function than the translation of dream-thoughts in accordance with the four
conditions to which it is subject; and that the question whether the mind operates in dreams with
all its intellectual faculties or with only a part of them is wrongly framed and disregards the facts.
Since, however, there are plenty of dreams in whose content judgements are passed, criticisms
made, and appreciations expressed, in which surprise is felt at some particular element of the
dream, in which explanations are attempted and argumentations embarked upon, I must now
proceed to meet the objections arising from facts of this kind by producing some chosen
examples.
[1900a, 891]
No complete theoretical explanation can here be given of this suppression of affect in the course of the dream-work. It would require to be preceded by a most painstaking investigation of the theory of affects and of the mechanism of repression. I will only permit myself a reference to two points. I am compelled - for other reasons - to picture the release of affects as a centrifugal process directed towards the interior of the body and analogous to the processes of motor and secretory innervation. Now just as in the state of sleep the sending out of motor impulses towards the external world appears to be suspended, so it may be that the centrifugal calling-up of affects by unconscious thinking may become more difficult during sleep. In that case the affective impulses occurring during the course of the dream-thoughts would from their very nature be weak impulses, and consequently those which found their was into the dream would be no less weak. On this view, then, the 'suppression of affect' would not in any way be the consequence of the dream-work but would result from the state of sleep. This may be true, but it cannot be the whole truth. We must also bear in mind that any relatively complex dream turns out to be a compromise produced by a conflict between psychical forces. For one thing, the thoughts constructing the wish are obliged to struggle against the opposition of a censoring agency; and for another thing, we have often seen that in unconscious thinking itself every train of thought is yoked with its contradictory opposite. Since all of these trains of thought are capable of carrying an affect, we shall by and large scarcely be wrong if we regard the suppression of affect as a consequence of the inhibition which these contraries exercise upon each other and which the censorship exercises upon the impulsions suppressed by it. The inhibition of affect, accordingly, must be considered as the second consequence of the censorship of dreams, just as dream-distortion is its first consequence.

[1900a, 911]

And now at last we can turn to the fourth of the factors concerned in the construction of dreams. If we pursue our investigation of the content of dreams in the manner in which we have begun it - that is, by comparing conspicuous events in the dream-content with their sources in the dream-thoughts, we shall come upon elements the explanation of which calls for an entirely new assumption. What I have in mind are cases in which the dreamer is surprised, annoyed or repelled in the dream, and, moreover, by a piece of the dream-content itself. As I have shown in a number of instances, the majority of these critical feelings in dreams are not in fact directed against the content of the dream, but turn out to be portions of the dream-thoughts which have been taken over and used to an appropriate end. But some material of this kind does not lend itself to this explanation; its correlate in the material of the dream-thoughts is nowhere to be found. What, for instance, is the meaning of a critical remark found so often in dreams: 'This is only a dream'? Here we have a genuine piece of criticism of the dream, such as might be made in waking life. Quite frequently, too, it is actually a prelude to waking up; and still more frequently it has been preceded by some distressing feeling which is set at rest by the recognition that the state is one of dreaming. When the thought 'this is only a dream' occurs during a dream, it has the same purpose in view as when the words are pronounced on the stage by la belle Hélène in Offenbach's comic opera of that name: it is aimed at reducing the importance of what has just been experienced and at making it possible to tolerate what is to follow. It serves to lull a particular agency to sleep which would have every reason at that moment to bestir itself and forbid the continuance of the dream - or the scene in the opera. It is more comfortable, however, to go on sleeping and tolerate the dream, because, after all, 'it is only a dream.' In my view the contemptuous critical judgement, 'it's only a dream', appears in a dream when the censorship, which is never quite asleep, feels that it has been taken unawares by a dream which has already been allowed through. It is too late to suppress it, and accordingly the censorship uses these words to meet the anxiety or the distressing feeling aroused by it. The phrase is an example of esprit d'escalier on the part of the psychical censorship.

[1900a, 928]
The function of 'secondary revision', which we have attributed to the fourth of the factors concerned in shaping the content of dreams, shows us in operation once more the activity which is able to find free vent in the creation of day-dreams without being inhibited by any other influences. We might put it simply by saying that this fourth factor of ours seeks to mould the material offered to it into something like a day-dream. If, however, a day-dream of this kind has already been formed within the nexus of the dream-thoughts, this fourth factor in the dream-work will prefer to take possession of the ready-made day-dream and seek to introduce it into the content of the dream. There are some dreams which consist merely in the repetition of a day-time phantasy which may perhaps have remained unconscious: such, for instance, as the boy's dream of driving in a war-chariot with the heroes of the Trojan War. In my 'Autodidasker' dream the second part at all events was a faithful reproduction of a daytime phantasy, innocent in itself, of a conversation with Professor N. In view of the complicated conditions which a dream has to satisfy when it comes into existence, it happens more frequently that the ready-made phantasy forms only a portion of the dream, or that only a portion of the phantasy forces its way into the dream. Thereafter, the phantasy is treated in general like any other portion of the latent material, though it often remains recognizable as an entity in the dream. There are often parts of my dreams which stand out as producing a different impression from the rest. They strike me as being, as it were, more fluent, more connected and at the same time more fleeting than other parts of the same dream. These, I know, are unconscious phantasies which have found their way into the fabric of the dream, but I have never succeeded in pinning down a phantasy of this kind. Apart from this, these phantasies, like any other component of the dream-thoughts, are compressed, condensed, superimposed on one another, and so on. There are, however, transitional cases, between the case in which they constitute the content (or at least the façade) of the dream unaltered and the extreme opposite in which they are represented in the content of the dream only by one of their elements or by a distant allusion. What happens to phantasies present in the dream-thoughts is evidently also determined by any advantages they may have to offer the requirements of the censorship and of the urge towards condensation.

[1900a, 932]

At this point it is impossible to avoid considering the relation between this secondary revision of the content of dreams and the remaining factors of the dream-work. Are we to suppose that what happens is that in the first instance the dream-constructing factors - the tendency towards condensation, the necessity for evading the censorship, and considerations of representability by the psychical means open to dreams - put together a provisional dream-content out of the material provided, and that this content is subsequently re-cast so as to conform so far as possible to the demands of a second agency! This is scarcely probable. We must assume rather that from the very first the demands of this second factor constitute one of the conditions which the dream must satisfy and that this condition, like those laid down by condensation, the censorship imposed by resistance, and representability, operates simultaneously in a conducive and selective sense upon the mass of material present in the dream-thoughts. In any case, however, of the four conditions for the formation of dreams, the one we have come to know last is the one whose demands appear to have the least cogent influence on dreams.

[1900a, 937]
I will now try to sum up this lengthy disquisition on the dream-work. We were faced by the question whether the mind employs the whole of its faculties without reserve in constructing dreams or only a functionally restricted fragment of them. Our investigations led us to reject entirely the form in which the question was framed as being inadequate to the circumstances. If, however, we had to reply to the question on the basis of the terms in which it was stated, we should be obliged to reply in the affirmative to both the alternatives, mutually exclusive though they appear to be. Two separate functions may be distinguished in mental activity during the construction of a dream: the production of the dream-thoughts, and their transformation into the content of the dream. The dream-thoughts are entirely rational and are constructed with an expenditure of all the psychical energy of which we are capable. They have their place among thought-processes that have not become conscious - processes from which, after some modification, our conscious thoughts, too, arise. However many interesting and puzzling questions the dream-thoughts may involve, such questions have, after all, no special relation to dreams and do not call for treatment among the problems of dreams.

On the other hand, the second function of mental activity during dream-construction, the transformation of the unconscious thoughts into the content of the dream, is peculiar to dream-life and characteristic of it. This dream-work proper diverges further from our picture of waking thought than has been supposed even by the most determined depreciator of psychical functioning during the formation of dreams. The dream-work is not simply more careless, more irrational, more forgetful and more incomplete than waking thought; it is completely different from it qualitatively and for that reason not immediately comparable with it. It does not think, calculate or judge in any way at all; it restricts itself to giving things a new form. It is exhaustively described by an enumeration of the conditions which it has to satisfy in producing its result. That product, the dream, has above all to evade the censorship, and with that end in view the dream-work makes use of a displacement of psychical intensities to the point of a transvaluation of all psychical values. The thoughts have to be reproduced exclusively or predominantly in the material of visual and acoustic memory-traces, and this necessity imposes upon the dream-work considerations of representability which it meets by carrying out fresh displacements. Greater intensities have probably to be produced than are available in the dream-thoughts at night, and this purpose is served by the extensive condensation which is carried out with the constituents of the dream-thoughts. Little attention is paid to the logical relations between the thoughts; those relations are ultimately given a disguised representation in certain formal characteristics of dreams. Any affect attached to the dream-thoughts undergoes less modification than their ideational content. Such affects are as a rule suppressed; when they are retained, they are detached from the ideas that properly belong to them, affects of a similar character being brought together. Only a single portion of the dream-work and one which operates to an irregular degree, the working over of the material by partly aroused waking thought, tallies to some extent with the view which other writers have sought to apply to the entire activity of dream-construction.

There can be no doubt what the peculiar feature is which attracts our interest to this brief dream. Hitherto we have been principally concerned with the secret meaning of dreams and the method of discovering it and with the means employed by the dream-work for concealing it. The problems of dream-interpretation have hitherto occupied the centre of the picture. And now we come upon a dream which raises no problem of interpretation and the meaning of which is obvious, but which, as we see, nevertheless retains the essential characteristics that differentiate dreams so strikingly from waking life and consequently call for explanation. It is only after we have disposed of everything that has to do with the work of interpretation that we can begin to realize the incompleteness of our psychology of dreams.
The explanation is in our favour, though without putting the other writers in the wrong. In the light of our newly-won understanding of the origin of dreams the contradiction disappears completely. It is true that we distort dreams in attempting to reproduce them; here we find at work once more the process which we have described as the secondary (and often ill-conceived) revision of the dream by the agency which carries out normal thinking. But this distortion is itself no more than a part of the revision to which the dream-thoughts are regularly subjected as a result of the dream-censorship. The other writers have at this point noticed or suspected the part of dream-distortion which operates manifestly; we are less interested, since we know that a much more far-reaching process of distortion, though a less obvious one, has already developed the dream out of the hidden dream-thoughts. The only mistake made by previous writers has been in supposing that the modification of the dream in the course of being remembered and put into words is an arbitrary one and cannot be further resolved and that it is therefore calculated to give us a misleading picture of the dream. They have underestimated the extent to which psychical events are determined. There is nothing arbitrary about them. It can be shown quite generally that if an element is left undetermined by one train of thought, its determination is immediately effected by a second one. For instance. I may try to think of a number arbitrarily. But this is impossible: the number that occurs to me will be unambiguously and necessarily determined by thoughts of mine, though they may be remote from my immediate intention.¹ The modifications to which dreams are submitted under the editorship of waking life are just as little arbitrary. They are associatively linked to the material which they replace, and serve to show us the way to that material, which may in its turn be a substitute for something else.

[1900a, 950]

It is only with the greatest difficulty that the beginner in the business of interpreting dreams can be persuaded that his task is not at an end when he has a complete interpretation in his hands - an interpretation which makes sense, is coherent and throws light upon every element of the dream's content. For the same dream may perhaps have another interpretation as well, an 'over-interpretation', which has escaped him. It is, indeed, not easy to form any conception of the abundance of the unconscious trains of thought, all striving to find expression, which are active in our minds. Nor is it easy to credit the skill shown by the dream-work in always hitting upon forms of expression that can bear several meanings - like the Little Tailor in the fairy story who hit seven flies at a blow. My readers will always be inclined to accuse me of introducing an unnecessary amount of ingenuity into my interpretations; but actual experience would teach them better.

[1900a, 957]

Having now repelled the objections that have been raised against us, or having at least indicated where our defensive weapons lie, we must no longer postpone the task of setting about the psychological investigations for which we have so long been arming ourselves. Let us summarize the principal findings of our enquiry so far as it has gone. Dreams are psychical acts of as much significance as any others; their motive force is in every instance a wish seeking fulfilment; the fact of their not being recognizable as wishes and their many peculiarities and absurdities are due to the influence of the psychical censorship to which they have been subjected during the process of their formation; apart from the necessity of evading this censorship, other factors which have contributed to their formation are a necessity for the condensation of their psychical material, a regard for the possibility of its being represented in sensory images and - though not invariably - a demand that the structure of the dream shall have a rational and intelligible exterior. Each of these propositions opens a way to fresh psychological postulates and speculations; the mutual relations between the wish which is the dream's motive force and the four conditions to which the dream's formation is subject, a well as the interrelations between the latter, require to be investigated; and the place of dreams in the nexus of mental life has to be assigned.

[1900a, 966]
In this particular dream the change made in the thoughts by the conversion of the expectation expressed by them into the present tense may not seem particularly striking. This is because of what can only be described as the unusually subordinate part played in this dream by wish-fulfilment. Consider instead another one, in which the dream-wish was not detached from the waking thoughts that were carried over into sleep - for instance, the dream of Irma's injection. There the dream-thought that was represented was in the optative: 'If only Otto were responsible for Irma's illness!' The dream repressed the optative and replaced it by a straightforward present: 'Yes, Otto is responsible for Irma's illness.' This, then, is the first of the transformations which is brought about in the dream-thoughts even by a distortionless dream. We need not linger long over this first peculiarity of dreams. We can deal with it by drawing attention to conscious phantasies - to day-dreams - which treat their ideational content in just the same manner. While Daudet's Monsieur Joyeuse was wandering, out of work, through the streets of Paris (though his daughters believed that he had a job and was sitting in an office), he was dreaming of developments that might bring him influential help and lead to his finding employment - and he was dreaming in the present tense. Thus dreams make use of the present tense in the same manner and by the same right as day-dreams. The present tense is the one in which wishes are represented as fulfilled.

[1900a, 967]
Once again it is impossible for me to present a complete analysis. I must restrict myself to bringing out a few salient points. Distressing anticipations from the previous day were what gave rise to the dream: we had once more been without news of our son at the front for over a week. It is easy to see that the content of the dream expressed a conviction that he had been wounded or killed. Energetic efforts were clearly being made at the beginning of the dream to replace the distressing thoughts by their contrary. I had some highly agreeable news to communicate - something about money being sent... distinction... distribution. (The sum of money was derived from an agreeable occurrence in my medical practice; it was an attempt at a complete diversion from the topic.) But these efforts failed. My wife suspected something dreadful and refused to listen to me. The disguises were too thin and references to what it was sought to repress pierced through them everywhere. If my son had been killed, his fellow-officers would send back his belongings and I should have to distribute what he left among his brothers and sisters and other people. A 'distinction' is often awarded to an officer who has fallen in battle. Thus the dream set about giving direct expression to what it had first sought to deny, though the inclination towards wish-fulfilment was still shown at work in the distortions. (The change of locality during the dream is no doubt to be understood as what Silberer has described as 'threshold symbolism'. We cannot tell, it is true, what it was that provided the dream with the motive force for thus giving expression to my distressing thoughts. My son did not appear as someone 'falling' but as someone 'climbing.' He had in fact been a keen mountaineer. He was not in uniform but in sports clothes; this meant that the place of the accident that I now feared had been taken by an earlier, sporting one; for he had had a fall during a skiing expedition and broken his thigh. The way in which he was dressed, on the other hand, which made him look like a seal, at once recalled someone younger - our funny little grandson; while the grey hair reminded me of the latter's father, our son-in-law, who had been hard hit by the war. What could this mean?... but I have said enough of it. - The locality in a store-closet and the cupboard from which he wanted to take something ('on which he wanted to put something' in the dream) - these allusions reminded me unmistakably of an accident of my own which I had brought on myself when I was between two and three years old. I had climbed up on to a stool in the store-closet to get something nice that was lying on a cupboard or table. The stool had tipped over and its corner had struck me behind my lower jaw; I might easily, I reflected, have knocked out all my teeth. The recollection was accompanied by an admonitory thought: 'that serves you right'; and this seemed as though it was a hostile impulse aimed at the gallant soldier. Deeper analysis at last enabled me to discover what the concealed impulse was which might have found satisfaction in the dreaded accident to my son: it was the envy which is felt for the young by those who have grown old, but which they believe they have completely stifled. And there can be no question that it was precisely the strength of the painful emotion which would have arisen if such a misfortune had really happened that caused that emotion to seek out a repressed wish-fulfilment of this kind in order to find some consolation.

[1900a, 991]

It has already been pointed out by Dugas that Goblot would have to disregard many facts before he could assert his thesis generally. Dreams occur from which we do not awaken for instance, some in which we dream that we are dreaming. With our knowledge of the dream-work, we could not possibly agree that it only covers the period of awakening. It seems probable, on the contrary, that the first portion of the dream-work has already begun during the day, under the control of the preconscious. Its second portion - the modification imposed by the censorship, the attraction exercised by unconscious scenes, and the forcing of its way to perception - no doubt proceeds all through the night; and in this respect we may perhaps always be right when we express a feeling of having been dreaming all night long, though we cannot say what.

[1900a, 1004]
But it seems to me unnecessary to suppose that dream-processes really maintain, up to the moment of becoming conscious, the chronological order in which I have described them: that the first thing to appear is the transferred dream-wish, that distortion by the censorship follows, then the regressive change in direction, and so on. I have been obliged to adopt this order in my description; but what happens in reality is no doubt a simultaneous exploring of one path and another, a swinging of the excitation now this way and now that, until at last it accumulates in the direction that is most opportune and one particular grouping becomes the permanent one. Certain personal experiences of my own lead me to suspect that the dream-work often requires more than a day and a night in order to achieve its result; and if this is so, we need no longer feel any amazement at the extraordinary ingenuity shown in the construction of the dream. In my opinion even the demand for the dream to be made intelligible as a perceptual event may be put into effect before the dream attracts consciousness to itself. From then onwards, however, the pace is accelerated, for at that point a dream is treated in the same fashion as anything else that is perceived. It is like a firework, which takes hours to prepare but goes off in a moment.

The dream-process has by now either acquired sufficient intensity though the dream-work to attract consciousness to itself and arouse the preconscious, irrespectively of the time and depth of sleep; or its intensity is insufficient to achieve this and it must remain in a state of readiness until, just before waking, attention becomes more mobile and comes to meet it. The majority of dreams appear to operate with comparatively low psychical intensities, for they mostly wait until the moment of waking. But this also explains the fact that, if we are suddenly woken from deep sleep, we usually perceive something that we have dreamt. In such cases, just as when we wake of our own accord, the first thing we see is the perceptual content that has been constructed by the dream-work and immediately afterwards we see the perceptual content that is offered to us from outside ourselves.

Now that the old antithesis between conscious life and dream life has been reduced to its proper proportions by the establishment of unconscious psychical reality, a number of dream-problems with which earlier writers were deeply concerned have lost their significance. Thus some of the activities whose successful performance in dreams excited astonishment are now no longer to be attributed to dreams but to unconscious thinking, which is active during the day no less than at night. If, as Scherner has said, dreams appear to engage in making symbolic representations of the body, we now know that those representations are the product of certain unconscious phantasies (deriving, probably, from sexual impulses) which find expression not only in dreams but also in hysterical phobias and other symptoms. If a dream carries on the activities of the day and completes them and even brings valuable fresh ideas to light, all we need do is to strip it of the dream disguise, which is the product of dream-work and the mark of assistance rendered by obscure forces from the depths of the mind (cf. the Devil in Tartini's sonata dream); the intellectual achievement is due to the same mental forces which produce every similar result during the daytime. We are probably inclined greatly to over-estimate the conscious character of intellectual and artistic production as well. Accounts given us by some of the most highly productive men, such as Goethe and Helmholtz, show rather that what is essential and new in their creations came to them without premeditation and as an almost ready-made whole. There is nothing strange if in other cases, where a concentration of every intellectual faculty was needed, conscious activity also contributed its share. But it is the much-abused privilege of conscious activity, wherever it plays a part, to conceal every other activity from our eyes.
But another achievement of the dream-work, tending as it does to produce incoherent dreams, is even more striking. If in any particular instance we compare the number of ideational elements or the space taken up in writing them down in the case of the dream and of the dream-thoughts to which the analysis leads us and of which traces are to be found in the dream itself, we shall be left in no doubt that the dream-work has carried out a work of compression or condensation on a large scale. It is impossible at first to form any judgement of the degree of this condensation; but the deeper we plunge into a dream-analysis the more impressive it seems. From every element in a dream's content associative threads branch out in two or more directions; every situation in a dream seems to be put together out of two or more impressions or experiences. For instance, I once had a dream of a sort of swimming-pool, in which the bathers were scattering in all directions; at one point on the edge of the pool someone was standing and bending towards one of the people bathing, as though to help her out of the water. The situation was put together from a memory of an experience I had had at puberty and from two paintings, one of which I had seen shortly before the dream. One was a picture from Schwind's series illustrating the legend of Mélusine, which showed the water-nymphs surprised in their pool (cf. the scattering bathers in the dream); the other was a picture of the Deluge by an Italian Master; while the little experience remembered from my puberty was of having seen the instructor at a swimming-school helping a lady out of the water who had stopped in until after the time set aside for men bathers. -In the case of the example which I chose for interpretation, an analysis of the situation led me to a small series of recollections each of which contributed something to the content of the dream. In the first place, there was the episode from the time of my engagement of which I have already spoken. The pressure upon my hand under the table, which was a part of that episode, provided the dream with the detail 'under the table' - a detail which I had to add as an afterthought to my memory of the dream. In the episode itself there was of course no question of 'turning to me'; the analysis showed that this element was the fulfilment of a wish by presenting the opposite of an actual event, and that it related to my wife's behaviour at the table d'hôte. But behind this recent recollection there lay concealed an exactly similar and far more important scene from the time of our engagement, which estranged us for a whole day. The intimate laying of a hand on my knee belonged to a quite different context and was concerned with quite other people. This element in the dream was in turn the starting-point of two separate sets of memories - and so on.

Condensation, together with the transformation of thoughts into situations ('dramatization'), is the most important and peculiar characteristic of the dream-work. So far, however, nothing has transpired as to any motive necessitating this compression of the material.

In the case of the complicated and confused dreams with which we are now concerned, condensation and dramatization alone are not enough to account for the whole of the impression that we gain of the dissimilarity between the content of the dream and the dream-thoughts. We have evidence of the operation of a third factor, and this evidence deserves careful sifting.
The dream-thoughts which we arrive at by means of analysis reveal themselves as a psychical complex of the most intricate possible structure. Its portions stand in the most manifold logical relations to one another: they represent foreground and background, conditions, digressions and illustrations, chains of evidence and counter-arguments. Each train of thought is almost invariably accompanied by its contradictory counterpart. This material lacks none of the characteristics that are familiar to us from our waking thinking. If now all of this is to be turned into a dream, the psychical material will be submitted to a pressure which will condense it greatly, to an internal fragmentation and displacement which will, as it were, create new surfaces, and to a selective operation in favour of those portions of it which are the most appropriate for the construction of situations. If we take into account the genesis of the material, a process of this sort deserves to be described as a 'regression.' In the course of this transformation, however, the logical links which have hitherto held the psychical material together are lost. It is only, as it were, the substantive content of the dream-thoughts that the dream-work has destroyed is a task which has to be performed by the work of analysis. [1901a, 1075]

We have not yet come to the end of our consideration of the dream-work. In addition to condensation, displacement and pictorial arrangement of the psychical material, we are obliged to assign it yet another activity, though this is not to be found in operation in every dream. I shall not deal exhaustively with this part of the dream-work, and will therefore merely remark that the easiest way of forming an idea of its nature is to suppose - though the supposition probably does not meet the facts - that it only comes into operation after the dream-content has already been constructed. Its function would then consist in arranging the constituents of the dream in such a way that they form an approximately connected whole, a dream-composition. In this way the dream is given a kind of façade (though this does not, it is true, hide its content at every point), and thus receives a first, preliminary interpretation, which is supported by interpolations and slight modifications. Incidentally, this revision of the dream-content is only possible if it is not too punctiliously carried out; nor does it present us with anything more than a glaring misunderstanding of the dream-thoughts. Before we start upon the analysis of a dream we have to clear the ground of this attempt at an interpretation. [1901a, 1080]

The dream-work exhibits no activities other than the four that have already been mentioned. If we keep to the definition of 'dream-work' as the process of transforming the dream-thoughts into the dream-content, it follows that the dream-work is not creative, that it develops no phantasies of its own, that it makes no judgements and draws no conclusions; it has no functions whatever other than condensation and displacement of the material and its modification into pictorial form, to which must be added as a variable factor the final bit of interpretative revision. It is true that we find various things in the dream-content which we should be inclined to regard as a product of some other and higher intellectual function; but in every case analysis shows convincingly that these intellectual operations have already been performed in the dream-thoughts and have only been TAKEN OVER by the dream-content. A conclusion drawn in a dream is nothing other than the repetition of a conclusion in the dream-thoughts; if the conclusion is taken over into the dream unmodified, it will appear impeccable; if the dream-work has displaced it on to some other material, it will appear nonsensical. A calculation in the dream-content signifies nothing more than that there is a calculation in the dream-thoughts; but while the latter is always rational, a dream-calculation may produce the wildest results if its factors are condensed or if its mathematical operations are displaced on to other material. Not even the speeches that occur in the dream-content are original compositions; they turn out to be a hotchpotch of speeches made, heard or read, which have been revived in the dream-thoughts and whose wording is exactly reproduced, while their origin is entirely disregarded and their meaning is violently changed. [1901a, 1082]
Having been made acquainted with the dream-work by the foregoing discussion, we shall no
doubt be inclined to pronounce it a quite peculiar psychical process, the like of which, so far as
we are aware, does not exist elsewhere. It is as though we were carrying over on to the dream-
work all the astonishment which used formerly to be aroused in us by its product, the dream. In
fact, however, the dream-work is only the first to be discovered of a whole series of psychical
processes, responsible for of hysterical symptoms, of phobias, obsessions and delusions.
Condensation and, above all, displacement are invariable characteristics of these other
processes as well. Modification into a pictorial form, on the other hand, remains a peculiarity of
the dream-work. If this explanation places dreams in a single series alongside the structures
produced by psychical illness, this makes it all the more important for us to discover the
essential determining conditions of such processes as those of dream-formation. We shall
probably be surprised to hear that neither the state of sleep nor illness is among these
indispensable conditions. A whole number of the phenomena of the everyday life of healthy
people - such as forgetting, slips of the tongue, bungled actions and a particular class of errors -
owe their origin to a psychical mechanism analogous to that of dreams and of the other
members of the series.
[1901a, 1084]

The heart of the problem lies in displacement, which is by far the most striking of the special
achievements of the dream-work. If we enter deeply into the subject, we come to realize that the
essential determining condition of displacement is a purely psychological one: something in the
nature of a motive. One comes upon its track if one takes into consideration certain experiences
which one cannot escape in analysing dreams. In analysing my specimen dream I was obliged
to break off my report of the dream-thoughts on p. 1059, because, as I confessed, there were
some among them which I should prefer to conceal from strangers and which I could not
communicate to other people without doing serious mischief in important directions. I added that
nothing would be gained if I were to choose another dream instead of that particular one with a
view to reporting its analysis: I should come upon dream-thoughts which required to be kept
secret in the case of every dream with an obscure or confused content. If, however, I were to
continue the analysis on my own account, without any reference to other people (whom, indeed,
an experience so personal as my dream cannot possibly have been intended to reach), I should
eventually arrive at thoughts which would surprise me, whose presence in me I was unaware of,
which were not only alien but also disagreeable to me, and which I should therefore feel inclined
to dispute energetically, although the chain of thoughts running through the analysis insisted
upon them remorselessly. There is only one way of accounting for this state of affairs, which is
of quite universal occurrence; and that is to suppose that these thoughts really were present in
my mind, and in possession of a certain amount of psychical intensity or energy, but that they
were in a peculiar psychological situation, as a consequence of which they could not become
conscious to me. (I describe this particular condition as one of 'repression.') We cannot help
concluding, then, that there is a causal connection between the obscurity of the dream-content
and the state of repression (in admissibility to consciousness) of certain of the dream-thoughts,
and that the dream had to be obscure so as not to betray the proscribed dream-thoughts. Thus
we are led to the concept of a 'dream-distortion', which is the product of the dream-work and
serves the purpose of dissimulation, that is, of disguise.
[1901a, 1085]
Hitherto philosophers have had no occasion to concern themselves with a psychology of repression. We may therefore be permitted to make a first approach to this hitherto unknown topic by constructing a pictorial image of the course of events in dream-formation. It is true that the schematic picture we have arrived at - not only from the study of dreams - is a fairly complicated one; but we cannot manage with anything simpler. Our hypothesis is that in our mental apparatus there are two thought-constructing agencies, of which the second enjoys the privilege of having free access to consciousness for its products whereas the activity of the first is in itself unconscious and can only reach consciousness by way of the second. On the frontier between the two agencies, where the first passes over to the second, there is a censorship, which only allows what is agreeable to it to pass through and holds back everything else. According to our definition, then, what is rejected by the censorship is in a state of repression. Under certain conditions, of which the state of sleep is one, the relation between the strength of the two agencies is modified in such a way that what is repressed can no longer be held back. In the state of sleep this probably occurs owing to a relaxation of the censorship; when this happens it becomes possible for what has hitherto been repressed to make a path for itself to consciousness. Since, however, the censorship is never completely eliminated but merely reduced, the repressed material must submit to certain alterations which mitigate its offensive features. What becomes conscious in such cases is a compromise between the intentions of one agency and the demands of the other. Repression - relaxation of the censorship - the formation of a compromise, this is the fundamental pattern for the generation not only of dreams but of many other psychopathological structures; and in the latter cases too we may observe that the formation of compromises is accompanied by processes of condensation and displacement and by the employment of superficial associations, which we have become familiar with in the dream-work. [1901a, 1089]

I have laid it down as the task of dream-interpretation to replace the dream by the latent dream-thoughts, that is, to unravel what the dream-work has woven. In so doing I have raised a number of new psychological problems dealing with the mechanism of this dream-work itself, as well as with the nature and conditions of what is described as repression; on the other hand I have asserted the existence of the dream-thoughts - a copious store of psychical structures of the highest order, which is characterized by all the signs of normal intellectual functioning, but is nevertheless withdrawn from consciousness till it emerges in distorted form in the dream-content. I cannot but assume that thoughts of this kind are present in everyone, since almost everyone, including the most normal people, is capable of dreaming. The unconscious material of the dream-thoughts and its relation to consciousness and to repression raise further questions of significance to psychology, the answers to which must no doubt be postponed until analysis has clarified the origin of other psychopathological structures, such as hysterical symptoms and obsessional ideas. [1901a, 1098]

(G) A few words should be said to indicate at least in what direction this wider context lies. The mechanism of parapraxes and chance actions, as we have come to know it by our employment of analysis, can be seen to correspond in its most essential points with the mechanism of dream-formation which I have discussed in the chapter on the 'dream-work' in my Interpretation of Dreams. In both cases we find condensations and compromise-formations (contaminations). We have the same situation: by unfamiliar paths, and by the way of external associations, unconscious thoughts find expression as modifications of other thoughts. The incongruities, absurdities and errors of the dream-content, which result in the dream being scarcely recognized as the product of psychical activity, originate in the same way, though it is true with a freer use of the means at hand, as our common mistakes in everyday life. In both cases the appearance of an incorrect function is explained by the peculiar mutual interference between two or several correct functions. [1901b, 1346]
We shall not be able to form a correct picture of the strange psychical work which brings about the occurrence of both parapraxes and dream images until we have learnt that psychoneurotic symptoms, and especially the psychical formations of hysteria and obsessional neurosis, repeat in their mechanism all the essential features of this mode of working. This is therefore the starting-point for the continuation of our researches. For us, however, there is yet another special interest in considering parapraxes, chance actions and symptomatic actions in the light of this last analogy. If we compare them to the products of the psychoneuroses, to neurotic symptoms, two frequently repeated statements - namely, that the borderline between the normal and the abnormal in nervous matters is a fluid one, and that we are all a little neurotic - acquire meaning and support. Without any medical experience we can construct various types of nervous illness of this kind which are merely hinted at - formes frustres¹ - of the neuroses: cases in which the symptoms are few, or occur rarely or not severely - in other words, cases whose comparative mildness is located in the number, intensity and duration of their pathological manifestations. But we might perhaps never arrive by conjecture at precisely the type that appears most frequently to form the transition between health and illness. For the type we are considering, whose pathological manifestations are parapraxes and symptomatic acts, is characterized by the fact that the symptoms are located in the least important psychical functions, while everything that can lay claim to higher psychical value remains free from disturbance. Where the symptoms are distributed in the reverse way - that is, where they make their appearance in the most important individual and social functions and are able to disturb nutrition, sexual intercourse, professional work and social life - this is the mark of severe cases of neurosis and is more characteristic of them than, for example, are the variety and vigour of their pathological manifestations.

Can we feel sure that none of the possible techniques of jokes has escaped our investigation? Of course not. But a continued examination of fresh material can convince us that we have got to know the commonest and most important technical methods of the joke-work - at all events as much as is required for forming a judgement on the nature of that psychical process. So far we have not arrived at any such judgement; but on the other hand we are now in possession of an important indication of the direction from which we may expect to receive further light upon the problem. The interesting processes of condensation accompanied by the formation of a substitute, which we have recognized as the core of the technique of verbal jokes, point towards the formation of dreams, in the mechanism of which the same psychical processes have been discovered. This is equally true, however, of the techniques of conceptual jokes - displacement, faulty reasoning, absurdity, indirect representation, representation by the opposite - which re-appear one and all in the technique of the dream-work. Displacement is responsible for the puzzling appearance of dreams, which prevents our recognizing that they are a continuation of our waking life. The use of absurdity and nonsense in dreams has cost them the dignity of being regarded as psychical products and has led the authorities to suppose that a disintegration of the mental activities and a cessation of criticism, morality and logic are necessary conditions of the formation of dreams. Representation by the opposite is so common in dreams that even the popular books of dream-interpretation, which are on a completely wrong tack, are in the habit of taking it into account. Indirect representation - the replacement of a dream-thought by an allusion, by something small, a symbolism akin to analogy - is precisely what distinguishes the mode of expression of dreams from that of our waking life.¹ So far-reaching an agreement between the methods of the joke-work and those of the dream-work can scarcely be a matter of chance. To demonstrate this agreement in detail and to examine its basis will be one of our later tasks.

¹[1901b, 1347]

¹[1905c, 1686]
The achievements of the dream-work can, however, be described as follows. A tissue of thoughts, usually a very complicated one, which has been built up during the day and has not been completely dealt with - 'a day's residue' - continues during the night to retain the quota of energy - the 'interest'- claimed by it, and threatens to disturb sleep. This 'day's residue' is transformed by the dream-work into a dream and made innocuous to sleep. In order to provide a fulcrum for the dream-work, the 'day's residue' must be capable of constructing a wish - which is not a very hard condition to fulfil. The wish arising from the dream-thoughts forms the preliminary stage and later the core of the dream. Experience derived from analyses - and not the theory of dreams - informs us that in children any wish left over from waking life is sufficient to call up a dream, which emerges as connected and ingenious but usually short, and which is easily recognized as a 'wish-fulfilment'. In the case of adults it seems to be a generally binding condition that the wish which creates the dream shall be one that is alien to conscious thinking - a repressed wish - or will possibly at least have reinforcements that are unknown to consciousness. Without assuming the existence of the unconscious in the sense explained above, I should not be able to develop the theory of dreams further or to interpret the material met with in dream-analyses. The action of this unconscious wish upon the consciously rational material of the dream-thoughts produces the dream. While this happens, the dream is, as it were, dragged down into the unconscious, or, more precisely, is submitted to a treatment such as is met with at the level of unconscious thought-processes and is characteristic of that level. Hitherto it is only from the results of the 'dream-work' that we are in fact acquainted with the characteristics of unconscious thinking and its differences from thinking that is capable of becoming conscious - 'preconscious' thinking.

[1905c, 1746]
The dream-work, then - to which I return after this digression - submits the thought-material, which is brought forward in the optative mood, to a most strange revision. First, it takes the step from the optative to the present indicative; it replaces 'Oh! if only . . .' by 'It is'. The 'It is' is then given a hallucinatory representation; and this I have called the 'regression' in the dream-work - the path that leads from thoughts to perceptual images, or, to use the terminology of the still unknown topography of the mental apparatus (which is not to be taken anatomically), from the region of thought-structures to that of sensory perceptions. On this path, which is in the reverse direction to that taken by the course of development of mental complications, the dream-thoughts are given a pictorial character; and eventually a plastic situation is arrived at which is the core of the manifest 'dream-picture'. In order for it to be possible for the dream-thoughts to be represented in sensory form, their expression has to undergo far-reaching modifications. But while the thoughts are being changed back into sensory images still further alterations occur in them, some of which can be seen to be necessary while others are surprising. We can understand that, as a subsidiary result of regression, almost all the internal relations between the thoughts which linked them together will be lost in the manifest dream. The dream-work, as we might say, only undertakes to represent the raw material of the ideas and not the logical relations in which they stand to one another; or at all events it reserves the liberty to disregard the latter. On the other hand, there is another part of the dream-work which we cannot attribute to regression, to the change back into sensory images; and it is precisely this part which has an important bearing on our analogy with the formation of jokes. In the course of the dream-work the material of the dream-thoughts is subjected to a quite extraordinary compression or condensation. A starting point for it is provided by any common elements that may be present in the dream-thoughts, whether by chance or from the nature of their content. Since these are not as a rule sufficient for any considerable condensation, new artificial and transient common elements are created in the dream-work, and to this end there is actually a preference for the use of words the sound of which expresses different meanings. The newly-created common elements of condensation enter the manifest content of the dream as representatives of the dream-thoughts, so that an element in the dream corresponds to a nodal point or junction in the dream-thoughts, and, as compared with these latter, must quite generally be described as 'overdetermined'. The fact of condensation is the piece of the dream-work which can be most easily recognized; it is only necessary to compare the text of a dream as it is noted down with the record of the dream-thoughts arrived at by analysis in order to get a good impression of the extensiveness of dream-condensation.

[1905c, 1748]
Transformation with a view to the possibility of representation, condensation and displacement are the three major achievements that may be ascribed to the dream-work. A fourth, which was perhaps too shortly considered in *The Interpretation of Dreams*, is not relevant for our present purposes. If the ideas of a 'topography of the mental apparatus' and of 'regression' are consistently followed up (and only in that way could these working hypotheses come to have any value), we must attempt to determine the stages of regression at which the various transformations of the dream-thoughts take place. This attempt has not yet been seriously undertaken; but it can at least be stated with certainty that displacement must take place in the thought-material while it is at the stage of the unconscious processes, while condensation must probably be pictured as a process stretching over the whole course of events till the perceptual region is reached. But in general we must be content to assume that all the forces which take part in the formation of dreams operate simultaneously. Though one must, as will be realized, exercise reserve in dealing with such problems, and though there are fundamental doubts, which cannot be entered into here, as to whether the question should be framed in this manner, yet I should like to venture on the assertion that the process of the dream-work preparatory to the dream must be located in the region of the unconscious. Thus, speaking roughly, there would in all be three stages to be distinguished in the formation of a dream: first, the transplanting of the preconscious day's residues into the unconscious, in which the conditions governing the state of sleep must play a part; then, the dream-work proper in the unconscious; and thirdly, the regression of the dream-material, thus revised, to perception, in which form the dream becomes conscious.

[1905c, 1749]

The following forces may be recognized as having a share in the formation of dreams: the wish to sleep, the cathectic energy that still remains in the day's residues after it has been lowered by the state of sleep, the psychic energy of the dream-constructing unconscious wish and the opposing force of the 'censorship', which dominates daytime life and is not completely lifted during sleep. The task of dream-formation is above all to overcome the inhibition from the censorship; and it is precisely this task which is solved by the displacements of psychic energy within the material of the dream-thoughts.

[1905c, 1750]

Let us now recall what it was during our investigation of jokes that gave us occasion to think of dreams. We found that the characteristics and effects of jokes are linked with certain forms of expression or technical methods, among which the most striking are condensation, displacement and indirect representation. Processes, however, which lead to the same results - condensation, displacement and indirect representation - have become known to us as peculiarities of the dream-work. Does not this agreement suggest the conclusion that joke-work and dream-work must, at least in some essential respect, be identical? The dream-work has, I think, been revealed to us as regards its most important characteristics. Of the psychical processes in jokes the part that is hidden from us is precisely the one that may be compared to the dream-work - namely, what happens during the formation of a joke in the first person. Shall we not yield to the temptation to construct that process on the analogy of the formation of a dream? A few of the characteristics of dreams are so alien to jokes that the part of the dream-work corresponding to those characteristics cannot be transferred to the formation of jokes. There is no doubt that the regression of the train of thought to perception is absent in jokes. But the other two stages of dream-formation, the sinking of a preconscious thought into the unconscious and its unconscious revision, if they could be supposed to occur in joke-formation, would present the precise outcome that we can observe in jokes. Let us decide, then, to adopt the hypothesis that this is the way in which jokes are formed in the first person: a preconscious thought is given over for a moment to unconscious revision and the outcome of this is at once grasped by conscious perception.

[1905c, 1750]
Apart from the dream-work and the technique of jokes, there is another kind of mental event in which I have been able to show that condensation is a regular and important process: namely the mechanism of normal (non-tendentious) forgetting. Unique impressions offer difficulties to forgetting; those that are analogous in any way are forgotten by being condensed in regard to their points of resemblance. Confusion between analogous impressions is one of the preliminary stages of forgetting.

We have entered so closely, in connection with the processes of condensation, into the importance of the analogy between jokes and dreams that we may be briefer in what follows. As we know, the displacements in the dream-work point to the operation of the censorship of conscious thinking, and accordingly, when we come across displacement among the techniques of jokes, we shall be inclined to suppose that an inhibitory force plays a part in the formation of jokes as well. And we already know that this is quite generally the case. The effort made by jokes to recover the old pleasure in nonsense or the old pleasure in words finds itself inhibited in normal moods by objections raised by critical reason; and in every individual case this has to be overcome. But the manner in which the joke-work accomplishes this task shows a sweeping distinction between jokes and dreams. In the dream-work it is habitually accomplished by displacements, by the selection of ideas which are sufficiently remote from the objectionable one for the censorship to allow them to pass, but which are nevertheless derivatives of that idea and have taken over its psychical cathexis by means of a complete transference. For this reason displacements are never absent in a dream and are far more comprehensive.

The abundant and unrestrained use in the dream-work of indirect representation, of displacements, and especially of allusions, has a result which I mention not for its own importance but because it became my subjective reason for taking up the problem of jokes. If one gives an account to an uninformed or unaccustomed person of a dream-analysis, in which are set out, therefore, the strange processes of allusions and displacements - processes so obnoxious to waking life - of which the dream-work has made use, the reader receives an uncomfortable impression and declares that these interpretations are 'in the nature of a joke'. But he clearly does not regard them as successful jokes, but as forced, and in some way violating the rules of jokes. It is easy to explain this impression. It arises from the fact that the dream-work operates by the same methods as jokes, but in its use of them it transgresses the limits that are respected by jokes. We shall presently learn that, as a result of the part played by the third person, jokes are bound by a certain condition which does not apply to dreams.

But let us now consider the case in which a thought, not worthless in itself, arises in the course of a train of thought and is expressed as a joke. In order to enable this thought to be turned into a joke, it is clearly necessary to select from among the possible forms of expression the precise one which brings along with it a yield of verbal pleasure. We know from self-observation that this selection is not made by conscious attention; but it will certainly help the selection if the cathexis of the preconscious thought is reduced to an unconscious one, for, as we have learnt from the dream-work, the connecting paths which start out from words are in the unconscious treated in the same way as connections between things. An unconscious cathexis offers far more favourable conditions for selecting the expression. Moreover, we can immediately assume that the possible form of expression that involves a yield of verbal pleasure exercises the same downward drag on the still unsettled wording of the preconscious thought as did the unconscious purpose in the earlier case. To meet the simpler case of the jest, we may suppose that an intention which is all the time on the look-out to achieve a yield of verbal pleasure grasps the occasion offered in the preconscious for dragging the cathetic process down into the unconscious according to the familiar pattern.
Are we to venture on an attempt at interpreting this dream too - that is, at replacing it by the latent thoughts from whose distortion it must have arisen? It is as senseless as only a dream can be expected to be; and this absurdity of dreams is the mainstay of the view which refuses to characterize dreams as completely valid psychical acts and maintains that they arise out of a purposeless excitation of the elements of the mind.

But the distinction between foreconscious and unconscious activity, and the recognition of the barrier which keeps them asunder, is not the last or the most important result of the psycho-analytic investigation of psychical life. There is one psychical product to be met with in the most normal persons, which yet presents a very striking analogy to the wildest productions of insanity, and was no more intelligible to philosophers than insanity itself. I refer to dreams. Psycho-analysis is founded upon the analysis of dreams; the interpretation of dreams is the most complete piece of work the young science has done up to the present. One of the most common types of dream-formation may be described as follows: a train of thoughts has been aroused by the working of the mind in the daytime, and retained some of its activity, escaping from the general inhibition of interests which introduces sleep and constitutes the psychical preparation for sleeping. During the night this train of thoughts succeeds in finding connections with one of the unconscious tendencies present ever since his childhood in the mind of the dreamer, but ordinarily repressed and excluded from his conscious life. By the borrowed force of this unconscious help, the thoughts, the residue of the day's work, now become active again, and emerge into consciousness in the shape of the dream. Now three things have happened:

The present state of our knowledge leads us to conclude that the essential factor in the construction of dreams is an unconscious wish - as a rule an infantile wish, now repressed - which can come to expression in this somatic or psychical material (in the day's residues too, therefore) and can thus supply these with a force which enables them to press their way through to consciousness even during the suspension of thought at night. The dream is in every case a fulfilment of this unconscious wish, whatever else it may contain - warning, reflection, admission, or any other part of the rich content of preconscious waking life that has persisted undealt-with into the night. It is this unconscious wish that gives the dream-work its peculiar character as an unconscious revision of preconscious material. A psycho-analyst can characterize as dreams only the products of the dream-work: in spite of the fact that the latent dream-thoughts are only arrived at from the interpretation of the dream, he cannot reckon them as part of the dream, but only as part of preconscious reflection. (Secondary revision by the conscious agency is here reckoned as part of the dream-work. Even if one were to separate it, this would not involve any alteration in our conception. We should then have to say: dreams in the analytic sense comprise the dream-work proper together with the secondary revision of its products.) The conclusion to be drawn from these considerations is that one cannot put the wish-fulfilling character of dreams on a par with their character as warnings, admissions, attempts at solution, etc., without denying the concept of a psychical dimension of depth - that is to say, without denying the standpoint of psycho-analysis.
I have said that animism is a system of thought, the first complete theory of the universe, and I shall now go on to draw certain conclusions from the psycho-analytic view of such systems. Every day of our lives our experience is in a position to show us the principal characteristics of a 'system'. We have dreams during the night and we have learnt how to interpret them during the day. Dreams may, without contradicting their nature, appear confused and disconnected. But they may, on the contrary, simulate the orderly impressions of a real experience, they may make one event follow from another and make one portion of their content refer to another. Such a result can be more or less successfully achieved; but it scarcely ever succeeds so completely as to leave no absurdity, no rift in its texture, visible. When we come to submit a dream to interpretation, we find that the erratic and irregular arrangement of its constituent parts is quite unimportant from the point of view of our understanding it. The essential elements in a dream are the dream-thoughts, and these have meaning, connection and order. But their order is quite other than that remembered by us as present in the manifest dream. In the latter the connection between the dream-thoughts has been abandoned and may either remain completely lost or be replaced by the new connection exhibited in the manifest content. The elements of the dream, apart from their being condensed, are almost invariably arranged in a new order more or less independent of their earlier arrangement. Finally, it must be added that whatever the original material of the dream-thoughts has been turned into by the dream-work is then subjected to a further influence. This is what is known as 'secondary revision', and its purpose is evidently to get rid of the disconnectedness and unintelligibility produced by the dream-work and replace it by a new 'meaning'. But this new meaning, arrived at by secondary revision, is no longer the meaning of the dream-thoughts.

Let us now return to the animistic system with which we are dealing. The insight we have gained into other psychological systems enables us to conclude that with primitive man, too, 'superstition' need not be the only or the real reason for some particular custom or observance and does not excuse us from the duty of searching for its hidden motives. Under the domination of an animistic system it is inevitable that every observance and every activity shall have a systematic basis, which nowadays we describe as 'superstitious'. 'Superstition' - like 'anxiety', 'dreams' and 'demons' - is one of those provisional psychological concepts which have crumbled under the impact of psycho-analytic research. Once we have penetrated behind these constructions, which are like screens erected as defences against correct understanding, we begin to realize that the mental life and cultural level of savages have not hitherto had all the recognition they deserve.

The dream-work is a psychological process the like of which has hitherto been unknown to psychology. It has claims upon our interest in two main directions. In the first place, it brings to our notice novel processes such as 'condensation' (of ideas) and 'displacement' (of psychical emphasis from one idea to another), processes which we have never come across at all in our waking life, or only as the basis of what are known as 'errors in thought'. In the second place, it enables us to detect the operation in the mind of a play of forces which was concealed from our conscious perception. We find that there is a 'censorship', a testing agency, at work in us, which decides whether an idea cropping up in the mind shall be allowed to reach consciousness, and which, so far as lies within its power, ruthlessly excludes anything that might produce or revive unpleasure. And it will be recalled at this point that in our analysis of parapraxes we found traces of this same intention to avoid unpleasure in remembering things and of similar conflicts between mental impulses.
These two observations, then, argue in favour of what we have called hypochondriacal speech or 'organ-speech'. But, what seems to us more important, they also point to something else, of which we have innumerable instances (for example, in the cases collected in Bleuler’s monograph) and which may be reduced to a definite formula. In schizophrenia words are subjected to the same process as that which makes the dream images out of latent dream-thoughts - to what we have called the primary psychical process. They undergo condensation, and by means of displacement transfer their cathexes to one another in their entirety. The process may go so far that a single word, if it is specially suitable on account of its numerous connections, takes over the representation of a whole train of thought. The works of Bleuler, Jung and their pupils offer a quantity of material which particularly supports this assertion.¹

A restrictive modification of this kind is, as we shall discover later, necessary in the theory of dementia praecox as well. This must be to the effect that the repressed portion of the system Ucs. does not comply with the wish to sleep that comes from the ego, that it retains its cathexis in whole or in part, and that in general, in consequence of repression, it has acquired a certain measure of independence of the ego. Accordingly, too, some amount of the expenditure on repression (anticathexis) would have to be maintained throughout the night, in order to meet the instinctual danger - though the inaccessible of all paths leading to a release of affect and to motility may considerably diminish the height of the anticathexis that is necessary. Thus we should picture the situation which leads to the formation of dreams as follows. The wish to sleep endeavours to draw in all the cathexes sent out by the ego and to establish an absolute narcissism. This can only partly succeed, for what is repressed in the system Ucs. does not obey the wish to sleep. A part of the anticathexes has therefore to be maintained, and the censorship between the Ucs. and the Pcs. must remain, even if not at its full strength. So far as the dominance of the ego extends, all the systems are emptied of cathexes. The stronger the Ucs. instinctual cathexes are, the more unstable is sleep. We are acquainted, too, with the extreme case where the ego gives up the wish to sleep, because it feels unable to inhibit the repressed impulses set free during sleep - in other words, where it renounces sleep because of its fear of its dreams.

The possibility mentioned above - that some of the preconscious thoughts of the day may also prove resistant and retain a part of their cathexis - must be recognized as a second breach in narcissism. At bottom, the two cases may be identical. The resistance of the day's residues may originate in a link with unconscious impulses which is already in existence during waking life; or the process may be somewhat less simple, and the day's residues which have not been wholly emptied of cathexis may establish a connection with the repressed material only after the state of sleep has set in, thanks to the easing of communication between the Pcs. and the Ucs. In both cases there follows the same decisive step in dream-formation: the preconscious dream-wish is formed, which gives expression to the unconscious impulse in the material of the preconscious day's residues. This dream-wish must be sharply distinguished from the day's residues; it need not have existed in waking life and it may already display the irrational character possessed by everything that is unconscious when we translate it into the conscious. Again, the dream-wish must not be confused with the wishful impulses which may have been present, though they certainly need not necessarily be present, amongst the preconscious (latent) dream-thoughts. If, however, there were any such preconscious wishes, the dream-wish associates itself with them, as a most effective reinforcement of them.

¹[1915e, 3021]

[1917d, 3030]

[1917d, 3031]
We have now to consider the further vicissitudes undergone by this wishful impulse, which in its essence represents an unconscious instinctual demand and which has been formed in the *Pcs.* as a dream-wish (a wish-fulfilling phantasy). Reflection tells us that this wishful impulse may be dealt with along three different paths. It may follow the path that would be normal in waking life, by pressing from the *Pcs.* to consciousness; or it may bypass the *Cs.* and find direct motor discharge; or it may take the unexpected path which observation enables us in fact to trace. In the first case, it would become a *delusion* having as content the fulfilment of the wish; but in the state of sleep this never happens. With our scanty knowledge of the metapsychological conditions of mental processes, we may perhaps take this fact as a hint that a complete emptying of a system renders it little susceptible to instigation. The second case, that of direct motor discharge, should be excluded by the same principle; for access to motility normally lies yet another step beyond the censorship of consciousness. But we do meet with exceptional instances in which this happens, in the form of somnambulism. We do not know what conditions make this possible, or why it does not happen more often. What actually happens in dream-formation is a very remarkable and quite unforeseen turn of events. The process, begun in the *Pcs.* and reinforced by the *Ucs.*, pursues a backward course, through the *Ucs.* to perception, which is pressing upon consciousness. This *regression* is the third phase of dream-formation. For the sake of clarity, we will repeat the two earlier ones: the reinforcement of the *Pcs.* by the *Ucs.*, and the setting up of the dream-wish.

We call this kind of regression a *topographical* one, to distinguish it from the previously mentioned *temporal* or developmental regression. The two do not necessarily always coincide, but they do so in the particular example before us. The reversal of the course of the excitation from the *Pcs.* through the *Ucs.* to perception is at the same time a return to the early stage of hallucinatory wish-fulfilment.

Now it is in this respect that the essential difference between the dream-work and schizophrenia becomes clear. In the latter, what becomes the subject of modification by the primary process are the words themselves in which the preconscious thought was expressed; in dreams, what are subject to this modification are not the words, but the thing-presentations to which the words have been taken back. In dreams there is a topographical regression; in schizophrenia there is not. In dreams there is free communication between (*Pcs.*) word-cathexes and (*Ucs.*) thing-cathexes, while it is characteristic of schizophrenia that this communication is cut off. The impression this difference makes on one is lessened precisely by the dream-interpretations we carry out in psycho-analytic practice. For, owing to the fact that dream-interpretation traces the course taken by the dream-work, follows the paths which lead from the latent thoughts to the dream-elements, reveals the way in which verbal ambiguities have been exploited, and points out the verbal bridges between different groups of material - owing to all this, we get an impression now of a joke, now of schizophrenia, and are apt to forget that for a dream all operations with words are no more than a preparation for a regression to things.

The completion of the dream-process consists in the thought-content - regressively transformed and worked over into a wishful phantasy - becoming conscious as a sense-perception; while this is happening it undergoes secondary revision, to which every perceptual concept is subject. The dream-wish, as we say, is *hallucinated*, and, as a hallucination, meets with belief in the reality of its fulfilment. It is precisely round this concluding piece in the formation of dreams that the gravest uncertainties centre, and it is in order to clear them up that we are proposing to compare dreams with pathological states akin to them.
The formation of the wishful phantasy and its regression to hallucination are the most essential parts of the dream-work, but they do not belong exclusively to dreams. They are also found in two morbid states: in acute hallucinatory confusion (Meynert's 'amentia'), and in the hallucinatory phase of schizophrenia. The hallucinatory delirium of amentia is a clearly recognizable wishful phantasy, often completely well ordered like a perfect day-dream. One might speak quite generally of a 'hallucinatory wishful psychosis', and attribute it equally to dreams and amentia. There are even dreams which consist of nothing but undistorted wishful phantasies with a very rich content. The hallucinatory phase of schizophrenia has been less thoroughly studied; it seems as a rule to be of a composite nature, but in its essence it might well correspond to a fresh attempt at restitution, designed to restore a libidinal cathexis to the ideas of objects.¹ I cannot extend the comparison to the other hallucinatory states in various pathological disorders, because in their case I have no experience of my own upon which to draw, and cannot utilize that of other observers.

The first achievement of the dream-work is condensation. By that we understand the fact that the manifest dream has a smaller content than the latent one, and is thus an abbreviated translation of it. Condensation can on occasion be absent; as a rule it is present, and very often it is enormous. It is never changed into the reverse; that is to say, we never find that the manifest dream is greater in extent or content than the latent one. Condensation is brought about (1) by the total omission of certain latent elements, (2) by only a fragment of some complexes in the latent dream passing over into the manifest one and (3) by latent elements which have something in common being combined and fused into a single unity in the manifest dream.

If you prefer it, we can reserve the term 'condensation' for the last only of these processes. Its results are particularly easy to demonstrate. You will have no difficulty in recalling instances from your own dreams of different people being condensed into a single one. A composite figure of this kind may look like A perhaps, but may be dressed like B, may do something that we remember C doing, and at the same time we may know that he is D. This composite structure is of course emphasizing something that the four people have in common. It is possible, naturally, to make a composite structure out of things or places in the same way as out of people, provided that the various things and places have in common something which is emphasized by the latent dream. The process is like constructing a new and transitory concept which has this common element as its nucleus. The outcome of this superimposing of the separate elements that have been condensed together is as a rule a blurred and vague image, like what happens if you take several photographs on the same plate.
The production of composite structures like these must be of great importance to the dream-work, since we can show that, where in the first instance the common elements necessary for them were missing, they are deliberately introduced - for instance, through the choice of the words by which a thought is expressed. We have already come across condensations and composite structures of this sort. They played a part in the production of some slips of the tongue. You will recall the young man who offered to ‘begleitdigen’ (‘begleiten (accompany)’ + ‘beleidigen (insult)’) a lady. Moreover, there are jokes of which the technique is based on a condensation like this. But apart from these cases, it may be said that the process is something quite unusual and strange. It is true that counterparts to the construction of these composite figures are to be found in some creations of our imagination, which is ready to combine into a unity components of things that do not belong together in our experience - in the centaurs, for instance, and the fabulous beasts which appear in ancient mythology or in Böcklin’s pictures. The ‘creative’ imagination, indeed, is quite incapable of inventing anything; it can only combine components that are strange to one another. But the remarkable thing about the procedure of the dream-work lies in what follows. The material offered to the dream-work consists of thoughts - a few of which may be objectionable and unacceptable, but which are correctly constructed and expressed. The dream-work puts these thoughts into another form, and it is a strange and incomprehensible fact that in making this translation (this rendering, as it were, into another script or language) these methods of merging or combining are brought into use. After all, a translation normally endeavours to preserve the distinctions made in the text and particularly to keep things that are similar separate. The dream-work, quite the contrary, tries to condense two different thoughts by seeking out (like a joke) an ambiguous word in which the two thoughts may come together. We need not try to understand this feature all at once, but it may become important for our appreciation of the dream-work.

But although condensation makes dreams obscure, it does not give one the impression of being an effect of the dream-censorship. It seems traceable rather to some mechanical or economic factor, but in any case the censorship profits by it.

The achievements of condensation can be quite extraordinary. It is sometimes possible by its help to combine two quite different latent trains of thought into one manifest dream, so that one can arrive at what appears to be a sufficient interpretation of a dream and yet in doing so can fail to notice a possible ‘over-interpretation’.

Thus the dream-work carries out a very unusual kind of transcription of the dream-thoughts: it is not a word-for-word or a sign-for-sign translation; nor is it a selection made according to fixed rules - as though one were to reproduce only the consonants in a word and to leave out the vowels; nor is it what might be described as a representative selection - one element being invariably chosen to take the place of several; it is something different and far more complicated.

The second achievement of the dream-work is displacement. Fortunately we have made some preliminary examination of this: for we know that it is entirely the work of the dream censorship. It manifests itself in two ways: in the first, a latent element is replaced not by a component part of itself but by something more remote - that is, by an allusion; and in the second, the psychical accent is shifted from an important element on to another which is unimportant, so that the dream appears differently centred and strange.
Replacing something by an allusion to it is a process familiar in our waking thought as well, but there is a difference. In waking thought the allusion must be easily intelligible, and the substitute must be related in its subject-matter to the genuine thing it stands for. Jokes, too, often make use of allusion. They drop the precondition of there being an association in subject matter, and replace it by unusual external associations such as similarity of sound, verbal ambiguity, and so on. But they retain the precondition of intelligibility: a joke would lose all its efficiency if the path back from the allusion to the genuine thing could not be followed easily. The allusions employed for displacement in dreams have set themselves free from both of these restrictions. They are connected with the element they replace by the most external and remote relations and are therefore unintelligible; and when they are undone, their interpretation gives the impression of being a bad joke or of an arbitrary and forced explanation dragged in by the hair of its head. For the dream-censorship only gains its end if it succeeds in making it impossible to find the path back from the allusion to the genuine thing.

The third achievement of the dream-work is psychologically the most interesting. It consists in transforming thoughts into visual images. Let us keep it clear that this transformation does not affect everything in the dream-thoughts; some of them retain their form and appear as thoughts or knowledge in the manifest dream as well; nor are visual images the only form into which thoughts are transformed. Nevertheless they comprise the essence of the formation of dreams; this part of the dream-work is, as we already know, the second most regular one, and we have already made the acquaintance of the 'plastic' representation of words in the case of individual dream-elements.

It is clear that this achievement is not an easy one. To form some idea of its difficulties, let us suppose that you have undertaken the task of replacing a political leading article in a newspaper by a series of illustrations. You will thus have been thrown back from alphabetic writing to picture writing. In so far as the article mentioned people and concrete objects you will replace them easily and perhaps even advantageously by pictures; but your difficulties will begin when you come to the representation of abstract words and of all those parts of speech which indicate relations between thoughts - such as particles, conjunctions and so on. In the case of abstract words you will be able to help yourselves out by means of a variety of devices. For instance, you will endeavour to give the text of the article a different wording, which may perhaps sound less usual but which will contain more components that are concrete and capable of being represented. You will then recall that most abstract words are 'watered-down' concrete ones, and you will for that reason hark back as often as possible to the original concrete meaning of such words. Thus you will be pleased to find that you can represent the 'possession' of an object by a real, physical sitting down on it.¹ And the dream-work does just the same thing. In such circumstances you will scarcely be able to expect very great accuracy from your representation: similarly, you will forgive the dream-work for replacing an element so hard to put into pictures as, for example, 'adultery' ['Ehebruch', literally, 'breach of marriage'], by another breach - a broken leg ['Beinbruch'].² And in this way you will succeed to some extent in compensating for the clumsiness of the picture writing that is supposed to take the place of the alphabetic script.
For representing the parts of speech which indicate relations between thoughts - 'because', 'therefore', 'however', etc. - you will have no similar aids at your disposal; those constituents of the text will be lost so far as translation into pictures goes. In the same way, the dream-work reduces the content of the dream-thoughts to its raw material of objects and activities. You will feel pleased if there is a possibility of in some way hinting, through the subtler details of the pictures, at certain relations not in themselves capable of being represented. And just so does the dream-work succeed in expressing some of the content of the latent dream-thoughts by peculiarities in the form of the manifest dream-by its clarity or obscurity, by its division into several pieces, and so on. The number of part dreams into which a dream is divided usually corresponds to the number of main topics or groups of thoughts in the latent dream. A short introductory dream will often stand in the relation of a prelude to a following, more detailed, main dream or may give the motive for it; a subordinate clause in the dream-thoughts will be replaced by the interpolation of a change of scene into the manifest dream, and so on. Thus the form of dreams is far from being without significance and itself calls for interpretation. When several dreams occur during the same night, they often have the same meaning and indicate that an attempt is being made to deal more and more efficiently with a stimulus of increasing insistence. In individual dreams a particularly difficult element may be represented by several symbols - by 'doublets'.

Among the most surprising findings is the way in which the dream-work treats contraries that occur in the latent dream. We know already that conformities in the latent material are replaced by condensations in the manifest dream. Well, contraries are treated in the same way as conformities, and there is a special preference for expressing them by the same manifest element. Thus an element in the manifest dream which is capable of having a contrary may equally well be expressing either itself or its contrary or both together: only the sense can decide which translation is to be chosen. This connects with the further fact that a representation of 'no' - or at any rate an unambiguous one - is not to be found in dreams.

Reversals like this, which occur here with individual words, take place in various ways in the dream-work. We already know reversal of meaning, replacement of something by its opposite. Besides this we find in dreams reversals of situation, of the relation between two people - a 'topsy-turvy' world. Quite often in dreams it is the hare that shoots the sportsman. Or again we find a reversal in the order of events, so that what precedes an event causally comes after it in the dream - like a theatrical production by a third-rate touring company, in which the hero falls down dead and the shot that killed him is not fired in the wings till afterwards. Or there are dreams where the whole order of the elements is reversed, so that to make sense in interpreting it we must take the last one first and the first one last. You will remember too from our study of dream symbolism that going or falling into the water means the same as coming out of it - that is, giving birth or being born, and that climbing up a staircase or a ladder is the same thing as coming down it. It is not hard to see the advantage that dream-distortion can derive from this freedom of representation.
And now a few more considerations. In the case of the dream-work it is clearly a matter of transforming the latent thoughts which are expressed in words into sensory images, mostly of a visual sort. Now our thoughts originally arose from sensory images of that kind: their first material and their preliminary stages were sense impressions, or, more properly, mnemonic images of such impressions. Only later were words attached to them and the words in turn linked up into thoughts. The dream-work thus submits thoughts to a regressive treatment and undoes their development; and in the course of the regression everything has to be dropped that had been added as a new acquisition in the course of the development of the mnemic images into thoughts.

[1916-1917, 3271]

On the other hand, we must not over-estimate the dream-work and attribute too much to it. The achievements I have enumerated exhaust its activity; it can do no more than condense, displace, represent in plastic form and subject the whole to a secondary revision. What appear in the dream as expressions of judgement, of criticism, of astonishment or of inference - none of these are achievements of the dream-work and they are very rarely expressions of afterthoughts of the dream; they are for the most part portions of the latent dream-thoughts which have passed over into the manifest dream with a greater or less amount of modification and adaptation to the context. Nor can the dream-work compose speeches. With a few assignable exceptions, speeches in dreams are copies and combinations of speeches which one has heard or spoken oneself on the day before the dream and which have been included in the latent thoughts either as material or as the instigator of the dream. The dream-work is equally unable to carry out calculations. Such of them as appear in the manifest dream are mostly combinations of numbers, sham calculations which are quite senseless quà calculations and are once again only copies of calculations in the latent dream-thoughts. In these circumstances it is not to be wondered at that the interest which had turned to the dream-work soon tends to move away from it to the latent dream-thoughts, which are revealed, distorted to a greater or less degree, by the manifest dream. But there is no justification for carrying this shift of interest so far that, in looking at the matter theoretically, one replaces the dream entirely by the latent dream-thoughts and makes some assertion about the former which only applies to the latter. It is strange that the findings of psycho-analysis could be misused to bring about this confusion. One cannot give the name of 'dream' to anything other than the product of the dream-work - that is to say, the form into which the latent thoughts have been transmuted by the dream-work.

[1916-1917, 3273]

The dream-work is a process of quite a singular kind, of which the like has not yet become known in mental life. Condensations, displacements, regressive transformations of thoughts into images - such things are novelties whose discovery has already richly rewarded the labours of psycho-analysis. And you can see once more, from the parallels to the dream-work, the connections which have been revealed between psycho-analytic studies and other fields - especially those concerned in the development of speech and thought. You will only be able to form an idea of the further significance of these discoveries when you learn that the mechanism of dream-construction is the model of the manner in which neurotic symptoms arise.

[1916-1917, 3274]

You can see now how this incomprehensible dream came about. It was done by producing a strange and misleading condensation, by disregarding all the thoughts that were in the centre of the latent thought-process and by creating ambiguous substitutes for the deepest and chronologically most remote of those thoughts.

[1916-1917, 3281]
As the outcome of our whole enquiry, let us grasp two discoveries, though they only signify the beginning of fresh enigmas and fresh doubts. First, the regression of the dream-work is not only a formal but also a material one. It not only translates our thoughts into a primitive form of expression; but it also revives the characteristics of our primitive mental life - the old dominance of the ego, the initial impulses of our sexual life, and even, indeed, our old intellectual endowment, if symbolic connections may be regarded as such. And secondly, all this, which is old and infantile and was once dominant and alone dominant, must to-day be ascribed to the unconscious, our ideas of which are now becoming altered and extended. 'Unconscious' is no longer the name of what is latent at the moment; the unconscious is a particular realm of the mind with its own wishful impulses, its own mode of expression and its peculiar mental mechanisms which are not in force elsewhere. But the latent dream-thoughts which we have discovered by interpreting dreams do not belong to this realm; they are on the contrary thoughts just as we might have thought them in waking life. Nevertheless, they are unconscious. How, then, is this contradiction to be solved? We begin to suspect that a distinction is to be drawn here. Something which is derived from our conscious life and shares its characteristics - we call it 'the day's residues' - combines with something else coming from the realm of the unconscious in order to construct a dream. The dream-work is accomplished between these two components. The influence exercised upon the day's residues by the addition of the unconscious is no doubt among the determinants of regression. This is the deepest insight that we can reach here into the essential nature of dreams - until we have investigated further regions of the mind. But the time will soon have come to provide another name for the unconscious character of the latent dream-thoughts in order to distinguish it from the unconscious which comes from the realm of the infantile.

[1916-1917, 3299]

You will not be able to escape the resemblance of this example to a joke; and it has in fact often happened that a joke of the dreamer's has been regarded as a joke of the interpreter's. There are other instances in which it has been far from easy to decide whether what we are dealing with is a joke or a dream. But you will recall that the same doubt arose in the case of some parapraxes - slips of the tongue. A man reported as a dream of his that his uncle had given him a kiss while they were sitting in his auto (mobile). He himself very quickly added the interpretation: it meant 'auto-erotism' (a term from the theory of the libido, indicating satisfaction obtained without any outside object). Had the man set out, then, to have some fun with us and was he passing off a joke that had occurred to him as a dream? I think not; I believe he really dreamt it. But what is the origin of this puzzling similarity? This question once led me temporarily aside from my path by compelling me to make jokes themselves the subject of a detailed investigation. It was there shown how jokes originate: a preconscious train of thought is abandoned for a moment to be worked over in the unconscious, and from this it emerges as a joke. Under the influence of the unconscious it is subjected to the effects of the mechanisms that hold sway there - condensation and displacement - the same processes that we have found concerned in the dream-work; and it is to this common feature that is to be ascribed the similarity, when it occurs, between jokes and dreams. But the unintended 'dream-joke' brings none of the yield of pleasure of a true joke. You can learn why if you go more deeply into the study of jokes. A 'dream-joke' strikes us as a bad joke; it does not make us laugh, it leaves us cold.

[1916-1917, 3321]
The path to perversion branches off sharply from that to neurosis. If these regressions rouse no objection from the ego, no neurosis will come about either; and the libido will arrive at some real, even though no longer normal, satisfaction. But if the ego, which has under its control not only consciousness but also the approaches to motor innervation and accordingly to the realization of mental desires, does not agree with these regressions, conflict will follow. The libido is, as it were, cut off and must try to escape in some direction where, in accordance with the requirements of the pleasure principle, it can find a discharge for its cathexis of energy. It must withdraw from the ego. An escape of this kind is offered it by the fixations on the path of its development which it has now entered on regressively - fixations from which the ego had protected itself in the past by repressions. By cathecting these repressed positions as it flows backward, the libido has withdrawn from the ego and its laws, and has at the same time renounced all the education it has acquired under the ego's influence. It was docile so long as satisfaction beckoned to it; but under the double pressure of external and internal frustration it becomes refractory, and recalls earlier and better times. Such is the libido's fundamentally unchangeable character. The ideas to which it now transfers its energy as a cathexis belong to the system of the unconscious and are subject to the processes which are possible there, particularly to condensation and displacement. In this way conditions are established which completely resemble those in dream-construction. The dream proper, which has been completed in the unconscious and is the fulfilment of an unconscious wishful phantasy, is brought up against a portion of (pre)conscious activity which exercises the office of censorship and which, when it has been indemnified, permits the formation of the manifest dream as a compromise. In the same way, what represents the libido in the unconscious has to reckon with the power of the preconscious ego. The opposition which had been raised against it in the ego pursues it as an 'anticathexis' and compels it to choose a form of expression which can at the same time become an expression of the opposition itself. Thus the symptom emerges as a many-times-distorted derivative of the unconscious libidinal wish-fulfilment, an ingeniously chosen piece of ambiguity with two meanings in complete mutual contradiction. In this last respect, however, there is a distinction between the construction of a dream and of a symptom. For in dream-formation the preconscious purpose is merely concerned to preserve sleep, to allow nothing that would disturb it to make its way into consciousness; it does not insist upon calling out sharply 'No! on the contrary!' to the unconscious wishful impulse. It can afford to be more tolerant because the situation of someone sleeping is less perilous. The state of sleep in itself bars any outlet into reality.

[1916-1917, 3418]
It is something else besides that makes symptoms seem strange to us and incomprehensible as a means of libidinal satisfaction. They do not remind us in the very least of anything from which we are in the habit of normally expecting satisfaction. Usually they disregard objects and in so doing abandon their relation to external reality. We can see that this is a consequence of turning away from the reality principle and of returning to the pleasure principle. But it is also a return to a kind of extended auto-erotism, of the sort that offered the sexual instinct its first satisfactions. In place of a change in the external world these substitute a change in the subject's own body: they set an internal act in place of an external one, an adaptation in place of an action - once again, something that corresponds, phylogenetically, to a highly significant regression. We shall only understand this in connection with something new that we have still to learn from the analytic researches into the formation of symptoms. We must further remember that the same processes belonging to the unconscious play a part in the formation of symptoms as in the formation of dreams - namely, condensation and displacement. A symptom, like a dream, represents something as fulfilled: a satisfaction in the infantile manner. But by means of extreme condensation that satisfaction can be compressed into a single sensation or innervation, and by means of extreme displacement it can be restricted to one small detail of the entire libidinal complex. It is not to be wondered at if we, too, often have difficulty in recognizing in a symptom the libidinal satisfaction whose presence we suspect and which is invariably confirmed.

[1916-1917, 3423]

I can imagine that to point out the existence of lying dreams of this kind, 'obliging' dreams, will arouse a positive storm of helpless indignation in some readers who call themselves analysts. 'What!' they will exclaim, 'the unconscious, the real centre of our mental life, the part of us that is so much nearer the divine than our poor consciousness - it too can lie! Then how can we still build on the interpretations of analysis and the accuracy of our findings?' To which one must reply that the recognition of these lying dreams does not constitute any shattering novelty. I know, indeed, that the craving of mankind for mysticism is ineradicable, and that it makes ceaseless efforts to win back for mysticism the territory it has been deprived of by The Interpretation of Dreams, but surely in the case under consideration everything is simple enough. A dream is not the 'unconscious'; it is the form into which a thought left over from preconscious, or even from conscious, waking life, can, thanks to the favouring state of sleep, be recast. In the state of sleep this thought has been reinforced by unconscious wishful impulses and has thus experienced distortion through the dream-work, which is determined by the mechanisms prevailing in the unconscious. With our dreamer, the intention to mislead me, just as she did her father, certainly emanated from the preconscious, and may indeed have been conscious; it could come to expression by entering into connection with the unconscious wishful impulse to please her father (or father-substitute), and in this way it created a lying dream. The two intentions, to betray and to please her father, originated in the same complex; the former resulted from the repression of the latter, and the later one was brought back by the dream-work to the earlier one. There can therefore be no question of any devaluation of the unconscious, nor of a shattering of our confidence in the results of analysis.

[1920a, 3854]
If you prefer to assume that a telepathic message about the daughter's confinement reached the sleeper, further questions arise of the relation of a message such as this to a dream and of its influence on the formation of dreams. The answer is not far to seek and is quite unambiguous. A telepathic message will be treated as a portion of the material that goes to the formation of a dream, like any other external or internal stimulus, like a disturbing noise in the street or an insistent organic sensation in the sleeper's own body. In our example it is evident how the message, with the help of a lurking repressed wish, became remodelled into a wish-fulfilment; it is unfortunately less easy to show that it combined with other material that had become active at the same time and was blended into a dream. Telepathic messages - if we are justified in recognizing their existence - can thus make no alteration in the process of forming a dream; telepathy has nothing to do with the nature of dreams. And in order to avoid the impression that I am trying to conceal a vague notion behind abstract and fine-sounding words, I am willing to repeat: the essential nature of dreams consists in the peculiar process of 'dream-work' which, with the help of an unconscious wish, carries the preconscious thoughts (day's residues) over into the manifest content of the dream. The problem of telepathy concerns dreams as little as does the problem of anxiety.

[1922a, 3887]

I am hoping that you will grant this, but that you will raise the objection that there are, nevertheless, other telepathic dreams in which there is no difference between the event and the dream, and in which there is nothing else to be found but an undistorted reproduction of the event. I have no knowledge of such dreams from my own experience, but I know they have often been reported. If we assume that we have such an undisguised and unadulterated telepathic dream to deal with, another question arises. Ought we to call such a telepathic experience a 'dream' at all? You will certainly do so as long as you keep to popular usage, in which everything that takes place in mental life during sleep is called a dream. You, too, perhaps say, 'I tossed about in my dream', and still less are you conscious of anything incorrect when you say, 'I shed tears in my dream' or 'I felt apprehensive in my dream'. But you will no doubt notice that in all these cases you are using 'dream' and 'sleep' and 'state of being asleep' interchangeably, as if there were no distinction between them. I think it would be in the interests of scientific accuracy to keep 'dream' and 'state of sleep' more distinctly separate. Why should we provide a counterpart to the confusion evoked by Maeder who, by refusing to distinguish between the dream-work and the latent dream-thoughts, has discovered a new function for dreams? Supposing, then, that we are brought face to face with a pure telepathic 'dream', let us rather call it instead a telepathic experience in a state of sleep. A dream without condensation, distortion, dramatization, above all, without wish-fulfilment, surely does not deserve the name. You will remind me that, if so, there are other mental products in sleep to which the right to be called 'dreams' would have to be refused. Actual experiences of the day are sometimes simply repeated in sleep; reproductions of traumatic scenes in 'dreams' have led us only lately to revise the theory of dreams. There are dreams which are to be distinguished from the usual type by certain special qualities, which are, properly speaking, nothing but night-phantasies, not having undergone additions or alterations of any kind and being in all other ways similar to the familiar day-dreams. It would be awkward, no doubt, to exclude these structures from the domain of 'dreams'. But still they all come from within, are products of our mental life, whereas the very conception of the purely 'telepathic dream' lies in its being a perception of something external, in relation to which the mind remains passive and receptive.

[1922a, 3887]
We also describe the latent dream-thoughts, on account of their connection with waking life, as 'residues of the day'. By the operation of the dream-work (to which it would be quite incorrect to ascribe any 'creative' character) the latent dream thoughts are condensed in a remarkable way, are distorted by the displacement of psychical intensities and are arranged with a view to being represented in visual pictures; and, besides all this, before the manifest dream is arrived at, they are submitted to a process of secondary revision which seeks to give the new product something in the nature of sense and coherence. Strictly speaking, this last process does not form a part of the dream-work.

[1923a, 3918]

The Theory of Repression. - These theoretical considerations, taken together with the immediate impressions derived from analytic work, lead to a view of the neuroses which may be described in the roughest outline as follows. The neuroses are the expression of conflicts between the ego and such of the sexual impulses as seem to the ego incompatible with its integrity or with its ethical standards. Since these impulses are not ego-syntonic, the ego has repressed them: that is to say, it has withdrawn its interest from them and has shut them off from becoming conscious as well as from obtaining satisfaction by motor discharge. If in the course of analytic work one attempts to make these repressed impulses conscious, one becomes aware of the repressive forces in the form of resistance. But the achievement of repression fails particularly readily in the case of the sexual instincts. Their dammed-up libido finds other ways out from the unconscious: for it regresses to earlier phases of development and earlier attitudes towards objects, and, at weak points in the libidinal development where there are infantile fixations, it breaks through into consciousness and obtains discharge. What results is a symptom and consequently in its essence a substitutive sexual satisfaction. Nevertheless the symptom cannot entirely escape from the repressive forces of the ego and must therefore submit to modifications and displacements exactly as happens with dreams - by means of which its characteristic of being a sexual satisfaction becomes unrecognizable. Consequently symptoms are in the nature of compromises between the repressed sexual instincts and the repressing ego-instincts; they represent a wish-fulfilment for both partners to the conflict simultaneously, but one which is incomplete for each of them. This is quite strictly true of the symptoms of hysteria, while in the symptoms of obsessional neurosis there is often a stronger emphasis upon the side of the repressing function owing to the erection of reaction-formations, which are assurances against sexual satisfaction.

[1923a, 3923]
In the present discussion, moreover, I am only putting forward a hypothesis; I have no proof to offer. It seems a plausible view that this displaceable and neutral energy, which is no doubt active in both in the ego and in the id, proceeds from the narcissistic store of libido - that it is desexualized Eros. (The erotic instincts appear to be altogether more plastic, more readily diverted and displaced than the destructive instincts.) From this we can easily go on to assume that this displaceable libido is employed in the service of the pleasure principle to obviate blockages and to facilitate discharge. In this connection it is easy to observe a certain indifference as to the path along which the discharge takes place, so long as it takes place somehow. We know this trait; it is characteristic of the cathetic processes in the id. It is found in erotic cathexes, where a peculiar indifference in regard to the object displays itself; and it is especially evident in the transferences arising in analysis, which develop inevitably, irrespective of the persons who are their object. Not long ago Rank published some good examples of the way in which neurotic acts of revenge can be directed against the wrong people. Such behaviour on the part of the unconscious reminds one of the comic story of the three village tailors, one of whom had to be hanged because the only village blacksmith had committed a capital offence. Punishment must be exacted even if it does not fall upon the guilty. It was in studying the dream-work that we first came upon this kind of looseness in the displacements brought about by the primary process. In that case it was the objects that were thus relegated to a position of no more than secondary importance, just as in the case we are now discussing it is the paths of discharge. It would be characteristic of the ego to be more particular about the choice both of an object and of a path of discharge.

[1923b, 3979]

What conclusions can one draw from a correctly translated dream? I have an impression that analytic practice has not always avoided errors and over-estimations on this point, partly owing to an exaggerated respect for the 'mysterious unconscious'. It is only too easy to forget that a dream is as a rule merely a thought like any other, made possible by a relaxation of the censorship and by unconscious reinforcement, and distorted by the operation of the censorship and by unconscious revision.

[1923c, 4033]

There is no difficulty in discovering the general function of dreaming. It serves the purpose of fending off, by a kind of soothing action, external or internal stimuli which would tend to arouse the sleeper, and thus of securing sleep against interruption. External stimuli are fended off by being given a new interpretation and by being woven into some harmless situation; internal stimuli, caused by instinctual demands, are given free play by the sleeper and allowed to find satisfaction in the formation of dreams, so long as the latent dream-thoughts submit to the control of the censorship. But if they threaten to break free and the meaning of the dream becomes too plain, the sleeper cuts short the dream and wakes in a fright. (Dreams of this class are known as anxiety-dreams.) A similar failure in the function of dreaming occurs if an external stimulus becomes too strong to be fended off. (This is the class of arousal-dreams.) I have given the name of dream-work to the process which, with the co-operation of the censorship, converts the latent thoughts into the manifest content of the dream. It consists of a peculiar way of treating the preconscious material of thought, so that its component parts become condensed, its psychical emphasis becomes displaced, and the whole of it is translated into visual images or dramatized, and completed by a deceptive secondary revision. The dream-work is an excellent example of the processes occurring in the deeper, unconscious layers of the mind, which differ considerably from the familiar normal processes of thought. It also displays a number of archaic characteristics, such as the use of a symbolism (in this case of a predominantly sexual kind) which it has since also been possible to discover in other spheres of mental activity.

[1925d, 4220]
In the same way that psycho-analysis makes use of dream-interpretation, it also profits by the study of the numerous little slips and mistakes which people make - symptomatic actions, as they are called. I investigated this subject in a series of papers which were published for the first time in book form in 1904 under the title of *The Psychopathology of Everyday Life*. In this widely circulated work I have pointed out that these phenomena are not accidental, that they require more than physiological explanations, that they have a meaning and can be interpreted, and that one is justified in inferring from them the presence of restrained or repressed impulses and intentions. But what constitutes the enormous importance of dream-interpretation, as well as of this latter study, is not the assistance they give to the work of analysis but another of their attributes. Previously psycho-analysis had only been concerned with solving pathological phenomena and in order to explain them it had often been driven into making assumptions whose comprehensiveness was out of all proportion to the importance of the actual material under consideration. But when it came to dreams, it was no longer dealing with a pathological symptom, but with a phenomenon of normal mental life which might occur in any healthy person. If dreams turned out to be constructed like symptoms, if their explanation required the same assumptions - the repression of impulses, substitutive formation, compromise-formation, the dividing of the conscious and the unconscious into various psychical systems - then psycho-analysis was no longer an auxiliary science in the field of psychopathology, it was rather the starting-point of a new and deeper science of the mind which would be equally indispensable for the understanding of the normal. Its postulates and findings could be carried over to other regions of mental happening; a path lay open to it that led far afield, into spheres of universal interest.

[1925d, 4222]

I was able to show from a short story by W. Jensen called *Gradiva*, which has no particular merit in itself, that invented dreams can be interpreted in the same way as real ones and that the unconscious mechanisms familiar to us in the 'dream-work' are thus also operative in the processes of imaginative writing. My book on *Jokes and their Relation to the Unconscious* was a side-issue directly derived from *The Interpretation of Dreams*. The only friend of mine who was at that time interested in my work remarked to me that my interpretations of dreams often impressed him as being like jokes. In order to throw some light on this impression, I began to investigate jokes and found that their essence lay in the technical methods employed in them, and that these were the same as the means used in the 'dream-work' - that is to say, condensation, displacement, the representation of a thing by its opposite or by something very small, and so on. This led to an economic enquiry into the origin of the high degree of pleasure obtained from hearing a joke. And to this the answer was that it was due to the momentary suspension of the expenditure of energy upon maintaining repression, owing to the attraction exercised by the offer of a bonus of pleasure (*fore-pleasure*).

[1925d, 4239]
You have long been aware that this censorship is not an institution peculiar to dream-life. You know that the conflict between the two psychical agencies, which we - inaccurately - describe as the 'unconscious repressed' and the 'conscious', dominates our whole mental life and that the resistance against the interpretation of dreams, the sign of the dream-censorship, is nothing other than the resistance due to repression by which the two agencies are separated. You know too that the conflict between these two agencies may under certain conditions produce other psychical structures which, like dreams, are the outcome of compromises; and you will not expect me to repeat to you here everything that was contained in my introduction to the theory of the neuroses in order to demonstrate to you what we know of the determinants of the formation of such compromises. You have realized that the dream is a pathological product, the first member of the class which includes hysterical symptoms, obsessions and delusions, but that it is distinguished from the others by its transitoriness and by its occurrence under conditions which are part of normal life. For let us bear firmly in mind that, as was already pointed out by Aristotle, dream life is the way in which our mind works during the state of sleep. The state of sleep involves a turning-away from the real external world, and there we have the necessary condition for the development of a psychosis. The most careful study of the severe psychoses will not reveal to us a single feature that is more characteristic of those pathological conditions. In psychoses, however, the turning-away from reality is brought about in two kinds of way: either by the unconscious repressed becoming excessively strong so that it overwhelms the conscious, which is attached to reality, or because reality has become so intolerably distressing that the threatened ego throws itself into the arms of the unconscious instinctual forces in a desperate revolt. The harmless dream-psychosis is the result of a withdrawal from the external world which is consciously willed and only temporary, and it disappears when relations to the external world are resumed. During the isolation of the sleeping individual an alteration in the distribution of his psychical energy also sets in; a part of the expenditure on repression, which is normally required in order to hold the unconscious down, can be saved, for if the unconscious makes use of its relative liberation for active purposes, it finds its path to motility closed and the only path open to it is the harmless one leading to hallucinatory satisfaction. Now, therefore, a dream can be formed; but the fact of the dream-censorship shows that even during sleep enough of the resistance due to repression is retained.

[1933a, 4629]

This piece of the dream-work gives us information about some of the most striking and peculiar features of dreams. I will repeat the course of events in dream-formation. As an introduction: the wish to sleep and intentional turning away from the external world. Next, two consequences of this for the mental apparatus: first, the possibility for older and more primitive methods of working to emerge in it - regression; secondly, the lowering of the resistance due to repression which weighs down upon the unconscious. As a result of this last factor the possibility arises for the formation of a dream and this is taken advantage of by the precipitating causes, the internal and external stimuli which have become active. The dream which originates in this way is already a compromise-structure. It has a double function; on the one hand it is ego-syntonic, since, by getting rid of the stimuli which are interfering with sleep, it serves the wish to sleep; on the other hand it allows a repressed instinctual impulse to obtain the satisfaction that is possible in these circumstances, in the form of the hallucinated fulfilment of a wish. The whole process of forming a dream which is permitted by the sleeping ego is, however, subject to the condition of the censorship, which is exercised by the residue of the repression still in operation. I cannot present the process more simply: it is not more simple. But I can proceed now with my description of the dream-work.

[1933a, 4632]
Let us go back once more to the latent dream-thoughts. Their most powerful element is the repressed instinctual impulse which has created in them an expression for itself on the basis of the presence of chance stimuli and by transference on to the day's residues - though an expression that is toned down and disguised. Like every instinctual impulse, it too presses for satisfaction by action; but its path to motility is blocked by the physiological regulations implied in the state of sleep; it is compelled to take the backwards course in the direction of perception and to be content with a hallucinated satisfaction. The latent dream-thoughts are thus transformed into a collection of sensory images and visual scenes. It is as they travel on this course that what seems to us so novel and so strange occurs to them. All the linguistic instruments by which we express the subtler relations of thought - the conjunctions and prepositions, the changes in declension and conjugation - are dropped, because there are no means of representing them; just as in a primitive language without any grammar, only the raw material of thought is expressed and abstract terms are taken back to the concrete ones that are at their basis. What is left over after this may well appear disconnected. The copious employment of symbols, which have become alien to conscious thinking, for representing certain objects and processes is in harmony alike with the archaic regression in the mental apparatus and with the demands of the censorship.

[1933a, 4632]

But other changes made in the elements of the dream-thoughts go far beyond this. Such of those elements as allow any point of contact to be found between them are condensed into new unities. In the process of transforming the thoughts into pictures, preference is unmistakably given to such as permit of this putting-together, this condensation; it is as though a force were at work which was subjecting the material to compression and concentration. As a result of condensation, one element in the manifest dream may correspond to numerous elements in the latent dream-thoughts; but, conversely too, one element in the dream-thoughts may be represented by several images in the dream.

[1933a, 4633]

Still more remarkable is the other process - displacement or shifting of accent - which in conscious thinking we come across only as faulty reasoning or as means for a joke. The different ideas in the dream-thoughts are, indeed, not all of equal value; they are cathected with quotas of affect of varying magnitude and are correspondingly judged to be important and deserving of interest to a greater or less degree. In the dream-work these ideas are separated from the affects attaching to them. The affects are dealt with independently; they may be displaced on to something else, they may be retained, they may undergo alterations, or they may not appear in the dream at all. The importance of the ideas that have been stripped of their affect returns in the dream as sensory strength in the dream-pictures; but we observe that this accent has passed over from important elements to indifferent ones. Thus something that played only a minor part in the dream-thoughts seems to be pushed into the foreground in the dream as the main thing, while, on the contrary, what was the essence of the dream-thoughts finds only passing and indistinct representation in the dream. No other part of the dream-work is so much responsible for making the dream strange and incomprehensible to the dreamer. Displacement is the principal means used in the dream-distortion to which the dream-thoughts must submit under the influence of the censorship.

[1933a, 4633]
After these influences have been brought to bear upon the dream-thoughts the dream is almost complete. A further, somewhat variable, factor also comes into play - known as 'secondary revision' - after the dream has been presented before consciousness as an object of perception. At that point we treat it as we are in general accustomed to treat the contents of our perception: we fill in gaps and introduce connections, and in doing so are often guilty of gross misunderstandings. But this activity, which might be described as a rationalizing one and which at best provides the dream with a smooth façade that cannot fit its true content, may also be omitted or only be expressed to a very modest degree - in which case the dream will display all its rents and cracks openly. It must not be forgotten, on the other hand, that the dream-work does not always operate with equal energy either; it often restricts itself to certain portions of the dream-thoughts only and others of them are allowed to appear in the dream unaltered. In such cases an impression is given of the dream having carried out the most delicate and complex intellectual operations, of its having speculated, made jokes, arrived at decisions and solved problems, whereas all this is a product of our normal mental activity, may have been performed equally well during the day before the dream as during the night, has nothing to do with the dream-work and brings nothing to light that is characteristic of dreams. Nor is it superfluous to insist once more on the contrast within the dream-thoughts themselves between the unconscious instinctual impulse and the day's residues. While the latter exhibit all the multiplicity of our mental acts, the former, which becomes the motive force proper of the forming of the dream, finds its outlet invariably in the fulfilment of a wish.

We find our way to the understanding ('interpretation') of a dream by assuming that what we recollect as the dream after we have woken up is not the true dream-process but only a façade behind which that process lies concealed. Here we have our distinction between the manifest content of a dream and the latent dream-thoughts. The process which produces the former out of the latter is described as the dream-work. The study of the dream-work teaches us by an excellent example the way in which unconscious material from the id (originally unconscious and repressed unconscious alike) forces its way into the ego, becomes preconscious and, as a result of the ego's opposition, undergoes the changes which we know as dream-distortion. There are no features of a dream which cannot be explained in this way.

But what makes dreams so invaluable in giving us insight is the circumstance that, when the unconscious material makes its way into the ego, it brings its own modes of working along with it. This means that the preconscious thoughts in which the unconscious material has found its expression are handled in the course of the dream-work as though they were unconscious portions of the id; and, in the case of the alternative method of dream-formation, the preconscious thoughts which have obtained reinforcement from an unconscious instinctual impulse are brought down to the unconscious state. It is only in this way that we learn the laws which govern the passage of events in the unconscious and the respects in which they differ from the rules that are familiar to us in waking thought. Thus the dream-work is essentially an instance of the unconscious working-over of preconscious thought-processes. To take an analogy from history: invading conquerors govern a conquered country, not according to the judicial system which they find in force there, but according to their own. It is, however, an unmistakable fact that the outcome of the dream-work is a compromise. The ego-organization is not yet paralysed, and its influence is to be seen in the distortion imposed on the unconscious material and in what are often very ineffective attempts at giving the total result a form not too unacceptable to the ego (secondary revision). In our analogy this would be an expression of the continued resistance of the defeated people.
The laws that govern the passage of events in the unconscious, which come to light in this manner, are remarkable enough and suffice to explain most of what seems strange to us about dreams. Above all there is a striking tendency to condensation, an inclination to form fresh unities out of elements which in our waking thought we should certainly have kept separate. As a consequence of this, a single element of the manifest dream often stands for a whole number of latent dream-thoughts as though it were a combined allusion to all of them; and in general the compass of the manifest dream is extraordinarily small in comparison with the wealth of material from which it has sprung. Another peculiarity of the dream-work, not entirely independent of the former one, is the ease with which psychical intensities (cathexes) are displaced from one element to another, so that it often happens that an element which was of little importance in the dream-thoughts appears as the clearest and accordingly most important feature of the manifest dream, and, vice versa, that essential elements of the dream-thoughts are represented in the manifest dream only by slight allusions. Moreover, as a rule the existence of quite insignificant points in common between two elements is enough to allow the dream-work to replace one by the other in all further operations. It will easily be imagined how greatly these mechanisms of condensation and displacement can increase the difficulty of interpreting a dream and of revealing the relations between the manifest dream and the latent dream-thoughts. From the evidence of the existence of these two tendencies to condensation and displacement our theory infers that in the unconscious id the energy is in a freely mobile state and that the id sets more store by the possibility of discharging quantities of excitation than by any other consideration;¹ and our theory makes use of these two peculiarities in defining the character of the primary process we have attributed to the id.

[1940a [1938], 4978]

As the dream-work proceeds, sometimes the unconscious will press forward more successfully and sometimes the ego will defend itself with greater energy. Anxiety dreams are mostly those whose content has undergone the least distortion. If the demand made by the unconscious is too great for the sleeping ego to be in a position to fend it off by the means at its disposal, it abandons the wish to sleep and returns to waking life. We shall be taking every experience into account if we say that a dream is invariably an attempt to get rid of a disturbance of sleep by means of a wish-fulfilment, so that the dream is a guardian of sleep. The attempt may succeed more or less completely; it may also fail, and in that case the sleeper wakes up, apparently woken precisely by the dream. So, too, there are occasions when that excellent fellow the night-watchman, whose business it is to guard the little township's sleep, has no alternative but to sound the alarm and waken the sleeping townspeople.

[1940a [1938], 4981]
These recollections might have been described as hallucinations if a belief in their actual presence had been added to their clearness. The importance of this analogy seemed greater when I noticed that true hallucinations occasionally occurred in the case of other patients who were certainly not psychotic. My line of thought proceeded as follows. Perhaps it may be a general characteristic of hallucinations to which sufficient attention has not hitherto been paid that in them something that has been experienced in infancy and then forgotten returns - something that the child has seen or heard at a time when he could still hardly speak and that now forces its way into consciousness, probably distorted and displaced owing to the operation of forces that are opposed to this return. And, in view of the close relation between hallucinations and particular forms of psychosis, our line of thought may be carried still further. It may be that the delusions into which these hallucinations are so constantly incorporated may themselves be less independent of the upward drive of the unconscious and the return of the repressed than we usually assume. In the mechanism of a delusion we stress as a rule only two factors: the turning away from the real world and its motive forces on the one hand, and the influence exercised by wish-fulfilment on the content of the delusion on the other. But may it not be that the dynamic process is rather that the turning away from reality is exploited by the upward drive of the repressed in order to force its content into consciousness, while the resistances stirred up by this process and the trend to wish-fulfilment share the responsibility for the distortion and displacement of what is recollected? This is after all the familiar mechanism of dreams, which intuition has equated with madness from time immemorial.

[1937d, 5058]
Thus the wish to sleep (which the conscious ego is concentrated upon, and which, together with the dream-censorship and the 'secondary revision' which I shall mention later, constitute the conscious ego's share in dreaming) must in every case be reckoned as one of the motives for the formation of dreams, and every successful dream is a fulfilment of that wish. We shall discuss elsewhere the relations subsisting between this universal, invariably present and unchanging wish to sleep and the other wishes, of which now one and now another is fulfilled by the content of the dream. But we have found in the wish to sleep the factor that is able to fill the gap in the theory of Strümpell and Wundt and to explain the perverse and capricious manner in which external stimuli are interpreted. The correct interpretation, which the sleeping mind is perfectly capable of making, would involve an active interest and would require that sleep should be brought to an end; for that reason, of all the possible interpretations, only those are admitted which are consistent with the absolute censorship exercised by the wish to sleep. 'It is the nightingale and not the lark.' For if it were the lark it would mean the end of the lovers' night. Among the interpretations of the stimulus which are accordingly admissible, that one is then selected which can provide the best link with the wishful impulses lurking in the mind. Thus everything is unambiguously determined and nothing is left to arbitrary decision. The misinterpretation is not an illusion but, as one might say, an evasion. Here once again, however, just as when, in obedience to the dream-censorship, a substitution is effected by displacement, we have to admit that we are faced by an act which deviates from normal psychical processes.

[1900a, 713]

In which of these systems, then, are we to locate the impetus to the construction of dreams? For simplicity's sake, in the system $Ucs$. It is true that in the course of our future discussion we shall learn that this is not entirely accurate, and that the process of forming dreams is obliged to attach itself to dream-thoughts belonging to the preconscious system. But when we consider the dream-wish, we shall find that the motive force for producing dreams is supplied by the $Ucs$; and owing to this latter factor we shall take the unconscious system as the starting-point of dream-formation. Like all other thought structures, this dream-instigator will make an effort to advance into the $Pcs$. and from there to obtain access to consciousness.

[1900a, 974]
This determined wish on the part of the preconscious to sleep exercises a generally facilitating effect on the formation of dreams. Let me recall the dream dreamt by the man who was led to infer from the glare of light coming out of the next room that his child's body might be on fire. The father drew this inference in a dream instead of allowing himself to be woken up by the glare; and we have suggested that one of the psychical forces responsible for this result was a wish which prolonged by that one moment the life of the child whom he pictured in the dream. Other wishes, originating from the repressed, probably escape us, since we are unable to analyse the dream. But we may assume that a further motive force in the production of the dream was the father's need to sleep; his sleep, like the child's life, was prolonged by one moment by the dream. 'Let the dream go on' - such was his motive - 'or I shall have to wake up.' In every other dream, just as in this one, the wish to sleep lends its support to the unconscious wish. On p. 624 f. I described some dreams which appeared openly as dreams of convenience. But in fact all dreams can claim a right to the same description. The operation of the wish to continue sleeping is most easily to be seen in arousal dreams, which modify external sensory stimuli in such a way as to make them compatible with a continuance of sleep; they weave them into a dream in order to deprive them of any possibility of acting as reminders of the external world. That same wish must, however, play an equal part in allowing the occurrence of all other dreams, though it may only be from within that they threaten to shake the subject out of his sleep. In some cases, when a dream carries things too far, the Ucs. says to consciousness: 'Never mind! go on sleeping! after all it's only a dream!' But this describes in general the attitude of our dominant mental activity towards dreams, though it may not be openly expressed. I am driven to conclude that throughout our whole sleeping state we know just as certainly that we are dreaming as we know that we are sleeping. We must not pay too much attention to the counter-argument that our consciousness is never brought to bear on the latter piece of knowledge and that it is only brought to bear on the former on particular occasions when the censorship feels that it has, as it were, been taken off its guard.

On the other hand, there are some people who are quite clearly aware during the night that they are asleep and dreaming and who thus seem to possess the faculty of consciously directing their dreams. If, for instance, a dreamer of this kind is dissatisfied with the turn taken by a dream, he can break it off without waking up and start it again in another direction - just as a popular dramatist may under pressure give his play a happier ending. Or another time, if his dream has led him into a sexually exciting situation, he can think to himself: 'I won't go on with this dream any further and exhaust myself with an emission; I'll hold it back for a real situation instead.'

The Marquis d'Hervey de Saint-Denys, quoted by Vaschide (1911, 139), claimed to have acquired the power of accelerating the course of his dreams just as he pleased, and of giving them any direction he chose. It seems as though in his case the wish to sleep had given place to another preconscious wish, namely to observe his dreams and enjoy them. Sleep is just as compatible with a wish of this sort as it is with a mental reservation to wake up if some particular condition is fulfilled (e.g. in the case of a nursing mother or wet-nurse). Moreover, it is a familiar fact that anyone who takes an interest in dreams remembers a considerably greater number of them after waking.
The purposes against which the dream-censorship is directed must be described in the first instance from the point of view of that agency itself. If so, one can only say that they are invariably of a reprehensible nature, repulsive from the ethical, aesthetic and social point of view - matters of which one does not venture to think at all or thinks only with disgust. These wishes, which are censored and given a distorted expression in dreams, are first and foremost manifestations of an unbridled and ruthless egoism. And, to be sure, the dreamer's own ego appears in every dream and plays the chief part in it, even if it knows quite well how to hide itself so far as the manifest content goes. This 'sacro egoismo' of dreams is certainly not unrelated to the attitude we adopt when we sleep, which consists in our withdrawing our interest from the whole external world.

[1916-1917, 3237]

So far as I can at present see, dreams that occur in a traumatic neurosis are the only genuine exceptions, and punishment dreams are the only apparent exceptions, to the rule that dreams are directed towards wish-fulfilment. In the latter class of dreams we are met by the remarkable fact that actually nothing belonging to the latent dream-thoughts is taken up into the manifest content of the dream. Something quite different appears instead, which must be described as a reaction-formation against the dream-thoughts, a rejection and complete contradiction of them. Such offensive action as this against the dream can only be ascribed to the critical agency of the ego and it must therefore be assumed that the latter, provoked by the unconscious wish-fulfilment, has been temporarily re-established even during the sleeping state. It might have reacted to the undesirable content of the dream by waking up; but it has found a means, by the construction of the punishment dream, of avoiding an interruption of sleep.

[1923c, 4039]

We find our way to the understanding ('interpretation') of a dream by assuming that what we recollect as the dream after we have woken up is not the true dream-process but only a façade behind which that process lies concealed. Here we have our distinction between the manifest content of a dream and the latent dream-thoughts. The process which produces the former out of the latter is described as the dream-work. The study of the dream-work teaches us by an excellent example the way in which unconscious material from the id (originally unconscious and repressed unconscious alike) forces its way into the ego, becomes preconscious and, as a result of the ego's opposition, undergoes the changes which we know as dream-distortion. There are no features of a dream which cannot be explained in this way.

[1940a [1938], 4975]

But what makes dreams so invaluable in giving us insight is the circumstance that, when the unconscious material makes its way into the ego, it brings its own modes of working along with it. This means that the preconscious thoughts in which the unconscious material has found its expression are handled in the course of the dream-work as though they were unconscious portions of the id; and, in the case of the alternative method of dream-formation, the preconscious thoughts which have obtained reinforcement from an unconscious instinctual impulse are brought down to the unconscious state. It is only in this way that we learn the laws which govern the passage of events in the unconscious and the respects in which they differ from the rules that are familiar to us in waking thought. Thus the dream-work is essentially an instance of the unconscious working-over of preconscious thought-processes. To take an analogy from history: invading conquerors govern a conquered country, not according to the judicial system which they find in force there, but according to their own. It is, however, an unmistakable fact that the outcome of the dream-work is a compromise. The ego-organization is not yet paralysed, and its influence is to be seen in the distortion imposed on the unconscious material and in what are often very ineffective attempts at giving the total result a form not too unacceptable to the ego (secondary revision). In our analogy this would be an expression of the continued resistance of the defeated people.

[1940a [1938], 4977]
It remains for us to give a dynamic explanation of why the sleeping ego takes on the task of the dream-work at all. The explanation is fortunately easy to find. With the help of the unconscious, every dream that is in process of formation makes a demand upon the ego - for the satisfaction of an instinct, if the dream originates from the id; for the solution of a conflict, the removal of a doubt or the forming of an intention, if the dream originates from a residue of preconscious activity in waking life. The sleeping ego, however, is focused on the wish to maintain sleep; it feels this demand as a disturbance and seeks to get rid of the disturbance. The ego succeeds in doing this by what appears to be an act of compliance: it meets the demand with what is in the circumstances a harmless fulfilment of a wish and so gets rid of it. This replacement of the demand by the fulfilment of a wish remains the essential function of the dream-work. It may perhaps be worth while to illustrate this by three simple examples - a hunger dream, a dream of convenience and a dream prompted by sexual desire. A need for food makes itself felt in a dreamer during his sleep: he has a dream of a delicious meal and sleeps on. The choice, of course, was open to him either of waking up and eating something or of continuing his sleep. He decided in favour of the latter and satisfied his hunger by means of the dream - for the time being, at all events, for if his hunger had persisted he would have had to wake up nevertheless. Here is the second example. A sleeper had to wake up so as to be in time for his work at the hospital. But he slept on, and had a dream that he was already at the hospital - but as a patient, who has no need to get up. Or again, a desire becomes active during the night for the enjoyment of a forbidden sexual object, the wife of a friend of the sleeper. He has a dream of sexual intercourse - not, indeed, with this person but with someone else of the same name to whom he is in fact indifferent; or his struggle against the desire may find expression in his mistress remaining altogether anonymous.

As the dream-work proceeds, sometimes the unconscious will press forward more successfully and sometimes the ego will defend itself with greater energy. Anxiety dreams are mostly those whose content has undergone the least distortion. If the demand made by the unconscious is too great for the sleeping ego to be in a position to fend it off by the means at its disposal, it abandons the wish to sleep and returns to waking life. We shall be taking every experience into account if we say that a dream is invariably an attempt to get rid of a disturbance of sleep by means of a wish-fulfilment, so that the dream is a guardian of sleep. The attempt may succeed more or less completely; it may also fail, and in that case the sleeper wakes up, apparently woken precisely by the dream. So, too, there are occasions when that excellent fellow the night-watchman, whose business it is to guard the little township's sleep, has no alternative but to sound the alarm and waken the sleeping townspeople.
As regards the embittered and apparently irreconcilable dispute as to whether the mind sleeps at night or is as much in command of all its faculties as it is by day, we have found that both parties are right but that neither is wholly right. We have found evidence in the dream-thoughts of a highly complex intellectual function, operating with almost the whole resources of the mental apparatus. Nevertheless it cannot be disputed that these dream-thoughts originated during the day, and it is imperative to assume that there is such a thing as a sleeping state of the mind. Thus even the theory of partial sleep has shown its value, though we have found that what characterizes the state of sleep is not the disintegration of mental bonds but the concentration of the psychical system which is in command during the day upon the wish to sleep. The factor of withdrawal from the external world retains its significance in our scheme; it helps, though not as the sole determinant, to make possible the regressive character of representation in dreams. The renunciation of voluntary direction of the flow of ideas cannot be disputed; but this does not deprive mental life of all purpose, for we have seen how, after voluntary purposive ideas have been abandoned, involuntary ones assume command. We have not merely accepted the fact of the looseness of associative connections in dreams, but we have shown that it extends far further than had been suspected; we have found, however, that these loose connections are merely obligatory substitutes for others which are valid and significant. It is quite true that we have described dreams as absurd; but examples have taught us how sensible a dream can be even when it appears to be absurd.

With the help of these ideas we are now able to explain a whole number of mental states or, to express it more modestly, to describe them in terms of the libido theory - states which we must reckon as belonging to normal life, such as the psychical behaviour of a person in love, during an organic illness or when asleep. As regards the state of sleep, we assumed that it was based on turning-away from the external world and adopting a wish to sleep. The mental activity during the night which is manifested in dreams takes place, we found, in obedience to a wish to sleep and is moreover dominated by purely egoistic motives. We may now add, on the lines of the libido theory, that sleep is a state in which all object-cathexes, libidinal as well as egoistic, are given up and withdrawn into the ego. May not this throw a fresh light on the recuperating effect of sleep and on the nature of fatigue in general? The picture of the blissful isolation of intra-uterine life which a sleeper conjures up once more before us every night is in this way completed on its psychical side as well. In a sleeper the primal state of distribution of the libido is restored - total narcissism, in which libido and ego-interest, still united and indistinguishable, dwell in the self-sufficing ego.

My second remark is a supplement to the theory of dreams. We cannot explain the origin of dreams unless we adopt the hypothesis that the repressed unconscious has achieved some degree of independence of the ego, so that it does not acquiesce in the wish to sleep and retains its cathexes even when all the object-cathexes depending on the ego have been withdrawn in order to encourage sleep. Only if that is so can we understand how the unconscious can make use of the lifting or reduction of the censorship which occurs at night, and can succeed in obtaining control over the day's residues so as to construct a forbidden dream-wish out of their material. On the other hand, it may be that these day's residues have to thank an already existing connection with the repressed unconscious for some of their resistance to the withdrawal of libido commanded by the wish to sleep. We will, then, insert this dynamically important feature into our view of the formation of dreams by way of supplement.
In the further course of psycho-analytic work, however, even these distinctions have proved to be inadequate and, for practical purposes, insufficient. This has become clear in more ways than one; but the decisive instance is as follows. We have formed the idea that in each individual there is a coherent organization of mental processes; and we call this his ego. It is to this ego that consciousness is attached; the ego controls the approaches to motility - that is, to the discharge of excitations into the external world; it is the mental agency which supervises all its own constituent processes, and which goes to sleep at night, though even then it exercises the censorship on dreams. From this ego proceed the repressions, too, by means of which it is sought to exclude certain trends in the mind not merely from consciousness but also from other forms of effectiveness and activity. In analysis these trends which have been shut out stand in opposition to the ego, and the analysis is faced with the task of removing the resistances which the ego displays against concerning itself with the repressed. Now we find during analysis that, when we put certain tasks before the patient, he gets into difficulties; his associations fail when they should be coming near the repressed. We then tell him that he is dominated by a resistance; but he is quite unaware of the fact, and, even if he guesses from his unpleasurable feelings that a resistance is now at work in him, he does not know what it is or how to describe it. Since, however, there can be no question but that this resistance emanates from his ego and belongs to it, we find ourselves in an unforeseen situation. We have come upon something in the ego itself which is also unconscious, which behaves exactly like the repressed - that is, which produces powerful effects without itself being conscious and which requires special work before it can be made conscious. From the point of view of analytic practice, the consequence of this discovery is that we land in endless obscurities and difficulties if we keep to our habitual forms of expression and try, for instance, to derive neuroses from a conflict between the conscious and the unconscious. We shall have to substitute for this antithesis another, taken from our insight into the structural conditions of the mind - the antithesis between the coherent ego and the repressed which is split off from it.¹

[1923b, 3951]
There were now a whole series of questions to be answered, among the most important of them being whether the formation of dreams had a motive, under what conditions it took place, by what methods the dream-thoughts (which are invariably full of sense) become converted into the dream (which is often senseless), and others besides. I attempted to solve all of these problems in *The Interpretation of Dreams*, which I published in the year 1900. I can only find space here for the briefest abstract of my investigation. When the latent dream-thoughts that are revealed by the analysis of a dream are examined, one of them is found to stand out from among the rest, which are intelligible and well known to the dreamer. These latter thoughts are residues of waking life (the day's residues, as they are called technically); but the isolated thought is found to be a wishful impulse, often of a very repellent kind, which is foreign to the waking life of the dreamer and is consequently disavowed by him with surprise or indignation. This impulse is the actual constructor of the dream: it provides the energy for its production and makes use of the day's residues as material. The dream which thus originates represents a situation of satisfaction for the impulse, it is the fulfilment of its wish. It would not be possible for this process to take place without being favoured by the presence of something in the nature of a state of sleep. The necessary mental precondition of sleep is the concentration of the ego upon the wish to sleep and the withdrawal of psychical energy from all the interests of life. Since at the same time all the paths of approach to motility are blocked, the ego is also able to reduce the expenditure by which at other times it maintains the repressions. The unconscious impulse makes use of this nocturnal relaxation of repression in order to push its way into consciousness with the dream. But the repressive resistance of the ego is not abolished in sleep but merely reduced. Some of it remains in the shape of a censorship of dreams and forbids the unconscious impulse to express itself in the forms which it would properly assume. In consequence of the severity of the censorship of dreams, the latent dream-thoughts are obliged to submit to being altered and softened so as to make the forbidden meaning of the dream unrecognizable. This is the explanation of dream-distortion, which accounts for the most striking characteristics of the manifest dream. We are therefore justified in asserting that a dream is the (disguised) fulfilment of a (repressed) wish. It will now be seen that dreams are constructed like a neurotic symptom: they are compromises between the demands of a repressed impulse and the resistance of a censoring force in the ego. Since they have a similar origin they are equally unintelligible and stand in equal need of interpretation.

[1925d, 4219]

*Here are the principal characteristics of the ego.* In consequence of the pre-established connection between sense perception and muscular action, the ego has voluntary movement at its command. It has the task of self-preservation. As regards external events, it performs that task by becoming aware of stimuli, by storing up experiences about them (in the memory), by avoiding excessively strong stimuli (through flight), by dealing with moderate stimuli (through adaptation) and finally by learning to bring about expedient changes in the external world to its own advantage (through activity). As regards internal events, in relation to the id, it performs that task by gaining control over the demands of the instincts, by deciding whether they are to be allowed satisfaction, by postponing that satisfaction to times and circumstances favourable in the external world or by suppressing their excitations entirely. It is guided in its activity by consideration of the tensions produced by stimuli, whether these tensions are present in it or introduced into it. The raising of these tensions is in general felt as displeasure and their lowering as pleasure. It is probable, however, that what is felt as pleasure or displeasure is not the absolute height of this tension but something in the rhythm of the changes in them. The ego strives after pleasure and seeks to avoid displeasure. An increase in displeasure that is expected and foreseen is met by a signal of anxiety; the occasion of such an increase, whether it threatens from without or within, is known as a danger. From time to time the ego gives up its connection with the external world and withdraws into the state of sleep, in which it makes far-reaching changes in its organization. It is to be inferred from the state of sleep that this organization consists in a particular distribution of mental energy.

[1940a [1938], 4957]
It is best to begin by pointing out that the formation of a dream can be provoked in two different ways. Either, on the one hand, an instinctual impulse which is ordinarily suppressed (an unconscious wish) finds enough strength during sleep to make itself felt by the ego, or, on the other hand, an urge left over from waking life, a preconscious train of thought with all the conflicting impulses attached to it, finds reinforcement during sleep from an unconscious element. In short, dreams may arise either from the id or from the ego. The mechanism of dream-formation is in both cases the same and so also is the necessary dynamic precondition. The ego gives evidence of its original derivation from the id by occasionally ceasing its functions and allowing a reversion to an earlier state of things. This is logically brought about by its breaking off its relations with the external world and withdrawing its cathexes from the sense organs. We are justified in saying that there arises at birth an instinct to return to the intra-uterine life that has been abandoned - an instinct to sleep. Sleep is a return of this kind to the womb. Since the waking ego governs motility, that function is paralysed in sleep, and accordingly a good part of the inhibitions imposed on the unconscious id become superfluous. The withdrawal or reduction of these 'anticathexes' thus allows the id what is now a harmless amount of liberty.

But what makes dreams so invaluable in giving us insight is the circumstance that, when the unconscious material makes its way into the ego, it brings its own modes of working along with it. This means that the preconscious thoughts in which the unconscious material has found its expression are handled in the course of the dream-work as though they were unconscious portions of the id; and, in the case of the alternative method of dream-formation, the preconscious thoughts which have obtained reinforcement from an unconscious instinctual impulse are brought down to the unconscious state. It is only in this way that we learn the laws which govern the passage of events in the unconscious and the respects in which they differ from the rules that are familiar to us in waking thought. Thus the dream-work is essentially an instance of the unconscious working-over of preconscious thought-processes. To take an analogy from history: invading conquerors govern a conquered country, not according to the judicial system which they find in force there, but according to their own. It is, however, an unmistakable fact that the outcome of the dream-work is a compromise. The ego-organization is not yet paralysed, and its influence is to be seen in the distortion imposed on the unconscious material and in what are often very ineffective attempts at giving the total result a form not too unacceptable to the ego (secondary revision). In our analogy this would be an expression of the continued resistance of the defeated people.

We already know a number of things preliminary to such an undertaking. According to our hypothesis it is the ego's task to meet the demands raised by its three dependent relations to reality, to the id and to the super-ego - and nevertheless at the same time to preserve its own organization and maintain its own autonomy. The necessary precondition of the pathological states under discussion can only be a relative or absolute weakening of the ego which makes the fulfilment of its tasks impossible. The severest demand on the ego is probably the keeping down of the instinctual claims of the id, to accomplish which it is obliged to maintain large expenditures of energy on anticathexes. But the demands made by the super-ego too may become so powerful and so relentless that the ego may be paralysed, as it were, in the face of its other tasks. We may suspect that, in the economic conflicts which arise at this point, the id and the super-ego often make common cause against the hard-pressed ego which tries to cling to reality in order to retain its normal state. If the other two become too strong, they succeed in loosening and altering the ego's organization, so that its proper relation to reality is disturbed or even brought to an end. We have seen it happen in dreaming: when the ego is detached from the reality of the external world, it slips down, under the influence of the internal world, into psychosis.
Now while this agency, in which we recognize our normal ego, is concentrated on the wish to sleep, it appears to be compelled by the psycho-physiological conditions of sleep to relax the energy with which it is accustomed to hold down the repressed material during the day. In itself, no doubt, this relaxation does no harm; however much the suppressed impulses of the childish mind may prance around, their access to consciousness is still difficult and their access to movement is barred as the result of this same state of sleep. The danger of sleep being disturbed by them must, however, be guarded against. We must in any case suppose that even during deep sleep a certain amount of free attention is on duty as a guard against sensory stimuli, and that this guard may sometimes consider waking more advisable than a continuation of sleep. Otherwise there would be no explanation of how it is that we can be woken up at any moment by sensory stimuli of some particular quality. As the physiologist Burdach insisted long ago, a mother, for instance, will be roused by the whimpering of her baby, or a miller if his mill comes to a stop, or most people if they are called softly by their own name. Now the attention which is thus on guard is also directed towards internal wishful stimuli arising from the repressed material, and combines with them to form the dream which, as a compromise, simultaneously satisfies both of the two agencies. The dream provides a kind of psychical consummation for the wish that has been suppressed (or formed with the help of repressed material) by representing it as fulfilled; but it also satisfies the other agency by allowing sleep to continue. In this respect our ego is ready to behave like a child; it gives credence to the dream images, as though what it wanted to say was: "Yes, yes! you're quite right, but let me go on sleeping!" The low estimate which we form of dreams when we are awake, and which we relate to their confused and apparently illogical character, is probably nothing other than the judgement passed by our sleeping ego upon the repressed impulses, a judgement based, with better right, upon the motor impotence of these disturbers of sleep. We are sometimes aware in our sleep of this contemptuous judgement. If the content of a dream goes too far in overstepping the censorship, we think: "After all, it's only a dream!" - and go on sleeping.

[1901a, 1092]
Thus the wish to sleep (which the conscious ego is concentrated upon, and which, together with the dream-censorship and the 'secondary revision' which I shall mention later, constitute the conscious ego's share in dreaming) must in every case be reckoned as one of the motives for the formation of dreams, and every successful dream is a fulfilment of that wish. We shall discuss elsewhere the relations subsisting between this universal, invariably present and unchanging wish to sleep and the other wishes, of which now one and now another is fulfilled by the content of the dream. But we have found in the wish to sleep the factor that is able to fill the gap in the theory of Strümpell and Wundt and to explain the perverse and capricious manner in which external stimuli are interpreted. The correct interpretation, which the sleeping mind is perfectly capable of making, would involve an active interest and would require that sleep should be brought to an end; for that reason, of all the possible interpretations, only those are admitted which are consistent with the absolute censorship exercised by the wish to sleep. 'It is the nightingale and not the lark.' For if it were the lark it would mean the end of the lovers' night. Among the interpretations of the stimulus which are accordingly admissible, that one is then selected which can provide the best link with the wishful impulses lurking in the mind. Thus everything is unambiguously determined and nothing is left to arbitrary decision. The misinterpretation is not an illusion but, as one might say, an evasion. Here once again, however, just as when, in obedience to the dream-censorship, a substitution is effected by displacement, we have to admit that we are faced by an act which deviates from normal psychical processes. [1900a, 713]
The other members of this class of wish-fulfilments - hysterical symptoms, for instance - possess one essential characteristic, however, which I cannot discover in dreams. I have learnt from the researches which I have mentioned so often in the course of this work that in order to bring about the formation of a hysterical symptom both currents of our mind must converge. A symptom is not merely the expression of a realized unconscious wish; a wish from the preconscious which is fulfilled by the same symptom must also be present. So that the symptom will have of at least two determinants, one arising from each of the systems involved in the conflict. As in the case of dreams, there are no limits to the further determinants that may be present - to the 'overdetermination' of the symptoms. The determinant which does not arise from the Ucs. is invariably, so far as I know, a train of thought reacting against the unconscious wish - a self-punishment, for instance. I can therefore make the quite general assertion that a hysterical symptom develops only where the fulfilments of two opposing wishes, arising each from a different psychical system, are able to converge in a single expression. (Compare in this connection my most recent formulations on the origin of hysterical symptoms in my paper on hysterical phantasies and their relation to bisexuality.) Examples would serve very little purpose here, since nothing but an exhaustive elucidation of the complications involved could carry conviction. I will therefore leave my assertion to stand for itself and only quote an example in order to make the point clear, and not to carry conviction. In one of my women patients, then, hysterical vomiting turned out to be on the one hand the fulfilment of an unconscious phantasy dating from her puberty - of a wish, that is, that she might be continuously pregnant and have innumerable children, with a further wish, added later, that she might have them by as many men as possible. A powerful defensive impulse had sprung up against this unbridled wish. And, since the patient might lose her figure and her good looks as a result of her vomiting, and so might cease to be attractive to anyone, the symptom was acceptable to the punitive train of thought as well; and since it was permitted by both sides it could become a reality. This was the same method of treating a wish-fulfilment as was adopted by the Parthian queen towards the Roman triumvir Crassus. Believing that he had embarked on his expedition out of love of gold, she ordered molten gold to be poured down his throat when he was dead: 'Now', she said, 'you have what you wanted.' But all that we so far know about dreams is that they express the fulfilment of a wish from the unconscious; it seems as though the dominant, preconscious system acquiesces in this after insisting upon a certain number of distortions. Nor is it possible as a general rule to find a train of thought opposed to the dream-wish and, like its counterpart, realized in the dream. Only here and there in dream-analyses do we come upon signs of reactive creations, like, for instance, my affectionate feelings for my friend R. in the dream of my uncle (cf. p. 637 ff.). But we can find the missing ingredient from the preconscious elsewhere. Whereas the wish from the Ucs. is able to find expression in the dream after undergoing distortions of every kind, the dominant system withdraws into a wish to sleep, realizes that wish by bringing about the modifications which it is able to produce in the cathexes within the psychical apparatus, and persists in that wish throughout the whole duration of sleep.¹ [1900a, 999]
This determined wish on the part of the preconscious to sleep exercises a generally facilitating effect on the formation of dreams. Let me recall the dream dreamt by the man who was led to infer from the glare of light coming out of the next room that his child's body might be on fire. The father drew this inference in a dream instead of allowing himself to be woken up by the glare; and we have suggested that one of the psychical forces responsible for this result was a wish which prolonged by that one moment the life of the child whom he pictured in the dream. Other wishes, originating from the repressed, probably escape us, since we are unable to analyse the dream. But we may assume that a further motive force in the production of the dream was the father's need to sleep; his sleep, like the child's life, was prolonged by one moment by the dream. 'Let the dream go on' - such was his motive - 'or I shall have to wake up.' In every other dream, just as in this one, the wish to sleep lends its support to the unconscious wish. On p. 624 f. I described some dreams which appeared openly as dreams of convenience. But in fact all dreams can claim a right to the same description. The operation of the wish to continue sleeping is most easily to be seen in arousal dreams, which modify external sensory stimuli in such a way as to make them compatible with a continuance of sleep; they weave them into a dream in order to deprive them of any possibility of acting as reminders of the external world. That same wish must, however, play an equal part in allowing the occurrence of all other dreams, though it may only be from within that they threaten to shake the subject out of his sleep. In some cases, when a dream carries things too far, the Ucs. says to consciousness: 'Never mind! go on sleeping! after all it's only a dream!' But this describes in general the attitude of our dominant mental activity towards dreams, though it may not be openly expressed. I am driven to conclude that throughout our whole sleeping state we know just as certainly that we are dreaming as we know that we are sleeping. We must not pay too much attention to the counter-argument that our consciousness is never brought to bear on the latter piece of knowledge and that it is only brought to bear on the former on particular occasions when the censorship feels that it has, as it were, been taken off its guard.

Now that we know that all through the night the preconscious is concentrated upon the wish to sleep, we are in a position to carry our understanding of the process of dreaming a stage further. But first let us summarize what we have learnt so far.

I must assume that the state of sleep makes the sensory surface of consciousness which is directed towards the Pcs. far more insusceptible to excitation than the surface directed towards the Pcs. systems. Moreover, this abandonment of interest in thought-processes during the night has a purpose: thinking is to come to a standstill, for the Pcs. requires sleep. Once, however, a dream has become a perception, it is in a position to excite consciousness, by means of the qualities it has now acquired. This sensory excitation proceeds to perform what is its essential function: it directs a part of the available cathetic energy in the Pcs. into attention to what is causing the excitation. It must therefore be admitted that every dream has an arousing effect, that it sets a part of the quiescent force of the Pcs. in action. The dream is then submitted by this force to the influence which we have described as secondary revision with an eye to consecutiveness and intelligibility. That is to say, the dream is treated by it just like any other perceptual content; it is met by the same anticipatory ideas, in so far as its subject-matter allows. So far as this third portion of the dream-process has any direction it is once again a progressive one.
As regards the embittered and apparently irreconcilable dispute as to whether the mind sleeps at night or is as much in command of all its faculties as it is by day, we have found that both parties are right but that neither is wholly right. We have found evidence in the dream-thoughts of a highly complex intellectual function, operating with almost the whole resources of the mental apparatus. Nevertheless it cannot be disputed that these dream-thoughts originated during the day, and it is imperative to assume that there is such a thing as a sleeping state of the mind. Thus even the theory of partial sleep has shown its value, though we have found that what characterizes the state of sleep is not the disintegration of mental bonds but the concentration of the psychical system which is in command during the day upon the wish to sleep. The factor of withdrawal from the external world retains its significance in our scheme; it helps, though not as the sole determinant, to make possible the regressive character of representation in dreams. The renunciation of voluntary direction of the flow of ideas cannot be disputed; but this does not deprive mental life of all purpose, for we have seen how, after voluntary purposive ideas have been abandoned, involuntary ones assume command. We have not merely accepted the fact of the looseness of associative connections in dreams, but we have shown that it extends far further than had been suspected; we have found, however, that these loose connections are merely obligatory substitutes for others which are valid and significant. It is quite true that we have described dreams as absurd; but examples have taught us how sensible a dream can be even when it appears to be absurd. [1900a, 1017]

Now while this agency, in which we recognize our normal ego, is concentrated on the wish to sleep, it appears to be compelled by the psycho-physiological conditions of sleep to relax the energy with which it is accustomed to hold down the repressed material during the day. In itself, no doubt, this relaxation does no harm; however much the suppressed impulses of the childish mind may prance around, their access to consciousness is still difficult and their access to movement is barred as the result of this same state of sleep. The danger of sleep being disturbed by them must, however, be guarded against. We must in any case suppose that even during deep sleep a certain amount of free attention is on duty as a guard against sensory stimuli, and that this guard may sometimes consider waking more advisable than a continuation of sleep. Otherwise there would be no explanation of how it is that we can be woken up at any moment by sensory stimuli of some particular quality. As the physiologist Burdach insisted long ago, a mother, for instance, will be roused by the whimpering of her baby, or a miller if his mill comes to a stop, or most people if they are called softly by their own name. Now the attention which is thus on guard is also directed towards internal wishful stimuli arising from the repressed material, and combines with them to form the dream which, as a compromise, simultaneously satisfies both of the two agencies. The dream provides a kind of psychical consummation for the wish that has been suppressed (or formed with the help of repressed material) by representing it as fulfilled; but it also satisfies the other agency by allowing sleep to continue. In this respect our ego is ready to behave like a child; it gives credence to the dream images, as though what it wanted to say was: 'Yes, yes! you're quite right, but let me go on sleeping!' The low estimate which we form of dreams when we are awake, and which we relate to their confused and apparently illogical character, is probably nothing other than the judgement passed by our sleeping ego upon the repressed impulses, a judgement based, with better right, upon the motor impotence of these disturbers of sleep. We are sometimes aware in our sleep of this contemptuous judgement. If the content of a dream goes too far in overstepping the censorship, we think: 'After all, it's only a dream!' - and go on sleeping. [1901a, 1092]
The following forces may be recognized as having a share in the formation of dreams: the wish to sleep, the cathexis of energy that still remains in the day's residues after it has been lowered by the state of sleep, the psychical energy of the dream-constructing unconscious wish and the opposing force of the 'censorship', which dominates daytime life and is not completely lifted during sleep. The task of dream-formation is above all to overcome the inhibition from the censorship; and it is precisely this task which is solved by the displacements of psychical energy within the material of the dream-thoughts.

With this last contribution, however, which explains, even though still only hypothetically, the joke-work in the first person, our interest in jokes is, strictly speaking, at an end. It remains for us to make a further short comparison between jokes and the better-known dream; and we may expect that, apart from the single conformity we have already considered, two such dissimilar mental functions will only reveal differences. The most important difference lies in their social behaviour. A dream is a completely asocial mental product; it has nothing to communicate to anyone else; it arises within the subject as a compromise between the mental forces struggling in him, it remains unintelligible to the subject himself and is for that reason totally uninteresting to other people. Not only does it not need to set any store by intelligibility, it must actually avoid being understood, for otherwise it would be destroyed; it can only exist in masquerade. For that reason it can without hindrance make use of the mechanism that dominates unconscious mental processes, to the point of a distortion which can no longer be set straight. A joke, on the other hand, is the most social of all the mental functions that aim at a yield of pleasure. It often calls for three persons and its completion requires the participation of someone else in the mental process it starts. The condition of intelligibility is, therefore, binding on it; it may only make use of possible distortion in the unconscious through condensation and displacement up to the point at which it can be set straight by the third person's understanding. Moreover, jokes and dreams have grown up in quite different regions of mental life and must be allotted to points in the psychological system far remote from each other. A dream still remains a wish, even though one that has been made unrecognizable; a joke is developed play. Dreams, in spite of all their practical nonentity, retain their connection with the major interests of life; they seek to fulfil needs by the regressive detour of hallucination, and they are permitted to occur for the sake of the one need that is active during the night - the need to sleep. Jokes, on the other hand, seek to gain a small yield of pleasure from the mere activity, untrammelled by needs, of our mental apparatus. Later they try to catch hold of that pleasure as a by-product during the activity of that apparatus and thus arrive secondarily at not unimportant functions directed to the external world. Dreams serve predominantly for the avoidance of unpleasure, jokes for the attainment of pleasure; but all our mental activities converge in these two aims.
The path to perversion branches off sharply from that to neurosis. If these regressions rouse no objection from the ego, no neurosis will come about either; and the libido will arrive at some real, even though no longer normal, satisfaction. But if the ego, which has under its control not only consciousness but also the approaches to motor innervation and accordingly to the realization of mental desires, does not agree with these regressions, conflict will follow. The libido is, as it were, cut off and must try to escape in some direction where, in accordance with the requirements of the pleasure principle, it can find a discharge for its cathexis of energy. It must withdraw from the ego. An escape of this kind is offered it by the fixations on the path of its development which it has now entered on regressively - fixations from which the ego had protected itself in the past by repressions. By cathecting these repressed positions as it flows backward, the libido has withdrawn from the ego and its laws, and has at the same time renounced all the education it has acquired under the ego's influence. It was docile so long as satisfaction beckoned to it; but under the double pressure of external and internal frustration it becomes refractory, and recalls earlier and better times. Such is the libido's fundamentally unchangeable character. The ideas to which it now transfers its energy as a cathexis belong to the system of the unconscious and are subject to the processes which are possible there, particularly to condensation and displacement. In this way conditions are established which completely resemble those in dream-construction. The dream proper, which has been completed in the unconscious and is the fulfilment of an unconscious wishful phantasy, is brought up against a portion of (pre)conscious activity which exercises the office of censorship and which, when it has been indemnified, permits the formation of the manifest dream as a compromise. In the same way, what represents the libido in the unconscious has to reckon with the power of the preconscious ego. The opposition which had been raised against it in the ego pursues it as an 'anticathexis' and compels it to choose a form of expression which can at the same time become an expression of the opposition itself. Thus the symptom emerges as a many-times-distorted derivative of the unconscious libidinal wish-fulfilment, an ingeniously chosen piece of ambiguity with two meanings in complete mutual contradiction. In this last respect, however, there is a distinction between the construction of a dream and of a symptom. For in dream-formation the preconscious purpose is merely concerned to preserve sleep, to allow nothing that would disturb it to make its way into consciousness; it does not insist upon calling out sharply 'No! on the contrary!' to the unconscious wishful impulse. It can afford to be more tolerant because the situation of someone sleeping is less perilous. The state of sleep in itself bars any outlet into reality.

The Dynamic Theory of Dream-Formation. The motive power for the formation of dreams is not provided by the latent dream-thoughts or day's residues, but by an unconscious impulse, repressed during the day, with which the day's residues have been able to establish contact and which contrives to make a wish-fulfilment for itself out of the material of the latent thoughts. Thus every dream is on the one hand the fulfilment of a wish on the part of the unconscious and on the other hand (in so far as it succeeds in guarding the state of sleep against being disturbed) the fulfilment of the normal wish to sleep which set the sleep going. If we disregard the unconscious contribution to the formation of the dream and limit the dream to its latent thoughts, it can represent anything with which waking life has been concerned - a reflection, a warning, an intention, a preparation for the immediate future or, once again, the satisfaction of an unfulfilled wish. The unrecognizability, strangeness and absurdity of the manifest dream are partly the result of the translation of the thoughts into a different, so to say archaic, method of expression, but partly the effect of a restrictive, critically disapproving agency in the mind which does not entirely cease to function during sleep. It is plausible to suppose that the 'dream-censorship', which we regard as being responsible in the first instance for the distortion of the dream-thoughts into the manifest dream, is an expression of the same mental forces which during the day-time had held back or repressed the unconscious wishful impulse.
There were now a whole series of questions to be answered, among the most important of them being whether the formation of dreams had a motive, under what conditions it took place, by what methods the dream-thoughts (which are invariably full of sense) become converted into the dream (which is often senseless), and others besides. I attempted to solve all of these problems in *The Interpretation of Dreams*, which I published in the year 1900. I can only find space here for the briefest abstract of my investigation. When the latent dream-thoughts that are revealed by the analysis of a dream are examined, one of them is found to stand out from among the rest, which are intelligible and well known to the dreamer. These latter thoughts are residues of waking life (the day's residues, as they are called technically); but the isolated thought is found to be a wishful impulse, often of a very repellent kind, which is foreign to the waking life of the dreamer and is consequently disavowed by him with surprise or indignation. This impulse is the actual constructor of the dream: it provides the energy for its production and makes use of the day's residues as material. The dream which thus originates represents a situation of satisfaction for the impulse, it is the fulfillment of its wish. It would not be possible for this process to take place without being favoured by the presence of something in the nature of a state of sleep. The necessary mental precondition of sleep is the concentration of the ego upon the wish to sleep and the withdrawal of psychical energy from all the interests of life. Since at the same time all the paths of approach to motility are blocked, the ego is also able to reduce the expenditure by which at other times it maintains the repressions. The unconscious impulse makes use of this nocturnal relaxation of repression in order to push its way into consciousness with the dream. But the repressive resistance of the ego is not abolished in sleep but merely reduced. Some of it remains in the shape of a censorship of dreams and forbids the unconscious impulse to express itself in the forms which it would properly assume. In consequence of the severity of the censorship of dreams, the latent dream-thoughts are obliged to submit to being altered and softened so as to make the forbidden meaning of the dream unrecognizable. This is the explanation of dream-distortion, which accounts for the most striking characteristics of the manifest dream. We are therefore justified in asserting that a dream is the (disguised) fulfillment of a (repressed) wish. It will now be seen that dreams are constructed like a neurotic symptom: they are compromises between the demands of a repressed impulse and the resistance of a censoring force in the ego. Since they have a similar origin they are equally unintelligible and stand in equal need of interpretation.

Here we are presented with a means of answering the question of whether dreams have a function too, whether they are entrusted with any useful achievement. The condition of rest free from stimulus, which the state of sleep wishes to establish, is threatened from three directions: in a relatively accidental manner by external stimuli during sleep, and by interests of the previous day which cannot be broken off, and in an unavoidable manner by unsated repressed instinctual impulses which are on the watch for an opportunity of finding expression. In consequence of the diminishing of repressions at night there would be a risk that the rest afforded by sleep would be interrupted whenever an instigation from outside or from inside succeeded in linking up with an unconscious instinctual source. The process of dreaming allows the product of a collaboration of this kind to find an outlet in a harmless hallucinatory experience and in that way assures a continuation of sleep. The fact that a dream occasionally awakens the sleeper, to the accompaniment of a generation of anxiety, is no contradiction of this function but rather, perhaps, a signal that the watchman regards the situation as too dangerous and no longer feels able to control it. And very often then, while we are still asleep, a consolation occurs to us which seeks to prevent our waking up: 'But after all it's only a dream!'
This piece of the dream-work gives us information about some of the most striking and peculiar features of dreams. I will repeat the course of events in dream-formation. As an introduction: the wish to sleep and intentional turning away from the external world. Next, two consequences of this for the mental apparatus: first, the possibility for older and more primitive methods of working to emerge in it - regression; secondly, the lowering of the resistance due to repression which weighs down upon the unconscious. As a result of this last factor the possibility arises for the formation of a dream and this is taken advantage of by the precipitating causes, the internal and external stimuli which have become active. The dream which originates in this way is already a compromise-structure. It has a double function; on the one hand it is ego-syntonic, since, by getting rid of the stimuli which are interfering with sleep, it serves the wish to sleep; on the other hand it allows a repressed instinctual impulse to obtain the satisfaction that is possible in these circumstances, in the form of the hallucinated fulfilment of a wish. The whole process of forming a dream which is permitted by the sleeping ego is, however, subject to the condition of the censorship, which is exercised by the residue of the repression still in operation. I cannot present the process more simply: it is not more simple. But I can proceed now with my description of the dream-work.

[1933a, 4632]

It remains for us to give a dynamic explanation of why the sleeping ego takes on the task of the dream-work at all. The explanation is fortunately easy to find. With the help of the unconscious, every dream that is in process of formation makes a demand upon the ego - for the satisfaction of an instinct, if the dream originates from the id; for the solution of a conflict, the removal of a doubt or the forming of an intention, if the dream originates from a residue of preconscious activity in waking life. The sleeping ego, however, is focused on the wish to maintain sleep; it feels this demand as a disturbance and seeks to get rid of the disturbance. The ego succeeds in doing this by what appears to be an act of compliance: it meets the demand with what is in the circumstances a harmless fulfilment of a wish and so gets rid of it. This replacement of the demand by the fulfilment of a wish remains the essential function of the dream-work. It may perhaps be worth while to illustrate this by three simple examples - a hunger dream, a dream of convenience and a dream prompted by sexual desire. A need for food makes itself felt in a dreamer during his sleep: he has a dream of a delicious meal and sleeps on. The choice, of course, was open to him either of waking up and eating something or of continuing his sleep. He decided in favour of the latter and satisfied his hunger by means of the dream - for the time being, at all events, for if his hunger had persisted he would have had to wake up nevertheless. Here is the second example. A sleeper had to wake up so as to be in time for his work at the hospital. But he slept on, and had a dream that he was already at the hospital - but as a patient, who has no need to get up. Or again, a desire becomes active during the night for the enjoyment of a forbidden sexual object, the wife of a friend of the sleeper. He has a dream of sexual intercourse - not, indeed, with this person but with someone else of the same name to whom he is in fact indifferent; or his struggle against the desire may find expression in his mistress remaining altogether anonymous.

[1940a [1938], 4980]
As the dream-work proceeds, sometimes the unconscious will press forward more successfully and sometimes the ego will defend itself with greater energy. Anxiety dreams are mostly those whose content has undergone the least distortion. If the demand made by the unconscious is too great for the sleeping ego to be in a position to fend it off by the means at its disposal, it abandons the wish to sleep and returns to waking life. We shall be taking every experience into account if we say that a dream is invariably an attempt to get rid of a disturbance of sleep by means of a wish-fulfilment, so that the dream is a guardian of sleep. The attempt may succeed more or less completely; it may also fail, and in that case the sleeper wakes up, apparently woken precisely by the dream. So, too, there are occasions when that excellent fellow the night-watchman, whose business it is to guard the little township's sleep, has no alternative but to sound the alarm and waken the sleeping townspeople.

[1940a [1938], 4981]
On the other hand, there are some people who are quite clearly aware during the night that they are asleep and dreaming and who thus seem to possess the faculty of consciously directing their dreams. If, for instance, a dreamer of this kind is dissatisfied with the turn taken by a dream, he can break it off without waking up and start it again in another direction - just as a popular dramatist may under pressure give his play a happier ending. Or another time, if his dream has led him into a sexually exciting situation, he can think to himself: 'I won't go on with this dream any further and exhaust myself with an emission; I'll hold it back for a real situation instead.'

The Marquis d'Hervey de Saint-Denys, quoted by Vaschide (1911, 139), claimed to have acquired the power of accelerating the course of his dreams just as he pleased, and of giving them any direction he chose. It seems as though in his case the wish to sleep had given place to another preconscious wish, namely to observe his dreams and enjoy them. Sleep is just as compatible with a wish of this sort as it is with a mental reservation to wake up if some particular condition is fulfilled (e.g. in the case of a nursing mother or wet-nurse). Moreover, it is a familiar fact that anyone who takes an interest in dreams remembers a considerably greater number of them after waking.

Greater theoretical interest, however, attaches to the dreams which have the power to rouse us in the middle of our sleep. Bearing in mind the expediency which is everywhere else the rule, we may ask why a dream, that is, an unconscious wish, is given the power to interfere with sleep, that is, with the fulfillment of the preconscious wish. The explanation no doubt lies in relations of energy of which we have no knowledge. If we possessed such knowledge, we should probably find that allowing the dream to take its course and expending a certain amount of more or less detached attention on it is an economy of energy compared with holding the unconscious as tightly under control at night as in the daytime. Experience shows that dreaming is compatible with sleeping, even if it interrupts sleep several times during the night. One wakes up for an instant and then falls asleep again at once. It is like brushing away a fly in one's sleep: a case of ad hoc awakening. If one falls asleep again, the interruption has been disposed of. As is shown by such familiar examples as the sleep of a nursing mother or wet nurse, the fulfillment of the wish to sleep is quite compatible with maintaining a certain expenditure of attention in some particular direction.
Now while this agency, in which we recognize our normal ego, is concentrated on the wish to sleep, it appears to be compelled by the psycho-physiological conditions of sleep to relax the energy with which it is accustomed to hold down the repressed material during the day. In itself, no doubt, this relaxation does no harm; however much the suppressed impulses of the childish mind may prance around, their access to consciousness is still difficult and their access to movement is barred as the result of this same state of sleep. The danger of sleep being disturbed by them must, however, be guarded against. We must in any case suppose that even during deep sleep a certain amount of free attention is on duty as a guard against sensory stimuli, and that this guard may sometimes consider waking more advisable than a continuation of sleep. Otherwise there would be no explanation of how it is that we can be woken up at any moment by sensory stimuli of some particular quality. As the physiologist Burdach insisted long ago, a mother, for instance, will be roused by the whimpering of her baby, or a miller if his mill comes to a stop, or most people if they are called softly by their own name. Now the attention which is thus on guard is also directed towards internal wishful stimuli arising from the repressed material, and combines with them to form the dream which, as a compromise, simultaneously satisfies both of the two agencies. The dream provides a kind of psychical consummation for the wish that has been suppressed (or formed with the help of repressed material) by representing it as fulfilled; but it also satisfies the other agency by allowing sleep to continue. In this respect our ego is ready to behave like a child; it gives credence to the dream images, as though what it wanted to say was: 'Yes, yes! you’re quite right, but let me go on sleeping!' The low estimate which we form of dreams when we are awake, and which we relate to their confused and apparently illogical character, is probably nothing other than the judgement passed by our sleeping ego upon the repressed impulses, a judgement based, with better right, upon the motor impotence of these disturbers of sleep. We are sometimes aware in our sleep of this contemptuous judgement. If the content of a dream goes too far in overstepping the censorship, we think: 'After all, it's only a dream!' - and go on sleeping. [1901a, 1092]

My second remark is a supplement to the theory of dreams. We cannot explain the origin of dreams unless we adopt the hypothesis that the repressed unconscious has achieved some degree of independence of the ego, so that it does not acquiesce in the wish to sleep and retains its cathexes even when all the object-cathexes depending on the ego have been withdrawn in order to encourage sleep. Only if that is so can we understand how the unconscious can make use of the lifting or reduction of the censorship which occurs at night, and can succeed in obtaining control over the day's residues so as to construct a forbidden dream-wish out of their material. On the other hand, it may be that these day's residues have to thank an already existing connection with the repressed unconscious for some of their resistance to the withdrawal of libido commanded by the wish to sleep. We will, then, insert this dynamically important feature into our view of the formation of dreams by way of supplement. [1916-1917, 3464]
The Dynamic Theory of Dream-Formation. The motive power for the formation of dreams is not provided by the latent dream-thoughts or day's residues, but by an unconscious impulse, repressed during the day, with which the day's residues have been able to establish contact and which contrives to make a wish-fulfilment for itself out of the material of the latent thoughts. Thus every dream is on the one hand the fulfilment of a wish on the part of the unconscious and on the other hand (in so far as it succeeds in guarding the state of sleep against being disturbed) the fulfilment of the normal wish to sleep which set the sleep going. If we disregard the unconscious contribution to the formation of the dream and limit the dream to its latent thoughts, it can represent anything with which waking life has been concerned - a reflection, a warning, an intention, a preparation for the immediate future or, once again, the satisfaction of an unfulfilled wish. The unrecognizability, strangeness and absurdity of the manifest dream are partly the result of the translation of the thoughts into a different, so to say archaic, method of expression, but partly the effect of a restrictive, critically disapproving agency in the mind which does not entirely cease to function during sleep. It is plausible to suppose that the 'dream-censorship', which we regard as being responsible in the first instance for the distortion of the dream-thoughts into the manifest dream, is an expression of the same mental forces which during the day-time had held back or repressed the unconscious wishful impulse.

[1923a, 3918]

What conclusions can one draw from a correctly translated dream? I have an impression that analytic practice has not always avoided errors and over-estimations on this point, partly owing to an exaggerated respect for the 'mysterious unconscious'. It is only too easy to forget that a dream is as a rule merely a thought like any other, made possible by a relaxation of the censorship and by unconscious reinforcement, and distorted by the operation of the censorship and by unconscious revision.

[1923c, 4033]
There were now a whole series of questions to be answered, among the most important of them being whether the formation of dreams had a motive, under what conditions it took place, by what methods the dream-thoughts (which are invariably full of sense) become converted into the dream (which is often senseless), and others besides. I attempted to solve all of these problems in *The Interpretation of Dreams*, which I published in the year 1900. I can only find space here for the briefest abstract of my investigation. When the latent dream-thoughts that are revealed by the analysis of a dream are examined, one of them is found to stand out from among the rest, which are intelligible and well known to the dreamer. These latter thoughts are residues of waking life (the day's residues, as they are called technically); but the isolated thought is found to be a wishful impulse, often of a very repellent kind, which is foreign to the waking life of the dreamer and is consequently disavowed by him with surprise or indignation. This impulse is the actual constructor of the dream: it provides the energy for its production and makes use of the day's residues as material. The dream which thus originates represents a situation of satisfaction for the impulse, it is the fulfilment of its wish. It would not be possible for this process to take place without being favoured by the presence of something in the nature of a state of sleep. The necessary mental precondition of sleep is the concentration of the ego upon the wish to sleep and the withdrawal of psychical energy from all the interests of life. Since at the same time all the paths of approach to motility are blocked, the ego is also able to reduce the expenditure by which at other times it maintains the repressions. The unconscious impulse makes use of this nocturnal relaxation of repression in order to push its way into consciousness with the dream. But the repressive resistance of the ego is not abolished in sleep but merely reduced. Some of it remains in the shape of a censorship of dreams and forbids the unconscious impulse to express itself in the forms which it would properly assume. In consequence of the severity of the censorship of dreams, the latent dream-thoughts are obliged to submit to being altered and softened so as to make the forbidden meaning of the dream unrecognizable. This is the explanation of dream-distortion, which accounts for the most striking characteristics of the manifest dream. We are therefore justified in asserting that a dream is the (disguised) fulfilment of a (repressed) wish. It will now be seen that dreams are constructed like a neurotic symptom: they are compromises between the demands of a repressed impulse and the resistance of a censoring force in the ego. Since they have a similar origin they are equally unintelligible and stand in equal need of interpretation.

[1925d, 4219]
You have long been aware that this censorship is not an institution peculiar to dream-life. You know that the conflict between the two psychical agencies, which we - inaccurately - describe as the 'unconscious repressed' and the 'conscious', dominates our whole mental life and that the resistance against the interpretation of dreams, the sign of the dream-censorship, is nothing other than the resistance due to repression by which the two agencies are separated. You know too that the conflict between these two agencies may under certain conditions produce other psychical structures which, like dreams, are the outcome of compromises; and you will not expect me to repeat to you here everything that was contained in my introduction to the theory of the neuroses in order to demonstrate to you what we know of the determinants of the formation of such compromises. You have realized that the dream is a pathological product, the first member of the class which includes hysterical symptoms, obsessions and delusions, but that it is distinguished from the others by its transitoriness and by its occurrence under conditions which are part of normal life. For let us bear firmly in mind that, as was already pointed out by Aristotle, dream life is the way in which our mind works during the state of sleep. The state of sleep involves a turning-away from the real external world, and there we have the necessary condition for the development of a psychosis. The most careful study of the severe psychoses will not reveal to us a single feature that is more characteristic of those pathological conditions. In psychoses, however, the turning-away from reality is brought about in two kinds of way: either by the unconscious repressed becoming excessively strong so that it overwhells the conscious, which is attached to reality, or because reality has become so intolerably distressing that the threatened ego throws itself into the arms of the unconscious instinctual forces in a desperate revolt. The harmless dream-psychosis is the result of a withdrawal from the external world which is consciously willed and only temporary, and it disappears when relations to the external world are resumed. During the isolation of the sleeping individual an alteration in the distribution of his psychical energy also sets in; a part of the expenditure on repression, which is normally required in order to hold the unconscious down, can be saved, for if the unconscious makes use of its relative liberation for active purposes, it finds its path to motility closed and the only path open to it is the harmless one leading to hallucinatory satisfaction. Now, therefore, a dream can be formed; but the fact of the dream-censorship shows that even during sleep enough of the resistance due to repression is retained.

[1933a, 4629]

Here we are presented with a means of answering the question of whether dreams have a function too, whether they are entrusted with any useful achievement. The condition of rest free from stimulus, which the state of sleep wishes to establish, is threatened from three directions: in a relatively accidental manner by external stimuli during sleep, and by interests of the previous day which cannot be broken off, and in an unavoidable manner by unsated repressed instinctual impulses which are on the watch for an opportunity of finding expression. In consequence of the diminishing of repressions at night there would be a risk that the rest afforded by sleep would be interrupted whenever an instigation from outside or from inside succeeded in linking up with an unconscious instinctual source. The process of dreaming allows the product of a collaboration of this kind to find an outlet in a harmless hallucinatory experience and in that way assures a continuation of sleep. The fact that a dream occasionally awakens the sleeper, to the accompaniment of a generation of anxiety, is no contradiction of this function but rather, perhaps, a signal that the watchman regards the situation as too dangerous and no longer feels able to control it. And very often then, while we are still asleep, a consolation occurs to us which seeks to prevent our waking up: 'But after all it's only a dream!'

[1933a, 4630]
In what follows I shall not be able to avoid a schematic method of exposition. Let us assume that in a particular case we have before us all the latent thoughts, charged with a greater or less amount of affect, by which the manifest dream has been replaced after its interpretation has been completed. We shall then be struck by one difference among these latent thoughts, and that difference will take us a long way. Almost all these dream-thoughts are recognized by the dreamer or acknowledged by him; he admits that he has thought this, now or at some other time, or that he might have thought it. There is only one single thought that he refuses to accept; it is strange to him or even perhaps repellent; he may possibly reject it with passionate feeling. It now becomes evident to us that the other thoughts are portions of a conscious, or, more accurately, a preconscious train of thinking. They might have been thought in waking life too, and indeed they were probably formed during the previous day. This one repudiated thought, however, or, properly speaking, this one impulse, is a child of night; it belongs to the dreamer's unconscious and on that account it is repudiated and rejected by him. It had to wait for the nightly relaxation of repression in order to arrive at any kind of expression. And in any case this expression is a weakened, distorted and disguised one; without our work of dream-interpretation we should not have found it. This unconscious impulse has to thank its link with the other, unobjectionable, dream-thoughts for the opportunity of slipping past the barrier of the censorship in an inconspicuous disguise. On the other hand, the preconscious dream-thoughts have to thank this same link for the power to occupy mental life during sleep as well. For there is no doubt about it: this unconscious impulse is the true creator of the dream; it is what produces the psychical energy for the dream's construction. Like any other instinctual impulse, it cannot strive for anything other than its own satisfaction; and our experience in interpreting dreams shows us too that that is the sense of all dreaming. In every dream an instinctual wish has to be represented as fulfilled. The shutting-off of mental life from reality at night and the regression to primitive mechanisms which this makes possible enable this wished-for instinctual satisfaction to be experienced in a hallucinatory manner as occurring in the present. As a result of this same regression, ideas are transformed in the dream into visual pictures: the latent dream-thoughts, that is to say, are dramatized and illustrated.

This piece of the dream-work gives us information about some of the most striking and peculiar features of dreams. I will repeat the course of events in dream-formation. As an introduction: the wish to sleep and intentional turning away from the external world. Next, two consequences of this for the mental apparatus: first, the possibility for older and more primitive methods of working to emerge in it - regression; secondly, the lowering of the resistance due to repression which weighs down upon the unconscious. As a result of this last factor the possibility arises for the formation of a dream and this is taken advantage of by the precipitating causes, the internal and external stimuli which have become active. The dream which originates in this way is already a compromise-structure. It has a double function; on the one hand it is ego-syntonic, since, by getting rid of the stimuli which are interfering with sleep, it serves the wish to sleep; on the other hand it allows a repressed instinctual impulse to obtain the satisfaction that is possible in these circumstances, in the form of the hallucinated fulfilment of a wish. The whole process of forming a dream which is permitted by the sleeping ego is, however, subject to the condition of the censorship, which is exercised by the residue of the repression still in operation. I cannot present the process more simply: it is not more simple. But I can proceed now with my description of the dream-work.
With the traumatic neuroses things are different. In their case the dreams regularly end in the generation of anxiety. We should not, I think, be afraid to admit that here the function of the dream has failed. I will not invoke the saying that the exception proves the rule: its wisdom seems to me most questionable. But no doubt the exception does not overturn the rule. If, for the sake of studying it, we isolate one particular psychical function, such as dreaming, from the psychical machinery as a whole, we make it possible to discover the laws that are peculiar to it; but when we insert it once more into the general context we must be prepared to discover that these findings are obscured or impaired by collision with other forces. We say that a dream is the fulfilment of a wish; but if you want to take these latter objections into account, you can say nevertheless that a dream is an attempt at the fulfilment of a wish. No one who can properly appreciate the dynamics of the mind will suppose that you have said anything different by this. In certain circumstances a dream is only able to put its intention into effect very incompletely, or must abandon it entirely. Unconscious fixation to a trauma seems to be foremost among these obstacles to the function of dreaming. While the sleeper is obliged to dream, because the relaxation of repression at night allows the upward pressure of the traumatic fixation to become active, there is a failure in the functioning of his dream-work, which would like to transform the memory-traces of the traumatic event into the fulfilment of a wish. In these circumstances it will happen that one cannot sleep, that one gives up sleep from dread of the failure of the function of dreaming. Traumatic neuroses are here offering us an extreme case; but we must admit that childhood experiences, too, are of a traumatic nature, and we need not be surprised if comparatively trivial interferences with the function of dreams may arise under other conditions as well.

[1933a, 4642]
Dream-distortion was the profoundest and most difficult problem of dream life. And light was thrown on it by the following consideration, which placed dreams in a class along with other psychopathological formations and revealed them, as it were, as the normal psychoses of human beings. For our mind, that precious instrument by whose means we maintain ourselves in life, is no peacefully self-contained unity. It is rather to be compared with a modern State in which a mob, eager for enjoyment and destruction, has to be held down forcibly by a prudent superior class. The whole flux of our mental life and everything that finds expression in our thoughts are derivations and representatives of the multifarious instincts that are innate in our physical constitution. But these instincts are not all equally susceptible to direction and education, or equally ready to fall in with the demands of the external world and of human society. A number of them have retained their primitive, ungovernable nature; if we let them have their way, they would infallibly bring us to ruin. Consequently, learning by experience, we have developed organizations in our mind which, in the form of inhibitions, set themselves up against the direct manifestations of the instincts. Every impulse in the nature of a wish that arises from the sources of instinctual energy must submit itself to examination by the highest agencies of our mind, and, if it is not approved, is rejected and restrained from exercising any influence upon our movements - that is, from coming into execution. Often enough, indeed, such wishes are even forbidden to enter consciousness, which is habitually unaware even of the existence of these dangerous instinctual sources. We describe such impulses as being repressed from the point of view of consciousness, and as surviving only in the unconscious. If what is repressed contrives somehow to force its way into consciousness or into movement or into both, we are no longer normal: at that point the whole range of neurotic and psychotic symptoms arise. The maintenance of the necessary inhibitions and repressions imposes upon our mind a great expenditure of energy, from which it is glad to be relieved. A good opportunity for this seems to be offered at night by the state of sleep, since sleep involves a cessation of our motor functions. The situation seems safe, and the severity of our internal police-force may therefore be relaxed. It is not entirely withdrawn, since one cannot be certain: it may be that the unconscious never sleeps at all. And now the reduction of pressure upon the repressed unconscious produces its effect. Wishes arise from it which during sleep might find the entrance to consciousness open. If we were to know them we should be appalled, alike by their subject-matter, their unrestraint and indeed the mere possibility of their existence. This, however, occurs only seldom, and when it does we awake as speedily as possible, in a state of fear. But as a rule our consciousness does not experience the dream as it really was. It is true that the inhibitory forces (the dream censorship, as we may call them) are not completely awake, but neither are they wholly asleep. They have had an influence on the dream while it was struggling to find an expression in words and pictures, they have got rid of what was most objectionable, they have altered other parts of it till they are unrecognizable, they have severed real connections while introducing false ones, until the honest but brutal wishful phantasy which lay behind the dream has turned into the manifest dream as we remember it - more or less confused and almost always strange and incomprehensible. Thus the dream (or the distortion which characterizes it) is the expression of a compromise, the evidence of a conflict between the mutually incompatible impulses and strivings of our mental life. And do not let us forget that the same process, the same interplay of forces, which explains the dreams of a normal sleeper, gives us the key to understanding all the phenomena of neurosis and psychosis.

[1932c, 4809]
It is best to begin by pointing out that the formation of a dream can be provoked in two different ways. Either, on the one hand, an instinctual impulse which is ordinarily suppressed (an unconscious wish) finds enough strength during sleep to make itself felt by the ego, or, on the other hand, an urge left over from waking life, a preconscious train of thought with all the conflicting impulses attached to it, finds reinforcement during sleep from an unconscious element. In short, dreams may arise either from the id or from the ego. The mechanism of dream-formation is in both cases the same and so also is the necessary dynamic precondition. The ego gives evidence of its original derivation from the id by occasionally ceasing its functions and allowing a reversion to an earlier state of things. This is logically brought about by its breaking off its relations with the external world and withdrawing its cathexes from the sense organs. We are justified in saying that there arises at birth an instinct to return to the intra-uterine life that has been abandoned - an instinct to sleep. Sleep is a return of this kind to the womb. Since the waking ego governs motility, that function is paralysed in sleep, and accordingly a good part of the inhibitions imposed on the unconscious id become superfluous. The withdrawal or reduction of these 'anticathexes' thus allows the id what is now a harmless amount of liberty.

[1940a [1938], 4976]
Why is it, then, that, though the occasion of my dreaming was a daytime impression by which I had been justifiably stirred, I nevertheless actually dreamt of something indifferent? The most obvious explanation, no doubt, is that we are once more faced by one of the phenomena of dream-distortion, which in my last chapter I traced to a psychical force acting as a censorship. My recollection of the monograph on the genus Cyclamen would thus serve the purpose of being an allusion to the conversation with my friend, just as the 'smoked salmon' in the dream of the abandoned supper-party served as an allusion to the dreamer's thought of her woman friend. The only question is as to the intermediate links which enabled the impression of the monograph to serve as an allusion to the conversation with the eye-surgeon, since at first sight there is no obvious connection between them. In the example of the abandoned supper-party the connection was given at once: 'smoked salmon', being the friend's favourite dish, was an immediate constituent of the group of ideas which were likely to be aroused in the dreamer's mind by the personality of her friend. In this later example there were two detached impressions which at a first glance only had in common the fact of their having occurred on the same day: I had caught sight of the monograph in the morning and had had the conversation the same evening. The analysis enabled us to solve the problem as follows: connections of this kind, when they are not present in the first instance, are woven retrospectively between the ideational content of one impression and that of the other. I have already drawn attention to the intermediate links in the present case by the words I have italicized in my record of the analysis. If there had been no influences from another quarter, the idea of the monograph on the Cyclamen would only, I imagine, have led to the idea of its being my wife's favourite flower, and possibly also to Frau L.'s absent bouquet. I scarcely think that these background thoughts would have sufficed to evoke a dream. As we are told in Hamlet:

[1900a, 662]

Thus the fact that the content of dreams includes remnants of trivial experiences is to be explained as a manifestation of dream-distortion (by displacement); and it will be recalled that we came to the conclusion that dream-distortion was the product of a censorship operating in the passage-way between two psychical agencies. It is to be expected that the analysis of a dream will regularly reveal its true, psychically significant source in waking life, though the emphasis has been displaced from the recollection of that source on to that of an indifferent one. This explanation brings us into complete conflict with Robert's theory, which ceases to be of any service to us. For the fact which Robert sets out to explain is a non-existent one. His acceptance of it rests on a misunderstanding, on his failure to replace the apparent content of dreams by their real meaning. And there is another objection that can be raised to Robert's theory. If it were really the business of dreams to relieve our memory of the 'dregs' of daytime recollections by a special psychical activity, our sleep would be more tormented and harder worked than our mental life while we are awake. For the number of indifferent impressions from which our memory would need to be protected is clearly immensely large: the night would not be long enough to cope with such a mass. It is far more likely that the process of forgetting indifferent impressions goes forward without the active intervention of our psychical forces. [1900a, 665]
Thus the wish to sleep (which the conscious ego is concentrated upon, and which, together with the dream-censorship and the 'secondary revision' which I shall mention later, constitute the conscious ego's share in dreaming) must in every case be reckoned as one of the motives for the formation of dreams, and every successful dream is a fulfilment of that wish. We shall discuss elsewhere the relations subsisting between this universal, invariably present and unchanging wish to sleep and the other wishes, of which now one and now another is fulfilled by the content of the dream. But we have found in the wish to sleep the factor that is able to fill the gap in the theory of Strümpell and Wundt and to explain the perverse and capricious manner in which external stimuli are interpreted. The correct interpretation, which the sleeping mind is perfectly capable of making, would involve an active interest and would require that sleep should be brought to an end; for that reason, of all the possible interpretations, only those are admitted which are consistent with the absolute censorship exercised by the wish to sleep. 'It is the nightingale and not the lark.' For if it were the lark it would mean the end of the lovers' night. Among the interpretations of the stimulus which are accordingly admissible, that one is then selected which can provide the best link with the wishful impulses lurking in the mind. Thus everything is unambiguously determined and nothing is left to arbitrary decision. The misinterpretation is not an illusion but, as one might say, an evasion. Here once again, however, just as when, in obedience to the dream-censorship, a substitution is effected by displacement, we have to admit that we are faced by an act which deviates from normal psychical processes.

It is also instructive to consider the relation of these dreams to anxiety-dreams. In the dreams we have been discussing, a repressed wish has found a means of evading censorship - and the distortion which censorship involves. The invariable concomitant is that painful feelings are experienced in the dream. In just the same way anxiety-dreams only occur if the censorship has been wholly or partly overpowered; and, on the other hand, the overpowering of the censorship is facilitated if anxiety has already been produced as an immediate sensation arising from somatic sources. We can thus plainly see the purpose for which the censorship exercises its office and brings about the distortion of dreams: it does so in order to prevent the generation of anxiety or other forms of distressing affect.

¹ [Footnote added 1909:] Since I may say that the kernel of my theory of dreams lies in my derivation of dream-distortion from the censorship, I will here insert the last part of a story from Phantasien ein Realisten by 'Lynkeus' (Vienna, 2nd edition, 1900), in which I have found this principal feature of my theory once more expounded.

One and one only of these logical relations is very highly favoured by the mechanism of dream-formation; namely, the relation of similarity, consonance or approximation - the relation of 'just as'. This relation, unlike any other, is capable of being represented in dreams in a variety of ways.¹ Parallels or instances of 'just as' inherent in the material of the dream-thoughts constitute the first foundations for the construction of a dream; and no inconsiderable part of the dream-work consists in creating fresh parallels where those which are already present cannot find their way into the dream owing to the censorship imposed by resistance. The representation of the relation of similarity is assisted by the tendency of the dream-work towards condensation.
This second species of displacement which occurs in dream-formation is not only of great theoretical interest but is also specially well calculated to explain the appearance of fantastic absurdity in which dreams are disguised. The direction taken by the displacement usually results in a colourless and abstract expression in the dream-thought being exchanged for a pictorial and concrete one. The advantage, and accordingly the purpose, of such a change jumps to the eyes. A thing that is pictorial is, from the point of view of a dream, a thing that is *capable of being represented*: it can be introduced into a situation in which abstract expressions offer the same kind of difficulties to representation in dreams as a political leading article in a newspaper would offer to an illustrator. But not only representability, but the interests of condensation and the censorship as well can be the gainers from this exchange. A dream-thought is unusable so long as it is expressed in an abstract form; but when once it has been transformed into pictorial language, contrasts and identifications of the kind which the dream-work requires, and which it creates if they are not already present, can be established more easily than before between the new form of expression and the remainder of the material underlying the dream. This is so because in every language concrete terms, in consequence of the history of their development, are richer in associations than conceptual ones. We may suppose that a good part of the intermediate work done during the formation of a dream, which seeks to reduce the dispersed dream-thoughts to the most succinct and unified expression possible, proceeds along the line of finding appropriate verbal transformations for the individual thoughts. Any one thought, whose form of expression may happen to be fixed for other reasons, will operate in a determinant and selective manner on the possible forms of expression allotted to the other thoughts, and it may do so, perhaps, from the very start - as is the case in writing a poem. If a poem is to be written in rhymes, the second line of a couplet is limited by two conditions: it must express an appropriate meaning, and the expression of that meaning must rhyme with the first line. No doubt the best poem will be one in which we fail to notice the intention of finding a rhyme, and in which the two thoughts have, by mutual influence, chosen from the very start a verbal expression which will allow a rhyme to emerge with only slight subsequent adjustment.

[1900a, 809]
Hitherto philosophers have had no occasion to concern themselves with a psychology of repression. We may therefore be permitted to make a first approach to this hitherto unknown topic by constructing a pictorial image of the course of events in dream-formation. It is true that the schematic picture we have arrived at - not only from the study of dreams - is a fairly complicated one; but we cannot manage with anything simpler. Our hypothesis is that in our mental apparatus there are two thought-constructing agencies, of which the second enjoys the privilege of having free access to consciousness for its products whereas the activity of the first is in itself unconscious and can only reach consciousness by way of the second. On the frontier between the two agencies, where the first passes over to the second, there is a censorship, which only allows what is agreeable to it to pass through and holds back everything else. According to our definition, then, what is rejected by the censorship is in a state of repression.

Under certain conditions, of which the state of sleep is one, the relation between the strength of the two agencies is modified in such a way that what is repressed can no longer be held back. In the state of sleep this probably occurs owing to a relaxation of the censorship; when this happens it becomes possible for what has hitherto been repressed to make a path for itself to consciousness. Since, however, the censorship is never completely eliminated but merely reduced, the repressed material must submit to certain alterations which mitigate its offensive features. What becomes conscious in such cases is a compromise between the intentions of one agency and the demands of the other. Repression - relaxation of the censorship - the formation of a compromise, this is the fundamental pattern for the generation not only of dreams but of many other psychopathological structures; and in the latter cases too we may observe that the formation of compromises is accompanied by processes of condensation and displacement and by the employment of superficial associations, which we have become familiar with in the dream-work.

The following forces may be recognized as having a share in the formation of dreams: the wish to sleep, the cathexis of energy that still remains in the day's residues after it has been lowered by the state of sleep, the psychical energy of the dream-constructing unconscious wish and the opposing force of the 'censorship', which dominates daytime life and is not completely lifted during sleep. The task of dream-formation is above all to overcome the inhibition from the censorship; and it is precisely this task which is solved by the displacements of psychical energy within the material of the dream-thoughts.

We have entered so closely, in connection with the processes of condensation, into the importance of the analogy between jokes and dreams that we may be briefer in what follows. As we know, the displacements in the dream-work point to the operation of the censorship of conscious thinking, and accordingly, when we come across displacement among the techniques of jokes, we shall be inclined to suppose that an inhibitory force plays a part in the formation of jokes as well. And we already know that this is quite generally the case. The effort made by jokes to recover the old pleasure in nonsense or the old pleasure in words finds itself inhibited in normal moods by objections raised by critical reason; and in every individual case this has to be overcome. But the manner in which the joke-work accomplishes this task shows a sweeping distinction between jokes and dreams. In the dream-work it is habitually accomplished by displacements, by the selection of ideas which are sufficiently remote from the objectionable one for the censorship to allow them to pass, but which are nevertheless derivatives of that idea and have taken over its psychical cathexis by means of a complete transference. For this reason displacements are never absent in a dream and are far more comprehensive.
With this last contribution, however, which explains, even though still only hypothetically, the joke-work in the first person, our interest in jokes is, strictly speaking, at an end. It remains for us to make a further short comparison between jokes and the better-known dream; and we may expect that, apart from the single conformity we have already considered, two such dissimilar mental functions will only reveal differences. The most important difference lies in their social behaviour. A dream is a completely asocial mental product; it has nothing to communicate to anyone else; it arises within the subject as a compromise between the mental forces struggling in him, it remains unintelligible to the subject himself and is for that reason totally uninteresting to other people. Not only does it not need to set any store by intelligibility, it must actually avoid being understood, for otherwise it would be destroyed; it can only exist in masquerade. For that reason it can without hindrance make use of the mechanism that dominates unconscious mental processes, to the point of a distortion which can no longer be set straight. A joke, on the other hand, is the most social of all the mental functions that aim at a yield of pleasure. It often calls for three persons and its completion requires the participation of someone else in the mental process it starts. The condition of intelligibility is, therefore, binding on it; it may only make use of possible distortion in the unconscious through condensation and displacement up to the point at which it can be set straight by the third person's understanding. Moreover, jokes and dreams have grown up in quite different regions of mental life and must be allotted to points in the psychological system far remote from each other. A dream still remains a wish, even though one that has been made unrecognizable; a joke is developed play. Dreams, in spite of all their practical nonentity, retain their connection with the major interests of life; they seek to fulfil needs by the regressive detour of hallucination, and they are permitted to occur for the sake of the one need that is active during the night - the need to sleep. Jokes, on the other hand, seek to gain a small yield of pleasure from the mere activity, untrammelled by needs, of our mental apparatus. Later they try to catch hold of that pleasure as a by-product during the activity of that apparatus and thus arrive secondarily at not unimportant functions directed to the external world. Dreams serve predominantly for the avoidance of unpleasure, jokes for the attainment of pleasure; but all our mental activities converge in these two aims.

It is very much more convenient to study dream-symbolism in folklore than in actual dreams. Dreams are obliged to conceal things and only surrender their secrets to interpretation; these comic anecdotes, however, which are disguised as dreams, are intended as communications, meant to give pleasure to the person who tells them as well as to the listener, and therefore the interpretation is added quite unashamedly to the symbol. These stories delight in stripping off the veiling symbols.

The dream-work is a psychological process the like of which has hitherto been unknown to psychology. It has claims upon our interest in two main directions. In the first place, it brings to our notice novel processes such as 'condensation' (of ideas) and 'displacement' (of psychical emphasis from one idea to another), processes which we have never come across at all in our waking life, or only as the basis of what are known as 'errors in thought'. In the second place, it enables us to detect the operation in the mind of a play of forces which was concealed from our conscious perception. We find that there is a 'censorship', a testing agency, at work in us, which decides whether an idea cropping up in the mind shall be allowed to reach consciousness, and which, so far as lies within its power, ruthlessly excludes anything that might produce or revive unpleasure. And it will be recalled at this point that in our analysis of parapraxes we found traces of this same intention to avoid unpleasure in remembering things and of similar conflicts between mental impulses.

[1905c, 1761]

[1957a [1911], 2524]

[1913], 2807]
The psychological novelties inferred from dreams and parapraxes must be applicable as an explanation of other phenomena if we are to believe in the value of these novelties, or, indeed, in their existence. And we do in fact find that psycho-analysis has shown that the hypotheses of unconscious mental activity, of censorship and repression and of distortion and substitution, at which we have arrived from our study of these normal phenomena, also afford us a first understanding of a number of pathological phenomena and, as one might say, put into our hands the key to all the riddles of the psychology of the neuroses. Thus dreams are to be regarded as the normal prototypes of all psychopathological structures. Anyone who understands dreams can also grasp the psychical mechanism of the neuroses and psychoses.

You will, I hope, think it plausible to suppose that it was precisely the objectionable nature of these passages that was the motive for their suppression. Where shall we find a parallel to such an event? You need not look far in these days. Take up any political newspaper and you will find that here and there the text is absent and in its place nothing except the white paper is to be seen. This, as you know, is the work of the press censorship. In these empty places there was something that displeased the higher censorship authorities and for that reason it was removed - a pity, you feel, since no doubt it was the most interesting thing in the paper - the 'best bit'.

On other occasions the censorship has not gone to work on a passage after it has already been completed. The author has seen in advance which passages might expect to give rise to objections from the censorship and has on that account toned them down in advance, modified them slightly, or has contented himself with approximations and allusions to what would genuinely have come from his pen. In that case there are no blank places in the paper, but circumlocutions and obscurities of expression appearing at certain points will enable you to guess where regard has been paid to the censorship in advance.

Well, we can keep close to this parallel. It is our view that the omitted pieces of the speeches in the dream which were concealed by a mumble have likewise been sacrificed to a censorship. We speak in so many words of a 'dream-censorship', to which some share in dream-distortion is to be attributed. Wherever there are gaps in the manifest dream the dream-censorship is responsible for them. We should go further, and regard it as a manifestation of the censorship wherever a dream-element is remembered especially faintly, indefinitely and doubtfully among other elements that are more clearly constructed. But it is only rarely that this censorship manifests itself so undisguisedly - so naively, one might say - as in this example of the dream of 'love services'. The censorship takes effect much more frequently according to the second method, by producing softenings, approximations and allusions instead of the genuine thing.
I know of no parallel in the operations of the press-censorship to a third manner of working by the dream-censorship; but I am able to demonstrate it from precisely the one example of a dream which we have analysed so far. You will recall the dream of the 'three bad theatre-tickets for 1 florin 50'. In the latent thoughts of that dream the element 'over-hurriedly, too early' stood in the foreground. Thus: it was absurd to marry so early - it was also absurd to take the theatre-tickets so early - it was ridiculous of the sister-in-law to part with her money in such a hurry to buy jewellery with it. Nothing of this central element of the dream-thoughts passed over into the manifest dream; in it the central position is taken by the 'going to the theatre' and 'taking the tickets'. As a result of this displacement of accent, this fresh grouping of the elements of the content, the manifest dream has become so unlike the latent dream-thoughts that no-one would suspect the presence of the latter behind the former. This displacement of accent is one of the chief instruments of dream-distortion and it is what gives the dream the strangeness on account of which the dreamer himself is not inclined to recognize it as his own production.

After these remarks on the activities of the dream-censorship, we will now turn to its dynamics. I hope you do not take the term too anthropomorphically, and do not picture the 'censor of dreams' as a severe little manikin or a spirit living in a closet in the brain and there discharging his office; but I hope too that you do not take the term in too 'localizing' a sense, and do not think of a 'brain-centre', from which a censoring influence of this kind issues, an influence which would be brought to an end if the 'centre' were damaged or removed. For the time being it is nothing more than a serviceable term for describing a dynamic relation. The word does not prevent our asking by what purposes this influence is exercised and against what purposes it is directed. And we shall not be surprised to learn that we have come up against the dream-censorship once already, though perhaps without recognizing it.

For that is in fact the case. You will recall that when we began to make use of our technique of free association we made a surprising discovery. We became aware that our efforts at proceeding from the dream-element to the unconscious element for which it is a substitute were being met by a resistance. This resistance, we said, could be of different magnitudes, sometimes enormous and sometimes quite insignificant. In the latter case we need to pass through only a small number of intermediate links in our work of interpretation; but when the resistance is large we have to traverse long chains of associations from the dream-element, we are led far away from it and on our path we have to overcome all the difficulties which represent themselves as critical objections to the ideas that occur. What we met with as resistance in our work of interpretation must now be introduced into the dream-work in the form of the dream-censorship. The resistance to interpretation is only a putting into effect of the dream-censorship. It also proves to us that the force of the censorship is not exhausted in bringing about the distortion of dreams and thereafter extinguished, but that the censorship persists as a permanent institution which has as its aim the maintenance of the distortion. Moreover, just as the strength of the resistance varies in the interpretation of each element in a dream, so too the magnitude of the distortion introduced by the censorship varies for each element in the same dream. If we compare the manifest and the latent dream, we shall find that some particular latent elements have been completely eliminated, others modified to a greater or less extent, while yet others have been carried over into the manifest content of the dream unaltered or even perhaps strengthened.
But we wanted to enquire what are the purposes which exercise the censorship and against what purposes it is directed. Now this question, which is fundamental for the understanding of dreams and perhaps, indeed, of human life, is easy to answer if we look through the series of dreams which have been interpreted. The purposes which exercise the censorship are those which are acknowledged by the dreamer's waking judgement, those with which he feels himself at one. You may be sure that if you reject an interpretation of one of your own dreams which has been correctly carried out, you are doing so for the same motives for which the dream-censorship has been exercised, the dream-distortion brought about and the interpretation made necessary. Take the dream of our fifty-year-old lady. She thought her dream disgusting without having analysed it, and she would have been still more indignant if Dr. von Hug-Hellmuth had told her anything of its inevitable interpretation; it was precisely because of this condemnation by the dreamer that the objectionable passages in her dream were replaced by a mumble.

The purposes against which the dream-censorship is directed must be described in the first instance from the point of view of that agency itself. If so, one can only say that they are invariably of a reprehensible nature, repulsive from the ethical, aesthetic and social point of view - matters of which one does not venture to think at all or thinks only with disgust. These wishes, which are censored and given a distorted expression in dreams, are first and foremost manifestations of an unbridled and ruthless egoism. And, to be sure, the dreamer's own ego appears in every dream and plays the chief part in it, even if it knows quite well how to hide itself so far as the manifest content goes. This 'sacro egoismo' of dreams is certainly not unrelated to the attitude we adopt when we sleep, which consists in our withdrawing our interest from the whole external world.

But you must not blame the dream itself on account of its evil content. Do not forget that it performs the innocent and indeed useful function of preserving sleep from disturbance. This wickedness is not part of the essential nature of dreams. Indeed you know too that there are dreams which can be recognized as the satisfaction of justified wishes and of pressing bodily needs. These, it is true, have no dream-distortion; but they have no need of it, for they can fulfil their function without insulting the ethical and aesthetic purposes of the ego. Bear in mind, too, that dream-distortion is proportionate to two factors. On the one hand it becomes greater the worse the wish that has to be censored; but on the other hand it also becomes greater the more severe the demands of the censorship at the moment. Thus a strictly brought-up and prudish young girl, with a relentless censorship, will distort dream-impulses which we doctors, for instance, would have to regard as permissible, harmless, libidinal wishes, and on which in ten years' time the dreamer herself will make the same judgement.

You will represent to me that I am giving a one-sided judgement on the War: that it has also brought to light what is finest and noblest in men, their heroism, their self-sacrifice, their social sense. No doubt; but are you not now showing yourselves as accessories to the injustice that has so often been done to psycho-analysis in reproaching it with denying one thing because it has asserted another? It is not our intention to dispute the noble endeavours of human nature, nor have we ever done anything to detract from their value. On the contrary; I am exhibiting to you not only the evil dream-wishes which are censored but also the censorship, which suppresses them and makes them unrecognizable. We lay a stronger emphasis on what is evil in men only because other people disavow it and thereby make the human mind, not better, but incomprehensible. If now we give up this one-sided ethical valuation, we shall undoubtedly find a more correct formula for the relation between good and evil in human nature.
There it is, then. We need not give up the findings of our work on the interpretation of dreams even though we cannot but regard them as strange. Perhaps we shall be able to approach an understanding of them later from another direction. For the time being let us hold fast to this: dream-distortion is a result of the censorship which is exercised by recognized purposes of the ego against wishful impulses in any way objectionable that stir within us at night-time during our sleep. Why this should happen particularly at night-time and where these reprehensible wishes come from - these are matters on which, no doubt, much still remains for questioning and research.

[1916-1917, 3242]

LADIES AND GENTLEMEN, - We have found that the distortion in dreams, which interferes with our understanding of them, is the result of a censoring activity which is directed against unacceptable, unconscious wishful impulses. We have not, of course, maintained that the censorship is the sole factor responsible for the distortion in dreams, and in fact when we study them further we can discover that other factors play a part in producing this result. This amounts to our saying that even if the dream-censorship was out of action we should still not be in a position to understand dreams, the manifest dream would still not be identical with the latent dream-thoughts.

[1916-1917, 3243]

The fourth of my reflections takes us back to the beginning and directs us along our prescribed path. I have said that even if there were no dream-censorship dreams would still not be easily intelligible to us, for we should still be faced with the task of translating the symbolic language of dreams into that of our waking thought. Thus symbolism is a second and independent factor in the distortion of dreams, alongside of the dream-censorship. It is plausible to suppose, however, that the dream-censorship finds it convenient to make use of symbolism, since it leads towards the same end - the strangeness and incomprehensibility of dreams.

[1916-1917, 3261]

LADIES AND GENTLEMEN, - When you have thoroughly grasped the dream-censorship and representation by symbols, you will not yet, it is true, have completely mastered the distortion in, dreams, but you will nevertheless be in a position to understand most dreams. In doing so you will make use of both of the two complementary techniques: calling up ideas that occur to the dreamer till you have penetrated from the substitute to the genuine thing and, on the ground of your own knowledge, replacing the symbols by what they mean. Later on we shall discuss some uncertainties that arise in this connection.

[1916-1917, 3262]

I hope you will never again confuse these two things with each other. If you reach that point, you will probably have gone further in understanding dreams than most readers of my Interpretation of Dreams. And let me remind you once again that the work which transforms the latent dream into the manifest one is called the dream-work. The work which proceeds in the contrary direction, which endeavours to arrive at the latent dream from the manifest one, is our work of interpretation. This work of interpretation seeks to undo the dream-work. The dreams of infantile type which we recognize as obvious fulfilments of wishes have nevertheless experienced some amount of dream-work - they have been transformed from a wish into an actual experience and also, as a rule, from thoughts into visual images. In their case there is no need for interpretation but only for undoing these two transformations. The additional dream-work that occurs in other dreams is called 'dream-distortion', and this has to be undone by our work of interpretation.

[1916-1917, 3262]
It is natural that we should lose some of our interest in the manifest dream. It is bound to be a matter of indifference to us whether it is well put together, or is broken up into a series of disconnected separate pictures. Even if it has an apparently sensible exterior, we know that this has only come about through dream-distortion and can have as little organic relation to the internal content of the dream as the façade of an Italian church has to its structure and plan. There are other occasions when this façade of the dream has its meaning, and reproduces an important component of the latent dream-thoughts with little or no distortion. But we cannot know this before we have submitted the dream to interpretation and have been able to form a judgement from it as to the amount of distortion that has taken place. A similar doubt arises when two elements in a dream appear to have been brought into a close relation to each other. This may give us a valuable hint that we may bring together what corresponds to these elements in the latent dream as well; but on other occasions we can convince ourselves that what belongs together in the dream-thoughts has been torn apart in the dream.

A short time ago we submitted a series of dreams to interpretation, but we left wish-fulfilment completely out of account. I feel sure that you must have repeatedly been driven to ask yourselves: 'But where is the wish-fulfilment, which is supposed to be the aim of the dream-work?' The question is an important one, for it has become the question raised by our lay critics. Human beings, as you know, have an instinctive tendency to fend off intellectual novelties. One of the ways in which this tendency is manifested is by immediately reducing the novelty to the smallest proportions, by compressing it if possible into a single catch-word. 'Wish-fulfilment' has become the catch word for the new theory of dreams. The layman asks: 'Where is the wish-fulfilment?' And instantly, having heard that dreams are supposed to be wish-fulfilments, and in the very act of asking the question, he answers it with a rejection. He immediately thinks of countless experiences of his own with dreams, in which the dream has been accompanied by feelings ranging from the unpleasurable to severe anxiety, so that the assertion made by the psycho-analytic theory of dreams seems to him most improbable. We have no difficulty in replying that in distorted dreams the wish-fulfilment cannot be obvious but must be looked for, so that it cannot be pointed out until the dream has been interpreted. We know too that the wishes in these distorted dreams are forbidden ones - rejected by the censorship - whose existence was precisely the cause of the dream's distortion, the reason for the intervention of the dream censorship. But it is difficult to make the lay critic understand that before a dream has been interpreted one cannot enquire about the fulfilment of its wish. He will keep on forgetting this. His rejection of the theory of wish-fulfilment is actually nothing other than a consequence of the dream-censorship, a substitute for the rejection of the censored dream-wishes and an effluence from it.

When does it happen that a dream-wish is in a position to overpower the censorship? The condition necessary for this may be fulfilled equally well by the dream-wish or by the dream censorship. The wish may for an unknown reason be excessively strong on some occasion; but one gets an impression that it is more often the behaviour of the dream-censorship that is responsible for this displacement of their relative strengths. We have already seen that the censorship acts with varying intensity in each particular case, that it treats each element of a dream with a different degree of severity. We can now add a further hypothesis to the effect that it is in general very variable and does not always employ equal severity to the same objectionable element. If things turn out so that on some occasion it feels itself powerless against a dream-wish which threatens to take it by surprise, instead of distortion, it makes use of its last remaining expedient and abandons the state of sleep, at the same time generating anxiety.
On the whole, therefore, I have made no concession to your objection to the theory of wish-fulfilment. It is our duty, however, to be able to indicate the wish-fulfilment in any distorted dream we may come across, and we shall certainly not evade the task. Let us go back to the dream we have already interpreted of the three bad theatre-tickets for 1 florin 50, from which we have already learnt so much. I hope you still recollect it. A lady, whose husband had told her during the day that her friend Elise, who was only three months her junior, had become engaged, dreamt that she was at the theatre with her husband. One side of the stalls was almost empty. Her husband said to her that Elise and her fiancé had wanted to go to the theatre too but had not been able to, since they had only got bad seats - three for 1 florin 50. She thought it would not really have done any harm if they had. We found that the dream-thoughts related to her anger at having married so early and to her dissatisfaction with her husband. We may be curious to discover how these gloomy thoughts were transformed into the fulfilment of a wish and where any trace of it is to be found in the manifest content of the dream. We already know that the element 'too early, in a hurry' was eliminated from the dream by the censorship. The empty stalls were an allusion to it. The mysterious 'three for 1 florin 50' now becomes more intelligible to us with the help of the symbolism with which we have meanwhile become acquainted. The '3' really means a man and the manifest element is easy to translate: buying a husband with her dowry. ('I could have got one ten times better with my dowry.') 'Marrying' is clearly replaced by 'going to the theatre'. 'Taking the theatre tickets too early' is, indeed, an immediate substitute for 'marrying too early'. This substitution is, however, the work of a wish-fulfilment. Our dreamer was not always so dissatisfied with her early marriage as she was on the day when she received the news of her friend's engagement. She had been proud of it at one time and regarded herself as at an advantage over her friend. Simple-minded girls, after becoming engaged, are reputed often to express their joy that they will soon be able to go to the theatre, to all the plays which have hitherto been prohibited, and will be allowed to see everything. The pleasure in looking, or curiosity, which is revealed in this was no doubt originally a sexual desire to look, directed towards sexual happenings and especially on to the girls’ parents, and hence it became a powerful motive for urging them to an early marriage. In this way a visit to the theatre became an obvious substitute, by way of allusion, for being married. Thus the dreamer, in her present anger at her early marriage, harked back to the time at which early marriage was the fulfilment of a wish because it satisfied her scopophilia, and, under the lead of this old wishful impulse, she replaced marriage by going to the theatre.

[1916-1917, 3308]

It must, of course, be admitted that the system of expression by dreams occupies a far more unfavourable position than any of these ancient languages and scripts. For after all they are fundamentally intended for communication: that is to say, they are always, by whatever method and with whatever assistance, meant to be understood. But precisely this characteristic is absent in dreams. A dream does not want to say anything to anyone. It is not a vehicle for communication; on the contrary, it is meant to remain ununderstood. For that reason we must not be surprised or at a loss if it turns out that a number of ambiguities and obscurities in dreams remain undecided. The one certain gain we have derived from our comparison is the discovery that these points of uncertainty which people have tried to use as objections to the soundness of our dream-interpretations are on the contrary regular characteristics of all primitive systems of expression.

[1916-1917, 3317]
The matter under consideration relates in essence to the results of displacement, which you have become acquainted with as the most powerful instrument of the dream-censorship. With the help of displacement the dream-censorship creates substitutive structures which we have described as allusions. But they are allusions which are not easily recognizable as such, from which the path back to the genuine thing is not easily traced, and which are connected with the genuine thing by the strangest, most unusual, external associations. In all these cases it is a question, however, of things which are meant to be hidden, which are condemned to concealment, for that is what the dream-censorship is aiming at. But we must not expect that a thing which has been hidden will be found in its own place, in its proper position. The frontier-control commissions which are operating to-day are more cunning in this respect than the Swiss school authorities. In their search for documents and plans they are not content with examining brief-cases and portfolios, but they consider the possibility that spies and smugglers may have these forbidden things in the most secret portions of their clothing where they decidedly do not belong - for instance, between the double soles of their boots. If the hidden things are there, it will certainly be possible to call them 'far-fetched', but it is also true that a great deal will have been found.

[1916-1917, 3319]

Perhaps you recognize, moreover, what it is that supports our hypotheses of the two systems, and their relation to each other and to consciousness? After all, the watchman between the unconscious and the preconscious is nothing else than the censorship, to which, as we found, the form taken by the manifest dream is subject. The day's residues, which we recognized as the instigators of the dream, were preconscious material which, at night-time and in the state of sleep, had been under the influence of unconscious and repressed wishful impulses; they had been able, in combination with those impulses and thanks to their energy, to construct the latent dream. Under the dominance of the unconscious system this material had been worked over (by condensation and displacement) in a manner which is unknown or only exceptionally permissible in normal mental life - that is, in the preconscious system. We came to regard this difference in their manner of operating as what characterizes the two systems; the relation which the preconscious has to consciousness was regarded by us merely as an indication of its belonging to one of the two systems. Dreams are not pathological phenomena; they can appear in any healthy person under the conditions of a state of sleep. Our hypothesis about the structure of the mental apparatus, which allows us to understand the formation alike of dreams and of neurotic symptoms, has an incontrovertible claim to being taken into account in regard to normal mental life as well.

[1916-1917, 3370]
The path to perversion branches off sharply from that to neurosis. If these regressions rouse no objection from the ego, no neurosis will come about either; and the libido will arrive at some real, even though no longer normal, satisfaction. But if the ego, which has under its control not only consciousness but also the approaches to motor innervation and accordingly to the realization of mental desires, does not agree with these regressions, conflict will follow. The libido is, as it were, cut off and must try to escape in some direction where, in accordance with the requirements of the pleasure principle, it can find a discharge for its cathexis of energy. It must withdraw from the ego. An escape of this kind is offered it by the fixations on the path of its development which it has now entered on regressively - fixations from which the ego had protected itself in the past by repressions. By cathecting these repressed positions as it flows backward, the libido has withdrawn from the ego and its laws, and has at the same time renounced all the education it has acquired under the ego's influence. It was docile so long as satisfaction beckoned to it; but under the double pressure of external and internal frustration it becomes refractory, and recalls earlier and better times. Such is the libido's fundamentally unchangeable character. The ideas to which it now transfers its energy as a cathexis belong to the system of the unconscious and are subject to the processes which are possible there, particularly to condensation and displacement. In this way conditions are established which completely resemble those in dream-construction. The dream proper, which has been completed in the unconscious and is the fulfillment of an unconscious wishful phantasy, is brought up against a portion of (pre)conscious activity which exercises the office of censorship and which, when it has been indemnified, permits the formation of the manifest dream as a compromise. In the same way, what represents the libido in the unconscious has to reckon with the power of the preconscious ego. The opposition which had been raised against it in the ego pursues it as an 'anticathexis' and compels it to choose a form of expression which can at the same time become an expression of the opposition itself. Thus the symptom emerges as a many-times-distorted derivative of the unconscious libidinal wish-fulfilment, an ingeniously chosen piece of ambiguity with two meanings in complete mutual contradiction. In this last respect, however, there is a distinction between the construction of a dream and of a symptom. For in dream-formation the preconscious purpose is merely concerned to preserve sleep, to allow nothing that would disturb it to make its way into consciousness; it does not insist upon calling out sharply 'No! on the contrary!' to the unconscious wishful impulse. It can afford to be more tolerant because the situation of someone sleeping is less perilous. The state of sleep in itself bars any outlet into reality.

[1916-1917, 3418]

I told you too that we hoped that the analysis of the narcissistic disorders would give us an insight into the way in which our ego is put together and built up out of different agencies. We have already made a start with this at one point. From the analysis of delusions of observation we have drawn the conclusion that there actually exists in the ego an agency which unceasingly observes, criticizes and compares, and in that way sets itself over against the other part of the ego. We believe, therefore, that the patient is betraying a truth to us which is not yet sufficiently appreciated when he complains that he is spied upon and observed at every step he takes and that every one of his thoughts is reported and criticized. His only mistake is in regarding this uncomfortable power as something alien to him and placing it outside himself. He senses an agency holding sway in his ego which measures his actual ego and each of its activities by an ideal ego that he has created for himself in the course of his development. We believe, too, that this creation was made with the intention of re-establishing the self-satisfaction which was attached to primary infantile narcissism but which since then has suffered so many disturbances and mortifications. We know the self-observing agency as the ego-censor, the conscience; it is this that exercises the dream-censorship during the night, from which the repressions of inadmissible wishful impulses proceed. When in delusions of observation it becomes split up, it reveals to us its origin from the influences of parents, educators and social environment - from an identification with some of these model figures.

[1916-1917, 3472]
We also describe the latent dream-thoughts, on account of their connection with waking life, as 'residues of the day'. By the operation of the dream-work (to which it would be quite incorrect to ascribe any 'creative' character) the latent dream thoughts are condensed in a remarkable way, are distorted by the displacement of psychical intensities and are arranged with a view to being represented in visual pictures; and, besides all this, before the manifest dream is arrived at, they are submitted to a process of secondary revision which seeks to give the new product something in the nature of sense and coherence. Strictly speaking, this last process does not form a part of the dream-work.

The Dynamic Theory of Dream-Formation. The motive power for the formation of dreams is not provided by the latent dream-thoughts or day's residues, but by an unconscious impulse, repressed during the day, with which the day's residues have been able to establish contact and which contrives to make a wish-fulfilment for itself out of the material of the latent thoughts. Thus every dream is on the one hand the fulfilment of a wish on the part of the unconscious and on the other hand (in so far as it succeeds in guarding the state of sleep against being disturbed) the fulfilment of the normal wish to sleep which set the sleep going. If we disregard the unconscious contribution to the formation of the dream and limit the dream to its latent thoughts, it can represent anything with which waking life has been concerned - a reflection, a warning, an intention, a preparation for the immediate future or, once again, the satisfaction of an unfulfilled wish. The unrecognizability, strangeness and absurdity of the manifest dream are partly the result of the translation of the thoughts into a different, so to say archaic, method of expression, but partly the effect of a restrictive, critically disapproving agency in the mind which does not entirely cease to function during sleep. It is plausible to suppose that the 'dream-censorship', which we regard as being responsible in the first instance for the distortion of the dream-thoughts into the manifest dream, is an expression of the same mental forces which during the day-time had held back or repressed the unconscious wishful impulse.

The Theory of Repression. - These theoretical considerations, taken together with the immediate impressions derived from analytic work, lead to a view of the neuroses which may be described in the roughest outline as follows. The neuroses are the expression of conflicts between the ego and such of the sexual impulses as seem to the ego incompatible with its integrity or with its ethical standards. Since these impulses are not ego-syntonic, the ego has repressed them: that is to say, it has withdrawn its interest from them and has shut them off from becoming conscious as well as from obtaining satisfaction by motor discharge. If in the course of analytic work one attempts to make these repressed impulses conscious, one becomes aware of the repressive forces in the form of resistance. But the achievement of repression fails particularly readily in the case of the sexual instincts. Their dammed-up libido finds other ways out from the unconscious: for it regresses to earlier phases of development and earlier attitudes towards objects, and, at weak points in the libidinal development where there are infantile fixations, it breaks through into consciousness and obtains discharge. What results is a symptom and consequently in its essence a substitutive sexual satisfaction. Nevertheless the symptom cannot entirely escape from the repressive forces of the ego and must therefore submit to modifications and displacements exactly as happens with dreams - by means of which its characteristic of being a sexual satisfaction becomes unrecognizable. Consequently symptoms are in the nature of compromises between the repressed sexual instincts and the repressing ego-instincts; they represent a wish-fulfilment for both partners to the conflict simultaneously, but one which is incomplete for each of them. This is quite strictly true of the symptoms of hysteria, while in the symptoms of obsessional neurosis there is often a stronger emphasis upon the side of the repressing function owing to the erection of reaction-formations, which are assurances against sexual satisfaction.
In the further course of psycho-analytic work, however, even these distinctions have proved to be inadequate and, for practical purposes, insufficient. This has become clear in more ways than one; but the decisive instance is as follows. We have formed the idea that in each individual there is a coherent organization of mental processes; and we call this his ego. It is to this ego that consciousness is attached; the ego controls the approaches to motility - that is, to the discharge of excitations into the external world; it is the mental agency which supervises all its own constituent processes, and which goes to sleep at night, though even then it exercises the censorship on dreams. From this ego proceed the repressions, too, by means of which it is sought to exclude certain trends in the mind not merely from consciousness but also from other forms of effectiveness and activity. In analysis these trends which have been shut out stand in opposition to the ego, and the analysis is faced with the task of removing the resistances which the ego displays against concerning itself with the repressed. Now we find during analysis that, when we put certain tasks before the patient, he gets into difficulties; his associations fail when they should be coming near the repressed. We then tell him that he is dominated by a resistance; but he is quite unaware of the fact, and, even if he guesses from his unpleasurable feelings that a resistance is now at work in him, he does not know what it is or how to describe it. Since, however, there can be no question but that this resistance emanates from his ego and belongs to it, we find ourselves in an unforeseen situation. We have come upon something in the ego itself which is also unconscious, which behaves exactly like the repressed - that is, which produces powerful effects without itself being conscious and which requires special work before it can be made conscious. From the point of view of analytic practice, the consequence of this discovery is that we land in endless obscurities and difficulties if we keep to our habitual forms of expression and try, for instance, to derive neuroses from a conflict between the conscious and the unconscious. We shall have to substitute for this antithesis another, taken from our insight into the structural conditions of the mind - the antithesis between the coherent ego and the repressed which is split off from it.¹

What conclusions can one draw from a correctly translated dream? I have an impression that analytic practice has not always avoided errors and over-estimations on this point, partly owing to an exaggerated respect for the 'mysterious unconscious'. It is only too easy to forget that a dream is as a rule merely a thought like any other, made possible by a relaxation of the censorship and by unconscious reinforcement, and distorted by the operation of the censorship and by unconscious revision.

[1923b, 3951]

[1923c, 4033]

We know now that the manifest content is a deception, a façade. It is not worth while to submit it to an ethical examination or to take its breaches of morality any more seriously than its breaches of logic or mathematics. When the 'content' of the dream is spoken of, what must be referred to can only be the content of the preconscious thoughts and of the repressed wishful impulse which are revealed behind the façade of the dream by the work of interpretation. Nevertheless, this immoral façade has a question to put to us. We have heard that the latent dream-thoughts have to submit to a severe censorship before they are allowed access to the manifest content. How can it happen, then, that this censorship, which makes difficulties over more trivial things, breaks down so completely over these manifestly immoral dreams?

[1925i, 4048]
The answer is not easy to come by and may perhaps not seem completely satisfying. If, in the first place, one submits these dreams to interpretation, one finds that some of them have given no offence to the censorship because *au fond* the have no bad meaning. They are innocent boastings or identifications that put up a mask of pretence; they have not been censored because they do not tell the truth. But others of them - and, it must be admitted, the majority - really mean what they say and have undergone no distortion from the censorship. They are an expression of immoral, incestuous and perverse impulses or of murderous and sadistic lusts. The dreamer reacts to many of these dreams by waking up in a fright, in which case the situation is no longer obscure to us. The censorship has neglected its task, this has been noticed too late, and the generation of anxiety is a substitute for the distortion that has been omitted. In still other instances of such dreams, even that expression of affect is absent. The objectionable matter is carried along by the height of the sexual excitement that has been reached during sleep, or it is viewed with the same tolerance with which even a waking person can regard a fit of rage, an angry mood or the indulgence in cruel phantasies.

But our interest in the genesis of these manifestly immoral dreams is greatly reduced when we find from analysis that the majority of dreams - innocent dreams, dreams without affect and anxiety-dreams - are revealed, when the distortions of the censorship have been undone, as the fulfilments of immoral - egoistic, sadistic, perverse or incestuous - wishful impulses. As in the world of waking life, these masked criminals are far commoner than those with their visors raised. The straightforward dream of sexual relations with one's mother, which Jocasta alludes to in the *Oedipus Rex*, is a rarity in comparison with all the multiplicity of dreams which psycho-analysis must interpret in the same sense.

The analysis of dreams led further: it was brought to public notice by the present writer as early as in 1900 in *The Interpretation of Dreams*. This showed that dreams are constructed in just the same way as neurotic symptoms. Like them, they may appear strange and senseless; but, if we examine them by a technique which differs little from the free association used in psycho-analysis, we are led from their manifest content to a secret meaning, to the latent dream-thoughts. This latent meaning is always a wishful impulse which is represented as fulfilled at the moment of the dream. But, except in young children and under the pressure of imperative physical needs, this secret wish can never be expressed recognizably. It has first to submit to a distortion, which is the work of restrictive, censoring forces in the dreamer's ego. In this way the manifest dream, as it is remembered in waking life, comes about. It is distorted, to the pitch of being unrecognizable, by concessions made to the dream-censorship; but it can be revealed once more by analysis as an expression of a situation of satisfaction or as the fulfilment of a wish. It is a compromise between two conflicting groups of mental trends, just as we have found to be the case with hysterical symptoms. The formula which, at bottom, best meets the essence of the dream is this: a dream is a (disguised) fulfilment of a (repressed) wish. The study of the process which transforms the latent dream-wish into the manifest content of the dream - a process known as the 'dream-work' - has taught us the best part of what we know of unconscious mental life.
In my case, too, the originality of many of the new ideas employed by me in the interpretation of dreams and in psycho-analysis has evaporated in this way. I am ignorant of the source of only one of these ideas. It was no less than the key to my view of dreams and helped me to solve their riddles, so far as it has been possible to solve them hitherto. I started out from the strange, confused and senseless character of so many dreams, and hit upon the notion that dreams were bound to become like that because something was struggling for expression in them which was opposed by a resistance from other mental forces. In dreams hidden impulses were stirring which stood in contradiction to what might be called the dreamer's official ethical and aesthetic creed; the dreamer was thus ashamed of these impulses, turned away from them and refused to acknowledge them in day-time, and if during the night he could not withhold expression of some kind from them, he submitted them to a 'dream-distortion' which made the content of the dream appear confused and senseless. To the mental force in human beings which keeps watch on this internal contradiction and distorts the dream's primitive instinctual impulses in favour of conventional or of higher moral standards, I gave the name of 'dream-censorship'.

There were now a whole series of questions to be answered, among the most important of them being whether the formation of dreams had a motive, under what conditions it took place, by what methods the dream-thoughts (which are invariably full of sense) become converted into the dream (which is often senseless), and others besides. I attempted to solve all of these problems in *The Interpretation of Dreams*, which I published in the year 1900. I can only find space here for the briefest abstract of my investigation. When the latent dream-thoughts that are revealed by the analysis of a dream are examined, one of them is found to stand out from among the rest, which are intelligible and well known to the dreamer. These latter thoughts are residues of waking life (the *day's residues*, as they are called technically); but the isolated thought is found to be a wishful impulse, often of a very repellent kind, which is foreign to the waking life of the dreamer and is consequently disavowed by him with surprise or indignation. This impulse is the actual constructor of the dream: it provides the energy for its production and makes use of the day's residues as material. The dream which thus originates represents a situation of satisfaction for the impulse, it is the fulfilment of its wish. It would not be possible for this process to take place without being favoured by the presence of something in the nature of a state of sleep. The necessary mental precondition of sleep is the concentration of the ego upon the wish to sleep and the withdrawal of psychical energy from all the interests of life. Since at the same time all the paths of approach to motility are blocked, the ego is also able to reduce the expenditure by which at other times it maintains the repressions. The unconscious impulse makes use of this nocturnal relaxation of repression in order to push its way into consciousness with the dream. But the repressive resistance of the ego is not abolished in sleep but merely reduced. Some of it remains in the shape of a *censorship of dreams* and forbids the unconscious impulse to express itself in the forms which it would properly assume. In consequence of the severity of the censorship of dreams, the latent dream-thoughts are obliged to submit to being altered and softened so as to make the forbidden meaning of the dream unrecognizable. This is the explanation of *dream-distortion*, which accounts for the most striking characteristics of the manifest dream. We are therefore justified in asserting that a *dream is the (disguised) fulfilment of a (repressed) wish*. It will now be seen that dreams are constructed like a neurotic symptom: they are compromises between the demands of a repressed impulse and the resistance of a censoring force in the ego. Since they have a similar origin they are equally unintelligible and stand in equal need of interpretation.

[1923f, 4159]

[1925d, 4219]
There is no difficulty in discovering the general function of dreaming. It serves the purpose of fending off, by a kind of soothing action, external or internal stimuli which would tend to arouse the sleeper, and thus of securing sleep against interruption. External stimuli are fended off by being given a new interpretation and by being woven into some harmless situation; internal stimuli, caused by instinctual demands, are given free play by the sleeper and allowed to find satisfaction in the formation of dreams, so long as the latent dream-thoughts submit to the control of the censorship. But if they threaten to break free and the meaning of the dream becomes too plain, the sleeper cuts short the dream and wakes in a fright. (Dreams of this class are known as *anxiety-dreams*.) A similar failure in the function of dreaming occurs if an external stimulus becomes too strong to be fended off. (This is the class of *arousal-dreams*.) I have given the name of *dream-work* to the process which, with the co-operation of the censorship, converts the latent thoughts into the manifest content of the dream. It consists of a peculiar way of treating the preconscious material of thought, so that its component parts become *condensed*, its psychical emphasis becomes *displaced*, and the whole of it is translated into visual images or *dramatized*, and completed by a deceptive *secondary revision*. The dream-work is an excellent example of the processes occurring in the deeper, unconscious layers of the mind, which differ considerably from the familiar normal processes of thought. It also displays a number of archaic characteristics, such as the use of a *symbolism* (in this case of a predominantly sexual kind) which it has since also been possible to discover in other spheres of mental activity.

[1925d, 4220]

But what is creating the resistance and against what is it aimed? Well, the resistance is the surest sign to us of a conflict. There must be a force here which is seeking to express something and another which is striving to prevent its expression. What comes about in consequence as a manifest dream may combine all the decisions into which this struggle between two trends has been condensed. At one point one of these forces may have succeeded in putting through what it wanted to say, while at another point it is the opposing agency which has managed to blot out the intended communication completely or to replace it by something that reveals not a trace of it. The commonest and most characteristic cases of dream-construction are those in which the conflict has ended in a compromise, so that the communicating agency has, it is true, been able to say what it wanted but not in the way it wanted - only in a softened down, distorted and unrecognized form. If, then, dreams do not give a faithful picture of the dream-thoughts and if the work of interpretation is required in order to bridge the gap between them, that is the outcome of the opposing, inhibiting and restricting agency which we have inferred from our perception of the resistance while we interpret dreams. So long as we studied dreams as isolated phenomena independent of the psychical structures akin to them, we named this agency the *censor of dreams*.

[1933a, 4628]
You have long been aware that this censorship is not an institution peculiar to dream-life. You know that the conflict between the two psychical agencies, which we inaccurately describe as the 'unconscious repressed' and the 'conscious', dominates our whole mental life and that the resistance against the interpretation of dreams, the sign of the dream-censorship, is nothing other than the resistance due to repression by which the two agencies are separated. You know too that the conflict between these two agencies may under certain conditions produce other psychical structures which, like dreams, are the outcome of compromises; and you will not expect me to repeat to you here everything that was contained in my introduction to the theory of the neuroses in order to demonstrate to you what we know of the determinants of the formation of such compromises. You have realized that the dream is a pathological product, the first member of the class which includes hysterical symptoms, obsessions and delusions, but that it is distinguished from the others by its transitoriness and by its occurrence under conditions which are part of normal life. For let us bear firmly in mind that, as was already pointed out by Aristotle, dream life is the way in which our mind works during the state of sleep. The state of sleep involves a turning-away from the real external world, and there we have the necessary condition for the development of a psychosis. The most careful study of the severe psychoses will not reveal to us a single feature that is more characteristic of those pathological conditions. In psychoses, however, the turning-away from reality is brought about in two kinds of way: either by the unconscious repressed becoming excessively strong so that it overpowers the conscious, which is attached to reality, or because reality has become so intolerably distressing that the threatened ego throws itself into the arms of the unconscious instinctual forces in a desperate revolt. The harmless dream-psychosis is the result of a withdrawal from the external world which is consciously willed and only temporary, and it disappears when relations to the external world are resumed. During the isolation of the sleeping individual an alteration in the distribution of his psychical energy also sets in; a part of the expenditure on repression, which is normally required in order to hold the unconscious down, can be saved, for if the unconscious makes use of its relative liberation for active purposes, it finds its path to motility closed and the only path open to it is the harmless one leading to hallucinatory satisfaction. Now, therefore, a dream can be formed; but the fact of the dream-censorship shows that even during sleep enough of the resistance due to repression is retained.

This piece of the dream-work gives us information about some of the most striking and peculiar features of dreams. I will repeat the course of events in dream-formation. As an introduction: the wish to sleep and intentional turning away from the external world. Next, two consequences of this for the mental apparatus: first, the possibility for older and more primitive methods of working to emerge in it - regression; secondly, the lowering of the resistance due to repression which weighs down upon the unconscious. As a result of this last factor the possibility arises for the formation of a dream and this is taken advantage of by the precipitating causes, the internal and external stimuli which have become active. The dream which originates in this way is already a compromise-structure. It has a double function; on the one hand it is ego-syntonic, since, by getting rid of the stimuli which are interfering with sleep, it serves the wish to sleep; on the other hand it allows a repressed instinctual impulse to obtain the satisfaction that is possible in these circumstances, in the form of the hallucinated fulfilment of a wish. The whole process of forming a dream which is permitted by the sleeping ego is, however, subject to the condition of the censorship, which is exercised by the residue of the repression still in operation. I cannot present the process more simply: it is not more simple. But I can proceed now with my description of the dream-work.
Let us go back once more to the latent dream-thoughts. Their most powerful element is the repressed instinctual impulse which has created in them an expression for itself on the basis of the presence of chance stimuli and by transference on to the day's residues - though an expression that is toned down and disguised. Like every instinctual impulse, it too presses for satisfaction by action; but its path to motility is blocked by the physiological regulations implied in the state of sleep; it is compelled to take the backwards course in the direction of perception and to be content with a hallucinated satisfaction. The latent dream-thoughts are thus transformed into a collection of sensory images and visual scenes. It is as they travel on this course that what seems to us so novel and so strange occurs to them. All the linguistic instruments by which we express the subtler relations of thought - the conjunctions and prepositions, the changes in declension and conjugation - are dropped, because there are no means of representing them; just as in a primitive language without any grammar, only the raw material of thought is expressed and abstract terms are taken back to the concrete ones that are at their basis. What is left over after this may well appear disconnected. The copious employment of symbols, which have become alien to conscious thinking, for representing certain objects and processes is in harmony alike with the archaic regression in the mental apparatus and with the demands of the censorship.

[1933a, 4632]

For I think my hypothesis - that, in order to gain control over fire, men had to renounce the homosexually-tinged desire to put it out with a stream of urine - can be confirmed by an interpretation of the Greek myth of Prometheus, provided that we bear in mind the distortions which must be expected to occur in the transition from facts to the contents of a myth. These distortions are of the same sort as, and no worse than, those which we acknowledge every day, when we reconstruct from patients' dreams the repressed but extremely important experiences of their childhood. The mechanisms employed in the distortions I have in mind are symbolic representation and turning into the opposite. I should not venture to explain all the features of our myth in this fashion; apart from the original set of facts, other and later occurrences may have contributed to its content. But the elements which admit of analytic interpretation are, after all, the most striking and important - viz. the manner in which Prometheus transported the fire, the character of his act (an outrage, a theft, a defrauding of the gods) and the meaning of his punishment.

[1932a, 4781]

To begin with, I naturally understood no more about my patients' dreams than the dreamers did themselves. But by applying to these dreams, and more particularly to my own dreams, the procedure which I had already used for the study of other abnormal psychological structures, I succeeded in answering most of the questions which could be raised by an interpretation of dreams. There were many such questions: What do we dream about? Why do we dream at all? What is the origin of all the strange characteristics which distinguish dreams from waking life? - and many more such questions besides. Some of the answers were easily given and turned out to confirm views that had already been put forward; but others involved completely new hypotheses with regard to the structure and functioning of the apparatus of the mind. People dream about the things that have engaged their minds during the waking day. People dream in order to allay impulses that seek to disturb sleep, and in order to be able to sleep on. But why was it possible for dreams to present such a strange appearance, so confusedly senseless, so obviously contrasted with the content of waking thought, in spite of being concerned with the same material? There could be no doubt that dreams were only a substitute for a rational process of thought and could be interpreted - that is to say, translated into a rational process. But what needed explaining was the fact of the distortion which the dream-work had carried out upon the rational and intelligible material.

[1932c, 4808]
Dream-distortion was the profoundest and most difficult problem of dream life. And light was thrown on it by the following consideration, which placed dreams in a class along with other psychopathological formations and revealed them, as it were, as the normal psychoses of human beings. For our mind, that precious instrument by whose means we maintain ourselves in life, is no peacefully self-contained unity. It is rather to be compared with a modern State in which a mob, eager for enjoyment and destruction, has to be held down forcibly by a prudent superior class. The whole flux of our mental life and everything that finds expression in our thoughts are derivations and representatives of the multifarious instincts that are innate in our physical constitution. But these instincts are not all equally susceptible to direction and education, or equally ready to fall in with the demands of the external world and of human society. A number of them have retained their primitive, ungovernable nature; if we let them have their way, they would infallibly bring us to ruin. Consequently, learning by experience, we have developed organizations in our mind which, in the form of inhibitions, set themselves up against the direct manifestations of the instincts. Every impulse in the nature of a wish that arises from the sources of instinctual energy must submit itself to examination by the highest agencies of our mind, and, if it is not approved, is rejected and restrained from exercising any influence upon our movements - that is, from coming into execution. Often enough, indeed, such wishes are even forbidden to enter consciousness, which is habitually unaware even of the existence of these dangerous instinctual sources. We describe such impulses as being repressed from the point of view of consciousness, and as surviving only in the unconscious. If what is repressed contrives somehow to force its way into consciousness or into movement or into both, we are no longer normal: at that point the whole range of neurotic and psychotic symptoms arise. The maintenance of the necessary inhibitions and repressions imposes upon our mind a great expenditure of energy, from which it is glad to be relieved. A good opportunity for this seems to be offered at night by the state of sleep, since sleep involves a cessation of our motor functions. The situation seems safe, and the severity of our internal police-force may therefore be relaxed. It is not entirely withdrawn, since one cannot be certain: it may be that the unconscious never sleeps at all. And now the reduction of pressure upon the repressed unconscious produces its effect. Wishes arise from it which during sleep might find the entrance to consciousness open. If we were to know them we should be appalled, alike by their subject-matter, their unrestraint and indeed the mere possibility of their existence. This, however, occurs only seldom, and when it does we awake as speedily as possible, in a state of fear. But as a rule our consciousness does not experience the dream as it really was. It is true that the inhibitory forces (the dream censorship, as we may call them) are not completely awake, but neither are they wholly asleep. They have had an influence on the dream while it was struggling to find an expression in words and pictures, they have got rid of what was most objectionable, they have altered other parts of it till they are unrecognizable, they have severed real connections while introducing false ones, until the honest but brutal wishful phantasy which lay behind the dream has turned into the manifest dream as we remember it - more or less confused and almost always strange and incomprehensible. Thus the dream (or the distortion which characterizes it) is the expression of a compromise, the evidence of a conflict between the mutually incompatible impulses and strivings of our mental life. And do not let us forget that the same process, the same interplay of forces, which explains the dreams of a normal sleeper, gives us the key to understanding all the phenomena of neurosis and psychosis.

[1932c, 4809]
We find our way to the understanding ('interpretation') of a dream by assuming that what we recollect as the dream after we have woken up is not the true dream-process but only a façade behind which that process lies concealed. Here we have our distinction between the manifest content of a dream and the latent dream-thoughts. The process which produces the former out of the latter is described as the dream-work. The study of the dream-work teaches us by an excellent example the way in which unconscious material from the id (originally unconscious and repressed unconscious alike) forces its way into the ego, becomes preconscious and, as a result of the ego's opposition, undergoes the changes which we know as dream-distortion. There are no features of a dream which cannot be explained in this way.

[1940a [1938], 4975]

But what makes dreams so invaluable in giving us insight is the circumstance that, when the unconscious material makes its way into the ego, it brings its own modes of working along with it. This means that the preconscious thoughts in which the unconscious material has found its expression are handled in the course of the dream-work as though they were unconscious portions of the id; and, in the case of the alternative method of dream-formation, the preconscious thoughts which have obtained reinforcement from an unconscious instinctual impulse are brought down to the unconscious state. It is only in this way that we learn the laws which govern the passage of events in the unconscious and the respects in which they differ from the rules that are familiar to us in waking thought. Thus the dream-work is essentially an instance of the unconscious working-over of preconscious thought-processes. To take an analogy from history: invading conquerors govern a conquered country, not according to the judicial system which they find in force there, but according to their own. It is, however, an unmistakable fact that the outcome of the dream-work is a compromise. The ego-organization is not yet paralysed, and its influence is to be seen in the distortion imposed on the unconscious material and in what are often very ineffective attempts at giving the total result a form not too unacceptable to the ego (secondary revision). In our analogy this would be an expression of the continued resistance of the defeated people.

[1940a [1938], 4977]
I know of no parallel in the operations of the press-censorship to a third manner of working by the dream-censorship; but I am able to demonstrate it from precisely the one example of a dream which we have analysed so far. You will recall the dream of the 'three bad theatre-tickets for 1 florin 50'. In the latent thoughts of that dream the element 'over-hurriedly, too early' stood in the foreground. Thus: it was absurd to marry so early - it was also absurd to take the theatre-tickets so early - it was ridiculous of the sister-in-law to part with her money in such a hurry to buy jewellery with it. Nothing of this central element of the dream-thoughts passed over into the manifest dream; in it the central position is taken by the 'going to the theatre' and 'taking the tickets'. As a result of this displacement of accent, this fresh grouping of the elements of the content, the manifest dream has become so unlike the latent dream-thoughts that no-one would suspect the presence of the latter behind the former. This displacement of accent is one of the chief instruments of dream-distortion and it is what gives the dream the strangeness on account of which the dreamer himself is not inclined to recognize it as his own production.

Omission, modification, fresh grouping of the material - these, then, are the activities of the dream-censorship and the instruments of dream-distortion. The dream-censorship itself is the originator, or one of the originators, of the dream-distortion which we are now engaged in examining. We are in the habit of combining the concepts of modification and re-arrangement under the term 'displacement'.

Still more remarkable is the other process - displacement or shifting of accent - which in conscious thinking we come across only as faulty reasoning or as means for a joke. The different ideas in the dream-thoughts are, indeed, not all of equal value; they are cathected with quotas of affect of varying magnitude and are correspondingly judged to be important and deserving of interest to a greater or less degree. In the dream-work these ideas are separated from the affects attaching to them. The affects are dealt with independently; they may be displaced on to something else, they may be retained, they may undergo alterations, or they may not appear in the dream at all. The importance of the ideas that have been stripped of their affect returns in the dream as sensory strength in the dream-pictures; but we observe that this accent has passed over from important elements to indifferent ones. Thus something that played only a minor part in the dream-thoughts seems to be pushed into the foreground in the dream as the main thing, while, on the contrary, what was the essence of the dream-thoughts finds only passing and indistinct representation in the dream. No other part of the dream-work is so much responsible for making the dream strange and incomprehensible to the dreamer. Displacement is the principal means used in the dream-distortion to which the dream-thoughts must submit under the influence of the censorship.

The myth tells us that Prometheus the Titan, a culture-hero who was still a god¹ and who was perhaps originally himself a demiurge and a creator of men, brought fire to men, having stolen it from the gods, hidden in a hollow stick, a fennel-stalk. If we were interpreting a dream we should be inclined to regard such an object as a penis symbol, although the unusual stress laid on its hollowness might make us hesitate. But how can we bring this penis-tube into connection with the preservation of fire? There seems little chance of doing this, till we remember the procedure of reversal, of turning into the opposite, of inverting relationships, which is so common in dreams and which so often conceals their meaning from us. What a man harbours in his penis-tube is not fire. On the contrary, it is the means of quenching fire; it is the water of his stream of urine. This relationship between fire and water then connects up with a wealth of familiar analytic material.
Jessen (1855, 547) writes with special emphasis on this point: 'Moreover, in investigating and interpreting coherent and consistent dreams a particular circumstance must be borne in mind which, as it seems to me, has hitherto received too little attention. In such cases the truth is almost always obscured by the fact that when we recall dreams of this kind to our memory we almost always - unintentionally and without noticing the fact - fill in the gaps in the dream-images. It is seldom or never that a coherent dream was in fact as coherent as it seems to us in memory. Even the most truth-loving of men is scarcely able to relate a noteworthy dream without some additions or embellishments. The tendency of the human mind to see everything connectedly is so strong that in memory it unwittingly fills in any lack of coherence there may be in an incoherent dream.'

Very similar ideas are expressed by Spitta (1882, 338), who seems to believe that it is not until we try to reproduce a dream that we introduce order of any kind into its loosely associated elements: we 'change things that are merely juxtaposed into sequences or causal chains, that is to say, we introduce a process of logical connection which is lacking in the dream.'

This is just the situation in our dream. It is hardly rash to assume that the unintelligibility of the dream's content, as it exists in the memory has led to its being recast in a form designed to make sense of the situation. That situation, however, is in the process deprived of its original meaning and put to extraneous uses. But, as we shall see later, it is a common thing for the conscious thought-activity of a second psychical system to misunderstand the content of a dream in this way, and this misunderstanding must be regarded as one of the factors in determining the final form assumed by dreams. Moreover we shall learn that similar misunderstandings (taking place, once again, within one and the same psychical personality) play a major part in the construction of obsessions and phobias.

There is an unmistakable indication in the text of Sophocles' tragedy itself that the legend of Oedipus sprang from some primaeval dream-material which had as its content the distressing disturbance of a child's relation to his parents owing to the first stirrings of sexuality. At a point when Oedipus, though he is not yet enlightened, has begun to feel troubled by his recollection of the oracle, Jocasta consoles him by referring to a dream which many people dream, though, as she thinks, it has no meaning:

The resolution of what are ostensibly acts of judgement in dreams may serve to remind us of the rules laid down at the beginning of this book for carrying out the work of interpretation: namely, that we should disregard the apparent coherence between a dream's constituents as an unessential illusion, and that we should trace back the origin of each of its elements on its own account. A dream is a conglomerate which, for purposes of investigation, must be broken up once more into fragments. On the other hand, however, it will be observed that a psychical force is at work in dreams which creates this apparent connectedness, which, that is to say, submits the material produced by the dream-work to a 'secondary revision'. This brings us face to face with the manifestations of a force whose importance we shall later assess as the fourth of the factors concerned in the construction of dreams.
It is unnecessary, I think, to accumulate further examples. They would merely serve to confirm what we have gathered from those I have already quoted - that an act of judgement in a dream is only a repetition of some prototype in the dream-thoughts. As a rule, the repetition is ill-applied and interpolated into an inappropriate context, but occasionally, as in our last instances, it is so neatly employed that to begin with it may give the impression of independent intellectual activity in the dream. From this point we might turn our attention to the psychical activity which, though it does not appear to accompany the construction of dreams invariably, yet, whenever it does so, is concerned to fuse together elements in a dream which are of disparate origin into a whole which shall make sense and be without contradiction. Before approaching that subject, however, we are under an urgent necessity to consider the expressions of affect which occur in dreams and to compare them with the affects which analysis uncovers in the dream-thoughts. [1900a, 903]

And now at last we can turn to the fourth of the factors concerned in the construction of dreams. If we pursue our investigation of the content of dreams in the manner in which we have begun it - that is, by comparing conspicuous events in the dream-content with their sources in the dream-thoughts, we shall come upon elements the explanation of which calls for an entirely new assumption. What I have in mind are cases in which the dreamer is surprised, annoyed or repelled in the dream, and, moreover, by a piece of the dream-content itself. As I have shown in a number of instances, the majority of these critical feelings in dreams are not in fact directed against the content of the dream, but turn out to be portions of the dream-thoughts which have been taken over and used to an appropriate end. But some material of this kind does not lend itself to this explanation; its correlate in the material of the dream-thoughts is nowhere to be found. What, for instance, is the meaning of a critical remark found so often in dreams: 'This is only a dream'? Here we have a genuine piece of criticism of the dream, such as might be made in waking life. Quite frequently, too, it is actually a prelude to waking up; and still more frequently it has been preceded by some distressing feeling which is set at rest by the recognition that the state is one of dreaming. When the thought 'this is only a dream' occurs during a dream, it has the same purpose in view as when the words are pronounced on the stage by la belle Hélène in Offenbach's comic opera of that name: it is aimed at reducing the importance of what has just been experienced and at making it possible to tolerate what is to follow. It serves to lull a particular agency to sleep which would have every reason at that moment to bestir itself and forbid the continuance of the dream - or the scene in the opera. It is more comfortable, however, to go on sleeping and tolerate the dream, because, after all, 'it is only a dream.' In my view the contemptuous critical judgement, 'it's only a dream,' appears in a dream when the censorship, which is never quite asleep, feels that it has been taken unawares by a dream which has already been allowed through. It is too late to suppress it, and accordingly the censorship uses these words to meet the anxiety or the distressing feeling aroused by it. The phrase is an example of esprit d'escalier on the part of the psychical censorship. [1900a, 928]

This instance, however, provides us with convincing evidence that not everything contained in a dream is derived from the dream-thoughts, but that contributions to its content may be made by a psychical function which is indistinguishable from on our waking thoughts. The question now arises whether this only occurs in exceptional cases, or whether the psychical agency which otherwise operates only as a censorship plays a habitual part in the construction of dreams. [1900a, 929]
We can have no hesitation in deciding in favour of the second alternative. There can be no doubt that the censoring agency, whose influence we have so far only recognized in limitations and omissions in the dream-content, is also responsible for interpolations and additions in it. The interpolations are easy to recognize. They are often reported with hesitation, and introduced by an 'as though'; they are not in themselves particularly vivid and are always introduced at points at which they can serve as links between two portions of the dream-content or to bridge a gap between two parts of the dream. They are less easily retained in the memory than genuine derivatives of the material of the dream-thoughts; if the dream is to be forgotten they are the first part of it to disappear, and I have a strong suspicion that the common complaint of having dreamt a lot, but of having forgotten most of it and of having only retained fragments, is based upon the rapid disappearance precisely of these connecting thoughts. In a complete analysis these interpolations are sometimes betrayed by the fact that no material connected with them is to be found in the dream-thoughts. But careful examination leads me to regard this as the less frequent case; as a rule the connecting thoughts lead back nevertheless to material in the dream-thoughts, but to material which could have no claim to acceptance in the dream either on its own account or owing to its being over-determined. Only in extreme cases, it seems, does the psychical function in dream-formation which we are now considering proceed to make new creations. So long as possible, it employs anything appropriate that it can find in the material of the dream-thoughts.

[1900a, 929]

The thing that distinguishes and at the same time reveals this part of the dream-work is its purpose. This function behaves in the manner which the poet maliciously ascribes to philosophers: it fills up the gaps in the dream-structure with shreds and patches. As a result of its efforts, the dream loses its appearance of absurdity and disconnectedness and approximates to the model of an intelligible experience. But its efforts are not always crowned with success. Dreams occur which, at a superficial view, may seem faultlessly logical and reasonable; they start from a possible situation, carry it on through a chain of consistent modifications and - though far less frequently - bring it to a conclusion which causes no surprise. Dreams which are of such a kind have been subjected to a far-reaching revision by this psychical function that is akin to waking thought; they appear to have a meaning, but that meaning is as far removed as possible from their true significance. If we analyse them, we can convince ourselves that it is in these dreams that the secondary revision has played about with the material the most freely, and has retained the relations present in that material to the least extent. They are dreams which might be said to have been already interpreted once, before being submitted to waking interpretation. In other dreams this tendentious revision has only partly succeeded; coherence seems to rule for a certain distance, but the dream then becomes senseless or confused, while perhaps later on in its course it may for a second time present an appearance of rationality. In yet other dreams the revision has failed altogether; we find ourselves hopelessly face to face with a heap of fragmentary material.

[1900a, 930]
I do not wish to deny categorically that this fourth power in dream-construction - which we shall soon recognize as all old acquaintance, since in fact it is the only one of the four with which we are familiar in other connections - I do not wish to deny that this fourth factor has the capacity to create new contributions to dreams. It is certain, however, that, like the others, it exerts its influence principally by its preferences and selections from psychical material in the dream-thoughts that has already been formed. Now there is one case in which it is to a great extent spared the labour of, as it were, building up a façade for the dream - the case, namely, in which a formation of that kind already exists, available for use in the material of the dream-thoughts. I am in the habit of describing the element in the dream-thoughts which I have in mind as a 'phantasy.' I shall perhaps avoid misunderstanding if I mention the 'day-dream' as something analogous to it in waking life.¹ The part played in our mental life by these structures has not yet been fully recognized and elucidated by psychiatrists, though M. Benedikt has made what seems to me a very promising start in that direction. The importance of day-dreams has not escaped the unerring vision of imaginative writers; there is, for instance, a well-known account by Alphonse Daudet in *Le Nabab* of the day-dreams of one of the minor characters in that story. The study of the psychoneuroses leads to the surprising discovery that these phantasies or day-dreams are the immediate forerunners of hysterical symptoms, or at least of a whole number of them. Hysterical symptoms are not attached to actual memories, but to phantasies erected on the basis of the basis of memories. The frequent occurrence of conscious daytime phantasies brings these structures to our knowledge; but just as there are phantasies of this kind which are conscious, so, too, there are unconscious ones in great numbers, which have to remain unconscious on account of their content and of their origin from repressed material. Closer investigation of the characteristics of these day-time phantasies shows us how right it is that these formations should bear the same name as we give to the products of our thought during the night - the name, that is, of 'dreams.' They share a large number of their properties with night-dreams, and their investigation might, in fact, have served as the shortest and best approach to an understanding of night-dreams.

[1900a, 931]
The function of 'secondary revision', which we have attributed to the fourth of the factors concerned in shaping the content of dreams, shows us in operation once more the activity which is able to find free vent in the creation of day-dreams without being inhibited by any other influences. We might put it simply by saying that this fourth factor of ours seeks to mould the material offered to it into something like a day-dream. If, however, a day-dream of this kind has already been formed within the nexus of the dream-thoughts, this fourth factor in the dream-work will prefer to take possession of the ready-made day-dream and seek to introduce it into the content of the dream. There are some dreams which consist merely in the repetition of a day-time phantasy which may perhaps have remained unconscious: such, for instance, as the boy's dream of driving in a war-chariot with the heroes of the Trojan War. In my 'Autodidasker' dream the second part at all events was a faithful reproduction of a daytime phantasy, innocent in itself, of a conversation with Professor N. In view of the complicated conditions which a dream has to satisfy when it comes into existence, it happens more frequently that the ready-made phantasy forms only a portion of the dream, or that only a portion of the phantasy forces its way into the dream. Thereafter, the phantasy is treated in general like any other portion of the latent material, though it often remains recognizable as an entity in the dream. There are often parts of my dreams which stand out as producing a different impression from the rest. They strike me as being, as it were, more fluent, more connected and at the same time more fleeting than other parts of the same dream. These, I know, are unconscious phantasies which have found their way into the fabric of the dream, but I have never succeeded in pinning down a phantasy of this kind. Apart from this, these phantasies, like any other component of the dream-thoughts, are compressed, condensed, superimposed on one another, and so on. There are, however, transitional cases, between the case in which they constitute the content (or at least the façade) of the dream unaltered and the extreme opposite in which they are represented in the content of the dream only by one of their elements or by a distant allusion. What happens to phantasies present in the dream-thoughts is evidently also determined by any advantages they may have to offer the requirements of the censorship and of the urge towards condensation.

At this point it is impossible to avoid considering the relation between this secondary revision of the content of dreams and the remaining factors of the dream-work. Are we to suppose that what happens is that in the first instance the dream-constructing factors - the tendency towards condensation, the necessity for evading the censorship, and considerations of representability by the psychical means open to dreams - put together a provisional dream-content out of the material provided, and that this content is subsequently re-cast so as to conform so far as possible to the demands of a second agency! This is scarcely probable. We must assume rather that from the very first the demands of this second factor constitute one of the conditions which the dream must satisfy and that this condition, like those laid down by condensation, the censorship imposed by resistance, and representability, operates simultaneously in a conducive and selective sense upon the mass of material present in the dream-thoughts. In any case, however, of the four conditions for the formation of dreams, the one we have come to know last is the one whose demands appear to have the least cogent influence on dreams.
The following consideration makes it highly probable that the psychical function which carries out what we have described as the secondary revision of the content of dreams is to be identified with the activity of our waking thought. Our waking (preconscious) thinking behaves towards any perceptual material with which it meets in just the same way in which the function we are considering behaves towards the content of dreams. It is the nature of our waking thought to establish order in material of that kind, to set up relations in it and to make it conform to our expectations of an intelligible whole. In fact, we go too far in that direction. An adept in sleight of hand can trick us by relying upon this intellectual habit of ours. In our efforts at making an intelligible pattern of the sense-impressions that are offered to us, we often fall into the strangest errors or even falsify the truth about the material before us.

[1900a, 937]

There is no doubt, then, that it is our normal thinking that is the psychical agency which approaches the content of dreams with a demand that it must be intelligible, which subjects it to a first interpretation and which consequently produces a complete misunderstanding of it. For the purposes of our interpretation it remains an essential rule invariably to leave out of account the ostensible continuity of a dream as being of suspect origin, and to follow the same path back to the material of the dream-thoughts, no matter whether the dream itself is clear or confused.

[1900a, 938]

We now perceive, incidentally, on what it is that the range in the quality of dreams between confusion and clarity which was discussed on p. 779 f. depends. Those parts of a dream on which the secondary revision has been able to produce some effect are clear, while those parts on which its efforts have failed are confused. Since the confused parts of a dream are so often at the same time the less vivid parts, we may conclude that the secondary dream-work is also to be held responsible for a contribution to the plastic intensity of the different dream-elements.

[1900a, 938]

If I look around for something with which to compare the final form assumed by a dream as it appears after normal thought has made its contribution, I can think of nothing better than the enigmatic inscriptions with which Fliegende Blätter has for so long entertained its readers. They are intended to make the reader believe that a certain sentence - for the sake of contrast, a sentence in dialect and as scurrilous as possible - is a Latin inscription. For this purpose the letters contained in the words are torn out of their combination into syllables and arranged in a new order. Here and there a genuine Latin word appears; at other points we seem to see abbreviations of Latin words before us; and at still other points in the inscription we may allow ourselves to be deceived into overlooking the senselessness of isolated letters by parts of the inscription seeming to be defaced or showing lacunae. If we are to avoid being taken in by the joke, we must disregard everything that makes it seem like an inscription, look firmly at the letters, pay no attention to their ostensible arrangement, and so combine them into words belonging to our own mother tongue.

[1900a, 939]

Secondary revision is the one factor in the dream-work which has been observed by the majority of writers on the subject and of which the significance has been appreciated. Havelock Ellis (1911, 10-11) has given an amusing account of its functioning: 'Sleeping consciousness we may even imagine as saying to itself in effect: "Here comes our master, Waking Consciousness, who attaches such mighty importance to reason and logic and so forth. Quick! gather things up, put them in order - any order will do - before he enters to take possession."

[1900a, 939]
The identity of its method of working with that of waking thought has been stated with particular clarity by Delacroix (1904, 926): 'Cette fonction d'interprétation n'est pas particulière au rêve; c'est le même travail de coordination logique que nous faisons sur nos sensations pendant la veille.'¹ James Sully is of the same opinion. So, too, is Tobowolska (1900, 93): 'Sur ces successions incohérentes d'hallucinations, l'esprit s'efforce de faire le même travail de coordination logique qu'il fait pendant la veille sur les sensations. Il relie entre elles par un lien imaginaire toutes ces images décousues et bouche les écarts trop grands qui se trouvaient entre elles.'²

According to some writers, this process of arranging and interpreting begins during the dream itself and is continued after waking. Thus Paulhan (1894, 546): 'Cependant j'ai souvent pensé qu'il pouvait y avoir une certaine déformation, ou plutôt reformation, du rêve dans le souvenir. . . La tendance systématisante de l'imagination pourrait fort bien achever après le réveil ce qu'elle a ébauché pendant le sommeil. De la sorte, la rapidité réelle de la pensée serait augmentée en apparence par les perfectionnements dus à l'imagination éveillée.'¹ Bernard-Leroy and Tobowolska (1901, 592): 'Dans le rêve, au contraire, l'interprétation et la coordination se font non seullement à l'aide des données du rêve, mais encore à l'aide de celles de la veille. . . .'²

Inevitably, therefore, this one recognized factor in the formation of dreams has had its importance over-estimated, so that it has been credited with the whole achievement of the creation of dreams. This act of creation, as Goblot (1896, 280 f.) and still more Foucault (1906) suppose, is performed at the moment of waking; for these two writers attribute to waking thought an ability to construct a dream out of the thoughts that emerge during sleep. Bernard-Leroy and Tobowolska (1901) comment on this view: 'On a cru pouvoir placer le rêve au moment du réveil, et ils ont attribué à la pensée de la veille la fonction de construire le rêve avec les images présentes dans la pensée du sommeil.'³

We are ready to recognize the fact that Silberer's phenomena constitute a second contribution on the part of waking thought to the construction of dreams; though it is less regularly present and less significant than the first one, which has already been introduced under the name of 'secondary revision.' It has been shown that a part of the attention which operates during the day continues to be directed towards dreams during the state of sleep, that it keeps a check on them and criticizes them and reserves the power to interrupt them. It has seemed plausible to recognize in the mental agency which thus remains awake the censor to whom we have had to attribute such a powerful restricting influence upon the form taken by dreams. What Silberer's observations have added to this is the fact that in certain circumstances a species of self-observation plays a part in this and makes a contribution to the content of the dream. The probable relations of this self-observing agency, which may be particularly prominent in philosophical minds, to endopsychic perception, to delusions of observation, to conscience and to the censor of dreams can be more appropriately treated elsewhere.'¹

¹[1900a, 939]
²[1900a, 940]
³[1900a, 943]
I will now try to sum up this lengthy disquisition on the dream-work. We were faced by the question whether the mind employs the whole of its faculties without reserve in constructing dreams or only a functionally restricted fragment of them. Our investigations led us to reject entirely the form in which the question was framed as being inadequate to the circumstances. If, however, we had to reply to the question on the basis of the terms in which it was stated, we should be obliged to reply in the affirmative to both the alternatives, mutually exclusive though they appear to be. Two separate functions may be distinguished in mental activity during the construction of a dream: the production of the dream-thoughts, and their transformation into the content of the dream. The dream-thoughts are entirely rational and are constructed with an expenditure of all the psychical energy of which we are capable. They have their place among thought-processes that have not become conscious - processes from which, after some modification, our conscious thoughts, too, arise. However many interesting and puzzling questions the dream-thoughts may involve, such questions have, after all, no special relation to dreams and do not call for treatment among the problems of dreams.¹ On the other hand, the second function of mental activity during dream-construction, the transformation of the unconscious thoughts into the content of the dream, is peculiar to dream-life and characteristic of it. This dream-work proper diverges further from our picture of waking thought than has been supposed even by the most determined depreciator of psychical functioning during the formation of dreams. The dream-work is not simply more careless, more irrational, more forgetful and more incomplete than waking thought; it is completely different from it qualitatively and for that reason not immediately comparable with it. It does not think, calculate or judge in any way at all; it restricts itself to giving things a new form. It is exhaustively described by an enumeration of the conditions which it has to satisfy in producing its result. That product, the dream, has above all to evade the censorship, and with that end in view the dream-work makes use of a *displacement of psychical intensities* to the point of a transvaluation of all psychical values. The thoughts have to be reproduced exclusively or predominantly in the material of visual and acoustic memory-traces, and this necessity imposes upon the dream-work *considerations of representability* which it meets by carrying out fresh displacements. Greater intensities have probably to be produced than are available in the dream-thoughts at night, and this purpose is served by the extensive *condensation* which is carried out with the constituents of the dream-thoughts. Little attention is paid to the logical relations between the thoughts; those relations are ultimately given a disguised representation in certain *formal* characteristics of dreams. Any affect attached to the dream-thoughts undergoes less modification than their ideational content. Such affects are as a rule suppressed; when they are retained, they are detached from the ideas that properly belong to them, affects of a similar character being brought together. Only a single portion of the dream-work and one which operates to an irregular degree, the working over of the material by partly aroused waking thought, tallies to some extent with the view which other writers have sought to apply to the entire activity of dream-construction.

[1900a, 944]
The explanation is in our favour, though without putting the other writers in the wrong. In the light of our newly-won understanding of the origin of dreams the contradiction disappears completely. It is true that we distort dreams in attempting to reproduce them; here we find at work once more the process which we have described as the secondary (and often ill-conceived) revision of the dream by the agency which carries out normal thinking. But this distortion is itself no more than a part of the revision to which the dream-thoughts are regularly subjected as a result of the dream-censorship. The other writers have at this point noticed or suspected the part of dream-distortion which operates manifestly; we are less interested, since we know that a much more far-reaching process of distortion, though a less obvious one, has already developed the dream out of the hidden dream-thoughts. The only mistake made by previous writers has been in supposing that the modification of the dream in the course of being remembered and put into words is an arbitrary one and cannot be further resolved and that it is therefore calculated to give us a misleading picture of the dream. They have underestimated the extent to which psychical events are determined. There is nothing arbitrary about them. It can be shown quite generally that if an element is left undetermined by one train of thought, its determination is immediately effected by a second one. For instance, I may try to think of a number arbitrarily. But this is impossible: the number that occurs to me will be unambiguously and necessarily determined by thoughts of mine, though they may be remote from my immediate intention.¹ The modifications to which dreams are submitted under the editorship of waking life are just as little arbitrary. They are associatively linked to the material which they replace, and serve to show us the way to that material, which may in its turn be a substitute for something else.

[1900a, 950]

Having now repelled the objections that have been raised against us, or having at least indicated where our defensive weapons lie, we must no longer postpone the task of setting about the psychological investigations for which we have so long been arming ourselves. Let us summarize the principal findings of our enquiry so far as it has gone. Dreams are psychical acts of as much significance as any others; their motive force is in every instance a wish seeking fulfilment; the fact of their not being recognizable as wishes and their many peculiarities and absurdities are due to the influence of the psychical censorship to which they have been subjected during the process of their formation; apart from the necessity of evading this censorship, other factors which have contributed to their formation are a necessity for the condensation of their psychical material, a regard for the possibility of its being represented in sensory images and - though not invariably - a demand that the structure of the dream shall have a rational and intelligible exterior. Each of these propositions opens a way to fresh psychological postulates and speculations; the mutual relations between the wish which is the dream's motive force and the four conditions to which the dream's formation is subject, as well as the interrelations between the latter, require to be investigated; and the place of dreams in the nexus of mental life has to be assigned.

[1900a, 966]
I must assume that the state of sleep makes the sensory surface of consciousness which is directed towards the Pcs. far more insusceptible to excitation than the surface directed towards the Pcpt. systems. Moreover, this abandonment of interest in thought-processes during the night has a purpose: thinking is to come to a standstill, for the Pcs. requires sleep. Once, however, a dream has become a perception, it is in a position to excite consciousness, by means of the qualities it has now acquired. This sensory excitation proceeds to perform what is its essential function: it directs a part of the available cathectic energy in the Pcs. into attention to what is causing the excitation. It must therefore be admitted that every dream has an arousing effect, that it sets a part of the quiescent force of the Pcs. in action. The dream is then submitted by this force to the influence which we have described as secondary revision with an eye to consequitiveness and intelligibility. That is to say, the dream is treated by it just like any other perceptual content; it is met by the same anticipatory ideas, in so far as its subject-matter allows. So far as this third portion of the dream-process has any direction it is once again a progressive one.
[1900a, 1004]

But it seems to me unnecessary to suppose that dream-processes really maintain, up to the moment of becoming conscious, the chronological order in which I have described them: that the first thing to appear is the transferred dream-wish, that distortion by the censorship follows, then the regressive change in direction, and so on. I have been obliged to adopt this order in my description; but what happens in reality is no doubt a simultaneous exploring of one path and another, a swinging of the excitation now this way and now that, until at last it accumulates in the direction that is most opportune and one particular grouping becomes the permanent one. Certain personal experiences of my own lead me to suspect that the dream-work often requires more than a day and a night in order to achieve its result; and if this is so, we need no longer feel any amazement at the extraordinary ingenuity shown in the construction of the dream. In my opinion even the demand for the dream to be made intelligible as a perceptual event may be put into effect before the dream attracts consciousness to itself. From then onwards, however, the pace is accelerated, for at that point a dream is treated in the same fashion as anything else that is perceived. It is like a firework, which takes hours to prepare but goes off in a moment.
[1900a, 1005]
It is dozens of years since I myself had a true anxiety-dream, but I remember one from my seventh or eighth year, which I submitted to interpretation some thirty years later. It was a very vivid one, and in it I saw my beloved mother, with a peculiarly peaceful, sleeping expression on her features, being carried into the room by two (or three) people with bird's beaks and laid upon the bed. I awoke in tears and screaming, and interrupted my parents' sleep. The strangely draped and unnaturally tall figures with birds' beaks were derived from the illustrations to Philippson's Bible. I fancy they must have been gods with falcons' heads from an ancient Egyptian funerary relief. Besides this, the analysis brought to mind an ill-mannered boy, a son of a concierge, who used to play with us on the grass in front of the house when we were children, and who I am inclined to think was called Philipp. It seems to me that it was from this boy that I first heard the vulgar term for sexual intercourse, instead of which educated people always use a Latin word, 'to copulate', and which was clearly enough indicated by the choice of the falcons' heads. I must have guessed the sexual significance of the word from the face of my young instructor, who was well acquainted with the facts of life. The expression on my mother's features in the dream was copied from the view I had had of any grandfather a few days before his death as he lay snoring in a coma. The interpretation carried out in the dream by the 'secondary revision' must therefore have been that my mother was dying; the funerary relief fitted in with this. I awoke in anxiety, which did not cease till I had woken my parents up. I remember that I suddenly grew calm when I saw my mother's face, as though I had needed to be reassured that she was not dead. But this 'secondary' interpretation of the dream had already been made under the influence of the anxiety which had developed. I was not anxious because I had dreamt that my mother was dying; but I interpreted the dream in that sense in my preconscious revision of it because I was already under the influence of the anxiety. The anxiety can be traced back, when repression is taken into account, to an obscure and evidently sexual craving that had found appropriate expression in the visual content of the dream.

[1900a, 1011]
There is, however, another point to which I attach importance; and I must confess that it is solely on its account that I have embarked here upon all these discussions of the two psychical systems and their modes of activity and of repression. It is not now a question of whether I have formed an approximately correct opinion of the psychological factors with which we are concerned, or whether, which is quite possible in such difficult matters, my picture of them is distorted and incomplete. However many changes may be made in our reading of the psychical censorship and of the rational and abnormal revisions made of the dream-content, it remains true that processes of this sort are at work in the formation of dreams and that they show the closest analogy in their essentials to the processes observable in the formation of hysterical symptoms. A dream, however, is no pathological phenomenon; it presupposes no disturbance of psychical equilibrium; it leaves behind it no loss of efficiency. The suggestion may be made that no conclusions as to the dreams of normal people can be drawn from my dreams or those of my patients; but this, I think, is an objection which can be safely disregarded. If, then, we may argue back from the phenomena to their motive forces, we must recognize that the psychical mechanism employed by neuroses is not created by the impact of a pathological disturbance upon the mind but is present already in the normal structure of the mental apparatus. The two psychical systems, the censorship upon the passage from one of them to the other, the inhibition and overlaying of one activity by the other, the relations of both of them to consciousness - or whatever more correct interpretations of the observed facts may take their place - all of these form part of the normal structure of our mental instrument, and dreams show us one of the paths leading to an understanding of its structure. If we restrict ourselves to the minimum of new knowledge which has been established with certainty, we can still say this of dreams: they have proved that what is suppressed continues to exist in normal people as well as abnormal, and remains capable of psychical functioning. Dreams themselves are among the manifestations of this suppressed material; this is so theoretically in every case, and it can be observed empirically in a great number of cases at least, and precisely in cases which exhibit most clearly the striking peculiarities of dream-life. In waking life the suppressed material in the mind is prevented from finding expression and is cut off from internal perception owing to the fact that the contradictions present in it are eliminated - one side being disposed of in favour of the other; but during the night, under the sway of an impetus towards the construction of compromises, this suppressed material finds methods and means of forcing its way into consciousness.

We have not yet come to the end of our consideration of the dream-work. In addition to condensation, displacement and pictorial arrangement of the psychical material, we are obliged to assign it yet another activity, though this is not to be found in operation in every dream. I shall not deal exhaustively with this part of the dream-work, and will therefore merely remark that the easiest way of forming an idea of its nature is to suppose - though the supposition probably does not meet the facts - that it only comes into operation after the dream-content has already been constructed. Its function would then consist in arranging the constituents of the dream in such a way that they form an approximately connected whole, a dream-composition. In this way the dream is given a kind of façade (though this does not, it is true, hide its content at every point), and thus receives a first, preliminary interpretation, which is supported by interpolations and slight modifications. Incidentally, this revision of the dream-content is only possible if it is not too punctiliously carried out; nor does it present us with anything more than a glaring misunderstanding of the dream-thoughts. Before we start upon the analysis of a dream we have to clear the ground of this attempt at an interpretation.
The motive for this part of the dream-work is particularly obvious. Considerations of intelligibility are what lead to this final revision of a dream; and this reveals the origin of the activity. It behaves towards the dream-content lying before it just as our normal psychical activity behaves in general towards any perceptual content that may be presented to it. It understands that content on the basis of certain anticipatory ideas, and arranges it, even at the moment of perceiving it, on the presupposition of its being intelligible; in so doing it runs a risk of falsifying it, and in fact, if it cannot bring it into line with anything familiar, is a prey to the strangest misunderstandings. As is well known, we are incapable of seeing a series of unfamiliar signs or of hearing a succession of unknown words, without at once falsifying the perception from considerations of intelligibility, on the basis of something already known to us. [1901a, 1080]

Dreams which have undergone a revision of this kind at the hands of a psychical activity completely analogous to waking thought may be described as 'well-constructed.' In the case of other dreams this activity has completely broken down; no attempt even has been made to arrange or interpret the material, and, since after we have woken up we feel ourselves identical with this last part of the dream-work, we make a judgement that the dream was 'hopelessly confused.' From the point of view of analysis, however, a dream that resembles a disordered heap of disconnected fragments is just as valuable as one that has been beautifully polished and provided with a surface. In the former case, indeed, we are saved the trouble of demolishing what has been superimposed upon the dream-content. [1901a, 1081]

(19) Furthermore, there is nothing to prevent our treating misprints as 'writing mistakes' on the compositor's part, and our regarding them as being in a very great measure motivated. I have not set about making a systematic collection of such parapraxes, which could be very amusing and instructive. In the work which I have already referred to a number of times, Jones has devoted a special section to misprints. [1901b, 1213]

Transformation with a view to the possibility of representation, condensation and displacement are the three major achievements that may be ascribed to the dream-work. A fourth, which was perhaps too shortly considered in The Interpretation of Dreams, is not relevant for our present purposes. If the ideas of a 'topography of the mental apparatus' and of 'regression' are consistently followed up (and only in that way could these working hypotheses come to have any value), we must attempt to determine the stages of regression at which the various transformations of the dream-thoughts take place. This attempt has not yet been seriously undertaken; but it can at least be stated with certainty that displacement must take place in the thought-material while it is at the stage of the unconscious processes, while condensation must probably be pictured as a process stretching over the whole course of events till the perceptual region is reached. But in general we must be content to assume that all the forces which take part in the formation of dreams operate simultaneously. Though one must, as will be realized, exercise reserve in dealing with such problems, and though there are fundamental doubts, which cannot be entered into here, as to whether the question should be framed in this manner, yet I should like to venture on the assertion that the process of the dream-work preparatory to the dream must be located in the region of the unconscious. Thus, speaking roughly, there would in all be three stages to be distinguished in the formation of a dream: first, the transplanting of the preconscious day's residues into the unconscious, in which the conditions governing the state of sleep must play a part; then, the dream-work proper in the unconscious; and thirdly, the regression of the dream-material, thus revised, to perception, in which form the dream becomes conscious. [1905c, 1749]
To these phantasies which have succeeded in dominating the man's love in real life, the urge to rescue the loved one seems to bear merely a loose and superficial relation, and one that is fully accounted for by conscious reasons. By her propensity to be fickle and unfaithful the loved one brings herself into dangerous situations, and thus it is understandable that the lover should be at pains to protect her from these dangers by watching over her virtue and counteracting her bad inclinations. However, the study of people's screen-memories, phantasies and nocturnal dreams shows that we have here a particularly felicitous 'rationalization' of an unconscious motive, a process which may be compared to a successful secondary revision of a dream. In actual fact the 'rescue-motif' has a meaning and history of its own, and is an independent derivative of the mother-complex, or more accurately, of the parental complex. When a child hears that he owes his life to his parents, or that his mother gave him life, his feelings of tenderness unite with impulses which strive at power and independence, and they generate the wish to return this gift to the parents and to repay them with one of equal value. It is as though the boy's defiance were to make him say: 'I want nothing from my father; I will give him back all I have cost him.' He then forms the phantasy of rescuing his father from danger and saving his life; in this way he puts his account square with him. This phantasy is commonly enough displaced on to the emperor, king or some other great man; after being thus distorted it becomes admissible to consciousness, and may even be made use of by creative writers. In its application to a boy's father it is the defiant meaning in the idea of rescuing which is by far the most important; where his mother is concerned it is usually its tender meaning. The mother gave the child life, and it is not easy to find a substitute, of equal value for this unique gift. With a slight change of meaning, such as is easily effected in the unconscious and is comparable to the way in which in consciousness concepts shade into one another, rescuing his mother takes on the significance of giving her a child or making a child for her - needless to say, one like himself. This is not too remote from the original sense of rescuing, and the change in meaning is not an arbitrary one. His mother gave him a life - his own life - and in exchange he gives her another life, that of a child which has the greatest resemblance to himself. The son shows his gratitude by wishing to have by his mother a son who is like himself: in other words, in the rescue-phantasy he is completely identifying himself with his father. All his instincts, those of tenderness, gratitude, lustfulness, defiance and independence, find satisfaction in the single wish to be his own father. Even the element of danger has not been lost in the change of meaning; for the act of birth itself is the danger from which he was saved by his mother's efforts. Birth is both the first of all dangers to life and the prototype of all the later ones that cause us to feel anxiety, and the experience of birth has probably left behind in us the expression of affect which we call anxiety. Macduff of the Scottish legend, who was not born of his mother but ripped from her womb, was for that reason unacquainted with anxiety.

[1910h, 2333]
The present state of our knowledge leads us to conclude that the essential factor in the construction of dreams is an unconscious wish - as a rule an infantile wish, now repressed - which can come to expression in this somatic or psychical material (in the day's residues too, therefore) and can thus supply these with a force which enables them to press their way through to consciousness even during the suspension of thought at night. The dream is in every case a fulfilment of this unconscious wish, whatever else it may contain - warning, reflection, admission, or any other part of the rich content of preconscious waking life that has persisted undealt-with into the night. It is this unconscious wish that gives the dream-work its peculiar character as an unconscious revision of preconscious material. A psycho-analyst can characterize as dreams only the products of the dream-work: in spite of the fact that the latent dream-thoughts are only arrived at from the interpretation of the dream, he cannot reckon them as part of the dream, but only as part of preconscious reflection. (Secondary revision by the conscious agency is here reckoned as part of the dream-work. Even if one were to separate it, this would not involve any alteration in our conception. We should then have to say: dreams in the analytic sense comprise the dream-work proper together with the secondary revision of its products.) The conclusion to be drawn from these considerations is that one cannot put the wish-fulfilling character of dreams on a par with their character as warnings, admissions, attempts at solution, etc., without denying the concept of a psychical dimension of depth - that is to say, without denying the standpoint of psycho-analysis.

[1913a, 2591]

The projection of their own evil impulses into demons is only one portion of a system which constituted the Weltanschauung of primitive peoples, and which we shall come to know as 'animism' in the following essay. There we shall have to investigate that system's psychological characteristics, and we shall do so once again by reference to the similar systems which we find constructed by neurotics. For the moment I will only say that the prototype of all such systems is what we have termed the 'secondary revision' of the content of dreams. And we must not forget that, at and after the stage at which systems are constructed, two sets of reasons can be assigned for every psychical event that is consciously judged - one set belonging to the system and the other set real but unconscious.¹

[1912-1913, 2709]
I have said that animism is a system of thought, the first complete theory of the universe, and I shall now go on to draw certain conclusions from the psycho-analytic view of such systems. Every day of our lives our experience is in a position to show us the principal characteristics of a 'system'. We have dreams during the night and we have learnt how to interpret them during the day. Dreams may, without contradicting their nature, appear confused and disconnected. But they may, on the contrary, simulate the orderly impressions of a real experience, they may make one event follow from another and make one portion of their content refer to another. Such a result can be more or less successfully achieved; but it scarcely ever succeeds so completely as to leave no absurdity, no rift in its texture, visible. When we come to submit a dream to interpretation, we find that the erratic and irregular arrangement of its constituent parts is quite unimportant from the point of view of our understanding it. The essential elements in a dream are the dream-thoughts, and these have meaning, connection and order. But their order is quite other than that remembered by us as present in the manifest dream. In the latter the connection between the dream-thoughts has been abandoned and may either remain completely lost or be replaced by the new connection exhibited in the manifest content. The elements of the dream, apart from their being condensed, are almost invariably arranged in a new order more or less independent of their earlier arrangement. Finally, it must be added that whatever the original material of the dream-thoughts has been turned into by the dream-work is then subjected to a further influence. This is what is known as 'secondary revision', and its purpose is evidently to get rid of the disconnectedness and unintelligibility produced by the dream-work and replace it by a new 'meaning'. But this new meaning, arrived at by secondary revision, is no longer the meaning of the dream-thoughts.

The secondary revision of the product of the dream-work is an admirable example of the nature and pretensions of a system. There is an intellectual function in us which demands unity, connection and intelligibility from any material, whether of perception or thought, that comes within its grasp; and if, as a result of special circumstances, it is unable to establish a true connection, it does not hesitate to fabricate a false one. Systems constructed in this way are known to us not only from dreams, but also from phobias, from obsessive thinking and from delusions. The construction of systems is seen most strikingly in delusional disorders (in paranoia), where it dominates the symptomatic picture; but its occurrence in other forms of neuro-psychosis must not be overlooked. In all these cases it can be shown that a rearrangement of the psychical material has been made with a fresh aim in view; and the rearrangement may often have to be a drastic one if the outcome is to be made to appear intelligible from the point of view of the system. Thus a system is best characterized by the fact that at least two reasons can be discovered for each of its products: a reason based upon the premises of the system (a reason, then, which may be delusional) and a concealed reason, which we must judge to be the truly operative and the real one.

The Adlerian theory was from the very beginning a 'system' - which psycho-analysis was careful to avoid becoming. It is also a remarkably good example of 'secondary revision', such as occurs, for instance, in the process to which dream-material is submitted by the action of waking thought. In Adler's case the place of dream-material is taken by the new material obtained through psycho-analytic studies; this is then viewed purely from the standpoint of the ego, reduced to the categories with which the ego is familiar, translated, twisted and - exactly as happens in dream-formation - is misunderstood. Moreover, the Adlerian theory is characterized less by what it asserts than by what it denies, so that it consists of three sorts of elements of quite dissimilar value: useful contributions to the psychology of the ego, superfluous but admissible translations of the analytic facts into the new 'jargon', and distortions and perversions of these facts when they do not comply with the requirements of the ego.
The completion of the dream-process consists in the thought-content - regressively transformed and worked over into a wishful phantasy - becoming conscious as a sense-perception; while this is happening it undergoes secondary revision, to which every perceptual concept is subject. The dream-wish, as we say, is hallucinated, and, as a hallucination, meets with belief in the reality of its fulfilment. It is precisely round this concluding piece in the formation of dreams that the gravest uncertainties centre, and it is in order to clear them up that we are proposing to compare dreams with pathological states akin to them.

One of the ways in which the ego is related to its neuroses is, however, so obvious that it was possible to take it into account from the first. It seems never to be absent; but it is most clearly recognizable in a disorder which we are even to-day far from understanding - traumatic neurosis. For you must know that the same factors always come into operation in the causation and mechanism of every possible form of neurosis; but the chief importance in the construction of the symptoms falls now upon one and now upon another of these factors. The position is like that among the members of a theatrical company. Each of them is regularly cast for his own stock role - hero, confidant, villain, and so on; but each of them will choose a different piece for his benefit performance. In the same way phantasies which turn into symptoms are nowhere more obvious than in hysteria; the anticathexes or reaction-formations of the ego dominate the picture in obsessional neurosis; what in the case of dreams we have termed 'secondary revision' stands in the forefront in paranoia in the shape of delusions, and so on.

We also describe the latent dream-thoughts, on account of their connection with waking life, as 'residues of the day'. By the operation of the dream-work (to which it would be quite incorrect to ascribe any 'creative' character) the latent dream thoughts are condensed in a remarkable way, are distorted by the displacement of psychical intensities and are arranged with a view to being represented in visual pictures; and, besides all this, before the manifest dream is arrived at, they are submitted to a process of secondary revision which seeks to give the new product something in the nature of sense and coherence. Strictly speaking, this last process does not form a part of the dream-work.

What conclusions can one draw from a correctly translated dream? I have an impression that analytic practice has not always avoided errors and over-estimations on this point, partly owing to an exaggerated respect for the 'mysterious unconscious'. It is only too easy to forget that a dream is as a rule merely a thought like any other, made possible by a relaxation of the censorship and by unconscious reinforcement, and distorted by the operation of the censorship and by unconscious revision.
Astonishment is sometimes expressed at the fact that the dreamer's ego can appear two or more times in the manifest dream, once as himself and again disguised behind the figures of other people. During the course of the construction of the dream, the secondary revision has evidently sought to obliterate this multiplicity of the ego, which cannot fit in with any possible scenic situation; but it is re-established by the work of interpretation. In itself this multiplicity is no more remarkable than the multiple appearance of the ego in a waking thought, especially when the ego divides itself into subject and object, puts one part of itself as an observing and critical agency in contrast to the other, or compares its present nature with its recollected past, which was also ego once; for instance, in such sentences as 'When I think what I've done to this man' or 'When I think that I too was a child once'. But I should reject as a meaningless and unjustifiable piece of speculation the notion that all figures that appear in a dream are to be regarded as fragmentations and representatives of the dreamer's own ego. It is enough that we should keep firmly to the fact that the separation of the ego from an observing, critical, punishing agency (an ego ideal) must be taken into account in the interpretation of dreams as well.

There is no difficulty in discovering the general function of dreaming. It serves the purpose of fending off, by a kind of soothing action, external or internal stimuli which would tend to arouse the sleeper, and thus of securing sleep against interruption. External stimuli are fended off by being given a new interpretation and by being woven into some harmless situation; internal stimuli, caused by instinctual demands, are given free play by the sleeper and allowed to find satisfaction in the formation of dreams, so long as the latent dream-thoughts submit to the control of the censorship. But if they threaten to break free and the meaning of the dream becomes too plain, the sleeper cuts short the dream and wakes in a fright. (Dreams of this class are known as anxiety-dreams.) A similar failure in the function of dreaming occurs if an external stimulus becomes too strong to be fended off. (This is the class of arousal-dreams.) I have given the name of dream-work to the process which, with the co-operation of the censorship, converts the latent thoughts into the manifest content of the dream. It consists of a peculiar way of treating the preconscious material of thought, so that its component parts become condensed, its psychical emphasis becomes displaced, and the whole of it is translated into visual images or dramatized, and completed by a deceptive secondary revision. The dream-work is an excellent example of the processes occurring in the deeper, unconscious layers of the mind, which differ considerably from the familiar normal processes of thought. It also displays a number of archaic characteristics, such as the use of a symbolism (in this case of a predominantly sexual kind) which it has since also been possible to discover in other spheres of mental activity.

[1923c, 4041]

[1925d, 4220]
But what makes dreams so invaluable in giving us insight is the circumstance that, when the unconscious material makes its way into the ego, it brings its own modes of working along with it. This means that the preconscious thoughts in which the unconscious material has found its expression are handled in the course of the dream-work as though they were unconscious portions of the id; and, in the case of the alternative method of dream-formation, the preconscious thoughts which have obtained reinforcement from an unconscious instinctual impulse are brought down to the unconscious state. It is only in this way that we learn the laws which govern the passage of events in the unconscious and the respects in which they differ from the rules that are familiar to us in waking thought. Thus the dream-work is essentially an instance of the unconscious working-over of preconscious thought-processes. To take an analogy from history: invading conquerors govern a conquered country, not according to the judicial system which they find in force there, but according to their own. It is, however, an unmistakable fact that the outcome of the dream-work is a compromise. The ego-organization is not yet paralysed, and its influence is to be seen in the distortion imposed on the unconscious material and in what are often very ineffective attempts at giving the total result a form not too unacceptable to the ego (secondary revision). In our analogy this would be an expression of the continued resistance of the defeated people.

[1940a [1938], 4977]
Throughout the entire illness her two states of consciousness persisted side by side: the primary one in which she was quite normal psychically, and the secondary one which may well be likened to a dream in view of its wealth of imaginative products and hallucinations, its large gaps of memory and the lack of inhibition and control in its associations. In this secondary state the patient was in a condition of alienation. The fact that the patient's mental condition was entirely dependent on the intrusion of this secondary state into the normal one seems to throw considerable light on at least one class of hysterical psychosis. Every one of her hypnoses in the evening afforded evidence that the patient was entirely clear and well-ordered in her mind and normal as regards her feeling and volition so long as none of the products of her secondary state was acting as a stimulus 'in the unconscious'. The extremely marked psychosis which appeared whenever there was any considerable interval in this unburdening process showed the degree to which those products influenced the psychical events of her 'normal' state. It is hard to avoid expressing the situation by saying that the patient was split into two personalities of which one was mentally normal and the other insane. The sharp division between the two states in the present patient only exhibits more clearly, in my opinion, what has given rise to a number of unexplained problems in many other hysterical patients. It was especially noticeable in Anna O. how much the products of her 'bad self', as she herself called it, affected her moral habit of mind. If these products had not been continually disposed of, we should have been faced by a hysteric of the malicious type - refractory, lazy, disagreeable and ill-natured; but, as it was, after the removal of those stimuli her true character, which was the opposite of all these, always reappeared at once.

We have no difference of opinion over the functions that are to be assigned to dreams. The view that dreams act as a safety valve to the mind and that, in the words of Robert, all kinds of harmful things are made harmless by being presented in a dream - not only does this view coincide exactly with our theory of the double wish-fulfilment brought about by dreams, but the way in which it is phrased is more intelligible to us than to Robert himself. The view that the mind has free play in its functioning in dreams is represented in our theory by the fact of the preconscious activity allowing dreams to take their course. Such phrases as 'the return of the mind in dreams to an embryonic point of view' or the words used by Havelock Ellis to describe dreams - 'an archaic world of vast emotions and imperfect thoughts' - strike us as happy anticipations of our own assertions that primitive modes of activity which are suppressed during the day are concerned in the construction of dreams. We have been able to accept entirely as our own what Sully has written: 'Our dreams are a means of conserving these successive personalities. When asleep we go back to the old ways of looking at things and of feeling about them, to impulses and activities which long ago dominated us'. For us no less than for Delage what has been 'suppressed' has become 'the motive force of dreams.'

We have thus been able to find a place in our structure for the most various and contradictory findings of earlier writers, thanks to the novelty of our theory of dreams, which combines them, as it were, into a higher unity. Some of those findings we have put to other uses, but we have wholly rejected only a few. Nevertheless our edifice is still uncompleted. Apart from the many perplexing questions in which we have become involved in making our way into the obscurities of psychology, we seem to be troubled by a fresh contradiction. On the one hand we have supposed that the dream-thoughts arise through entirely normal mental activity; but on the other hand we have discovered a number of quite abnormal processes of thought among the dream-thoughts, which extend into the dream-content, and which we then repeat in the course of our dream-interpretation. Everything that we have described as the 'dream-work' seems to depart so widely from what we recognize as rational thought-processes that the most severe strictures passed by earlier writers on the low level of psychical functioning in dreams must appear fully justified.
From this point onwards the train of thought undergoes a series of transformations which we can no longer recognize as normal psychical processes and which lead to a result that bewilders us - a psychopathological structure. I will enumerate these processes and classify them.

[1900a, 1022]

The direction in which condensations in dreams proceed is determined on the one hand by the rational preconscious relations of the dream-thoughts, and on the other by the attraction exercised by visual memories in the unconscious. The outcome of the activity of condensation is the achievement of the intensities required for forcing a way through into the perceptual systems.

[1900a, 1022]

These are some of the most striking of the abnormal processes to which the dream-thoughts, previously constructed on rational lines, are subjected in the course of the dream-work. It will be seen that the chief characteristic of these processes is that the whole stress is laid upon making the cathecting energy mobile and capable of discharge; the content and the proper meaning of the psychical elements to which the cathexes are attached are treated as of little consequence. It might have been supposed that condensation and the formation of compromises is only carried out for the sake of facilitating regression, that is, when it is a question of transforming thoughts into images. But the analysis - and still more the synthesis - of dreams which include no such regression to images, e.g. the dream of 'Autodidasker', exhibits the same processes of displacement and condensation as the rest.

[1900a, 1023]

Thus we are driven to conclude that two fundamentally different kinds of psychical process are concerned in the formation of dreams. One of these produces perfectly rational dream-thoughts, of no less validity than normal thinking; while the other treats these thoughts in a manner which is in the highest degree bewildering and irrational. We have already in Chapter VI segregated this second psychical process as being the dream-work proper. What light have we now to throw upon its origin?

[1900a, 1024]

It would not be possible for us to answer this question if we had not made some headway in the study of the psychology of the neuroses, and particularly of hysteria. We have found from this that the same irrational psychical processes, and others that we have not specified, dominate the production of hysterical symptoms. In hysteria, too, we come across a series of perfectly rational thoughts, equal in validity to our conscious thoughts; but to begin with we know nothing of their existence in this form and we can only reconstruct them subsequently. If they force themselves upon our notice at any point, we discover by analysing the symptom which has been produced that these normal thoughts have been submitted to abnormal treatment: they have been transformed into the symptom by means of condensation and the formation of compromises, by way of superficial associations and in disregard of contradictions, and also, it may be, along the path of regression. In view of the complete identity between the characteristic features of the dream-work and those of the psychical activity which issues in psychoneurotic symptoms, we feel justified in carrying over to dreams the conclusions we have been led to by hysteria.

[1900a, 1024]
This, however, is not the gap in the functional efficiency of our mental apparatus which makes it possible for thoughts, which represent themselves as products of the secondary thought activity, to become subject to the primary psychical process - for such is the formula in which we can now describe the activity which leads to dreams and to hysterical symptoms. Inefficiency arises from the convergence of two factors derived from our developmental history. One of these factors devolves entirely upon the mental apparatus and has had a decisive influence on the relation between the two systems, while the other makes itself felt to a variable degree and introduces instinctual forces of organic origin into mental life. Both of them originate in childhood and are a precipitate of the modifications undergone by our mental and somatic organism since our infancy. [1900a, 1030]

There is, however, another point to which I attach importance; and I must confess that it is solely on its account that I have embarked here upon all these discussions of the two psychical systems and their modes of activity and of repression. It is not now a question of whether I have formed an approximately correct opinion of the psychological factors with which we are concerned, or whether, which is quite possible in such difficult matters, my picture of them is distorted and incomplete. However many changes may be made in our reading of the psychical censorship and of the rational and abnormal revisions made of the dream-content, it remains true that processes of this sort are at work in the formation of dreams and that they show the closest analogy in their essentials to the processes observable in the formation of hysterical symptoms. A dream, however, is no pathological phenomenon; it presupposes no disturbance of psychical equilibrium; it leaves behind it no loss of efficiency. The suggestion may be made that no conclusions as to the dreams of normal people can be drawn from my dreams or those of my patients; but this, I think, is an objection which can be safely disregarded. If, then, we may argue back from the phenomena to their motive forces, we must recognize that the psychical mechanism employed by neuroses is not created by the impact of a pathological disturbance upon the mind but is present already in the normal structure of the mental apparatus. The two psychical systems, the censorship upon the passage from one of them to the other, the inhibition and overlaying of one activity by the other, the relations of both of them to consciousness - or whatever more correct interpretations of the observed facts may take their place - all of these form part of the normal structure of our mental instrument, and dreams show us one of the paths leading to an understanding of its structure. If we restrict ourselves to the minimum of new knowledge which has been established with certainty, we can still say this of dreams: they have proved that **what is suppressed continues to exist in normal people as well as abnormal, and remains capable of psychical functioning**. Dreams themselves are among the manifestations of this suppressed material; this is so theoretically in every case, and it can be observed empirically in a great number of cases at least, and precisely in cases which exhibit most clearly the striking peculiarities of dream-life. In waking life the suppressed material in the mind is prevented from finding expression and is cut off from internal perception owing to the fact that the contradictions present in it are eliminated - one side being disposed of in favour of the other; but during the night, under the sway of an impetus towards the construction of compromises, this suppressed material finds methods and means of forcing its way into consciousness. [1900a, 1034]
Now that the old antithesis between conscious life and dream life has been reduced to its proper proportions by the establishment of unconscious psychical reality, a number of dream-problems with which earlier writers were deeply concerned have lost their significance. Thus some of the activities whose successful performance in dreams excited astonishment are now no longer to be attributed to dreams but to unconscious thinking, which is active during the day no less than at night. If, as Scherner has said, dreams appear to engage in making symbolic representations of the body, we now know that those representations are the product of certain unconscious phantasies (deriving, probably, from sexual impulses) which find expression not only in dreams but also in hysterical phobias and other symptoms. If a dream carries on the activities of the day and completes them and even brings valuable fresh ideas to light, all we need do is to strip it of the dream disguise, which is the product of dream-work and the mark of assistance rendered by obscure forces from the depths of the mind (cf. the Devil in Tartini’s sonata dream); the intellectual achievement is due to the same mental forces which produce every similar result during the daytime. We are probably inclined greatly to over-estimate the conscious character of intellectual and artistic production as well. Accounts given us by some of the most highly productive men, such as Goethe and Helmholtz, show rather that what is essential and new in their creations came to them without premeditation and as an almost ready-made whole. There is nothing strange if in other cases, where a concentration of every intellectual faculty was needed, conscious activity also contributed its share. But it is the much-abused privilege of conscious activity, wherever it plays a part, to conceal every other activity from our eyes.

Hitherto philosophers have had no occasion to concern themselves with a psychology of repression. We may therefore be permitted to make a first approach to this hitherto unknown topic by constructing a pictorial image of the course of events in dream-formation. It is true that the schematic picture we have arrived at - not only from the study of dreams - is a fairly complicated one; but we cannot manage with anything simpler. Our hypothesis is that in our mental apparatus there are two thought-constructing agencies, of which the second enjoys the privilege of having free access to consciousness for its products whereas the activity of the first is in itself unconscious and can only reach consciousness by way of the second. On the frontier between the two agencies, where the first passes over to the second, there is a censorship, which only allows what is agreeable to it to pass through and holds back everything else. According to our definition, then, what is rejected by the censorship is in a state of repression. Under certain conditions, of which the state of sleep is one, the relation between the strength of the two agencies is modified in such a way that what is repressed can no longer be held back. In the state of sleep this probably occurs owing to a relaxation of the censorship; when this happens it becomes possible for what has hitherto been repressed to make a path for itself to consciousness. Since, however, the censorship is never completely eliminated but merely reduced, the repressed material must submit to certain alterations which mitigate its offensive features. What becomes conscious in such cases is a compromise between the intentions of one agency and the demands of the other. Repression - relaxation of the censorship - the formation of a compromise, this is the fundamental pattern for the generation not only of dreams but of many other psychopathological structures; and in the latter cases too we may observe that the formation of compromises is accompanied by processes of condensation and displacement and by the employment of superficial associations, which we have become familiar with in the dream-work.
An important conclusion can be drawn from this conformity. The peculiar mode of working, whose most striking achievement we see in the content of dreams, cannot be attributed to the sleeping state of mental life if we possess such abundant evidence in the form of parapraxes that it operates during our waking life as well. The same connection also forbids our assuming that these psychical processes, which strike us as abnormal and strange, are determined by a deep-seated decay in mental activity or by pathological states of functioning.¹
[1901b, 1346]

We shall not be able to form a correct picture of the strange psychical work which brings about the occurrence of both parapraxes and dream images until we have learnt that psychoneurotic symptoms, and especially the psychical formations of hysteria and obsessional neurosis, repeat in their mechanism all the essential features of this mode of working. This is therefore the starting-point for the continuation of our researches. For us, however, there is yet another special interest in considering parapraxes, chance actions and symptomatic actions in the light of this last analogy. If we compare them to the products of the psychoneuroses, to neurotic symptoms, two frequently repeated statements - namely, that the borderline between the normal and the abnormal in nervous matters is a fluid one, and that we are all a little neurotic - acquire meaning and support. Without any medical experience we can construct various types of nervous illness of this kind which are merely hinted at - formes frustres¹ - of the neurones: cases in which the symptoms are few, or occur rarely or not severely - in other words, cases whose comparative mildness is located in the number, intensity and duration of their pathological manifestations. But we might perhaps never arrive by conjecture at precisely the type that appears most frequently to form the transition between health and illness. For the type we are considering, whose pathological manifestations are parapraxes and symptomatic acts, is characterized by the fact that the symptoms are located in the least important psychical functions, while everything that can lay claim to higher psychical value remains free from disturbance. Where the symptoms are distributed in the reverse way - that is, where they make their appearance in the most important individual and social functions and are able to disturb nutrition, sexual intercourse, professional work and social life - this is the mark of severe cases of neurosis and is more characteristic of them than, for example, are the variety and vigour of their pathological manifestations.
[1901b, 1347]
Are processes similar to those which we have described here as the technique of jokes known already in any other field of mental events? They are - in a single field, and an apparently very remote one. In 1900 I published a book which, as its title (*The Interpretation of Dreams*) indicates, attempted to throw light on what is puzzling in dreams and to establish them as derivatives of our normal mental functioning. I found occasion there to contrast the manifest, and often strange, content of the dream with the latent, but perfectly logical, dream-thoughts from which the dream is derived; and I entered into an investigation of the processes which make the dream out of the latent dream-thoughts, as well as of the psychical forces which are involved in that transformation. To the totality of these transforming processes I gave the name of the 'dream-work'; and I have described as a part of this dream-work a process of condensation which shows the greatest similarity to the one found in the technique of jokes - which, like it, leads to abbreviation, and creates substitute-formations of the same character. Everyone will be familiar, from a recollection of his own dreams, with the composite structures both of people and of things which emerge in dreams. Indeed, dreams even construct them out of words, and they can then be dissected in analysis. (For instance, 'Autodidasker' = 'Autodidakt' + 'Lasker'.) On other occasions - much more often, in fact - what the work of condensation in dreams produces is not composite structures but pictures which exactly resemble one thing or one person except for an addition or alteration derived from another source - modifications, that is, just like those in Herr N.'s jokes. We cannot doubt that in both cases we are faced by the same psychical process, which we may recognize from its identical results. Such a far-reaching analogy between the technique of jokes and the dream-work will undoubtedly increase our interest in the former and raise an expectation in us that a comparison between jokes and dreams may help to throw light on jokes. But we will refrain from entering upon this task, for we must reflect that so far we have investigated the technique of only a very small number of jokes, so that we cannot tell whether the analogy by which we are proposing to be guided will in fact hold good. We will therefore turn away from the comparison with dreams and go back to the technique of jokes, though at this point we shall, as it were, be leaving a loose end to our enquiry, which at some later stage we may perhaps pick up once more. [1905c, 1634]
Can we feel sure that none of the possible techniques of jokes has escaped our investigation? Of course not. But a continued examination of fresh material can convince us that we have got to know the commonest and most important technical methods of the joke-work - at all events as much as is required for forming a judgement on the nature of that psychical process. So far we have not arrived at any such judgement; but on the other hand we are now in possession of an important indication of the direction from which we may expect to receive further light upon the problem. The interesting processes of condensation accompanied by the formation of a substitute, which we have recognized as the core of the technique of verbal jokes, point towards the formation of dreams, in the mechanism of which the same psychical processes have been discovered. This is equally true, however, of the techniques of conceptual jokes - displacement, faulty reasoning, absurdity, indirect representation, representation by the opposite - which reappear one and all in the technique of the dream-work. Displacement is responsible for the puzzling appearance of dreams, which prevents our recognizing that they are a continuation of our waking life. The use of absurdity and nonsense in dreams has cost them the dignity of being regarded as psychical products and has led the authorities to suppose that a disintegration of the mental activities and a cessation of criticism, morality and logic are necessary conditions of the formation of dreams. Representation by the opposite is so common in dreams that even the popular books of dream-interpretation, which are on a completely wrong tack, are in the habit of taking it into account. Indirect representation - the replacement of a dream-thought by an allusion, by something small, a symbolism akin to analogy - is precisely what distinguishes the mode of expression of dreams from that of our waking life.¹ So far-reaching an agreement between the methods of the joke-work and those of the dream-work can scarcely be a matter of chance. To demonstrate this agreement in detail and to examine its basis will be one of our later tasks.

These two observations, then, argue in favour of what we have called hypochondriacal speech or 'organ-speech'. But, what seems to us more important, they also point to something else, of which we have innumerable instances (for example, in the cases collected in Bleuler's monograph) and which may be reduced to a definite formula. In schizophrenia words are subjected to the same process as that which makes the dream images out of latent dream-thoughts - to what we have called the primary psychical process. They undergo condensation, and by means of displacement transfer their cathexes to one another in their entirety. The process may go so far that a single word, if it is specially suitable on account of its numerous connections, takes over the representation of a whole train of thought. The works of Bleuler, Jung and their pupils offer a quantity of material which particularly supports this assertion.¹ [1915e, 3021]
We have already in *The Interpretation of Dreams* described the way in which the regression of the preconscious day's residues takes place in dream-formation. In this process thoughts are transformed into images, mainly of a visual sort; that is to say, word-presentations are taken back to the thing-presentations which correspond to them, as if, in general, the process were dominated by considerations of representability. When regression has been completed, a number of cathexes are left over in the system *Ucs*. - cathexes of memories of things. The primary psychical process is brought to bear on these memories, till, by condensation of them and displacement between their respective cathexes, it has shaped the manifest dream-content. Only where the word-presentations occurring in the day's residues are recent and current residues of perceptions, and not the expression of thoughts, are they themselves treated like thing-presentations, and subjected to the influence of condensation and displacement. Hence the rule laid down in *The Interpretation of Dreams*, and since confirmed beyond all doubt, that words and speeches in the dream-content are not freshly formed, but are modelled on speeches from the day preceding the dream (or on some other recent impressions, such as something that has been read). It is very noteworthy how little the dream-work keeps to the word-presentations; it is always ready to exchange one word for another till it finds the expression which is most handy for plastic representation.¹

Perhaps you recognize, moreover, what it is that supports our hypotheses of the two systems, and their relation to each other and to consciousness? After all, the watchman between the unconscious and the preconscious is nothing else than the censorship, to which, as we found, the form taken by the manifest dream is subject. The day's residues, which we recognized as the instigators of the dream, were preconscious material which, at night-time and in the state of sleep, had been under the influence of unconscious and repressed wishful impulses; they had been able, in combination with those impulses and thanks to their energy, to construct the latent dream. Under the dominance of the unconscious system this material had been worked over (by condensation and displacement) in a manner which is unknown or only exceptionally permissible in normal mental life - that is, in the preconscious system. We came to regard this difference in their manner of operating as what characterizes the two systems; the relation which the preconscious has to consciousness was regarded by us merely as an indication of its belonging to one of the two systems. Dreams are not pathological phenomena; they can appear in any healthy person under the conditions of a state of sleep. Our hypothesis about the structure of the mental apparatus, which allows us to understand the formation alike of dreams and of neurotic symptoms, has an incontrovertible claim to being taken into account in regard to normal mental life as well.

[1916-1917, 3370]
It will perhaps not be thought too rash to suppose that the impulses arising from the instincts do not belong to the type of bound nervous processes but of freely mobile processes which press towards discharge. The best part of what we know of these processes is derived from our study of the dream-work. We there discovered that the processes in the unconscious systems were fundamentally different from those in the preconscious (or conscious) systems. In the unconscious, cathexes can easily be completely transferred, displaced and condensed. Such treatment, however, could produce only invalid results if it were applied to preconscious material; and this accounts for the familiar peculiarities exhibited by manifest dreams after the preconscious residues of the preceding day have been worked over in accordance with the laws operating in the unconscious. I described the type of process found in the unconscious as the 'primary' psychical process, in contradistinction to the 'secondary' process which is the one obtaining in our normal waking life. Since all instinctual impulses have the unconscious systems as their point of impact, it is hardly an innovation to say that they obey the primary process. Again, it is easy to identify the primary psychical process with Breuer's freely mobile cathexis and the secondary process with changes in his bound or tonic cathexis.¹ If so, it would be the task of the higher strata of the mental apparatus to bind the instinctual excitation reaching the primary process. A failure to effect this binding would provoke a disturbance analogous to a traumatic neurosis; and only after the binding has been accomplished would it be possible for the dominance of the pleasure principle (and of its modification, the reality principle) to proceed unhindered. Till then the other task of the mental apparatus, the task of mastering or binding excitations, would have precedence - not, indeed, in opposition to the pleasure principle, but independently of it and to some extent in disregard of it.

¹[1920g, 3737]

I can imagine that to point out the existence of lying dreams of this kind, 'obliging' dreams, will arouse a positive storm of helpless indignation in some readers who call themselves analysts. 'What!' they will exclaim, 'the unconscious, the real centre of our mental life, the part of us that is so much nearer the divine than our poor consciousness - it too can lie! Then how can we still build on the interpretations of analysis and the accuracy of our findings?' To which one must reply that the recognition of these lying dreams does not constitute any shattering novelty. I know, indeed, that the craving of mankind for mysticism is ineradicable, and that it makes ceaseless efforts to win back for mysticism the territory it has been deprived of by The Interpretation of Dreams, but surely in the case under consideration everything is simple enough. A dream is not the 'unconscious'; it is the form into which a thought left over from preconscious, or even from conscious, waking life, can, thanks to the favouring state of sleep, be recast. In the state of sleep this thought has been reinforced by unconscious wishful impulses and has thus experienced distortion through the dream-work, which is determined by the mechanisms prevailing in the unconscious. With our dreamer, the intention to mislead me, just as she did her father, certainly emanated from the preconscious, and may indeed have been conscious; it could come to expression by entering into connection with the unconscious wishful impulse to please her father (or father-substitute), and in this way it created a lying dream. The two intentions, to betray and to please her father, originated in the same complex; the former resulted from the repression of the latter, and the later one was brought back by the dream-work to the earlier one. There can therefore be no question of any devaluation of the unconscious, nor of a shattering of our confidence in the results of analysis.

[1920a, 3854]
In the present discussion, moreover, I am only putting forward a hypothesis; I have no proof to offer. It seems a plausible view that this displaceable and neutral energy, which is no doubt active in both in the ego and in the id, proceeds from the narcissistic store of libido - that it is desexualized Eros. (The erotic instincts appear to be altogether more plastic, more readily diverted and displaced than the destructive instincts.) From this we can easily go on to assume that this displaceable libido is employed in the service of the pleasure principle to obviate blockages and to facilitate discharge. In this connection it is easy to observe a certain indifference as to the path along which the discharge takes place, so long as it takes place somehow. We know this trait; it is characteristic of the cathetic processes in the id. It is found in erotic cathexes, where a peculiar indifference in regard to the object displays itself; and it is especially evident in the transfers arising in analysis, which develop inevitably, irrespective of the persons who are their object. Not long ago Rank published some good examples of the way in which neurotic acts of revenge can be directed against the wrong people. Such behaviour on the part of the unconscious reminds one of the comic story of the three village tailors, one of whom had to be hanged because the only village blacksmith had committed a capital offence. Punishment must be exacted even if it does not fall upon the guilty. It was in studying the dream-work that we first came upon this kind of looseness in the displacements brought about by the primary process. In that case it was the objects that were thus relegated to a position of no more than secondary importance, just as in the case we are now discussing it is the paths of discharge. It would be characteristic of the ego to be more particular about the choice both of an object and of a path of discharge.

[1923b, 3979]

There is no difficulty in discovering the general function of dreaming. It serves the purpose of fending off, by a kind of soothing action, external or internal stimuli which would tend to arouse the sleeper, and thus of securing sleep against interruption. External stimuli are fended off by being given a new interpretation and by being woven into some harmless situation; internal stimuli, caused by instinctual demands, are given free play by the sleeper and allowed to find satisfaction in the formation of dreams, so long as the latent dream-thoughts submit to the control of the censorship. But if they threaten to break free and the meaning of the dream becomes too plain, the sleeper cuts short the dream and wakes in a fright. (Dreams of this class are known as anxiety-dreams.) A similar failure in the function of dreaming occurs if an external stimulus becomes too strong to be fended off. (This is the class of arousal-dreams.) I have given the name of dream-work to the process which, with the co-operation of the censorship, converts the latent thoughts into the manifest content of the dream. It consists of a peculiar way of treating the preconscious material of thought, so that its component parts become condensed, its psychical emphasis becomes displaced, and the whole of it is translated into visual images or dramatized, and completed by a deceptive secondary revision. The dream-work is an excellent example of the processes occurring in the deeper, unconscious layers of the mind, which differ considerably from the familiar normal processes of thought. It also displays a number of archaic characteristics, such as the use of a symbolism (in this case of a predominantly sexual kind) which it has since also been possible to discover in other spheres of mental activity.

[1925d, 4220]
I was able to show from a short story by W. Jensen called *Gradiva*, which has no particular merit in itself, that invented dreams can be interpreted in the same way as real ones and that the unconscious mechanisms familiar to us in the ‘dream-work’ are thus also operative in the processes of imaginative writing. My book on *Jokes and their Relation to the Unconscious* was a side-issue directly derived from *The Interpretation of Dreams*. The only friend of mine who was at that time interested in my work remarked to me that my interpretations of dreams often impressed him as being like jokes. In order to throw some light on this impression, I began to investigate jokes and found that their essence lay in the technical methods employed in them, and that these were the same as the means used in the ‘dream-work’ - that is to say, condensation, displacement, the representation of a thing by its opposite or by something very small, and so on. This led to an economic enquiry into the origin of the high degree of pleasure obtained from hearing a joke. And to this the answer was that it was due to the momentary suspension of the expenditure of energy upon maintaining repression, owing to the attraction exercised by the offer of a bonus of pleasure (*fore-pleasure*).

[1925d, 4239]

The laws that govern the passage of events in the unconscious, which come to light in this manner, are remarkable enough and suffice to explain most of what seems strange to us about dreams. Above all there is a striking tendency to *condensation*, an inclination to form fresh unities out of elements which in our waking thought we should certainly have kept separate. As a consequence of this, a single element of the manifest dream often stands for a whole number of latent dream-thoughts as though it were a combined allusion to all of them; and in general the compass of the manifest dream is extraordinarily small in comparison with the wealth of material from which it has sprung. Another peculiarity of the dream-work, not entirely independent of the former one, is the ease with which psychical intensities (cathexes) are *displaced* from one element to another, so that it often happens that an element which was of little importance in the dream-thoughts appears as the clearest and accordingly most important feature of the manifest dream, and, *vice versa*, that essential elements of the dream-thoughts are represented in the manifest dream only by slight allusions. Moreover, as a rule the existence of quite insignificant points in common between two elements is enough to allow the dream-work to replace one by the other in all further operations. It will easily be imagined how greatly these mechanisms of condensation and displacement can increase the difficulty of interpreting a dream and of revealing the relations between the manifest dream and the latent dream-thoughts. From the evidence of the existence of these two tendencies to condensation and displacement our theory infers that in the unconscious id the energy is in a freely mobile state and that the id sets more store by the possibility of discharging quantities of excitation than by any other consideration;¹ and our theory makes use of these two peculiarities in defining the character of the primary process we have attributed to the id.

[1940a [1938], 4978]
From this point onwards the train of thought undergoes a series of transformations which we
can no longer recognize as normal psychical processes and which lead to a result that
bewilders us - a psychopathological structure. I will enumerate these processes and classify
them.
[1900a, 1022]

The direction in which condensations in dreams proceed is determined on the one hand by
the rational preconscious relations of the dream-thoughts, and on the other by the attraction
exercised by visual memories in the unconscious. The outcome of the activity of condensation
is the achievement of the intensities required for forcing a way through into the perceptual
systems.
[1900a, 1022]

It will perhaps not be thought too rash to suppose that the impulses arising from the instincts
do not belong to the type of bound nervous processes but of freely mobile processes which
press towards discharge. The best part of what we know of these processes is derived from our
study of the dream-work. We there discovered that the processes in the unconscious systems
were fundamentally different from those in the preconscious (or conscious) systems. In the
unconscious, cathexes can easily be completely transferred, displaced and condensed. Such
treatment, however, could produce only invalid results if it were applied to preconscious
material; and this accounts for the familiar peculiarities exhibited by manifest dreams after the
preconscious residues of the preceding day have been worked over in accordance with the laws
operating in the unconscious. I described the type of process found in the unconscious as the
'primary' psychical process, in contradistinction to the 'secondary' process which is the one
obtaining in our normal waking life. Since all instinctual impulses have the unconscious systems
as their point of impact, it is hardly an innovation to say that they obey the primary process.
Again, it is easy to identify the primary psychical process with Breuer's freely mobile cathexis
and the secondary process with changes in his bound or tonic cathexis.¹ If so, it would be the
task of the higher strata of the mental apparatus to bind the instinctual excitation reaching the
primary process. A failure to effect this binding would provoke a disturbance analogous to a
traumatic neurosis; and only after the binding has been accomplished would it be possible for
the dominance of the pleasure principle (and of its modification, the reality principle) to proceed
unhindered. Till then the other task of the mental apparatus, the task of mastering or binding
excitations, would have precedence - not, indeed, in opposition to the pleasure principle, but
independently of it and to some extent in disregard of it.
[1920g, 3737]
There is no difficulty in discovering the general function of dreaming. It serves the purpose of fending off, by a kind of soothing action, external or internal stimuli which would tend to arouse the sleeper, and thus of securing sleep against interruption. External stimuli are fended off by being given a new interpretation and by being woven into some harmless situation; internal stimuli, caused by instinctual demands, are given free play by the sleeper and allowed to find satisfaction in the formation of dreams, so long as the latent dream-thoughts submit to the control of the censorship. But if they threaten to break free and the meaning of the dream becomes too plain, the sleeper cuts short the dream and wakes in a fright. (Dreams of this class are known as *anxiety-dreams*.) A similar failure in the function of dreaming occurs if an external stimulus becomes too strong to be fended off. (This is the class of *arousal-dreams.*) I have given the name of *dream-work* to the process which, with the co-operation of the censorship, converts the latent thoughts into the manifest content of the dream. It consists of a peculiar way of treating the preconscious material of thought, so that its component parts become *condensed*, its psychical emphasis becomes *displaced*, and the whole of it is translated into visual images or *dramatized*, and completed by a deceptive *secondary revision*. It also displays a number of archaic characteristics, such as the use of a *symbolism* (in this case of a predominantly sexual kind) which it has since also been possible to discover in other spheres of mental activity.

[1925d, 4220]
The following observations may help us towards clearing up this point. If in the course of a single day we have two or more experiences suitable for provoking a dream, the dream will make a combined reference to them as a single whole; it is under a necessity to combine them into a unity. Here is an instance. One afternoon during the summer I entered a railway compartment in which I found two acquaintances who were strangers to each other. One of them was an eminent medical colleague and the other was a member of a distinguished family with which I had professional relations. I introduced the two gentlemen to each other, but all through the long journey they conducted their conversation with me as a go-between, so that I presently found myself discussing various topics alternately, first with the one and then with the other. I asked my doctor friend to use his influence on behalf of a common acquaintance of ours who was just starting a medical practice. The doctor replied that he was convinced of the young man's capacity, but that his homely appearance would make it hard for him to make his way in families of the better class; to which I replied that that was the very reason why he needed influential assistance. Turning to my other fellow-traveller, I enquired after the health of his aunt - the mother of one of my patients - who was lying seriously ill at the time. During the night following the journey I had a dream that the young friend on whose behalf I had pleaded was sitting in a fashionable drawing-room in a select company composed of all the distinguished and wealthy people of my acquaintance and, with the easy bearing of a man of the world, was delivering a funeral oration on the old lady (who was already dead so far as my dream was concerned), the aunt of my second fellow-traveller. (I must confess that I had not been on good terms with that lady.) Thus my dream had, once again, worked out connections between the two sets of impressions of the previous day and had combined them into a single situation.

Many experiences such as this lead me to assert that the dream-work is under some kind of necessity to combine all the sources which have acted as stimuli for the dream into a single unity in the dream itself.¹

¹ The tendency of the dream-work to fuse into a single action all events of interest which occur simultaneously has already been remarked on by several writers; e.g. Delage (1891, 41) and Delboeuf (1885, 237), who speaks of 'rapprochement forcé' ['enforced convergence'].

The first thing that becomes clear to anyone who compares the dream-content with the dream-thoughts is that a work of condensation on a large scale has been carried out. Dreams are brief, meagre and laconic in comparison with the range and wealth of the dream-thoughts. If a dream is written out it may perhaps fill half a page. The analysis setting out the dream-thoughts underlying it may occupy six, eight or a dozen times as much space. This relation varies with different dreams; but so far as my experience goes its direction never varies. As a rule one underestimates the amount of compression that has taken place, since one is inclined to regard the dream-thoughts that have been brought to light as the complete material, whereas if the work of interpretation is carried further it may reveal still more thoughts concealed behind the dream. I have already had occasion to point out that it is in fact never possible to be sure that a dream has been completely interpreted. Even if the solution seems satisfactory and without gaps, the possibility always remains that the dream may have yet another meaning. Strictly speaking, then, it is impossible to determine the amount of condensation.

[1900a, 666]

[1900a, 666]
There is an answer, which at first sight seems most plausible, to the argument that the great lack of proportion between the dream-content and the dream-thoughts implies that the psychical material has undergone an extensive process of condensation in the course of the formation of the dream. We very often have an impression that we have dreamt a great deal all through the night and have since forgotten most of what we dreamt. On this view, the dream which we remember when we wake up would only be a fragmentary remnant of the total dream-work; and this, if we could recollect it in its entirety, might well be as extensive as the dream-thoughts. There is undoubtedly some truth in this: there can be no question that dreams can be reproduced most accurately if we try to recall them as soon as we wake up and that our memory of them becomes more and more incomplete towards evening. But on the other hand it can be shown that the impression that we have dreamt a great deal more than we can reproduce is very often based on an illusion, the origin of which I shall discuss later. Moreover the hypothesis that condensation occurs during the dream-work is not affected by the possibility of dreams being forgotten, since this hypothesis is proved to be correct by the quantities of ideas which are related to each individual piece of the dream which has been retained. Even supposing that a large piece of the dream has escaped recollection, this may merely have prevented our having access to another group of dream-thoughts. There is no justification for supposing that the lost pieces of the dream would have related to the same thoughts which we have already reached from the pieces of the dream that have survived.¹

¹ [Footnote added 1914:] The occurrence of condensation in dreams has been hinted at by many writers. Du Prel (1885, 85) has a passage in which he says it is absolutely certain that there has been a process of condensation of the groups of ideas in dreams.

The unquestionable fact remains, however, that the formation of dreams is based on a process of condensation. How is that condensation brought about?

When we reflect that only a small minority of all the dream-thoughts revealed are represented in the dream by one of their ideational elements, we might conclude that condensation is brought about by omission: that is, that the dream is not a faithful translation or a point-for-point projection of the dream thoughts, but a highly incomplete and fragmentary version of them. This view, as we shall soon discover, is a most inadequate one. But we may take it as a provisional starting-point and go on to a further question. If only a few elements from the dream-thoughts find their way into the dream-content, what are the conditions which determine their selection?

In order to get some light on this question we must turn our attention to those elements of the dream-content which must have fulfilled these conditions. And the most favourable material for such an investigation will be a dream to the construction of which a particularly intense process of condensation has contributed. I shall accordingly begin by choosing for the purpose the dream which I have already recorded on p. 657 ff.

To provide a third opportunity for studying condensation in the formation of dreams, I will give part of the analysis of another dream, which I owe to an elderly lady undergoing psycho-analytic treatment. As was to be expected from the severe anxiety-states from which the patient suffered, her dreams contained a very large number of sexual thoughts, the first realization of which both surprised and alarmed her. Since I shall not be able to pursue the interpretation of the dream to the end, its material will appear to fall into several groups without any visible connection.
In all three of the dreams which I have just recorded, I have indicated by italics the points at which one of the elements of the dream-content reappears in the dream-thoughts, so as to show clearly the multiplicity of connections arising from the former. Since, however, the analysis of none of these dreams has been traced to its end, it will perhaps be worth while to consider a dream whose analysis has been recorded exhaustively, so as to show how its content is overdetermined. For this purpose I will take the dream of Irma's injection. It will be easy to see from that example that the work of condensation makes use of more than one method in the construction of dreams.

None of these figures whom I lighted upon by following up 'Irma' appeared in the dream in bodily shape. They were concealed behind the dream figure of 'Irma', which was thus turned into a collective image with, it must be admitted, a number of contradictory characteristics. Irma became the representative of all these other figures which had been sacrificed to the work of condensation, since I passed over to her, point by point, everything that reminded me of them.

The construction of collective and composite figures is one of the chief methods by which condensation operates in dreams. I shall presently have occasion to deal with them in another context.

Another interesting example of condensation in this dream was the mention in it of 'propyls'. What was contained in the dream-thoughts was not 'propyls' but 'amyls.' It might be supposed that a single displacement had taken place at this point in the construction of the dream. This was indeed the case. But the displacement served the purposes of condensation, as is proved by the following addition to the analysis of the dream. When I allowed my attention to dwell for a moment longer on the word 'propyls', it occurred to me that it sounded like 'Propylaea'. But there are Propylaea not only in Athens but in Munich. A year before the dream I had gone to Munich to visit a friend who was seriously ill at the time - the same friend who was unmistakably alluded to in the dream by the word 'trimethylamin' which occurred immediately after 'propyls.'

Our study of the dream of Irma's injection has already enabled us to gain some insight into the processes of condensation during the formation of dreams. We have been able to observe certain of their details, such as how preference is given to elements that occur several times over in the dream-thoughts, how new unities are formed (in the shape of collective figures and composite structures), and how intermediate common entities are constructed. The further questions of the purpose of condensation and of the factors which tend to produce it will not be raised till we come to consider the whole question of the psychical processes at work in the formation of dreams. We will be content for the present with recognizing the fact that dream-condensation is a notable characteristic of the relation between dream-thoughts and dream-content.

In the process of transforming the latent thoughts into the manifest content of a dream we have found two factors at work: dream-condensation and dream-displacement. As we continue our investigation we shall, in addition to these, come across two further determinants which exercise an undoubted influence on the choice of the material which is to find access to the dream.
One and one only of these logical relations is very highly favoured by the mechanism of dream-formation; namely, the relation of similarity, consonance or approximation - the relation of 'just as'. This relation, unlike any other, is capable of being represented in dreams in a variety of ways.¹ Parallels or instances of 'just as' inherent in the material of the dream-thoughts constitute the first foundations for the construction of a dream; and no inconsiderable part of the dream-work consists in creating fresh parallels where those which are already present cannot find their way into the dream owing to the censorship imposed by resistance. The representation of the relation of similarity is assisted by the tendency of the dream-work towards condensation.

In identification, only one of the persons who are linked by a common element succeeds in being represented in the manifest content of the dream, while the second or remaining persons seem to be suppressed in it. But this single covering figure appears in the dream in all the relations and situations which apply either to him or to the figures which he covers. In composition, where this is extended to persons, the dream-image contains features which are peculiar to one or other of the persons concerned but not common to them; so that the combination of these features leads to the appearance of a new unity, a composite figure. The actual process of composition can be carried out in various ways. On the one hand, the dream-figure may bear the name of one of the persons related to it - in which case we simply know directly, in a manner analogous to our waking knowledge, that this or that person is intended - while its visual features may belong to the other person. Or, on the other hand, the dream-image itself may be composed of visual features belonging in reality partly to the one person and partly to the other. Or again the second person's share in the dream-image may lie, not in its visual features, but in the gestures that we attribute to it, the words that we make it speak, or the situation in which we place it. In this last case the distinction between identification and the construction of a composite figure begins to lose its sharpness. But it may also happen that the formation of a composite figure of this kind is unsuccessful. If so, the scene in the dream is attributed to one of the persons concerned, while the other (and usually the more important one) appears as an attendant figure without any other function. The dreamer may describe the position in such a phrase as: 'My mother was there as well.' (Stekel.) An element of this kind in the dream-content may be compared to the 'determinatives' used in hieroglyphic script, which are not meant to be pronounced but serve merely to elucidate other signs.

[1900a, 790]
The common element which justifies, or rather causes, the combination of the two persons may be represented in the dream or may be omitted from it. As a rule the identification or construction of a composite person takes place for the very purpose of avoiding the representation of the common element. Instead of saying: 'A has hostile feelings towards me and so has B', I make a composite figure out of A and B in the dream, or I imagine A performing an act of some other kind which is characteristic of B. The dream-figure thus constructed appears in the dream in some quite new connection, and the circumstance that it represents both A and B justifies me in inserting at the appropriate point in the dream the element which is common to both of them, namely a hostile attitude towards me. It is often possible in this way to achieve quite a remarkable amount of condensation in the content of a dream; I can save myself the need for giving a direct representation of very complicated circumstances relating to one person, if I can find another person to whom some of these circumstances apply equally. It is easy to see, too, how well this method of representation by means of identification can serve to evade the censorship due to resistance, which imposes such severe conditions upon the dream-work. What the censorship objects to may lie precisely in certain ideas which, in the material of the dream-thoughts, are attached to a particular person; so I proceed to find a second person, who is also connected with the objectionable material, but only with part of it. The contact between the two persons upon this censorable point now justifies me in constructing a composite figure characterized by indifferent features derived from both. This figure, arrived at by identification or composition, is then admissible to the dream-content without censorship, and thus, by making use of dream-condensation, I have satisfied the claims of the dream-censorship.

[1900a, 791]

When a common element between two persons is represented in a dream, it is usually a hint for us to look for another, concealed common element whose representation has been made impossible by the censorship. A displacement in regard to the common element has been made in order, as it were, to facilitate its representation. The fact that the composite figure appears in the dream with an indifferent common element leads us to conclude that there is another far from indifferent common element present in the dream-thoughts.

[1900a, 792]

Accordingly, identification or the construction of composite figures serves various purposes in dreams: firstly to represent an element common to two persons, secondly to represent a displaced common element, and thirdly, too, to express a merely wishful common element. Since wishing that two persons had a common element frequently coincides with exchanging one for the other, this latter relation is also expressed in dreams by means of identification. In the dream of Irma's injection, I wished to exchange her for another patient: I wished, that is, that the other woman might be my patient just as Irma was. The dream took this wish into account by showing me a person who was called Irma, but who was examined in a position in which I had only had occasion to see the other woman. In the dream about my uncle an exchange of this kind became the central point of the dream: I identified myself with the Minister by treating and judging my colleagues no better than he did.

[1900a, 792]
It is my experience, and one to which I have found no exception, that every dream deals with the dreamer himself. Dreams are completely egoistical.¹ Whenever my own ego does not appear in the content of the dream, but only some extraneous person, I may safely assume that my own ego lies concealed, by identification, behind this other person; I can insert my ego into the context. On other occasions, when my own ego does appear in the dream, the situation in which it occurs may teach me that some other person lies concealed, by identification behind my ego. In that case the dream should warn me to transfer on to myself, when I am interpreting the dream, the concealed common element attached to this other person. There are also dreams in which my ego appears along with other people who, when the identification is resolved, are revealed once again as my ego. These identifications should then make it possible for me to bring into contact with my ego certain ideas whose acceptance has been forbidden by the censorship. Thus my ego may be represented in a dream several times over, now directly and now through identification with extraneous persons. By means of a number of such identifications it becomes possible to condense an extraordinary amount of thought-material.² The fact that the dreamer's own ego appears several times, or in several forms, in a dream is at bottom no more remarkable than that the ego should be contained in a conscious thought several times or in different places or connections - e.g. in the sentence 'when I think what a healthy child I was'.
[1900a, 793]

Identifications in the case of proper names of localities are resolved even more easily than in the case of persons, since here there is no interference by the ego, which occupies such a dominating place in dreams. In one of my dreams about Rome (see p. 680 f.), the place in which I found myself was called Rome, but I was astonished at the quantity of German posters at a street-corner. This latter point was a wish-fulfilment, which at once made me think of Prague; and the wish itself may perhaps have dated from a German-nationalist phase which I passed through during my youth, but have since got over. At the time at which I had the dream there was a prospect of my meeting my friend in Prague; so that the identification of Rome and Prague can be explained as a wishful common element: I would rather have met my friend in Rome than in Prague and I would have liked to exchange Prague for Rome for the purpose of this meeting.
[1900a, 793]
The possibility of creating composite structures stands foremost among the characteristics which so often lend dreams a fantastic appearance, for it introduces into the content of dreams elements which could never have been objects of actual perception. The psychical process of constructing composite images in dreams is evidently the same as when we imagine or portray a centaur or a dragon in waking life. The only difference is that what determines the production of the imaginary figure in waking life is the impression which the new structure itself is intended to make; whereas the formation of the composite structure in a dream is determined by a factor extraneous to its actual shape - namely the common element in the dream-thoughts. Composite structures in dreams can be formed in a great variety of ways. The most naïve of these procedures merely represents the attributes of one thing to the accompaniment of a knowledge that they also belong to something else. A more painstaking technique combines the features of both objects into a new image and in so doing makes clever use of any similarities that the two objects may happen to possess in reality. The new structure may seem entirely absurd or may strike us as an imaginative success, according to the material and to the ingenuity with which it is put together. If the objects which are to be condensed into a single unity are much too incongruous, the dream-work is often content with creating a composite structure with a comparatively distinct nucleus, accompanied by a number of less distinct features. In that case the process of unification into a single image may be said to have failed. The two representations are superimposed and produce something in the nature of a contest between the two visual images. One might arrive at similar representations in a drawing, if one tried to illustrate the way in which a general concept is formed from a number of individual perceptual images.

[1900a, 794]
Dreams are, of course, a mass of these composite structures. I have given some examples of them in dreams that I have already analysed; and I will now add a few more. In the dream reported below on p. 816 ff., which describes the course of the patient's life 'in the language of flowers' the dream-ego held a blossoming branch in her hand which, as we have seen, stood both for innocence and for sexual sinfulness. The branch, owing to the way in which the blossoms were placed on it, also reminded the dreamer of cherry-blossom; the blossoms themselves, regarded individually, were camellias, and moreover the general impression was of an exotic growth. The common factor among the elements of this composite structure was shown by the dream-thoughts. The blossoming branch was composed of allusions to gifts made to her in order to win, or attempt to win, her favour. Thus she had been given cherries in her childhood and, later in life, a camellia-plant; while 'exotic' was an allusion to a much-travelled naturalist who had tried to win her favour with a flower-drawing. - Another of my women patients produced in one of her dreams a thing that was intermediate between a bathing-hut at the seaside, an outside closet in the country and an attic in a town house. The first two elements have in common a connection with people naked and undressed; and their combination with the third element leads to the conclusion that (in her childhood) an attic had also been a scene of undressing. - Another dreamer, a man, produced a composite locality out of two places where 'treatments' are carried out: one of them being my consulting-room and the other the place of entertainment where he had first made his wife's acquaintance. - A girl dreamt, after her elder brother had promised to give her a feast of caviare, that this same brother's legs were covered all over with black grains of caviare. The element of 'contagion' (in the moral sense) and a recollection of a rash in her childhood, which had covered her legs all over with red spots, instead of black ones, had been combined with the grains of caviare into a new concept - namely the concept of 'what she had got from her brother.' In this dream, as in others, parts of the human body were treated like objects. - In a dream recorded by Ferenczi, a composite image occurred was made up from the figure of a doctor and of a horse and was also dressed in a nightshirt. The element common to these three components was arrived at in the analysis after the woman-patient had recognized that the night-shirt was an allusion to her father in a scene from her childhood. In all three cases it was a question of an object of her sexual curiosity. When she was a child she had often been taken by her nurse to a military stud-farm where she had ample opportunities of gratifying what was at that time her still uninhibited curiosity.

[1900a, 795]

We have been occupied so far with investigating the means by which dreams represent the relations between the dream-thoughts. In the course of this investigation, however, we have more than once touched upon the further topic of the general nature of the modifications which the material of the dream-thoughts undergoes for the purpose of the formation of a dream. We have learnt that that material, stripped to a large extent of its relations, is submitted to a process of compression, while at the same time displacements of intensity between its elements necessarily bring about a psychical transvaluation of the material. The displacements we have hitherto considered turned out to consist in the replacing of some one particular idea by another in some way closely associated with it, and they were used to facilitate condensation in so far as, by their means, instead of two elements, a single common element intermediate between them found its way into the dream. We have not yet referred to any other sort of displacement. Analyses show us, however, that another sort exists and that it reveals itself in a change in the verbal expression of the thoughts concerned. In both cases there is a displacement along a chain of associations; but a process of such a kind can occur in various psychical spheres, and the outcome of the displacement may in one case be that one element is replaced by another, while the outcome in another case may be that a single element has its verbal form replaced by another.

[1900a, 808]
This second species of displacement which occurs in dream-formation is not only of great theoretical interest but is also specially well calculated to explain the appearance of fantastic absurdity in which dreams are disguised. The direction taken by the displacement usually results in a colourless and abstract expression in the dream-thought being exchanged for a pictorial and concrete one. The advantage, and accordingly the purpose, of such a change jumps to the eyes. A thing that is pictorial is, from the point of view of a dream, a thing that is capable of being represented: it can be introduced into a situation in which abstract expressions offer the same kind of difficulties to representation in dreams as a political leading article in a newspaper would offer to an illustrator. But not only representability, but the interests of condensation and the censorship as well can be the gainers from this exchange. A dream-thought is unusable so long as it is expressed in an abstract form; but when once it has been transformed into pictorial language, contrasts and identifications of the kind which the dream-work requires, and which it creates if they are not already present, can be established more easily than before between the new form of expression and the remainder of the material underlying the dream. This is so because in every language concrete terms, in consequence of the history of their development, are richer in associations than conceptual ones. We may suppose that a good part of the intermediate work done during the formation of a dream, which seeks to reduce the dispersed dream-thoughts to the most succinct and unified expression possible, proceeds along the line of finding appropriate verbal transformations for the individual thoughts. Any one thought, whose form of expression may happen to be fixed for other reasons, will operate in a determinant and selective manner on the possible forms of expression allotted to the other thoughts, and it may do so, perhaps, from the very start - as is the case in writing a poem. If a poem is to be written in rhymes, the second line of a couplet is limited by two conditions: it must express an appropriate meaning, and the expression of that meaning must rhyme with the first line. No doubt the best poem will be one in which we fail to notice the intention of finding a rhyme, and in which the two thoughts have, by mutual influence, chosen from the very start a verbal expression which will allow a rhyme to emerge with only slight subsequent adjustment.

[1900a, 809]

The foregoing discussion has led us at last to the discovery of a third factor whose share in the transformation of the dream thoughts into the dream-content is not to be underrated: namely, considerations of representability in the peculiar psychical material of which dreams make use - for the most part, that is, representability in visual images. Of the various subsidiary thoughts attached to the essential dream-thoughts, those will be preferred which admit of visual representation; and the dream-work does not shrink from the effort of recasting unadaptable thoughts into a new verbal form - even into a less usual one - provided that that process facilitates representation and so relieves the psychological pressure caused by constricted thinking. This pouring of the content of a thought into another mould may at the same time serve the purposes of the activity of condensation and may create connections, which might not otherwise have been present, with some other thought; while this second thought itself may already have had its original form of expression changed, with a view to meeting the first one half-way.

[1900a, 813]
Anyone who has formed even the slightest idea of the extent of condensation in dreams will easily imagine what a number of pages would be filled by a full analysis of this dream. Fortunately, however, in the present context I need only take up one point in it, which provides an example of astonishment in dreams, as exhibited in the interpolation 'strangely enough'. The following was the occasion of the dream. Louise N., the lady who was assisting me in my job in the dream, had been calling on me. 'Lend me something to read', she had said. I offered her Rider Haggard's *She*. 'A strange book, but full of hidden meaning', I began to explain to her; 'the eternal feminine, the immortality of our emotions . . .' Here she interrupted me: 'I know it already. Have you nothing of your own?' - 'No, my own immortal works have not yet been written.' - 'Well, when are we to expect these so-called ultimate explanations of yours which you've promised even we shall find readable?' she asked, with a touch of sarcasm. At that point I saw that someone else was admonishing me through her mouth and I was silent. I reflected on the amount of self-discipline it was costing me to offer the public even my book upon dreams - I should have to give away so much of my own private character in it. [1900a, 899]

The function of 'secondary revision', which we have attributed to the fourth of the factors concerned in shaping the content of dreams, shows us in operation once more the activity which is able to find free vent in the creation of day-dreams without being inhibited by any other influences. We might put it simply by saying that this fourth factor of ours seeks to mould the material offered to it into something like a day-dream. If, however, a day-dream of this kind has already been formed within the nexus of the dream-thoughts, this fourth factor in the dream-work will prefer to take possession of the ready-made day-dream and seek to introduce it into the content of the dream. There are some dreams which consist merely in the repetition of a day-time phantasy which may perhaps have remained unconscious: such, for instance, as the boy's dream of driving in a war-chariot with the heroes of the Trojan War. In my 'Autodidasker' dream the second part at all events was a faithful reproduction of a daytime phantasy, innocent in itself, of a conversation with Professor N. In view of the complicated conditions which a dream has to satisfy when it comes into existence, it happens more frequently that the ready-made phantasy forms only a portion of the dream, or that only a portion of the phantasy forces its way into the dream. Thereafter, the phantasy is treated in general like any other portion of the latent material, though it often remains recognizable as an entity in the dream. There are often parts of my dreams which stand out as producing a different impression from the rest. They strike me as being, as it were, more fluent, more connected and at the same time more fleeting than other parts of the same dream. These, I know, are unconscious phantasies which have found their way into the fabric of the dream, but I have never succeeded in pinning down a phantasy of this kind. Apart from this, these phantasies, like any other component of the dream-thoughts, are compressed, condensed, superimposed on one another, and so on. There are, however, transitional cases, between the case in which they constitute the content (or at least the façade) of the dream unaltered and the extreme opposite in which they are represented in the content of the dream only by one of their elements or by a distant allusion. What happens to phantasies present in the dream-thoughts is evidently also determined by any advantages they may have to offer the requirements of the censorship and of the urge towards condensation. [1900a, 932]
Having now repelled the objections that have been raised against us, or having at least indicated where our defensive weapons lie, we must no longer postpone the task of setting about the psychological investigations for which we have so long been arming ourselves. Let us summarize the principal findings of our enquiry so far as it has gone. Dreams are psychical acts of as much significance as any others; their motive force is in every instance a wish seeking fulfilment; the fact of their not being recognizable as wishes and their many peculiarities and absurdities are due to the influence of the psychical censorship to which they have been subjected during the process of their formation; apart from the necessity of evading this censorship, other factors which have contributed to their formation are a necessity for the condensation of their psychical material, a regard for the possibility of its being represented in sensory images and - though not invariably - a demand that the structure of the dream shall have a rational and intelligible exterior. Each of these propositions opens a way to fresh psychological postulates and speculations; the mutual relations between the wish which is the dream's motive force and the four conditions to which the dream's formation is subject, as well as the interrelations between the latter, require to be investigated; and the place of dreams in the nexus of mental life has to be assigned.

[1900a, 966]

This regression, then, is undoubtedly one of the psychological characteristics of the process of dreaming; but we must remember that it does not occur only in dreams. Intentional recollection and other constituent processes of our normal thinking involve a retrogressive movement in the psychical apparatus from a complex ideational act back to the raw material of the memory-traces underlying it. In the waking state, however, this backward movement never extends beyond the mnemonic images; it does not succeed in producing a hallucinatory revival of the perceptual images. Why is it otherwise in dreams? When we were considering the work of condensation in dreams we were driven to suppose that the intensities attaching to ideas can be completely transferred by the dream-work from one idea to another. It is probably this alteration in the normal psychical procedure which makes possible the cathexis of the system \textit{Pcpt.} in the reverse direction, starting from thoughts, to the pitch of complete sensory vividness.

[1900a, 976]
(1) The intensities of the individual ideas become capable of discharge *en bloc* and pass over from one idea to another, so that certain ideas are formed which are endowed with great intensity. And since this process is repeated several times, the intensity of a whole train of thought may eventually be concentrated in a single ideational element. Here we have the fact of 'compression' or 'condensation', which has become familiar in the dream-work. It is this that is mainly responsible for the bewildering impression made on us by dreams, for nothing at all analogous to it is known to us in mental life that is normal and accessible to consciousness. In normal mental life too, we find ideas which, being the nodal points or end results of whole chains of thought, possess a high degree of psychical significance; but their significance is not expressed by any feature that is obvious in a sensory manner to internal perception; their perceptual presentation is not in any respect more intense on account of their psychical significance. In the process of condensation, on the other hand, every psychical interconnection is transformed into an *intensification* of its ideational content. The case is the same as when, in preparing a book for the press, I have some word which is of special importance for understanding the text printed in spaced or heavy type; or in speech I should pronounce the same word loudly and slowly and with special emphasis. The first of these two analogies reminds us at once of an example provided by the dream-work itself: the word 'trimethylamin' in the dream of Irma's injection. Art historians have drawn our attention to the fact that the earliest historical sculptures obey a similar principle: they express the rank of the persons represented by their size. A king is represented twice or three times as large as his attendants or as his defeated enemies. A sculpture of Roman date would make use of subtler means for producing the same result. The figure of the Emperor would be placed in the middle, standing erect, and would be modelled with especial care, while his enemies would be prostrate at his feet; but he would no longer be a giant among dwarfs. The bows with which inferiors greet their superiors among ourselves to-day are an echo of the same ancient principle of representation.

[1900a, 1022]

The direction in which condensations in dreams proceed is determined on the one hand by the rational preconscious relations of the dream-thoughts, and on the other by the attraction exercised by visual memories in the unconscious. The outcome of the activity of condensation is the achievement of the intensities required for forcing a way through into the perceptual systems.

[1900a, 1022]

(2) Owing, once more, to the freedom with which the intensities can be transferred, 'intermediate ideas', resembling compromises, are constructed under the sway of condensation. (Cf. the numerous instances I have given of this.) This is again something unheard-of in normal chains of ideas, where the main stress is laid on the selection and retention of the 'right' ideational element. On the other hand, composite structures and compromises occur with remarkable frequency when we try to express preconscious thoughts in speech. They are then regarded as species of 'slips of the tongue.'

[1900a, 1023]

(4) Thoughts which are mutually contradictory make no attempt to do away with each other, but persist side by side. They often combine to form condensations, just as though there were no contradiction between them, or arrive at compromises such as our conscious thoughts would never tolerate but such as are often admitted in our actions.

[1900a, 1023]
These are some of the most striking of the abnormal processes to which the dream-thoughts, previously constructed on rational lines, are subjected in the course of the dream-work. It will be seen that the chief characteristic of these processes is that the whole stress is laid upon making the cathecting energy mobile and capable of discharge; the content and the proper meaning of the psychical elements to which the cathexes are attached are treated as of little consequence. It might have been supposed that condensation and the formation of compromises is only carried out for the sake of facilitating regression, that is, when it is a question of transforming thoughts into images. But the analysis - and still more the synthesis - of dreams which include no such regression to images, e.g. the dream of 'Autodidasker', exhibits the same processes of displacement and condensation as the rest.

[1900a, 1023]

Two other things are already clear. The content of the dream is very much shorter than the thoughts for which I regard it as a substitute; and analysis has revealed that the instigator of the dream was an unimportant event of the evening before I dreamt it.

[1901a, 1058]

But another achievement of the dream-work, tending as it does to produce incoherent dreams, is even more striking. If in any particular instance we compare the number of ideational elements or the space taken up in writing them down in the case of the dream and of the dream-thoughts to which the analysis leads us and of which traces are to be found in the dream itself, we shall be left in no doubt that the dream-work has carried out a work of compression or condensation on a large scale. It is impossible at first to form any judgement of the degree of this condensation; but the deeper we plunge into a dream-analysis the more impressive it seems. From every element in a dream's content associative threads branch out in two or more directions; every situation in a dream seems to be put together out of two or more impressions or experiences. For instance, I once had a dream of a sort of swimming-pool, in which the bathers were scattering in all directions; at one point on the edge of the pool someone was standing and bending towards one of the people bathing, as though to help her out of the water. The situation was put together from a memory of an experience I had had at puberty and from two paintings, one of which I had seen shortly before the dream. One was a picture from Schwind's series illustrating the legend of Mélusine, which showed the water-nymphs surprised in their pool (cf. the scattering bathers in the dream); the other was a picture of the Deluge by an Italian Master; while the little experience remembered from my puberty was of having seen the instructor at a swimming-school helping a lady out of the water who had stopped in until after the time set aside for men bathers. - In the case of the example which I chose for interpretation, an analysis of the situation led me to a small series of recollections each of which contributed something to the content of the dream. In the first place, there was the episode from the time of my engagement of which I have already spoken. The pressure upon my hand under the table, which was a part of that episode, provided the dream with the detail 'under the table' - a detail which I had to add as an afterthought to my memory of the dream. In the episode itself there was of course no question of 'turning to me'; the analysis showed that this element was the fulfilment of a wish by presenting the opposite of an actual event, and that it related to my wife's behaviour at the table d'hôte. But behind this recent recollection there lay concealed an exactly similar and far more important scene from the time of our engagement, which estranged us for a whole day. The intimate laying of a hand on my knee belonged to a quite different context and was concerned with quite other people. This element in the dream was in turn the starting-point of two separate sets of memories - and so on.

[1901a, 1066]
The material in the dream-thoughts which is packed together for the purpose of constructing a dream-situation must of course in itself be adaptable for that purpose. There must be one or more common elements in all the components. The dream-work then proceeds just as Francis Galton did in constructing his family photographs. It superimposes, as it were, the different components upon one another. The common element in them then stands out clearly in the composite picture, while contradictory details more or less wipe one another out. This method of production also explains to some extent the varying degrees of characteristic vagueness shown by so many elements in the content of dreams. Basing itself on this discovery, dream-interpretation has laid down the following rule: In analysing a dream, if an uncertainty can be resolved into an 'either-or', we must replace it for purposes of interpretation by an 'and', and take each of the apparent alternatives as an independent starting-point for a series of associations.

If a common element of this kind between the dream-thoughts is not present, the dream-work sets about creating one, so that it may be possible for the thoughts to be given a common representation in the dream. The most convenient way of bringing together two dream-thoughts which, to start with, have nothing in common, is to alter the verbal form of one of them, and thus bring it half-way to meet the other, which may be similarly clothed in a new form of words. A parallel process is involved in hammering out a rhyme, where a similar sound has to be sought for in the same way as a common element is in our present case. A large part of the dream-work consists in the creation of intermediate thoughts of this kind which are often highly ingenious, though they frequently appear far-fetched; these then form a link between the composite picture in the manifest content of the dream and the dream-thoughts, which are themselves diverse both in form and essence and have been determined by the exciting factors of the dream. The analysis of our sample dream affords us an instance of this kind in which a thought has been given a new form in order to bring it into contact with another which is essentially foreign to it. In carrying out the analysis I came upon the following thought: 'I should like to get something sometimes without paying for it'. But in that form the thought could not be employed in the dream-content. It was therefore given a fresh form: 'I should like to get some enjoyment without cost ["Kosten"]'. Now the word 'Kosten' in its second sense fits into the 'table d'hôte' circle of ideas, and could thus be represented in the 'spinach' which was served in the dream. When a dish appears at our table and the children refuse it, their mother begins by trying persuasion, and urges them 'just to taste [kosten] a bit of it'. It may seem strange that the dream-work should make such free use of verbal ambiguity, but further experience will teach us that the occurrence is quite a common one.

The process of condensation further explains certain constituents of the content of dreams which are peculiar to them and are not found in waking ideation. What I have in mind are 'collective' and 'composite figures' and the strange 'composite structures', which are creations not unlike the composite animals invented by the folk-imagination of the Orient. The latter, however, have already assumed stereotyped shapes in our thought, whereas in dreams fresh composite forms are being perpetually constructed in an inexhaustible variety. We are all of us familiar with such structures from our own dreams.
There are many sorts of ways in which figures of this kind can be put together. I may build up a figure by giving it the features of two people; or I may give it the form of one person but think of it in the dream as having the name of another person; or I may have a visual picture of one person, but put it in a situation which is appropriate to another. In all these cases the combination of different persons into a single representative in the content of the dream has a meaning; it is intended to indicate an 'and' or 'just as', or to compare the original persons with each other in some particular respect, which may even be specified in the dream itself. As a rule, however, this common element between the combined persons can only be discovered by analysis, and is only indicated in the contents of the dream by the formation of the collective figure.

The composite structures which occur in dreams in such immense numbers are put together in an equal variety of ways, and the same rules apply to their resolution. There is no need for me to quote any instances. Their strangeness disappears completely when once we have made up our minds not to class them with the objects of our waking perception, but to remember that they are products of dream-condensation and are emphasizing in an effectively abbreviated form some common characteristic of the objects which they are thus combining. Here again the common element has as a rule to be discovered by analysis. The content of the dream merely says as it were: 'All these things have an element x in common.' The dissection of these composite structures by means of analysis is often the shortest way to finding the meaning of a dream. - Thus, I dreamt on one occasion that I was sitting on a bench with one of my former University teachers, and that the bench, which was surrounded by other benches, was moving forward at a rapid pace. This was a combination of a lecture theatre and a trottoir roulant.¹ I will not pursue this train of ideas further. - Another time I was sitting in a railway carriage and holding on my lap an object in the shape of a top-hat ['Zylinderhut', literally 'cylinder-hat'], which however was made of transparent glass. The situation made me think at once of the proverb: 'Mit dem Hute in der Hand kommt man durchs ganze land.'² The glass cylinder led me by a short détour to think of an incandescent gas-mantle; and I soon saw that I should like to make a discovery which would make me as rich and independent as my fellow-countryman Dr. Auer von Welsbach was made by his, and that I should like to travel instead of stopping in Vienna. In the dream I was travelling with my discovery, the hat in the shape of a glass cylinder - a discovery which, it is true, was not as yet of any great practical use. - The dream-work is particularly fond of representing two contrary ideas by the same composite structure. Thus, for instance, a woman had a dream in which she saw herself carrying a tall spray of flowers, such as the angel is represented as holding in pictures of the Annunciation. (This stood for innocence; incidentally, her own name was Maria.) On the other hand, the spray was covered with large white flowers like camellias. (This stood for the opposite of innocence; it was associated with La dame aux camélias.)

A good proportion of what we have learnt about condensation in dreams may be summarized in this formula: each element in the content of a dream is 'overdetermined' by material in the dream-thoughts; it is not derived from a single element in the dream-thoughts, but may be traced back to a whole number. These elements need not necessarily be closely related to each other in the dream-thoughts themselves; they may belong to the most widely separated regions of the fabric of those thoughts. A dream-element is, in the strictest sense of the word, the 'representative' of all this disparate material in the content of the dream. But analysis reveals yet another side of the complicated relation between the content of the dream and the dream-thoughts. Just as connections lead from each element of the dream to several dream-thoughts, so as a rule a single dream-thought is represented by more than one dream-element; the threads of association do not simply converge from the dream-thoughts to the dream-content, they cross and interweave with each other many times over in the course of their journey.
Condensation, together with the transformation of thoughts into situations (‘dramatization’), is the most important and peculiar characteristic of the dream-work. So far, however, nothing has transpired as to any motive necessitating this compression of the material.

[1901a, 1069]

In the case of the complicated and confused dreams with which we are now concerned, condensation and dramatization alone are not enough to account for the whole of the impression that we gain of the dissimilarity between the content of the dream and the dream-thoughts. We have evidence of the operation of a third factor, and this evidence deserves careful sifting.

[1901a, 1070]

I cannot leave the subject of dream-displacement without drawing attention to a remarkable process which occurs in the formation of dreams and in which condensation and displacement combine to produce the result. In considering condensation we have already seen the way in which two ideas in the dream-thoughts which have something in common, some point of contact, are replaced in the dream-content by a composite idea, in which a relatively distinct nucleus represents what they have in common, while indistinct subordinate details correspond to the respects in which they differ from each other. If displacement takes place in addition to condensation, what is constructed is not a composite idea but an ‘intermediate common entity’, which stands in a relation to the two different elements similar to that in which the resultant in a parallelogram of forces stands to its components. For instance, in the content of one of my dreams there was a question of an injection with propyl. To begin with, the analysis only led me to an indifferent experience which had acted as dream-instigator, and in which a part was played by amyl. I was not yet able to justify the confusion between amyl and propyl. In the group of ideas behind this same dream, however, there was also a recollection of my first visit to Munich, where I had been struck by the Propylaea. The details of the analysis made it plausible to suppose that it was the influence of this second group of ideas upon the first one that was responsible for the displacement from amyl to propyl. Propyl is as it were an intermediate idea between amyl and Propylaea, and found its way into the content of the dream as a kind of compromise, by means of simultaneous condensation and displacement.

[1901a, 1073]

There is a still more urgent necessity in the case of the process of displacement than in that of condensation to discover the motive for these puzzling efforts on the part of the dream-work.

[1901a, 1073]

The dream-thoughts which we arrive at by means of analysis reveal themselves as a psychical complex of the most intricate possible structure. Its portions stand in the most manifold logical relations to one another: they represent foreground and background, conditions, digressions and illustrations, chains of evidence and counter-arguments. Each train of thought is almost invariably accompanied by its contradictory counterpart. This material lacks none of the characteristics that are familiar to us from our waking thinking. If now all of this is to be turned into a dream, the psychical material will be submitted to a pressure which will condense it greatly, to an internal fragmentation and displacement which will, as it were, create new surfaces, and to a selective operation in favour of those portions of it which are the most appropriate for the construction of situations. If we take into account the genesis of the material, a process of this sort deserves to be described as a ‘regression.’ In the course of this transformation, however, the logical links which have hitherto held the psychical material together are lost. It is only, as it were, the substantive content of the dream-thoughts that the dream-work takes over and manipulates. The restoration of the connections which the dream-work has destroyed is a task which has to be performed by the work of analysis.

[1901a, 1075]
One and one only of these logical relations— that of similarity, consonance, the possession of common attributes—is very highly favoured by the mechanism of dream-formation. The dream-work makes use of such cases as a foundation for dream-condensation, by bringing together everything that shows an agreement of this kind into a new unity.

[1901a, 1077]

Having been made acquainted with the dream-work by the foregoing discussion, we shall no doubt be inclined to pronounce it a quite peculiar psychical process, the like of which, so far as we are aware, does not exist elsewhere. It is as though we were carrying over on to the dream-work all the astonishment which used formerly to be aroused in us by its product, the dream. In fact, however, the dream-work is only the first to be discovered of a whole series of psychical processes, responsible for of hysterical symptoms, of phobias, obsessions and delusions. Condensation and, above all, displacement are invariable characteristics of these other processes as well. Modification into a pictorial form, on the other hand, remains a peculiarity of the dream-work. If this explanation places dreams in a single series alongside the structures produced by psychical illness, this makes it all the more important for us to discover the essential determining conditions of such processes as those of dream-formation. We shall probably be surprised to hear that neither the state of sleep nor illness is among these indispensable conditions. A whole number of the phenomena of the everyday life of healthy people—such as forgetting, slips of the tongue, bungled actions and a particular class of errors—owe their origin to a psychical mechanism analogous to that of dreams and of the other members of the series.

[1901a, 1084]

Hitherto philosophers have had no occasion to concern themselves with a psychology of repression. We may therefore be permitted to make a first approach to this hitherto unknown topic by constructing a pictorial image of the course of events in dream-formation. It is true that the schematic picture we have arrived at—not only from the study of dreams—is a fairly complicated one; but we cannot manage with anything simpler. Our hypothesis is that in our mental apparatus there are two thought-constructing agencies, of which the second enjoys the privilege of having free access to consciousness for its products whereas the activity of the first is in itself unconscious and can only reach consciousness by way of the second. On the frontier between the two agencies, where the first passes over to the second, there is a censorship, which only allows what is agreeable to it to pass through and holds back everything else. According to our definition, then, what is rejected by the censorship is in a state of repression. Under certain conditions, of which the state of sleep is one, the relation between the strength of the two agencies is modified in such a way that what is repressed can no longer be held back. In the state of sleep this probably occurs owing to a relaxation of the censorship; when this happens it becomes possible for what has hitherto been repressed to make a path for itself to consciousness. Since, however, the censorship is never completely eliminated but merely reduced, the repressed material must submit to certain alterations which mitigate its offensive features. What becomes conscious in such cases is a compromise between the intentions of one agency and the demands of the other. Repression - relaxation of the censorship - the formation of a compromise, this is the fundamental pattern for the generation not only of dreams but of many other psychopathological structures; and in the latter cases too we may observe that the formation of compromises is accompanied by processes of condensation and displacement and by the employment of superficial associations, which we have become familiar with in the dream-work.

[1901a, 1089]
Now in my *Interpretation of Dreams* (1900a) I have demonstrated the part played by the work of *condensation* in forming what is called the manifest dream-content out of the latent dream-thoughts. A similarity of any sort between two elements of the unconscious material - a similarity between the things themselves or between their verbal presentations - is taken as an opportunity for creating a third, which is a composite or compromise idea. In the dream-content this third element represents both its components; and it is as a consequence of its originating in this way that it so frequently has various contradictory characteristics. The formation of substitutions and contaminations which occurs in slips of the tongue is accordingly a beginning of the work of condensation which we find taking a most vigorous share in the construction of dreams.

[1901b, 1149]

A comparative examination of my examples of misreading and slips of the pen leads to the same conclusions. As with slips of the tongue, certain cases appear to owe their origin to a work of condensation which has no further motivation (e.g. the ‘Apfe’). It would however be satisfactory to learn whether special conditions may not have to be fulfilled if such a condensation, which is normal in dream-work but a fault in our waking thought, is to take place. No information on this problem can be obtained from the examples themselves. I should however refuse to conclude from this that there are in fact no conditions other than, for instance, a relaxation of conscious attention, since I know from other sources that it is precisely automatic activities which are characterized by correctness and reliability. I should prefer to stress the fact that here, as so often in biology, normal circumstances or those approaching the normal are less favourable subjects for investigation than pathological ones. I expect that what remains obscure in the elucidation of these very slight disturbances will be illuminated by the explanation of serious disturbances.

[1901b, 1342]

(G) A few words should be said to indicate at least in what direction this wider context lies. The mechanism of parapraxes and chance actions, as we have come to know it by our employment of analysis, can be seen to correspond in its most essential points with the mechanism of dream-formation which I have discussed in the chapter on the ‘dream-work’ in my *Interpretation of Dreams*. In both cases we find condensations and compromise-formations (contaminations). We have the same situation: by unfamiliar paths, and by the way of external associations, unconscious thoughts find expression as modifications of other thoughts. The incongruities, absurdities and errors of the dream-content, which result in the dream being scarcely recognized as the product of psychical activity, originate in the same way, though it is true with a freer use of the means at hand, as our common mistakes in everyday life. In both cases the appearance of an incorrect function is explained by the peculiar mutual interference between two or several correct functions.

[1901b, 1346]

‘Mother's jewel-case’ was therefore introduced in two places in the dream; and this element replaced all mention of Dora's infantile jealousy, of the drops (that is, of the sexual wetness), of being dirtied by the discharge, and, on the other hand, of her present thoughts connected with the temptation - the thoughts which were urging her to reciprocate the man's love, and which depicted the sexual situation (alike desirable and menacing) that lay before her. The element of 'jewel-case' was more than any other a product of condensation and displacement, and a compromise between contrary mental currents. The multiplicity of its origin - both from infantile and contemporary sources - is no doubt pointed to by its double appearance in the content of the dream.

[1905e, 1427]
Are processes similar to those which we have described here as the technique of jokes known already in any other field of mental events? They are - in a single field, and an apparently very remote one. In 1900 I published a book which, as its title (The Interpretation of Dreams) indicates, attempted to throw light on what is puzzling in dreams and to establish them as derivatives of our normal mental functioning. I found occasion there to contrast the manifest, and often strange, content of the dream with the latent, but perfectly logical, dream-thoughts from which the dream is derived; and I entered into an investigation of the processes which make the dream out of the latent dream-thoughts, as well as of the psychical forces which are involved in that transformation. To the totality of these transforming processes I gave the name of the 'dream-work'; and I have described as a part of this dream-work a process of condensation which shows the greatest similarity to the one found in the technique of jokes - which, like it, leads to abbreviation, and creates substitute-formations of the same character. Everyone will be familiar, from a recollection of his own dreams, with the composite structures both of people and of things which emerge in dreams. Indeed, dreams even construct them out of words, and they can then be dissected in analysis. (For instance, 'Autodidasker' = 'Autodidakt' + 'Lasker'.) On other occasions - much more often, in fact - what the work of condensation in dreams produces is not composite structures but pictures which exactly resemble one thing or one person except for an addition or alteration derived from another source - modifications, that is, just like those in Herr N.'s jokes. We cannot doubt that in both cases we are faced by the same psychical process, which we may recognize from its identical results. Such a far-reaching analogy between the technique of jokes and the dream-work will undoubtedly increase our interest in the former and raise an expectation in us that a comparison between jokes and dreams may help to throw light on jokes. But we will refrain from entering upon this task, for we must reflect that so far we have investigated the technique of only a very small number of jokes, so that we cannot tell whether the analogy by which we are proposing to be guided will in fact hold good. We will therefore turn away from the comparison with dreams and go back to the technique of jokes, though at this point we shall, as it were, be leaving a loose end to our enquiry, which at some later stage we may perhaps pick up once more.

[1905c, 1634]
The dream-work, then - to which I return after this digression - submits the thought-material, which is brought forward in the optative mood, to a most strange revision. First, it takes the step from the optative to the present indicative; it replaces 'Oh! if only . . .' by 'It is'. The 'It is' is then given a hallucinatory representation; and this I have called the 'regression' in the dream-work - the path that leads from thoughts to perceptual images, or, to use the terminology of the still unknown topography of the mental apparatus (which is not to be taken anatomically), from the region of thought-structures to that of sensory perceptions. On this path, which is in the reverse direction to that taken by the course of development of mental complications, the dream-thoughts are given a pictorial character; and eventually a plastic situation is arrived at which is the core of the manifest 'dream-picture'. In order for it to be possible for the dream-thoughts to be represented in sensory form, their expression has to undergo far-reaching modifications. But while the thoughts are being changed back into sensory images still further alterations occur in them, some of which can be seen to be necessary while others are surprising. We can understand that, as a subsidiary result of regression, almost all the internal relations between the thoughts which linked them together will be lost in the manifest dream. The dream-work, as we might say, only undertakes to represent the raw material of the ideas and not the logical relations in which they stand to one another; or at all events it reserves the liberty to disregard the latter. On the other hand, there is another part of the dream-work which we cannot attribute to regression, to the change back into sensory images; and it is precisely this part which has an important bearing on our analogy with the formation of jokes. In the course of the dream-work the material of the dream-thoughts is subjected to a quite extraordinary compression or condensation. A starting point for it is provided by any common elements that may be present in the dream-thoughts, whether by chance or from the nature of their content. Since these are not as a rule sufficient for any considerable condensation, new artificial and transient common elements are created in the dream-work, and to this end there is actually a preference for the use of words the sound of which expresses different meanings. The newly-created common elements of condensation enter the manifest content of the dream as representatives of the dream-thoughts, so that an element in the dream corresponds to a nodal point or junction in the dream-thoughts, and, as compared with these latter, must quite generally be described as 'overdetermined'. The fact of condensation is the piece of the dream-work which can be most easily recognized; it is only necessary to compare the text of a dream as it is noted down with the record of the dream-thoughts arrived at by analysis in order to get a good impression of the extensiveness of dream-condensation.

[1905c, 1748]
There is a rule in interpreting dreams which runs as follows: 'A speech heard in a dream is always derived from one that has been heard or made by the dreamer in waking life.' This rule seems to have been observed here: Gradiva's speech is only a modification of the old zoologist's speech which Hanold had heard the day before. Another rule in dream-interpretation would tell us that when one person is replaced by another or when two people are mixed up together (for instance, by one of them being shown in a situation that is characteristic of the other), it means that the two people are being equated, that there is a similarity between them. If we venture to apply this rule too to our dream, we should arrive at this translation: 'Gradiva catches lizards just like the old man; she is skilled in lizard-catching just as he is.' This result cannot exactly be said to be intelligible as yet; but we have yet another puzzle to solve. To what impression of the previous day are we to relate the 'lady colleague' who in the dream replaces the famous zoologist Eimer? Fortunately we have very little choice here. A 'lady colleague' can only mean another girl - that is to say, represents/represented the sympathetic young lady whom Hanold had taken for a sister travelling with her brother. 'She was wearing a red Sorrento rose in her dress, the sight of which reminded him of something as he looked across from his corner of the dining-room, but he could not think what.' This remark of the author's gives us a right to regard her as the 'lady colleague' in the dream. What Hanold could not recall were, it cannot be doubted, the words spoken by the supposed Gradiva, who had told him, as she asked him for the white flowers of the dead, that in the spring people give happier girls roses. But behind those words there had lain a hint of wooing. So what sort of lizard-catching was it that the happier 'lady colleague' had carried out so successfully?
[1907a, 1868]

The replacement of the lizard-catcher by Gradiva in the content of the dream is accordingly a representation of the relation between the two figures which was known to Hanold in his unconscious; the introduction of the 'lady colleague' instead of 'our colleague Eimer' allowed the dream to express Hanold's realization that she was wooing a man. So far the dream welded together ('condensed', as we say) two experiences of the previous day into one situation, in order to bring to expression (in a very obscure way, it is true) two discoveries which were not allotted to become conscious. But we can go further, we can diminish the strangeness of the dream still more and we can demonstrate the influence of his other experiences of the previous day on the form taken by the manifest dream.
[1907a, 1870]

You can also obtain a view, by a kind of synthetic work, of the process which has brought about the distortion of the unconscious dream-thoughts into the manifest content of the dream. We call this process the 'dream-work'. It deserves our closest theoretical interest, since we are able to study in it, as nowhere else, what unsuspected psychical processes can occur in the unconscious, or rather, to put it more accurately, between two separate psychical systems like the conscious and unconscious. Among these freshly discovered psychical processes those of condensation and displacement are especially noticeable. The dream-work is a special case of the effects produced by two different mental groupings on each other - that is, of the consequences of mental splitting; and it seems identical in all essentials with the process of distortion which transforms the repressed complexes into symptoms where there is unsuccessful repression.
[1910a, 2223]
'The way in which dreams treat the category of contraries and contradictories is highly remarkable. It is simply disregarded. "No" seems not to exist so far as dreams are concerned. They show a particular preference for combining contraries into a unity or for representing them as one and the same thing. Dreams feel themselves at liberty, moreover, to represent any element by its wishful contrary; so that there is no way of deciding at a first glance whether any element that admits of a contrary is present in the dream-thoughts as a positive or as a negative.'¹

[1910e, 2318]

I have said that animism is a system of thought, the first complete theory of the universe, and I shall now go on to draw certain conclusions from the psycho-analytic view of such systems. Every day of our lives our experience is in a position to show us the principal characteristics of a 'system'. We have dreams during the night and we have learnt how to interpret them during the day. Dreams may, without contradicting their nature, appear confused and disconnected. But they may, on the contrary, simulate the orderly impressions of a real experience, they may make one event follow from another and make one portion of their content refer to another. Such a result can be more or less successfully achieved; but it scarcely ever succeeds so completely as to leave no absurdity, no rift in its texture, visible. When we come to submit a dream to interpretation, we find that the erratic and irregular arrangement of its constituent parts is quite unimportant from the point of view of our understanding it. The essential elements in a dream are the dream-thoughts, and these have meaning, connection and order. But their order is quite other than that remembered by us as present in the manifest dream. In the latter the connection between the dream-thoughts has been abandoned and may either remain completely lost or be replaced by the new connection exhibited in the manifest content. The elements of the dream, apart from their being condensed, are almost invariably arranged in a new order more or less independent of their earlier arrangement. Finally, it must be added that whatever the original material of the dream-thoughts has been turned into by the dream-work is then subjected to a further influence. This is what is known as 'secondary revision', and its purpose is evidently to get rid of the disconnectedness and unintelligibility produced by the dream-work and replace it by a new 'meaning'. But this new meaning, arrived at by secondary revision, is no longer the meaning of the dream-thoughts.

[1912-1913, 2737]

Among the most surprising findings is the way in which the dream-work treats contraries that occur in the latent dream. We know already that conformities in the latent material are replaced by condensations in the manifest dream. Well, contraries are treated in the same way as conformities, and there is a special preference for expressing them by the same manifest element. Thus an element in the manifest dream which is capable of having a contrary may equally well be expressing either itself or its contrary or both together: only the sense can decide which translation is to be chosen. This connects with the further fact that a representation of 'no' - or at any rate an unambiguous one - is not to be found in dreams.

[1916-1917, 3269]
You may have formed an impression that, even though the technique is correctly carried out, the findings of our interpretative work on dreams admit of so many uncertainties as to defeat any secure translation of the manifest dream into the latent dream-thoughts. You will argue in support of this that in the first place one never knows whether a particular element of the dream is to be understood in its actual sense or as a symbol, since the things employed as symbols do not cease on that account to be themselves. If, however, one has no objective clue for deciding this, the interpretation must at that point be left to the arbitrary choice of the interpreter. Furthermore, as a result of the fact that in the dream-work contraries coalesce, it is always left undetermined whether a particular element is to be understood in a positive or negative sense - as itself or as its contrary. Here is a fresh opportunity for the interpreter to exercise an arbitrary choice. Thirdly, in consequence of the reversals of every kind of which dreams are so fond, it is open to the interpreter to carry out a reversal like this in connection with any passage in the dream he chooses. And lastly, you will mention having heard that one is never certain whether the interpretation one has found for a dream is the only possible one. We run the risk of overlooking a perfectly admissible 'over-interpretation' of the same dream. In these circumstances, you will conclude, so much room is left to the interpreter's arbitrary decision as to be incompatible with objective certainty in the findings. Or alternatively you may suppose that the fault does not lie with dreams but that the inadequacies of our dream-interpretation are to be attributed to errors in our views and premisses.

Let us recall that we have said that the dream-work makes a translation of the dream-thoughts into a primitive mode of expression similar to picture-writing. All such primitive systems of expression, however, are characterized by indefiniteness and ambiguity of this sort, without justifying us in casting doubts on their serviceability. The coalescence of contraries in the dream-work is, as you know, analogous to the so-called 'antithetical meaning of primal words' in the most ancient languages. Indeed, Abel (1884), the philologist to whom we owe this line of thought, implores us not to suppose that communications made by one person to another with the help of such ambivalent words were on that account ambiguous. On the contrary, intonation and gesture must have made it quite certain in the context of the speech which of the two contraries the speaker intended to convey. In writing, where gesture is absent, its place was taken by an additional pictograph which was not intended to be spoken - for instance by a picture of a little man, limply squatting or stiffly erect, according to whether the ambiguous hieroglyph 'ken' was to mean 'weak' or 'strong'. In this way, in spite of the ambiguity of the sounds and signs, misunderstanding was avoided.
Perhaps you recognize, moreover, what it is that supports our hypotheses of the two systems, and their relation to each other and to consciousness? After all, the watchman between the unconscious and the preconscious is nothing else than the censorship, to which, as we found, the form taken by the manifest dream is subject. The day's residues, which we recognized as the instigators of the dream, were preconscious material which, at night-time and in the state of sleep, had been under the influence of unconscious and repressed wishful impulses; they had been able, in combination with those impulses and thanks to their energy, to construct the latent dream. Under the dominance of the unconscious system this material had been worked over (by condensation and displacement) in a manner which is unknown or only exceptionally permissible in normal mental life - that is, in the preconscious system. We came to regard this difference in their manner of operating as what characterizes the two systems; the relation which the preconscious has to consciousness was regarded by us merely as an indication of its belonging to one of the two systems. Dreams are not pathological phenomena; they can appear in any healthy person under the conditions of a state of sleep. Our hypothesis about the structure of the mental apparatus, which allows us to understand the formation alike of dreams and of neurotic symptoms, has an incontrovertible claim to being taken into account in regard to normal mental life as well.

[1916-1917, 3370]

I am hoping that you will grant this, but that you will raise the objection that there are, nevertheless, other telepathic dreams in which there is no difference between the event and the dream, and in which there is nothing else to be found but an undistorted reproduction of the event. I have no knowledge of such dreams from my own experience, but I know they have often been reported. If we assume that we have such an undisguised and unadulterated telepathic dream to deal with, another question arises. Ought we to call such a telepathic experience a 'dream' at all? You will certainly do so as long as you keep to popular usage, in which everything that takes place in mental life during sleep is called a dream. You, too, perhaps say, 'I tossed about in my dream', and still less are you conscious of anything incorrect when you say, 'I shed tears in my dream' or 'I felt apprehensive in my dream'. But you will no doubt notice that in all these cases you are using 'dream' and 'sleep' and 'state of being asleep' interchangeably, as if there were no distinction between them. I think it would be in the interests of scientific accuracy to keep 'dream' and 'state of sleep' more distinctly separate. Why should we provide a counterpart to the confusion evoked by Maeder who, by refusing to distinguish between the dream-work and the latent dream-thoughts, has discovered a new function for dreams? Supposing, then, that we are brought face to face with a pure telepathic 'dream', let us rather call it instead a telepathic experience in a state of sleep. A dream without condensation, distortion, dramatization, above all, without wish-fulfilment, surely does not deserve the name. You will remind me that, if so, there are other mental products in sleep to which the right to be called 'dreams' would have to be refused. Actual experiences of the day are sometimes simply repeated in sleep; reproductions of traumatic scenes in 'dreams' have led us only lately to revise the theory of dreams. There are dreams which are to be distinguished from the usual type by certain special qualities, which are, properly speaking, nothing but night-phantasies, not having undergone additions or alterations of any kind and being in all other ways similar to the familiar day-dreams. It would be awkward, no doubt, to exclude these structures from the domain of 'dreams'. But still they all come from within, are products of our mental life, whereas the very conception of the purely 'telepathic dream' lies in its being a perception of something external, in relation to which the mind remains passive and receptive.

[1922a, 3887]
We also describe the latent dream-thoughts, on account of their connection with waking life, as 'residues of the day'. By the operation of the dream-work (to which it would be quite incorrect to ascribe any 'creative' character) the latent dream thoughts are condensed in a remarkable way, are distorted by the displacement of psychical intensities and are arranged with a view to being represented in visual pictures; and, besides all this, before the manifest dream is arrived at, they are submitted to a process of secondary revision which seeks to give the new product something in the nature of sense and coherence. Strictly speaking, this last process does not form a part of the dream-work.

[1923a, 3918]

I was able to show from a short story by W. Jensen called Gradiva, which has no particular merit in itself, that invented dreams can be interpreted in the same way as real ones and that the unconscious mechanisms familiar to us in the 'dream-work' are thus also operative in the processes of imaginative writing. My book on Jokes and their Relation to the Unconscious was a side-issue directly derived from The Interpretation of Dreams. The only friend of mine who was at that time interested in my work remarked to me that my interpretations of dreams often impressed him as being like jokes. In order to throw some light on this impression, I began to investigate jokes and found that their essence lay in the technical methods employed in them, and that these were the same as the means used in the 'dream-work' - that is to say, condensation, displacement, the representation of a thing by its opposite or by something very small, and so on. This led to an economic enquiry into the origin of the high degree of pleasure obtained from hearing a joke. And to this the answer was that it was due to the momentary suspension of the expenditure of energy upon maintaining repression, owing to the attraction exercised by the offer of a bonus of pleasure (fore-pleasure).

[1925d, 4239]

But other changes made in the elements of the dream-thoughts go far beyond this. Such of those elements as allow any point of contact to be found between them are condensed into new unities. In the process of transforming the thoughts into pictures, preference is unmistakably given to such as permit of this putting-together, this condensation; it is as though a force were at work which was subjecting the material to compression and concentration. As a result of condensation, one element in the manifest dream may correspond to numerous elements in the latent dream-thoughts; but, conversely too, one element in the dream-thoughts may be represented by several images in the dream.

[1933a, 4633]
The laws that govern the passage of events in the unconscious, which come to light in this manner, are remarkable enough and suffice to explain most of what seems strange to us about dreams. Above all there is a striking tendency to condensation, an inclination to form fresh unities out of elements which in our waking thought we should certainly have kept separate. As a consequence of this, a single element of the manifest dream often stands for a whole number of latent dream-thoughts as though it were a combined allusion to all of them; and in general the compass of the manifest dream is extraordinarily small in comparison with the wealth of material from which it has sprung. Another peculiarity of the dream-work, not entirely independent of the former one, is the ease with which psychical intensities (cathexes) are displaced from one element to another, so that it often happens that an element which was of little importance in the dream-thoughts appears as the clearest and accordingly most important feature of the manifest dream, and, vice versa, that essential elements of the dream-thoughts are represented in the manifest dream only by slight allusions. Moreover, as a rule the existence of quite insignificant points in common between two elements is enough to allow the dream-work to replace one by the other in all further operations. It will easily be imagined how greatly these mechanisms of condensation and displacement can increase the difficulty of interpreting a dream and of revealing the relations between the manifest dream and the latent dream-thoughts. From the evidence of the existence of these two tendencies to condensation and displacement our theory infers that in the unconscious id the energy is in a freely mobile state and that the id sets more store by the possibility of discharging quantities of excitation than by any other consideration;¹ and our theory makes use of these two peculiarities in defining the character of the primary process we have attributed to the id.

[1940a [1938], 4978]
The work of condensation in dreams is seen at its clearest when it handles words and names. It is true in general that words are frequently treated in dreams as though they were things, and for that reason they are apt to be combined in just the same way as are presentations of things. Dreams of this sort offer the most amusing and curious neologisms.

The verbal malformations in dreams greatly resemble those which are familiar in paranoia but which are also present in hysteria and obsessions. The linguistic tricks performed by children, who sometimes actually treat words as though they were objects and moreover invent new languages and artificial syntactic forms, are the common source of these things in dreams and psychoneuroses alike.

The analysis of the nonsensical verbal forms that occur in dreams is particularly well calculated to exhibit the dream work's achievements in the way of condensation. The reader should not conclude from the paucity of the instances which I have given that material of this kind is rare or observed at all exceptionally. On the contrary, it is very common. But as a result of the fact that dream-interpretation is dependent upon psycho-analytic treatment, only a very small number of instances are observed and recorded and the analyses of such instances are as a rule only intelligible to experts in the pathology of the neuroses. Thus a dream of this kind was reported by Dr. von Karpinska (1914) containing the nonsensical verbal form: "Svingnum elvi." It is also worth mentioning those cases in which a word appears in a dream which is not in itself meaningless but which has lost its proper meaning and combines a number of other meanings to which it is related in just the same way as a 'meaningless' word would be. This is what occurred, for instance, in the ten-year-old boy's dream of a 'category' which was recorded by Tausk (1913). 'Category' in that case meant 'female genitals', and to 'categorate' meant the same as 'to micturate.'

If a common element of this kind between the dream-thoughts is not present, the dream-work sets about creating one, so that it may be possible for the thoughts to be given a common representation in the dream. The most convenient way of bringing together two dream-thoughts which, to start with, have nothing in common, is to alter the verbal form of one of them, and thus bring it half-way to meet the other, which may be similarly clothed in a new form of words. A parallel process is involved in hammering out a rhyme, where a similar sound has to be sought for in the same way as a common element is in our present case. A large part of the dream-work consists in the creation of intermediate thoughts of this kind which are often highly ingenious, though they frequently appear far-fetched; these then form a link between the composite picture in the manifest content of the dream and the dream-thoughts, which are themselves diverse both in form and essence and have been determined by the exciting factors of the dream. The analysis of our sample dream affords us an instance of this kind in which a thought has been given a new form in order to bring it into contact with another which is essentially foreign to it. In carrying out the analysis I came upon the following thought: 'I should like to get something sometimes without paying for it.' But in that form the thought could not be employed in the dream-content. It was therefore given a fresh form: 'I should like to get some enjoyment without cost ['Kosten']." Now the word 'Kosten' in its second sense fits into the 'table d'hôte' circle of ideas, and could thus be represented in the 'spinach' which was served in the dream. When a dish appears at our table and the children refuse it, their mother begins by trying persuasion, and urges them 'just to taste [kosten] a bit of it'. It may seem strange that the dream-work should make such free use of verbal ambiguity, but further experience will teach us that the occurrence is quite a common one.
Are processes similar to those which we have described here as the technique of jokes known already in any other field of mental events? They are - in a single field, and an apparently very remote one. In 1900 I published a book which, as its title (The Interpretation of Dreams) indicates, attempted to throw light on what is puzzling in dreams and to establish them as derivatives of our normal mental functioning. I found occasion there to contrast the manifest, and often strange, content of the dream with the latent, but perfectly logical, dream-thoughts from which the dream is derived; and I entered into an investigation of the processes which make the dream out of the latent dream-thoughts, as well as of the psychical forces which are involved in that transformation. To the totality of these transforming processes I gave the name of the 'dream-work'; and I have described as a part of this dream-work a process of condensation which shows the greatest similarity to the one found in the technique of jokes - which, like it, leads to abbreviation, and creates substitute-formations of the same character. Everyone will be familiar, from a recollection of his own dreams, with the composite structures both of people and of things which emerge in dreams. Indeed, dreams even construct them out of words, and they can then be dissected in analysis. (For instance, 'Autodidasker' = 'Autodidakt' + 'Lasker'.) On other occasions - much more often, in fact - what the work of condensation in dreams produces is not composite structures but pictures which exactly resemble one thing or one person except for an addition or alteration derived from another source - modifications, that is, just like those in Herr N.'s jokes. We cannot doubt that in both cases we are faced by the same psychical process, which we may recognize from its identical results. Such a far-reaching analogy between the technique of jokes and the dream-work will undoubtedly increase our interest in the former and raise an expectation in us that a comparison between jokes and dreams may help to throw light on jokes. But we will refrain from entering upon this task, for we must reflect that so far we have investigated the technique of only a very small number of jokes, so that we cannot tell whether the analogy by which we are proposing to be guided will in fact hold good. We will therefore turn away from the comparison with dreams and go back to the technique of jokes, though at this point we shall, as it were, be leaving a loose end to our enquiry, which at some later stage we may perhaps pick up once more.

[1905c, 1634]

Now it is in this respect that the essential difference between the dream-work and schizophrenia becomes clear. In the latter, what becomes the subject of modification by the primary process are the words themselves in which the preconscious thought was expressed; in dreams, what are subject to this modification are not the words, but the thing-presentations to which the words have been taken back. In dreams there is a topographical regression; in schizophrenia there is not. In dreams there is free communication between (Pcs.) word-cathexes and (Ucs.) thing-cathexes, while it is characteristic of schizophrenia that this communication is cut off. The impression this difference makes on one is lessened precisely by the dream-interpretations we carry out in psycho-analytic practice. For, owing to the fact that dream-interpretation traces the course taken by the dream-work, follows the paths which lead from the latent thoughts to the dream-elements, reveals the way in which verbal ambiguities have been exploited, and points out the verbal bridges between different groups of material - owing to all this, we get an impression now of a joke, now of schizophrenia, and are apt to forget that for a dream all operations with words are no more than a preparation for a regression to things.

[1917d, 3034]
A psychological process by which, according to our account, indifferent experiences take the place of psychically significant ones, cannot fail to arouse suspicion and bewilderment. It will be our task in a later chapter to make the peculiarities of this apparently irrational operation more intelligible. At this point we are only concerned with the effects of a process whose reality I have been driven to assume by innumerable and regularly recurrent observations made in analysing dreams. What takes place would seem to be something in the nature of a ‘displacement’ - of psychical emphasis, shall we say? - by means of intermediate links; in this way, ideas which originally had only a weak charge of intensity take over the charge from ideas which were originally intensely cathected and at last attain enough strength to enable them to force an entry into consciousness. Displacements of this kind are no surprise to us where it is a question of dealing with quantities of affect or with motor activities in general. When a lonely old maid transfers her affection to animals, or a bachelor becomes an enthusiastic collector, when a soldier defends a scrap of coloured cloth - a flag - with his life's blood, when a few seconds’ extra pressure in a hand-shake means bliss to a lover, or when, in Othello, a lost handkerchief precipitates an outburst of rage - all of these are instances of psychical displacements to which we raise no objection. But when we hear that a decision as to what shall reach our consciousness and what shall be kept out of it - what we shall think, in short - has been arrived at in the same manner and on the same principles, we have an impression of a pathological event and, if such things happen in waking life, we describe them as errors in thought. I will anticipate the conclusions to which we shall later be led, and suggest that the psychical process which we have found at work in dream-displacement, though it cannot be described as a pathological disturbance, nevertheless differs from the normal and is to be regarded as a process of a more primary nature.

Thus the fact that the content of dreams includes remnants of trivial experiences is to be explained as a manifestation of dream-distortion (by displacement); and it will be recalled that we came to the conclusion that dream-distortion was the product of a censorship operating in the passage-way between two psychical agencies. It is to be expected that the analysis of a dream will regularly reveal its true, psychically significant source in waking life, though the emphasis has been displaced from the recollection of that source on to that of an indifferent one. This explanation brings us into complete conflict with Robert’s theory, which ceases to be of any service to us. For the fact which Robert sets out to explain is a non-existent one. His acceptance of it rests on a misunderstanding, on his failure to replace the apparent content of dreams by their real meaning. And there is another objection that can be raised to Robert’s theory. If it were really the business of dreams to relieve our memory of the ‘dregs’ of daytime recollections by a special psychical activity, our sleep would be more tormented and harder worked than our mental life while we are awake. For the number of indifferent impressions from which our memory would need to be protected is clearly immensely large: the night would not be long enough to cope with such a mass. It is far more likely that the process of forgetting indifferent impressions goes forward without the active intervention of our psychical forces.
It will be seen that in interpreting dreams we find one condition always fulfilled: one component of the content of the dream is a repetition of a recent impression of the previous day. This impression that is to be represented in the dream may either itself belong to the circle of ideas surrounding the actual instigator of the dream - whether as an essential or as a trivial portion of it - or it may be derived from the field of an indifferent impression which has been brought into connection with the ideas surrounding the dream-instigator by more or less numerous links. The apparent multiplicity of governing conditions is in fact merely dependent upon the two alternatives of whether a displacement has or has not taken place; and it is worth pointing out that we are enabled by these alternatives to explain the range of contrast between different dreams just as easily as the medical theory is enabled to do by its hypothesis of brain-cells ranging from partial to total wakefulness. (See above, p. 583 ff.) [1900a, 667]

This objection can be completely dealt with by a reference to the findings of the psycho-analysis of neurotics. The explanation is that the displacement which replaces psychically important by indifferent material (alike in dreaming and in thinking) has in these cases already taken place at the early period of life in question and since then become fixed in the memory. These particular elements which were originally indifferent are indifferent no longer, since taking over (by means of displacement) the value of psychically significant material. Nothing that has really remained indifferent can be reproduced in a dream. [1900a, 669]

When anything in a dream has the character of direct speech, that is to say, when it is said or heard and not merely thought (and it is easy as a rule to make the distinction with certainty), then it is derived from something actually spoken in waking life - though, to be sure, this something is merely treated as raw material and may be cut up and slightly altered and, more especially, divorced from its context.¹ In carrying out an interpretation, one method is to start from spoken phrases of this kind. What, then, was the origin of the butcher's remark 'That's not obtainable any longer'? The answer was that it came from me myself. A few days earlier I had explained to the patient that the earliest experiences of childhood were 'not obtainable any longer as such', but were replaced in analysis by 'transferences' and dreams. So I was the butcher and she was rejecting these transferences into the present of old habits of thinking and feeling. -What, again, was the origin of her own remark in the dream 'I don't recognize that; I won't take it'? For the purposes of the analysis this had to be divided up. 'I don't recognize that' was something she had said the day before to her cook, with whom she had had a dispute; but at the time she had gone on: 'Behave yourself properly!' At this point there had clearly been a displacement. Of the two phrases that she had used in the dispute with her cook, she had chosen the insignificant one for inclusion in the dream. But it was only the suppressed one, 'Behave yourself properly!' that fitted in with the rest of the content of the dream: those would have been the appropriate words to use if someone had ventured to make improper suggestions and had forgotten 'to close his meat-shop'. The allusions underlying the incident with the vegetable-seller were a further confirmation that our interpretation was on the right track. A vegetable that is sold tied up in bundles (lengthways, as the patient added afterwards) and is also black, could only be a dream-combination of asparagus and black (Spanish) radishes. No knowledgeable person of either sex will ask for an interpretation of asparagus. But the other vegetable - 'Schwarzer Retting' - can be taken as an exclamation - 'Schwarzer rett dich!' -, and accordingly it too seems to hint at the same sexual topic which we suspected at the very beginning, when we felt inclined to introduce the phrase about the meat-shop being closed into the original account of the dream. We need not enquire now into the full meaning of the dream. So much is quite clear: it had a meaning and that meaning was far from innocent.² [1900a, 671]
She either failed to hear or did not understand the last word and had to get her husband to give her the necessary explanation. The verse was replaced in the content of the dream by an innocent recollection of some job she had done clumsily when she was at school, and the replacement was made possible owing to the common element of closed shutters. The connection between the topics of masturbation and impotence is obvious enough. The 'Apollo' in the latent content of this dream linked it with an earlier one in which the virgin Pallas figured. Altogether far from innocent.

[1900a, 673]

All the dreams of one of my women patients were characterized by her being 'rushed': she would be in a violent rush to get somewhere in time not to miss a train, and so on. In one dream she was going to call on a woman friend; her mother told her to take a cab and not to walk; but she ran instead and kept on falling down. -The material which came up in analysis led to memories of rushing about and romping as a child. One particular dream recalled the favourite children's game of saying a sentence 'Die Kuh rannte, bies sie fiel' ['The cow ran till it fell'] so quickly that it sounds as though it were a single word - another rush in fact. All these innocent rushings-about with little girl friends were remembered because they took the place of other, less innocent ones.

[1900a, 683]

Thus the wish to sleep (which the conscious ego is concentrated upon, and which, together with the dream-censorship and the 'secondary revision' which I shall mention later, constitute the conscious ego's share in dreaming) must in every case be reckoned as one of the motives for the formation of dreams, and every successful dream is a fulfilment of that wish. We shall discuss elsewhere the relations subsisting between this universal, invariably present and unchanging wish to sleep and the other wishes, of which now one and now another is fulfilled by the content of the dream. But we have found in the wish to sleep the factor that is able to fill the gap in the theory of Strümpell and Wundt and to explain the perverse and capricious manner in which external stimuli are interpreted. The correct interpretation, which the sleeping mind is perfectly capable of making, would involve an active interest and would require that sleep should be brought to an end; for that reason, of all the possible interpretations, only those are admitted which are consistent with the absolute censorship exercised by the wish to sleep. 'It is the nightingale and not the lark.' For if it were the lark it would mean the end of the lovers' night. Among the interpretations of the stimulus which are accordingly admissible, that one is then selected which can provide the best link with the wishful impulses lurking in the mind. Thus everything is unambiguously determined and nothing is left to arbitrary decision. The misinterpretation is not an illusion but, as one might say, an evasion. Here once again, however, just as when, in obedience to the dream-censorship, a substitution is effected by displacement, we have to admit that we are faced by an act which deviates from normal psychical processes.

[1900a, 713]

Another interesting example of condensation in this dream was the mention in it of 'propyls'. What was contained in the dream-thoughts was not 'propyls' but 'amyls.' It might be supposed that a single displacement had taken place at this point in the construction of the dream. This was indeed the case. But the displacement served the purposes of condensation, as is proved by the following addition to the analysis of the dream. When I allowed my attention to dwell for a moment longer on the word 'propyls', it occurred to me that it sounded like 'Propylaea'. But there are Propylaeae not only in Athens but in Munich. A year before the dream I had gone to Munich to visit a friend who was seriously ill at the time - the same friend who was unmistakably alluded to in the dream by the word 'trimethylamin' which occurred immediately after 'propyls.'

[1900a, 767]
In making our collection of instances of condensation in dreams, the existence of another relation, probably of no less importance, had already become evident. It could be seen that the elements which stand out as the principal components of the manifest content of the dream are far from playing the same part in the dream-thoughts. And, as a corollary, the converse of this assertion can be affirmed: what is clearly the essence of the dream-thoughts need not be represented in the dream at all. The dream is, as it were, differently centred from the dream thoughts - its content has different elements as its central point. Thus in the dream of the botanical monograph, for instance, the central point of the dream-content was obviously the element 'botanical'; whereas the dream-thoughts were concerned with the complications and conflicts arising between colleagues from their professional obligations, and further with the charge that I was in the habit of sacrificing too much for the sake of my hobbies. The element 'botanical' had no place whatever in this core of the dream-thoughts, unless it was loosely connected with it by an antithesis - the fact that botany never had a place among my favourite studies. In my patient's Sappho dream the central position was occupied by climbing up and down and being up above and down below; the dream-thoughts, however, dealt with the dangers of sexual relations with people of an inferior social class. So that only a single element of the dream-thoughts seems to have found its way into the dream-content, though that element was expanded to a disproportionate extent. Similarly, in the dream of the may-beetles, the topic of which was the relations of sexuality to cruelty, it is true that the factor of cruelty emerged in the dream-content; but it did so in another connection and without any mention of sexuality, that is to say, divorced from its context and consequently transformed into something extraneous. Once again, in my dream about my uncle, the fair beard which formed its centre-point seems to have had no connection in its meaning with my ambitious wishes which, as we saw, were the core of the dream-thoughts. Dreams such as these give a justifiable impression of 'displacement.' In complete contrast to these examples, we can see that in the dream of Irma's injection the different elements were able to retain, during the process of constructing the dream, the approximate place which they occupied in the dream-thoughts. This further relation between the dream-thoughts and the dream-content, wholly variable as it is in its sense or direction, is calculated at first to create astonishment. If we are considering a psychical process in normal life and find that one out of its several component ideas has been picked out and has acquired a special degree of vividness in consciousness, we usually regard this effect as evidence that a specially high amount of psychical value - some particular degree of interest - attaches to this predominant idea. But we now discover that, in the case of the different elements of the dream-thoughts, a value of this kind does not persist or is disregarded in the process of dream-formation. There is never any doubt as to which of the elements of the dream-thoughts have the highest psychical value, we learn that by direct judgement. In the course of the formation of a dream these essential elements, charged, as they are, with intense interest, may be treated as though they were of small value, and their place may be taken in the dream by other elements, of whose small value in the dream-thoughts there can be no question. At first sight it looks as though no attention whatever is paid to the psychical intensity of the various ideas in making the choice among them for the dream, and as though the only thing considered is the greater or less degree of multiplicity of their determination. What appears in dreams, we might suppose, is not what is important in the dream-thoughts but what occurs in them several times over. But this hypothesis does not greatly assist our understanding of dream-formation, since from the nature of things it seems clear that the two factors of multiple determination and inherent psychical value must necessarily operate in the same sense. The ideas which are most important among the dream-thoughts will almost certainly be those which occur most often in them, since the different dream-thoughts will, as it were, radiate out from them. Nevertheless a dream can reject elements which are thus both highly stressed in themselves and reinforced from many directions, and can select for its content other elements which possess only the second of these attributes.

[1900a, 778]
It thus seems plausible to suppose that in the dream-work a psychical force is operating which on the one hand strips the elements which have a high psychical value of their intensity, and on the other hand, by means of overdetermination, creates from elements of low psychical value new values, which afterwards find their way into the dream-content. If that is so, a transference and displacement of psychical intensities occurs in the process of dream-formation, and it is as a result of these that the difference between the text of the dream-content and that of the dream thoughts comes about. The process which we are here presuming is nothing less than the essential portion of the dream work; and it deserves to be described as 'dream-displacement.' Dream-displacement and dream-condensation are the two governing factors to whose activity we may in essence ascribe the form assumed by dreams.

Nor do I think we shall have any difficulty in recognizing the psychical force which manifests itself in the facts of dream-displacement. The consequence of the displacement is that the dream-content no longer resembles the core of the dream-thoughts and that the dream gives no more than a distortion of the dream-wish which exists in the unconscious. But we are already familiar with dream-distortion. We traced it back to the censorship which is exercised by one psychical agency in the mind over another. Dream-displacement is one of the chief methods by which that distortion is achieved. Is fecit cui profuit. We may assume, then, that dream-displacement comes about through the influence of the same censorship - that is, the censorship of endopsychic defence.¹

The question of the interplay of these factors - of displacement, condensation and overdetermination - in the construction of dreams, and the question which is a dominant factor and which a subordinate one - all of this we shall leave aside for later investigation. But we can state provisionally a second condition which must be satisfied by those elements of the dream-thoughts which make their way into the dream: they must escape the censorship imposed by resistance. And henceforward in interpreting dreams we shall take dream-displacement into account as an undeniable fact.

In the process of transforming the latent thoughts into the manifest content of a dream we have found two factors at work: dream-condensation and dream-displacement. As we continue our investigation we shall, in addition to these, come across two further determinants which exercise an undoubted influence on the choice of the material which is to find access to the dream.

¹ [1900a, 779]

[1900a, 780]
We have been occupied so far with investigating the means by which dreams represent the relations between the dream-thoughts. In the course of this investigation, however, we have more than once touched upon the further topic of the general nature of the modifications which the material of the dream-thoughts undergoes for the purpose of the formation of a dream. We have learnt that that material, stripped to a large extent of its relations, is submitted to a process of compression, while at the same time displacements of intensity between its elements necessarily bring about a psychical transvaluation of the material. The displacements we have hitherto considered turned out to consist in the replacing of some one particular idea by another in some way closely associated with it, and they were used to facilitate condensation in so far as, by their means, instead of two elements, a single common element intermediate between them found its way into the dream. We have not yet referred to any other sort of displacement. Analyses show us, however, that another sort exists and that it reveals itself in a change in the verbal expression of the thoughts concerned. In both cases there is a displacement along a chain of associations; but a process of such a kind can occur in various psychical spheres, and the outcome of the displacement may in one case be that one element is replaced by another, while the outcome in another case may be that a single element has its verbal form replaced by another.

Previous writers have had less justification in devoting so much space to the doubt with which our judgement receives accounts of dreams. For this doubt has no intellectual warrant. There is in general no guarantee of the correctness of our memory; and yet we yield to the compulsion to attach belief to its data far more often than is objectively justified. Doubt whether a dream or certain of its details have been correctly reported is once more a derivative of the dream-censorship, of resistance to the penetration of the dream-thoughts into consciousness. This resistance has not been exhausted even by the displacements and substitutions it has brought about; it persists in the form of doubt attaching to the material which has been allowed through. We are especially inclined to misunderstand this doubt since it is careful never to attack the more intense elements of a dream but only the weak and indistinct ones. As we already know, however, a complete reversal of all psychical values takes place between the dream-thoughts and the dream. Distortion is only made possible by a withdrawal of psychical value; it habitually expresses itself by that means and is occasionally content to require nothing more. If, then, an indistinct element of a dream's content is in addition attacked by doubt, we have a sure indication that we are dealing with a comparatively direct derivative of one of the proscribed dream-thoughts. The state of things is what it was after some sweeping revolution in one of the republics of antiquity or the Renaissance. The noble and powerful families which had previously dominated the scene were sent into exile and all the high offices were filled by newcomers. Only the most impoverished and powerless members of the vanquished families, or their remote dependants, were allowed to remain in the city; and even so they did not enjoy full civic rights and were viewed with distrust. The distrust in this analogy corresponds to the doubt in the case we are considering. That is why in analysing a dream I insist that the whole scale of estimates of certainty shall be abandoned and that the faintest possibility that something of this or that sort may have occurred in the dream shall be treated as complete certainty. In tracing any element of a dream it will be found that unless this attitude is firmly adopted the analysis will come to a standstill. If any doubt is thrown upon the value of the element in question, the psychical result in the patient is that none of the involuntary ideas underlying that element comes into his head. This result is not a self-evident one. It would not make nonsense if someone were to say: 'I don't know for certain whether such and such a thing came into the dream, but here is what occurs to me in connection with it.' But in fact no one ever does say this; and it is precisely the fact that doubt produces this interrupting effect upon an analysis that reveals it as a derivative and tool of psychical resistance. Psycho-analysis is justly suspicious. One of its rules is that whatever interrupts the progress of analytic work is a resistance.¹

[1900a, 808]

[1900a, 951]
The situation is this. Either residues of the previous day have been left over from the activity of waking life and it has not been possible to withdraw the whole cathexis of energy from them; or the activity of waking life during the course of the day has led to the stirring up of an unconscious wish; or these two events have happened to coincide. (We have already discussed the various possibilities in this connection.) The unconscious wish links itself up with the day's residues and effects a transference on to them; this may happen either in the course of the day or not until a state of sleep has been established. A wish now arises which has been transferred on to the recent material; or a recent wish, having been suppressed, gains fresh life by being reinforced from the unconscious. This wish seeks to force its way along the normal path taken by thought processes, though the Pcs. (to which, indeed, it in part belongs) to consciousness. But it comes up against the censorship, which is still functioning and to the influence of which it now submits. At this point it takes on the distortion for which the way has already been paved by the transference of the wish on to recent material. So far it is on the way to becoming an obsessive idea or a delusion or something of the kind - that is, a thought which has been intensified by transference and distorted in its expression by censorship. Its further advance is halted, however, by the sleeping state of the preconscious. (The probability is that that system has protected itself against the invasion by diminishing its own excitations.) The dream-process consequently enters on a regressive path, which lies open to it precisely owing to the peculiar nature of the state of sleep, and it is led along that path by the attraction exercised on it by groups of memories; some of these memories themselves exist only in the form of visual cathexes and not as translations into the terminology of the later systems. In the course of its regressive path the dream-process acquires the attribute of representability. (I shall deal later with the question of compression.) It has now completed the second portion of its zigzag journey. The first portion was a progressive one, leading from the unconscious scenes or phantasies to the preconscious; the second portion led from the frontier of the censorship back again to perceptions. But when the content of the dream process has become perceptual, by that fact it has, as it were, found a way of evading the obstacle put in its way by the censorship and the state of sleep in the Pcs. It succeeds in drawing attention to itself and in being noticed by consciousness.

(2) Owing, once more, to the freedom with which the intensities can be transferred, 'intermediate ideas', resembling compromises, are constructed under the sway of condensation. (Cf. the numerous instances I have given of this.) This is again something unheard-of in normal chains of ideas, where the main stress is laid on the selection and retention of the 'right' ideational element. On the other hand, composite structures and compromises occur with remarkable frequency when we try to express preconscious thoughts in speech. They are then regarded as species of 'slips of the tongue.'

These are some of the most striking of the abnormal processes to which the dream-thoughts, previously constructed on rational lines, are subjected in the course of the dream-work. It will be seen that the chief characteristic of these processes is that the whole stress is laid upon making the cathecting energy mobile and capable of discharge; the content and the proper meaning of the psychical elements to which the cathexes are attached are treated as of little consequence. It might have been supposed that condensation and the formation of compromises is only carried out for the sake of facilitating regression, that is, when it is a question of transforming thoughts into images. But the analysis - and still more the synthesis - of dreams which include no such regression to images, e.g. the dream of 'Autodidasker', exhibits the same processes of displacement and condensation as the rest.
Between the scene in which her wish had been fulfilled and the time of the dream more than twenty-five years elapsed. In the meantime Frau B. had become the widow of a second husband who left her with a child and a fortune. The old lady's affection was still centred on Dr. K., who was now her adviser and the administrator of her estate and whom she saw frequently. Let us suppose that during the few days before the dream she had been expecting a visit from him, but that this had not taken place - he was no longer so pressing as he used to be. She may then have quite well had a nostalgic dream one night which took her back to the old days. Her dream was probably of a rendez-vous at the time of her love affair, and the chain of her dream-thoughts carried her back to the occasion when, without any pre-arrangement, he had come in at the very moment at which she had been longing for him. She probably had dreams of this kind quite often now; they were a part of the belated punishment with which a woman pays for her youthful cruelty. But such dreams - derivatives of a suppressed current of thought, filled with memories of rendez-vous of which, since her second marriage, she no longer liked to think - such dreams were put aside on waking. And that was what happened to our ostensibly prophetic dream. She then went out, and in the Kärntnerstrasse, at a spot which was in itself indifferent, she met her old family doctor, Dr. K. It was a very long time since she had seen him. He was intimately associated with the excitements of that happy-unhappy time. He too had been a helper, and we may suppose that he had been used in her thoughts, and perhaps in her dreams as well, as a screen figure behind which she concealed the better-loved figure of the other Dr. K. This meeting now revived her recollection of the dream. She must have thought: 'Yes, I had a dream last night of my rendez-vous with Dr. K.' But this recollection had to undergo the distortion which the dream escaped only because it had been completely forgotten. She inserted the indifferent K. (who had reminded her of the dream) in place of the beloved K. The content of the dream - the rendez-vous - was transferred to a belief that she had dreamt of that particular spot, for a rendez-vous consists in two people coming to the same spot at the same time. And if she then had an impression that a dream had been fulfilled, she was only giving effect in that way to her memory of the scene in which she had longed in her misery for him to come and her longing had at once been fulfilled.

[1900a, 1048]

In the case of the complicated and confused dreams with which we are now concerned, condensation and dramatization alone are not enough to account for the whole of the impression that we gain of the dissimilarity between the content of the dream and the dream-thoughts. We have evidence of the operation of a third factor, and this evidence deserves careful sifting.

[1901a, 1070]
First and foremost, when by means of analysis we have arrived at a knowledge of the dream-thoughts, we observe that the manifest dream-content deals with quite different material from the latent thoughts. This, to be sure, is no more than an appearance, which evaporates under closer examination, for we find ultimately that the whole of the dream-content is derived from the dream-thoughts, and that almost all the dream-thoughts are represented in the dream-content. Nevertheless, something of the distinction still remains. What stands out boldly and clearly in the dream as its essential content must, after analysis, be satisfied with playing an extremely subordinate role among the dream-thoughts; and what, on the evidence of our feelings, can claim to be the most prominent among the dream-thoughts is either not present at all as ideational material in the content of the dream or is only remotely alluded to in some obscure region of it. We may put it in this way: in the course of the dream-work the psychical intensity passes over from the thoughts and ideas to which it properly belongs on to others which in our judgement have no claim to any such emphasis. No other process contributes so much to concealing the meaning of a dream and to making the connection between the dream-content and the dream-thoughts unrecognizable. In the course of this process, which I shall describe as ‘dream-displacement’, the psychical intensity, significance or affective potentiality of the thoughts is, as we further find, transformed into sensory vividness. We assume as a matter of course that the most distinct element in the manifest content of a dream is the most important one; but in fact it is often an indistinct element which turns out to be the most direct derivative of the essential dream-thought.

[1901a, 1070]

What I have called dream-displacement might equally be described as ‘a transvaluation of psychical values.’ I shall not have given an exhaustive estimate of this phenomenon, however, unless I add that this work of displacement or transvaluation is performed to a very varying degree in different dreams. There are dreams which come about almost without any displacement. These are the ones which make sense and are intelligible, such, for instance, as those which we have recognized as undisguised wishful dreams. On the other hand, there are dreams in which not a single piece of the dream-thoughts has retained its own psychical value, or in which everything that is essential in the dream-thoughts has been replaced by something trivial. And we can find a complete series of transitional cases between these two extremes. The more obscure and confused a dream appears to be, the greater the share in its construction which may be attributed to the factor of displacement.

[1901a, 1071]

Our specimen dream exhibits displacement to this extent at least, that its content seems to have a different centre from its dream-thoughts. In the foreground of the dream-content a prominent place is taken by a situation in which a woman seems to be making advances to me; while in the dream-thoughts the chief emphasis is laid on a wish for once to enjoy unselfish love, love which ‘costs nothing’ - an idea concealed behind the phrase about ‘beautiful eyes’ and the far-fetched allusion to ‘spinach.’

[1901a, 1071]
Analysis does away with the misleading appearance upon which this derogatory judgement is founded. If the content of a dream puts forward some indifferent impression as being its instigator, analysis invariably brings to light a significant experience, and one by which the dreamer has good reason to be stirred. This experience has been replaced by the indifferent one, with which it is connected by copious associative links. Where the content of the dream treats of insignificant and uninteresting ideational material, analysis uncovers the numerous associative paths connecting these trivialities with things that are of the highest psychical importance in the dreamer's estimation. *If what makes their way into the content of dreams are impressions and material which are indifferent and trivial rather than justifiably stirring and interesting, that is only the effect of the process of displacement.* If we answer our questions about dream-instigators and the connection between dreaming and daily affairs on the basis of the new insight we have gained from replacing the manifest by the latent content of dreams, we arrive at these conclusions: *dreams are never concerned with things with which we should not think it worth while to be concerned during the day, and trivialities which do no affect us during the day are unable to pursue us in our sleep.*

[1901a, 1072]

I cannot leave the subject of dream-displacement without drawing attention to a remarkable process which occurs in the formation of dreams and in which condensation and displacement combine to produce the result. In considering condensation we have already seen the way in which two ideas in the dream-thoughts which have something in common, some point of contact, are replaced in the dream-content by a composite idea, in which a relatively distinct nucleus represents what they have in common, while indistinct subordinate details correspond to the respects in which they differ from each other. If displacement takes place in addition to condensation, what is constructed is not a composite idea but an 'intermediate common entity', which stands in a relation to the two different elements similar to that in which the resultant in a parallelogram of forces stands to its components. For instance, in the content of one of my dreams there was a question of an injection with propyl. To begin with, the analysis only led me to an indifferent experience which had acted as dream-instigator, and in which a part was played by amyl. I was not yet able to justify the confusion between amyl and propyl. In the group of ideas behind this same dream, however, there was also a recollection of my first visit to Munich, where I had been struck by the Propylaea. The details of the analysis made it plausible to suppose that it was the influence of this second group of ideas upon the first one that was responsible for the displacement from amyl to propyl. Propyl is as it were an intermediate idea between amyl and Propylaea, and found its way into the content of the dream as a kind of compromise, by means of simultaneous condensation and displacement.

[1901a, 1073]

There is a still more urgent necessity in the case of the process of displacement than in that of condensation to discover the motive for these puzzling efforts on the part of the dream-work.

[1901a, 1073]
It is the process of displacement which is chiefly responsible for our being unable to discover or recognize the dream-thoughts in the dream-content, unless we understand the reason for their distortion. Nevertheless, the dream-thoughts are also submitted to another and milder sort of transformation, which leads to our discovering a new achievement on the part of the dream-work - one, however, which is easily intelligible. The dream-thoughts which we first come across as we proceed with our analysis often strike us by the unusual form in which they are expressed; they are not clothed in the prosaic language usually employed by our thoughts, but are on the contrary represented symbolically by means of similes and metaphors, in images resembling those of poetic speech. There is no difficulty in accounting for the constraint imposed upon the form in which the dream-thoughts are expressed. The manifest content of dreams consists for the most part in pictorial situations; and the dream-thoughts must accordingly be submitted in the first place to a treatment which will make them suitable for a representation of this kind. If we imagine ourselves faced by the problem of representing the arguments in a political leading article or the speeches of counsel before a court of law in a series of pictures, we shall easily understand the modifications which must necessarily be carried out by the dream-work owing to considerations of representability in the content of the dream.

The dream-thoughts which we arrive at by means of analysis reveal themselves as a psychical complex of the most intricate possible structure. Its portions stand in the most manifold logical relations to one another: they represent foreground and background, conditions, digressions and illustrations, chains of evidence and counter-arguments. Each train of thought is almost invariably accompanied by its contradictory counterpart. This material lacks none of the characteristics that are familiar to us from our waking thinking. If now all of this is to be turned into a dream, the psychical material will be submitted to a pressure which will condense it greatly, to an internal fragmentation and displacement which will, as it were, create new surfaces, and to a selective operation in favour of those portions of it which are the most appropriate for the construction of situations. If we take into account the genesis of the material, a process of this sort deserves to be described as a 'regression.' In the course of this transformation, however, the logical links which have hitherto held the psychical material together are lost. It is only, as it were, the substantive content of the dream-thoughts that the dream-work takes over and manipulates. The restoration of the connections which the dream-work has destroyed is a task which has to be performed by the work of analysis.

The second speech - 'I don't recognize that' - occurred in an entirely different connection. On the previous day she had reproved her cook, who incidentally also appeared in the dream, with the words: 'Behave yourself properly! I don't recognize that!' meaning, no doubt, that she did not understand such behaviour and would not put up with it. As the result of a displacement, it was the more innocent part of this speech which made its way into the content of the dream; but in the dream-thoughts it was only the other part of the speech that played a part. For the dream-work had reduced to complete unintelligibility and extreme innocence an imaginary situation in which I was behaving improperly to the lady in a particular way. But this situation which the patient was expecting in her imagination was itself only a new edition of something she had once actually experienced.
Having been made acquainted with the dream-work by the foregoing discussion, we shall no doubt be inclined to pronounce it a quite peculiar psychical process, the like of which, so far as we are aware, does not exist elsewhere. It is as though we were carrying over on to the dream-work all the astonishment which used formerly to be aroused in us by its product, the dream. In fact, however, the dream-work is only the first to be discovered of a whole series of psychical processes, responsible for of hysterical symptoms, of phobias, obsessions and delusions. Condensation and, above all, displacement are invariable characteristics of these other processes as well. Modification into a pictorial form, on the other hand, remains a peculiarity of the dream-work. If this explanation places dreams in a single series alongside the structures produced by psychical illness, this makes it all the more important for us to discover the essential determining conditions of such processes as those of dream-formation. We shall probably be surprised to hear that neither the state of sleep nor illness is among these indispensable conditions. A whole number of the phenomena of the everyday life of healthy people - such as forgetting, slips of the tongue, bungled actions and a particular class of errors - owe their origin to a psychical mechanism analogous to that of dreams and of the other members of the series.

[1901a, 1084]

The heart of the problem lies in displacement, which is by far the most striking of the special achievements of the dream-work. If we enter deeply into the subject, we come to realize that the essential determining condition of displacement is a purely psychological one: something in the nature of a motive. One comes upon its track if one takes into consideration certain experiences which one cannot escape in analysing dreams. In analysing my specimen dream I was obliged to break off my report of the dream-thoughts on p. 1059, because, as I confessed, there were some among them which I should prefer to conceal from strangers and which I could not communicate to other people without doing serious mischief in important directions. I added that nothing would be gained if I were to choose another dream instead of that particular one with a view to reporting its analysis: I should come upon dream-thoughts which required to be kept secret in the case of every dream with an obscure or confused content. If, however, I were to continue the analysis on my own account, without any reference to other people (whom, indeed, an experience so personal as my dream cannot possibly have been intended to reach), I should eventually arrive at thoughts which would surprise me, whose presence in me I was unaware of, which were not only alien but also disagreeable to me, and which I should therefore feel inclined to dispute energetically, although the chain of thoughts running through the analysis insisted upon them remorselessly. There is only one way of accounting for this state of affairs, which is of quite universal occurrence; and that is to suppose that these thoughts really were present in my mind, and in possession of a certain amount of psychical intensity or energy, but that they were in a peculiar psychological situation, as a consequence of which they could not become conscious to me. (I describe this particular condition as one of ‘repression.’) We cannot help concluding, then, that there is a causal connection between the obscurity of the dream-content and the state of repression (in admissibility to consciousness) of certain of the dream-thoughts, and that the dream had to be obscure so as not to betray the proscribed dream-thoughts. Thus we are led to the concept of a ‘dream-distortion’, which is the product of the dream-work and serves the purpose of dissimulation, that is, of disguise.

[1901a, 1085]

There are also clear dreams with a distressing content, which, however, is not felt as distressing in the dream itself. For this reason they cannot be counted as anxiety-dreams; but they have always been taken as evidence of the fact that dreams are without meaning and have no psychical value. An analysis of a dream of this kind will show that we are dealing with well-disguised fulfilsments of repressed wishes, that is to say with a dream of the second class; it will also show how admirably the process of displacement is adapted for disguising wishes.

[1901a, 1088]
Hitherto philosophers have had no occasion to concern themselves with a psychology of repression. We may therefore be permitted to make a first approach to this hitherto unknown topic by constructing a pictorial image of the course of events in dream-formation. It is true that the schematic picture we have arrived at - not only from the study of dreams - is a fairly complicated one; but we cannot manage with anything simpler. Our hypothesis is that in our mental apparatus there are two thought-constructing agencies, of which the second enjoys the privilege of having free access to consciousness for its products whereas the activity of the first is in itself unconscious and can only reach consciousness by way of the second. On the frontier between the two agencies, where the first passes over to the second, there is a censorship, which only allows what is agreeable to it to pass through and holds back everything else. According to our definition, then, what is rejected by the censorship is in a state of repression. Under certain conditions, of which the state of sleep is one, the relation between the strength of the two agencies is modified in such a way that what is repressed can no longer be held back. In the state of sleep this probably occurs owing to a relaxation of the censorship; when this happens it becomes possible for what has hitherto been repressed to make a path for itself to consciousness. Since, however, the censorship is never completely eliminated but merely reduced, the repressed material must submit to certain alterations which mitigate its offensive features. What becomes conscious in such cases is a compromise between the intentions of one agency and the demands of the other. Repression - relaxation of the censorship - the formation of a compromise, this is the fundamental pattern for the generation not only of dreams but of many other psychopathological structures; and in the latter cases too we may observe that the formation of compromises is accompanied by processes of condensation and displacement and by the employment of superficial associations, which we have become familiar with in the dream-work.

[1901a, 1089]

'Mother's jewel-case' was therefore introduced in two places in the dream; and this element replaced all mention of Dora's infantile jealousy, of the drops (that is, of the sexual wetness), of being dirtied by the discharge, and, on the other hand, of her present thoughts connected with the temptation - the thoughts which were urging her to reciprocate the man's love, and which depicted the sexual situation (alike desirable and menacing) that lay before her. The element of 'jewel-case' was more than any other a product of condensation and displacement, and a compromise between contrary mental currents. The multiplicity of its origin - both from infantile and contemporary sources - is no doubt pointed to by its double appearance in the content of the dream.

[1905e, 1427]
I may here add a few supplementary interpretations to those that have already been given: The 'Madonna' was obviously Dora herself; in the first place because of the 'adorer' who had sent her the pictures, in the second place because she had won Herr K.'s love chiefly by the motherliness she had shown towards his children, and lastly because she had had a child though she was still a girl (this being a direct allusion to the phantasy of childbirth). Moreover, the notion of the 'Madonna' is a favourite counter-idea in the mind of girls who feel themselves oppressed by imputations of sexual guilt, - which was the case with Dora. A first suspicion of this connection came to me while I was working as a physician at the Psychiatric Clinic of the University. I there came across a case of confusional insanity with hallucinations, in which the attack, which ran a rapid course, turned out to be a reaction to a reproach made against the patient by her fiancé. - If the analysis had been continued, Dora's maternal longing for a child would probably have been revealed as an obscure though powerful motive in her behaviour. The numerous questions which she had been raising latterly seem to have been belated derivatives of questions inspired by the sexual curiosity which she had tried to gratify with the encyclopaedia. The subjects which she read up in it were presumably pregnancy, childbirth, virginity, and so on. - In reproducing the dream Dora had forgotten one of the questions which need to be inserted into the course of the second situation in the dream. This question could only be; 'Does Herr -- live here?' or 'Where does Herr -- live?' There must have been some reason for her having forgotten this apparently innocent question, especially as she need not have brought it into the dream at all. This reason, it seems to me, lay in her surname itself, which also denoted an object and in fact more than one kind of object, and which could therefore be regarded as an 'ambiguous' word. Unluckily I cannot give the name and show how well designed it was to indicate something 'ambiguous' and 'improper'. This interpretation was supported by the discovery of a similar play upon words in another part of the dream, where the material was derived from Dora's recollections of her aunt's death ('they have already gone to the cemetery') and where there was similarly a play upon her aunt's name. These improper words seemed to point to a second and oral source of information, since the encyclopaedia would not cover them. I should not have been surprised to hear that this source had been Frau K. herself, Dora's calumniator. In that case she would have been the one person whom Dora generously spared, while she pursued the others with an almost malignant vindictiveness. Behind the almost limitless series of displacements which were thus brought to light, it was possible to divine the operation of a single simple factor - Dora's deep-rooted homosexual love for Frau K.

Can we feel sure that none of the possible techniques of jokes has escaped our investigation? Of course not. But a continued examination of fresh material can convince us that we have got to know the commonest and most important technical methods of the joke-work - at all events as much as is required for forming a judgement on the nature of that psychical process. So far we have not arrived at any such judgement; but on the other hand we are now in possession of an important indication of the direction from which we may expect to receive further light upon the problem. The interesting processes of condensation accompanied by the formation of a substitute, which we have recognized as the core of the technique of verbal jokes, point towards the formation of dreams, in the mechanism of which the same psychical processes have been discovered. This is equally true, however, of the techniques of conceptual jokes - displacement, faulty reasoning, absurdity, indirect representation, representation by the opposite - which re-appear one and all in the technique of the dream-work. Displacement is responsible for the puzzling appearance of dreams, which prevents our recognizing that they are a continuation of our waking life. The use of absurdity and nonsense in dreams has cost them the dignity of being regarded as psychical products and has led the authorities to suppose that a disintegration of the mental activities and a cessation of criticism, morality and logic are necessary conditions of the formation of dreams. Representation by the opposite is so common in dreams that even the popular books of dream-interpretation, which are on a completely wrong tack, are in the habit of taking it into account. Indirect representation - the replacement of a dream-thought by an allusion, by something small, a symbolism akin to analogy - is precisely what distinguishes the mode of expression of dreams from that of our waking life.¹ So far-reaching an agreement between the methods of the joke-work and those of the dream-work can scarcely be a matter of chance. To demonstrate this agreement in detail and to examine its basis will be one of our later tasks.

[1905e, 1439]

[1905c, 1686]
It is less easy to convince oneself of the second great modification of the dream-thoughts that is brought about by the dream-work - the process that I have named 'dream-displacement'. This is exhibited in the fact that things that lie on the periphery of the dream-thoughts and are of minor importance occupy a central position and appear with great sensory intensity in the manifest dream, and vice versa. This gives the dream the appearance of being displaced in relation to the dream-thoughts, and this displacement is precisely what brings it about that the dream confronts waking mental life as something alien and incomprehensible. In order that a displacement of this kind may occur, it must be possible for the cathectic energy to pass over uninhibited from the important ideas to the unimportant ones - which, in normal thought that is capable of being conscious, can only give an impression of 'faulty reasoning'.
[1905c, 1749]

The following forces may be recognized as having a share in the formation of dreams: the wish to sleep, the cathectic energy that still remains in the day's residues after it has been lowered by the state of sleep, the psychical energy of the dream-constructing unconscious wish and the opposing force of the 'censorship', which dominates daytime life and is not completely lifted during sleep. The task of dream-formation is above all to overcome the inhibition from the censorship; and it is precisely this task which is solved by the displacements of psychical energy within the material of the dream-thoughts.
[1905c, 1750]

We have entered so closely, in connection with the processes of condensation, into the importance of the analogy between jokes and dreams that we may be briefer in what follows. As we know, the displacements in the dream-work point to the operation of the censorship of conscious thinking, and accordingly, when we come across displacement among the techniques of jokes, we shall be inclined to suppose that an inhibitory force plays a part in the formation of jokes as well. And we already know that this is quite generally the case. The effort made by jokes to recover the old pleasure in nonsense or the old pleasure in words finds itself inhibited in normal moods by objections raised by critical reason; and in every individual case this has to be overcome. But the manner in which the joke-work accomplishes this task shows a sweeping distinction between jokes and dreams. In the dream-work it is habitually accomplished by displacements, by the selection of ideas which are sufficiently remote from the objectionable one for the censorship to allow them to pass, but which are nevertheless derivatives of that idea and have taken over its psychical cathectic by means of a complete transference. For this reason displacements are never absent in a dream and are far more comprehensive.
[1905c, 1755]

Among displacements are to be counted not merely diversions from a train of thought but every sort of indirect representation as well, and in particular the replacement of an important but objectionable element by one that is indifferent and that appears innocent to the censorship, something that seems like a very remote allusion to the other one - substitution by a piece of symbolism, or an analogy, or something small. It cannot be disputed that portions of such indirect representation are already present in the dream's preconscious thoughts - for instance, representation by symbols or analogies - because otherwise the thought would not have reached the stage of preconscious expression at all. Indirect representations of this kind, and allusions whose reference to the thing intended is easy to discover, are indeed permissible and much-used methods of expression in our conscious thinking as well. The dream-work, however, exaggerates this method of indirect expression beyond all bounds. Under the pressure of the censorship, any sort of connection is good enough to serve as a substitute by allusion, and displacement is allowed from any element to any other. Replacement of internal associations (similarity, causal connection, etc.) by what are known as external ones (simultaneity in time, contiguity in space, similarity of sound) is quite specially striking and characteristic of the dream-work.
[1905c, 1755]
Strange to say, it does. The sense is merely disguised in a particular way so that it is not immediately recognizable. Hanold learned in the dream that the girl he was looking for was living in a town and contemporaneously with him. Now this was true of Zoe Bertgang; only in the dream the town was not the German university town but Pompeii, and the time was not the present but the year 79 A.D. It is, as it were, a distortion by displacement: what we have is not Gradiva in the present but the dreamer transported into the past. Nevertheless, in this manner, the essential and new fact is stated: he is in the same place and time as the girl he is looking for. But whence come this displacement and disguise which were bound to deceive both us and the dreamer over the true meaning and content of the dream? Well, we already have the means at our disposal for giving a satisfactory answer to that question.

We have noted as a curious and derogatory characteristic of obsessional neurosis that its ceremonials are concerned with the small actions of daily life and are expressed in foolish regulations and restrictions in connection with them. We cannot understand this remarkable feature of the clinical picture until we have realized that the mechanism of psychical displacement, which was first discovered by me in the construction of dreams,¹ dominates the mental processes of obsessional neurosis. It is already clear from the few examples of obsessive actions given above that their symbolism and the detail of their execution are brought about by a displacement from the actual, important thing on to a small one which takes its place - for instance, from a husband on to a chair. It is this tendency to displacement which progressively changes the clinical picture and eventually succeeds in turning what is apparently the most trivial matter into something of the utmost importance and urgency. It cannot be denied that in the religious field as well there is a similar tendency to a displacement of psychical values, and in the same direction, so that the petty ceremonials of religious practice gradually become the essential thing and push aside the underlying thoughts. That is why religions are subject to reforms which work retroactively and aim at a re-establishment of the original balance of values.

You can also obtain a view, by a kind of synthetic work, of the process which has brought about the distortion of the unconscious dream-thoughts into the manifest content of the dream. We call this process the 'dream-work'. It deserves our closest theoretical interest, since we are able to study in it, as nowhere else, what unsuspected psychical processes can occur in the unconscious, or rather, to put it more accurately, between two separate psychical systems like the conscious and unconscious. Among these freshly discovered psychical processes those of condensation and displacement are especially noticeable. The dream-work is a special case of the effects produced by two different mental groupings on each other - that is, of the consequences of mental splitting; and it seems identical in all essentials with the process of distortion which transforms the repressed complexes into symptoms where there is unsuccessful repression.
One of the characteristics of this ambivalent relation which I have repeatedly stressed as fundamental - the fact that the positive current of desire is an unconscious one - opens the way to further considerations and to further possible explanations. Psychical processes in the unconscious are not in every respect identical with those with which our conscious mind is familiar; they enjoy some remarkable liberties that are forbidden to the latter. An unconscious impulse need not have arisen at the point where it makes its appearance; it may arise from some quite other region and have applied originally to quite other persons and connections; it may have reached the place at which it attracts our attention though the mechanism of 'displacement'. Owing, moreover, to the indestructibility and insusceptibility to correction which are attributes of unconscious processes, it may have survived from very early times to which it was appropriate into later times and circumstances in which its manifestations are bound to seem strange. These are no more than hints, but if they were attentively developed their importance for our understanding of the growth of civilization would become apparent.

[1912-1913, 2714]

I know of no parallel in the operations of the press-censorship to a third manner of working by the dream-censorship; but I am able to demonstrate it from precisely the one example of a dream which we have analysed so far. You will recall the dream of the 'three bad theatre-tickets for 1 florin 50'. In the latent thoughts of that dream the element 'over-hurriedly, too early' stood in the foreground. Thus: it was absurd to marry so early - it was also absurd to take the theatre-tickets so early - it was ridiculous of the sister-in-law to part with her money in such a hurry to buy jewellery with it. Nothing of this central element of the dream-thoughts passed over into the manifest dream; in it the central position is taken by the 'going to the theatre' and 'taking the tickets'. As a result of this displacement of accent, this fresh grouping of the elements of the content, the manifest dream has become so unlike the latent dream-thoughts that no-one would suspect the presence of the latter behind the former. This displacement of accent is one of the chief instruments of dream-distortion and it is what gives the dream the strangeness on account of which the dreamer himself is not inclined to recognize it as his own production.

[1916-1917, 3235]

Omission, modification, fresh grouping of the material - these, then, are the activities of the dream-censorship and the instruments of dream-distortion. The dream-censorship itself is the originator, or one of the originators, of the dream-distortion which we are now engaged in examining. We are in the habit of combining the concepts of modification and re-arrangement under the term 'displacement'.

[1916-1917, 3236]

You will no doubt recognize the pursuit by the officer in the red cap and the breathless climbing upstairs as representing the sexual act. The fact that it was the dreamer who locked herself up against her pursuer will serve as an example of the reversals that are used so commonly in dreams, for it was the man who had avoided the consummation of the sexual act. In the same way, her grief was displaced on to the man, for it was he who wept in the dream - and this was simultaneously a representation of the emission of semen.

[1916-1917, 3283]
The courtyard in which the sheet of tin was spread out is not to be taken symbolically in the first instance. It was derived from the business premises of the dreamer's father. For reasons of discretion I have substituted 'tin' for another material in which his father actually dealt: but I have made no other change in the wording of the dream. The dreamer had entered his father's business and had taken violent objection to the somewhat dubious practices on which the firm's earnings in part depended. Consequently the dream-thought I have just interpreted may have continued in this way: 'If I had asked him, he would have deceived me just as he deceives his customers.' As regards the 'pulling off' which served to represent his father's dishonesty in business, the dreamer himself produced a second explanation - namely that it stood for masturbatory. Not only have we long been familiar with this interpretation, but there was something to confirm it in the fact that the secret nature of masturbation was represented by its reverse: it might be done openly. Just as we should expect, the masturbatory activity was once again displaced on to the dreamer's father, like the questioning in the first scene of the dream. He promptly interpreted the shaft as a vagina, having regard to the soft cushioning of its walls. I added on my own authority that climbing down, like climbing up in other cases, described sexual intercourse in the vagina.

[1916-1917, 3285]

The matter under consideration relates in essence to the results of displacement, which you have become acquainted with as the most powerful instrument of the dream-censorship. With the help of displacement the dream-censorship creates substitutive structures which we have described as allusions. But they are allusions which are not easily recognizable as such, from which the path back to the genuine thing is not easily traced, and which are connected with the genuine thing by the strangest, most unusual, external associations. In all these cases it is a question, however, of things which are meant to be hidden, which are condemned to concealment, for that is what the dream-censorship is aiming at. But we must not expect that a thing which has been hidden will be found in its own place, in its proper position. The frontier-control commissions which are operating to-day are more cunning in this respect than the Swiss school authorities. In their search for documents and plans they are not content with examining brief-cases and portfolios, but they consider the possibility that spies and smugglers may have these forbidden things in the most secret portions of their clothing where they decidedly do not belong - for instance, between the double soles of their boots. If the hidden things are there, it will certainly be possible to call them 'far-fetched', but it is also true that a great deal will have been found.

[1916-1917, 3319]

Perhaps you recognize, moreover, what it is that supports our hypotheses of the two systems, and their relation to each other and to consciousness? After all, the watchman between the unconscious and the preconscious is nothing else than the censorship, to which, as we found, the form taken by the manifest dream is subject. The day's residues, which we recognized as the instigators of the dream, were preconscious material which, at night-time and in the state of sleep, had been under the influence of unconscious and repressed wishful impulses; they had been able, in combination with those impulses and thanks to their energy, to construct the latent dream. Under the dominance of the unconscious system this material had been worked over (by condensation and displacement) in a manner which is unknown or only exceptionally permissible in normal mental life - that is, in the preconscious system. We came to regard this difference in their manner of operating as what characterizes the two systems; the relation which the preconscious has to consciousness was regarded by us merely as an indication of its belonging to one of the two systems. Dreams are not pathological phenomena; they can appear in any healthy person under the conditions of a state of sleep. Our hypothesis about the structure of the mental apparatus, which allows us to understand the formation alike of dreams and of neurotic symptoms, has an incontrovertible claim to being taken into account in regard to normal mental life as well.

[1916-1917, 3370]
We also describe the latent dream-thoughts, on account of their connection with waking life, as 'residues of the day'. By the operation of the dream-work (to which it would be quite incorrect to ascribe any 'creative' character ) the latent dream thoughts are condensed in a remarkable way, are distorted by the displacement of psychical intensities and are arranged with a view to being represented in visual pictures; and, besides all this, before the manifest dream is arrived at, they are submitted to a process of secondary revision which seeks to give the new product something in the nature of sense and coherence. Strictly speaking, this last process does not form a part of the dream-work.
[1923a, 3918]

The Theory of Repression. - These theoretical considerations, taken together with the immediate impressions derived from analytic work, lead to a view of the neuroses which may be described in the roughest outline as follows. The neuroses are the expression of conflicts between the ego and such of the sexual impulses as seem to the ego incompatible with its integrity or with its ethical standards. Since these impulses are not ego-syntonic, the ego has repressed them: that is to say, it has withdrawn its interest from them and has shut them off from becoming conscious as well as from obtaining satisfaction by motor discharge. If in the course of analytic work one attempts to make these repressed impulses conscious, one becomes aware of the repressive forces in the form of resistance. But the achievement of repression fails particularly readily in the case of the sexual instincts. Their dammed-up libido finds other ways out from the unconscious: for it regresses to earlier phases of development and earlier attitudes towards objects, and, at weak points in the libidinal development where there are infantile fixations, it breaks through into consciousness and obtains discharge. What results is a symptom and consequently in its essence a substitutive sexual satisfaction. Nevertheless the symptom cannot entirely escape from the repressive forces of the ego and must therefore submit to modifications and displacements exactly as happens with dreams - by means of which its characteristic of being a sexual satisfaction becomes unrecognizable. Consequently symptoms are in the nature of compromises between the repressed sexual instincts and the repressing ego-insefts; they represent a wish-fulfilment for both partners to the conflict simultaneously, but one which is incomplete for each of them. This is quite strictly true of the symptoms of hysteria, while in the symptoms of obsessional neurosis there is often a stronger emphasis upon the side of the repressing function owing to the erection of reaction-formations, which are assurances against sexual satisfaction.
[1923a, 3923]
In the present discussion, moreover, I am only putting forward a hypothesis; I have no proof to offer. It seems a plausible view that this displaceable and neutral energy, which is no doubt active in both in the ego and in the id, proceeds from the narcissistic store of libido - that it is desexualized Eros. (The erotic instincts appear to be altogether more plastic, more readily diverted and displaced than the destructive instincts.) From this we can easily go on to assume that this displaceable libido is employed in the service of the pleasure principle to obviate blockages and to facilitate discharge. In this connection it is easy to observe a certain indifference as to the path along which the discharge takes place, so long as it takes place somehow. We know this trait; it is characteristic of the cathetic processes in the id. It is found in erotic cathexes, where a peculiar indifference in regard to the object displays itself; and it is especially evident in the transferences arising in analysis, which develop inevitably, irrespective of the persons who are their object. Not long ago Rank published some good examples of the way in which neurotic acts of revenge can be directed against the wrong people. Such behaviour on the part of the unconscious reminds one of the comic story of the three village tailors, one of whom had to be hanged because the only village blacksmith had committed a capital offence. Punishment must be exacted even if it does not fall upon the guilty. It was in studying the dream-work that we first came upon this kind of looseness in the displacements brought about by the primary process. In that case it was the objects that were thus relegated to a position of no more than secondary importance, just as in the case we are now discussing it is the paths of discharge. It would be characteristic of the ego to be more particular about the choice both of an object and of a path of discharge.

[1923b, 3979]

I was able to show from a short story by W. Jensen called Gradiva, which has no particular merit in itself, that invented dreams can be interpreted in the same way as real ones and that the unconscious mechanisms familiar to us in the ‘dream-work’ are thus also operative in the processes of imaginative writing. My book on Jokes and their Relation to the Unconscious was a side-issue directly derived from The Interpretation of Dreams. The only friend of mine who was at that time interested in my work remarked to me that my interpretations of dreams often impressed him as being like jokes. In order to throw some light on this impression, I began to investigate jokes and found that their essence lay in the technical methods employed in them, and that these were the same as the means used in the ‘dream-work’ - that is to say, condensation, displacement, the representation of a thing by its opposite or by something very small, and so on. This led to an economic enquiry into the origin of the high degree of pleasure obtained from hearing a joke. And to this the answer was that it was due to the momentary suspension of the expenditure of energy upon maintaining repression, owing to the attraction exercised by the offer of a bonus of pleasure (fore-pleasure).

[1925d, 4239]
Still more remarkable is the other process - displacement or shifting of accent - which in conscious thinking we come across only as faulty reasoning or as means for a joke. The different ideas in the dream-thoughts are, indeed, not all of equal value; they are cathected with quotas of affect of varying magnitude and are correspondingly judged to be important and deserving of interest to a greater or less degree. In the dream-work these ideas are separated from the affects attaching to them. The affects are dealt with independently; they may be displaced on to something else, they may be retained, they may undergo alterations, or they may not appear in the dream at all. The importance of the ideas that have been stripped of their affect returns in the dream as sensory strength in the dream-pictures; but we observe that this accent has passed over from important elements to indifferent ones. Thus something that played only a minor part in the dream-thoughts seems to be pushed into the foreground in the dream as the main thing, while, on the contrary, what was the essence of the dream-thoughts finds only passing and indistinct representation in the dream. No other part of the dream-work is so much responsible for making the dream strange and incomprehensible to the dreamer. Displacement is the principal means used in the dream-distortion to which the dream-thoughts must submit under the influence of the censorship.

[1933a, 4633]

The laws that govern the passage of events in the unconscious, which come to light in this manner, are remarkable enough and suffice to explain most of what seems strange to us about dreams. Above all there is a striking tendency to condensation, an inclination to form fresh unities out of elements which in our waking thought we should certainly have kept separate. As a consequence of this, a single element of the manifest dream often stands for a whole number of latent dream-thoughts as though it were a combined allusion to all of them; and in general the compass of the manifest dream is extraordinarily small in comparison with the wealth of material from which it has sprung. Another peculiarity of the dream-work, not entirely independent of the former one, is the ease with which psychical intensities (cathexes) are displaced from one element to another, so that it often happens that an element which was of little importance in the dream-thoughts appears as the clearest and accordingly most important feature of the manifest dream, and, vice versa, that essential elements of the dream-thoughts are represented in the manifest dream only by slight allusions. Moreover, as a rule the existence of quite insignificant points in common between two elements is enough to allow the dream-work to replace one by the other in all further operations. It will easily be imagined how greatly these mechanisms of condensation and displacement can increase the difficulty of interpreting a dream and of revealing the relations between the manifest dream and the latent dream-thoughts. From the evidence of the existence of these two tendencies to condensation and displacement our theory infers that in the unconscious id the energy is in a freely mobile state and that the id sets more store by the possibility of discharging quantities of excitation than by any other consideration;¹ and our theory makes use of these two peculiarities in defining the character of the primary process we have attributed to the id.

[1940a [1938], 4978]
The view which postulates that in all psychoses there is a splitting of the ego could not call for so much notice if it did not turn out to apply to other states more like the neuroses and, finally, to the neuroses themselves. I first became convinced of this in cases fetishism. This abnormality, which may be counted as one of the perversions, is, as is well known, based on the patient (who is almost always male) not recognizing the fact that females have no penis - a fact which is extremely undesirable to him since it is a proof of the possibility of his being castrated himself. He therefore disavows his own sense-perception which showed him that the female genitals lack a penis and holds fast to the contrary conviction. The disavowed perception does not, however, remain entirely without influence for, in spite of everything, he has not the courage to assert that he actually saw a penis. He takes hold of something else instead - a part of the body or some other object - and assigns it the role of the penis which he cannot do without. It is usually something that he in fact saw at the moment at which he saw the female genitals, or it is something that can suitably serve as a symbolic substitute for the penis. Now it would be incorrect to describe this process when a fetish is constructed as a splitting of the ego; it is a compromise formed with the help of displacement, such as we have been familiar with in dreams. But our observations show us still more. The creation of the fetish was due to an intention to destroy the evidence for the possibility of castration, so that fear of castration could be avoided. If females, like other living creatures, possess a penis, there is no need to tremble for the continued possession of one's own penis. Now we come across fetishists who have developed the same fear of castration as non-fetishists and react in the same way to it. Their behaviour is therefore simultaneously expressing two contrary premisses. On the one hand they are disavowing the fact of their perception - the fact that they saw no penis in the female genitals; and on the other hand they are recognizing the fact that females have no penis and are drawing the correct conclusions from it. The two attitudes persist side by side throughout their lives without influencing each other. Here is what may rightly be called a splitting of the ego. This circumstance also enables us to understand how it is that fetishism is so often only partially developed. It does not govern the choice of object exclusively but leaves room for a greater or lesser amount of normal sexual behaviour; sometimes, indeed, it retires into playing a modest part or is limited to a mere hint. In fetishists, therefore, the detachment of the ego from the reality of the external world has never succeeded completely.

[1940a [1938], 5008]
I cannot leave the subject of dream-displacement without drawing attention to a remarkable process which occurs in the formation of dreams and in which condensation and displacement combine to produce the result. In considering condensation we have already seen the way in which two ideas in the dream-thoughts which have something in common, some point of contact, are replaced in the dream-content by a composite idea, in which a relatively distinct nucleus represents what they have in common, while indistinct subordinate details correspond to the respects in which they differ from each other. If displacement takes place in addition to condensation, what is constructed is not a composite idea but an 'intermediate common entity', which stands in a relation to the two different elements similar to that in which the resultant in a parallelogram of forces stands to its components. For instance, in the content of one of my dreams there was a question of an injection with propyl. To begin with, the analysis only led me to an indifferent experience which had acted as dream-instigator, and in which a part was played by amyl. I was not yet able to justify the confusion between amyl and propyl. In the group of ideas behind this same dream, however, there was also a recollection of my first visit to Munich, where I had been struck by the Propylaea. The details of the analysis made it plausible to suppose that it was the influence of this second group of ideas upon the first one that was responsible for the displacement from amyl to propyl. Propyl is as it were an intermediate idea between amyl and Propylaea, and found its way into the content of the dream as a kind of compromise, by means of simultaneous condensation and displacement.

[1901a, 1073]
The most outstanding point in the content of this dream was the way in which Hofrat L. held the lamp (or magnifying glass) before him, with his eyes peering into the distance. It was many years since I had last seen him; but I knew at once that he was only a substitute figure in the place of someone else, someone greater than he - Archimedes, whose statue stands near the Fountain of Arethusa at Syracuse in that very attitude, holding up his burning-glass and peering out towards the besieging army of the Romans. When did I see that statue for the first (and last) time? According to my diary it was on the evening of September 17th; and between then and the time of the dream 13 + 10 = 23 days had elapsed - Fliess's 'male period'.

[1900a, 656]

'That is to say, you knew that it was so. - The meaning of the dream is now becoming even clearer. You said to yourself: "This man is persecuting me; he wants to force his way into my room. My 'jewel-case' is in danger, and if anything happens it will be Father's fault." For that reason in the dream you chose a situation which expresses the opposite - a danger from which your father is saving you. In this part of the dream everything is turned into its opposite; you will soon discover why. As you say, the mystery turns upon your mother. You ask how she comes into the dream? She is, as you know, your former rival in your father's affections. In the incident of the bracelet, you would have been glad to accept what your mother had rejected. Now let us just put "give" instead of "accept" and "withhold" instead of "reject". Then it means that you were ready to give your father what your mother withheld from him; and the thing in question was connected with jewellery.¹ Now bring your mind back to the jewel-case which Herr K. gave you. You have there the starting-point for a parallel line of thoughts, in which Herr K. is to be put in the place of your father just as he was in the matter of standing beside your bed. He gave you a jewel-case; so you are to give him your jewel-case. That was why I spoke just now of a "return-present". In this line of thoughts your mother must be replaced by Frau K. (You will not deny that she, at any rate, was present at the time.) So you are ready to give Herr K, what his wife withholds from him. That is the thought which has had to be repressed with so much energy, and which has made it necessary for every one of its elements to be turned into its opposite. The dream confirms once more what I had already told you before you dreamt it - that you are summoning up your old love for your father in order to protect yourself against your love for Herr K. But what do all these efforts show? Not only that you are afraid of Herr K., but that you are still more afraid of yourself, and of the temptation you feel to yield to him. In short, these efforts prove once more how deeply you loved him.'²

[1905e, 1407]

According to the necessary conditions of dream-formation the imagined situation must be chosen so as to reproduce a situation in infancy. A special triumph is achieved if a recent situation, perhaps even the very situation which is the exciting cause of the dream, can be transformed into an infantile one. This has actually been achieved in the present case, by a purely chance disposition of the material. Just as Herr K. had stood beside her sofa and woken her up, so her father had often done in her childhood. The whole trend of her thoughts could be most aptly symbolized by her substitution of her father for Herr K. in that situation.

[1905e, 1425]
The matter under consideration relates in essence to the results of displacement, which you have become acquainted with as the most powerful instrument of the dream-censorship. With the help of displacement the dream-censorship creates substitutive structures which we have described as allusions. But they are allusions which are not easily recognizable as such, from which the path back to the genuine thing is not easily traced, and which are connected with the genuine thing by the strangest, most unusual, external associations. In all these cases it is a question, however, of things which are meant to be hidden, which are condemned to concealment, for that is what the dream-censorship is aiming at. But we must not expect that a thing which has been hidden will be found in its own place, in its proper position. The frontier-control commissions which are operating to-day are more cunning in this respect than the Swiss school authorities. In their search for documents and plans they are not content with examining brief-cases and portfolios, but they consider the possibility that spies and smugglers may have these forbidden things in the most secret portions of their clothing where they decidedly do not belong - for instance, between the double soles of their boots. If the hidden things are there, it will certainly be possible to call them 'far-fetched', but it is also true that a great deal will have been found.

[1916-1917, 3319]

The laws that govern the passage of events in the unconscious, which come to light in this manner, are remarkable enough and suffice to explain most of what seems strange to us about dreams. Above all there is a striking tendency to condensation, an inclination to form fresh unities out of elements which in our waking thought we should certainly have kept separate. As a consequence of this, a single element of the manifest dream often stands for a whole number of latent dream-thoughts as though it were a combined allusion to all of them; and in general the compass of the manifest dream is extraordinarily small in comparison with the wealth of material from which it has sprung. Another peculiarity of the dream-work, not entirely independent of the former one, is the ease with which psychical intensities (cathexes) are displaced from one element to another, so that it often happens that an element which was of little importance in the dream-thoughts appears as the clearest and accordingly most important feature of the manifest dream, and, vice versa, that essential elements of the dream-thoughts are represented in the manifest dream only by slight allusions. Moreover, as a rule the existence of quite insignificant points in common between two elements is enough to allow the dream-work to replace one by the other in all further operations. It will easily be imagined how greatly these mechanisms of condensation and displacement can increase the difficulty of interpreting a dream and of revealing the relations between the manifest dream and the latent dream-thoughts. From the evidence of the existence of these two tendencies to condensation and displacement our theory infers that in the unconscious id the energy is in a freely mobile state and that the id sets more store by the possibility of discharging quantities of excitation than by any other consideration;¹ and our theory makes use of these two peculiarities in defining the character of the primary process we have attributed to the id.

[1940a [1938], 4978]
In which of these systems, then, are we to locate the impetus to the construction of dreams? For simplicity's sake, in the system Ucs. It is true that in the course of our future discussion we shall learn that this is not entirely accurate, and that the process of forming dreams is obliged to attach itself to dream-thoughts belonging to the preconscious system. But when we consider the dream-wish, we shall find that the motive force for producing dreams is supplied by the Ucs.; and owing to this latter factor we shall take the unconscious system as the starting-point of dream-formation. Like all other thought structures, this dream-instigator will make an effort to advance into the Pcs. and from there to obtain access to consciousness.

It is best to begin by pointing out that the formation of a dream can be provoked in two different ways. Either, on the one hand, an instinctual impulse which is ordinarily suppressed (an unconscious wish) finds enough strength during sleep to make itself felt by the ego, or, on the other hand, an urge left over from waking life, a preconscious train of thought with all the conflicting impulses attached to it, finds reinforcement during sleep from an unconscious element. In short, dreams may arise either from the id or from the ego. The mechanism of dream-formation is in both cases the same and so also is the necessary dynamic precondition. The ego gives evidence of its original derivation from the id by occasionally ceasing its functions and allowing a reversion to an earlier state of things. This is logically brought about by its breaking off its relations with the external world and withdrawing its cathexes from the sense organs. We are justified in saying that there arises at birth an instinct to return to the intra-uterine life that has been abandoned - an instinct to sleep. Sleep is a return of this kind to the womb. Since the waking ego governs motility, that function is paralysed in sleep, and accordingly a good part of the inhibitions imposed on the unconscious id become superfluous. The withdrawal or reduction of these 'anticathexes' thus allows the id what is now a harmless amount of liberty.

The evidence of the share taken by the unconscious id in the formation of dreams is abundant and convincing. (a) Memory is far more comprehensive in dreams than in waking life. Dreams bring up recollections which the dreamer has forgotten, which are inaccessible to him when he is awake. (b) Dreams make an unrestricted use of linguistic symbols, the meaning of which is for the most part unknown to the dreamer. Our experience, however, enables us to confirm their sense. They probably originate from earlier phases in the development of speech. (c) Memory very often reproduces in dreams impressions from the dreamer's early childhood of which we can definitely assert not only that they had been forgotten but that they had become unconscious owing to repression. That explains the help - usually indispensable - given us by dreams in the attempts we make during the analytic treatment of neuroses to reconstruct the dreamer's early life. (d) Furthermore, dreams bring to light material which cannot have originated either from the dreamer's adult life or from his forgotten childhood. We are obliged to regard it as part of the archaic heritage which a child brings with him into the world, before any experience of his own, influenced by the experiences of his ancestors. We find the counterpart of this phylogenetic material in the earliest human legends and in surviving customs. Thus dreams constitute a source of human prehistory which is not to be despised.
It remains for us to give a dynamic explanation of why the sleeping ego takes on the task of the dream-work at all. The explanation is fortunately easy to find. With the help of the unconscious, every dream that is in process of formation makes a demand upon the ego - for the satisfaction of an instinct, if the dream originates from the id; for the solution of a conflict, the removal of a doubt or the forming of an intention, if the dream originates from a residue of preconscious activity in waking life. The sleeping ego, however, is focused on the wish to maintain sleep; it feels this demand as a disturbance and seeks to get rid of the disturbance. The ego succeeds in doing this by what appears to be an act of compliance: it meets the demand with what is in the circumstances a harmless fulfillment of a wish and so gets rid of it. This replacement of the demand by the fulfillment of a wish remains the essential function of the dream-work. It may perhaps be worth while to illustrate this by three simple examples - a hunger dream, a dream of convenience and a dream prompted by sexual desire. A need for food makes itself felt in a dreamer during his sleep: he has a dream of a delicious meal and sleeps on. The choice, of course, was open to him either of waking up and eating something or of continuing his sleep. He decided in favour of the latter and satisfied his hunger by means of the dream - for the time being, at all events, for if his hunger had persisted he would have had to wake up nevertheless. Here is the second example. A sleeper had to wake up so as to be in time for his work at the hospital. But he slept on, and had a dream that he was already at the hospital - but as a patient, who has no need to get up. Or again, a desire becomes active during the night for the enjoyment of a forbidden sexual object, the wife of a friend of the sleeper. He has a dream of sexual intercourse - not, indeed, with this person but with someone else of the same name to whom he is in fact indifferent; or his struggle against the desire may find expression in his mistress remaining altogether anonymous.

As the dream-work proceeds, sometimes the unconscious will press forward more successfully and sometimes the ego will defend itself with greater energy. Anxiety dreams are mostly those whose content has undergone the least distortion. If the demand made by the unconscious is too great for the sleeping ego to be in a position to fend it off by the means at its disposal, it abandons the wish to sleep and returns to waking life. We shall be taking every experience into account if we say that a dream is invariably an attempt to get rid of a disturbance of sleep by means of a wish-fulfillment, so that the dream is a guardian of sleep. The attempt may succeed more or less completely; it may also fail, and in that case the sleeper wakes up, apparently woken precisely by the dream. So, too, there are occasions when that excellent fellow the night-watchman, whose business it is to guard the little township's sleep, has no alternative but to sound the alarm and waken the sleeping townspeople.
When external nervous stimuli and internal somatic stimuli are intense enough to force psychical attention to themselves, then - provided that their outcome is dreaming and not waking up - they serve as a fixed point for the formation of a dream, a nucleus in its material; a wish-fulfilment is then looked for that shall correspond to this nucleus, just as (see above) intermediate ideas are looked for between two psychical dream stimuli. To that extent it is true that in a number of dreams the content of the dream is dictated by the somatic element. In this extreme instance it may even happen that a wish which is not actually a currently active one is called up for the sake of constructing a dream. A dream, however, has no alternative but to represent a wish in the situation of having been fulfilled; it is, as it were, faced with the problem of looking for a wish which can be represented as fulfilled by the currently active sensation. If this immediate material is of a painful or distressing kind, that does not necessarily mean that it cannot be used for the construction of a dream. The mind has wishes at its disposal whose fulfilment produces unpleasure. This seems self-contradictory; but it becomes intelligible when we take into account the presence of two psychical agencies and a censorship between them.

As we have seen, there are 'repressed' wishes in the mind, which belong to the first system and whose fulfilment is opposed by the second system. In saying that there are such wishes I am not making a historical statement to the effect that they once existed and were later abolished. The theory of repression, which is essential to the study of the psychoneuroses, asserts that these repressed wishes still exist - though there is a simultaneous inhibition which holds them down. Linguistic usage hits the mark in speaking of the 'suppression' of these impulses. The psychical arrangements that make it possible for such impulses to force their way to realization remain in being and in working order. Should it happen, however, that a suppressed wish of this kind is carried into effect, and that its inhibition by the second system (the system that is admissible to consciousness) is defeated, this defeat finds expression as unpleasure. In conclusion: if sensations of an unpleasurable nature arising from somatic sources occur during sleep, the dream-work makes use of that event in order to represent - subject to the continuance of the censorship to a greater or less degree - the fulfilment of some wish which is normally suppressed.

I cannot leave the subject of typical dreams of the death of loved relatives, without adding a few more words to throw light on their significance for the theory of dreams in general. In these dreams we find the highly unusual condition realized of a dream-thought formed by a repressed wish entirely eluding censorship and passing into the dream without modification. There must be special factors at work to make this event possible, and I believe that the occurrence of these dreams is facilitated by two such factors. Firstly, there is no wish that seems more remote from us than this one: 'we couldn't even dream' - so we believe - of wishing such a thing. For this reason the dream-censorship is not armed to meet such a monstrosity, just as Solon's penal code contained no punishment for parricide. Secondly, in this case the repressed and unsuspected wish is particularly often met half-way by a residue from the previous day in the form of a worry about the safety of the person concerned. This worry can only make its way into the dream by availing itself of the corresponding wish; while the wish can disguise itself behind the worry that has become active during the day. We may feel inclined to think that things are simpler than this and that one merely carries on during the night and in dreams with what one has been turning over in one's mind during the day; but if so we shall be leaving dreams of the death of people of whom the dreamer is fond completely in the air and without any connection with our explanation of dreams in general, and we shall thus be clinging quite unnecessarily to a riddle which is perfectly capable of solution.
Nor do I think we shall have any difficulty in recognizing the psychical force which manifests itself in the facts of dream-displacement. The consequence of the displacement is that the dream-content no longer resembles the core of the dream-thoughts and that the dream gives no more than a distortion of the dream-wish which exists in the unconscious. But we are already familiar with dream-distortion. We traced it back to the censorship which is exercised by one psychical agency in the mind over another. Dream-displacement is one of the chief methods by which that distortion is achieved. *Is fecit cui profuit.* We may assume, then, that dream-displacement comes about through the influence of the same censorship - that is, the censorship of endopsychic defence.¹

I have only a few more remarks to add on the subject of affect in dreams from another point of view. A dominating element in a sleeper's mind may be constituted by what we call a 'mood' - or tendency to some affect - and this may then have a determining influence upon his dreams. A mood of this kind may arise from his experiences or thoughts during the preceding day, or its sources may be somatic. In either case it will be accompanied by the trains of thought appropriate to it. From the point of view of dream-construction it is a matter of indifference whether, as sometimes happens, these ideational contents of the dream-thoughts determine the mood in a primary fashion, or whether they are themselves aroused secondarily by the dreamer's emotional disposition which is in its turn to be explained on a somatic basis. In any case the construction of dreams is subject to the condition that it can only represent something which is the fulfilment of a wish and that it is only from wishes that it can derive its psychical motive force. A currently active mood is treated in the same way as a sensation arising and becoming currently active during sleep (cf. p. 714), which can be either disregarded or given a fresh interpretation in the sense of a wish-fulfilment. Distressing moods during sleep can become the motive force of a dream by arousing energetic wishes which the dream is supposed to fulfill. The material to which moods are attached is worked over until it can be used to express the fulfilment of a wish. The more intense and dominating a part is played in the dream-thoughts by the distressing mood, the more certain it becomes that the most strongly suppressed wishful impulses will make use of the opportunity in order to achieve representation. For, since the unpleasure which they would otherwise necessarily produce themselves is already present, they find the harder part of their task - the task of forcing their way through to representation - already accomplished for them. Here once more we are brought up against the problem of anxiety-dreams; and these, as we shall find, form a marginal case in the function of dreaming.²

Like dreams, they are wish-fulfilments; like dreams, they are based to a great extent on impressions of infantile experiences; like dreams, they benefit by a certain degree of relaxation of censorship. If we examine their structure, we shall perceive the way in which the wishful purpose that is at work in their production has mixed up the material of which they are built, has rearranged it and has formed it into a new whole. They stand in much the same relation to the childhood memories from which they are derived as do some of the Baroque palaces of Rome to the ancient ruins whose pavements and columns have provided the material for the more recent structures.

¹[1900a, 780]
²[1900a, 927]
Having now repelled the objections that have been raised against us, or having at least indicated where our defensive weapons lie, we must no longer postpone the task of setting about the psychological investigations for which we have so long been arming ourselves. Let us summarize the principal findings of our enquiry so far as it has gone. Dreams are psychical acts of as much significance as any others; their motive force is in every instance a wish seeking fulfilment; the fact of their not being recognizable as wishes and their many peculiarities and absurdities are due to the influence of the psychical censorship to which they have been subjected during the process of their formation; apart from the necessity of evading this censorship, other factors which have contributed to their formation are a necessity for the condensation of their psychical material, a regard for the possibility of its being represented in sensory images and - though not invariably - a demand that the structure of the dream shall have a rational and intelligible exterior. Each of these propositions opens a way to fresh psychical postulates and speculations; the mutual relations between the wish which is the dream's motive force and the four conditions to which the dream's formation is subject, as well as the interrelations between the latter, require to be investigated; and the place of dreams in the nexus of mental life has to be assigned.

[1900a, 966]

The first thing that strikes us is that this apparatus, compounded of \( \Psi \)-systems, has a sense or direction. All our psychical activity starts from stimuli (whether internal or external) and ends in innervations. Accordingly, we shall ascribe a sensory and a motor end to the apparatus. At the sensory end there lies a system which receives perceptions; at the motor end there lies another, which opens the gateway to motor activity. Psychical processes advance in general from the perceptual end to the motor end. Thus the most general schematic picture of the psychical apparatus may be represented thus (Fig. 1):

[1900a, 970]

This, however, does no more than fulfil a requirement with which we have long been familiar, namely that the psychical apparatus must be constructed like a reflex apparatus. Reflex processes remain the model of every psychical function.

[1900a, 971]

We will describe the last of the systems at the motor end as 'the preconscious', to indicate that the excitatory processes occurring in it can enter consciousness without further impediment provided that certain other conditions are fulfilled: for instance, that they reach a certain degree of intensity, that the function which can only be described as 'attention' is distributed in a particular way, and so on. This is at the same time the system which holds the key to voluntary movement. We will describe the system that lies behind it as 'the unconscious', because it has no access to consciousness except via the preconscious, in passing through which its excitatory process is obliged to submit to modifications.¹

[1900a, 974]

In which of these systems, then, are we to locate the impetus to the construction of dreams? For simplicity's sake, in the system \( U_cs \). It is true that in the course of our future discussion we shall learn that this is not entirely accurate, and that the process of forming dreams is obliged to attach itself to dream-thoughts belonging to the preconscious system. But when we consider the dream-wish, we shall find that the motive force for producing dreams is supplied by the \( U_cs \); and owing to this latter factor we shall take the unconscious system as the starting-point of dream-formation. Like all other thought structures, this dream-instigator will make an effort to advance into the \( P_cs \) and from there to obtain access to consciousness.

[1900a, 974]
We must not delude ourselves into exaggerating the importance of these considerations. We have done no more than give a name to an inexplicable phenomenon. We call it 'regression' when in a dream an idea is turned back into the sensory image from which it was originally derived. But even this step requires justification. What is the point of this nomenclature if it teaches us nothing new? I believe the name 'regression' is of help to us in so far as it connects a fact that was already known to us with our schematic picture, in which the mental apparatus was given a sense or direction. And it is at this point that that picture begins to repay us for having constructed it. For an examination of it, without any further reflection, reveals a further characteristic of dream-formation. If we regard the process of dreaming as a regression occurring in our hypothetical mental apparatus, we at once arrive at the explanation of the empirically established fact that all the logical relations belonging to the dream-thoughts disappear during the dream-activity or can only find expression with difficulty. According to our schematic picture, these relations are contained not in the first Mnem. systems but in later ones; and in case of regression they would necessarily lose any means of expression except in perceptual images. *In regression the fabric of the dream-thoughts is resolved into its raw material.*

[1900a, 976]

I cannot offer any proof here that the truth is nevertheless otherwise; but I may say that I am strongly inclined to suppose that dream-wishes are more strictly determined. It is true that children's dreams prove beyond a doubt that a wish that has not been dealt with during the day can act as a dream-instigator. But it must not be forgotten that it is a *child's* wish, a wishful impulse of the strength proper to children. I think it is highly doubtful whether in the case of an adult a wish that has not been fulfilled during the day would be strong enough to produce a dream. It seems to me, on the contrary, that, with the progressive control exercised upon our instinctual life by our thought-activity, we are more and more inclined to renounce as unprofitable the formation or retention of such intense wishes as children know. It is possible that there are individual differences in this respect, and that some people retain an infantile type of mental process longer than others, just as there are similar differences in regard to the diminution of visual imagery, which is so vivid in early years. But in general, I think, a wish that has been left over unfulfilled from the previous day is insufficient to produce a dream in the case of an adult. I readily admit that a wishful impulse originating in the conscious will contribute to the instigation of a dream, but it will probably not do more than that. The dream would not materialize if the preconscious wish did not succeed in finding reinforcement from elsewhere.

[1900a, 984]
From the unconscious, in fact. My supposition is that a conscious wish can only become a dream-instigator if it succeeds in awakening an unconscious wish with the same tenor and in obtaining reinforcement from it. From indications derived from the psycho-analysis of the neuroses, I consider that these unconscious wishes are always on the alert, ready at any time to find their way to expression when an opportunity arises for allying themselves with an impulse from the conscious and for transferring their own great intensity on to the latter's lesser one.¹ It will then appear as though the conscious wish alone had been realized in the dream; only some small peculiarity in the dream’s configuration will serve as a finger-post to put us on the track of the powerful ally from the unconscious. These wishes in our unconscious, ever on the alert and, so to say, immortal, remind one of the legendary Titans, weighed down since primaeval ages by the massive bulk of the mountains which were once hurled upon them by the victorious gods and which are still shaken from time to time by the convulsion of their limbs. But these wishes, held under repression, are themselves of infantile origin, as we are taught by psychological research into the neuroses. I would propose, therefore, to set aside the assertion made just now, that the place of origin of dream-wishes is a matter of indifference and replace it by another one to the following effect: a wish which is represented in a dream must be an infantile one. In the case of adults it originates from the Ucs., in the case of children, where there is as yet no division or censorship between the Ucs. and the Pcs., or where that division is only gradually being set up, it is an unfulfilled, unrepressed wish from waking life. I am aware that this assertion cannot be proved to hold universally; but it can be proved to hold frequently, even in unsuspected cases, and it cannot be contradicted as a general proposition.

[1900a, 985]

Let us take one of the dreams I have already recorded - for instance, the one in which my friend Otto appeared with the signs of Graves’ disease. (See p. 746 ff.) I had been worried during the previous day by Otto’s looks; and, like everything else concerned with him, this worry affected me closely. And it pursued me, as I may assume, into my sleep. I was probably anxious to discover what could be wrong with him. This worry found expression during the night in the dream I have described, the content of which was in the first place nonsensical and in the second place was in no respect the fulfilment of a wish. I then began to investigate the origin of this inappropriate expression of the worry I had felt during the day, and by means of analysis I found a connection through the fact of my having identified my friend with a certain Baron L. and myself with Professor R. There was only one explanation of my having been obliged to choose this particular substitute for my daytime thought. I must have been prepared at all times in my Ucs. to identify myself with Professor R., since by means of that identification one of the immortal wishes of childhood - the megalomaniac wish - was fulfilled. Ugly thoughts hostile to my friend, which were certain to be repudiated during the day, had seized the opportunity of slipping through with the wish and getting themselves represented in the dream; but my daytime worry had also found some sort of expression in the content of the dream by means of a substitute. The daytime thought, which was not in itself a wish but on the contrary a worry, was obliged to find a connection in some way or other with an infantile wish which was now unconscious and suppressed, and which would enable it - suitably decocted, it is true - to 'originate' in consciousness. The more dominating was the worry, the more far-fetched a link could be established; there was no necessity for there being any connection whatever between the content of the wish and that of the worry, and in fact no such connection existed in our example.

[1900a, 988]
Unpleasurable dreams may also be ‘punishment-dreams’. It must be admitted that their recognition means in a certain sense a new addition to the theory of dreams. What is fulfilled in them is equally an unconscious wish, namely a wish that the dreamer may be punished for a repressed and forbidden wishful impulse. To that extent dreams of this kind fall in with the condition that has been laid down here that the motive force for constructing a dream must be provided by a wish belonging to the unconscious. A closer psychological analysis, however, shows how they differ from other wishful dreams. In the cases forming Group B the dream-constructing wish is an unconscious one and belongs to the repressed, while in punishment-dreams, though it is equally an unconscious one, it must be reckoned as belonging not to the repressed but to the ‘ego.’ Thus punishment-dreams indicate the possibility that the ego may have a greater share than was supposed in the construction of dreams. The mechanism of dream-formation would in general be greatly clarified if instead of the opposition between ‘conscious’ and ‘unconscious’ we were to speak of that between the ‘ego’ and the ‘repressed.’ This cannot be done, however, without taking account of the processes underlying the psychoneuroses, and for that reason it has not been carried out in the present work. I will only add that punishment-dreams are not in general subject to the condition that the day's residues shall be of a distressing kind. On the contrary, they occur most easily where the opposite is the case - where the day's residues are thoughts of a satisfying nature but the satisfaction which they express is a forbidden one. The only trace of these thoughts that appears in the manifest dream is their diametric opposite, just as in the case of dreams belonging to Group A. The essential characteristic of punishment-dreams would thus be that in their case the dream-constructing wish is not an unconscious wish derived from the repressed (from the system Ucs.), but a punitive one reacting against it and belonging to the ego, though at the same time an unconscious (that is to say, preconscious) one.¹

I am now in a position to give a precise account of the part played in dreams by the unconscious wish. I am ready to admit that there is a whole class of dreams the instigation to which arises principally or even exclusively from the residues of daytime life; and I think that even my wish that I might at long last become a Professor Extraordinarius might have allowed me to sleep through the night in peace if my worry over my friend's health had not still persisted from the previous day. But the worry alone could not have made a dream. The motive force which the dream required had to be provided by a wish; it was the business of the worry to get hold of a wish to act as the motive force of the dream.

The position may be explained by an analogy. A daytime thought may very well play the part of entrepreneur for a dream; but the entrepreneur, who, as people say, has the idea and the initiative to carry it out, can do nothing without capital; he needs a capitalist who can afford the outlay, and the capitalist who provides the psychical outlay for the dream is invariably and indisputably, whatever may be the thoughts of the previous day, a wish from the unconscious.¹

Sometimes the capitalist is himself the entrepreneur, and indeed in the case of dreams this is the commoner event: an unconscious wish is stirred up by daytime activity and proceeds to construct a dream. So, too, the other possible variations in the economic situation that I have taken as an analogy have their parallel in dream-processes. The entrepreneur may himself make a small contribution to the capital; several entrepreneurs may apply to the same capitalist; several capitalists may combine to put up what is necessary for the entrepreneur. In the same way, we come across dreams that are supported by more than one dream-wish; and so too with other similar variations, which could easily be run through, but which would be of no further interest to us. We must reserve until later what remains to be said of the dream-wish.
The *tertium comparationis* in the analogy that I have just used - the quantity put at the disposal of the *entrepreneur* in an appropriate amount - is capable of being applied in still greater detail to the purpose of elucidating the structure of dreams. In most dreams it is possible to detect a central point which is marked by peculiar sensory intensity, as I have shown on p. 778. This central point is as a rule the direct representation of the wish-fulfilment, for, if we undo the displacements brought about by the dream-work, we find that the *psychical* intensity of the elements in the dream-thoughts has been replaced by the *sensory* intensity of the elements in the content of the actual dream. The elements in the *neighbourhood* of the wish-fulfilment often have nothing to do with its meaning, but turn out to be derivatives of distressing thoughts that run contrary to the wish. But owing to their being in what is often an artificially established connection with the central element, they have acquired enough intensity to become capable of being represented in the dream. Thus the wish-fulfilment's power of bringing about representation is diffused over a certain sphere surrounding it, within which all the elements - including even those possessing no means of their own - become empowered to obtain representation. In the case of dreams that are actuated by *several* wishes, it is easy to delimit the spheres of the different wish-fulfillments, and gaps in the dream may often be understood as frontier zones between those spheres.

[1900a, 992]

Though the preceding considerations have reduced the importance of the part played by the day's residues in dreams, it is worth while devoting a little more attention to them. It must be that they are essential ingredients in the formation of dreams, since experience has revealed the surprising fact that in the content of every dream some link with a recent daytime impression - often of the most insignificant sort - is to be detected. We have not hitherto been able to explain the necessity for this addition to the mixture that constitutes a dream (see p. 669). And it is only possible to do so if we bear firmly in mind the part played by the unconscious wish and then seek for information from the psychology of the neuroses. We learn from the latter that an unconscious idea is as such quite incapable of entering the preconscious and that it can only exercise any effect there by establishing a connection with an idea which already belongs to the preconscious, by transferring its intensity on to it and by getting itself 'covered' by it. Here we have the fact of 'transference', which provides an explanation of so many striking phenomena in the mental life of neurotics. The preconscious idea, which thus acquires an undeserved degree of intensity may either be left unaltered by the transference, or it may have a modification forced upon it, derived from the content of the idea which effects the transference. I hope I may be forgiven for drawing analogies from everyday life, but I am tempted to say that the position of a repressed idea resembles that of an American dentist in this country: he is not allowed to set up in practice unless he can make use of a legally qualified medical practitioner to serve as a stalking-horse and to act as a 'cover' in the eyes of the law. And just as it is not exactly the physicians with the largest practices who form alliances of this kind with dentists, so in the same way preconscious or conscious ideas which have already attracted a sufficient amount of the attention that is operating in the preconscious will not be the ones to be chosen to act as covers for a repressed idea. The unconscious prefers to weave its connections round preconscious impressions and ideas which are either indifferent and have thus had no attention paid to them, or have been rejected and have thus had attention promptly withdrawn from them. It is a familiar article in the doctrine of association, and one that is entirely confirmed by experience, that an idea which is bound by a very intimate tie in one direction, tends, as it were, to repel whole groups of new ties. I once attempted to base a theory of hysterical paralyses on this proposition. [1900a, 993]
We have so far been studying dream-wishes: we have traced them from their origin in the region of the Ucs. and have analysed their relations to the day's residues, which in their turn may either be wishes or psychical impulses of some other kind or simply recent impressions. In this way we have allowed room for every claim that may be raised by any of the multifarious waking thought-activities on behalf of the importance of the part played by them in the process of constructing dreams. It is not impossible, even, that our account may have provided an explanation of the extreme cases in which a dream, pursuing the activities of daytime, arrives at a happy solution of some unsolved problem of waking life. All we need is an example of this kind, so that we might analyse it and trace the source of the infantile or repressed wishes whose help has been enlisted and has reinforced the efforts of preconscious activity with such success. But all this has not brought us a step nearer to solving the riddle of why it is that the unconscious has nothing else to offer during sleep but the motive force for the fulfilment of a wish. The answer to this question must throw light upon the psychical nature of wishes, and I propose to give the answer by reference to our schematic picture of the psychical apparatus.

³ [Footnote added 1914:] I have elsewhere carried this train of thought further in a paper on the two principles of mental functioning (Freud 1911b) - the pleasure principle and the reality principle, as I have proposed calling them.

We are now well on the way to proceeding further with the erection of the psychological scaffolding, which we stopped at the point at which we introduced the two systems Ucs. and Pcs. But there are reasons for continuing a little with our consideration of wishes as the sole psychical motive force for the construction of dreams. We have accepted the idea that the reason why dreams are invariably wish-fulfillments is that they are products of the system Ucs., whose activity knows no other aim than the fulfilment of wishes and which has at its command no other forces than wishful impulses. If we insist, for even a moment longer, upon our right to base such far-reaching psychological speculations upon the interpretation of dreams, we are in duty found to prove that those speculations have enabled us to insert dreams into a nexus which can include other psychical structures as well. If such a thing as a system Ucs. exists (or something analogous to it for the purposes of our discussion), dreams cannot be its only manifestation; every dream may be a wish-fulfilment, but apart from dreams there must be other forms of abnormal wish-fulfillments. And it is a fact that the theory governing all psychoneurotic symptoms culminates in a single proposition, which asserts that they too are to be regarded as fulfilments of unconscious wishes.¹ Our explanation makes the dream only the first member of a class which is of the greatest significance to psychiatrists and an understanding of which implies the solution of the purely psychological side of the problem of psychiatry.²

The fact that dreams are hypermnestic and have access to material from childhood has become one of the corner-stones of our teaching. Our theory of dreams regards wishes originating in infancy as the indispensable motive force for the formation of dreams.
We have no difference of opinion over the functions that are to be assigned to dreams. The view that dreams act as a safety valve to the mind and that, in the words of Robert, all kinds of harmful things are made harmless by being presented in a dream - not only does this view coincide exactly with our theory of the double wish-fulfilment brought about by dreams, but the way in which it is phrased is more intelligible to us than to Robert himself. The view that the mind has free play in its functioning in dreams is represented in our theory by the fact of the preconscious activity allowing dreams to take their course. Such phrases as 'the return of the mind in dreams to an embryonic point of view' or the words used by Havelock Ellis to describe dreams - 'an archaic world of vast emotions and imperfect thoughts' - strike us as happy anticipations of our own assertions that primitive modes of activity which are suppressed during the day are concerned in the construction of dreams. We have been able to accept entirely as our own what Sully has written: 'Our dreams are a means of conserving these successive personalities. When asleep we go back to the old ways of looking at things and of feeling about them, to impulses and activities which long ago dominated us'. For us no less than for Delage what has been 'suppressed' has become 'the motive force of dreams.'

[1900a, 1018]

We accordingly borrow the following thesis from the theory of hysteria: a normal train of thought is only submitted to abnormal psychical treatment of the sort we have been describing if an unconscious wish, derived from infancy and in a state of repression has been transferred on to it. In accordance with this thesis we have constructed our theory of dreams on the assumption that the dream-wish which provides the motive power invariably originates from the unconscious - an assumption which, as I myself am ready to admit, cannot be proved to hold generally, though neither can it be disproved. But in order to explain what is meant by 'repression', a term with which we have already made play so many times, it is necessary to proceed a stage further with our psychological scaffolding.

[1900a, 1025]

We have already explored the fiction of a primitive psychical apparatus whose activities are regulated by an effort to avoid an accumulation of excitation and to maintain itself so far as possible without excitation. For that reason it is built upon the plan of a reflex apparatus. The power of movement, which is in the first instance a means of bringing about internal alterations in its body, is at its disposal as the path to discharge. We went on to discuss the psychical consequences of an 'experience of satisfaction'; and in that connection we were already able to add a second hypothesis, to the effect that the accumulation of excitation (brought about in various ways that need not concern us) is felt as unpleasure and that it sets the apparatus in action with a view to repeating the experience of satisfaction, which involved a diminution of excitation and was felt as pleasure. A current of this kind in the apparatus, starting from unpleasure and aiming at pleasure, we have termed a 'wish'; and we have asserted that only a wish is able to set the apparatus in motion and that the course of the excitation in it is automatically regulated by feelings of pleasure and unpleasure. The first wishing seems to have been a hallucinatory cathecting of the memory of satisfaction. Such hallucinations, however, if they were not to be maintained to the point of exhaustion, proved to be inadequate to bring about the cessation of the need or, accordingly, the pleasure attaching to satisfaction.

[1900a, 1025]
A second activity - or, as we put it, the activity of a second system - became necessary, which would not allow the mnemic cathexis to proceed as far as perception and from there to bind the psychical forces; instead, it diverted the excitation arising from the need along a roundabout path which ultimately, by means of voluntary movement, altered the external world in such a way that it became possible to arrive at a real perception of the object of satisfaction. We have already outlined our schematic picture of the psychical apparatus up to this point; the two systems are the germ of what, in the fully developed apparatus, we have described as the Ucs. and Pcs.

In order to be able to employ the power of movement to make alterations in the external world that shall be effective, it is necessary to accumulate a great number of experiences in the mnemic systems and a multiplicity of permanent records of the associations called up in this mnemic material by different purposive ideas. We can now carry our hypotheses a step further. The activity of this second system, constantly feeling its way, and alternately sending out and withdrawing cathexes, needs on the one hand to have the whole of the material of memory freely at its command; but on the other hand it would be an unnecessary expenditure of energy if it sent out large quantities of cathexis along the various paths of thought and thus caused them to drain away to no useful purpose and diminish the quantity available for altering the external world. I therefore postulate that for the sake of efficiency the second system succeeds in retaining the major part of its cathexes of energy in a state of quiescence and in employing only a small part on displacement. The mechanics of these processes are quite unknown to me; anyone who wished to take these ideas seriously would have to look for physical analogies to them and find a means of picturing the movements that accompany excitation of neurones. All that I insist upon is the idea that the activity of the first $Ψ$-system is directed towards securing the free discharge of the quantities of excitation, while the second system, by means of the cathexes emanating from it, succeeds in inhibiting this discharge and in transforming the cathexis into a quiescent one, no doubt with a simultaneous raising of its level. I presume, therefore, that under the dominion of the second system the discharge of excitation is governed by quite different mechanical conditions from those in force under the dominion of the first system. When once the second system has concluded its exploratory thought-activity, it releases the inhibition and damming-up of the excitations and allows them to discharge themselves in movement.

The theory of the psychoneuroses asserts as an indisputable and invariable fact that only sexual wishful impulses from infancy, which have undergone repression (i.e. a transformation of their affect) during the developmental period of childhood, are capable of being revived during later developmental periods (whether as a result of the subject's sexual constitution, which is derived from an initial bisexuality, or as a result of unfavourable influences acting upon the course of his sexual life) and are thus able to furnish the motive force for the formation of psychoneurotic symptoms of every kind. It is only by reference to these sexual forces that we can close the gaps that are still patent in the theory of repression. I will leave it an open question whether these sexual and infantile factors are equally required in the theory of dreams: I will leave that theory incomplete at this point, since I have already gone a step beyond what can be demonstrated in assuming that dream-wishes are invariably derived from the unconscious.¹ Nor do I propose to enquire further into the nature of the distinction between the play of psychical forces in the formation of dreams and in that of hysterical symptoms: we are still without a sufficiently accurate knowledge of one of the two objects of the comparison.

[1900a, 1026]
Now that we have established the concept of repression and have brought dream-distortion into relation with repressed psychical material, we can express in general terms the principal finding to which we have been led by the analysis of dreams. In the case of dreams which are intelligible and have a meaning, we have found that they are undisguised wish-fulfilments; that is, that in their case the dream-situation represents as fulfilled a wish which is known to consciousness, which is left over from daytime life, and which is deservedly of interest. Analysis has taught us something entirely analogous in the case of obscure and confused dreams: once again the dream-situation represents a wish as fulfilled - a wish which invariably arises from the dream-thoughts, but one which is represented in an unrecognizable form and can only be explained when it has been traced back in analysis. The wish in such cases is either itself a repressed one and alien to consciousness, or it is intimately connected with repressed thoughts and is based upon them. Thus the formula for such dreams is as follows: they are disguised fulfilments of repressed wishes. It is interesting in this connection to observe that the popular belief that dreams always foretell the future is confirmed. Actually the future which the dream shows us is not the one which will occur but the one which we should like to occur. The popular mind is behaving here as it usually does: what it wishes, it believes.

No one who accepts the view that the censorship is the chief reason for dream-distortion will be surprised to learn from the results of dream-interpretation that most of the dreams of adults are traced back by analysis to erotic wishes. This assertion is not aimed at dreams with an undisguised sexual content, which are no doubt familiar to all dreamers from their own experience and are as a rule the only ones to be described as 'sexual dreams.' Even dreams of this latter kind offer enough surprises in their choice of the people whom they make into sexual objects, in their disregard of all the limitations which the dreamer imposes in his waking life upon his sexual desires, and by their many strange details, hinting at what are commonly known as 'perversions.' A great many other dreams, however, which show no sign of being erotic in their manifest content, are revealed by the work of interpretation in analysis as sexual wish-fulfilments; and, on the other hand, analysis proves that a great many of the thoughts left over from the activity of waking life as 'residues of the previous day' only find their way to representation in dreams through the assistance of repressed erotic wishes.

At this point I shall interrupt my report of the analysis in order to compare this small piece of dream-interpretation with the general statements I have made upon the mechanism of the formation of dreams. I argued in my book, The Interpretation of Dreams (1900), that every dream is a wish which is represented as fulfilled, that the representation acts as a takes disguise if the wish is a repressed one, belonging to the unconscious, and that except in the case of children's dreams only an unconscious wish or one which reaches down into the unconscious has the force necessary for the formation of a dream. I fancy my theory would have been more certain of general acceptance if I had contented myself with maintaining that every dream had a meaning, which could be discovered by means of a certain process of interpretation; and that when the interpretation had been completed the dream could be replaced by thoughts which would fall into place at an easily recognizable point in the waking mental life of the dreamer. I might then have gone on to say that the meaning of a dream turned out to be of as many different sorts as the processes of waking thought; that in one case it would be a fulfilled wish, in another a realized fear, or again a reflection persisting on into sleep, or an intention (as in the instance of Dora's dream), or a piece of creative thought during sleep, and so on. Such a theory would no doubt have proved attractive from its very simplicity, and it might have been supported by a great many examples of dreams that had been satisfactorily interpreted, as for instance by the one which has been analysed in these pages.
The dream from the analysis of which we have derived this information corresponded, as we have seen, to an intention which Dora carried with her into her sleep. It was therefore repeated each night until the intention had been carried out; and it reappeared years later when an occasion arose for forming an analogous intention. The intention might have been consciously expressed in some such words as these: 'I must fly from this house, for I see that my virginity is threatened here; I shall go away with my father, and I shall take precautions not to be surprised while I am dressing in the morning.' These thoughts were clearly expressed in the dream; they formed part of a mental current which had achieved consciousness and a dominating position in waking life. Behind them can be discerned obscure traces of a train of thought which formed part of a contrary current and had consequently been suppressed. This other train of thought culminated in the temptation to yield to the man, out of gratitude for the love and tenderness he had shown her during the last few years, and it may perhaps have revived the memory of the only kiss she had so far had from him. But according to the theory which I developed in my Interpretation of Dreams such elements as these are not enough for the formation of a dream. On that theory a dream is not an intention represented as having been carried out, but a wish represented as having been fulfilled, and, moreover, in most cases a wish dating from childhood. It is our business now to discover whether this principle may not be contradicted by the present dream.

I have made one or two observations in my Interpretation of Dreams on the relation between the waking thoughts which are continued into sleep (the 'day's residues') and the unconscious wish which forms the dream. I will quote them here as they stand, for I have nothing to add to them, and the analysis of this dream of Dora's proves afresh that the facts are as I have supposed: 'I am ready to admit that there is a whole class of dreams the instigation to which arises principally or even exclusively from the residues of daytime life; and I think that even my wish that I might at long last become a Professor Extraordinarius¹ might have allowed me to sleep through the night in peace if my worry over my friend's health had not still persisted from the previous day. But the worry alone could not have made a dream. The motive force which the dream required had to be provided by a wish; it was the business of the worry to get hold of a wish to act as the motive force of the dream.

'The position may be explained by an analogy. A daytime thought may very well play the part of entrepeneur for a dream; but the entrepeneur, who, as people say, has the idea and the initiative to carry it out, can do nothing without capital; he needs a capitalist who can afford the outlay, and the capitalist who provides the psychical outlay for the dream is invariably and indisputably, whatever may be the thoughts of the previous day, a wish from the unconscious.'

¹ Professor Extraordinarius is a rank in German universities denoting an assistant professor position.
I add a few remarks which may help towards the synthesis of this dream. The dream-work began on the afternoon of the day after the scene in the wood, after Dora had noticed that she was no longer able to lock the door of her room. She then said to herself: 'I am threatened by a serious danger here,' and formed her intention of not stopping on in the house alone but of going off with her father. This intention became capable of forming a dream, because it succeeded in finding a continuation in the unconscious. What corresponded to it there was her summoning up her infantile love for her father as a protection against the present temptation. The change which thus took place in her became fixed and brought her into the attitude shown by her supervalent train of thought - jealousy of Frau K. on her father's account, as though she herself were in love with him. There was a conflict within her between a temptation to yield to the man's proposal and a composite force rebelling against that feeling. This latter force was made up of motives of respectability and good sense, of hostile feelings caused by the governess's disclosures (jealousy and wounded pride, as we shall see later), and of a neurotic element, namely, the tendency to a repudiation of sexuality which was already present in her and was based on her childhood history. Her love for her father, which she summoned up to protect her against the temptation, had its origin in this same childhood history.

[1905e, 1424]

The application of a few of the rules of dream-interpretation to Hanold's first dream has thus resulted in making it intelligible to us in its main features and in inserting it into the nexus of the story. Surely, then, the author must have observed these rules in creating it? We might ask another question, too: why did the author introduce a dream at all to bring about the further development of the delusion? In my opinion it was an ingenious notion and once again true to reality. We have already heard that in real illnesses a delusion very often arises in connection with a dream, and, after what we have learnt about the nature of dreams, there is no need to see a fresh riddle in this fact. Dreams and delusions arise from the same source - from what is repressed. Dreams are, as one might say, the physiological delusions of normal people. Before what is repressed has become strong enough to break through into waking life as a delusion, it may easily have achieved a first success, under the more favourable conditions of the state of sleep, in the form of a dream with persisting effects. For during sleep, along with a general lowering of mental activity, there is a relaxation in the strength of the resistance with which the dominant psychical forces oppose what is repressed. It is this relaxation that makes the formation of dreams possible, and that is why dreams give us our best access to a knowledge of the unconscious part of the mind - except that, as a rule, with the re-establishment of the psychical cathexes of waking life, the dream once more takes to flight and the ground that had been won by the unconscious is evacuated once again.

[1907a, 1858]
We would seem to have reached the end. But an attentive reader might remind us that at the beginning we threw out an assertion that dreams are wishes represented as fulfilled and that we gave no proof of this. Well, is our reply, what we have described in these pages might show how little justification there is for trying to cover the explanations we have to give of dreams with the single formula that dreams are wish-fulfilments. Nevertheless the assertion stands and can easily be proved too for the dreams in *Gradiva*. The latent dream-thoughts - we know now what is meant by them - may be of the most various kinds; in *Gradiva* they are 'days' residues', thoughts that have been left over unnoticed and undealt-with from the mental activities of waking life. But in order for a dream to develop out of them, the co-operation of a wish (usually an unconscious one) is required; this contributes the motive force for constructing the dream, while the day's residues provide the material. In Norbert Hanold's first dream two wishes competed with each other in making the dream; one of them was actually admissible to consciousness, while the other belonged to the unconscious and operated from out of repression. The first was a wish, understandable in any archaeologist, to have been present as an eye-witness at the catastrophe in the year 79 A.D. What sacrifice would an archaeologist think too great if this wish could be realized in any way other than in a dream! The other wish, the other constructor of the dream, was of an erotic nature: it might be crudely and also incompletely stated as a wish to be there when the girl he loved lay down to sleep. This was the wish the rejection of which caused the dream to become an anxiety-dream. The wishes that were the motive forces of the second dream are perhaps less conspicuous; but if we recall its translation we shall not hesitate to describe them too as erotic. The wish to be taken captive by the girl he loved, to fall in with her wishes and to be subjected to her - for so we may construe the wish behind the situation of the lizard-catching - was in fact of a passive, masochistic character. Next day the dreamer hit the girl, as though he was dominated by the contrary erotic current . . . But we must stop here, or we may really forget that Hanold and Gradiva are only creatures of their author's mind.

Let me now proceed with my account of our findings. In another set of cases psycho-analytic investigation traces the symptoms back, it is true, not to sexual experiences but to commonplace traumatic ones. But this distinction loses its significance owing to another circumstance. For the work of analysis required for the thorough explanation and complete recovery of a case never comes to a stop at events that occurred at the time of the onset of the illness, but invariably goes back to the patient's puberty and early childhood; and it is only there that it comes upon the impressions and events which determined the later onset of the illness. It is only experiences in childhood that explain susceptibility to later traumas and it is only by uncovering these almost invariably forgotten memory-traces and by making them conscious that we acquire the power to get rid of the symptoms. And here we reach the same conclusion as in our investigation of dreams: the imperishable, repressed wishful impulses of childhood alone provided the power for the construction of symptoms, and without them the reaction to later traumas would have taken a normal course. But these powerful wishful impulses of childhood may without exception be described as sexual.

[1907a, 1884]

[1910a, 2228]
We cannot proceed any further in explaining the formation of dreams till we have overcome certain difficulties. The narcissism of the state of sleep implies a withdrawal of cathexis from all ideas of objects, from both the unconscious and the preconscious portions of those ideas. If, then, certain day's residues have retained their cathexis, we hesitate to suppose that they have acquired at night so much energy as to compel notice on the part of consciousness; we should be more inclined to suppose that the cathexis they have retained is far weaker than that which they possessed during the day. Here analysis saves us further speculation, for it shows that these day's residues must receive a reinforcement which has its source in unconscious instinctual impulses if they are to figure as constructors of dreams. This hypothesis presents no immediate difficulties, for we have every reason to suppose that in sleep the censorship between the Pcs. and the Ucs. is greatly reduced, so that communication between the two systems is made easier.

The possibility mentioned above - that some of the preconscious thoughts of the day may also prove resistant and retain a part of their cathexis - must be recognized as a second breach in narcissism. At bottom, the two cases may be identical. The resistance of the day's residues may originate in a link with unconscious impulses which is already in existence during waking life; or the process may be somewhat less simple, and the day's residues which have not been wholly emptied of cathexis may establish a connection with the repressed material only after the state of sleep has set in, thanks to the easing of communication between the Pcs. and the Ucs. In both cases there follows the same decisive step in dream-formation: the preconscious dream-wish is formed, which gives expression to the unconscious impulse in the material of the preconscious day's residues. This dream-wish must be sharply distinguished from the day's residues; it need not have existed in waking life and it may already display the irrational character possessed by everything that is unconscious when we translate it into the conscious. Again, the dream-wish must not be confused with the wishful impulses which may have been present, though they certainly need not necessarily be present, amongst the preconscious (latent) dream-thoughts. If, however, there were any such preconscious wishes, the dream-wish associates itself with them, as a most effective reinforcement of them.

We have now to consider the further vicissitudes undergone by this wishful impulse, which in its essence represents an unconscious instinctual demand and which has been formed in the Pcs. as a dream-wish (a wish-fulfilling phantasy). Reflection tells us that this wishful impulse may be dealt with along three different paths. It may follow the path that would be normal in waking life, by pressing from the Pcs. to consciousness; or it may bypass the Cs. and find direct motor discharge; or it may take the unexpected path which observation enables us in fact to trace. In the first case, it would become a delusion having as content the fulfilment of the wish; but in the state of sleep this never happens. With our scanty knowledge of the metapsychological conditions of mental processes, we may perhaps take this fact as a hint that a complete emptying of a system renders it little susceptible to instigation. The second case, that of direct motor discharge, should be excluded by the same principle; for access to motility normally lies yet another step beyond the censorship of consciousness. But we do meet with exceptional instances in which this happens, in the form of somnambulism. We do not know what conditions make this possible, or why it does not happen more often. What actually happens in dream-formation is a very remarkable and quite unforeseen turn of events. The process, begun in the Pcs. and reinforced by the Ucs., pursues a backward course, through the Ucs. to perception, which is pressing upon consciousness. This regression is the third phase of dream-formation. For the sake of clarity, we will repeat the two earlier ones: the reinforcement of the Pcs. by the Ucs., and the setting up of the dream-wish.
The only essential thing about dreams is the dream-work that has influenced the thought-material. We have no right to ignore it in our theory, even though we may disregard it in certain practical situations. Analytic observation shows further that the dream-work never restricts itself to translating these thoughts into the archaic or regressive mode of expression that is familiar to you. In addition, it regularly takes possession of something else, which is not part of the latent thoughts of the previous day, but which is the true motive force for the construction of the dream. This indispensable addition is the equally unconscious wish for the fulfilment of which the content of the dream is given its new form. A dream may thus be any sort of thing in so far as you are only taking into account the thoughts it represents - a warning, an intention, a preparation, and so on; but it is always also the fulfilment of an unconscious wish and, if you are considering it as a product of the dream-work, it is only that. A dream is therefore never simply an intention, or a warning, but always an intention, etc., translated into the archaic mode of thought by the help of an unconscious wish and transformed to fulfil that wish. The one characteristic, the wish-fulfilment, is the invariable one; the other may vary. It may for its part once more be a wish, in which case the dream will, with the help of an unconscious wish, represent as fulfilled a latent wish of the previous day.

[1916-1917, 3311]

The fresh consideration I wish to bring before you is to draw your attention to the latent dream-thoughts which have now been put in the foreground. I beg you not to forget that in the first place they are unconscious to the dreamer, and secondly that they are completely rational and coherent so that they can be understood as natural reactions to the precipitating cause of the dream, and thirdly that they can be the equivalent of any mental impulse or intellectual operation. I shall now describe these thoughts more strictly than before as the 'day's residues', whether the dreamer confesses to them or not. I shall now distinguish between the day's residues and the latent dream-thoughts, and, in conformity with our earlier usage, I shall designate as latent dream-thoughts everything we learn in interpreting the dream, whereas the day's residues are only a portion of the latent dream-thoughts. Our view is then that something is added to the day's residues, something that was also part of the unconscious, a powerful but repressed wishful impulse; and it is this alone that makes the construction of the dream possible. The influence of this wishful impulse on the day's residues creates the further portion of the latent dream-thoughts - that which need no longer appear rational and intelligible as being derived from waking life.

[1916-1917, 3313]

I have made use of an analogy for the relation of the day's residues to the unconscious wish, and I can only repeat it here. In every undertaking there must be a capitalist who covers the required outlay and an entrepreneur who has the idea and knows how to carry it out. In the construction of dreams, the part of the capitalist is always played by the unconscious wish alone; it provides the psychical energy for the construction of the dream. The entrepreneur is the day's residues, which decide how this outlay is to be employed. It is possible, of course, for the capitalist himself to have the idea and the expert knowledge or for the entrepreneur himself to possess capital. This simplifies the practical situation but makes its theoretical understanding more difficult. In economics the same person is constantly divided into his two aspects of capitalist and entrepreneur and this restores the fundamental situation on which our analogy was based. In dream-construction the same variations occur and I will leave them for you to follow out.

[1916-1917, 3313]
And now I have reached the point I wish to put before you. We have endeavoured to maintain the strictest impartiality and have allowed two conceptions of the dream to rank as equally probable and equally unproved. According to the first the dream is a reaction to a telepathic message: 'your daughter has just brought twins into the world.' According to the second an unconscious process of thought underlies the dream, which may be reproduced somewhat as follows: 'To-day is the day the confinement should take place if the young people in Berlin are really out in their reckoning by a month, as I suspect. And if my (first) wife were still alive, she certainly would not be content with one grandchild. To please her there would have to be at least twins!' If this second view is right, no new problems arise. It is simply a dream like any other. The (preconscious) dream-thoughts as outlined above are reinforced by the (unconscious) wish that no other than the daughter should be the dreamer's second wife, and thus the manifest dream as described to us arises.

[1922a, 3886]

If you prefer to assume that a telepathic message about the daughter's confinement reached the sleeper, further questions arise of the relation of a message such as this to a dream and of its influence on the formation of dreams. The answer is not far to seek and is quite unambiguous. A telepathic message will be treated as a portion of the material that goes to the formation of a dream, like any other external or internal stimulus, like a disturbing noise in the street or an insistent organic sensation in the sleeper's own body. In our example it is evident how the message, with the help of a lurking repressed wish, became remodelled into a wish-fulfilment; it is unfortunately less easy to show that it combined with other material that had become active at the same time and was blended into a dream. Telepathic messages - if we are justified in recognizing their existence - can thus make no alteration in the process of forming a dream; telepathy has nothing to do with the nature of dreams. And in order to avoid the impression that I am trying to conceal a vague notion behind abstract and fine-sounding words, I am willing to repeat: the essential nature of dreams consists in the peculiar process of 'dream-work' which, with the help of an unconscious wish, carries the preconscious thoughts (day's residues) over into the manifest content of the dream. The problem of telepathy concerns dreams as little as does the problem of anxiety.

[1922a, 3887]

There remains one element of the apparently intimate connection between telepathy and dreams which is not affected by any of these considerations: namely, the incontestable fact that sleep creates favourable conditions for telepathy. Sleep is not, it is true, indispensable to the occurrence of telepathic processes - whether they originate in messages or in unconscious activity. If you are not already aware of this, you will learn it from the instance given by our second correspondent, of the young man's message which came between nine and ten in the morning. We must add, however, that no one has a right to take exception to telepathic occurrences if the event and the intimation (or message) do not exactly coincide in astronomical time. It is perfectly conceivable that a telepathic message might arrive contemporaneously with the event and yet only penetrate to consciousness the following night during sleep (or even in waking life only after a while, during some pause in the activity of the mind). We are, as you know, of opinion that dream-formation itself does not necessarily wait for the onset of sleep before it begins. Often the latent dream-thoughts may have been being got ready during the whole day, till at night they find the contact with the unconscious wish that shapes them into a dream. But if the phenomenon of telepathy is only an activity of the unconscious mind, then, of course, no fresh problem lies before us. The laws of unconscious mental life may then be taken for granted as applying to telepathy.

[1922a, 3897]
The Dynamic Theory of Dream-Formation. The motive power for the formation of dreams is not provided by the latent dream-thoughts or day's residues, but by an unconscious impulse, repressed during the day, with which the day's residues have been able to establish contact and which contrives to make a wish-fulfilment for itself out of the material of the latent thoughts. Thus every dream is on the one hand the fulfilment of a wish on the part of the unconscious and on the other hand (in so far as it succeeds in guarding the state of sleep against being disturbed) the fulfilment of the normal wish to sleep which set the sleep going. If we disregard the unconscious contribution to the formation of the dream and limit the dream to its latent thoughts, it can represent anything with which waking life has been concerned - a reflection, a warning, an intention, a preparation for the immediate future or, once again, the satisfaction of an unfulfilled wish. The unrecognizability, strangeness and absurdity of the manifest dream are partly the result of the translation of the thoughts into a different, so to say archaic, method of expression, but partly the effect of a restrictive, critically disapproving agency in the mind which does not entirely cease to function during sleep. It is plausible to suppose that the 'dream-censorship', which we regard as being responsible in the first instance for the distortion of the dream-thoughts into the manifest dream, is an expression of the same mental forces which during the day-time had held back or repressed the unconscious wishful impulse.

It is possible to distinguish between dreams from above and dreams from below, provided the distinction is not made too sharply. Dreams from below are those which are provoked by the strength of an unconscious (repressed) wish which has found a means of being represented in some of the day's residues. They may be regarded as inroads of the repressed into waking life. Dreams from above correspond to thoughts or intentions of the day before which have contrived during the night to obtain reinforcement from repressed material that is debarred from the ego. When this is so, analysis as a rule disregards this unconscious ally and succeeds in inserting the latent dream-thoughts into the texture of waking thought. This distinction calls for no modification in the theory of dreams.

What conclusions can one draw from a correctly translated dream? I have an impression that analytic practice has not always avoided errors and over-estimations on this point, partly owing to an exaggerated respect for the 'mysterious unconscious'. It is only too easy to forget that a dream is as a rule merely a thought like any other, made possible by a relaxation of the censorship and by unconscious reinforcement, and distorted by the operation of the censorship and by unconscious revision.

It follows from this that it is on the whole a matter of indifference to the sleeping ego what may be dreamt during the night so long as the dream performs its task, and that those dreams best fulfil their function about which one knows nothing after waking. If it so often happens otherwise, if we remember dreams - even after years and decades - it always means that there has been an irruption of the repressed unconscious into the normal ego. Without this concession to it the repressed would not have consented to lend its help to the removal of the threat of disturbance to sleep. We know that it is the fact of this irruption that gives dreams their importance for psychopathology. If we can uncover a dream's motivating force, we shall obtain unsuspected information about the repressed impulses in the unconscious; and on the other hand, if we can undo its distortions, we shall overhear preconscious thought taking place in states of internal reflection which would not have attracted consciousness to themselves during the day-time.
In what follows I shall not be able to avoid a schematic method of exposition. Let us assume that in a particular case we have before us all the latent thoughts, charged with a greater or less amount of affect, by which the manifest dream has been replaced after its interpretation has been completed. We shall then be struck by one difference among these latent thoughts, and that difference will take us a long way. Almost all these dream-thoughts are recognized by the dreamer or acknowledged by him; he admits that he has thought this, now or at some other time, or that he might have thought it. There is only one single thought that he refuses to accept; it is strange to him or even perhaps repellent; he may possibly reject it with passionate feeling. It now becomes evident to us that the other thoughts are portions of a conscious, or, more accurately, a preconscious train of thinking. They might have been thought in waking life too, and indeed they were probably formed during the previous day. This one repudiated thought, however, or, properly speaking, this one impulse, is a child of night; it belongs to the dreamer's unconscious and on that account it is repudiated and rejected by him. It had to wait for the nightly relaxation of repression in order to arrive at any kind of expression. And in any case this expression is a weakened, distorted and disguised one; without our work of dream-interpretation we should not have found it. This unconscious impulse has to thank its link with the other, unobjectionable, dream-thoughts for the opportunity of slipping past the barrier of the censorship in an inconspicuous disguise. On the other hand, the preconscious dream-thoughts have to thank this same link for the power to occupy mental life during sleep as well. For there is no doubt about it: this unconscious impulse is the true creator of the dream; it is what produces the psychical energy for the dream's construction. Like any other instinctual impulse, it cannot strive for anything other than its own satisfaction; and our experience in interpreting dreams shows us too that that is the sense of all dreaming. In every dream an instinctual wish has to be represented as fulfilled. The shutting-off of mental life from reality at night and the regression to primitive mechanisms which this makes possible enable this wished-for instinctual satisfaction to be experienced in a hallucinatory manner as occurring in the present. As a result of this same regression, ideas are transformed in the dream into visual pictures: the latent dream-thoughts, that is to say, are dramatized and illustrated.

After these influences have been brought to bear upon the dream-thoughts the dream is almost complete. A further, somewhat variable, factor also comes into play - known as 'secondary revision' - after the dream has been presented before consciousness as an object of perception. At that point we treat it as we are in general accustomed to treat the contents of our perception: we fill in gaps and introduce connections, and in doing so are often guilty of gross misunderstandings. But this activity, which might be described as a rationalizing one and which at best provides the dream with a smooth façade that cannot fit its true content, may also be omitted or only be expressed to a very modest degree - in which case the dream will display all its rents and cracks openly. It must not be forgotten, on the other hand, that the dream-work does not always operate with equal energy either; it often restricts itself to certain portions of the dream-thoughts only and others of them are allowed to appear in the dream unaltered. In such cases an impression is given of the dream having carried out the most delicate and complex intellectual operations, of its having speculated, made jokes, arrived at decisions and solved problems, whereas all this is a product of our normal mental activity, may have been performed equally well during the day before the dream as during the night, has nothing to do with the dream-work and brings nothing to light that is characteristic of dreams. Nor is it superfluous to insist once more on the contrast within the dream-thoughts themselves between the unconscious instinctual impulse and the day's residues. While the latter exhibit all the multiplicity of our mental acts, the former, which becomes the motive force proper of the forming of the dream, finds its outlet invariably in the fulfillment of a wish.
It is best to begin by pointing out that the formation of a dream can be provoked in two different ways. Either, on the one hand, an instinctual impulse which is ordinarily suppressed (an unconscious wish) finds enough strength during sleep to make itself felt by the ego, or, on the other hand, an urge left over from waking life, a preconscious train of thought with all the conflicting impulses attached to it, finds reinforcement during sleep from an unconscious element. In short, dreams may arise either from the id or from the ego. The mechanism of dream-formation is in both cases the same and so also is the necessary dynamic precondition. The ego gives evidence of its original derivation from the id by occasionally ceasing its functions and allowing a reversion to an earlier state of things. This is logically brought about by its breaking off its relations with the external world and withdrawing its cathexes from the sense organs. We are justified in saying that there arises at birth an instinct to return to the intra-uterine life that has been abandoned - an instinct to sleep. Sleep is a return of this kind to the womb. Since the waking ego governs motility, that function is paralysed in sleep, and accordingly a good part of the inhibitions imposed on the unconscious id become superfluous. The withdrawal or reduction of these 'anticathexes' thus allows the id what is now a harmless amount of liberty.

[1940a [1938], 4976]

Naturally, every case is not so simple. Especially in dreams which have originated from undealt-with residues of the previous day, and which have only obtained an unconscious reinforcement during the state of sleep, it is often no easy task to uncover the unconscious motive force and its wish-fulfilment; but we may assume that it is always there. The thesis that dreams are the fulfilments of wishes will easily arouse scepticism when it is remembered how many dreams have an actually distressing content or even wake the dreamer in anxiety, quite apart from the numerous dreams without any definite feeling-tone. But the objection based on anxiety dreams cannot be sustained against analysis. It must not be forgotten that dreams are invariably the product of a conflict, that they are a kind of compromise-structure. Something that is a satisfaction for the unconscious id may for that very reason be a cause of anxiety for the ego.

[1940a [1938], 4980]
If we assume that the same need for transference on the part of repressed ideas which we have discovered in analysing the neuroses is also at work in dreams, two of the riddles of the dream are solved at a blow: the fact, namely, that every analysis of a dream shows some recent impression woven into its texture and that this recent element is often of the most trivial kind. I may add that (as we have already found elsewhere) the reason why these recent and indifferent elements so frequently find their way into dreams as substitutes for the most ancient of all the dream-thoughts is that they have least to fear from the censorship imposed by resistance. But while the fact that trivial elements are preferred is explained by their freedom from censorship, the fact that recent elements occur with such regularity points to the existence of a need for transference. Both groups of impressions satisfy the demand of the repressed for material that is still clear of associations - the indifferent ones because they have given no occasion for the formation of many ties, and the recent ones because they have not yet had time to form them.

It will be seen, then, that the day's residues, among which we may now class the indifferent impressions, not only borrow something from the Ucs. when they succeed in taking a share in the formation of a dream - namely the instinctual force which is at the disposal of the repressed wish - but that they also offer the unconscious something indispensable - namely the necessary point of attachment for a transference. If we wished to penetrate more deeply at this point into the processes of the mind, we should have to throw more light upon the interplay of excitations between the preconscious and the unconscious a subject towards which the study of the psychoneuroses draws us, but upon which, as it happens, dreams have no help to offer.

We have so far been studying dream-wishes: we have traced them from their origin in the region of the Ucs. and have analysed their relations to the day's residues, which in their turn may either be wishes or psychical impulses of some other kind or simply recent impressions. In this way we have allowed room for every claim that may be raised by any of the multifarious waking thought-activities on behalf of the importance of the part played by them in the process of constructing dreams. It is not impossible, even, that our account may have provided an explanation of the extreme cases in which a dream, pursuing the activities of daytime, arrives at a happy solution of some unsolved problem of waking life. All we need is an example of this kind, so that we might analyse it and trace the source of the infantile or repressed wishes whose help has been enlisted and has reinforced the efforts of preconscious activity with such success. But all this has not brought us a step nearer to solving the riddle of why it is that the unconscious has nothing else to offer during sleep but the motive force for the fulfilment of a wish. The answer to this question must throw light upon the psychical nature of wishes, and I propose to give the answer by reference to our schematic picture of the psychical apparatus.

There are other conjunctures which may lead to the formation of a dream. The preconscious train of thought may have been linked to the unconscious wish from the first and may for that reason have been repudiated by the dominant purposive cathexis; or an unconscious wish may become active for other reasons (from somatic causes, perhaps) and may seek to effect a transference on to the psychical residues that are uncathected by the Pcs. without their coming halfway to meet it. But all three cases have the same final outcome: a train of thought comes into being in the preconscious which is without a preconscious cathexis but has received a cathexis from an unconscious wish.
I have made one or two observations in my *Interpretation of Dreams* on the relation between the waking thoughts which are continued into sleep (the 'day's residues') and the unconscious wish which forms the dream. I will quote them here as they stand, for I have nothing to add to them, and the analysis of this dream of Dora's proves afresh that the facts are as I have supposed: 'I am ready to admit that there is a whole class of dreams the *instigation* to which arises principally or even exclusively from the residues of daytime life; and I think that even my wish that I might at long last become a Professor Extraordinarius¹ might have allowed me to sleep through the night in peace if my worry over my friend's health had not still persisted from the previous day. But the worry alone could not have made a dream. The *motive force* which the dream required had to be provided by a wish; it was the business of the worry to get hold of a wish to act as the motive force of the dream.

[1905e, 1423]

'The position may be explained by an analogy. A daytime thought may very well play the part of *entrepreneur* for a dream; but the *entrepreneur*, who, as people say, has the idea and the initiative to carry it out, can do nothing without capital; he needs a *capitalist* who can afford the outlay, and the capitalist who provides the psychical outlay for the dream is invariably and indisputably, whatever may be the thoughts of the previous day, a *wish from the unconscious*.'

[1905e, 1423]

I can imagine that to point out the existence of lying dreams of this kind, 'obliging' dreams, will arouse a positive storm of helpless indignation in some readers who call themselves analysts. 'What!' they will exclaim, 'the unconscious, the real centre of our mental life, the part of us that is so much nearer the divine than our poor consciousness - it too can lie! Then how can we still build on the interpretations of analysis and the accuracy of our findings?' To which one must reply that the recognition of these lying dreams does not constitute any shattering novelty. I know, indeed, that the craving of mankind for mysticism is ineradicable, and that it makes ceaseless efforts to win back for mysticism the territory it has been deprived of by *The Interpretation of Dreams*, but surely in the case under consideration everything is simple enough. A dream is not the 'unconscious'; it is the form into which a thought left over from preconscious, or even from conscious, waking life, can, thanks to the favouring state of sleep, be recast. In the state of sleep this thought has been reinforced by unconscious wishful impulses and has thus experienced distortion through the dream-work, which is determined by the mechanisms prevailing in the unconscious. With our dreamer, the intention to mislead me, just as she did her father, certainly emanated from the preconscious, and may indeed have been conscious; it could come to expression by entering into connection with the unconscious wishful impulse to please her father (or father-substitute), and in this way it created a lying dream. The two intentions, to betray and to please her father, originated in the same complex; the former resulted from the repression of the latter, and the later one was brought back by the dream-work to the earlier one. There can therefore be no question of any devaluation of the unconscious, nor of a shattering of our confidence in the results of analysis.

[1920a, 3854]

It is possible to distinguish between dreams *from above* and dreams *from below*, provided the distinction is not made too sharply. Dreams from below are those which are provoked by the strength of an unconscious (repressed) wish which has found a means of being represented in some of the day's residues. They may be regarded as inroads of the repressed into waking life. Dreams from above correspond to thoughts or intentions of the day before which have contrived during the night to obtain reinforcement from repressed material that is debarred from the ego. When this is so, analysis as a rule disregards this unconscious ally and succeeds in inserting the latent dream-thoughts into the texture of waking thought. This distinction calls for no modification in the theory of dreams.

[1923c, 4032]
In what follows I shall not be able to avoid a schematic method of exposition. Let us assume that in a particular case we have before us all the latent thoughts, charged with a greater or less amount of affect, by which the manifest dream has been replaced after its interpretation has been completed. We shall then be struck by one difference among these latent thoughts, and that difference will take us a long way. Almost all these dream-thoughts are recognized by the dreamer or acknowledged by him; he admits that he has thought this, now or at some other time, or that he might have thought it. There is only one single thought that he refuses to accept; it is strange to him or even perhaps repellent; he may possibly reject it with passionate feeling. It now becomes evident to us that the other thoughts are portions of a conscious, or, more accurately, a preconscious train of thinking. They might have been thought in waking life too, and indeed they were probably formed during the previous day. This one repudiated thought, however, or, properly speaking, this one impulse, is a child of night; it belongs to the dreamer's unconscious and on that account it is repudiated and rejected by him. It had to wait for the nightly relaxation of repression in order to arrive at any kind of expression. And in any case this expression is a weakened, distorted and disguised one; without our work of dream-interpretation we should not have found it. This unconscious impulse has to thank its link with the other, unobjectionable, dream-thoughts for the opportunity of slipping past the barrier of the censorship in an inconspicuous disguise. On the other hand, the preconscious dream-thoughts have to thank this same link for the power to occupy mental life during sleep as well. For there is no doubt about it: this unconscious impulse is the true creator of the dream; it is what produces the psychical energy for the dream's construction. Like any other instinctual impulse, it cannot strive for anything other than its own satisfaction; and our experience in interpreting dreams shows us too that that is the sense of all dreaming. In every dream an instinctual wish has to be represented as fulfilled. The shutting-off of mental life from reality at night and the regression to primitive mechanisms which this makes possible enable this wished-for instinctual satisfaction to be experienced in a hallucinatory manner as occurring in the present. As a result of this same regression, ideas are transformed in the dream into visual pictures: the latent dream-thoughts, that is to say, are dramatized and illustrated.

[1933a, 4631]

After these influences have been brought to bear upon the dream-thoughts the dream is almost complete. A further, somewhat variable, factor also comes into play - known as 'secondary revision' - after the dream has been presented before consciousness as an object of perception. At that point we treat it as we are in general accustomed to treat the contents of our perception: we fill in gaps and introduce connections, and in doing so are often guilty of gross misunderstandings. But this activity, which might be described as a rationalizing one and which at best provides the dream with a smooth façade that cannot fit its true content, may also be omitted or only be expressed to a very modest degree - in which case the dream will display all its rents and cracks openly. It must not be forgotten, on the other hand, that the dream-work does not always operate with equal energy either; it often restricts itself to certain portions of the dream-thoughts only and others of them are allowed to appear in the dream unaltered. In such cases an impression is given of the dream having carried out the most delicate and complex intellectual operations, of its having speculated, made jokes, arrived at decisions and solved problems, whereas all this is a product of our normal mental activity, may have been performed equally well during the day before the dream as during the night, has nothing to do with the dream-work and brings nothing to light that is characteristic of dreams. Nor is it superfluous to insist once more on the contrast within the dream-thoughts themselves between the unconscious instinctual impulse and the day's residues. While the latter exhibit all the multiplicity of our mental acts, the former, which becomes the motive force proper of the forming of the dream, finds its outlet invariably in the fulfillment of a wish.

[1933a, 4634]
But what makes dreams so invaluable in giving us insight is the circumstance that, when the unconscious material makes its way into the ego, it brings its own modes of working along with it. This means that the preconscious thoughts in which the unconscious material has found its expression are handled in the course of the dream-work as though they were unconscious portions of the id; and, in the case of the alternative method of dream-formation, the preconscious thoughts which have obtained reinforcement from an unconscious instinctual impulse are brought down to the unconscious state. It is only in this way that we learn the laws which govern the passage of events in the unconscious and the respects in which they differ from the rules that are familiar to us in waking thought. Thus the dream-work is essentially an instance of the unconscious working-over of preconscious thought-processes. To take an analogy from history: invading conquerors govern a conquered country, not according to the judicial system which they find in force there, but according to their own. It is, however, an unmistakable fact that the outcome of the dream-work is a compromise. The ego-organization is not yet paralysed, and its influence is to be seen in the distortion imposed on the unconscious material and in what are often very ineffective attempts at giving the total result a form not too unacceptable to the ego (secondary revision). In our analogy this would be an expression of the continued resistance of the defeated people.

[1940a [1938], 4977]

Naturally, every case is not so simple. Especially in dreams which have originated from undealt-with residues of the previous day, and which have only obtained an unconscious reinforcement during the state of sleep, it is often no easy task to uncover the unconscious motive force and its wish-fulfilment; but we may assume that it is always there. The thesis that dreams are the fulfilments of wishes will easily arouse scepticism when it is remembered how many dreams have an actually distressing content or even wake the dreamer in anxiety, quite apart from the numerous dreams without any definite feeling-tone. But the objection based on anxiety dreams cannot be sustained against analysis. It must not be forgotten that dreams are invariably the product of a conflict, that they are a kind of compromise-structure. Something that is a satisfaction for the unconscious id may for that very reason be a cause of anxiety for the ego.

[1940a [1938], 4980]
The position may be explained by an analogy. A daytime thought may very well play the part of entrepreneur for a dream; but the entrepreneur, who, as people say, has the idea and the initiative to carry it out, can do nothing without capital; he needs a capitalist who can afford the outlay, and the capitalist who provides the psychical outlay for the dream is invariably and indisputably, whatever may be the thoughts of the previous day, a wish from the unconscious. [1900a, 992]

Sometimes the capitalist is himself the entrepreneur, and indeed in the case of dreams this is the commoner event: an unconscious wish is stirred up by daytime activity and proceeds to construct a dream. So, too, the other possible variations in the economic situation that I have taken as an analogy have their parallel in dream-processes. The entrepreneur may himself make a small contribution to the capital; several entrepreneurs may apply to the same capitalist; several capitalists may combine to put up what is necessary for the entrepreneur. In the same way, we come across dreams that are supported by more than one dream-wish; and so too with other similar variations, which could easily be run through, but which would be of no further interest to us. We must reserve until later what remains to be said of the dream-wish. [1900a, 992]

The tertium comparationis in the analogy that I have just used - the quantity put at the disposal of the entrepreneur in an appropriate amount - is capable of being applied in still greater detail to the purpose of elucidating the structure of dreams. In most dreams it is possible to detect a central point which is marked by peculiar sensory intensity, as I have shown on p. 778. This central point is as a rule the direct representation of the wish-fulfilment, for, if we undo the displacements brought about by the dream-work, we find that the psychical intensity of the elements in the dream-thoughts has been replaced by the sensory intensity of the elements in the content of the actual dream. The elements in the neighbourhood of the wish-fulfilment often have nothing to do with its meaning, but turn out to be derivatives of distressing thoughts that run contrary to the wish. But owing to their being in what is often an artificially established connection with the central element, they have acquired enough intensity to become capable of being represented in the dream. Thus the wish-fulfilment's power of bringing about representation is diffused over a certain sphere surrounding it, within which all the elements - including even those possessing no means of their own - become empowered to obtain representation. In the case of dreams that are actuated by several wishes, it is easy to delimit the spheres of the different wish-fulfilments, and gaps in the dream may often be understood as frontier zones between those spheres. [1900a, 992]

'The position may be explained by an analogy. A daytime thought may very well play the part of entrepreneur for a dream; but the entrepreneur, who, as people say, has the idea and the initiative to carry it out, can do nothing without capital; he needs a capitalist who can afford the outlay, and the capitalist who provides the psychical outlay for the dream is invariably and indisputably, whatever may be the thoughts of the previous day, a wish from the unconscious.' [1905e, 1423]
I have made use of an analogy for the relation of the day's residues to the unconscious wish, and I can only repeat it here. In every undertaking there must be a capitalist who covers the required outlay and an entrepreneur who has the idea and knows how to carry it out. In the construction of dreams, the part of the capitalist is always played by the unconscious wish alone; it provides the psychical energy for the construction of the dream. The entrepreneur is the day's residues, which decide how this outlay is to be employed. It is possible, of course, for the capitalist himself to have the idea and the expert knowledge or for the entrepreneur himself to possess capital. This simplifies the practical situation but makes its theoretical understanding more difficult. In economics the same person is constantly divided into his two aspects of capitalist and entrepreneur and this restores the fundamental situation on which our analogy was based. In dream-construction the same variations occur and I will leave them for you to follow out.
[1916-1917, 3313]
These considerations may lead us to feel that the interpretation of dreams may enable us to draw conclusions as to the structure of our mental apparatus which we have hoped for in vain from philosophy. I do not propose, however, to follow this line of thought; but, having cleared up the matter of distortion in dreams, I shall go back to the problem from which we started. The question raised was how dreams with a distressing content can be resolved into wish-fulfilments. We now see that this is possible if dream-distortion has occurred and if the distressing content serves only to disguise something that is wished for. Bearing in mind our assumption of the existence of two psychical agencies, we can further say that distressing dreams do in fact contain something which is distressing to the second agency, but something which at the same time fulfils a wish on the part of the first agency. They are wishful dreams in so far as every dream arises from the first agency; the relation of the second agency towards dreams is of a defensive and not of a creative kind.¹ If we were to restrict ourselves to considering what the second agency contributes to dreams, we could never arrive at an understanding of them: all the conundrums which the authorities have observed in dreams would remain unsolved.

[1900a, 641]

The path to perversion branches off sharply from that to neurosis. If these regressions rouse no objection from the ego, no neurosis will come about either; and the libido will arrive at some real, even though no longer normal, satisfaction. But if the ego, which has under its control not only consciousness but also the approaches to motor innervation and accordingly to the realization of mental desires, does not agree with these regressions, conflict will follow. The libido is, as it were, cut off and must try to escape in some direction where, in accordance with the requirements of the pleasure principle, it can find a discharge for its cathexis of energy. It must withdraw from the ego. An escape of this kind is offered it by the fixations on the path of its development which it has now entered on regressively - fixations from which the ego had protected itself in the past by repressions. By cathecting these repressed positions as it flows backward, the libido has withdrawn from the ego and its laws, and has at the same time renounced all the education it has acquired under the ego's influence. It was docile so long as satisfaction beckoned to it; but under the double pressure of external and internal frustration it becomes refractory, and recalls earlier and better times. Such is the libido's fundamentally unchangeable character. The ideas to which it now transfers its energy as a cathexis belong to the system of the unconscious and are subject to the processes which are possible there, particularly to condensation and displacement. In this way conditions are established which completely resemble those in dream-construction. The dream proper, which has been completed in the unconscious and is the fulfilment of an unconscious wishful phantasy, is brought up against a portion of (pre)conscious activity which exercises the office of censorship and which, when it has been indemnified, permits the formation of the manifest dream as a compromise. In the same way, what represents the libido in the unconscious has to reckon with the power of the preconscious ego. The opposition which had been raised against it in the ego pursues it as an 'anticathexis' and compels it to choose a form of expression which can at the same time become an expression of the opposition itself. Thus the symptom emerges as a many-times-distorted derivative of the unconscious libidinal wish-fulfilment, an ingeniously chosen piece of ambiguity with two meanings in complete mutual contradiction. In this last respect, however, there is a distinction between the construction of a dream and of a symptom. For in dream-formation the preconscious purpose is merely concerned to preserve sleep, to allow nothing that would disturb it to make its way into consciousness; it does not insist upon calling out sharply 'No! on the contrary!' to the unconscious wishful impulse. It can afford to be more tolerant because the situation of someone sleeping is less perilous. The state of sleep in itself bars any outlet into reality.

[1916-1917, 3418]
The dream-thoughts which we arrive at by means of analysis reveal themselves as a psychical complex of the most intricate possible structure. Its portions stand in the most manifold logical relations to one another: they represent foreground and background, conditions, digressions and illustrations, chains of evidence and counter-arguments. Each train of thought is almost invariably accompanied by its contradictory counterpart. This material lacks none of the characteristics that are familiar to us from our waking thinking. If now all of this is to be turned into a dream, the psychical material will be submitted to a pressure which will condense it greatly, to an internal fragmentation and displacement which will, as it were, create new surfaces, and to a selective operation in favour of those portions of it which are the most appropriate for the construction of situations. If we take into account the genesis of the material, a process of this sort deserves to be described as a 'regression.' In the course of this transformation, however, the logical links which have hitherto held the psychical material together are lost. It is only, as it were, the substantive content of the dream-thoughts that the dream-work takes over and manipulates. The restoration of the connections which the dream-work has destroyed is a task which has to be performed by the work of analysis.

[1901a, 1075]
But what makes dreams so invaluable in giving us insight is the circumstance that, when the unconscious material makes its way into the ego, it brings its own modes of working along with it. This means that the preconscious thoughts in which the unconscious material has found its expression are handled in the course of the dream-work as though they were unconscious portions of the id; and, in the case of the alternative method of dream-formation, the preconscious thoughts which have obtained reinforcement from an unconscious instinctual impulse are brought down to the unconscious state. It is only in this way that we learn the laws which govern the passage of events in the unconscious and the respects in which they differ from the rules that are familiar to us in waking thought. Thus the dream-work is essentially an instance of the unconscious working-over of preconscious thought-processes. To take an analogy from history: invading conquerors govern a conquered country, not according to the judicial system which they find in force there, but according to their own. It is, however, an unmistakable fact that the outcome of the dream-work is a compromise. The ego-organization is not yet paralysed, and its influence is to be seen in the distortion imposed on the unconscious material and in what are often very ineffective attempts at giving the total result a form not too unacceptable to the ego (secondary revision). In our analogy this would be an expression of the continued resistance of the defeated people.

[1940a [1938], 4977]
In other cases the connection is not so simple. It consists only in what might be called a 'symbolic' relation between the precipitating cause and the pathological phenomenon - a relation such as healthy people form in dreams. For instance, a neuralgia may follow upon mental pain or vomiting upon a feeling of moral disgust. We have studied patients who used to make the most copious use of this sort of symbolization. In still other cases it is not possible to understand at first sight how they can be determined in the manner we have suggested. It is precisely the typical hysterical symptoms which fall into this class, such as hemi-anaesthesia, contraction of the field of vision, epileptiform convulsions, and so on. An explanation of our views on this group must be reserved for a fuller discussion of the subject.

[1895d, 8]

'And yet', continues Hildebrandt, 'what appears to be the contrary of this is equally true and correct. In spite of everything, the most intimate relationship goes hand in hand, I believe, with the seclusion and separation. We may even go so far as to say that whatever dreams may offer, they derive their material from reality and from the intellectual life that revolves around that reality. . . . Whatever strange results they may achieve, they can never in fact get free from the real world; and their most sublime as well as their most ridiculous structures must always borrow their basic material either from what has passed before our eyes in the world of the senses or from what has already found a place somewhere in the course of our waking thoughts - in other words from what we have already experienced either externally or internally.' [1900a, 524]

All the material making up the content of a dream is in some way derived from experience, that is to say, has been reproduced or remembered in the dream - so much at least we may regard as an undisputed fact. But it would be a mistake to suppose that a connection of this kind between the content of a dream and reality is bound to come to light easily, as an immediate result of comparing them. The connection requires, on the contrary, to be looked for diligently, and in a whole quantity of cases it may long remain hidden. The reason for this lies in a number of peculiarities which are exhibited by the faculty of memory in dreams and which, though generally remarked upon, have hitherto resisted explanation. It will be worth while to examine these characteristics more closely.

[1900a, 525]

One of the sources from which dreams derive material for reproduction - material which is in part neither remembered nor used in the activities of waking thought - is childhood experience. I will quote only a few of the authors who have noticed and stressed this fact.

[1900a, 529]

But Robert's theory is diametrically opposed to the ruling one in its estimate of the nature of the sources of dreams. According to the latter, there would be no dreaming at all if the mind were not being constantly wakened by external and internal sensory stimuli. But in Robert's view the impulsion to dreaming arises in the mind itself - in the fact of its becoming overloaded and requiring relief; and he concludes with perfect logic that causes derived from somatic conditions play a subordinate part as determinants of dreams, and that such causes would be quite incapable of provoking dreams in a mind in which there was no material for the construction of dreams derived from waking consciousness. The only qualification he makes is to admit that the phantasy-images arising in dreams out of the depths of the mind may be affected by nervous stimuli. (Ibid., 48.) After all, therefore, Robert does not regard dreams as so completely dependent upon somatic events. Nevertheless, in his view dreams are not psychical processes, they have no place among the psychical processes of waking life; they are somatic processes occurring every night in the apparatus that is concerned with mental activity, and they have as their function the task of protecting that apparatus from excessive tension - or, to change the metaphor - of acting as scavengers of the mind.

[1900a, 587]
The material with which dream-imagination accomplishes its artistic work is principally, according to Scherner, provided by the organic somatic stimuli which are so obscure during the daytime. (See above, p. 544 ff.) Thus the excessively fantastic hypothesis put forward by Scherner and the perhaps unduly sober doctrines of Wundt and other physiologists, which are poles asunder in other respects, are entirely at one in regard to their theory of the sources and instigators of dreams. According to the physiological view, however, the mental reaction to the internal somatic stimuli is exhausted with the provoking of certain ideas appropriate to the stimuli; these ideas give rise to others along associative lines and at this point the course of psychical events in dreams seems to be at an end. According to Scherner, on the other hand, the somatic stimuli do no more than provide the mind with material of which it can make use for its imaginative purposes. The formation of dreams only begins, in Scherner's eyes, at the point which the other writers regard as its end.

In the course of my psycho-analyses of neurotics I must already have analysed over a thousand dreams; but I do not propose to make use of this material in my present introduction to the technique and theory of dream-interpretation. Apart from the fact that such a course would be open to the objection that these are the dreams of neuropaths, from which no valid inferences could be made as to the dreams of normal people, there is quite another reason which forces this decision upon me. The subject to which these dreams of my patients lead up is always, of course, the case history which underlies their neurosis. Each dream would therefore necessitate a lengthy introduction and an investigation of the nature and aetiological determinants of the psychoneuroses. But these questions are in themselves novelties and highly bewildering and would distract attention from the problem of dreams. On the contrary, it is my intention to make use of my present elucidation of dreams as a preliminary step towards solving the more difficult problems of the psychology of the neuroses. If, however, I forego my principal material, the dreams of my neurotic patients, I must not be too particular about what is left to me. All that remains are such dreams as have been reported to me from time to time by normal persons of my acquaintance, and such others as have been quoted as instances in the literature dealing with dream-life. Unluckily, however, none of these dreams are accompanied by the analysis without which I cannot discover a dream's meaning. My procedure is not so convenient as the popular decoding method which translates any given piece of a dream's content by a fixed key. I, on the contrary, am prepared to find that the same piece of content may conceal a different meaning when it occurs in various people or in various contexts. Thus it comes about that I am led to my own dreams, which offer a copious and convenient material, derived from an approximately normal person and relating to multifarious occasions of daily life. No doubt I shall be met by doubts of the trustworthiness of 'self-analyses' of this kind; and I shall be told that they leave the door open to arbitrary conclusions. In my judgement the situation is in fact more favourable in the case of self-observation than in that of other people; at all events we may make the experiment and see how far self-analysis takes us with the interpretation of dreams. But I have other difficulties to overcome, which lie within myself. There is some natural hesitation about revealing so many intimate facts about one's mental life; nor can there be any guarantee against misinterpretation by strangers. But it must be possible to overcome such hesitations. 'Tout psychologue', writes Delboeuf, 'est obligé de faire l'aveu même de ses faiblesses s'il croit par là jeter du jour sur quelque problème obscur.' And it is safe to assume that my readers too will very soon find their initial interest in the indiscretions which I am bound to make replaced by an absorbing immersion in the psychological problems upon which they throw light.
But no sooner have we begun to rejoice at this discovery than we are assailed by a flood of questions. If, as we are told by dream-interpretation, a dream represents a fulfilled wish, what is the origin of the remarkable and puzzling form in which the wish-fulfilment is expressed? What alteration have the dream thoughts undergone before being changed into the manifest dream which we remember when we wake up? How does that alteration take place? What is the source of the material that has been modified into the dream? What is the source of the many peculiarities that are to be observed in the dream-thoughts - such, for instance, as the fact that they may be mutually contradictory? (Cf. the analogy of the borrowed kettle on p. 106.) Can a dream tell us anything new about our internal psychical processes? Can its content correct opinions we have held during the day?

Of the three characteristics of memory in dreams enumerated at the beginning of this chapter, one - the preference for non-essential material in the content of dreams - has been satisfactorily cleared up by being traced back to dream-distortion. We have been able to confirm the existence of the other two - the emphasis upon recent and upon infantile material - but we have not been able to account for them on the basis of the motives that lead to dreaming. These two characteristics inclusion of both recent and infantile material, whose explanation and appreciation remain to be discovered, must be kept in mind. Their proper place must be looked for elsewhere - either in the psychology of the state of sleep or in the discussion of the structure of the mental apparatus upon which we shall later embark, after we have learnt that the interpretation of dreams is like a window through which we can get a glimpse of the interior of that apparatus.

We have already taken the first step in this direction by advancing the thesis (see p. 666 f.) that the dream-work is under the necessity of combining into a unity all instigations to dreaming which are active simultaneously. We found that, when two or more experiences capable of creating an impression are left over from the previous day, the wishes derived from them are combined in a single dream, and similarly that the psychically significant impressions and the indifferent experiences from the previous day are brought together in the dream-material, provided always that it is possible to set up communicating ideas between them. Thus a dream appears to be a reaction to everything that is simultaneously present in the sleeping mind as currently active material. So far as we have hitherto analysed the material of dreams, we have seen it as a collection of psychical residues and memory-traces, to which (on account of the preference shown for recent and infantile material) we have been led to attribute a hitherto indefinable quality of being 'currently active'. We can foresee, then, without any great difficulty, what will happen if fresh material in the form of sensations is added during sleep to these currently active memories. It is once again owing to the fact of their being currently active that these sensory excitations are of importance for the dream; they are united with the other currently active psychical material to furnish what is used for the construction of the dream. To put it another way, stimuli arising during sleep are worked up into a wish-fulfilment the other constituents of which are the familiar psychical 'day's residues'. This combination need not occur; as I have already pointed out, there is more than one way of reacting to a somatic stimulus during sleep. When it does occur, it means that it has been possible to find ideational material to serve as the content of the dream of such a sort as to be able to represent both kinds of source of the dream - the somatic and the psychical.
I should, of course, not draw such far-reaching conclusions if only a single dream-analysis was at my disposal. If experience shows me, however, that by uncritically pursuing the associations arising from any dream I can arrive at a similar train of thoughts, among the elements of which the constituents of the dream re-appear and which are interconnected in a rational and intelligible manner, then it will be safe to disregard the slight possibility that the connections observed in a first experiment might be due to chance. I think I am justified, therefore, in adopting a terminology which will crystallize our new discovery. In order to contrast the dream as it is retained in my memory with the relevant material discovered by analysing it, I shall speak of the former as the 'manifest content of the dream' and the latter - without, in the first instance, making any further distinction - as the 'latent content of the dream.' I am now faced by two new problems which have not hitherto been formulated. (1) What is the psychical process which has transformed the latent content of the dream into the manifest one which is known to me from my memory? (2) What are the motive or motives which have necessitated this transformation? I shall describe the process which transforms the latent into the manifest content of dreams as the 'dream-work.' The counterpart to this activity - one which brings about a transformation in the opposite direction - is already known to us as the work of analysis. The remaining problems arising out of dreams - questions as to the instigators of dreams, as to the origin of their material, as to their possible meaning, as to the possible function of dreaming, and as to the reasons for dreams being forgotten - all these problems will be discussed by me on the basis, not of the manifest, but of the newly discovered latent dream-content. Since I attribute all the contradictory and incorrect views upon dream-life which appear in the literature of the subject to ignorance of the latent content of dreams as revealed by analysis, I shall be at the greatest pains henceforward to avoid confusing the manifest dream with the latent dream-thoughts. [1901a, 1059]

If we undo dream-displacement by means of analysis, we obtain what seems to be completely trustworthy information on two much-disputed problems concerning dreams: as to their instigators and as to their connection with waking life. There are dreams which immediately reveal their derivation from events of the day; there are others in which no trace of any such derivation is to be discovered. If we seek the help of analysis, we find that every dream without any possible exception goes back to an impression of the past few days, or, it is probably more correct to say, of the day immediately preceding the dream, of the 'dream-day.' The impression which plays the part of dream-instigator may be such an important one that we feel no surprise at being concerned with it in the daytime, and in that case we rightly speak of the dream as carrying on with the significant interests of our waking life. As a rule, however, if a connection is to be found in the content of the dream with any impression of the previous day, that impression is so trivial, insignificant and unmemorable, that it is only with difficulty that we ourselves can recall it. And in such cases the content of the dream itself, even if it is connected and intelligible, seems to be concerned with the most indifferent trivialities, which would be unworthy of our interest if we were awake. A good deal of the contempt in which dreams are held is due to the preference thus shown in their content for what is indifferent and trivial. [1901a, 1071]

The content of dreams, however, does not consist entirely of situations, but also includes disconnected fragments of visual images, speeches and even bits of unmodified thoughts. It may therefore perhaps be of interest to enumerate very briefly the modes of representation available to the dream-work for reproducing the dream-thoughts in the peculiar form of expression necessary in dreams. [1901a, 1075]
Thus a great number of the jokes in circulation have a certain length of life: their life runs a
course made up of a period of flowering and a period of decay and it ends in complete oblivion.
The need which men feel for deriving pleasure from their processes of thought is therefore
constantly creating new jokes based on the new interests of the day. The vital force of topical
jokes is not their own; it is borrowed, by the method of allusion, from those other interests, the
expiry of which determines the fate of the joke as well. The factor of topicality is a source of
pleasure, ephemeral it is true but particularly abundant, which supplements the sources
inherent in the joke itself. It cannot be simply equated with the rediscovery of what is familiar. It
is concerned rather with a particular category of what is familiar, which must in addition possess
the characteristic of being fresh, recent and untouched by forgetting. In the formation of dreams,
too, we come across a special preference for what is recent and we cannot escape a suspicion
that association with what is recent is rewarded, and so facilitated, by a peculiar bonus of
pleasure.

[1905c, 1715]

The so-called 'day's residues' can act as disturbers of sleep and constructors of dreams; they
are affectively cathected thought-processes from the dream-day, which have resisted the
general lowering through sleep. These day's residues are uncovered by tracing back the
manifest dream to the latent dream-thoughts; they constitute portions of the latter and are thus
among the activities of waking life - whether conscious or unconscious - which have been able
to persist into the period of sleep. In accordance with the multiplicity of thought-processes in the
conscious and preconscious, these day's residues have the most numerous and varied
meanings: they may be wishes or fears that have not been disposed of, or intentions,
reflections, warnings, attempts at adaptation to current tasks, and so on. To this extent the
classification of dreams that is under consideration seems to be justified by the content which is
uncovered by interpretation. These day's residues, however, are not the dream itself: they lack
the main essential of a dream. Of themselves they are not able to construct a dream. They are,
strictly speaking, only the psychical material for the dream-work, just as sensory and somatic
stimuli, whether accidental or produced under experimental conditions, constitute the somatic
material for the dream-work. To attribute to them the main part in the construction of dreams is
simply to repeat at a new point the pre-analytic error which explained dreams by referring them
to bad digestion or to pressure on the skin. Scientific errors, indeed, are tenacious of life, and
even when they have been refuted are ready to creep in again under new disguises.
[1913a, 2590]

We may here recall that we have found that the formation of dreams takes place under the
dominance of a censorship which compels distortion of the dream-thoughts. We did not,
however, picture this censorship as a special power, but chose the term to designate one side
of the repressive trends that govern the ego, namely the side which is turned towards the
dream-thoughts. If we enter further into the structure of the ego, we may recognize in the ego
ideal and in the dynamic utterances of conscience the dream-censor as well. If this censor is to
some extent on the alert even during sleep, we can understand how it is that its suggested
activity of self-observation and self-criticism - with such thoughts as, 'now he is too sleepy to
think', 'now he is waking up' - makes a contribution to the content of the dream.¹
[1914c, 2950]
Here we have a new type of relation between the manifest and latent dream-elements. The former is not so much a distortion of the latter as a representation of it, a plastic, concrete, portrayal of it, taking its start from the wording. But precisely on that account it is once more a distortion, for we have long since forgotten from what concrete image the word originated and consequently fail to recognize it when it is replaced by the image. When you consider that the manifest dream is made up predominantly of visual images and more rarely of thoughts and words, you can imagine what importance attaches to this kind of relation in the construction of dreams. You will see, too, that in this way it becomes possible in regard to a large number of abstract thoughts to create pictures to act as substitutes for them in the manifest dream while at the same time serving the purpose of concealment. This is the technique of the familiar picture-puzzles. Why it is that these representations have an appearance of being jokes is a special problem into which we need not enter here.

The manifestations of a compulsion to repeat (which we have described as occurring in the early activities of infantile mental life as well as among the events of psycho-analytic treatment) exhibit to a high degree an instinctual character and, when they act in opposition to the pleasure principle, give the appearance of some 'daemonic' force at work. In the case of children's play we seemed to see that children repeat unpleasant experiences for the additional reason that they can master a powerful impression far more thoroughly by being active than they could by merely experiencing it passively. Each fresh repetition seems to strengthen the mastery they are in search of. Nor can children have their pleasurable experiences repeated often enough, and they are inexorable in their insistence that the repetition shall be an identical one. This character trait disappears later on. If a joke is heard for a second time it produces almost no effect; a theatrical production never creates so great an impression the second time as the first; indeed, it is hardly possible to persuade an adult who has very much enjoyed reading a book to re-read it immediately. Novelty is always the condition of enjoyment. But children will never tire of asking an adult to repeat a game that he has shown them or played with them, till he is too exhausted to go on. And if a child has been told a nice story, he will insist on hearing it over and over again rather than a new one; and he will remorselessly stipulate that the repetition shall be an identical one and will correct any alterations of which the narrator may be guilty - though they may actually have been made in the hope of gaining fresh approval. None of this contradicts the pleasure principle; repetition, the re-experiencing of something identical, is clearly in itself a source of pleasure. In the case of a person in analysis, on the contrary, the compulsion to repeat the events of his childhood in the transference evidently disregards the pleasure principle in every way. The patient behaves in a purely infantile fashion and thus shows us that the repressed memory-traces of his primordial experiences are not present in him in a bound state and are indeed in a sense incapable of obeying the secondary process. It is to this fact of not being bound, moreover, that they owe their capacity for forming, in conjunction with the residues of the previous day, a wishful phantasy that emerges in a dream. This same compulsion to repeat frequently meets us as an obstacle to our treatment when at the end of an analysis we try to induce the patient to detach himself completely from his physician. It may be presumed, too, that when people unfamiliar with analysis feel an obscure fear - a dread of rousing something that, so they feel, is better left sleeping - what they are afraid of at bottom is the emergence of this compulsion with its hint of possession by some 'daemonic' power.

[1916-1917, 3217]

[1920g, 3738]
The Dynamic Theory of Dream-Formation. The motive power for the formation of dreams is not provided by the latent dream-thoughts or day's residues, but by an unconscious impulse, repressed during the day, with which the day's residues have been able to establish contact and which contrives to make a wish-fulfilment for itself out of the material of the latent thoughts. Thus every dream is on the one hand the fulfilment of a wish on the part of the unconscious and on the other hand (in so far as it succeeds in guarding the state of sleep against being disturbed) the fulfilment of the normal wish to sleep which set the sleep going. If we disregard the unconscious contribution to the formation of the dream and limit the dream to its latent thoughts, it can represent anything with which waking life has been concerned - a reflection, a warning, an intention, a preparation for the immediate future or, once again, the satisfaction of an unfulfilled wish. The unrecognizability, strangeness and absurdity of the manifest dream are partly the result of the translation of the thoughts into a different, so to say archaic, method of expression, but partly the effect of a restrictive, critically disapproving agency in the mind which does not entirely cease to function during sleep. It is plausible to suppose that the 'dream-censorship', which we regard as being responsible in the first instance for the distortion of the dream-thoughts into the manifest dream, is an expression of the same mental forces which during the day-time had held back or repressed the unconscious wishful impulse.

One interesting occurrence which has been insufficiently investigated is to be seen where the same manifest dream-content gives simultaneous expression to a set of concrete ideas and to an abstract line of thought based upon them. It is of course difficult for the dream-work to find a means for representing abstract thoughts.

But our interest in the genesis of these manifestly immoral dreams is greatly reduced when we find from analysis that the majority of dreams - innocent dreams, dreams without affect and anxiety-dreams - are revealed, when the distortions of the censorship have been undone, as the fulfilsments of immoral - egoistic, sadistic, perverse or incestuous - wishful impulses. As in the world of waking life, these masked criminals are far commoner than those with their vizors raised. The straightforward dream of sexual relations with one's mother, which Jocasta alludes to in the Oedipus Rex, is a rarity in comparison with all the multiplicity of dreams which psychoanalysis must interpret in the same sense.

And next, we obtain these associations. What they bring us is of the most various kinds: memories from the day before, the 'dream-day', and from times long past, reflections, discussions, with arguments for and against, confessions and enquiries. Some of them the patient pours out; when he comes to others he is held up for a time. Most of them show a clear connection to some element of the dream; no wonder, since those elements were their starting-point. But it also sometimes happens that the patient introduces them with these words: 'This seems to me to have nothing at all to do with the dream, but I tell it you because it occurs to me.'
To begin with, I naturally understood no more about my patients' dreams than the dreamers did themselves. But by applying to these dreams, and more particularly to my own dreams, the procedure which I had already used for the study of other abnormal psychological structures, I succeeded in answering most of the questions which could be raised by an interpretation of dreams. There were many such questions: What do we dream about? Why do we dream at all? What is the origin of all the strange characteristics which distinguish dreams from waking life? - and many more such questions besides. Some of the answers were easily given and turned out to confirm views that had already been put forward; but others involved completely new hypotheses with regard to the structure and functioning of the apparatus of the mind. People dream about the things that have engaged their minds during the waking day. People dream in order to allay impulses that seek to disturb sleep, and in order to be able to sleep on. But why was it possible for dreams to present such a strange appearance, so confusedly senseless, so obviously contrasted with the content of waking thought, in spite of being concerned with the same material? There could be no doubt that dreams were only a substitute for a rational process of thought and could be interpreted - that is to say, translated into a rational process. But what needed explaining was the fact of the distortion which the dream-work had carried out upon the rational and intelligible material.

[1932c, 4808]
Dream-distortion was the profoundest and most difficult problem of dream life. And light was thrown on it by the following consideration, which placed dreams in a class along with other psychopathological formations and revealed them, as it were, as the normal psychoses of human beings. For our mind, that precious instrument by whose means we maintain ourselves in life, is no peacefully self-contained unity. It is rather to be compared with a modern State in which a mob, eager for enjoyment and destruction, has to be held down forcibly by a prudent superior class. The whole flux of our mental life and everything that finds expression in our thoughts are derivations and representatives of the multifarious instincts that are innate in our physical constitution. But these instincts are not all equally susceptible to direction and education, or equally ready to fall in with the demands of the external world and of human society. A number of them have retained their primitive, ungovernable nature; if we let them have their way, they would infallibly bring us to ruin. Consequently, learning by experience, we have developed organizations in our mind which, in the form of inhibitions, set themselves up against the direct manifestations of the instincts. Every impulse in the nature of a wish that arises from the sources of instinctual energy must submit itself to examination by the highest agencies of our mind, and, if it is not approved, is rejected and restrained from exercising any influence upon our movements - that is, from coming into execution. Often enough, indeed, such wishes are even forbidden to enter consciousness, which is habitually unaware even of the existence of these dangerous instinctual sources. We describe such impulses as being repressed from the point of view of consciousness, and as surviving only in the unconscious. If what is repressed contrives somehow to force its way into consciousness or into movement or into both, we are no longer normal: at that point the whole range of neurotic and psychotic symptoms arise. The maintenance of the necessary inhibitions and repressions imposes upon our mind a great expenditure of energy, from which it is glad to be relieved. A good opportunity for this seems to be offered at night by the state of sleep, since sleep involves a cessation of our motor functions. The situation seems safe, and the severity of our internal police-force may therefore be relaxed. It is not entirely withdrawn, since one cannot be certain: it may be that the unconscious never sleeps at all. And now the reduction of pressure upon the repressed unconscious produces its effect. Wishes arise from it which during sleep might find the entrance to consciousness open. If we were to know them we should be appalled, alike by their subject-matter, their unrestraint and indeed the mere possibility of their existence. This, however, occurs only seldom, and when it does we awake as speedily as possible, in a state of fear. But as a rule our consciousness does not experience the dream as it really was. It is true that the inhibitory forces (the dream censorship, as we may call them) are not completely awake, but neither are they wholly asleep. They have had an influence on the dream while it was struggling to find an expression in words and pictures, they have got rid of what was most objectionable, they have altered other parts of it till they are unrecognizable, they have severed real connections while introducing false ones, until the honest but brutal wishful phantasy which lay behind the dream has turned into the manifest dream as we remember it - more or less confused and almost always strange and incomprehensible. Thus the dream (or the distortion which characterizes it) is the expression of a compromise, the evidence of a conflict between the mutually incompatible impulses and strivings of our mental life. And do not let us forget that the same process, the same interplay of forces, which explains the dreams of a normal sleeper, gives us the key to understanding all the phenomena of neurosis and psychosis.

[1932c, 4809]
The preponderant majority of writers, however, take a contrary view of the relation of dreams to waking life. Thus Haffner (1887, 245): 'In the first place, dreams carry on waking life. Our dreams regularly attach themselves to the ideas that have been in our consciousness shortly before. Accurate observation will almost always find a thread which connects a dream with the experiences of the previous day.' Weygandt (1893, 6) specifically contradicts Burdach's statement which I have just quoted: 'For it may often, and apparently in the majority of dreams, be observed that they actually lead us back to ordinary life instead of freeing us from it.' Maury (1878, 51) advances a concise formula: 'Nous rêvons de ce que nous avons vu, dit, désiré ou fait'; while Jessen, in his book on psychology (1855, 530), remarks at somewhat greater length: 'the content of a dream is invariably more or less determined by the individual personality of the dreamer, by his age, sex, class, standard of education and habitual way of living, and by the events and experiences of his whole previous life.'

The same view was taken in antiquity on the dependence of the content of dreams upon waking life. Radestock (1879, 134) tells us how before Xerxes started on his expedition against Greece, he was given sound advice of a discouraging kind but was always urged on again by his dreams; whereupon Artabanus, the sensible old Persian interpreter of dreams, observed to him pertinently that as a rule dream-pictures contain what the waking man already thinks.

Lucretius' didactic poem De rerum natura contains the following passage (IV, 962):

'Cicero (De divinatione, II, lxvii, 140) writes to exactly the same effect as Maury so many years later: 'Maximeque reliquiae rerum earum moventur in animis et agitantur de quibus vigilantes aut cogitavimus aut egimus.'

'And yet', continues Hildebrandt, 'what appears to be the contrary of this is equally true and correct. In spite of everything, the most intimate relationship goes hand in hand, I believe, with the seclusion and separation. We may even go so far as to say that whatever dreams may offer, they derive their material from reality and from the intellectual life that revolves around that reality. . . . Whatever strange results they may achieve, they can never in fact get free from the real world; and their most sublime as well as their most ridiculous structures must always borrow their basic material either from what has passed before our eyes in the world of the senses or from what has already found a place somewhere in the course of our waking thoughts - in other words from what we have already experienced either externally or internally.'

Several writers who are anxious not to cast doubts on the intimate connection between the content of dreams and waking life have been struck by the fact that impressions with which waking thoughts are intensely occupied only appear in dreams after they have been pushed somewhat aside by the workings of daytime thought. Thus, after the death of someone dear to them, people do not as a rule dream of him to begin with, while they are overwhelmed by grief (Delage, 1891). On the other hand one of the most recent observers, Miss Hallam (Hallam and Weed, 1896, 410-11), has collected instances to the contrary, thus asserting the right of each of us to psychological individualism in this respect.
It is easy to see how the remarkable preference shown by the memory in dreams for indifferent, and consequently unnoticed, elements in waking experience is bound to lead people to overlook in general the dependence of dreams upon waking life and at all events to make it difficult in any particular instance to prove that dependence. Thus Miss Whiton Galkins (1893, 315), in her statistical study of her own and her collaborator's dreams, found that in eleven per cent of the total there was no visible connection with waking life. Hildebrandt (1875) is unquestionably right in asserting that we should be able to explain the genesis of every dream-image if we devoted enough time and trouble to tracing its origin. He speaks of this as 'an exceedingly laborious and thankless task. For as a rule it ends in hunting out every kind of utterly worthless psychical event from the remotest corners of the chambers of one's memory, and in dragging to light once again every kind of completely indifferent moment of the past from the oblivion in which it was buried in the very hour, perhaps, after it occurred.' I can only regret that this keen-sighted author allowed himself to be deterred from following the path which had this inauspicious beginning; if he had followed it, it would have led him to the very heart of the explanation of dreams.

When we were dealing with the relations of dreams to waking life and with the material of dreams, we found that the most ancient and the most recent students of dreams were united in believing that men dream of what they do during the daytime and of what interests them while they are awake. Such an interest, carried over from waking life into sleep, would not only be a mental bond, a link between dreams and life, but would also provide us with a further source of dreams and one not to be despised. Indeed, taken in conjunction with the interests that develop during sleep - the stimuli that impinge on the sleeper - it might be enough to explain the origin of all dream-images. But we have also heard the opposite asserted, namely that dreams withdraw the sleeper from the interests of daytime and that, as a rule, we only start dreaming of the things that have most struck us during the day, after they have lost the spice of actuality in waking life. Thus at every step we take in our analysis of dream-life we come to feel that it is impossible to make generalizations without covering ourselves by such qualifying phrases as 'frequently', 'as a rule' or 'in most cases', and without being prepared to admit the validity of exceptions.

'It is impossible to think of any action in a dream for which the original motive has not in some way or other - whether as a wish, or desire or impulse - passed through the waking mind.' We must admit, Hildebrandt proceeds, that this original impulse was not invented by the dream; the dream merely copied it and spun it out, it merely elaborated in dramatic form a scrap of historical material which it had found in us; it merely dramatized the Apostle's words: 'Whosoever hateth his brother is a murderer'. And although after we have awoken, conscious of our moral strength, we may smile at the whole elaborate structure of the sinful dream, yet the original material from which the structure was derived will fail to raise a smile. We feel responsible for the dreamer's errors - not for the whole amount of them, but for a certain percentage. 'In short, if we understand in this scarcely disputable sense Christ's saying that "out of the heart proceed evil thoughts", we can hardly escape the conviction that a sin committed in a dream bears with it at least an obscure minimum of guilt.' (Hildebrandt, 1875, 51 ff.)

Thus Hildebrandt finds the source of immorality in dreams in the germs and hints of evil impulses which, in the form of temptations, pass through our minds during the day; and he does not hesitate to include these immoral elements in his estimate of a person's moral value. These same thoughts, as we know, and this same estimate of them, are what have led the pious and saintly in every age to confess themselves miserable sinners.
It is of some interest to learn the attitude of the Inquisition to our problem. In Caesar Carena's *Tractatus de Officio sanctissimae Inquisitionis*, 1659, the following passage occurs: 'If anyone speaks heresies in a dream, the inquisitors should take occasion to enquire into his way of life, for what occupies a man during the day is wont to come again in his sleep.' (Communicated by Dr. Ehniger, St. Urban, Switzerland.)

At this point I shall interpose a dream dreamt by a contemporary historical figure. I am doing so because in it an object that would in any case appropriately represent a male organ has a further attribute which established it in the clearest fashion as a phallic symbol. The fact of a riding whip growing to an endless length could scarcely be taken to mean anything but an erection. Apart from this, too, the dream is an excellent instance of the way in which thoughts of a serious kind, far removed from anything sexual, can come to be represented by infantile sexual material.

The dream of the burning child at the beginning of this chapter gives us a welcome opportunity of considering the difficulties with which the theory of wish-fulfilment is faced. It will no doubt have surprised all of us to be told that dreams are nothing other than fulfilsments of wishes, and not only on account of the contradiction offered by anxiety-dreams. When analysis first revealed to us that a meaning and a psychical value lay concealed behind dreams, we were no doubt quite unprepared to find that that meaning was of such a uniform character. According to Aristotle's accurate but bald definition, a dream is thinking that persists (in so far as we are asleep) in the state of sleep. Since, then, our daytime thinking produces psychical acts of such various sorts - judgements, inferences, denials, expectations, intentions, and so on - why should it be obliged during the night to restrict itself to the production of wishes alone? Are there not, on the contrary, numerous dreams which show us psychical acts of other kinds - worries, for instance - transformed into dream-shape? And was not the dream with which we began this chapter (a quite particularly transparent one) precisely a dream of this sort? When the glare of light fell on the eyes of the sleeping father, he drew the worrying conclusion that a candle had fallen over and might have set the dead body on fire. He turned this conclusion into a dream by clothing it in a sensory situation and in the present tense. What part was played in this by wish-fulfilment? Can we fail to see in it the predominating influence of a thought persisting from waking life or stimulated by a new sense-impression? All this is quite true and compels us to enter more closely into the part played by wish-fulfilment in dreams and into the importance of waking thoughts which persist into sleep.
There is no need to underestimate the importance of the psychical intensities which are introduced into the state of sleep by these residues of daytime life, and particularly of those in the group of unsolved problems. It is certain that these excitations continue to struggle for expression during the night; and we may assume with equal certainty that the state of sleep makes it impossible for the excitatory process to be pursued in the habitual manner in the preconscious and brought to an end by becoming conscious. In so far as our thought-processes are able to become conscious in the normal way at night, we are simply not asleep. I am unable to say what modification in the system \( \text{Pcs} \) is brought about by the state of sleep;¹ but there can be no doubt that the psychological characteristics of sleep are to be looked for essentially in modifications in the cathexis of this particular system - a system that is also in control of access to the power of movement, which is paralysed during sleep. On the other hand, nothing in the psychology of dreams gives me reason to suppose that sleep produces any modifications other than secondary ones in the state of things prevailing in the \( \text{Ucs} \). No other course, then, lies open to excitations occurring at night in the \( \text{Pcs} \) than that followed by wishful excitations arising from the \( \text{Ucs} \); the preconscious excitations must find reinforcement from the \( \text{Ucs} \) and must accompany the unconscious excitations along their circuitous paths. But what is the relation of the preconscious residues of the previous day to dreams? There is no doubt that they find their way into dreams in great quantity, and that they make use of the content of dreams in order to penetrate into consciousness even during the night. Indeed they occasionally dominate the content of a dream and force it to carry on the activity of daytime. It is certain, too, that the day's residues may be of any other character just as easily as wishes; but it is highly instructive in this connection, and of positively decisive importance for the theory of wish-fulfilment, to observe the condition to which they must submit in order to be received into a dream.

[1900a, 987]

Now that the old antithesis between conscious life and dream life has been reduced to its proper proportions by the establishment of unconscious psychical reality, a number of dream-problems with which earlier writers were deeply concerned have lost their significance. Thus some of the activities whose successful performance in dreams excited astonishment are now no longer to be attributed to dreams but to unconscious thinking, which is active during the day no less than at night. If, as Scherner has said, dreams appear to engage in making symbolic representations of the body, we now know that those representations are the product of certain unconscious phantasies (deriving, probably, from sexual impulses) which find expression not only in dreams but also in hysterical phobias and other symptoms. If a dream carries on the activities of the day and completes them and even brings valuable fresh ideas to light, all we need do is to strip it of the dream disguise, which is the product of dream-work and the mark of assistance rendered by obscure forces from the depths of the mind (cf. the Devil in Tartini's sonata dream); the intellectual achievement is due to the same mental forces which produce every similar result during the daytime. We are probably inclined greatly to over-estimate the conscious character of intellectual and artistic production as well. Accounts given us by some of the most highly productive men, such as Goethe and Helmholtz, show rather that what is essential and new in their creations came to them without premeditation and as an almost ready-made whole. There is nothing strange if in other cases, where a concentration of every intellectual faculty was needed, conscious activity also contributed its share. But it is the much-abused privilege of conscious activity, wherever it plays a part, to conceal every other activity from our eyes.

[1900a, 1038]

This small collection throws a direct light on a further characteristic of children's dreams: their connection with daytime life. The wishes which are fulfilled in them are carried over from daytime and as a rule from the day before, and in waking life they have been accompanied by intense emotion. Nothing unimportant or indifferent, or nothing which would strike a child as such, finds its way into the content of their dreams.

[1901a, 1063]
If we undo dream-displacement by means of analysis, we obtain what seems to be completely trustworthy information on two much-disputed problems concerning dreams: as to their instigators and as to their connection with waking life. There are dreams which immediately reveal their derivation from events of the day; there are others in which no trace of any such derivation is to be discovered. If we seek the help of analysis, we find that every dream without any possible exception goes back to an impression of the past few days, or, it is probably more correct to say, of the day immediately preceding the dream, of the ‘dream-day.’ The impression which plays the part of dream-instigator may be such an important one that we feel no surprise at being concerned with it in the daytime, and in that case we rightly speak of the dream as carrying on with the significant interests of our waking life. As a rule, however, if a connection is to be found in the content of the dream with any impression of the previous day, that impression is so trivial, insignificant and unmemorable, that it is only with difficulty that we ourselves can recall it. And in such cases the content of the dream itself, even if it is connected and intelligible, seems to be concerned with the most indifferent trivialities, which would be unworthy of our interest if we were awake. A good deal of the contempt in which dreams are held is due to the preference thus shown in their content for what is indifferent and trivial.
[1901a, 1071]

Analysis does away with the misleading appearance upon which this derogatory judgement is founded. If the content of a dream puts forward some indifferent impression as being its instigator, analysis invariably brings to light a significant experience, and one by which the dreamer has good reason to be stirred. This experience has been replaced by the indifferent one, with which it is connected by copious associative links. Where the content of the dream treats of insignificant and uninteresting ideational material, analysis uncovers the numerous associative paths connecting these trivialities with things that are of the highest psychical importance in the dreamer’s estimation. If what makes their way into the content of dreams are impressions and material which are indifferent and trivial rather than justifiably stirring and interesting, that is only the effect of the process of displacement. If we answer our questions about dream-instigators and the connection between dreaming and daily affairs on the basis of the new insight we have gained from replacing the manifest by the latent content of dreams, we arrive at these conclusions: dreams are never concerned with things with which we should not think it worth while to be concerned during the day, and trivialities which do no affect us during the day are unable to pursue us in our sleep.
[1901a, 1072]
The interpretation of the dream now seemed to me to be complete. But Dora brought me an addendum to the dream on the very next day. She had forgotten to relate, she said, that each time after waking up she had smelt smoke. Smoke, of course, fitted in well with fire, but it also showed that the dream had a special relation to myself; for when she used to assert that there was nothing concealed behind this or that, I would often say by way of rejoinder: 'There can be no smoke without fire!' Dora objected, however, to such a purely personal interpretation, saying that Herr K. and her father were passionate smokers - as I am too, for the matter of that. She herself had smoked during her stay by the lake, and Herr K. had rolled a cigarette for her before he began his unlucky proposal. She thought, too, that she clearly remembered having noticed the smell of smoke on the three occasions of the dream's occurrence at L--, and not for the first time at its recent reappearance. As she would give me no further information, it was left to me to determine how this addendum was to be introduced into the texture of the dream-thoughts. One thing which I had to go upon was the fact that the smell of smoke had only come up as an addendum to the dream, and must therefore have had to overcome a particularly strong effort on the part of repression. Accordingly it was probably related to the thoughts which were the most obscurely presented and the most successfully repressed in the dream, to the thoughts, that is, concerned with the temptation to show herself willing to yield to the man. If that were so, the addendum to the dream could scarcely mean anything else than the longing for a kiss, which, with a smoker, would necessarily smell of smoke. But a kiss had passed between Herr K. and Dora some two years further back, and it would certainly have been repeated more than once if she had given way to him. So the thoughts of temptation seemed in this way to have harked back to the earlier scene, and to have revived the memory of the kiss against whose seductive influence the little 'thumb-sucker' had defended herself at the time, by the feeling of disgust. Taking into consideration, finally, the indications which seemed to point to there having been a transference on to me - since I am a smoker too - I came to the conclusion that the idea had probably occurred to her one day during a session that she would like to have a kiss from me. This would have been the exciting cause which led her to repeat the warning dream and to form her intention of stopping the treatment. Everything fits together very satisfactorily upon this view; but owing to the characteristics of 'transference' its validity is not susceptible of definite proof.

[1905e, 1410]
Can we feel sure that none of the possible techniques of jokes has escaped our investigation? Of course not. But a continued examination of fresh material can convince us that we have got to know the commonest and most important technical methods of the joke-work - at all events as much as is required for forming a judgement on the nature of that psychical process. So far we have not arrived at any such judgement; but on the other hand we are now in possession of an important indication of the direction from which we may expect to receive further light upon the problem. The interesting processes of condensation accompanied by the formation of a substitute, which we have recognized as the core of the technique of verbal jokes, point towards the formation of dreams, in the mechanism of which the same psychical processes have been discovered. This is equally true, however, of the techniques of conceptual jokes - displacement, faulty reasoning, absurdity, indirect representation, representation by the opposite - which re-appear one and all in the technique of the dream-work. Displacement is responsible for the puzzling appearance of dreams, which prevents our recognizing that they are a continuation of our waking life. The use of absurdity and nonsense in dreams has cost them the dignity of being regarded as psychical products and has led the authorities to suppose that a disintegration of the mental activities and a cessation of criticism, morality and logic are necessary conditions of the formation of dreams. Representation by the opposite is so common in dreams that even the popular books of dream-interpretation, which are on a completely wrong tack, are in the habit of taking it into account. Indirect representation - the replacement of a dream-thought by an allusion, by something small, a symbolism akin to analogy - is precisely what distinguishes the mode of expression of dreams from that of our waking life.¹ So far-reaching an agreement between the methods of the joke-work and those of the dream-work can scarcely be a matter of chance. To demonstrate this agreement in detail and to examine its basis will be one of our later tasks.

[1905c, 1686]

Thus a great number of the jokes in circulation have a certain length of life: their life runs a course made up of a period of flowering and a period of decay and it ends in complete oblivion. The need which men feel for deriving pleasure from their processes of thought is therefore constantly creating new jokes based on the new interests of the day. The vital force of topical jokes is not their own; it is borrowed, by the method of allusion, from those other interests, the expiry of which determines the fate of the joke as well. The factor of topicality is a source of pleasure, ephemeral it is true but particularly abundant, which supplements the sources inherent in the joke itself. It cannot be simply equated with the rediscovery of what is familiar. It is concerned rather with a particular category of what is familiar, which must in addition possess the characteristic of being fresh, recent and untouched by forgetting. In the formation of dreams, too, we come across a special preference for what is recent and we cannot escape a suspicion that association with what is recent is rewarded, and so facilitated, by a peculiar bonus of pleasure.

[1905c, 1715]
Now in this dispute as to the estimation in which dreams should be held, imaginative writers seem to be on the same side as the ancients, as the superstitious public and as the author of *The Interpretation of Dreams*. For when an author makes the characters constructed by his imagination dream, he follows the everyday experience that people's thoughts and feelings are continued in sleep and he aims at nothing else than to depict his heroes' states of mind by their dreams. But creative writers are valuable allies and their evidence is to be prized highly, for they are apt to know a whole host of things between heaven and earth of which our philosophy has not yet let us dream. In their knowledge of the mind they are far in advance of us everyday people, for they draw upon sources which we have not yet opened up for science. If only this support given by writers in favour of dreams having a meaning were less ambiguous! A strictly critical eye might object that writers take their stand neither for nor against particular dreams having a psychical meaning; they are content to show how the sleeping mind twitches under the excitations which have remained active in it as off-shoots of waking life.

[1907a, 1813]

I can imagine that to point out the existence of lying dreams of this kind, 'obliging' dreams, will arouse a positive storm of helpless indignation in some readers who call themselves analysts. 'What!' they will exclaim, 'the unconscious, the real centre of our mental life, the part of us that is so much nearer the divine than our poor consciousness - it too can lie! Then how can we still build on the interpretations of analysis and the accuracy of our findings?' To which one must reply that the recognition of these lying dreams does not constitute any shattering novelty. I know, indeed, that the craving of mankind for mysticism is ineradicable, and that it makes ceaseless efforts to win back for mysticism the territory it has been deprived of by *The Interpretation of Dreams*, but surely in the case under consideration everything is simple enough. A dream is not the 'unconscious'; it is the form into which a thought left over from preconscious, or even from conscious, waking life, can, thanks to the favouring state of sleep, be recast. In the state of sleep this thought has been reinforced by unconscious wishful impulses and has thus experienced distortion through the dream-work, which is determined by the mechanisms prevailing in the unconscious. With our dreamer, the intention to mislead me, just as she did her father, certainly emanated from the preconscious, and may indeed have been conscious; it could come to expression by entering into connection with the unconscious wishful impulse to please her father (or father-substitute), and in this way it created a lying dream. The two intentions, to betray and to please her father, originated in the same complex; the former resulted from the repression of the latter, and the later one was brought back by the dream-work to the earlier one. There can therefore be no question of any devaluation of the unconscious, nor of a shattering of our confidence in the results of analysis.

[1920a, 3854]
The Dynamic Theory of Dream-Formation. The motive power for the formation of dreams is not provided by the latent dream-thoughts or day's residues, but by an unconscious impulse, repressed during the day, with which the day's residues have been able to establish contact and which contrives to make a wish-fulfilment for itself out of the material of the latent thoughts. Thus every dream is on the one hand the fulfilment of a wish on the part of the unconscious and on the other hand (in so far as it succeeds in guarding the state of sleep against being disturbed) the fulfilment of the normal wish to sleep which set the sleep going. If we disregard the unconscious contribution to the formation of the dream and limit the dream to its latent thoughts, it can represent anything with which waking life has been concerned - a reflection, a warning, an intention, a preparation for the immediate future or, once again, the satisfaction of an unfulfilled wish. The recognizability, strangeness and absurdity of the manifest dream are partly the result of the translation of the thoughts into a different, so to say archaic, method of expression, but partly the effect of a restrictive, critically disapproving agency in the mind which does not entirely cease to function during sleep. It is plausible to suppose that the 'dream-censorship', which we regard as being responsible in the first instance for the distortion of the dream-thoughts into the manifest dream, is an expression of the same mental forces which during the day-time had held back or repressed the unconscious wishful impulse.

We have explained that the unconscious instinctual impulse of the dream connects itself with a residue of the day, with some interest of waking life which has not been disposed of; it thus gives the dream which it constructs a double value for the work of analysis. For on the one hand a dream that has been analysed reveals itself as the fulfilment of a repressed wish; but on the other hand it may be a continuation of some preconscious activity of the day before and may contain every kind of subject-matter and give expression to an intention, a warning, a reflection, or once more to the fulfilment of a wish. Analysis exploits the dream in both directions, as a means of obtaining knowledge alike of the patient's conscious and of his unconscious processes. It also profits from the fact that dreams have access to the forgotten material of childhood, and so it happens that infantile amnesia is for the most part overcome in connection with the interpretation of dreams. In this respect dreams achieve a part of what was previously the task of hypnotism. On the other hand, I have never maintained the assertion which has so often been ascribed to me that dream-interpretation shows that all dreams have a sexual content or are derived from sexual motive forces. It is easy to see that hunger, thirst, or the need to excrete, can produce dreams of satisfaction just as well as any repressed sexual or egoistic impulse. The case of young children affords us a convenient test of the validity of our theory of dreams. In them the various psychical systems are not yet sharply divided and the repressions have not yet grown deep, so that we often come upon dreams which are nothing more than undisguised fulfilments of wishful impulses left over from waking life. Under the influence of imperative needs, adults may also produce dreams of this infantile type.

Our philosopher's dreams are what are known as 'dreams from above' ('Träume von oben'). That is to say, they are formulations of ideas which could have been created just as well in a waking state as during the state of sleep, and which have derived their content only in certain parts from mental states at a comparatively deep level. That is why these dreams offer for the most part a content which has an abstract, poetic or symbolic form.
We have already taken the first step in this direction by advancing the thesis (see p. 666 f.) that the dream-work is under the necessity of combining into a unity all instigations to dreaming which are active simultaneously. We found that, when two or more experiences capable of creating an impression are left over from the previous day, the wishes derived from them are combined in a single dream, and similarly that the psychically significant impressions and the indifferent experiences from the previous day are brought together in the dream-material, provided always that it is possible to set up communicating ideas between them. Thus a dream appears to be a reaction to everything that is simultaneously present in the sleeping mind as currently active material. So far as we have hitherto analysed the material of dreams, we have seen it as a collection of psychical residues and memory-traces, to which (on account of the preference shown for recent and infantile material) we have been led to attribute a hitherto indefinable quality of being 'currently active'. We can foresee, then, without any great difficulty, what will happen if fresh material in the form of sensations is added during sleep to these currently active memories. It is once again owing to the fact of their being currently active that these sensory excitations are of importance for the dream; they are united with the other currently active psychical material to furnish what is used for the construction of the dream. To put it another way, stimuli arising during sleep are worked up into a wish-fulfilment the other constituents of which are the familiar psychical 'day's residues'. This combination need not occur; as I have already pointed out, there is more than one way of reacting to a somatic stimulus during sleep. When it does occur, it means that it has been possible to find ideational material to serve as the content of the dream of such a sort as to be able to represent both kinds of source of the dream - the somatic and the psychical.

[1900a, 707]

The essential nature of the dream is not altered by the fact of somatic material being added to its psychical sources: a dream remains the fulfilment of a wish, no matter in what way the expression of that wish-fulfilment is determined by the currently active material.

[1900a, 707]

When external nervous stimuli and internal somatic stimuli are intense enough to force psychical attention to themselves, then - provided that their outcome is dreaming and not waking up - they serve as a fixed point for the formation of a dream, a nucleus in its material; a wish-fulfilment is then looked for that shall correspond to this nucleus, just as (see above) intermediate ideas are looked for between two psychical dream stimuli. To that extent it is true that in a number of dreams the content of the dream is dictated by the somatic element. In this extreme instance it may even happen that a wish which is not actually a currently active one is called up for the sake of constructing a dream. A dream, however, has no alternative but to represent a wish in the situation of having been fulfilled; it is, as it were, faced with the problem of looking for a wish which can be represented as fulfilled by the currently active sensation. If this immediate material is of a painful or distressing kind, that does not necessarily mean that it cannot be used for the construction of a dream. The mind has wishes at its disposal whose fulfilment produces unpleasure. This seems self-contradictory; but it becomes intelligible when we take into account the presence of two psychical agencies and a censorship between them.

[1900a, 714]
As we have seen, there are 'repressed' wishes in the mind, which belong to the first system and whose fulfilment is opposed by the second system. In saying that there are such wishes I am not making a historical statement to the effect that they once existed and were later abolished. The theory of repression, which is essential to the study of the psychoneuroses, asserts that these repressed wishes still exist - though there is a simultaneous inhibition which holds them down. Linguistic usage hits the mark in speaking of the 'suppression' of these impulses. The psychical arrangements that make it possible for such impulses to force their way to realization remain in being and in working order. Should it happen, however, that a suppressed wish of this kind is carried into effect, and that its inhibition by the second system (the system that is admissible to consciousness) is defeated, this defeat finds expression as unpleasure. In conclusion: if sensations of an unpleasurable nature arising from somatic sources occur during sleep, the dream-work makes use of that event in order to represent - subject to the continuance of the censorship to a greater or less degree - the fulfilment of some wish which is normally suppressed.

[1900a, 714]

Thus, in my opinion, somatic sources of stimulation during sleep (that is to say, sensations during sleep), unless they are of unusual intensity, play a similar part in the formation of dreams to that played by recent but indifferent impressions left over from the previous day. I believe, that is, that they are brought in to help in the formation of a dream if they fit in appropriately with the ideational content derived from the dream's psychical sources, but otherwise not. They are treated like some cheap material always ready to hand, which is employed whenever it is needed, in contrast to a precious material which itself prescribes the way in which it shall be employed. If, to take a simile, a patron of the arts brings an artist some rare stone, such as a piece of onyx, and asks him to create a work of art from it, then the size of the stone, its colour and markings, help to decide what head or what scene shall be represented in it. Whereas in the case of a uniform and plentiful material such as marble or sandstone, the artist merely follows some idea that is present in his own mind. It is only in this way, so it seems to me, that we can explain the fact that dream-content provided by somatic stimuli of no unusual intensity fails to appear in every dream or every night.¹

[1900a, 716]
The function of the dream as a guardian of sleep becomes particularly evident when an external stimulus impinges upon the senses of a sleeper. It is generally recognized that sensory stimuli arising during sleep influence the content of dreams; this can be proved experimentally and is among the few certain (but, incidentally, greatly overvalued) findings of medical investigation into dreams. But this finding involves a puzzle which has hitherto proved insoluble. For the sensory stimulus which the experimenter causes to impinge upon the sleeper is not correctly recognized in the dream; it is subjected to one of an indefinite number of possible interpretations, the choice being apparently left to an arbitrary psychical determination. But there is, of course, no such thing as arbitrary determination in the mind. There are several ways in which a sleeper may react to an external sensory stimulus. He may wake up or he may succeed in continuing his sleep in spite of it. In the latter case he may make use of a dream in order to get rid of the external stimulus, and here again there is more than one method open to him. For instance, he may get rid of the stimulus by dreaming that he is in a situation which is absolutely incompatible with the stimulus. Such was the line taken by a sleeper who was subject to disturbance by a painful abscess on the perineum. He dreamt that he was riding on a horse, making use of the poultice that was intended to mitigate his pain as a saddle, and in this way he avoided being disturbed. Or, as happens more frequently, the external stimulus is given an interpretation which brings it into the context of a repressed wish which is at the moment awaiting fulfilment; in this way the external stimulus is robbed of its reality and is treated as though it were a portion of the psychical material. Thus someone dreamt that he had written a comedy with a particular plot; it was produced in a theatre, the first act was over, and there were thunders of applause; the clapping was terrific. . . . The dreamer must have succeeded in prolonging his sleep till after the interference had ceased; for when he woke up he no longer heard the noise, but rightly concluded that someone must have been beating a carpet or mattress. Every dream which occurs immediately before the sleeper is woken by a loud noise has made an attempt at explaining away the arousing stimulus by providing another explanation of it and has thus sought to prolong sleep, even if only for a moment. [1901a, 1093]

There is no difficulty in discovering the general function of dreaming. It serves the purpose of fending off, by a kind of soothing action, external or internal stimuli which would tend to arouse the sleeper, and thus of securing sleep against interruption. External stimuli are fended off by being given a new interpretation and by being woven into some harmless situation; internal stimuli, caused by instinctual demands, are given free play by the sleeper and allowed to find satisfaction in the formation of dreams, so long as the latent dream-thoughts submit to the control of the censorship. But if they threaten to break free and the meaning of the dream becomes too plain, the sleeper cuts short the dream and wakes in a fright. (Dreams of this class are known as anxiety-dreams.) A similar failure in the function of dreaming occurs if an external stimulus becomes too strong to be fended off. (This is the class of arousal-dreams.) I have given the name of dream-work to the process which, with the co-operation of the censorship, converts the latent thoughts into the manifest content of the dream. It consists of a peculiar way of treating the preconscious material of thought, so that its component parts become condensed, its psychical emphasis becomes displaced, and the whole of it is translated into visual images or dramatized, and completed by a deceptive secondary revision. The dream-work is an excellent example of the processes occurring in the deeper, unconscious layers of the mind, which differ considerably from the familiar normal processes of thought. It also displays a number of archaic characteristics, such as the use of a symbolism (in this case of a predominantly sexual kind) which it has since also been possible to discover in other spheres of mental activity. [1925d, 4220]
I cannot leave the subject of typical dreams of the death of loved relatives, without adding a few more words to throw light on their significance for the theory of dreams in general. In these dreams we find the highly unusual condition realized of a dream-thought formed by a repressed wish entirely eluding censorship and passing into the dream without modification. There must be special factors at work to make this event possible, and I believe that the occurrence of these dreams is facilitated by two such factors. Firstly, there is no wish that seems more remote from us than this one: 'we couldn't even dream' - so we believe - of wishing such a thing. For this reason the dream-censorship is not armed to meet such a monstrosity, just as Solon's penal code contained no punishment for parricide. Secondly, in this case the repressed and unsuspected wish is particularly often met half-way by a residue from the previous day in the form of a worry about the safety of the person concerned. This worry can only make its way into the dream by availing itself of the corresponding wish; while the wish can disguise itself behind the worry that has become active during the day. We may feel inclined to think that things are simpler than this and that one merely carries on during the night and in dreams with what one has been turning over in one's mind during the day; but if so we shall be leaving dreams of the death of people of whom the dreamer is fond completely in the air and without any connection with our explanation of dreams in general, and we shall thus be clinging quite unnecessarily to a riddle which is perfectly capable of solution.

¹ [Footnote added 1911:] When Ernest Jones was giving a scientific lecture on the egoism of dreams before an American audience, a learned lady objected to this unscientific generalization, saying that the author of the present work could only judge of the dreams of Austrians and had no business to speak of the dreams of Americans. So far as she was concerned, she was certain that all her dreams were strictly altruistic. - [Added 1925:] By way of excuse for this patriotic lady, I may remark that the statement that dreams are entirely egoistic must not be misunderstood. Since anything whatever that occurs in preconscious thought can pass into a dream (whether into its actual content or into the latent dream-thoughts) that possibility is equally open to altruistic impulses. In the same way, an affectionate or erotic impulse towards someone else, if it is present in the unconscious, can appear in a dream. The truth in the assertion made in the text above is thus restricted to the fact that among the unconscious instigators of a dream we very frequently find egoistic impulses which seem to have been overcome in waking life.

² In which of these systems, then, are we to locate the impetus to the construction of dreams? For simplicity's sake, in the system Ucs. It is true that in the course of our future discussion we shall learn that this is not entirely accurate, and that the process of forming dreams is obliged to attach itself to dream-thoughts belonging to the preconscious system. But when we consider the dream-wish, we shall find that the motive force for producing dreams is supplied by the Ucs.; and owing to this latter factor we shall take the unconscious system as the starting-point of dream-formation. Like all other thought structures, this dream-instigator will make an effort to advance into the Pcs. and from there to obtain access to consciousness.

A little reflection will convince us, however, that this 'secondary' function of dreams has no claim to be considered as a part of the subject of dream-interpretation. Thinking ahead, forming intentions, framing attempted solutions which may perhaps be realized later in waking life, all these, and many other similar things, are products of the unconscious and preconscious activity of the mind; they may persist in the state of sleep as 'the day's residues' and combine with an unconscious wish (cf. p. 982 ff.) in forming a dream. Thus the dream's function of 'thinking ahead' is rather a function of preconscious waking thought, the products of which may be revealed to us by the analysis of dreams or of other phenomena. It has long been the habit to regard dreams as identical with their manifest content; but we must now beware equally of the mistake of confusing dreams with latent dream-thoughts.
It has naturally not occurred to us to throw any doubt on the significance, which has been experimentally demonstrated, of external sensory stimuli during sleep; but we have shown that such material stands in the same relation to the dream-wish as do the residues of thought left over from day time activity. Nor have we seen any reason to dispute the view that dreams interpret objective sensory stimuli just as illusions do; but we have found the motive which provides the reason for that interpretation, a reason which has been left unspecified by other writers. Interpretation is carried out in such a way that the object perceived shall not interrupt sleep and shall be usable for purposes of wish-fulfilment. As regards subjective states of excitation in the sense organs during sleep, the occurrence of which seems to have been proved by Trumbull Ladd, it is true that we have not accepted them as a particular source of dreams; but we have been able to explain them as resulting from the regressive revival of memories that are in operation behind the dream.

[1900a, 1016]

If one bears in mind that dreams are something different from the latent dream-thoughts which they work over, there is nothing surprising in patients dreaming of things with which their minds have been filled during the treatment, whether it be the 'life-task', or 'being on top' or 'underneath'. The dreams of people being analysed can undoubtedly be directed, in the same way as they are by stimuli produced for experimental purposes. One can determine a part of the material which appears in a dream; nothing in the essence or mechanism of dreams is altered by this. Nor do I believe that 'biographical' dreams, as they are called, occur outside analysis. If, on the other hand, one analyses dreams which occurred before treatment, or if one considers the dreamer's own additions to what has been suggested to him in the treatment, or if one avoids setting him any such tasks, then one may convince oneself how far removed it is from the purpose of a dream to produce attempted solutions of the life-task. Dreams are only a form of thinking; one can never reach an understanding of this form by reference to the content of the thoughts; only an appreciation of the dream-work will lead to that understanding.

[1914d, 2927]

I can imagine that to point out the existence of lying dreams of this kind, 'obliging' dreams, will arouse a positive storm of helpless indignation in some readers who call themselves analysts. 'What!' they will exclaim, 'the unconscious, the real centre of our mental life, the part of us that is so much nearer the divine than our poor consciousness - it too can lie! Then how can we still build on the interpretations of analysis and the accuracy of our findings?' To which one must reply that the recognition of these lying dreams does not constitute any shattering novelty. I know, indeed, that the craving of mankind for mysticism is ineradicable, and that it makes ceaseless efforts to win back for mysticism the territory it has been deprived of by The Interpretation of Dreams, but surely in the case under consideration everything is simple enough. A dream is not the 'unconscious'; it is the form into which a thought left over from preconscious, or even from conscious, waking life, can, thanks to the favouring state of sleep, be recast. In the state of sleep this thought has been reinforced by unconscious wishful impulses and has thus experienced distortion through the dream-work, which is determined by the mechanisms prevailing in the unconscious. With our dreamer, the intention to mislead me, just as she did her father, certainly emanated from the preconscious, and may indeed have been conscious; it could come to expression by entering into connection with the unconscious wishful impulse to please her father (or father-substitute), and in this way it created a lying dream. The two intentions, to betray and to please her father, originated in the same complex; the former resulted from the repression of the latter, and the later one was brought back by the dream-work to the earlier one. There can therefore be no question of any devaluation of the unconscious, nor of a shattering of our confidence in the results of analysis.

[1920a, 3854]
And now I have reached the point I wish to put before you. We have endeavoured to maintain the strictest impartiality and have allowed two conceptions of the dream to rank as equally probable and equally unproved. According to the first the dream is a reaction to a telepathic message: 'your daughter has just brought twins into the world.' According to the second an unconscious process of thought underlies the dream, which may be reproduced somewhat as follows: 'To-day is the day the confinement should take place if the young people in Berlin are really out in their reckoning by a month, as I suspect. And if my (first) wife were still alive, she certainly would not be content with one grandchild. To please her there would have to be at least twins!' If this second view is right, no new problems arise. It is simply a dream like any other. The (preconscious) dream-thoughts as outlined above are reinforced by the (unconscious) wish that no other than the daughter should be the dreamer's second wife, and thus the manifest dream as described to us arises.

[1922a, 3886]

If you prefer to assume that a telepathic message about the daughter's confinement reached the sleeper, further questions arise of the relation of a message such as this to a dream and of its influence on the formation of dreams. The answer is not far to seek and is quite unambiguous. A telepathic message will be treated as a portion of the material that goes to the formation of a dream, like any other external or internal stimulus, like a disturbing noise in the street or an insistent organic sensation in the sleeper's own body. In our example it is evident how the message, with the help of a lurking repressed wish, became remodelled into a wish-fulfilment; it is unfortunately less easy to show that it combined with other material that had become active at the same time and was blended into a dream. Telepathic messages - if we are justified in recognizing their existence - can thus make no alteration in the process of forming a dream; telepathy has nothing to do with the nature of dreams. And in order to avoid the impression that I am trying to conceal a vague notion behind abstract and fine-sounding words, I am willing to repeat: the essential nature of dreams consists in the peculiar process of 'dream-work' which, with the help of an unconscious wish, carries the preconscious thoughts (day's residues) over into the manifest content of the dream. The problem of telepathy concerns dreams as little as does the problem of anxiety.

[1922a, 3887]

A comparison of the dreams of the two patients shows, however, that the question whether or not paranoia (or any other psychoneurosis) can penetrate into dreams is based on a false conception of dreams. Dreams are distinguished from waking thought by the fact that they can include material (belonging to the region of the repressed) which must not emerge in waking thought. Apart from this, dreams are merely a form of thinking, a transformation of preconscious material of thought by the dream-work and its conditions. Our terminology of the neuroses is not applicable to repressed material; this cannot be called hysterical, nor obsessional, nor paranoic. As against this, the other part of the material which is subjected to the process of dream-formation - the preconscious thoughts - may be normal or may bear the character of any neurosis; they may be the products of any of the pathogenic processes in which the essence of a neurosis lies. There seems to be no reason why any such pathological idea should not be transformed into a dream. A dream may therefore quite simply represent a hysterical phantasy, an obsessional idea, or a delusion - that is, may reveal one or other of these upon interpretation. Observation of the two paranoics shows that the dreams of the one were quite normal while he was subject to his delusion, and that those of the other were paranoic in content while he was treating his delusional ideas with contempt. In both cases, therefore, the dream took up the material that was at the time forced into the background in waking life. This too, however, need not necessarily be an invariable rule.

[1922b, 3906]
The Dynamic Theory of Dream-Formation. The motive power for the formation of dreams is not provided by the latent dream-thoughts or day's residues, but by an unconscious impulse, repressed during the day, with which the day's residues have been able to establish contact and which contrives to make a wish-fulfilment for itself out of the material of the latent thoughts. Thus every dream is on the one hand the fulfilment of a wish on the part of the unconscious and on the other hand (in so far as it succeeds in guarding the state of sleep against being disturbed) the fulfilment of the normal wish to sleep which set the sleep going. If we disregard the unconscious contribution to the formation of the dream and limit the dream to its latent thoughts, it can represent anything with which waking life has been concerned - a reflection, a warning, an intention, a preparation for the immediate future or, once again, the satisfaction of an unfulfilled wish. The unrecognizability, strangeness and absurdity of the manifest dream are partly the result of the translation of the thoughts into a different, so to say archaic, method of expression, but partly the effect of a restrictive, critically disapproving agency in the mind which does not entirely cease to function during sleep. It is plausible to suppose that the 'dream-censorship', which we regard as being responsible in the first instance for the distortion of the dream-thoughts into the manifest dream, is an expression of the same mental forces which during the day-time had held back or repressed the unconscious wishful impulse.

[1923a, 3918]

It is possible to distinguish between dreams from above and dreams from below, provided the distinction is not made too sharply. Dreams from below are those which are provoked by the strength of an unconscious (repressed) wish which has found a means of being represented in some of the day's residues. They may be regarded as inroads of the repressed into waking life. Dreams from above correspond to thoughts or intentions of the day before which have contrived during the night to obtain reinforcement from repressed material that is debarred from the ego. When this is so, analysis as a rule disregards this unconscious ally and succeeds in inserting the latent dream-thoughts into the texture of waking thought. This distinction calls for no modification in the theory of dreams.

[1923c, 4032]

In spite of the caution which is prescribed by the importance, novelty and obscurity of the subject, I feel that I should not be justified in holding back any longer these considerations upon the problem of telepathy. All of this has only this much to do with dreams: if there are such things as telepathic messages, the possibility cannot be dismissed of their reaching someone during sleep and coming to his knowledge in a dream. Indeed, on the analogy of other perceptual and intellectual material, the further possibility arises that telepathic messages received in the course of the day may only be dealt with during a dream of the following night. There would then be nothing contradictory in the material that has been telepathically communicated being modified and transformed in the dream like any other material. It would be satisfactory if with the help of psycho-analysis we could obtain further and better authenticated knowledge of telepathy.

[1925i, 4055]
We have explained that the unconscious instinctual impulse of the dream connects itself with a residue of the day, with some interest of waking life which has not been disposed of; it thus gives the dream which it constructs a double value for the work of analysis. For on the one hand a dream that has been analysed reveals itself as the fulfilment of a repressed wish; but on the other hand it may be a continuation of some preconscious activity of the day before and may contain every kind of subject-matter and give expression to an intention, a warning, a reflection, or once more to the fulfilment of a wish. Analysis exploits the dream in both directions, as a means of obtaining knowledge alike of the patient's conscious and of his unconscious processes. It also profits from the fact that dreams have access to the forgotten material of childhood, and so it happens that infantile amnesia is for the most part overcome in connection with the interpretation of dreams. In this respect dreams achieve a part of what was previously the task of hypnotism. On the other hand, I have never maintained the assertion which has so often been ascribed to me that dream-interpretation shows that all dreams have a sexual content or are derived from sexual motive forces. It is easy to see that hunger, thirst, or the need to excrete, can produce dreams of satisfaction just as well as any repressed sexual or egoistic impulse. The case of young children affords us a convenient test of the validity of our theory of dreams. In them the various psychical systems are not yet sharply divided and the repressions have not yet grown deep, so that we often come upon dreams which are nothing more than undisguised fulfilments of wishful impulses left over from waking life. Under the influence of imperative needs, adults may also produce dreams of this infantile type.¹

In what follows I shall not be able to avoid a schematic method of exposition. Let us assume that in a particular case we have before us all the latent thoughts, charged with a greater or less amount of affect, by which the manifest dream has been replaced after its interpretation has been completed. We shall then be struck by one difference among these latent thoughts, and that difference will take us a long way. Almost all these dream-thoughts are recognized by the dreamer or acknowledged by him; he admits that he has thought this, now or at some other time, or that he might have thought it. There is only one single thought that he refuses to accept; it is strange to him or even perhaps repellent; he may possibly reject it with passionate feeling. It now becomes evident to us that the other thoughts are portions of a conscious, or, more accurately, a preconscious train of thinking. They might have been thought in waking life too, and indeed they were probably formed during the previous day. This one repudiated thought, however, or, properly speaking, this one impulse, is a child of night; it belongs to the dreamer's unconscious and on that account it is repudiated and rejected by him. It had to wait for the nightly relaxation of repression in order to arrive at any kind of expression. And in any case this expression is a weakened, distorted and disguised one; without our work of dream-interpretation we should not have found it. This unconscious impulse has to thank its link with the other, unobjectionable, dream-thoughts for the opportunity of slipping past the barrier of the censorship in an inconspicuous disguise. On the other hand, the preconscious dream-thoughts have to thank this same link for the power to occupy mental life during sleep as well. For there is no doubt about it: this unconscious impulse is the true creator of the dream; it is what produces the psychical energy for the dream's construction. Like any other instinctual impulse, it cannot strive for anything other than its own satisfaction; and our experience in interpreting dreams shows us too that that is the sense of all dreaming. In every dream an instinctual wish has to be represented as fulfilled. The shutting-off of mental life from reality at night and the regression to primitive mechanisms which this makes possible enable this wished-for instinctual satisfaction to be experienced in a hallucinatory manner as occurring in the present. As a result of this same regression, ideas are transformed in the dream into visual pictures: the latent dream-thoughts, that is to say, are dramatized and illustrated.

¹ [1933a, 4631]
To begin with, I naturally understood no more about my patients' dreams than the dreamers did themselves. But by applying to these dreams, and more particularly to my own dreams, the procedure which I had already used for the study of other abnormal psychological structures, I succeeded in answering most of the questions which could be raised by an interpretation of dreams. There were many such questions: What do we dream about? Why do we dream at all? What is the origin of all the strange characteristics which distinguish dreams from waking life? - and many more such questions besides. Some of the answers were easily given and turned out to confirm views that had already been put forward; but others involved completely new hypotheses with regard to the structure and functioning of the apparatus of the mind. People dream about the things that have engaged their minds during the waking day. People dream in order to allay impulses that seek to disturb sleep, and in order to be able to sleep on. But why was it possible for dreams to present such a strange appearance, so confusedly senseless, so obviously contrasted with the content of waking thought, in spite of being concerned with the same material? There could be no doubt that dreams were only a substitute for a rational process of thought and could be interpreted - that is to say, translated into a rational process. But what needed explaining was the fact of the distortion which the dream-work had carried out upon the rational and intelligible material.

[1932c, 4808]

It is best to begin by pointing out that the formation of a dream can be provoked in two different ways. Either, on the one hand, an instinctual impulse which is ordinarily suppressed (an unconscious wish) finds enough strength during sleep to make itself felt by the ego, or, on the other hand, an urge left over from waking life, a preconscious train of thought with all the conflicting impulses attached to it, finds reinforcement during sleep from an unconscious element. In short, dreams may arise either from the id or from the ego. The mechanism of dream-formation is in both cases the same and so also is the necessary dynamic precondition. The ego gives evidence of its original derivation from the id by occasionally ceasing its functions and allowing a reversion to an earlier state of things. This is logically brought about by its breaking off its relations with the external world and withdrawing its cathexes from the sense organs. We are justified in saying that there arises at birth an instinct to return to the intra-uterine life that has been abandoned - an instinct to sleep. Sleep is a return of this kind to the womb. Since the waking ego governs motility, that function is paralysed in sleep, and accordingly a good part of the inhibitions imposed on the unconscious id become superfluous. The withdrawal or reduction of these 'anticathexes' thus allows the id what is now a harmless amount of liberty.

[1940a [1938], 4976]
But what makes dreams so invaluable in giving us insight is the circumstance that, when the unconscious material makes its way into the ego, it brings its own modes of working along with it. This means that the preconscious thoughts in which the unconscious material has found its expression are handled in the course of the dream-work as though they were unconscious portions of the id; and, in the case of the alternative method of dream-formation, the preconscious thoughts which have obtained reinforcement from an unconscious instinctual impulse are brought down to the unconscious state. It is only in this way that we learn the laws which govern the passage of events in the unconscious and the respects in which they differ from the rules that are familiar to us in waking thought. Thus the dream-work is essentially an instance of the unconscious working-over of preconscious thought-processes. To take an analogy from history: invading conquerors govern a conquered country, not according to the judicial system which they find in force there, but according to their own. It is, however, an unmistakable fact that the outcome of the dream-work is a compromise. The ego-organization is not yet paralysed, and its influence is to be seen in the distortion imposed on the unconscious material and in what are often very ineffective attempts at giving the total result a form not too unacceptable to the ego (secondary revision). In our analogy this would be an expression of the continued resistance of the defeated people.

[1940a [1938], 4977]

It remains for us to give a dynamic explanation of why the sleeping ego takes on the task of the dream-work at all. The explanation is fortunately easy to find. With the help of the unconscious, every dream that is in process of formation makes a demand upon the ego - for the satisfaction of an instinct, if the dream originates from the id; for the solution of a conflict, the removal of a doubt or the forming of an intention, if the dream originates from a residue of preconscious activity in waking life. The sleeping ego, however, is focused on the wish to maintain sleep; it feels this demand as a disturbance and seeks to get rid of the disturbance. The ego succeeds in doing this by what appears to be an act of compliance: it meets the demand with what is in the circumstances a harmless fulfilment of a wish and so gets rid of it. This replacement of the demand by the fulfilment of a wish remains the essential function of the dream-work. It may perhaps be worth while to illustrate this by three simple examples - a hunger dream, a dream of convenience and a dream prompted by sexual desire. A need for food makes itself felt in a dreamer during his sleep: he has a dream of a delicious meal and sleeps on. The choice, of course, was open to him either of waking up and eating something or of continuing his sleep. He decided in favour of the latter and satisfied his hunger by means of the dream - for the time being, at all events, for if his hunger had persisted he would have had to wake up nevertheless. Here is the second example. A sleeper had to wake up so as to be in time for his work at the hospital. But he slept on, and had a dream that he was already at the hospital - but as a patient, who has no need to get up. Or again, a desire becomes active during the night for the enjoyment of a forbidden sexual object, the wife of a friend of the sleeper. He has a dream of sexual intercourse - not, indeed, with this person but with someone else of the same name to whom he is in fact indifferent; or his struggle against the desire may find expression in his mistress remaining altogether anonymous.

[1940a [1938], 4980]
A number of writers, on the other hand, assert that elements are to be found in most dreams, which are derived from the very last few days before they were dreamt; and this sounds like an attempt to counterbalance the laying of too much weight upon the part played in dream-life by experiences in childhood. Thus Robert (1886, 46) actually declares that normal dreams are as a rule concerned only with the impressions of the past few days. We shall find, however, that the theory of dreams constructed by Robert makes it essential for him to bring forward the most recent impressions and leave the oldest out of sight. None the less the fact stated by him remains correct, as I am able to confirm from my own investigations. An American writer, Nelson, is of the opinion that the impressions most frequently employed in a dream arise from the day next but one before the dream occurs, or from the day preceding that one - as though the impressions of the day immediately before the dream were not sufficiently attenuated or remote.

Strümpell (1877, 39): 'There are cases in which the analysis of a dream shows that some of its components are indeed derived from experiences of the previous day or its predecessor, but experiences so unimportant and trivial from the point of view of waking consciousness that they were forgotten soon after they occurred. Experiences of this kind include, for instance, remarks accidentally overheard, or another person's actions inattentively observed, or passing glimpses of people or things, or odd fragments of what one has read, and so on.'

(1) Dreams show a clear preference for the impressions of the immediately preceding days. Cf. Robert, Strümpell, Hildebrandt and Hallam and Weed.

Cyclamens, I reflected, were my wife's favourite flowers and I reproached myself for so rarely remembering to bring her flowers, which was what she liked. - The subject of 'bringing flowers' recalled an anecdote which I had recently repeated to a circle of friends and which I had used as evidence in favour of my theory that forgetting is very often determined by an unconscious purpose and that it always enables one to deduce the secret intentions of the person who forgets. A young woman was accustomed to receiving a bouquet of flowers from her husband on her birthday. One year this token of his affection failed to appear, and she burst into tears. Her husband came in and had no idea why she was crying till she told him that to-day was her birthday. One year this token of his affection failed to appear, and she burst into tears. Her husband came in and had no idea why she was crying till she told him that to-day was her birthday. He clasped his hand to his head and exclaimed: 'I'm so sorry, but I'd quite forgotten. I'll go out at once and fetch your flowers.' But she was not to be consoled; for she recognized that his forgetfulness was a proof that she no longer had the same place in his thoughts as she had formerly. - This lady, Frau L., had met my wife two days before I had the dream, had told her that she was feeling quite well and enquired after me. Some years ago she had come to me for treatment.
My thoughts then went on to the occasion when I had last been reminded of this business of the cocaine. It had been a few days earlier, when I had been looking at a copy of a *Festschrift* in which grateful pupils had celebrated the jubilee of their teacher and laboratory director. Among the laboratory’s claims to distinction which were enumerated in this book I had seen a mention of the fact that Koller had made his discovery there of the anaesthetic properties of cocaine. I then suddenly perceived that my dream was connected with an event of the previous evening. I had walked home precisely with Dr. Königstein and had got into conversation with him about a matter which never fails to excite my feelings whenever it is raised. While I was talking to him in the entrance-hall, Professor Gärtner and his wife had joined us; and I could not help congratulating them both on their blooming looks. But Professor Gärtner was one of the authors of the *Festschrift* I have just mentioned, and may well have reminded me of it. Moreover, the Frau L., whose disappointment on her birthday I described earlier, was mentioned - though only, it is true, in another connection - in my conversation with Dr. Königstein.

I will now proceed to the question of whether the instigating source of a dream, revealed by analysis, must invariably be a recent (and significant) event or whether an internal experience, that is, the *recollection* of a psychically important event - a train of thought - can assume the role of a dream-instigator. The answer, based upon a large number of analyses, is most definitely in favour of the latter alternative. A dream can be instigated by an internal process which has, as it were, become a recent event, owing to thought-activity during the previous day. This seems to be the appropriate moment for tabulating the different conditions to which we find that the sources of dreams are subject. The source of a dream may be either -

It will further be observed, if we consider these four possible cases, that a psychical element which is significant but not recent (e.g. a train of thought or a memory) can be replaced, for the purpose of forming a dream, by an element which is recent but indifferent, provided only that two conditions are fulfilled: (1) the content of the dream must be connected with a recent experience, and (2) the instigator of the dream must remain a psychically significant process. Only in one case - case (a) - are both of these conditions fulfilled by one and the same impression. It is to be noticed, moreover, that indifferent impressions which are capable of being used for constructing a dream so long as they are recent lose that capacity as soon as they are a day (or at the most a few days) older. From this we must conclude that the freshness of an impression gives it some kind of psychical value for purposes of dream-construction equivalent in some way to the value of emotionally coloured memories or trains of thought. The basis of the value which thus attaches to recent impressions in connection with the construction of dreams will only become evident in the course of our subsequent psychological discussions.¹

² *Footnote added 1919: An important contribution to the part played by recent material in the construction of dreams has been made by Pötzl (1917) in a paper which carries a wealth of implications. In a series of experiments Pötzl required the subjects to make a drawing of what they had consciously noted of a picture exposed to their view in a tachistoscope. He then turned his attention to the dreams dreamt by the subjects during the following night and required them once more to make drawings of appropriate portions of these dreams. It was shown unmistakably that those details of the exposed picture which had not been noted by the subject provided material for the construction of the dream, whereas those details which had been consciously perceived and recorded in the drawing made after the exposure did not recur in the manifest content of the dream manifest content of the dream. The material that was taken over by the dream-work was modified by it for the purposes of dream-construction in its familiar ‘arbitrary’ (or, more properly, ‘autocratic’) manner. The questions raised by Pötzl’s experiment go far beyond the sphere of dream-interpretation as dealt with in the present volume. In passing, it is worth remarking on the contrast between this new method of studying the formation of dreams experimentally and the earlier, crude technique for introducing into the dream stimuli which interrupted the subject’s sleep.*
An objection, however, may be raised which threatens to upset these last conclusions. If indifferent impressions can only find their way into a dream provided they are recent, how does it happen that the content of dreams also includes elements from an earlier period of life which at the time when they were recent possessed, to use Strümpell's words, no psychical value, and should therefore have been long since forgotten - elements, that is to say, which are neither fresh nor psychically significant?

Of the three characteristics of memory in dreams enumerated at the beginning of this chapter, one - the preference for non-essential material in the content of dreams - has been satisfactorily cleared up by being traced back to dream-distortion. We have been able to confirm the existence of the other two - the emphasis upon recent and upon infantile material - but we have not been able to account for them on the basis of the motives that lead to dreaming. These two characteristics inclusion of both recent and infantile material, whose explanation and appreciation remain to be discovered, must be kept in mind. Their proper place must be looked for elsewhere - either in the psychology of the state of sleep or in the discussion of the structure of the mental apparatus upon which we shall later embark, after we have learnt that the interpretation of dreams is like a window through which we can get a glimpse of the interior of that apparatus.

We have already taken the first step in this direction by advancing the thesis (see p. 666 f.) that the dream-work is under the necessity of combining into a unity all instigations to dreaming which are active simultaneously. We found that, when two or more experiences capable of creating an impression are left over from the previous day, the wishes derived from them are combined in a single dream, and similarly that the psychically significant impressions and the indifferent experiences from the previous day are brought together in the dream-material, provided always that it is possible to set up communicating ideas between them. Thus a dream appears to be a reaction to everything that is simultaneously present in the sleeping mind as currently active material. So far as we have hitherto analysed the material of dreams, we have seen it as a collection of psychical residues and memory-traces, to which (on account of the preference shown for recent and infantile material) we have been led to attribute a hitherto indefinable quality of being 'currently active'. We can foresee, then, without any great difficulty, what will happen if fresh material in the form of sensations is added during sleep to these currently active memories. It is once again owing to the fact of their being currently active that these sensory excitations are of importance for the dream; they are united with the other currently active psychical material to furnish what is used for the construction of the dream. To put it another way, stimuli arising during sleep are worked up into a wish-fulfilment the other constituents of which are the familiar psychical 'day's residues'. This combination need not occur; as I have already pointed out, there is more than one way of reacting to a somatic stimulus during sleep. When it does occur, it means that it has been possible to find ideational material to serve as the content of the dream of such a sort as to be able to represent both kinds of source of the dream - the somatic and the psychical.
Thus, in my opinion, somatic sources of stimulation during sleep (that is to say, sensations during sleep), unless they are of unusual intensity, play a similar part in the formation of dreams to that played by recent but indifferent impressions left over from the previous day. I believe, that is, that they are brought in to help in the formation of a dream if they fit in appropriately with the ideational content derived from the dream's psychical sources, but otherwise not. They are treated like some cheap material always ready to hand, which is employed whenever it is needed, in contrast to a precious material which itself prescribes the way in which it shall be employed. If, to take a simile, a patron of the arts brings an artist some rare stone, such as a piece of onyx, and asks him to create a work of art from it, then the size of the stone, its colour and markings, help to decide what head or what scene shall be represented in it. Whereas in the case of a uniform and plentiful material such as marble or sandstone, the artist merely follows some idea that is present in his own mind. It is only in this way, so it seems to me, that we can explain the fact that dream-content provided by somatic stimuli of no unusual intensity fails to appear in every dream or every night.¹

This indication of the way in which infantile scenes (or their reproductions as phantasies) function in a sense as models for the content of dreams, removes the necessity for one of the hypotheses put forward by Scherner and his followers in regard to internal sources of stimulation. Scherner supposes that, when dreams exhibit particularly vivid or particularly copious visual elements, there is present a state of 'visual stimulation', that is, of internal excitation in the organ of vision. We need not dispute this hypothesis, but can content ourselves with assuming that this state of excitation applies merely to the psychical perceptual system of the visual organ; we may, however, further point out that the state of excitation has been set up by a memory, that it is a revival of a visual excitation which was originally an immediate one. I cannot produce any good example from my own experience of an infantile memory producing this kind of result. My dreams are in general less rich in sensory elements than I am led to suppose is the case in other people. But in the case of my most vivid and beautiful dream of the last few years I was easily able to trace back the hallucinatory clarity of the dream's content to the sensory qualities of recent or fairly recent impressions. On p. 907 ff. I recorded a dream in which the deep blue colour of the water, the brown of the smoke coming from the ship's funnels, and the dark brown and red of the buildings left behind a profound impression on me. This dream, if any, should be traceable, to a visual stimulus. What was it that had brought my visual organ into this state of stimulation? A recent impression, which attached itself to a number of earlier ones. The colours which I saw were in the first instance those of a box of toy bricks with which, on the day before the dream, my children had put up a fine building and shown it off for my admiration. The big bricks were of the same dark red and the small ones were of the same blue and brown. This was associated with colour impressions from my last travels in Italy: the beautiful blue of the Isonzo and the lagoons and the brown of the Carso. The beauty of the colours in the dream was only a repetition of something seen in my memory.

¹ [1900a, 716]

[1900a, 979]
If we assume that the same need for transference on the part of repressed ideas which we have discovered in analysing the neuroses is also at work in dreams, two of the riddles of the dream are solved at a blow: the fact, namely, that every analysis of a dream shows some recent impression woven into its texture and that this recent element is often of the most trivial kind. I may add that (as we have already found elsewhere) the reason why these recent and indifferent elements so frequently find their way into dreams as substitutes for the most ancient of all the dream-thoughts is that they have least to fear from the censorship imposed by resistance. But while the fact that trivial elements are preferred is explained by their freedom from censorship, the fact that recent elements occur with such regularity points to the existence of a need for transference. Both groups of impressions satisfy the demand of the repressed for material that is still clear of associations - the indifferent ones because they have given no occasion for the formation of many ties, and the recent ones because they have not yet had time to form them.

The view that dreams carry on the occupations and interests of waking life has been entirely confirmed by the discovery of the concealed dream-thoughts. These are only concerned with what seems important to us and interests us greatly. Dreams are never occupied with minor details. But we have also found reason for accepting the contrary view, that dreams pick up indifferent refuse left over from the previous day and that they cannot get control of any major day time interest until it has been to some extent withdrawn from waking activity. We have found that this holds good of the dream's content, which gives expression to the dream-thoughts in a form modified by distortion. For reasons connected with the mechanism of association, as we have seen, the dream-process finds it easier to get control of recent or indifferent ideational material which has not yet been requisitioned by waking thought-activity; and for reasons of censorship it transfers psychical intensity from what is important but objectionable on to what is indifferent.

It has naturally not occurred to us to throw any doubt on the significance, which has been experimentally demonstrated, of external sensory stimuli during sleep; but we have shown that such material stands in the same relation to the dream-wish as do the residues of thought left over from day time activity. Nor have we seen any reason to dispute the view that dreams interpret objective sensory stimuli just as illusions do; but we have found the motive which provides the reason for that interpretation, a reason which has been left unspecified by other writers. Interpretation is carried out in such a way that the object perceived shall not interrupt sleep and shall be usable for purposes of wish-fulfilment. As regards subjective states of excitation in the sense organs during sleep, the occurrence of which seems to have been proved by Trumbull Ladd, it is true that we have not accepted them as a particular source of dreams; but we have been able to explain them as resulting from the regressive revival of memories that are in operation behind the dream.
What interests us here is the source of the figures in the material of the dream-thoughts and the transformations which they underwent. What was the origin of the 1 florin 50 kreuzers? It came from what was in fact an indifferent event of the previous day. Her sister-in-law had been given a present of 150 florins by her husband and had been in a hurry to get rid of them by buying a piece of jewellery. It is to be noticed that 150 florins is a hundred times as much as 1 florin 50 kreuzers. The only connection with the 'three', which was the number of the theatre tickets, was that her newly engaged friend was that number of months - three - her junior. The situation in the dream was a repetition of a small incident which her husband often teased her about. On one occasion she had been in a great hurry to buy tickets for a play in advance, and when she got to the theatre she had found that one side of the stalls was almost completely empty. There had been no need for her to be in such a hurry. Finally, we must not overlook the absurdity in the dream of two people taking three tickets for a play.

[1901a, 1083]
The preponderant majority of writers, however, take a contrary view of the relation of dreams to waking life. Thus Haffner (1887, 245): 'In the first place, dreams carry on waking life. Our dreams regularly attach themselves to the ideas that have been in our consciousness shortly before. Accurate observation will almost always find a thread which connects a dream with the experiences of the previous day.' Weygandt (1893, 6) specifically contradicts Burdach's statement which I have just quoted: 'For it may often, and apparently in the majority of dreams, be observed that they actually lead us back to ordinary life instead of freeing us from it.' Maury (1878, 51) advances a concise formula: 'Nous rêvons de ce que nous avons vu, dit, désiré ou fait'; while Jessen, in his book on psychology (1855, 530), remarks at somewhat greater length: 'the content of a dream is invariably more or less determined by the individual personality of the dreamer, by his age, sex, class, standard of education and habitual way of living, and by the events and experiences of his whole previous life.'

¹ [Footnote added 1909:] Subsequent experience leads me to add that it by no means rarely happens that innocent and unimportant actions of the previous day are repeated in a dream: such, for instance, as packing a trunk, preparing food in the kitchen, and so on. What the dreamer is himself stressing in dreams of this kind is not, however, the content of the memory but the fact of its being 'real': 'I really did do all that yesterday.'

This ruling theory, which regards dreams as a somatic process, underlies a most interesting hypothesis put forward for the first time by Robert in 1886. It is particularly attractive since it is able to suggest a function, a utilitarian purpose, for dreaming. Robert takes as the groundwork of his theory two facts of observation which we have already considered in the course of our examination of the material of dreams (see above, p. 532 ff.), namely that we dream so frequently of the most trivial daily impressions and that we so rarely carry over into our dreams our important daily interests. Robert (1886, 10) asserts that it is universally true that things which we have thoroughly thought out never become instigators of dreams but only things which are in our minds in an uncompleted shape or which have merely been touched upon by our thoughts in passing: 'The reason why it is usually impossible to explain dreams is precisely because they are caused by sensory impressions of the preceding day which failed to attract enough of the dreamer's attention.' Thus the condition which determines whether an impression shall find its way into a dream is whether the process of working over the impression was interrupted or whether the impression was too unimportant to have a right to be worked over at all.

Delage (1891, 41) tells us that he experienced in his own person, on the occasion of the death of someone of whom he was fond, the fact that we do not dream of what has occupied all our thoughts during the day, or not until it has begun to give place to other daytime concerns. His investigations among other people confirmed him in the general truth of this fact. He makes what would be an interesting observation of this kind, if it should prove to have general validity, on the dreams of young married couples: 'S'ils ont été fortement épris, presque jamais ils n'ont rêvé l'un de l'autre avant le mariage ou pendant la lune de miel; et s'ils ont rêvé d'amour c'est pour être infidèles avec quelque personne indifférente ou odieuse.' What, then, do we dream of? Delage identifies the material that occurs in our dreams as consisting of fragments and residues of the preceding days and of earlier times. Everything that appears in our dreams, even though we are inclined at first to regard it as a creation of our dream-life, turns out, when we have examined it more closely, to be unrecognized reproduction - 'souvenir inconscient'. But this ideational material possesses a common characteristic: it originates from impressions which probably affected our senses more strongly than our intelligence or from which our attention was diverted very soon after they emerged. The less conscious and at the same time the more powerful an impression has been, the more chance it has of playing a part in the next dream.
A young woman had been cut off from society for weeks on end while she nursed her child through an infectious illness. After the child's recovery, she had a dream of being at a party at which, among others, she met Alphonse Daudet, Paul Bourget, and Marcel Prévost; they were all most affable to her and highly amusing. All of the authors resembled their portraits, except Marcel Prévost, of whom she had never seen a picture; and he looked like . . . the disinfection officer who had fumigated the sick-room the day before and who had been her first visitor for so long. Thus it seems possible to give a complete translation of the dream: 'It's about time for something more amusing than this perpetual sick-nursing.'

[1900a, 625]

I answered, of course, that analysis was the only way of deciding on the meaning of the dream; though I admitted that at first sight it seemed sensible and coherent and looked like the reverse of a wish-fulfilment. 'But what material did the dream arise from? As you know, the instigation to a dream is always to be found in the events of the previous day.'

[1900a, 642]

The associations which she had so far produced had not been sufficient to interpret the dream. I pressed her for some more. After a short pause, such as would correspond to the overcoming of a resistance, she went on to tell me that the day before she had visited a woman friend of whom she confessed she felt jealous because her (my patient's) husband was constantly singing her praises. Fortunately this friend of hers is very skinny and thin and her husband admires a plumper figure. I asked her what she had talked about to her thing friend. Naturally, she replied, of that lady's wish to grow a little stouter. Her friend had enquired, too: 'When are you going to ask us to another meal? You always feed one so well.'

[1900a, 643]

If I examine my own experience on the subject of the origin of the elements included in the content of dreams, I must begin with an assertion that in every dream it is possible to find a point of contact with the experiences of the previous day. This view is confirmed by every dream that I look into, whether my own or anyone else's. Bearing this fact in mind, I am able, on occasion, to begin a dream's interpretation by looking for the event of the previous day which set it in motion; in many instances, indeed, this is the easiest method. In the two dreams which I have analysed in detail in my last chapters (the dream of Irma's injection and the dream of my uncle with a yellow beard) the connection with the previous day is so obvious as to require no further comment. But in order to show the regularity with which such a connection can be traced, I will go through the records of my own dreams and give some instances. I shall only quote enough of the dream to indicate the source we are looking for:

[1900a, 656]

The question may be raised whether the point of contact with the dream is invariably the events of the immediately preceding day or whether it may go back to impressions derived from a rather more extensive period of the most recent past. It is unlikely that this question involves any matter of theoretical importance; nevertheless I am inclined to decide in favour of the exclusiveness of the claims of the day immediately preceding the dream - which I shall speak of as the 'dream-day'. Whenever it has seemed at first that the source of a dream was an impression two or three days earlier, closer enquiry has convinced me that the impression had been recalled on the previous day and thus that it was possible to show that a reproduction of the impression, occurring on the previous day, could be inserted between the day of the original event and the time of the dream; moreover it has been possible to indicate the contingency on the previous day which may have led to the recalling of the older impression.

[1900a, 656]
Intervals such as this one, which cannot be fitted into the theory of periodicity without further manipulation, occur far more frequently in my dreams than intervals which can be so fitted. The only relation which I find occurs with regularity is the relation which I have insisted upon in the text and which connects the dream with some impression of the dream-day.

[1900a, 656]

That morning I had seen a new book in the window of a book-shop, bearing the title *The Genus Cyclamen* - evidently a *monograph* on that plant.

[1900a, 657]

We must now ask what was the relation of the two impressions of the dream-day to each other and to the dream of the subsequent night. In the manifest content of the dream only the *indifferent* impression was alluded to, which seems to confirm the notion that dreams have a preference for taking up unimportant details of waking life. All the strands of the interpretation, on the other hand, led to the *important* impression, to the one which had justifiably stirred my feelings. If the sense of the dream is judged, as it can only rightly be, by its latent content as revealed by the analysis, a new and significant fact is unexpectedly brought to light. The conundrum of why dreams are concerned only with worthless fragments of waking life seems to have lost all its meaning; nor can it any longer be maintained that waking life is not pursued further in dreams and that dreams are thus psychical activity wasted upon foolish material. The contrary is true: our dream-thoughts are dominated by the same material that has occupied us during the day and we only bother to dream of things which have given us cause for reflection in the daytime.

[1900a, 661]

Nevertheless we must not be in a hurry to take leave of Robert's ideas without further consideration. We have still not explained the fact that one of the indifferent impressions of waking life, one, moreover, dating from the day preceding the dream, invariably contributes towards the dream's content. The connections between this impression and the true source of the dream in the unconscious are not always there ready-made; as we have seen, they may only be established retrospectively, in the course of the dream-work, with a view, as it were, to making the intended displacement feasible. There must therefore be some compelling force in the direction of establishing connections precisely with a recent, though indifferent, impression; and the latter must possess some attribute which makes it especially suitable for this purpose. For if that were not so, it would be just as easy for the dream-thoughts to displace their emphasis on to an unimportant component in their *own* circle of ideas.

[1900a, 665]

I will now proceed to the question of whether the instigating source of a dream, revealed by analysis, must invariably be a recent (and significant) event or whether an internal experience, that is, the *recollection* of a psychically important event - a train of thought - can assume the role of a dream-instigator. The answer, based upon a large number of analyses, is most definitely in favour of the latter alternative. A dream can be instigated by an internal process which has, as it were, become a recent event, owing to thought-activity during the previous day. This seems to be the appropriate moment for tabulating the different conditions to which we find that the sources of dreams are subject. The source of a dream may be either -

[1900a, 667]
It will be seen that in interpreting dreams we find one condition always fulfilled: one component of the content of the dream is a repetition of a recent impression of the previous day. This impression that is to be represented in the dream may either itself belong to the circle of ideas surrounding the actual instigator of the dream - whether as an essential or as a trivial portion of it - or it may be derived from the field of an indifferent impression which has been brought into connection with the ideas surrounding the dream-instigator by more or less numerous links. The apparent multiplicity of governing conditions is in fact merely dependent upon the two alternatives of whether a displacement has or has not taken place; and it is worth pointing out that we are enabled by these alternatives to explain the range of contrast between different dreams just as easily as the medical theory is enabled to do by its hypothesis of brain-cells ranging from partial to total wakefulness. (See above, p. 583 ff.) [1900a, 667]

The dream's connection with the previous day was quite straightforward. She had actually gone to the market too late and had got nothing. The situation seemed to shape itself into the phrase 'Die Flieschbank war schon geschlossen'. I pulled myself up: was not that, or rather its opposite, a vulgar description of a certain sort of slovenliness in a man's dress? However, the dreamer herself did not use the phrase; she may perhaps have avoided using it. Let us endeavour, then, to arrive at an interpretation of the details of the dream. [1900a, 670]

Once again this was a repetition of a real event of the previous day. Her husband had asked this question and she had made some such reply. But what was the explanation of her dreaming it? She told me that the piano was a disgusting old box, that it made an ugly noise, that it had been in her husband's possession before their marriage,¹ and so on. But the key to the solution was only given by her words: 'It's not worth while.' These were derived from a visit she had paid the day before to a woman friend. She had been invited to take off her jacket, but had refused with the words: 'Thank you, but its not worth while; I can only stop a minute.' As she was telling me this, I recollected that during the previous day's analysis she had suddenly caught hold of her jacket, one of the buttons having come undone. Thus it was as though she were saying: 'Please don't look; its not worth while.' In the same way the 'box' ['Kasten'] was a substitute for a 'chest' ['Bruskasten']; and the interpretation of the dream led us back at once to the time of her physical development at puberty, when she had begun to be dissatisfied by her figure. We can hardly doubt that it led back to still earlier times, if we take the word 'disgusting' into account and the 'ugly noise', and if we remember how often - both in double entendres and in dreams - the lesser hemispheres of a woman's body are used, whether as contrasts or as substitutes, for the larger ones. [1900a, 672]
In another instance it became apparent that, though the wish which instigated the dream was a present-day one, it had received a powerful reinforcement from memories that stretched far back into childhood. What I have in mind is a series of dreams which are based upon a longing to visit Rome. For a long time to come, no doubt, I shall have to continue to satisfy that longing in my dreams: for at the season of the year when it is possible for me to travel, residence in Rome must be avoided for reasons of health.¹ For instance, I dreamt once that I was looking out of a railway-carriage window at the Tiber and the Ponte Sant'Angelo. The train began to move off, and it occurred to me that I had not so much as set foot in the city. The view that I had seen in my dream was taken from a well-known engraving which I had caught sight of for a moment the day before in the sitting-room of one of my patients. Another time someone led me to the top of a hill and showed me Rome half-shrouded in mist; it was so far away that I was surprised at my view of it being so clear. There was more in the content of this dream than I feel prepared to detail; but the theme of 'the promised land seen from afar' was obvious in it. The town which I saw in this way for the first time, shrouded in mist, was - Lübeck, and the prototype of the hill was - at Gleichenberg. In a third dream I had at last got to Rome, as the dream itself informed me; but I was disappointed to find that the scenery was far from being of an urban character. *There was a narrow stream of dark water; on one side of it were black cliffs and on the other meadows with big white flowers. I noticed a Herr Zucker (whom I knew slightly) and determined to ask him the way to the city.* I was clearly making a vain attempt to see in my dream a city which I had never seen in my waking life. Breaking up the landscape in the dream into its elements, I found that the white flowers took me to Ravenna, which I have visited and which, for a time at least, superseded Rome as capital of Italy. In the marshes round Ravenna we found the loveliest water-lilies growing in black water. Because we had had such difficulty in picking them out of the water, the dream made them grow in meadows like the narcissi at our own Aussee. The dark cliff, so close to the water, reminded me vividly of the valley of the Tepl near Karlsbad. *Karlsbad* enabled me to explain the curious detail of my having asked Herr Zucker the way. The material out of which the dream was woven included at this point two of those facetious Jewish anecdotes which contain so much profound and often bitter worldly wisdom and which we so greatly enjoy quoting in our talk and letters. Here is the first one: the *'constitution' story.* An impecunious Jew had stowed himself away without a ticket in the fast train to *Karlsbad*. He was caught, and each time tickets were inspected he was taken out of the train and treated more and more severely. At one of the stations on his *via dolorosa* he met an acquaintance, who asked him where he was travelling to. 'To Karlsbad', was his reply, 'if my constitution can stand it.' My memory then passed on to another story: of a Jew who could not speak French and had been recommended when he was in Paris to ask the way to the rue Richelieu. Paris itself had for many long years been another goal of my longings; and the blissful feelings with which I first set foot on its pavement seemed to me a guarantee that others of my wishes would be fulfilled as well. 'Asking the way', moreover, was a direct allusion to Rome, since it is well known that all roads lead there. Again, the name Zucker was once more an allusion to *Karlsbad;* for we are in the habit of prescribing treatment there for anyone suffering from the *constitutional* complaint of diabetes. The instigation to this dream had been a proposal made by my friend in Berlin that we should meet in Prague at Easter. What we were going to discuss there would have included something with a further connection with 'sugar' and 'diabetes'.

[1900a, 679]
The dream had made copious use of trivial events of the previous day. He had in fact seen two boys in the street, one of whom threw the other down. When he hurried up to stop the fight they had both taken to their heels. - *Barrel-maker's boys.* This was only explained by a subsequent dream in which he used the phrase 'knocking the bottom out of a barrel'. - From his experience he believed that *earrings with blue stones* were mostly worn by prostitutes. A line from a well-known piece of doggerel about *two boys* then occurred to him: 'The other boy was called Marie' (i.e. was a girl). - *The woman standing.* After the scene with the two boys he had gone for a walk along the bank of the Danube and had profited by the loneliness of the spot to micturate against a *wooden fence.* Further on, a respectably dressed elderly lady had smiled at him in a very friendly manner and had wanted to give him her visiting-card. Since the woman in the dream was standing in the same position as he had been in when he was micturating, it must have been a question of a micturating woman. This tallies with her terrible *look* and the *red flesh standing out*, which could only relate to the gaping of the genitals caused by stooping. This, seen in his childhood, reappeared in later memory as *'proud flesh'* - as a wound.

[1900a, 685]

Throughout the whole of this discussion of the theory of the somatic sources of dreams I have refrained from making use of the argument based upon my dream-analyses. If it can be proved, by a procedure which other writers have not employed upon their dream-material, that dreams possess a value of their own as psychical acts, that wishes are the motive for their construction and that experiences of the preceding day provide the immediate material for their content, then any other theory of dreams, which neglects so important a procedure of research and accordingly represents dreams as a useless and puzzling psychical reaction to somatic stimuli, stands condemned without there being any necessity for specific criticisms. Otherwise - and this seems highly improbable - there would have to be two quite different kinds of dreaming, one of which has come only under *my* observation and the other only under that of the earlier authorities. All that remains, therefore, is to find a place in my theory of dreams for the facts upon which the current theory of the somatic stimulation of dreams is based.

[1900a, 706]

We have already taken the first step in this direction by advancing the thesis (see p. 666 f.) that the dream-work is under the necessity of combining into a unity all instigations to dreaming which are active simultaneously. We found that, when two or more experiences capable of creating an impression are left over from the previous day, the wishes derived from them are combined in a single dream, and similarly that the psychically significant impressions and the indifferent experiences from the previous day are brought together in the dream-material, provided always that it is possible to set up communicating ideas between them. Thus a dream appears to be a reaction to everything that is simultaneously present in the sleeping mind as currently active material. So far as we have hitherto analysed the material of dreams, we have seen it as a collection of psychical residuals and memory-traces, to which (on account of the preference shown for recent and infantile material) we have been led to attribute a hitherto indefinable quality of being *'currently active'.* We can foresee, then, without any great difficulty, what will happen if fresh material in the form of sensations is added during sleep to these currently active memories. It is once again owing to the fact of their being currently active that these sensory excitations are of importance for the dream; they are united with the other currently active psychical material to furnish what is used for the construction of the dream. To put it another way, stimuli arising during sleep are worked up into a wish-fulfilment the other constituents of which are the familiar psychical 'day's residuals'. This combination need not occur; as I have already pointed out, there is more than one way of reacting to a somatic stimulus during sleep. When it does occur, it means that it has been possible to find ideational material to serve as the content of the dream of such a sort as to be able to represent both kinds of source of the dream - the somatic and the psychical.

[1900a, 707]
There can be no doubt that physical coenaesthesia is among the internal somatic stimuli which can dictate the content of dreams. It can do so, not in the sense that it can provide the dream's content, but in the sense that it can force upon the dream-thoughts a choice of the material to be represented in the content by putting forward one part of the material as being appropriate to its own character and by holding back another part. Apart from this, the coenaesthetic feelings left over from the preceding day link themselves up, no doubt, with the psychical residues which have such an important influence on dreams. This general mood may persist unchanged in the dream or it may be mastered, and thus, if it is unpleasurable, may be changed into its opposite.¹

Thus, in my opinion, somatic sources of stimulation during sleep (that is to say, sensations during sleep), unless they are of unusual intensity, play a similar part in the formation of dreams to that played by recent but indifferent impressions left over from the previous day. I believe, that is, that they are brought in to help in the formation of a dream if they fit in appropriately with the ideational content derived from the dream's psychical sources, but otherwise not. They are treated like some cheap material always ready to hand, which is employed whenever it is needed, in contrast to a precious material which itself prescribes the way in which it shall be employed. If, to take a simile, a patron of the arts brings an artist some rare stone, such as a piece of onyx, and asks him to create a work of art from it, then the size of the stone, its colour and markings, help to decide what head or what scene shall be represented in it. Whereas in the case of a uniform and plentiful material such as marble or sandstone, the artist merely follows some idea that is present in his own mind. It is only in this way, so it seems to me, that we can explain the fact that dream-content provided by somatic stimuli of no unusual intensity fails to appear in every dream or every night.¹

Now how did this staircase and this female figure come to be in my dream? The feeling of shame at not being completely dressed is no doubt of a sexual nature; but the maid-servant whom I dreamt about was older than I am, surly and far from attractive. The only answer to the problem that occurred to me was this. When I paid my morning visits to this house I used as a rule to be seized with a desire to clear my throat as I went up the stairs and the product of my expectoration would fall on the staircase. For on neither of these floors was there a spittoon; and the view I took was that the cleanliness of the stairs should not be maintained at my expense but should be made possible by the provision of a spittoon. The concierge, an equally elderly and surly woman (but of cleanly instincts, as I was prepared to admit), looked at the matter in a different light. She would lie in wait for me to see whether I should again make free of the stairs, and, if she found that I did, I used to hear her grumbling audibly; and for several days afterwards she would omit the usual greeting when we met. The day before I had the dream the concierge's party had received a reinforcement in the shape of the maid-servant. I had, as usual, concluded my hurried visit to the patient, when the servant stopped me in the hall and remarked: 'You might have wiped your boots, doctor, before you came into the room today. You've made the red carpet all dirty again with your feet.' This was the only claim the staircase and the maid-servant had to appearing in my dream.
I cannot leave the subject of typical dreams of the death of loved relatives, without adding a few more words to throw light on their significance for the theory of dreams in general. In these dreams we find the highly unusual condition realized of a dream-thought formed by a repressed wish entirely eluding censorship and passing into the dream without modification. There must be special factors at work to make this event possible, and I believe that the occurrence of these dreams is facilitated by two such factors. Firstly, there is no wish that seems more remote from us than this one: 'we couldn't even dream' - so we believe - of wishing such a thing. For this reason the dream-censorship is not armed to meet such a monstrosity, just as Solon's penal code contained no punishment for parricide. Secondly, in this case the repressed and unsuspected wish is particularly often met half-way by a residue from the previous day in the form of a worry about the safety of the person concerned. This worry can only make its way into the dream by availing itself of the corresponding wish; while the wish can disguise itself behind the worry that has become active during the day. We may feel inclined to think that things are simpler than this and that one merely carries on during the night and in dreams with what one has been turning over in one's mind during the day; but if so we shall be leaving dreams of the death of people of whom the dreamer is fond completely in the air and without any connection with our explanation of dreams in general, and we shall thus be clinging quite unnecessarily to a riddle which is perfectly capable of solution.

Who can the unknown person have been whose sumptuous banquet of meat was the subject of the little boy's dream? His experiences during the dream-day must enlighten us on the subject. By doctor's orders he had been put on a milk diet for the past few days. On the evening of the dream-day he had been naughty, and as a punishment he had been sent to bed without his supper. He had been through this hunger-cure once before and had been very brave about it. He knew he would get nothing, but would not allow himself to show by so much as a single word that he was hungry. Education had already begun to have an effect on him: it found expression in this dream, which exhibits the beginning of dream-distortion. There can be no doubt that the person whose wishes were aimed at this lavish meal - a meat meal, too - was himself. But since he knew he was not allowed it, he did not venture to sit down to the meal himself, as hungry children do in dreams. (Cf. my little daughter Anna's dream of strawberries on p. 628.) The person who ate the meal remained anonymous.
Otto is my family doctor, and I owe him more than I can ever hope to repay: he has watched over my children's health for many years, he has treated them successfully when they have been ill, and, in addition, whenever circumstances have given him an excuse, he has given them presents. He had visited us on the dream-day, and my wife had remarked that he looked tired and strained. That night I had my dream, which showed him with some of the signs of Basedow's disease. Anyone who interprets this dream without regard for my rules will conclude that I was worried about my friend's health and that this worry was realized in the dream. This would not only contradict my assertion that dreams are wish-fulfilments, but my other assertion, too, that they are accessible only to egoistic impulses. But I should be glad if anyone interpreting the dream in this way would be good enough to explain to me why my fears on Otto's behalf should have lighted on Basedow's disease - a diagnosis for which his actual appearance gives not the slightest ground. My analysis, on the other hand, brought up the following material from an occurrence six years earlier. A small group of us, which included Professor R., were driving in pitch darkness through the forest of N., which lay some hours' drive from the place at which we were spending our summer holidays. The coachman, who was not perfectly sober, spilt us, carriage and all, over an embankment, and it was only by a piece of luck that we all escaped injury. We were obliged, however, to spend the night in a neighbouring inn, at which the news of our accident brought us a lot of sympathy. A gentleman, with unmistakable signs of Basedow's disease - incidentally, just as in the dream, only the brown discoloration of the skin of the face and the protruding eyes, but no goitre - placed himself entirely at our disposal and asked what he could do for us. Professor R. replied in his decisive manner: 'Nothing except to lend me a night-shirt.' To which the fine gentleman rejoined: 'I'm sorry, but I can't do that', and left the room.

[1900a, 746]

The element in this dream which stood out most was the botanical monograph. This arose from the impressions of the dream day: I had in fact seen a monograph on the genus Cyclamen in the window of a book-shop. There was no mention of this genus in the content of the dream; all that was left in it was the monograph and its relation to botany. The 'botanical monograph' immediately revealed its connection with the work upon cocaine which I had once written. From 'cocaine' the chains of thought led on the one hand to the Festschrift and to certain events in a University laboratory, and on the other hand to my friend Dr. Königstein, the eye surgeon, who had had a share in the introduction of cocaine. The figure of Dr. Königstein further reminded me of the interrupted conversation which I had had with him the evening before and of my various reflections upon the payment for medical services among colleagues. This conversation was the actual currently active instigator of the dream; the monograph on the cyclamen was also a currently active impression, but one of an indifferent nature. As I perceived, the 'botanical monograph' in the dream turned out to be an 'intermediate common entity' between the two experiences of the previous day: it was taken over unaltered from the indifferent impression and was linked with the psychically significant event by copious associative connections.

[1900a, 755]
ANALYSIS. - Her husband was temporarily away from home, and her fourteen-year-old daughter was sleeping in the bed beside her. The evening before, the girl had drawn her attention to a moth which had fallen into her tumbler of water; but she had not taken it out and felt sorry for the poor creature next morning. The book she had been reading during the evening had told how some boys had thrown a cat into boiling water, and had described the animal's convulsions. These were the two precipitating causes of the dream - in themselves indifferent. She then pursued the subject of cruelty to animals further. Some years before, while they were spending the summer at a particular place, her daughter had been very cruel to animals. She was collecting butterflies and asked the patient for some arsenic to kill them with. On one occasion a moth with a pin through its body had gone on flying about the room for a long time; another time some caterpillars which the child was keeping to turn into chrysalises starved to death. At a still more tender age the same child used to tear the wings off beetles and butterflies. But to-day she would be horrified at all these cruel actions she had grown so kind-hearted.

The evening before the dream she had been rummaging among some old letters and had read some of them - some serious and some comic - aloud to her children. There had been a most amusing letter from a piano-teacher who had courted her when she was a girl, and another from an admirer of noble birth.¹

One of my women patients told me a short dream which ended in a meaningless verbal compound. She dreamt she was with her husband at a peasant festivity and said: 'This will end in a general "Maistolmütz."' In the dream she had a vague feeling that it was some kind of pudding made with maize - a sort of polenta. Analysis divided the word into 'Mais' ['maize'], 'toll' ['mad'], 'mannstoll' ['nymphomaniac' - literally 'mad for men'] and Olmütz [a town in Moravia]. All these fragments were found to be remnants of a conversation she had had at table with her relatives. The following words lay behind 'Mais' (in addition to a reference to the recently opened Jubilee Exhibition): 'Meissen' (a Meissen porcelain figure representing a bird); 'Miss' (her relatives' English governess had just gone to Olmütz); and 'mies' (a Jewish slang term, used jokingly to mean 'disgusting'). A long chain of thoughts and associations led off from each syllable of this verbal hotch potch.

[1900a, 762]

[1900a, 763]

[1900a, 769]
'Early this morning,' between dreaming and waking, I experienced a very nice example of verbal condensation. In the course of a mass of dream-fragments that I could scarcely remember, I was brought up short, as it were, by a word which I saw before me as though it were half written and half printed. The word was "erzefilisch", and it formed part of a sentence which slipped into my conscious memory apart from any context and in complete isolation: "That has an erzefilisch influence on the sexual emotions." I knew at once that the word ought really to have been "erzieherisch" ["educational"). And I was in doubt for some time whether the second "e" in "erzefilisch" should not have been an "i". In that connection the word "syphilis" occurred to me and, starting to analyse the dream while I was still half asleep, I racked my brains in an effort to make out how that word could have got into my dream, since I had nothing to do with the disease either personally or professionally. I then thought of "erzehlerisch" [another nonsense word], and this explained the "e" of the second syllable of "erzefilisch" by reminding me that the evening before I had been asked by our governess [Erzieherin] to say something to her on the problem of prostitution, and had given her Hesse's book on prostitution in order to influence her emotional life - for this had not developed quite normally; after which I had talked [erzählt] a lot to her on the problem. I then saw all at once that the word "syphilis" was not to be taken literally, but stood for "poison" - of course in relation to sexual life. When translated, therefore, the sentence in the dream ran quite logically: "My talk [Erzählung] was intended to have an educational [erzieherisch] influence on the emotional life of our governess [Erzieherin]; but I fear it may at the same time have had a poisonous effect." "Erzefilisch" was compounded from "erzäh-" and "erzieh-".'

[1900a, 775]

On the other hand, he (the patient) was the material which was being used for the analysis (or synthesis). What was in question was the success of the treatment. The reference to his legs in the dream reminded him of an experience of the previous evening. He had been having a dancing-lesson and had met a lady of whom he had been eager to make a conquest. He clasped her to himself so tightly that on one occasion she gave a scream. As he relaxed his pressure against her legs, he felt her strong responsive pressure against the lower part of his thighs as far down as his knees - the point mentioned in his dream. So that in this connection it was the woman who was the magnesium in the retort - things were working at last. He was feminine in relation to me, just as he was masculine in relation to the woman. If it was working with the lady it was working with him in the treatment. His feeling himself and the sensations in his knees pointed to masturbation and fitted in with his fatigue on the previous day. -His appointment with the lady had in fact been for half-past eleven. His wish to miss it by oversleeping and to stay with his sexual objects at home (that is, to keep to masturbation) corresponded to his resistance.

[1900a, 840]
I have already shown elsewhere that strikingly innocent dreams may embody crudely erotic wishes, and I could confirm this by many new instances. But it is also true that many dreams which appear to be indifferent and which one would not regard as in any respect peculiar lead back on analysis to wishful impulses which are unmistakably sexual and often of an unexpected sort. Who, for instance, would have suspected the presence of a sexual wish in the following dream before it had been interpreted? The dreamer gave this account of it: **Standing back a little behind two stately palaces was a little house with closed doors. My wife led me along the piece of street up to the little house and pushed the door open; I then slipped quickly and easily into the inside of a court which rose in an incline.** Anyone, however, who has had a little experience in translating dreams will at once reflect that penetrating into narrow spaces and opening closed doors are among the commonest sexual symbols, and will easily perceive in this dream a representation of an attempt at *coitus a tergo* (between the two stately buttocks of the female body). The narrow passage rising in an incline stood, of course, for the vagina. The assistance attributed by the dreamer to his wife forces us to conclude that in reality it was only consideration for her that restrained the dreamer from making attempts of this kind. It turned out that on the dream-day a girl had come to live in the dreamer's household who had attracted him and had given him the impression that she would raise no great objections to an approach of that kind. The little house between the two palaces was a reminiscence of the Hradshin in Prague and was a further reference to the same girl, who came from that place.

[1900a, 854]

Though the preceding considerations have reduced the importance of the part played by the day's residues in dreams, it is worth while devoting a little more attention to them. It must be that they are essential ingredients in the formation of dreams, since experience has revealed the surprising fact that in the content of every dream some link with a recent daytime impression - often of the most insignificant sort - is to be detected. We have not hitherto been able to explain the necessity for this addition to the mixture that constitutes a dream (see p. 669). And it is only possible to do so if we bear firmly in mind the part played by the unconscious wish and then seek for information from the psychology of the neuroses. We learn from the latter that an unconscious idea is as such quite incapable of entering the preconscious and that it can only exercise any effect there by establishing a connection with an idea which already belongs to the preconscious, by transferring its intensity on to it and by getting itself 'covered' by it. Here we have the fact of 'transference', which provides an explanation of so many striking phenomena in the mental life of neurotics. The preconscious idea, which thus acquires an undeserved degree of intensity may either be left unaltered by the transference, or it may have a modification forced upon it, derived from the content of the idea which effects the transference. I hope I may be forgiven for drawing analogies from everyday life, but I am tempted to say that the position of a repressed idea resembles that of an American dentist in this country: he is not allowed to set up in practice unless he can make use of a legally qualified medical practitioner to serve as a stalking-horse and to act as a 'cover' in the eyes of the law. And just as it is not exactly the physicians with the largest practices who form alliances of this kind with dentists, so in the same way preconscious or conscious ideas which have already attracted a sufficient amount of the attention that is operating in the preconscious will not be the ones to be chosen to act as covers for a repressed idea. The unconscious prefers to weave its connections round preconscious impressions and ideas which are either indifferent and have thus had no attention paid to them, or have been rejected and have thus had attention promptly withdrawn from them. It is a familiar article in the doctrine of association, and one that is entirely confirmed by experience, that an idea which is bound by a very intimate tie in one direction, tends, as it were, to repel whole groups of new ties. I once attempted to base a theory of hysterical paralyses on this proposition.

[1900a, 993]
If we assume that the same need for transference on the part of repressed ideas which we have discovered in analysing the neuroses is also at work in dreams, two of the riddles of the dream are solved at a blow: the fact, namely, that every analysis of a dream shows some recent impression woven into its texture and that this recent element is often of the most trivial kind. I may add that (as we have already found elsewhere) the reason why these recent and indifferent elements so frequently find their way into dreams as substitutes for the most ancient of all the dream-thoughts is that they have least to fear from the censorship imposed by resistance. But while the fact that trivial elements are preferred is explained by their freedom from censorship, the fact that recent elements occur with such regularity points to the existence of a need for transference. Both groups of impressions satisfy the demand of the repressed for material that is still clear of associations - the indifferent ones because they have given no occasion for the formation of many ties, and the recent ones because they have not yet had time to form them.

[1900a, 994]

It will be seen, then, that the day's residues, among which we may now class the indifferent impressions, not only borrow something from the Ucs. when they succeed in taking a share in the formation of a dream - namely the instinctual force which is at the disposal of the repressed wish - but that they also offer the unconscious something indispensable - namely the necessary point of attachment for a transference. If we wished to penetrate more deeply at this point into the processes of the mind, we should have to throw more light upon the interplay of excitations between the preconscious and the unconscious a subject towards which the study of the psychoneuroses draws us, but upon which, as it happens, dreams have no help to offer.

[1900a, 994]

The situation is this. Either residues of the previous day have been left over from the activity of waking life and it has not been possible to withdraw the whole cathexis of energy from them; or the activity of waking life during the course of the day has led to the stirring up of an unconscious wish; or these two events have happened to coincide. (We have already discussed the various possibilities in this connection.) The unconscious wish links itself up with the day's residues and effects a transference on to them; this may happen either in the course of the day or not until a state of sleep has been established. A wish now arises which has been transferred on to the recent material; or a recent wish, having been suppressed, gains fresh life by being reinforced from the unconscious. This wish seeks to force its way along the normal path taken by thought processes, though the Pcs. (to which, indeed, it in part belongs) to consciousness. But it comes up against the censorship, which is still functioning and to the influence of which it now submits. At this point it takes on the distortion for which the way has already been paved by the transference of the wish on to recent material. So far it is on the way to becoming an obsessive idea or a delusion or something of the kind - that is, a thought which has been intensified by transference and distorted in its expression by censorship. Its further advance is halted, however, by the sleeping state of the preconscious. (The probability is that that system has protected itself against the invasion by diminishing its own excitations.) The dream-process consequently enters on a regressive path, which lies open to it precisely owing to the peculiar nature of the state of sleep, and it is led along that path by the attraction exercised on it by groups of memories; some of these memories themselves exist only in the form of visual cathexes and not as translations into the terminology of the later systems. In the course of its regressive path the dream-process acquires the attribute of representability. (I shall deal later with the question of compression.) It has now completed the second portion of its zigzag journey. The first portion was a progressive one, leading from the unconscious scenes or phantasies to the preconscious; the second portion led from the frontier of the censorship back again to perceptions. But when the content of the dream process has become perceptual, by that fact it has, as it were, found a way of evading the obstacle put in its way by the censorship and the state of sleep in the Pcs. It succeeds in drawing attention to itself and in being noticed by consciousness.

[1900a, 1002]
The view that dreams carry on the occupations and interests of waking life has been entirely confirmed by the discovery of the concealed *dream-thoughts*. These are only concerned with what seems important to us and interests us greatly. Dreams are never occupied with minor details. But we have also found reason for accepting the contrary view, that dreams pick up indifferent refuse left over from the previous day and that they cannot get control of any major day time interest until it has been to some extent withdrawn from waking activity. We have found that this holds good of the dream's *content*, which gives expression to the dream-thoughts in a form modified by distortion. For reasons connected with the mechanism of association, as we have seen, the dream-process finds it easier to get control of recent or indifferent ideational material which has not yet been requisitioned by waking thought-activity; and for reasons of censorship it transfers psychical intensity from what is important but objectionable on to what is indifferent. [1900a, 1016]

It has naturally not occurred to us to throw any doubt on the significance, which has been experimentally demonstrated, of external sensory stimuli during sleep; but we have shown that such material stands in the same relation to the dream-wish as do the residues of thought left over from day time activity. Nor have we seen any reason to dispute the view that dreams interpret objective sensory stimuli just as illusions do; but we have found the motive which provides the reason for that interpretation, a reason which has been left unspecified by other writers. Interpretation is carried out in such a way that the object perceived shall not interrupt sleep and shall be usable for purposes of wish-fulfilment. As regards subjective states of excitation in the sense organs during sleep, the occurrence of which seems to have been proved by Trumbull Ladd, it is true that we have not accepted them as a particular source of dreams; but we have been able to explain them as resulting from the regressive revival of memories that are in operation behind the dream. [1900a, 1016]

*Company at table or table d'hôte.* This at once reminded me of an episode which occurred late yesterday evening. I came away from a small party in the company of a friend who offered to take a cab and drive me home in it. 'I prefer taking a cab with a taximeter', he said, 'it occupies one's mind so agreeably; one always has something to look at.' When we had taken our places in the cab and the driver had set the dial, so that the first charge of sixty hellers became visible, I carried the joke further. 'We've only just got in', I said, 'and already we owe him sixty hellers. A cab with a taximeter always reminds me of a table d'hôte. It makes me avaricious and selfish, because it keeps on reminding me of what I owe. My debt seems to be growing too fast, and I'm afraid of getting the worst of the bargain; and in just the same way at a table d'hôte I can't avoid feeling in a comic way that I'm getting too little, and must keep an eye on my own interests.' I went on to quote, somewhat discursively: [1901a, 1055]

This small collection throws a direct light on a further characteristic of children's dreams: their connection with daytime life. The wishes which are fulfilled in them are carried over from daytime and as a rule from the day before, and in waking life they have been accompanied by intense emotion. Nothing unimportant or indifferent, or nothing which would strike a child as such, finds its way into the content of their dreams. [1901a, 1063]
But another achievement of the dream-work, tending as it does to produce incoherent dreams, is even more striking. If in any particular instance we compare the number of ideational elements or the space taken up in writing them down in the case of the dream and of the dream-thoughts to which the analysis leads us and of which traces are to be found in the dream itself, we shall be left in no doubt that the dream-work has carried out a work of compression or condensation on a large scale. It is impossible at first to form any judgement of the degree of this condensation; but the deeper we plunge into a dream-analysis the more impressive it seems. From every element in a dream's content associative threads branch out in two or more directions; every situation in a dream seems to be put together out of two or more impressions or experiences. For instance, I once had a dream of a sort of swimming-pool, in which the bathers were scattering in all directions; at one point on the edge of the pool someone was standing and bending towards one of the people bathing, as though to help her out of the water. The situation was put together from a memory of an experience I had had at puberty and from two paintings, one of which I had seen shortly before the dream. One was a picture from Schwind's series illustrating the legend of Mélusine, which showed the water-nymphs surprised in their pool (cf. the scattering bathers in the dream); the other was a picture of the Deluge by an Italian Master; while the little experience remembered from my puberty was of having seen the instructor at a swimming-school helping a lady out of the water who had stopped in until after the time set aside for men bathers. -In the case of the example which I chose for interpretation, an analysis of the situation led me to a small series of recollections each of which contributed something to the content of the dream. In the first place, there was the episode from the time of my engagement of which I have already spoken. The pressure upon my hand under the table, which was a part of that episode, provided the dream with the detail 'under the table' - a detail which I had to add as an afterthought to my memory of the dream. In the episode itself there was of course no question of 'turning to me'; the analysis showed that this element was the fulfilment of a wish by presenting the opposite of an actual event, and that it related to my wife's behaviour at the table d'hôte. But behind this recent recollection there lay concealed an exactly similar and far more important scene from the time of our engagement, which estranged us for a whole day. The intimate laying of a hand on my knee belonged to a quite different context and was concerned with quite other people. This element in the dream was in turn the starting-point of two separate sets of memories - and so on.

If we undo dream-displacement by means of analysis, we obtain what seems to be completely trustworthy information on two much-disputed problems concerning dreams: as to their instigators and as to their connection with waking life. There are dreams which immediately reveal their derivation from events of the day; there are others in which no trace of any such derivation is to be discovered. If we seek the help of analysis, we find that every dream without any possible exception goes back to an impression of the past few days, or, it is probably more correct to say, of the day immediately preceding the dream, of the 'dream-day.' The impression which plays the part of dream-instigator may be such an important one that we feel no surprise at being concerned with it in the daytime, and in that case we rightly speak of the dream as carrying on with the significant interests of our waking life. As a rule, however, if a connection is to be found in the content of the dream with any impression of the previous day, that impression is so trivial, insignificant and unmemorable, that it is only with difficulty that we ourselves can recall it. And in such cases the content of the dream itself, even if it is connected and intelligible, seems to be concerned with the most indifferent trivialities, which would be unworthy of our interest if we were awake. A good deal of the contempt in which dreams are held is due to the preference thus shown in their content for what is indifferent and trivial.

[1901a, 1071]
What interests us here is the source of the figures in the material of the dream-thoughts and the transformations which they underwent. What was the origin of the 1 florin 50 kreuzers? It came from what was in fact an indifferent event of the previous day. Her sister-in-law had been given a present of 150 florins by her husband and had *been in a hurry* to get rid of them by buying a piece of jewellery. It is to be noticed that 150 florins is a *hundred* times as much as 1 florin 50 kreuzers. The only connection with the 'three', which was the number of the theatre tickets, was that her newly engaged friend was that number of months - three - her junior. The situation in the dream was a repetition of a small incident which her husband often teased her about. On one occasion she had been in a great hurry to buy tickets for a play in advance, and when she got to the theatre she had found that one side of the stalls was almost completely empty. There had been *no need for her to be in such a hurry*. Finally, we must not overlook the *absurdity* in the dream of two people taking three tickets for a play.

[1901a, 1083]

No one who accepts the view that the censorship is the chief reason for dream-distortion will be surprised to learn from the results of dream-interpretation that most of the dreams of adults are traced back by analysis to *erotic wishes*. This assertion is not aimed at dreams with an *undisguised* sexual content, which are no doubt familiar to all dreamers from their own experience and are as a rule the only ones to be described as ‘sexual dreams.’ Even dreams of this latter kind offer enough surprises in their choice of the people whom they make into sexual objects, in their disregard of all the limitations which the dreamer imposes in his waking life upon his sexual desires, and by their many strange details, hinting at what are commonly known as ‘perversions.’ A great many other dreams, however, which show no sign of being erotic in their manifest content, are revealed by the work of interpretation in analysis as sexual wish-fulfillments; and, on the other hand, analysis proves that a great many of the thoughts left over from the activity of waking life as ‘residues of the previous day’ only find their way to representation in dreams through the assistance of repressed erotic wishes.

[1901a, 1094]
(10) The following case could just as appropriately be included in the chapter below on 'Errors', but I quote it here, since the phonetic relations, which were the basis of one word being put in place of another, are quite unusually clear. A woman patient told me a dream: A child had resolved to kill itself by means of a snake-bite. It carried out its resolution. She watched it writhing in convulsions, and so on. She had now to find the impressions of the previous day which the dream had taken as its starting point. She immediately recalled that on the previous evening she had listened to a public lecture on first aid for snake-bites. If an adult and a child were bitten at the same time, the child's injury should be attended to first. She also remembered what the lecturer had prescribed by way of treatment. It would very much depend, he had said, on what kind of snake caused the bite. I interrupted at this point and asked: Surely he must have said that we have very few poisonous kinds in these parts and he must have told you which are the dangerous ones? 'Yes, he particularly mentioned the "Klapperschlange [rattlesnake]".' My laughter drew her attention to her having said something wrong. She did not correct the name, but took back her statement: 'Yes, of course, they aren't found here; he was talking of the viper. How can I have got the idea of the rattlesnake?' I suspected it was due to interference by the thoughts which had hidden behind her dream. Suicide by means of a snake-bite could hardly be anything other than an allusion to the beautiful Cleopatra [in German: 'Kleopatra']. The great similarity between the sound of the two words, the occurrence in both of the same letters 'Kl. . . p. . . ' in the same order, and of the same stressed 'a', was unmistakable. The close connection between the names 'Klapperschlange' and 'Kleopatra' resulted in her judgement being momentarily restricted, so that she saw no objection to asserting that the lecturer had given his audience in Vienna instructions on how to treat rattlesnake bites. In the ordinary way she knew as well as I did that that species of snake is not among the fauna of our country. We will not blame her for her equal lack of hesitation in transferring the rattlesnake to Egypt, for it is usual for us to lump together everything which is non-European and exotic, and I had myself to reflect for a moment before declaring that the rattlesnake is confined to the New World.

[1901b, 1156]

Thus a great number of the jokes in circulation have a certain length of life: their life runs a course made up of a period of flowering and a period of decay and it ends in complete oblivion. The need which men feel for deriving pleasure from their processes of thought is therefore constantly creating new jokes based on the new interests of the day. The vital force of topical jokes is not their own; it is borrowed, by the method of allusion, from those other interests, the expiry of which determines the fate of the joke as well. The factor of topicality is a source of pleasure, ephemeral it is true but particularly abundant, which supplements the sources inherent in the joke itself. It cannot be simply equated with the rediscovery of what is familiar. It is concerned rather with a particular category of what is familiar, which must in addition possess the characteristic of being fresh, recent and untouched by forgetting. In the formation of dreams, too, we come across a special preference for what is recent and we cannot escape a suspicion that association with what is recent is rewarded, and so facilitated, by a peculiar bonus of pleasure.

[1905c, 1715]
The achievements of the dream-work can, however, be described as follows. A tissue of thoughts, usually a very complicated one, which has been built up during the day and has not been completely dealt with - 'a day's residue' - continues during the night to retain the quota of energy - the 'interest' claimed by it, and threatens to disturb sleep. This 'day's residue' is transformed by the dream-work into a dream and made innocuous to sleep. In order to provide a fulcrum for the dream-work, the 'day's residue' must be capable of constructing a wish - which is not a very hard condition to fulfil. The wish arising from the dream-thoughts forms the preliminary stage and later the core of the dream. Experience derived from analyses - and not the theory of dreams - informs us that in children any wish left over from waking life is sufficient to call up a dream, which emerges as connected and ingenious but usually short, and which is easily recognized as a 'wish-fulfilment'. In the case of adults it seems to be a generally binding condition that the wish which creates the dream shall be one that is alien to conscious thinking - a repressed wish - or will possibly at least have reinforcements that are unknown to consciousness. Without assuming the existence of the unconscious in the sense explained above, I should not be able to develop the theory of dreams further or to interpret the material met with in dream-analyses. The action of this unconscious wish upon the consciously rational material of the dream-thoughts produces the dream. While this happens, the dream is, as it were, dragged down into the unconscious, or, more precisely, is submitted to a treatment such as is met with at the level of unconscious thought-processes and is characteristic of that level. Hitherto it is only from the results of the 'dream-work' that we are in fact acquainted with the characteristics of unconscious thinking and its differences from thinking that is capable of becoming conscious - 'preconscious' thinking.

But after all, what we really intended to do originally was only to investigate two or three dreams that are to be found here and there in Gradiva with the help of certain analytic methods. How has it come about, then, that we have been led into dissecting the whole story and examining the mental processes in the two chief characters? This has not in fact been an unnecessary piece of work; it was an essential preliminary. It is equally the case that when we try to understand the real dreams of a real person we have to concern ourselves intensively with his character and his career, and we must get to know not only his experiences shortly before the dream but also those dating far back into the past. It is even my view that we are still not free to turn to our proper task, but that we must linger a little more over the story itself and carry out some further preliminary work.

One of these rules is to the effect that a dream is invariably related to the events of the day before the dream. Our author seems to be wishing to show that he has followed this rule, for he attaches the dream immediately to Hanold's 'pedestrian researches'. Now these had no meaning other than a search for Gradiva, whose characteristic gait he was trying to recognize. So the dream ought to have contained an indication of where Gradiva was to be found. And it does so, by showing her in Pompeii; but that is no novelty to us.
'Somewhere in the sun Gradiva was sitting, catching lizards and speaking.' What impression of the previous day finds an echo in this part of the dream? Undoubtedly the encounter with the elderly gentleman, the lizard-catcher, who was thus replaced in the dream by Gradiva. He sat or lay 'on a sun-bathed slope' and he, too, spoke to Hanold. Furthermore, Gradiva's remarks in the dream were copied from this man's remarks: viz. 'The method prescribed by our colleague Eimer is a really good one; I have made use of it many times already with excellent results. Please keep quite still.' Gradiva used much the same words in the dream, except that 'our colleague Eimer' was replaced by an unnamed 'lady colleague'; moreover, the 'many times' in the zoologist's speech was omitted in the dream and the order of the sentences was somewhat altered. It seems, therefore, that this experience of the previous day was transformed into the dream with the help of a few changes and distortions. Why this particular experience? And what is the meaning of the changes - the replacement of the elderly gentleman by Gradiva and the introduction of the enigmatic 'lady colleague'?

The replacement of the lizard-catcher by Gradiva in the content of the dream is accordingly a representation of the relation between the two figures which was known to Hanold in his unconscious; the introduction of the 'lady colleague' instead of 'our colleague Eimer' allowed the dream to express Hanold's realization that she was wooing a man. So far the dream welded together ('condensed', as we say) two experiences of the previous day into one situation, in order to bring to expression (in a very obscure way, it is true) two discoveries which were not allotted to become conscious. But we can go further, we can diminish the strangeness of the dream still more and we can demonstrate the influence of his other experiences of the previous day on the form taken by the manifest dream.

We would seem to have reached the end. But an attentive reader might remind us that at the beginning we threw out an assertion that dreams are wishes represented as fulfilled and that we gave no proof of this. Well, is our reply, what we have described in these pages might show how little justification there is for trying to cover the explanations we have to give of dreams with the single formula that dreams are wish-fulfilments. Nevertheless the assertion stands and can easily be proved too for the dreams in Gradiva. The latent dream-thoughts - we know now what is meant by them - may be of the most various kinds; in Gradiva they are 'days' residues', thoughts that have been left over unnoticed and undealt-with from the mental activities of waking life. But in order for a dream to develop out of them, the co-operation of a wish (usually an unconscious one) is required; this contributes the motive force for constructing the dream, while the day's residues provide the material. In Norbert Hanold's first dream two wishes competed with each other in making the dream; one of them was actually admissible to consciousness, while the other belonged to the unconscious and operated from out of repression. The first was a wish, understandable in any archaeologist, to have been present as an eye-witness at the catastrophe in the year 79 A.D. What sacrifice would an archaeologist think too great if this wish could be realized in any way other than in a dream! The other wish, the other constructor of the dream, was of an erotic nature: it might be crudely and also incompletely stated as a wish to be there when the girl he loved lay down to sleep. This was the wish the rejection of which caused the dream to become an anxiety-dream. The wishes that were the motive forces of the second dream are perhaps less conspicuous; but if we recall its translation we shall not hesitate to describe them too as erotic. The wish to be taken captive by the girl he loved, to fall in with her wishes and to be subjected to her - for so we may construe the wish behind the situation of the lizard-catching - was in fact of a passive, masochistic character. Next day the dreamer hit the girl, as though he was dominated by the contrary erotic current . . . But we must stop here, or we may really forget that Hanold and Gradiva are only creatures of their author's mind.
Further questions made it clear that there was no visual content whatever in this dream, and that it was of the purely auditory type. During the last few days Hans has been playing parlour games and "forfeits" with our landlord's children, amongst whom are his friends Olga (aged seven) and Berta (aged five). (The game of forfeits is played in this way: A: "Whose is this forfeit in my hand?" B: "Mine." Then it is decided what B must do.) The dream was modelled on this game; only what Hans wished was that the person to whom the forfeit belonged should be condemned, not to give the usual kiss or be given the usual box on the ear, but to widdle, or rather to be made to widdle by someone.

You can convince yourself that there are such things as latent dream-thoughts and that the relation between them and the manifest content of the dream is really as I have described it, if you carry out an analysis of dreams, the technique of which is the same as that of psycho-analysis. You entirely disregard the apparent connections between the elements in the manifest dream and collect the ideas that occur to you in connection with each separate element of the dream by free association according to the psycho-analytic rule of procedure. From this material you arrive at the latent dream-thoughts, just as you arrived at the patient's hidden complexes from his associations to his symptoms and memories. The latent dream-thoughts which have been reached in this way will at once show you how completely justified we have been in tracing back adults' dreams to children's dreams. The true meaning of the dream, which has now taken the place of its manifest content, is always clearly intelligible; it has its starting-point in experiences of the previous day, and proves to be a fulfilment of unsatisfied wishes. The manifest dream, which you know from your memory when you wake up, can therefore only be described as a disguised fulfilment of repressed wishes.

The so-called 'day's residues' can act as disturbers of sleep and constructors of dreams; they are affectively cathected thought-processes from the dream-day, which have resisted the general lowering through sleep. These day's residues are uncovered by tracing back the manifest dream to the latent dream-thoughts; they constitute portions of the latter and are thus among the activities of waking life - whether conscious or unconscious - which have been able to persist into the period of sleep. In accordance with the multiplicity of thought-processes in the conscious and preconscious, these day's residues have the most numerous and varied meanings: they may be wishes or fears that have not been disposed of, or intentions, reflections, warnings, attempts at adaptation to current tasks, and so on. To this extent the classification of dreams that is under consideration seems to be justified by the content which is uncovered by interpretation. These day's residues, however, are not the dream itself: they lack the main essential of a dream. Of themselves they are not able to construct a dream. They are, strictly speaking, only the psychical material for the dream-work, just as sensory and somatic stimuli, whether accidental or produced under experimental conditions, constitute the somatic material for the dream-work. To attribute to them the main part in the construction of dreams is simply to repeat at a new point the pre-analytic error which explained dreams by referring them to bad digestion or to pressure on the skin. Scientific errors, indeed, are tenacious of life, and even when they have been refuted are ready to creep in again under new disguises.
The present state of our knowledge leads us to conclude that the essential factor in the construction of dreams is an unconscious wish - as a rule an infantile wish, now repressed - which can come to expression in this somatic or psychical material (in the day's residues too, therefore) and can thus supply these with a force which enables them to press their way through to consciousness even during the suspension of thought at night. The dream is in every case a fulfilment of this unconscious wish, whatever else it may contain - warning, reflection, admission, or any other part of the rich content of preconscious waking life that has persisted undealt-with into the night. It is this unconscious wish that gives the dream-work its peculiar character as an unconscious revision of preconscious material. A psycho-analyst can characterize as dreams only the products of the dream-work: in spite of the fact that the latent dream-thoughts are only arrived at from the interpretation of the dream, he cannot reckon them as part of the dream, but only as part of preconscious reflection. (Secondary revision by the conscious agency is here reckoned as part of the dream-work. Even if one were to separate it, this would not involve any alteration in our conception. We should then have to say: dreams in the analytic sense comprise the dream-work proper together with the secondary revision of its products.) The conclusion to be drawn from these considerations is that one cannot put the wish-fulfilling character of dreams on a par with their character as warnings, admissions, attempts at solution, etc., without denying the concept of a psychical dimension of depth - that is to say, without denying the standpoint of psycho-analysis.

[1913a, 2591]

On the day before she had the dream she herself had been just as furious with her husband and had exclaimed: 'I could tear him in two.'
[1913d, 2597]

Rumpelstiltskin was connected with the contemporary thoughts underlying the dream - the day's residues - by a neat antithetic relation. In the fairy tale he comes in order to take away the queen's first child. In the dream the little man comes in the shape of a father, because he had presumably brought a second child. But Rumpelstiltskin also gave access to the deeper, infantile stratum of the dream-thoughts. The droll little fellow, whose very name is unknown, whose secret is so eagerly canvassed, who can perform such extraordinary tricks - in the fairy tale he turns straw into gold - the fury against him, or rather against his possessor, who is envied for possessing him (the girl's envy for the penis) - all of these were elements whose relation to the foundations of the patient's neurosis can, as I have said, barely be touched upon in this paper. The short-cut hair of the manikin in the dream was no doubt also connected with the subject of castration.
[1913d, 2598]

In what way, however, can a case arise in which the intention to sleep meets with an interruption? The interruption may proceed from an internal excitation or from an external stimulus. Let us first consider the more obscure and more interesting case of interruption from within. Observation shows that dreams are instigated by residues from the previous day - thought-cathexes which have not submitted to the general withdrawal of cathexes, but have retained in spite of it a certain amount of libidinal or other interest. Thus the narcissism of sleep has from the outset had to admit an exception at this point, and it is here that the formation of dreams takes its start. In analysis we make the acquaintance of these 'day's residues' in the shape of latent dream-thoughts; and, both by reason of their nature and of the whole situation, we must regard them as preconscious ideas, as belonging to the system Pcs.
[1917d, 3029]
The first thing the dreamer reported to us was that the precipitating cause of the dream was touched on in its manifest content. Her husband had in fact told her that Elise L., who was approximately her contemporary, had just become engaged. The dream was a reaction to this information. We know already that it is easy in the case of many dreams to point to a precipitating cause like this from the previous day, and that the dreamer is often able to trace this for us without any difficulty. The dreamer in the present case put similar information at our disposal for other elements of the manifest dream as well. - Where did the detail come from about one side of the stalls being empty? It was an allusion to a real event of the previous week. She had planned to go to a particular play and had therefore bought her tickets early - so early that she had had to pay a booking fee. When they got to the theatre it turned out that her anxiety was quite uncalled-for, since one side of the stalls was almost empty. It would have been early enough if she had bought the tickets on the actual day of the performance. Her husband had kept on teasing her for having been in too much of a hurry. - What was the origin of the 1 florin 50 kreuzers? It arose in quite another connection, which had nothing to do with the former one but also alluded to some information from the previous day. Her sister-in-law had been given a present of 150 florins by her husband and had been in a great hurry - the silly goose - to rush off to the jewellers' and exchange the money for a piece of jewellery. - Where did the 'three' come from? She could think of nothing in connection with that, unless we counted the idea that her newly-engaged friend, Elise L., was only three months her junior, though she herself had been a married woman for nearly ten years. - And the absurd notion of taking three tickets for only two people? She had nothing to say to that, and refused to report any further ideas or information.

Symbolism is perhaps the most remarkable chapter of the theory of dreams. In the first place, since symbols are stable translations, they realize to some extent the ideal of the ancient as well as of the popular interpretation of dreams, from which, with our technique, we had departed widely. They allow us in certain circumstances to interpret a dream without questioning the dreamer, who indeed would in any case have nothing to tell, us about the symbol. If we are acquainted with the ordinary dream-symbols, and in addition with the dreamer's personality, the circumstances in which he lives and the impressions which preceded the occurrence of the dream, we are often in a position to interpret a dream straightaway - to translate it at sight, as it were. A piece of virtuosity of this kind flatters the dream-interpreter and impresses the dreamer; it forms an agreeable contrast to the laborious work of questioning the dreamer. But do not allow yourselves to be led astray by this. It is not our business to perform acts of virtuosity. Interpretation based on a knowledge of symbols is not a technique which can replace or compete with the associative one. It forms a supplement to the latter and yields results which are only of use when introduced into it. And as regards acquaintance with the dreamer's psychical situation, you must bear in mind that the dreams of people you know well are not the only ones you have to analyse, that you are not as a rule familiar with the events of the previous day, which were the instigators of the dream, but that the associations of the person you are analysing will provide you precisely with a knowledge of what we call the psychical situation.
The fresh consideration I wish to bring before you is to draw your attention to the latent dream-thoughts which have now been put in the foreground. I beg you not to forget that in the first place they are unconscious to the dreamer, and secondly that they are completely rational and coherent so that they can be understood as natural reactions to the precipitating cause of the dream, and thirdly that they can be the equivalent of any mental impulse or intellectual operation. I shall now describe these thoughts more strictly than before as the 'day's residues', whether the dreamer confesses to them or not. I shall now distinguish between the day's residues and the latent dream-thoughts, and, in conformity with our earlier usage, I shall designate as latent dream-thoughts everything we learn in interpreting the dream, whereas the day's residues are only a portion of the latent dream-thoughts. Our view is then that something is added to the day's residues, something that was also part of the unconscious, a powerful but repressed wishful impulse; and it is this alone that makes the construction of the dream possible. The influence of this wishful impulse on the day's residues creates the further portion of the latent dream-thoughts - that which need no longer appear rational and intelligible as being derived from waking life.

[1916-1917, 3313]

We cannot advance any further here, for you have probably long been disturbed by a doubt which deserves to be given a hearing. 'Are the day's residues,' you will ask, 'really unconscious in the same sense as the unconscious wish which must be added to them in order to make them capable of producing a dream?' Your suspicion is correct. This is the salient point of the whole business. They are not unconscious in the same sense. The dream-wish belongs to a different unconscious - to the one which we have already recognized as being of infantile origin and equipped with peculiar mechanisms. It would be highly opportune to distinguish these two kinds of unconscious by different names. But we would prefer to wait till we have become familiar with the field of phenomena of the neuroses. People consider a single unconscious as something fantastic. What will they say when we confess that we cannot make shift without two of them?

[1916-1917, 3314]

Perhaps you recognize, moreover, what it is that supports our hypotheses of the two systems, and their relation to each other and to consciousness? After all, the watchman between the unconscious and the preconscious is nothing else than the censorship, to which, as we found, the form taken by the manifest dream is subject. The day's residues, which we recognized as the instigators of the dream, were preconscious material which, at night-time and in the state of sleep, had been under the influence of unconscious and repressed wishful impulses; they had been able, in combination with those impulses and thanks to their energy, to construct the latent dream. Under the dominance of the unconscious system this material had been worked over (by condensation and displacement) in a manner which is unknown or only exceptionally permissible in normal mental life - that is, in the preconscious system. We came to regard this difference in their manner of operating as what characterizes the two systems; the relation which the preconscious has to consciousness was regarded by us merely as an indication of its belonging to one of the two systems. Dreams are not pathological phenomena; they can appear in any healthy person under the conditions of a state of sleep. Our hypothesis about the structure of the mental apparatus, which allows us to understand the formation alike of dreams and of neurotic symptoms, has an incontrovertible claim to being taken into account in regard to normal mental life as well.

[1916-1917, 3370]
My second remark is a supplement to the theory of dreams. We cannot explain the origin of dreams unless we adopt the hypothesis that the repressed unconscious has achieved some degree of independence of the ego, so that it does not acquiesce in the wish to sleep and retains its cathexes even when all the object-cathexes depending on the ego have been withdrawn in order to encourage sleep. Only if that is so can we understand how the unconscious can make use of the lifting or reduction of the censorship which occurs at night, and can succeed in obtaining control over the day's residues so as to construct a forbidden dream-wish out of their material. On the other hand, it may be that these day's residues have to thank an already existing connection with the repressed unconscious for some of their resistance to the withdrawal of libido commanded by the wish to sleep. We will, then, insert this dynamically important feature into our view of the formation of dreams by way of supplement.

[1916-1917, 3464]

It will perhaps not be thought too rash to suppose that the impulses arising from the instincts do not belong to the type of bound nervous processes but of freely mobile processes which press towards discharge. The best part of what we know of these processes is derived from our study of the dream-work. We there discovered that the processes in the unconscious systems were fundamentally different from those in the preconscious (or conscious) systems. In the unconscious, cathexes can easily be completely transferred, displaced and condensed. Such treatment, however, could produce only invalid results if it were applied to preconscious material; and this accounts for the familiar peculiarities exhibited by manifest dreams after the preconscious residues of the preceding day have been worked over in accordance with the laws operating in the unconscious. I described the type of process found in the unconscious as the 'primary' psychical process, in contradistinction to the 'secondary' process which is the one obtaining in our normal waking life. Since all instinctual impulses have the unconscious systems as their point of impact, it is hardly an innovation to say that they obey the primary process. Again, it is easy to identify the primary psychical process with Breuer's freely mobile cathexis and the secondary process with changes in his bound or tonic cathexis.¹ If so, it would be the task of the higher strata of the mental apparatus to bind the instinctual excitation reaching the primary process. A failure to effect this binding would provoke a disturbance analogous to a traumatic neurosis; and only after the binding has been accomplished would it be possible for the dominance of the pleasure principle (and of its modification, the reality principle) to proceed unhindered. Till then the other task of the mental apparatus, the task of mastering or binding excitations, would have precedence - not, indeed, in opposition to the pleasure principle, but independently of it and to some extent in disregard of it.

[1920g, 3737]
The manifestations of a compulsion to repeat (which we have described as occurring in the early activities of infantile mental life as well as among the events of psycho-analytic treatment) exhibit to a high degree an instinctual character and, when they act in opposition to the pleasure principle, give the appearance of some 'daemonic' force at work. In the case of children's play we seemed to see that children repeat unpleasurable experiences for the additional reason that they can master a powerful impression far more thoroughly by being active than they could by merely experiencing it passively. Each fresh repetition seems to strengthen the mastery they are in search of. Nor can children have their pleasurable experiences repeated often enough, and they are inexorable in their insistence that the repetition shall be an identical one. This character trait disappears later on. If a joke is heard for a second time it produces almost no effect; a theatrical production never creates so great an impression the second time as the first; indeed, it is hardly possible to persuade an adult who has very much enjoyed reading a book to re-read it immediately. Novelty is always the condition of enjoyment. But children will never tire of asking an adult to repeat a game that he has shown them or played with them, till he is too exhausted to go on. And if a child has been told a nice story, he will insist on hearing it over and over again rather than a new one; and he will remorselessly stipulate that the repetition shall be an identical one and will correct any alterations of which the narrator may be guilty - though they may actually have been made in the hope of gaining fresh approval. None of this contradicts the pleasure principle; repetition, the re-experiencing of something identical, is clearly in itself a source of pleasure. In the case of a person in analysis, on the contrary, the compulsion to repeat the events of his childhood in the transference evidently disregards the pleasure principle in every way. The patient behaves in a purely infantile fashion and thus shows us that the repressed memory-traces of his primaeval experiences are not present in him in a bound state and are indeed in a sense incapable of obeying the secondary process. It is to this fact of not being bound, moreover, that they owe their capacity for forming, in conjunction with the residues of the previous day, a wishful phantasy that emerges in a dream. This same compulsion to repeat frequently meets us as an obstacle to our treatment when at the end of an analysis we try to induce the patient to detach himself completely from his physician. It may be presumed, too, that when people unfamiliar with analysis feel an obscure fear - a dread of rousing something that, so they feel, is better left sleeping - what they are afraid of at bottom is the emergence of this compulsion with its hint of possession by some 'daemonic' power.

[1920g, 3738]

¹ In the interpretation of dreams, to which, indeed, we owe our best knowledge of unconscious mental life, we follow a technical rule of disregarding doubt and uncertainty in the narrative of the dream, and of treating every element of the manifest dream as being quite certain. We attribute doubt and uncertainty to the influence of the censorship to which the dream-work is subjected, and we assume that the primary dream-thoughts are not acquainted with doubt and uncertainty as critical processes. They may of course be present, like anything else, as part of the content of the day's residues which lead to the dream.
[1921c, 3773]
I can imagine that to point out the existence of lying dreams of this kind, 'obliging' dreams, will arouse a positive storm of helpless indignation in some readers who call themselves analysts. 'What!' they will exclaim, 'the unconscious, the real centre of our mental life, the part of us that is so much nearer the divine than our poor consciousness - it too can lie! Then how can we still build on the interpretations of analysis and the accuracy of our findings?' To which one must reply that the recognition of these lying dreams does not constitute any shattering novelty. I know, indeed, that the craving of mankind for mysticism is ineradicable, and that it makes ceaseless efforts to win back for mysticism the territory it has been deprived of by The Interpretation of Dreams, but surely in the case under consideration everything is simple enough. A dream is not the 'unconscious'; it is the form into which a thought left over from preconscious, or even from conscious, waking life, can, thanks to the favouring state of sleep, be recast. In the state of sleep this thought has been reinforced by unconscious wishful impulses and has thus experienced distortion through the dream-work, which is determined by the mechanisms prevailing in the unconscious. With our dreamer, the intention to mislead me, just as she did her father, certainly emanated from the preconscious, and may indeed have been conscious; it could come to expression by entering into connection with the unconscious wishful impulse to please her father (or father-substitute), and in this way it created a lying dream. The two intentions, to betray and to please her father, originated in the same complex; the former resulted from the repression of the latter, and the later one was brought back by the dream-work to the earlier one. There can therefore be no question of any devaluation of the unconscious, nor of a shattering of our confidence in the results of analysis.

[1920a, 3854]

If you prefer to assume that a telepathic message about the daughter's confinement reached the sleeper, further questions arise of the relation of a message such as this to a dream and of its influence on the formation of dreams. The answer is not far to seek and is quite unambiguous. A telepathic message will be treated as a portion of the material that goes to the formation of a dream, like any other external or internal stimulus, like a disturbing noise in the street or an insistent organic sensation in the sleeper's own body. In our example it is evident how the message, with the help of a lurking repressed wish, became remodelled into a wish-fulfilment; it is unfortunately less easy to show that it combined with other material that had become active at the same time and was blended into a dream. Telepathic messages - if we are justified in recognizing their existence - can thus make no alteration in the process of forming a dream; telepathy has nothing to do with the nature of dreams. And in order to avoid the impression that I am trying to conceal a vague notion behind abstract and fine-sounding words, I am willing to repeat: the essential nature of dreams consists in the peculiar process of 'dream-work' which, with the help of an unconscious wish, carries the preconscious thoughts (day's residues) over into the manifest content of the dream. The problem of telepathy concerns dreams as little as does the problem of anxiety.

[1922a, 3887]
I am hoping that you will grant this, but that you will raise the objection that there are, nevertheless, other telepathic dreams in which there is no difference between the event and the dream, and in which there is nothing else to be found but an undistorted reproduction of the event. I have no knowledge of such dreams from my own experience, but I know they have often been reported. If we assume that we have such an undisguised and unadulterated telepathic dream to deal with, another question arises. Ought we to call such a telepathic experience a 'dream' at all? You will certainly do so as long as you keep to popular usage, in which everything that takes place in mental life during sleep is called a dream. You, too, perhaps say, 'I tossed about in my dream', and still less are you conscious of anything incorrect when you say, 'I shed tears in my dream' or 'I felt apprehensive in my dream'. But you will no doubt notice that in all these cases you are using 'dream' and 'sleep' and 'state of being asleep' interchangeably, as if there were no distinction between them. I think it would be in the interests of scientific accuracy to keep 'dream' and 'state of sleep' more distinctly separate. Why should we provide a counterpart to the confusion evoked by Maeder who, by refusing to distinguish between the dream-work and the latent dream-thoughts, has discovered a new function for dreams? Supposing, then, that we are brought face to face with a pure telepathic 'dream', let us rather call it instead a telepathic experience in a state of sleep. A dream without condensation, distortion, dramatization, above all, without wish-fulfilment, surely does not deserve the name. You will remind me that, if so, there are other mental products in sleep to which the right to be called 'dreams' would have to be refused. Actual experiences of the day are sometimes simply repeated in sleep; reproductions of traumatic scenes in 'dreams' have led us only lately to revise the theory of dreams. There are dreams which are to be distinguished from the usual type by certain special qualities, which are, properly speaking, nothing but night-phantasies, not having undergone additions or alterations of any kind and being in all other ways similar to the familiar day-dreams. It would be awkward, no doubt, to exclude these structures from the domain of 'dreams'. But still they all come from within, are products of our mental life, whereas the very conception of the purely 'telepathic dream' lies in its being a perception of something external, in relation to which the mind remains passive and receptive.

[1922a, 3887]

We also describe the latent dream-thoughts, on account of their connection with waking life, as 'residues of the day'. By the operation of the dream-work (to which it would be quite incorrect to ascribe any 'creative' character ) the latent dream thoughts are condensed in a remarkable way, are distorted by the displacement of psychical intensities and are arranged with a view to being represented in visual pictures; and, besides all this, before the manifest dream is arrived at, they are submitted to a process of secondary revision which seeks to give the new product something in the nature of sense and coherence. Strictly speaking, this last process does not form a part of the dream-work.

[1923a, 3918]

Or one can (b) start the work of interpretation from some one particular element of the dream which one picks out from the middle of it. For instance, one can choose the most striking piece of it, or the piece which shows the greatest clarity or sensory intensity; or, again, one can start off from some spoken words in the dream, in the expectation that they will lead to the recollection of some spoken words in waking life.

[1923c, 4030]

Or one can (c) begin by entirely disregarding the manifest content and instead ask the dreamer what events of the previous day are associated in his mind with the dream he has just described.

[1923c, 4030]
It is possible to distinguish between dreams from above and dreams from below, provided the distinction is not made too sharply. Dreams from below are those which are provoked by the strength of an unconscious (repressed) wish which has found a means of being represented in some of the day's residues. They may be regarded as inroads of the repressed into waking life. Dreams from above correspond to thoughts or intentions of the day before which have contrived during the night to obtain reinforcement from repressed material that is debared from the ego. When this is so, analysis as a rule disregards this unconscious ally and succeeds in inserting the latent dream-thoughts into the texture of waking thought. This distinction calls for no modification in the theory of dreams.

[1923c, 4032]

The fact that the manifest content of dreams is influenced by the analytic treatment stands in no need of proof. It follows from our knowledge that dreams take their start from waking life and work over material derived from it. Occurrences during analytic treatment are of course among the impressions of waking life and soon become some of the most powerful of these. So it is not to be wondered at that patients should dream of things which the analyst has discussed with them and of which he has aroused expectations in them. At least it is no more to be wondered at than what is implied in the familiar fact of 'experimental' dreams.

[1923c, 4035]

But from here our interest proceeds to the question whether the latent dream-thoughts that have to be arrived at by interpretation can also be influenced or suggested by the analyst. And to this the answer must once more be that they obviously can be. For a portion of these latent dream-thoughts correspond to preconscious thought-formations, perfectly capable of being conscious, with which the dreamer might quite well have reacted to the physician's remarks in his waking state too - whether the patient's reactions were in harmony with those remarks or in opposition to them. In fact, if we replace the dream by the dream-thoughts which it contains, the question of how far one can suggest dreams coincides with the more general question of how far a patient in analysis is accessible to suggestion.

[1923c, 4035]

In spite of the caution which is prescribed by the importance, novelty and obscurity of the subject, I feel that I should not be justified in holding back any longer these considerations upon the problem of telepathy. All of this has only this much to do with dreams: if there are such things as telepathic messages, the possibility cannot be dismissed of their reaching someone during sleep and coming to his knowledge in a dream. Indeed, on the analogy of other perceptual and intellectual material, the further possibility arises that telepathic messages received in the course of the day may only be dealt with during a dream of the following night. There would then be nothing contradictory in the material that has been telepathically communicated being modified and transformed in the dream like any other material. It would be satisfactory if with the help of psycho-analysis we could obtain further and better authenticated knowledge of telepathy.

[1925i, 4055]
There were now a whole series of questions to be answered, among the most important of them being whether the formation of dreams had a motive, under what conditions it took place, by what methods the dream-thoughts (which are invariably full of sense) become converted into the dream (which is often senseless), and others besides. I attempted to solve all of these problems in *The Interpretation of Dreams*, which I published in the year 1900. I can only find space here for the briefest abstract of my investigation. When the latent dream-thoughts that are revealed by the analysis of a dream are examined, one of them is found to stand out from among the rest, which are intelligible and well known to the dreamer. These latter thoughts are residues of waking life (the day’s residues, as they are called technically); but the isolated thought is found to be a wishful impulse, often of a very repellent kind, which is foreign to the waking life of the dreamer and is consequently disavowed by him with surprise or indignation. This impulse is the actual constructor of the dream: it provides the energy for its production and makes use of the day’s residues as material. The dream which thus originates represents a situation of satisfaction for the impulse, it is the fulfilment of its wish. It would not be possible for this process to take place without being favoured by the presence of something in the nature of a state of sleep. The necessary mental precondition of sleep is the concentration of the ego upon the wish to sleep and the withdrawal of psychical energy from all the interests of life. Since at the same time all the paths of approach to motility are blocked, the ego is also able to reduce the expenditure by which at other times it maintains the repressions. The unconscious impulse makes use of this nocturnal relaxation of repression in order to push its way into consciousness with the dream. But the repressive resistance of the ego is not abolished in sleep but merely reduced. Some of it remains in the shape of a censorship of dreams and forbids the unconscious impulse to express itself in the forms which it would properly assume. In consequence of the severity of the censorship of dreams, the latent dream-thoughts are obliged to submit to being altered and softened so as to make the forbidden meaning of the dream unrecognizable. This is the explanation of dream-distortion, which accounts for the most striking characteristics of the manifest dream. We are therefore justified in asserting that a dream is the (disguised) fulfilment of a (repressed) wish. It will now be seen that dreams are constructed like a neurotic symptom: they are compromises between the demands of a repressed impulse and the resistance of a censoring force in the ego. Since they have a similar origin they are equally unintelligible and stand in equal need of interpretation.

We have explained that the unconscious instinctual impulse of the dream connects itself with a residue of the day, with some interest of waking life which has not been disposed of; it thus gives the dream which it constructs a double value for the work of analysis. For on the one hand a dream that has been analysed reveals itself as the fulfilment of a repressed wish; but on the other hand it may be a continuation of some preconscious activity of the day before and may contain every kind of subject-matter and give expression to an intention, a warning, a reflection, or once more to the fulfilment of a wish. Analysis exploits the dream in both directions, as a means of obtaining knowledge alike of the patient's conscious and of his unconscious processes. It also profits from the fact that dreams have access to the forgotten material of childhood, and so it happens that infantile amnesia is for the most part overcome in connection with the interpretation of dreams. In this respect dreams achieve a part of what was previously the task of hypnotism. On the other hand, I have never maintained the assertion which has so often been ascribed to me that dream-interpretation shows that all dreams have a sexual content or are derived from sexual motive forces. It is easy to see that hunger, thirst, or the need to excrete, can produce dreams of satisfaction just as well as any repressed sexual or egoistic impulse. The case of young children affords us a convenient test of the validity of our theory of dreams. In them the various psychical systems are not yet sharply divided and the repressions have not yet grown deep, so that we often come upon dreams which are nothing more than undisguised fulfilments of wishful impulses left over from waking life. Under the influence of imperative needs, adults may also produce dreams of this infantile type.¹

---

¹ [1925d, 4219]

[1925d, 4221]
That is a curious technique, is it not? - not the usual way of dealing with a communication or utterance. And no doubt you guess that behind this procedure there are assumptions which have not yet been expressly stated. But let us proceed. In what order are we to get the patient to take up the portions of his dream? There are various possibilities open to us. We can simply follow the chronological order in which they appeared in the account of the dream. That is what may be called the strictest, classical method. Or we can direct the dreamer to begin by looking out for the 'day's residues' in the dream; for experience has taught us that almost every dream includes the remains of a memory or an allusion to some event (or often to several events) of the day before the dream, and, if we follow these connections, we often arrive with one blow at the transition from the apparently far remote dream-world to the real life of the patient. Or, again, we may tell him to start with those elements of the dream's content which strike him by their special clarity and sensory strength; for we know that he will find it particularly easy to get associations to these. It makes no difference by which of these methods we approach the associations we are in search of.

[1933a, 4625]

And next, we obtain these associations. What they bring us is of the most various kinds: memories from the day before, the 'dream-day', and from times long past, reflections, discussions, with arguments for and against, confessions and enquiries. Some of them the patient pours out; when he comes to others he is held up for a time. Most of them show a clear connection to some element of the dream; no wonder, since those elements were their starting-point. But it also sometimes happens that the patient introduces them with these words: 'This seems to me to have nothing at all to do with the dream, but I tell it you because it occurs to me.'

[1933a, 4625]

After these influences have been brought to bear upon the dream-thoughts the dream is almost complete. A further, somewhat variable, factor also comes into play - known as 'secondary revision' - after the dream has been presented before consciousness as an object of perception. At that point we treat it as we are in general accustomed to treat the contents of our perception: we fill in gaps and introduce connections, and in doing so are often guilty of gross misunderstandings. But this activity, which might be described as a rationalizing one and which at best provides the dream with a smooth façade that cannot fit its true content, may also be omitted or only be expressed to a very modest degree - in which case the dream will display all its rents and cracks openly. It must not be forgotten, on the other hand, that the dream-work does not always operate with equal energy either; it often restricts itself to certain portions of the dream-thoughts only and others of them are allowed to appear in the dream unaltered. In such cases an impression is given of the dream having carried out the most delicate and complex intellectual operations, of its having speculated, made jokes, arrived at decisions and solved problems, whereas all this is a product of our normal mental activity, may have been performed equally well during the day before the dream as during the night, has nothing to do with the dream-work and brings nothing to light that is characteristic of dreams. Nor is it superfluous to insist once more on the contrast within the dream-thoughts themselves between the unconscious instinctual impulse and the day's residues. While the latter exhibit all the multiplicity of our mental acts, the former, which becomes the motive force proper of the forming of the dream, finds its outlet invariably in the fulfilment of a wish.

[1933a, 4634]
Actually I have little to tell you - only a modest fact. I will also at once reduce your expectations still further by saying that at bottom dreams have little to do with telepathy. Telepathy does not throw any fresh light on the nature of dreams nor do dreams give any direct evidence of the reality of telepathy. Moreover the phenomenon of telepathy is by no means bound up with dreams; it can occur as well during the waking state. The only reason for discussing the relation between dreams and telepathy is that the state of sleep seems particularly suited for receiving telepathic messages. In such cases one has what is called a telepathic dream and, when it is analysed, one forms a conviction that the telepathic news has played the same part as any other portion of the day's residues and that it has been changed in the same way by the dream-work and made to serve its purpose.

[1933a, 4649]

It is best to begin by pointing out that the formation of a dream can be provoked in two different ways. Either, on the one hand, an instinctual impulse which is ordinarily suppressed (an unconscious wish) finds enough strength during sleep to make itself felt by the ego, or, on the other hand, an urge left over from waking life, a preconscious train of thought with all the conflicting impulses attached to it, finds reinforcement during sleep from an unconscious element. In short, dreams may arise either from the id or from the ego. The mechanism of dream-formation is in both cases the same and so also is the necessary dynamic precondition. The ego gives evidence of its original derivation from the id by occasionally ceasing its functions and allowing a reversion to an earlier state of things. This is logically brought about by its breaking off its relations with the external world and withdrawing its cathexes from the sense organs. We are justified in saying that there arises at birth an instinct to return to the intra-uterine life that has been abandoned - an instinct to sleep. Sleep is a return of this kind to the womb. Since the waking ego governs motility, that function is paralysed in sleep, and accordingly a good part of the inhibitions imposed on the unconscious id become superfluous. The withdrawal or reduction of these 'anticathexes' thus allows the id what is now a harmless amount of liberty.

[1940a [1938], 4976]
In the first chapter I have given a detailed account of the views of the authorities on the relation of dreams with waking life and on the origin of the material of dreams. No doubt, too, my readers will recall the three characteristics of memory in dreams, which have been so often remarked on but which have never been explained:

[1900a, 655]

Of the three characteristics of memory in dreams enumerated at the beginning of this chapter, one - the preference for non-essential material in the content of dreams - has been satisfactorily cleared up by being traced back to dream-distortion. We have been able to confirm the existence of the other two - the emphasis upon recent and upon infantile material - but we have not been able to account for them on the basis of the motives that lead to dreaming. These two characteristics inclusion of both recent and infantile material, whose explanation and appreciation remain to be discovered, must be kept in mind. Their proper place must be looked for elsewhere - either in the psychology of the state of sleep or in the discussion of the structure of the mental apparatus upon which we shall later embark, after we have learnt that the interpretation of dreams is like a window through which we can get a glimpse of the interior of that apparatus.

[1900a, 699]

If we now bear in mind how great a part is played in the dream-thoughts by infantile experiences or by phantasies based upon them, how frequently portions of them re-emerge in the dream-content and how often the dream-wishes themselves are derived from them, we cannot dismiss the probability that in dreams too the transformation of thoughts into visual images may be in part the result of the attraction which memories couched in visual form and eager for revival bring to bear upon thoughts cut off from consciousness and struggling to find expression. On this view a dream might be described as a substitute for an infantile scene modified by being transferred on to a recent experience. The infantile scene is unable to bring about its own revival and has to be content with returning as a dream.

[1900a, 979]
This indication of the way in which infantile scenes (or their reproductions as phantasies) function in a sense as models for the content of dreams, removes the necessity for one of the hypotheses put forward by Scherner and his followers in regard to internal sources of stimulation. Scherner supposes that, when dreams exhibit particularly vivid or particularly copious visual elements, there is present a state of 'visual stimulation', that is, of internal excitation in the organ of vision. We need not dispute this hypothesis, but can content ourselves with assuming that this state of excitation applies merely to the psychical perceptual system of the visual organ; we may, however, further point out that the state of excitation has been set up by a memory, that it is a revival of a visual excitation which was originally an immediate one. I cannot produce any good example from my own experience of an infantile memory producing this kind of result. My dreams are in general less rich in sensory elements than I am led to suppose is the case in other people. But in the case of my most vivid and beautiful dream of the last few years, I was easily able to trace back the hallucinatory clarity of the dream's content to the sensory qualities of recent or fairly recent impressions. On p. 907 ff. I recorded a dream in which the deep blue colour of the water, the brown of the smoke coming from the ship's funnels, and the dark brown and red of the buildings left behind a profound impression on me. This dream, if any, should be traceable, to a visual stimulus. What was it that had brought my visual organ into this state of stimulation? A recent impression, which attached itself to a number of earlier ones. The colours which I saw were in the first instance those of a box of toy bricks with which, on the day before the dream, my children had put up a fine building and shown it off for my admiration. The big bricks were of the same dark red and the small ones were of the same blue and brown. This was associated with colour impressions from my last travels in Italy: the beautiful blue of the Isonzo and the lagoons and the brown of the Carso. The beauty of the colours in the dream was only a repetition of something seen in my memory. [1900a, 979]
The situation is this. Either residues of the previous day have been left over from the activity of waking life and it has not been possible to withdraw the whole cathexis of energy from them; or the activity of waking life during the course of the day has led to the stirring up of an unconscious wish; or these two events have happened to coincide. (We have already discussed the various possibilities in this connection.) The unconscious wish links itself up with the day’s residues and effects a transference on to them; this may happen either in the course of the day or not until a state of sleep has been established. A wish now arises which has been transferred on to the recent material; or a recent wish, having been suppressed, gains fresh life by being reinforced from the unconscious. This wish seeks to force its way along the normal path taken by thought processes, though the *Pcs.* (to which, indeed, it in part belongs) to consciousness. But it comes up against the censorship, which is still functioning and to the influence of which it now submits. At this point it takes on the distortion for which the way has already been paved by the transference of the wish on to recent material. So far it is on the way to becoming an obsessive idea or a delusion or something of the kind - that is, a *thought* which has been intensified by transference and distorted in its expression by censorship. Its further advance is halted, however, by the sleeping state of the preconscious. (The probability is that that system has protected itself against the invasion by diminishing its own excitations.) The dream-process consequently enters on a regressive path, which lies open to it precisely owing to the peculiar nature of the state of sleep, and it is led along that path by the attraction exercised on it by groups of memories; some of these memories themselves exist only in the form of visual cathexes and not as translations into the terminology of the later systems. In the course of its regressive path the dream-process acquires the attribute of representability. (I shall deal later with the question of compression.) It has now completed the second portion of its zigzag journey. The first portion was a progressive one, leading from the unconscious scenes or phantasies to the preconscious; the second portion led from the frontier of the censorship back again to perceptions. But when the content of the dream process has become perceptual, by that fact it has, as it were, found a way of evading the obstacle put in its way by the censorship and the state of sleep in the *Pcs.* It succeeds in drawing attention to itself and in being noticed by consciousness.

It has naturally not occurred to us to throw any doubt on the significance, which has been experimentally demonstrated, of external sensory stimuli during sleep; but we have shown that such material stands in the same relation to the dream-wish as do the residues of thought left over from day time activity. Nor have we seen any reason to dispute the view that dreams interpret objective sensory stimuli just as illusions do; but we have found the motive which provides the reason for that interpretation, a reason which has been left unspecified by other writers. Interpretation is carried out in such a way that the object perceived shall not interrupt sleep and shall be usable for purposes of wish-fulfilment. As regards subjective states of excitation in the sense organs during sleep, the occurrence of which seems to have been proved by Trumbull Ladd, it is true that we have not accepted them as a particular source of dreams; but we have been able to explain them as resulting from the regressive revival of memories that are in operation behind the dream.
An objection, however, may be raised which threatens to upset these last conclusions. If indifferent impressions can only find their way into a dream provided they are recent, how does it happen that the content of dreams also includes elements from an earlier period of life which at the time when they were recent possessed, to use Strümpell's words, no psychical value, and should therefore have been long since forgotten - elements, that is to say, which are neither fresh nor psychically significant?

But another achievement of the dream-work, tending as it does to produce incoherent dreams, is even more striking. If in any particular instance we compare the number of ideational elements or the space taken up in writing them down in the case of the dream and of the dream-thoughts to which the analysis leads us and of which traces are to be found in the dream itself, we shall be left in no doubt that the dream-work has carried out a work of compression or condensation on a large scale. It is impossible at first to form any judgement of the degree of this condensation; but the deeper we plunge into a dream-analysis the more impressive it seems. From every element in a dream's content associative threads branch out in two or more directions; every situation in a dream seems to be put together out of two or more impressions or experiences. For instance, I once had a dream of a sort of swimming-pool, in which the bathers were scattering in all directions; at one point on the edge of the pool someone was standing and bending towards one of the people bathing, as though to help her out of the water. The situation was put together from a memory of an experience I had had at puberty and from two paintings, one of which I had seen shortly before the dream. One was a picture from Schwind's series illustrating the legend of Mélusine, which showed the water-nymphs surprised in their pool (cf. the scattering bathers in the dream); the other was a picture of the Deluge by an Italian Master; while the little experience remembered from my puberty was of having seen the instructor at a swimming-school helping a lady out of the water who had stopped in until after the time set aside for men bathers. -In the case of the example which I chose for interpretation, an analysis of the situation led me to a small series of recollections each of which contributed something to the content of the dream. In the first place, there was the episode from the time of my engagement of which I have already spoken. The pressure upon my hand under the table, which was a part of that episode, provided the dream with the detail 'under the table' - a detail which I had to add as an afterthought to my memory of the dream. In the episode itself there was of course no question of 'turning to me'; the analysis showed that this element was the fulfilment of a wish by presenting the opposite of an actual event, and that it related to my wife's behaviour at the table d'hôte. But behind this recent recollection there lay concealed an exactly similar and far more important scene from the time of our engagement, which estranged us for a whole day. The intimate laying of a hand on my knee belonged to a quite different context and was concerned with quite other people. This element in the dream was in turn the starting-point of two separate sets of memories - and so on.

The psychical material of the dream-thoughts habitually includes recollections of impressive experiences - not infrequently dating back to early childhood - which are thus themselves perceived as a rule as situations having a visual subject matter. Wherever the possibility arises, this portion of the dream-thoughts exercises a determining influence upon the form taken by the content of the dream; it constitutes, as it were, a nucleus of crystallization, attracting the material of the dream-thoughts to itself and thus affecting their distribution. The situation in a dream is often nothing other than a modified repetition, complicated by interpolations, of an impressive experience of this kind; on the other hand, faithful and straightforward reproductions of real scenes only rarely appear in dreams.
The second speech - 'I don't recognize that' - occurred in an entirely different connection. On the previous day she had reproved her cook, who incidentally also appeared in the dream, with the words: 'Behave yourself properly! I don't recognize that!' meaning, no doubt, that she did not understand such behaviour and would not put up with it. As the result of a displacement, it was the more innocent part of this speech which made its way into the content of the dream; but in the dream-thoughts it was only the other part of the speech that played a part. For the dream-work had reduced to complete unintelligibility and extreme innocence an imaginary situation in which *I* was behaving improperly to the lady in a particular way. But this situation which the patient was expecting in her imagination was itself only a new edition of something she had once actually experienced.

[1901a, 1082]

But after all, what we really intended to do originally was only to investigate two or three dreams that are to be found here and there in *Gradiva* with the help of certain analytic methods. How has it come about, then, that we have been led into dissecting the whole story and examining the mental processes in the two chief characters? This has not in fact been an unnecessary piece of work; it was an essential preliminary. It is equally the case that when we try to understand the real dreams of a real person we have to concern ourselves intensively with his character and his career, and we must get to know not only his experiences shortly before the dream but also those dating far back into the past. It is even my view that we are still not free to turn to our proper task, but that we must linger a little more over the story itself and carry out some further preliminary work.

[1907a, 1842]

You are correct on all your minor points. A dream differs from a slip of the tongue, among other things, in the multiplicity of its elements. Our technique must take this into account. I therefore suggest to you that we should divide the dream into its elements and start a separate enquiry into each element; if we do this, the analogy with a slip of the tongue is re-established. You are also right in thinking that when the dreamer is questioned about the separate elements of the dream he may reply that nothing occurs to him. There are some instances in which we let this reply pass, and you will later hear which these are; strangely enough, they are instances in which definite ideas may occur to us ourselves. But in general if the dreamer asserts that nothing occurs to him we contradict him; we bring urgent pressure to bear on him, we insist that something must occur to him - and we turn out to be right. He will produce an idea - some idea, it is a matter of indifference to us which. He will give us certain pieces of information, which may be described as 'historical', with particular ease. He may say: 'That's something that happened yesterday' (as was the case in our two 'matter-of-fact' dreams), or: 'That reminds me of something that happened a short time ago' - and we shall discover in this way that dreams are connected with impressions of the last day or two much more often than we thought to begin with. And finally he will also recall, starting from the dream, events from further back and even perhaps from the far distant past.

[1916-1917, 3203]

I am not of opinion, however, that such scenes must necessarily be phantasies because they do not reappear in the shape of recollections. It seems to me absolutely equivalent to a recollection, if the memories are replaced (as in the present case) by dreams the analysis of which invariably leads back to the same scene and which reproduce every portion of its content in an inexhaustible variety of new shapes. Indeed, dreaming is another kind of remembering, though one that is subject to the conditions that rule at night and to the laws of dream-formation. It is this recurrence in dreams that I regard as the explanation of the fact that the patients themselves gradually acquire a profound conviction of the reality of these primal scenes, a conviction which is in no respect inferior to one based on recollection.¹

[1918b, 3538]
A passage in the first edition of my Interpretation of Dreams (1900a) will show at what an early stage I was occupied with this problem. On p. 670 of that work there is an analysis of a remark occurring in a dream: 'That's not obtainable any longer.' It is explained that the phrase originated from myself. 'A few days earlier I had explained to the patient that the earliest experiences of childhood were "not obtainable any longer as such" but were replaced in analysis by "transferences" and dreams.'

[1918b, 3538]

And next, we obtain these associations. What they bring us is of the most various kinds: memories from the day before, the 'dream-day', and from times long past, reflections, discussions, with arguments for and against, confessions and enquiries. Some of them the patient pours out; when he comes to others he is held up for a time. Most of them show a clear connection to some element of the dream; no wonder, since those elements were their starting-point. But it also sometimes happens that the patient introduces them with these words: 'This seems to me to have nothing at all to do with the dream, but I tell it you because it occurs to me.'

[1933a, 4625]

The evidence of the share taken by the unconscious id in the formation of dreams is abundant and convincing. (a) Memory is far more comprehensive in dreams than in waking life. Dreams bring up recollections which the dreamer has forgotten, which are inaccessible to him when he is awake. (b) Dreams make an unrestricted use of linguistic symbols, the meaning of which is for the most part unknown to the dreamer. Our experience, however, enables us to confirm their sense. They probably originate from earlier phases in the development of speech. (c) Memory very often reproduces in dreams impressions from the dreamer's early childhood of which we can definitely assert not only that they had been forgotten but that they had become unconscious owing to repression. That explains the help - usually indispensable - given us by dreams in the attempts we make during the analytic treatment of neuroses to reconstruct the dreamer's early life. (d) Furthermore, dreams bring to light material which cannot have originated either from the dreamer's adult life or from his forgotten childhood. We are obliged to regard it as part of the archaic heritage which a child brings with him into the world, before any experience of his own, influenced by the experiences of his ancestors. We find the counterpart of this phylogenetic material in the earliest human legends and in surviving customs. Thus dreams constitute a source of human prehistory which is not to be despised.

[1940a [1938], 4976]
All the material making up the content of a dream is in some way derived from experience, that is to say, has been reproduced or remembered in the dream - so much at least we may regard as an undisputed fact. But it would be a mistake to suppose that a connection of this kind between the content of a dream and reality is bound to come to light easily, as an immediate result of comparing them. The connection requires, on the contrary, to be looked for diligently, and in a whole quantity of cases it may long remain hidden. The reason for this lies in a number of peculiarities which are exhibited by the faculty of memory in dreams and which, though generally remarked upon, have hitherto resisted explanation. It will be worth while to examine these characteristics more closely.

It may happen that a piece of material occurs in the content of a dream which in the waking state we do not recognize as forming a part of our knowledge or experience. We remember, of course, having dreamt the thing in question, but we cannot remember whether or when we experienced it in real life. We are thus left in doubt as to the source which has been drawn upon by the dream and are tempted to believe that dreams have a power of independent production. Then at last, often after a long interval, some fresh experience recalls the lost memory of the other event and at the same time reveals the source of the dream. We are thus driven to admit that in the dream we knew and remembered something which was beyond the reach of our waking memory.

The fact that dreams have at their command memories which are inaccessible in waking life is so remarkable and of such theoretical importance that I should like to draw still more attention to it by relating some further 'hypermnesic' dreams. Maury tells us how for some time the word 'Mussidan' kept coming into his head during the day. He knew nothing about it except that it was the name of a town in France. One night he dreamt that he was talking to someone who told him he came from Mussidan, and who, on being asked where that was, replied that it was a small town in the Department of Dordogne. When he woke up, Maury had no belief in the information given him in the dream; he learnt from a gazetteer, however, that it was perfectly correct. In this case the fact of the dream's superior knowledge was confirmed, but the forgotten source of that knowledge was not discovered.

No one who occupies himself with dreams can, I believe, fail to discover that it is a very common event for a dream to give evidence of knowledge and memories which the waking subject is unaware of possessing. In my psycho-analytic work with nervous patients, of which I shall speak later, I am in a position several times a week to prove to patients from their dreams that they are really quite familiar with quotations, obscene words and so on, and make use of them in their dreams, though they have forgotten them in their waking life. I will add one more innocent case of hypermnesia in a dream, because of the great ease with which it was possible to trace the source of the knowledge that was accessible only in the dream.
Strümpell (1877, 40): 'The position is even more remarkable when we observe how dreams sometimes bring to light, as it were, from beneath the deepest piles of débris under which the earliest experiences of youth are buried in later times, pictures of particular localities, things or people, completely intact and with all their original freshness. This is not limited to experiences which created a lively impression when they occurred or enjoy a high degree of psychical importance and return later in a dream as genuine recollections at which waking consciousness will rejoice. On the contrary, the depths of memory in dreams also include pictures of people, things, localities and events dating from the earliest times, which either never possessed any psychical importance or more than a slight degree of vividness, or which have long since lost what they may have possessed of either, and which consequently seem completely alien and unknown alike to the dreaming and waking mind till their earlier origin has been discovered.' [1900a, 529]

Volkelt (1875, 119): 'It is especially remarkable how readily memories of childhood and youth make their way into dreams. Dreams are continually reminding us of things which we have ceased to think of and which have long ceased to be important to us.' [1900a, 530]

Since dreams have material from childhood at their command, and since, as we all know, that material is for the most part blotted out by gaps in our conscious faculty of memory, these circumstances give rise to interesting hypermnestic dreams, of which I will once more give a few examples. [1900a, 530]

Maury (ibid., 143-4) gives another equally well corroborated example of the accuracy of a memory of childhood emerging in a dream. It was dreamt by a Monsieur F., who as a child had lived at Montbrison. Twenty-five years after leaving it, he decided to revisit his home and some friends of the family whom he had not since met. During the night before his departure he dreamt that he was already at Montbrison and, near the town, met a gentleman whom he did not know by sight but who told him he was Monsieur T., a friend of his father's. The dreamer was aware that when he was a child he had known someone of that name, but in his waking state no longer remembered what he looked like. A few days later he actually reached Montbrison, found the locality which in his dream had seemed unknown to him, and there met a gentleman whom he at once recognized as the Monsieur T. in the dream. The real person, however, looked much older than he had appeared in the dream. [1900a, 530]

Binz (1878, 44-5) actually makes this particular peculiarity of memory in dreams the occasion for expressing his dissatisfaction with the explanations of dreams which he himself has supported: 'And the natural dream raises similar problems. Why do we not always dream of the mnemonic impressions of the day we have just lived through? Why do we often, without any apparent motive, plunge instead into the remote and almost extinct past? Why does consciousness so often in dreams receive the impression of indifferent mnemonic images, while the brain cells, just where they carry the most sensitive marks of what has been experienced, lie for the most part silent and still, unless they have been stirred into fresh activity shortly before, during waking life?' [1900a, 533]
The way in which the memory behaves in dreams is undoubtedly of the greatest importance for any theory of memory in general. It teaches us that 'nothing which we have once mentally possessed can be entirely lost' (Scholz, 1893, 59); or, as Delboeuf puts it, 'que toute impression même la plus insignifiante, laisse une trace inaltérable, indéfiniment susceptible de reparâitre au jour.' This is a conclusion to which we are also driven by many pathological phenomena of mental life. Certain theories about dreams which we shall mention later seek to account for their absurdity and incoherence by a partial forgetting of what we know during the day. When we bear in mind the extraordinary efficiency that we have just seen exhibited by memory in dreams we shall have a lively sense of the contradiction which these theories involve.

Our scientific consideration of dreams starts off from the assumption that they are products of our own mental activity. Nevertheless the finished dream strikes us as something alien to us. We are so little obliged to acknowledge our responsibility for it that we are just as ready to say 'mir hat geträumt' ['I had a dream', literally 'a dream came to me'] as 'ich habe geträumt' ['I dreamt']. What is the origin of this feeling that dreams are extraneous to our minds? In view of our discussion upon the sources of dreams, we must conclude that the strangeness cannot be due to the material that finds its way into their content, since that material is for the most part common to dreaming and waking life. The question arises whether in dreams there may not be modifications in the processes of the mind which produce the impression we are discussing; and we shall therefore make an attempt at drawing a picture of the psychological attributes of dreams.

Nevertheless, the writers who in general take so unfavourable a view of psychical functioning in dreams allow that a certain remnant of mental activity still remains in them. This is explicitly admitted by Wundt, whose theories have had a determining influence on so many other workers in this field. What, it may be asked, is the nature of the remnant of normal mental activity which persists in dreams? There is fairly general agreement that the reproductive faculty, the memory, seems to have suffered least, and indeed that it shows a certain superiority to the same function in waking life (see Section B above), though some part of the absurdities of dreaming seems to be explicable by its forgetfulness. In the opinion of Spitta (1882, 84 f.) the part of the mind which is not affected by sleep is the life of the sentiments and it is this which directs dreams. By 'sentiment' ['Gemüt'] he means 'the stable assemblage of feelings which constitutes the innermost subjective essence of a human being'.

Of the superior faculties which even a sober comparison may be inclined to attribute to dream-life, the most marked is that of memory; we have already discussed at length the not uncommon evidence in favour of this view. Another point of superiority in dream-life, often praised by earlier writers - that it rises superior to distance in time and space - may easily be shown to have no basis in fact. As Hildebrandt (1875) points out, this advantage is an illusory one; for dreaming rises superior to time and space in precisely the same way as does waking thought, and for the very reason that it is merely a form of thought. It has been claimed for dreams that they enjoy yet another advantage over waking life in relation to time - that they are independent of the passage of time in yet another respect. Dreams such as the one dreamt by Maury of his own guillotining (see above, p. 539 f.) seem to show that a dream is able to compress into a very short space of time an amount of perceptual matter far greater than the amount of ideational matter that can be dealt with by our waking mind. This conclusion has however been countered by various arguments; since the papers by Le Lorrain (1894) and Egger (1895) on the apparent duration of dreams, a long and interesting discussion on the subject has developed, but it seems unlikely that the last word has yet been said on this subtle question and the deep implications which it involves.
It will be seen that the emergence of impulses which are foreign to our moral consciousness is merely analogous to what we have already learnt - the fact that dreams have access to ideational material which is absent in our waking state or plays but a small part in it. Thus Benini (1898) writes: 'Certe nostre inclinazioni che si credevano soffocate e spente da un pezzo, si ridestano; passioni vecchie e sepolte rivivono; cose e persone a cui non pensiamo mai, ci vengono dinanzi.' And Volkelt (1875, 105): 'Ideas, too, which have entered waking consciousness almost unnoticed and have perhaps never again been called to memory, very frequently announce their presence in the mind through dreams.' At this point, finally, we may recall Schleiermacher's assertion that the act of falling asleep is accompanied by the appearance of 'involuntary ideas' or images.

Delage (1891, 41) tells us that he experienced in his own person, on the occasion of the death of someone of whom he was fond, the fact that we do not dream of what has occupied all our thoughts during the day, or not until it has begun to give place to other daytime concerns. His investigations among other people confirmed him in the general truth of this fact. He makes what would be an interesting observation of this kind, if it should prove to have general validity, on the dreams of young married couples: 'S'ils ont été fortement épris, presque jamais ils n'ont révé l'un de l'autre avant le mariage ou pendant la lune de miel; et s'ils ont rêvé d'amour c'est pour être infidèles avec quelque personne indifférente ou odieuse.' What, then, do we dream of? Delage identifies the material that occurs in our dreams as consisting of fragments and residues of the preceding days and of earlier times. Everything that appears in our dreams, even though we are inclined at first to regard it as a creation of our dream-life, turns out, when we have examined it more closely, to be unrecognized reproduction - 'souvenir inconscient'. But this ideational material possesses a common characteristic: it originates from impressions which probably affected our senses more strongly than our intelligence or from which our attention was diverted very soon after they emerged. The less conscious and at the same time the more powerful an impression has been, the more chance it has of playing a part in the next dream.

Radestock (1879, 219) adds a few more features - analogies between the material in the two cases: 'The majority of hallucinations and illusions occur in the region of the senses of sight and hearing and of coenaesthesia. As in the case of dreams, the senses of smell and taste provide the fewest elements. - Both in patients suffering from fever and in dreamers memories arise from the remote past; both sleeping and sick men recollect things which waking and healthy men seem to have forgotten.' The analogy between dreams and psychoses is only fully appreciated when it is seen to extend to the details of expressive movement and to particular characteristics of facial expression.
Trimethylamin. I saw the chemical formula of this substance in my dream, which bears witness to a great effort on the part of my memory. Moreover, the formula was printed in heavy type, as though there had been a desire to lay emphasis on some part of the context as being of quite special importance. What was it, then, to which my attention was to be directed in this way by trimethylamin? It was to a conversation with another friend who had for many years been familiar with all my writings during the period of their gestation, just as I had been with his. He had at that time confided some ideas to me on the subject of the chemistry of the sexual processes, and had mentioned among other things that he believed that one of the products of sexual metabolism was trimethylamin. Thus this substance led me to sexuality, the factor to which I attributed the greatest importance in the origin of the nervous disorders which it was my aim to cure. My patient Irma was a young widow; if I wanted to find an excuse for the failure of my treatment in her case, what I could best appeal to would no doubt be this fact of her widowhood, which her friends would be so glad to see changed. And how strangely, I thought to myself, a dream like this is put together! The other woman, whom I had as a patient in the dream instead of Irma, was also a young widow.

[1900a, 616]

(3) They have at their disposal the earliest impressions of our childhood and even bring up details from that period of our life which, once again, strike us as trivial and which in our waking state we believe to have been long since forgotten.¹

[1900a, 655]

The fact that dreams are hypermnesic and have access to material from childhood has become one of the corner-stones of our teaching. Our theory of dreams regards wishes originating in infancy as the indispensable motive force for the formation of dreams.

[1900a, 1016]

If anyone should feel inclined to over-estimate the state of our present knowledge of mental life, a reminder of the function of memory is all that would be needed to force him to be more modest. No psychological theory has yet succeeded in giving a connected account of the fundamental phenomenon of remembering and forgetting; in fact, the complete analysis of what can actually be observed has so far scarcely been begun. To-day forgetting has perhaps become more of a puzzle than remembering, ever since we have learnt from the study of dreams and pathological phenomena that even something we thought had been forgotten long ago may suddenly re-emerge in consciousness.

[1901b, 1218]
Another and far more surprising discovery has been that, in spite of all the later development that occurs in the adult, none of the infantile mental formations perish. All the wishes, instinctual impulses, modes of reaction and attitudes of childhood are still demonstrably present in maturity and in appropriate circumstances can emerge once more. They are not destroyed but merely overlaid - to use the spatial mode of description which psycho-analytic psychology has been obliged to adopt. Thus it is part of the nature of the mental past that, unlike the historic past, it is not absorbed by its derivatives; it persists (whether actually or only potentially) alongside what has proceeded from it. The proof of this assertion lies in the fact that the dreams of normal people revive their childhood characters every night and reduce their whole mental life to an infantile level. This same return to psychical infantilism ('regression') appears in the neuroses and psychoses, whose peculiarities may to a great extent be described as psychical archaisms. The strength in which the residues of infancy are still present in the mind shows us the amount of disposition to illness; that disposition may accordingly be regarded as an expression of an inhibition in development. The part of a person's psychical material which has remained infantile and has been repressed as being unserviceable constitutes the core of his unconscious. And we believe we can follow in our patients' life-histories the way in which this unconscious, held back as it is by the forces of repression, lies in wait for a chance to become active and makes use of its opportunities if the later and higher psychical structures fail to master the difficulties of real life.

[1913j, 2820]

In psycho-analytic treatments we are invariably faced by the task of filling up these gaps in the memory of childhood; and in so far as the treatment is to any extent successful - that is to say, extremely frequently - we also succeed in bringing to light the content of these forgotten years of childhood. Those impressions had never been really forgotten, they were only inaccessible, latent, and had formed part of the unconscious. But it can come about that they emerge from the unconscious spontaneously, and this happens in connection with dreams. It appears that dream-life knows how to find access to these latent, infantile experiences. Excellent examples of this have been reported in the literature and I myself have been able to provide a contribution of the kind. I once dreamt in a certain connection of a person who must have done me a service and whom I saw clearly before me. He was a one-eyed man of small stature, stout, and with his head sunk deep in his shoulders. I concluded from the context that he was a doctor. Luckily I was able to enquire from my mother, who was still alive, what the doctor at my birth-place (which I had left when I was three) had looked like; and I learnt from her that he was one-eyed, short, stout and with his head sunk deep in his shoulders; and I also learnt what the accident was for which he had come to my help and which I myself had forgotten. This fact of dreams having at their disposal the forgotten material of the first years of childhood is thus a further archaic feature.

[1916-1917, 3290]

Let us now bring together what our researches into child psychology have contributed to our understanding of dreams. We have not only found that the material of the forgotten experiences of childhood is accessible to dreams, but we have also seen that the mental life of children with all its characteristics, its egoism, its incestuous choice of love-objects, and so on, still persists in dreams - that is, in the unconscious, and that dreams carry us back every night to this infantile level. The fact is thus confirmed that what is unconscious in mental life is also what is infantile. The strange impression of there being so much evil in people begins to diminish. This frightful evil is simply the initial, primitive, infantile part of mental life, which we can find in actual operation in children, but which, in part, we overlook in them on account of their small size, and which in part we do not take seriously since we do not expect any high ethical standard from children. Since dreams regress to this level, they give the appearance of having brought to light the evil in us. But this is a deceptive appearance, by which we have allowed ourselves to be scared. We are not so evil as we were inclined to suppose from the interpretation of dreams.

[1916-1917, 3298]
Children are alone in not falling in with these conventions. They assert their animal rights with complete naïveté and give constant evidence that they have still to travel the road to purity. Strangely enough, the people who deny the existence of sexuality in children do not on that account become milder in their educational efforts but pursue the manifestations of what they deny exists with the utmost severity - describing them as 'childish naughtinesses'. It is also of the highest theoretical interest that the period of life which contradicts the prejudice of an asexual childhood most glaringly - the years of a child's life up to the age of five or six - is afterwards covered in most people by the veil of amnesia which is only completely torn away by an analytic enquiry, though it has been permeable earlier for the construction of a few dreams. [1916-1917, 3383]

But there is something else that I cannot pass by. The reminder of dreams given to us by the mother and wife of Oedipus must not be allowed to remain fruitless. Do you recall the outcome of our dream-analyses - how the wishes that construct dreams are so often of a perverse or incestuous nature or reveal an unsuspected hostility to those who are nearest and dearest to the dreamer? At that time we gave no explanation of the origin of these evil impulses. Now you can find it for yourselves. They are allocations of the libido and object-cathexes which date from early infancy and have long since been abandoned as far as conscious life is concerned, but which prove still to be present at night-time and to be capable of functioning in a certain sense. Since, however, everyone, and not only neurotics, experiences these perverse, incestuous and murderous dreams, we may conclude that people who are normal to-day have passed along a path of development that has led through the perversions and object-cathexes of the Oedipus complex, that that is the path of normal development and that neurotics merely exhibit to us in a magnified and coarsened form what the analysis of dreams reveals to us in healthy people as well. And this is one of the reasons why I dealt with the study of dreams before that of neurotic symptoms. [1916-1917, 3402]

I am not of opinion, however, that such scenes must necessarily be phantasies because they do not reappear in the shape of recollections. It seems to me absolutely equivalent to a recollection, if the memories are replaced (as in the present case) by dreams the analysis of which invariably leads back to the same scene and which reproduce every portion of its content in an inexhaustible variety of new shapes. Indeed, dreaming is another kind of remembering, though one that is subject to the conditions that rule at night and to the laws of dream-formation. It is this recurrence in dreams that I regard as the explanation of the fact that the patients themselves gradually acquire a profound conviction of the reality of these primal scenes, a conviction which is in no respect inferior to one based on recollection.¹ [1918b, 3538]

¹ A passage in the first edition of my Interpretation of Dreams (1900a) will show at what an early stage I was occupied with this problem. On p. 670 of that work there is an analysis of a remark occurring in a dream: 'That's not obtainable any longer.' It is explained that the phrase originated from myself. 'A few days earlier I had explained to the patient that the earliest experiences of childhood were "not obtainable any longer as such" but were replaced in analysis by "transferences" and dreams.' [1918b, 3538]
We have explained that the unconscious instinctual impulse of the dream connects itself with a residue of the day, with some interest of waking life which has not been disposed of; it thus gives the dream which it constructs a double value for the work of analysis. For on the one hand a dream that has been analysed reveals itself as the fulfilment of a repressed wish; but on the other hand it may be a continuation of some preconscious activity of the day before and may contain every kind of subject-matter and give expression to an intention, a warning, a reflection, or once more to the fulfilment of a wish. Analysis exploits the dream in both directions, as a means of obtaining knowledge alike of the patient's conscious and of his unconscious processes. It also profits from the fact that dreams have access to the forgotten material of childhood, and so it happens that infantile amnesia is for the most part overcome in connection with the interpretation of dreams. In this respect dreams achieve a part of what was previously the task of hypnotism. On the other hand, I have never maintained the assertion which has so often been ascribed to me that dream-interpretation shows that all dreams have a sexual content or are derived from sexual motive forces. It is easy to see that hunger, thirst, or the need to excrete, can produce dreams of satisfaction just as well as any repressed sexual or egoistic impulse. The case of young children affords us a convenient test of the validity of our theory of dreams. In them the various psychical systems are not yet sharply divided and the repressions have not yet grown deep, so that we often come upon dreams which are nothing more than undisguised fulfilments of wishful impulses left over from waking life. Under the influence of imperative needs, adults may also produce dreams of this infantile type.¹

[1925d, 4221]

We meet with the second of these facts almost every day in the course of our analytic work; and it does not imply such an important objection as the other does. One of the tasks of psychoanalysis, as you know, is to lift the veil of amnesia which hides the earliest years of childhood and to bring to conscious memory the manifestations of early infantile sexual life which are contained in them. Now these first sexual experiences of a child are linked to painful impressions of anxiety, prohibition, disappointment and punishment. We can understand their having been repressed; but, that being so, we cannot understand how it is that they have such free access to dream-life, that they provide the pattern for so many dream-phantasies and that dreams are filled with reproductions of these scenes from childhood and with allusions to them. It must be admitted that their unpleasurable character and the dream-work's wish-fulfilling purpose seem far from mutually compatible. But it may be that in this case we are magnifying the difficulty. After all, these same infantile experiences have attached to them all the imperishable, unfulfilled instinctual wishes which throughout life provide the energy for the construction of dreams, and to which we may no doubt credit the possibility, in their mighty uprush, of forcing to the surface, along with the rest, the material of distressing events. And on the other hand the manner and form in which this material is reproduced shows unmistakably the efforts of the dream-work directed to denying the unpleasure by means of distortion and to transforming disappointment into attainment.

[1933a, 4641]
But the moralist will console himself for a long time to come with the improbability of our speculations. A queer instinct indeed, directed to the destruction of its own organic home! Poets, it is true, talk of such things; but poets are irresponsible people and enjoy the privilege of poetic licence. Incidentally, such ideas are not foreign even to physiology: consider the notion, for instance, of the mucous membrane of the stomach digesting itself. It must be admitted, however, that our self-destructive instinct calls for support on a wider basis. One cannot, after all, venture on a hypothesis of such a wide range merely because a few poor fools have linked their sexual satisfaction to a peculiar condition. A more profound study of the instincts will, I believe, give us what we need. The instincts rule not only mental but also vegetative life, and these organic instincts exhibit a characteristic which deserves our deepest interest. (We shall not be able to judge until later whether it is a general characteristic of instincts.) For they reveal an effort to restore an earlier state of things. We may suppose that from the moment at which a state of things that has once been attained is upset, an instinct arises to create it afresh and brings about phenomena which we can describe as a 'compulsion to repeat'. Thus the whole of embryology is an example of the compulsion to repeat. A power of regenerating lost organs extends far up into the animal kingdom, and the instinct for recovery to which, alongside of therapeutic assistance, our cures are due must be the residue of this capacity which is so enormously developed in the lower animals. The spawning migrations of fishes, the migratory flights of birds, and possibly all that we describe as manifestations of instinct in animals, take place under the orders of the compulsion to repeat, which expresses the conservative nature of the instincts. Nor have we far to look in the mental field for its manifestations. We have been struck by the fact that the forgotten and repressed experiences of childhood are reproduced during the work of analysis in dreams and reactions, particularly in those occurring in the transference, although their revival runs counter to the interest of the pleasure principle; and we have explained this by supposing that in these cases a compulsion to repeat is overcoming even the pleasure principle. Outside analysis, too, something similar can be observed. There are people in whose lives the same reactions are perpetually being repeated uncorrected, to their own detriment, or others who seem to be pursued by a relentless fate, though closer investigation teaches us that they are unwittingly bringing this fate on themselves. In such cases we attribute a 'daemonic' character to the compulsion to repeat.

[1933a, 4710]

The evidence of the share taken by the unconscious id in the formation of dreams is abundant and convincing. (a) Memory is far more comprehensive in dreams than in waking life. Dreams bring up recollections which the dreamer has forgotten, which are inaccessible to him when he is awake. (b) Dreams make an unrestricted use of linguistic symbols, the meaning of which is for the most part unknown to the dreamer. Our experience, however, enables us to confirm their sense. They probably originate from earlier phases in the development of speech. (c) Memory very often reproduces in dreams impressions from the dreamer's early childhood of which we can definitely assert not only that they had been forgotten but that they had become unconscious owing to repression. That explains the help - usually indispensable - given us by dreams in the attempts we make during the analytic treatment of neuroses to reconstruct the dreamer's early life. (d) Furthermore, dreams bring to light material which cannot have originated either from the dreamer's adult life or from his forgotten childhood. We are obliged to regard it as part of the archaic heritage which a child brings with him into the world, before any experience of his own, influenced by the experiences of his ancestors. We find the counterpart of this phylogenetic material in the earliest human legends and in surviving customs. Thus dreams constitute a source of human prehistory which is not to be despised.

[1940a [1938], 4976]
I shall conclude this brief paper with a few remarks which open up a wider perspective. I have been struck by the manner in which, in certain analyses, the communication of an obviously apt construction has evoked in the patients a surprising and at first incomprehensible phenomenon. They have had lively recollections called up in them - which they themselves have described as 'ultra-clear' - but what they have recollected has not been the event that was the subject of the construction but details relating to that subject. For instance, they have recollected with abnormal sharpness the faces of the people involved in the construction or the rooms in which something of the sort might have happened, or, a step further away, the furniture in such rooms - on the subject of which the construction had naturally no possibility of any knowledge. This has occurred both in dreams immediately after the construction had been put forward and in waking states resembling phantasies. These recollections have themselves led to nothing further and it has seemed plausible to regard them as the product of a compromise. The 'upward drive' of the repressed, stirred into activity by the putting forward of the construction, has striven to carry the important memory-traces into consciousness; but a resistance has succeeded, not, it is true, in stopping that movement, but in displacing it on to adjacent objects of minor significance.
[1937d, 5057]
One of the sources from which dreams derive material for reproduction - material which is in part neither remembered nor used in the activities of waking thought - is childhood experience. I will quote only a few of the authors who have noticed and stressed this fact.

[1900a, 529]

Strümpell (1877, 40): 'The position is even more remarkable when we observe how dreams sometimes bring to light, as it were, from beneath the deepest piles of débris under which the earliest experiences of youth are buried in later times, pictures of particular localities, things or people, completely intact and with all their original freshness. This is not limited to experiences which created a lively impression when they occurred or enjoy a high degree of psychical importance and return later in a dream as genuine recollections at which waking consciousness will rejoice. On the contrary, the depths of memory in dreams also include pictures of people, things, localities and events dating from the earliest times, which either never possessed any psychical importance or more than a slight degree of vividness, or which have long since lost what they may have possessed of either, and which consequently seem completely alien and unknown alike to the dreaming and waking mind till their earlier origin has been discovered.'

[1900a, 529]

¹ [Footnote added 1911:] The appearance of gigantic figures in a dream gives grounds for supposing that some scene from the dreamer's childhood is involved. - [Added 1925:] Incidentally, the interpretation given in the text, pointing to a reminiscence of Gulliver's Travels, is a good example of what an interpretation ought not to be. The interpreter of a dream should not give free play to his own ingenuity and neglect the dreamer's associations.

[1900a, 542]

¹ The view adopted by Robert that the purpose of dreams is to unburden our memory of the useless impressions of daytime is plainly no longer tenable if indifferent memory images from our childhood appear at all frequently in dreams. Otherwise we could only conclude that dreams perform their function most inadequately.

[1900a, 655]

Like every other writer on the subject, with the exception of Robert, I have pointed out as a third peculiarity of the content of dreams that it may include impressions which date back to earliest childhood, and which seem not to be accessible to waking memory. It is naturally hard to determine how rarely or how frequently this occurs, since the origin of the dream elements in question is not recognized after waking. Proof that what we are dealing with are impressions from childhood must therefore be established by external evidence and there is seldom an opportunity for doing this. A particularly convincing example is that given by Maury of the man who determined one day to revisit his old home after an absence of more than twenty years. During the night before his departure he dreamt that he was in a totally unknown place and there met an unknown man in the street and had a conversation with him. When he reached his home, he found that the unknown place was a real one in the immediate neighbourhood of his native town, and the unknown man in the dream turned out to be a friend of his dead father's who was still living there. This was conclusive evidence that he had seen both the man and the place in his childhood. This dream is also to be interpreted as a dream of impatience like that of the girl with the concert-ticket in her pocket (p. 647 f.), that of the child whose father had promised to take her on an excursion to the Hameau (cf. p. 628 f.), and similar ones. The motives which led the dreamers to reproduce one particular impression from their childhood rather than any other cannot, of course, be discovered without an analysis.

[1900a, 675]
There is another way in which it can be established with certainty without the assistance of interpretation that a dream contains elements from childhood. This is where the dream is of what has been called the 'recurrent' type: that is to say, where a dream was first dreamt in childhood and then constantly reappears from time to time during adult sleep. I am able to add to the familiar examples of such dreams a few from my own records, though I have never myself experienced one. A physician in his thirties told me that from the earliest days of his childhood to the present time a yellow lion frequently appeared in his dreams; he was able to give a minute description of it. This lion out of his dreams made its appearance one day in bodily form, as a china ornament that had long disappeared. The young man then learnt from his mother that this object had been his favourite toy during his early childhood, though he himself had forgotten the fact.
[1900a, 675]

If we turn now from the manifest content of dreams to the dream-thoughts which only analysis uncovers, we find to our astonishment that experiences from childhood also play a part in dreams whose content would never have led one to suppose it. I owe a particularly agreeable and instructive example of a dream of this kind to my respected colleague of the yellow lion. After reading Nansen's narrative of his polar expedition, he had a dream of being in a field of ice and of giving the gallant explorer galvanic treatment for an attack of sciatica from which he was suffering. In the course of analysing the dream, he thought of a story dating from his childhood, which alone, incidentally, made the dream intelligible. One day, when he was a child of three or four, he had heard the grown-ups talking of voyages of discovery and had asked his father whether that was a serious illness. He had evidently confused 'Reisen' ['voyages'] with 'Reissen' ['gripes'], and his brothers and sisters saw to it that he never forgot this embarrassing mistake.
[1900a, 676]

The deeper one carries the analysis of a dream, the more often one comes upon the track of experiences in childhood which have played a part among the sources of that dream's latent content.
[1900a, 681]

It is true that as a rule the childhood scene is only represented in the dream's manifest content by an allusion, and has to be arrived at by an interpretation of the dream. Such instances when they are recorded, cannot carry much conviction, since as a rule there is no other evidence of these childhood experiences having occurred: if they date back to a very early age they are no longer recognized as memories. The general justification for inferring the occurrence of these childhood experiences from dreams is provided by a whole number of factors in psycho-analytic work, which are mutually consistent and thus seem sufficiently trustworthy. If I record some of these inferred childhood experiences torn from their context for the purposes of dream-interpretation, they may perhaps create little impression, especially as I shall not even be able to quote all the material on which the interpretations were based. Nevertheless I shall not allow this to deter me from relating them.
[1900a, 682]
My records naturally include a large collection of patients’ dreams the analysis of which led to obscure or entirely forgotten impressions of childhood, often going back to the first three years of life. But it would be unsafe to apply any conclusions drawn from them to dreams in general. The persons concerned were in every instance neurotics and in particular hysterics; and it is possible that the part played by childhood scenes in their dreams might be determined by the nature of their neurosis and not by the nature of dreams. Nevertheless, in analysing my own dreams - and, after all, I am not doing so on account of any gross pathological symptoms - it happens no less frequently that in the latent content of a dream I come unexpectedly upon a scene from childhood, and that all at once a whole series of my dreams link up with the associations branching out from some experience of my childhood. I have already given some instances of this, and I shall have others to give in a variety of connections. I cannot, perhaps, bring this section to a better close than by reporting one or two dreams of mine in which recent occasions and long-forgotten experiences of childhood came together as sources of the dream. [1900a, 687]

My experiences in analysing dreams have drawn my attention to the fact that trains of thought reaching back to earliest childhood lead off even from dreams which seem at first sight to have been completely interpreted, since their sources and instigating wish have been discovered without difficulty. I have therefore been compelled to ask myself whether this characteristic may not be a further essential precondition of dreaming. Stated in general terms, this would imply that every dream was linked in its manifest content with recent experiences and in its latent content with the most ancient experiences. And I have in fact been able to show in my analysis of hysteria that these ancient experiences have remained recent in the proper sense of the word up to the immediate present. It is still extremely hard to demonstrate the truth of this suspicion; and I shall have to return in another connection (Chapter VII) to a consideration of the probable part played by the earliest experiences of childhood in the formation of dreams. [1900a, 698]

Of the three characteristics of memory in dreams enumerated at the beginning of this chapter, one - the preference for non-essential material in the content of dreams - has been satisfactorily cleared up by being traced back to dream-distortion. We have been able to confirm the existence of the other two - the emphasis upon recent and upon infantile material - but we have not been able to account for them on the basis of the motives that lead to dreaming. These two characteristics inclusion of both recent and infantile material, whose explanation and appreciation remain to be discovered, must be kept in mind. Their proper place must be looked for elsewhere - either in the psychology of the state of sleep or in the discussion of the structure of the mental apparatus upon which we shall later embark, after we have learnt that the interpretation of dreams is like a window through which we can get a glimpse of the interior of that apparatus. [1900a, 699]
We have already taken the first step in this direction by advancing the thesis (see p. 666 f.) that the dream-work is under the necessity of combining into a unity all instigations to dreaming which are active simultaneously. We found that, when two or more experiences capable of creating an impression are left over from the previous day, the wishes derived from them are combined in a single dream, and similarly that the psychically significant impressions and the indifferent experiences from the previous day are brought together in the dream-material, provided always that it is possible to set up communicating ideas between them. Thus a dream appears to be a reaction to everything that is simultaneously present in the sleeping mind as currently active material. So far as we have hitherto analysed the material of dreams, we have seen it as a collection of psychical residues and memory-traces, to which (on account of the preference shown for recent and infantile material) we have been led to attribute a hitherto indefinable quality of being 'currently active'. We can foresee, then, without any great difficulty, what will happen if fresh material in the form of sensations is added during sleep to these currently active memories. It is once again owing to the fact of their being currently active that these sensory excitations are of importance for the dream; they are united with the other currently active psychical material to furnish what is used for the construction of the dream. To put it another way, stimuli arising during sleep are worked up into a wish-fulfilment the other constituents of which are the familiar psychical 'day's residues'. This combination need not occur; as I have already pointed out, there is more than one way of reacting to a somatic stimulus during sleep. When it does occur, it means that it has been possible to find ideational material to serve as the content of the dream of such a sort as to be able to represent both kinds of source of the dream - the somatic and the psychical.

[1900a, 707]

In the case of our dream we are in a position to indicate the material upon which the misinterpretation is based. The impostor is the dream and the Emperor is the dreamer himself; the moralizing purpose of the dream reveals an obscure knowledge of the fact that the latent dream-content is concerned with forbidden wishes that have fallen victim to repression. For the context in which dreams of this sort appear during my analyses of neurotics leaves no doubt that they are based upon memories from earliest childhood. It is only in our childhood that we are seen in inadequate clothing both by members of our family and by strangers - nurses, maid-servants, and visitors; and it is only then that we feel no shame at our nakedness.¹ We can observe how undressing has an almost intoxicating effect on many children even in their later years, instead of making them feel ashamed. They laugh and jump about and slap themselves, while their mother, or whoever else may be there, reproves them and says: 'Ugh! Shocking! You mustn't ever do that!' Children frequently manifest a desire to exhibit. One can scarcely pass through a country village in our part of the world without meeting some child of two or three who lifts up his little shirt in front of one - in one's honour, perhaps. One of my patients has a conscious memory of a scene in his eighth year, when at bed-time he wanted to dance into the next room where his little sister slept, dressed in his night-shirt, but was prevented by his nurse. In the early history of neurotics an important part is played by exposure to children of the opposite sex; in paranoia delusions of being observed while dressing and undressing are to be traced back to experiences of this kind; while among persons who have remained at the stage of perversion there is one class in which this infantile impulse has reached the pitch of a symptom - the class of 'exhibitionists'.

[1900a, 723]
When we look back at this unashamed period of childhood it seems to us a Paradise; and Paradise itself is no more than a group phantasy of the childhood of the individual. That is why mankind were naked in Paradise and were without shame in one another's presence; till a moment arrived when shame and anxiety awoke, expulsion followed, and sexual life and the tasks of cultural activity began. But we can regain this Paradise every night in our dreams. I have already expressed a suspicion that impressions of earliest childhood (that is, from the prehistoric epoch until about the end of the third year of life) strive to achieve reproduction, from their very nature and irrespectively perhaps of their actual content, and that their repetition constitutes the fulfilment of a wish. Thus dreams of being naked are dreams of exhibiting.¹

[1900a, 724]

The deepest and eternal nature of man, upon whose evocation in his hearers the poet is accustomed to rely, lies in those impulses of the mind which have their roots in a childhood that has since become prehistoric. Suppressed and forbidden wishes from childhood break through in the dream behind the exile's unobjectionable wishes which are capable of entering consciousness; and that is why the dream which finds concrete expression in the legend of Nausicaä ends as a rule as an anxiety-dream.

[1900a, 725]

My own dream (recorded on p. 717) of running upstairs and of soon afterwards finding myself glued to the steps was equally a dream of exhibiting, since it bears the essential marks of being one. It should be possible, therefore, to trace it back to experiences during my childhood, and if these could be discovered they should enable us to judge how far the maid-servant's behaviour to me - her accusing me of dirtying the carpet - helped to give her her place in my dream. I can, as it happens, provide the necessary particulars. In a psycho-analysis one learns to interpret propinquity in time as representing connection in subject-matter. Two thoughts which occur in immediate sequence without any apparent connection are in fact part of a single unity which has to be discovered; in just the same way, if I write an 'a' and a 'b' in succession, they have to be pronounced as a single syllable 'ab'. The same is true of dreams. The staircase dream to which I have referred was one of a series of dreams; and I understood the interpretation of the other members of the series. Since this particular dream was surrounded by the others it must have dealt with the same subject. Now these other dreams were based on a recollection of a nurse in whose charge I had been from some date during my earliest infancy till I was two and a half. I even retain an obscure conscious memory of her. According to what I was told not long ago by my mother, she was old and ugly, but very sharp and efficient. From what I can infer from my own dreams her treatment of me was not always excessive in its amiability and her words could be harsh if I failed to reach the required standard of cleanliness. And thus the maid servant, since she had undertaken the job of carrying on this educational work, acquired the right to be treated in my dream as a reincarnation of the prehistoric old nurse. It is reasonable to suppose that the child loved the old woman who taught him these lessons, in spite of her rough treatment of him.¹

[1900a, 726]
I have already discussed a dream which taught us that the wishes which are represented in dreams as fulfilled are not always present-day wishes. They may also be wishes of the past which have been abandoned, overlaid and repressed, and to which we have to attribute some sort of continued existence only because of their re-emergence in a dream. They are not dead in our sense of the word but only like the shades in the Odyssey, which awoke to some sort of life as soon as they had tasted blood. In the dream of the dead child in the 'case' (p. 154) what was involved was a wish which had been an immediate one fifteen years earlier and was frankly admitted as having existed at that time. I may add - and this may not be without its bearing upon the theory of dreams - that even behind this wish there lay a memory from the dreamer's earliest childhood. When she was a small child - the exact date could not be fixed with certainty - she had heard that her mother had fallen into a deep depression during the pregnancy of which she had been the fruit and had passionately wished that the child she was bearing might die. When the dreamer herself was grown-up and pregnant, she merely followed her mother's example.

[1900a, 728]

The context of the analysis gave us every ground for supposing that the dream went back to an impression in childhood. If so, it must have referred to the wet-nurse of the dreamer, who was by now a man almost thirty years old. For an infant the breasts of his wet-nurse are nothing more nor less than an inn. The wet-nurse, as well as Daudet's Sappho, seem to have been allusions to the mistress whom the patient had recently dropped.

[1900a, 760]

ANALYSIS. -The lawyer was a jovial old gentleman who, the dreamer seemed to remember, had really once brought some pears along. The window-sill was as he had seen it in the dream. Nothing else occurred to him in connection with it - only that his mother had told him a dream shortly before. She had had two birds sitting on her head and had asked herself when they would fly away; they did not fly away, but one of them flew to her mouth and sucked at it.

[1900a, 832]

The information provided by psycho-analyses forces me to conclude that these dreams, too, reproduce impressions of childhood; they relate, that is, to games involving movement, which are extraordinarily attractive to children. There cannot be a single uncle who has not shown a child how to fly by rushing across the room with him in his outstretched arms, or who has not played at letting him fall by riding him on his knee and then suddenly stretching out his leg, or by holding him up high and then suddenly pretending to drop him. Children are delighted by such experiences and never tire of asking to have them repeated, especially if there is something about them that causes a little fright or giddiness. In after years they repeat these experiences in dreams; but in the dreams they leave out the hands which held them up, so that they float or fall unsupported. The delight taken by young children in games of this kind (as well as in swings and see-saws) is well known; when they come to see acrobatic feats in a circus their memory of such games is revived. Hysterical attacks in boys sometimes consist merely in reproductions of feats of this kind, carried out with great skill. It not uncommonly happens that these games of movement, though innocent in themselves, give rise to sexual feelings. Childish romping ['Hetzen'], if I may use a word which commonly describes all such activities, is what is being repeated in dreams of flying, falling, giddiness and so on; while the pleasurable feelings attached to these experiences are transformed into anxiety. But, often enough, as every mother knows, romping among children actually ends in squabbling and tears.

[1900a, 850]
The interpretation of dreams of fire justifies the nursery law which forbids a child to 'play with fire' - so that he shall not wet his bed at night. For in their case, too, there is an underlying recollection of the enuresis of childhood. In my 'Fragment of an Analysis of a Case of Hysteria', I have given a complete analysis and synthesis of a fire dream of this kind in connection with the dreamer's case history, and I have shown what impulses of adult years this infantile material can be used to represent.

[1900a, 852]

Such was the material out of which the dream emerged. Meyer's short story brought up in addition a recollection of scenes from my childhood. (Cf. the last episode in the dream about Count Thun.) The day-time mood of revulsion and disgust persisted into the dream in so far as it was able to provide almost the entire material of its manifest content. But during the night a contrary mood of powerful and even exaggerated self-assertiveness arose and displaced the former one. The content of the dream had to find a form which would enable it to express both the delusions of inferiority and the megalomania in the same material. The compromise between them produced an ambiguous dream-content; but it also resulted in an indifferent feeling-tone owing to the mutual inhibition of these contrary impulses.

[1900a, 913]

Like dreams, they are wish-fulfilments; like dreams, they are based to a great extent on impressions of infantile experiences; like dreams, they benefit by a certain degree of relaxation of censorship. If we examine their structure, we shall perceive the way in which the wishful purpose that is at work in their production has mixed up the material of which they are built, has rearranged it and has formed it into a new whole. They stand in much the same relation to the childhood memories from which they are derived as do some of the Baroque palaces of Rome to the ancient ruins whose pavements and columns have provided the material for the more recent structures.

[1900a, 932]

If we now bear in mind how great a part is played in the dream-thoughts by infantile experiences or by phantasies based upon them, how frequently portions of them re-emerge in the dream-content and how often the dream-wishes themselves are derived from them, we cannot dismiss the probability that in dreams too the transformation of thoughts into visual images may be in part the result of the attraction which memories couched in visual form and eager for revival bring to bear upon thoughts cut off from consciousness and struggling to find expression. On this view a dream might be described as a substitute for an infantile scene modified by being transferred on to a recent experience. The infantile scene is unable to bring about its own revival and has to be content with returning as a dream.

[1900a, 979]
This indication of the way in which infantile scenes (or their reproductions as phantasies) function in a sense as models for the content of dreams, removes the necessity for one of the hypotheses put forward by Scherner and his followers in regard to internal sources of stimulation. Scherner supposes that, when dreams exhibit particularly vivid or particularly copious visual elements, there is present a state of 'visual stimulation', that is, of internal excitation in the organ of vision. We need not dispute this hypothesis, but can content ourselves with assuming that this state of excitation applies merely to the *psychical* perceptual system of the visual organ; we may, however, further point out that the state of excitation has been set up by a *memory*, that it is a *revival* of a visual excitation which was originally an immediate one. I cannot produce any good example from my own experience of an *infantile* memory producing this kind of result. My dreams are in general less rich in sensory elements than I am led to suppose is the case in other people. But in the case of my most vivid and beautiful dream of the last few years I was easily able to trace back the hallucinatory clarity of the dream's content to the sensory qualities of recent or fairly recent impressions. On p. 907 ff. I recorded a dream in which the deep blue colour of the water, the brown of the smoke coming from the ship's funnels, and the dark brown and red of the buildings left behind a profound impression on me. This dream, if any, should be traceable, to a visual stimulus. What was it that had brought my visual organ into this state of stimulation? A recent impression, which attached itself to a number of earlier ones. The colours which I saw were in the first instance those of a box of toy bricks with which, on the day before the dream, my children had put up a fine building and shown it off for my admiration. The big bricks were of the same dark red and the small ones were of the same blue and brown. This was associated with colour impressions from my last travels in Italy: the beautiful blue of the Isonzo and the lagoons and the brown of the Carso. The beauty of the colours in the dream was only a repetition of something seen in my memory. [1900a, 979]

Nor can we leave the subject of regression in dreams without setting down in words a notion by which we have already repeatedly been struck and which will recur with fresh intensity when we have entered more deeply into the study of the psycho-neuroses: namely that dreaming is on the whole an example of regression to the dreamer's earliest condition, a revival of his childhood, of the instinctual impulses which dominated it and of the methods of expression which were then available to him. Behind this childhood of the individual we are promised a picture of a phylogenetic childhood - a picture of the development of the human race, of which the individual's development is in fact an abbreviated recapitulation influenced by the chance circumstances of life. We can guess how much to the point is Nietzsche's assertion that in dreams 'some primaeval relic of humanity is at work which we can now scarcely reach any longer by a direct path'; and we may expect that the analysis of dreams will lead us to a knowledge of man's archaic heritage, of what is psychically innate in him. Dreams and neuroses seem to have preserved more mental antiquities than we could have imagined possible; so that psycho-analysis may claim a high place among the sciences which are concerned with the reconstruction of the earliest and most obscure periods of the beginnings of the human race. [1900a, 981]

The fact that dreams are hypermnnesic and have access to material from childhood has become one of the corner-stones of our teaching. Our theory of dreams regards wishes originating in infancy as the indispensable motive force for the formation of dreams. [1900a, 1016]
The psychical material of the dream-thoughts habitually includes recollections of impressive experiences - not infrequently dating back to early childhood - which are thus themselves perceived as a rule as situations having a visual subject matter. Wherever the possibility arises, this portion of the dream-thoughts exercises a determining influence upon the form taken by the content of the dream; it constitutes, as it were, a nucleus of crystallization, attracting the material of the dream-thoughts to itself and thus affecting their distribution. The situation in a dream is often nothing other than a modified repetition, complicated by interpolations, of an impressive experience of this kind; on the other hand, faithful and straightforward reproductions of real scenes only rarely appear in dreams.

[1901a, 1074]

It would be a mistake, however, to suppose that these dream-façades are nothing other than mistaken and somewhat arbitrary revisions of the dream-content by the conscious agency of our mental life. In the erection of a dream-façade use is not infrequently made of wishful phantasies which are present in the dream-thoughts in a pre-constructed form, and are of the same character as the appropriately named 'day-dreams' familiar to us in waking life. The wishful phantasies revealed by analysis in night-dreams often turn out to be repetitions or modified versions of scenes from infancy; thus in some cases the façade of the dream directly reveals the dream's actual nucleus, distorted by an admixture of other material.

[1901a, 1081]

I should like, further, to draw special attention to the fact that the analysis of this dream has given us access to certain details of the pathogenically operative events which had otherwise been inaccessible to memory, or at all events to reproduction. The recollection of the bed-wetting in childhood had, as we have seen, already been repressed. And Dora had never mentioned the details of her persecution by Herr K.; they had never occurred to her mind.

[1905e, 1424]

According to the necessary conditions of dream-formation the imagined situation must be chosen so as to reproduce a situation in infancy. A special triumph is achieved if a recent situation, perhaps even the very situation which is the exciting cause of the dream, can be transformed into an infantile one. This has actually been achieved in the present case, by a purely chance disposition of the material. Just as Herr K. had stood beside her sofa and woken her up, so her father had often done in her childhood. The whole trend of her thoughts could be most aptly symbolized by her substitution of her father for Herr K. in that situation.

[1905e, 1425]

But after all, what we really intended to do originally was only to investigate two or three dreams that are to be found here and there in Gradiva with the help of certain analytic methods. How has it come about, then, that we have been led into dissecting the whole story and examining the mental processes in the two chief characters? This has not in fact been an unnecessary piece of work; it was an essential preliminary. It is equally the case that when we try to understand the real dreams of a real person we have to concern ourselves intensively with his character and his career, and we must get to know not only his experiences shortly before the dream but also those dating far back into the past. It is even my view that we are still not free to turn to our proper task, but that we must linger a little more over the story itself and carry out some further preliminary work.

[1907a, 1842]
This short postscript to my analysis of a paranoid patient may serve to show that Jung had excellent grounds for his assertion that the mythopoeic forces of mankind are not extinct, but that to this very day they give rise in the neuroses to the same psychical products as in the remotest past ages. I should like to take up a suggestion that I myself made some time ago,¹ and add that the same holds good of the forces that construct religions. And I am of opinion that the time will soon be ripe for us to make an extension of a thesis which has long been asserted by psycho-analysts, and to complete what has hitherto had only an individual and ontogenetic application by the addition of its anthropological counterpart, which is to be conceived phylogenetically. 'In dreams and in neuroses', so our thesis has run, 'we come once more upon the child and the peculiarities which characterize his modes of thought and his emotional life.' 'And we come upon the savage too,' we may now add, 'upon the primitive man, as he stands revealed to us in the light of the researches of archaeology and of ethnology.'

[1911c, 2447]

Another and far more surprising discovery has been that, in spite of all the later development that occurs in the adult, none of the infantile mental formations perish. All the wishes, instinctual impulses, modes of reaction and attitudes of childhood are still demonstrably present in maturity and in appropriate circumstances can emerge once more. They are not destroyed but merely overlaid - to use the spatial mode of description which psycho-analytic psychology has been obliged to adopt. Thus it is part of the nature of the mental past that, unlike the historic past, it is not absorbed by its derivatives; it persists (whether actually or only potentially) alongside what has proceeded from it. The proof of this assertion lies in the fact that the dreams of normal people revive their childhood characters every night and reduce their whole mental life to an infantile level. This same return to psychical infantilism ('regression') appears in the neuroses and psychoses, whose peculiarities may to a great extent be described as psychical archaisms. The strength in which the residues of infancy are still present in the mind shows us the amount of disposition to illness; that disposition may accordingly be regarded as an expression of an inhibition in development. The part of a person's psychical material which has remained infantile and has been repressed as being unserviceable constitutes the core of his unconscious. And we believe we can follow in our patients' life-histories the way in which this unconscious, held back as it is by the forces of repression, lies in wait for a chance to become active and makes use of its opportunities if the later and higher psychical structures fail to master the difficulties of real life.

[1913], 2820]

In psycho-analytic treatments we are invariably faced by the task of filling up these gaps in the memory of childhood; and in so far as the treatment is to any extent successful - that is to say, extremely frequently - we also succeed in bringing to light the content of these forgotten years of childhood. Those impressions had never been really forgotten, they were only inaccessible, latent, and had formed part of the unconscious. But it can come about that they emerge from the unconscious spontaneously, and this happens in connection with dreams. It appears that dream-life knows how to find access to these latent, infantile experiences. Excellent examples of this have been reported in the literature and I myself have been able to provide a contribution of the kind. I once dreamt in a certain connection of a person who must have done me a service and whom I saw clearly before me. He was a one-eyed man of small stature, stout, and with his head sunk deep in his shoulders. I concluded from the context that he was a doctor. Luckily I was able to enquire from my mother, who was still alive, what the doctor at my birth-place (which I had left when I was three) had looked like; and I learnt from her that he was one-eyed, short, stout and with his head sunk deep in his shoulders; and I also learnt what the accident was for which he had come to my help and which I myself had forgotten. This fact of dreams having at their disposal the forgotten material of the first years of childhood is thus a further archaic feature.

[1916-1917, 3290]
We found from both sources that the dream-work consists essentially in the transformation of thoughts into a hallucinatory experience. How this can happen is sufficiently mysterious; but it is a problem of general psychology with which we are not properly concerned here. We learnt from children’s dreams that it is the intention of the dream-work to get rid of a mental stimulus, which is disturbing sleep, by means of the fulfilment of a wish. We were unable to say anything similar of distorted dreams till we found out how to interpret them. But it was from the first our expectation that we should be able to regard distorted dreams in the same light as those of children. The first confirmation of this expectation was brought to us by the discovery that in point of fact all dreams are children’s dreams, that they work with the same infantile material, with the mental impulses and mechanisms of childhood. Now that we believe we have overcome dream-distortion, we must go on to enquire whether the view of dreams as the fulfilment of wishes is also valid of distorted dreams.

[1916-1917, 3301]

Children are alone in not falling in with these conventions. They assert their animal rights with complete naïveté and give constant evidence that they have still to travel the road to purity. Strangely enough, the people who deny the existence of sexuality in children do not on that account become milder in their educational efforts but pursue the manifestations of what they deny exists with the utmost severity - describing them as 'childish naughtinesses'. It is also of the highest theoretical interest that the period of life which contradicts the prejudice of an asexual childhood most glaringly - the years of a child’s life up to the age of five or six - is afterwards covered in most people by the veil of amnesia which is only completely torn away by an analytic enquiry, though it has been permeable earlier for the construction of a few dreams.

[1916-1917, 3383]

But there is something else that I cannot pass by. The reminder of dreams given to us by the mother and wife of Oedipus must not be allowed to remain fruitless. Do you recall the outcome of our dream-analyses - how the wishes that construct dreams are so often of a perverse or incestuous nature or reveal an unsuspected hostility to those who are nearest and dearest to the dreamer? At that time we gave no explanation of the origin of these evil impulses. Now you can find it for yourselves. They are allocations of the libido and object-cathexes which date from early infancy and have long since been abandoned as far as conscious life is concerned, but which prove still to be present at night-time and to be capable of functioning in a certain sense. Since, however, everyone, and not only neurotics, experiences these perverse, incestuous and murderous dreams, we may conclude that people who are normal to-day have passed along a path of development that has led through the perversions and object-cathexes of the Oedipus complex, that that is the path of normal development and that neurotics merely exhibit to us in a magnified and coarsened form what the analysis of dreams reveals to us in healthy people as well. And this is one of the reasons why I dealt with the study of dreams before that of neurotic symptoms.

[1916-1917, 3402]

If it was to be assumed that behind the content of the dream there lay some such unknown scene - one, that is, which had already been forgotten at the time of the dream - then it must have taken place very early. The dreamer, it will be recalled, said: 'I was three, four, or at most five years old at the time I had the dream.' And we can add: 'And I was reminded by the dream of something that must have belonged to an even earlier period.'

[1918b, 3524]
I am not of opinion, however, that such scenes must necessarily be phantasies because they do not reappear in the shape of recollections. It seems to me absolutely equivalent to a recollection, if the memories are replaced (as in the present case) by dreams the analysis of which invariably leads back to the same scene and which reproduce every portion of its content in an inexhaustible variety of new shapes. Indeed, dreaming is another kind of remembering, though one that is subject to the conditions that rule at night and to the laws of dream-formation. It is this recurrence in dreams that I regard as the explanation of the fact that the patients themselves gradually acquire a profound conviction of the reality of these primal scenes, a conviction which is in no respect inferior to one based on recollection.¹

¹ A passage in the first edition of my Interpretation of Dreams (1900a) will show at what an early stage I was occupied with this problem. On p. 670 of that work there is an analysis of a remark occurring in a dream: 'That's not obtainable any longer.' It is explained that the phrase originated from myself. 'A few days earlier I had explained to the patient that the earliest experiences of childhood were "not obtainable any longer as such" but were replaced in analysis by "transferences" and dreams.'

¹ A page in the first edition of my Interpretation of Dreams (1900a) will show at what an early stage I was occupied with this problem. On p. 670 of that work there is an analysis of a remark occurring in a dream: 'That's not obtainable any longer.' It is explained that the phrase originated from myself. 'A few days earlier I had explained to the patient that the earliest experiences of childhood were "not obtainable any longer as such" but were replaced in analysis by "transferences" and dreams.'

The manifestations of a compulsion to repeat (which we have described as occurring in the early activities of infantile mental life as well as among the events of psycho-analytic treatment) exhibit to a high degree an instinctual character and, when they act in opposition to the pleasure principle, give the appearance of some 'daemonic' force at work. In the case of children's play we seemed to see that children repeat unpleasurable experiences for the additional reason that they can master a powerful impression far more thoroughly by being active than they could by merely experiencing it passively. Each fresh repetition seems to strengthen the mastery they are in search of. Nor can children have their pleasurable experiences repeated often enough, and they are inexorable in their insistence that the repetition shall be an identical one. This character trait disappears later on. If a joke is heard for a second time it produces almost no effect; a theatrical production never creates so great an impression the second time as the first; indeed, it is hardly possible to persuade an adult who has very much enjoyed reading a book to re-read it immediately. Novelty is always the condition of enjoyment. But children will never tire of asking an adult to repeat a game that he has shown them or played with them, till he is too exhausted to go on. And if a child has been told a nice story, he will insist on hearing it over and over again rather than a new one; and he will remorselessly stipulate that the repetition shall be an identical one and will correct any alterations of which the narrator may be guilty - though they may actually have been made in the hope of gaining fresh approval. None of this contradicts the pleasure principle; repetition, the re-experiencing of something identical, is clearly in itself a source of pleasure. In the case of a person in analysis, on the contrary, the compulsion to repeat the events of his childhood in the transference evidently disregards the pleasure principle in every way. The patient behaves in a purely infantile fashion and thus shows us that the repressed memory-traces of his primaeval experiences are not present in him in a bound state and are indeed in a sense incapable of obeying the secondary process. It is to this fact of not being bound, moreover, that they owe their capacity for forming, in conjunction with the residues of the previous day, a wishful phantasy that emerges in a dream. This same compulsion to repeat frequently meets us as an obstacle to our treatment when at the end of an analysis we try to induce the patient to detach himself completely from his physician. It may be presumed, too, that when people unfamiliar with analysis feel an obscure fear - a dread of rousing something that, so they feel, is better left sleeping - what they are afraid of at bottom is the emergence of this compulsion with its hint of possession by some 'daemonic' power.

[1918b, 3538]
None of the applications of psycho-analysis has excited so much interest and aroused so many
hopes, and none, consequently, has attracted so many capable workers, as its use in the theory
and practice of education. It is easy to understand why; for children have become the main
subject of psycho-analytic research and have thus replaced in importance the neurotics on
whom its studies began. Analysis has shown how the child lives on, almost unchanged, in the
sick man as well as in the dreamer and the artist; it has thrown light on the motive forces and
trends which set its characteristic stamp upon the childish nature; and it has traced the stages
through which a child grows to maturity. No wonder, therefore, if an expectation has arisen that
psycho-analytic concern with children will benefit the work of education, whose aim it is to guide
and assist children on their forward path and to shield them from going astray.
[1925f, 4167]

We have explained that the unconscious instinctual impulse of the dream connects itself with
a residue of the day, with some interest of waking life which has not been disposed of; it thus
gives the dream which it constructs a double value for the work of analysis. For on the one hand
a dream that has been analysed reveals itself as the fulfilment of a repressed wish; but on the
other hand it may be a continuation of some preconscious activity of the day before and may
contain every kind of subject-matter and give expression to an intention, a warning, a reflection,
or once more to the fulfilment of a wish. Analysis exploits the dream in both directions, as a
means of obtaining knowledge alike of the patient's conscious and of his unconscious
processes. It also profits from the fact that dreams have access to the forgotten material of
childhood, and so it happens that infantile amnesia is for the most part overcome in connection
with the interpretation of dreams. In this respect dreams achieve a part of what was previously
the task of hypnotism. On the other hand, I have never maintained the assertion which has so
often been ascribed to me that dream-interpretation shows that all dreams have a sexual
content or are derived from sexual motive forces. It is easy to see that hunger, thirst, or the
need to excrete, can produce dreams of satisfaction just as well as any repressed sexual or
egoistic impulse. The case of young children affords us a convenient test of the validity of our
theory of dreams. In them the various psychical systems are not yet sharply divided and the
repressions have not yet grown deep, so that we often come upon dreams which are nothing
more than undisguised fulfilments of wishful impulses left over from waking life. Under the
influence of imperative needs, adults may also produce dreams of this infantile type.¹
[1925d, 4221]

We meet with the second of these facts almost every day in the course of our analytic work;
and it does not imply such an important objection as the other does. One of the tasks of psycho-
analysis, as you know, is to lift the veil of amnesia which hides the earliest years of childhood
and to bring to conscious memory the manifestations of early infantile sexual life which are
contained in them. Now these first sexual experiences of a child are linked to painful
impressions of anxiety, prohibition, disappointment and punishment. We can understand their
having been repressed; but, that being so, we cannot understand how it is that they have such
free access to dream-life, that they provide the pattern for so many dream-phantasies and that
dreams are filled with reproductions of these scenes from childhood and with allusions to them.
It must be admitted that their unpleasurable character and the dream-work's wish-fulfilling
purpose seem far from mutually compatible. But it may be that in this case we are magnifying
the difficulty. After all, these same infantile experiences have attached to them all the
imperishable, unfulfilled instinctual wishes which throughout life provide the energy for the
construction of dreams, and to which we may no doubt credit the possibility, in their mighty
uprush, of forcing to the surface, along with the rest, the material of distressing events. And on
the other hand the manner and form in which this material is reproduced shows unmistakably
the efforts of the dream-work directed to denying the unpleasure by means of distortion and to
transforming disappointment into attainment.
[1933a, 4641]
But the moralist will console himself for a long time to come with the improbability of our speculations. A queer instinct indeed, directed to the destruction of its own organic home! Poets, it is true, talk of such things; but poets are irresponsible people and enjoy the privilege of poetic licence. Incidentally, such ideas are not foreign even to physiology: consider the notion, for instance, of the mucous membrane of the stomach digesting itself. It must be admitted, however, that our self-destructive instinct calls for support on a wider basis. One cannot, after all, venture on a hypothesis of such a wide range merely because a few poor fools have linked their sexual satisfaction to a peculiar condition. A more profound study of the instincts will, I believe, give us what we need. The instincts rule not only mental but also vegetative life, and these organic instincts exhibit a characteristic which deserves our deepest interest. (We shall not be able to judge until later whether it is a general characteristic of instincts.) For they reveal an effort to restore an earlier state of things. We may suppose that from the moment at which a state of things that has once been attained is upset, an instinct arises to create it afresh and brings about phenomena which we can describe as a 'compulsion to repeat'. Thus the whole of embryology is an example of the compulsion to repeat. A power of regenerating lost organs extends far up into the animal kingdom, and the instinct for recovery to which, alongside of therapeutic assistance, our cures are due must be the residue of this capacity which is so enormously developed in the lower animals. The spawning migrations of fishes, the migratory flights of birds, and possibly all that we describe as manifestations of instinct in animals, take place under the orders of the compulsion to repeat, which expresses the conservative nature of the instincts. Nor have we far to look in the mental field for its manifestations. We have been struck by the fact that the forgotten and repressed experiences of childhood are reproduced during the work of analysis in dreams and reactions, particularly in those occurring in the transference, although their revival runs counter to the interest of the pleasure principle; and we have explained this by supposing that in these cases a compulsion to repeat is overcoming even the pleasure principle. Outside analysis, too, something similar can be observed. There are people in whose lives the same reactions are perpetually being repeated uncorrected, to their own detriment, or others who seem to be pursued by a relentless fate, though closer investigation teaches us that they are unwittingly bringing this fate on themselves. In such cases we attribute a 'daemonic' character to the compulsion to repeat.

[1933a, 4710]

For I think my hypothesis - that, in order to gain control over fire, men had to renounce the homosexually-tinged desire to put it out with a stream of urine - can be confirmed by an interpretation of the Greek myth of Prometheus, provided that we bear in mind the distortions which must be expected to occur in the transition from facts to the contents of a myth. These distortions are of the same sort as, and no worse than, those which we acknowledge every day, when we reconstruct from patients' dreams the repressed but extremely important experiences of their childhood. The mechanisms employed in the distortions I have in mind are symbolic representation and turning into the opposite. I should not venture to explain all the features of our myth in this fashion; apart from the original set of facts, other and later occurrences may have contributed to its content. But the elements which admit of analytic interpretation are, after all, the most striking and important - viz. the manner in which Prometheus transported the fire, the character of his act (an outrage, a theft, a defrauding of the gods) and the meaning of his punishment.

[1932a, 4781]
It has long since become common knowledge that the experiences of a person's first five years exercise a determining effect on his life, which nothing later can withstand. Much that deserves knowing might be said about the way in which these early impressions maintain themselves against any influences in more mature periods of life - but it would not be relevant here. It may, however, be less well known that the strongest compulsive influence arises from impressions which impinge upon a child at a time when we would have to regard his psychical apparatus as not yet completely receptive. The fact itself cannot be doubted; but it is so puzzling that we may make it more comprehensible by comparing it with a photographic exposure which can be developed after any interval of time and transformed into a picture. I am nevertheless glad to point out that this uncomfortable discovery of ours has been anticipated by an imaginative writer, with the boldness that is permitted to poets. E. T. A. Hoffmann used to trace back the wealth of figures that put themselves at his disposal for his creative writings to the changing images and impressions which he had experienced during a journey of some weeks in a post-chaise while he was still an infant at his mother's breast. What children have experienced at the age of two and have not understood, need never be remembered by them except in dreams; they may only come to know of it through psycho-analytic treatment. But at some later time it will break into their life with obsessional impulses, it will govern their actions, it will decide their sympathies and antipathies and will quite often determine their choice of a love-object, for which it is so frequently impossible to find a rational basis. The two points at which these facts touch upon our problem cannot be mistaken.

The evidence of the share taken by the unconscious id in the formation of dreams is abundant and convincing. (a) Memory is far more comprehensive in dreams than in waking life. Dreams bring up recollections which the dreamer has forgotten, which are inaccessible to him when he is awake. (b) Dreams make an unrestricted use of linguistic symbols, the meaning of which is for the most part unknown to the dreamer. Our experience, however, enables us to confirm their sense. They probably originate from earlier phases in the development of speech. (c) Memory very often reproduces in dreams impressions from the dreamer's early childhood of which we can definitely assert not only that they had been forgotten but that they had become unconscious owing to repression. That explains the help - usually indispensable - given us by dreams in the attempts we make during the analytic treatment of neuroses to reconstruct the dreamer's early life. (d) Furthermore, dreams bring to light material which cannot have originated either from the dreamer's adult life or from his forgotten childhood. We are obliged to regard it as part of the archaic heritage which a child brings with him into the world, before any experience of his own, influenced by the experiences of his ancestors. We find the counterpart of this phylogenetic material in the earliest human legends and in surviving customs. Thus dreams constitute a source of human prehistory which is not to be despised.

[1939a, 4944]

[1940a [1938], 4976]
(2) A woman patient told me a dream in which all the people were especially big. 'That means', she went on, 'that the dream must be to do with events in my early childhood, for at that time, of course, all grown-up people seemed to me enormously big.' She herself did not appear in the content of this dream. - The fact of a dream referring to childhood may also be expressed in another way, namely by a translation of time into space. The characters and scenes are seen as though they were at a great distance, at the end of a long road, or as though they were being looked at through the wrong end of a pair of opera-glasses.
[1900a, 863]

(8) The time of day in dreams very often stands for the age of the dreamer at some particular period in his childhood. Thus, in one dream, 'a quarter past five in the morning' meant the age of five years and three months, which was significant, since that was the dreamer's age at the time of the birth of his younger brother.
[1900a, 864]

(9) Here is another method of representing ages in a dream. A woman dreamt that she was walking with two little girls whose ages differed by fifteen months. She was unable to recall any family of her acquaintance to whom this applied. She herself put forward the interpretation that the two children both represented herself and that the dream was reminding her that the two traumatic events of her childhood were separated from each other by precisely that interval. One had occurred when she was three and a half, the other when she was four and three-quarters.
[1900a, 864]
Footnote added 1920: The phantasies of the pubertal period have as their starting-point the infantile sexual researches that were abandoned in childhood. No doubt, too, they are also present before the end of the latency period. They may persist wholly, or to a great extent, unconsciously and for that reason it is often impossible to date them accurately. They are of great importance in the origin of many symptoms, since they precisely constitute preliminary stages of these symptoms and thus lay down the forms in which the repressed libidinal components find satisfaction. In the same way, they are the prototypes of the nocturnal phantasies which become conscious as dreams. Dreams are often nothing more than revivals of pubertal phantasies of this kind under the influence of, and in relation to, some stimulus left over from the waking life of the previous day (the 'day's residues'). Some among the sexual phantasies of the pubertal period are especially prominent, and are distinguished by their very general occurrence and by being to a great extent independent of individual experience. Such are the adolescent’s phantasies of overhearing his parents in sexual intercourse, of having been seduced at an early age by someone he loves and of having been threatened with castration; such, too, are his phantasies of being in the womb, and even of experiences there, and the so-called 'Family Romance', in which he reacts to the difference between his attitude towards his parents now and in his childhood. The close relations existing between these phantasies and myths has been demonstrated in the case of the last instance by Otto Rank (1909).

She saw a deep pit in the vineyard, which she knew had been caused by a tree being torn out. She added a remark that the tree was missing. She meant that she had not seen the tree in her dream; but the same wording served to express another thought which made the symbolic interpretation quite certain. The dream referred to another piece of infantile sexual theory - to the belief that girls originally had the same genitals as boys and that their later shape was the result of castration (the tearing out of a tree).

She was standing in front of the drawer of her writing-table which she was so familiar with that she could tell at once if anyone had been into it. Like all drawers, chests and cases, the writing-table drawer stood for the female genitals. She knew that indications of sexual intercourse (and, as she thought, of touching) could be observed on the genitals and had long feared such a discovery. In all these three dreams, I think, the accent is to be placed on knowledge. She was recalling the period of her sexual researches when she was a child, of whose outcome she had been quite proud at the time.
Let us once again take up the dream we have already so often returned to: the dream of the three theatre-tickets for 1 florin 50. (I can assure you that I originally chose out this example without any special purpose in view.) You know the latent dream thoughts: anger at having been in such a hurry to get married which arose when she heard the news that her friend had only just become engaged, putting a low value on her husband and the idea that she might have got a better one if only she had waited. We already know the wish which made a dream out of these thoughts: it was the desire to look, to be able to go to the theatre, most probably an offshoot of her old curiosity to discover at long last what really happens when one is married. This curiosity is, as we know, regularly directed by children towards their parents' sexual life,: it is an infantile curiosity, and, so far as it still persists later, an instinctual impulse with roots reaching back into infancy. But the news the dreamer had received during the day gave no occasion for awakening this desire to look, but only for awakening anger and regret. This wishful impulse was not in the first instance connected with the latent dream-thoughts; and we were able to include the outcome of the dream-interpretation in the analysis without taking any account of that impulse. But the anger in itself was not capable of creating a dream. A dream could not arise out of the thoughts that 'it was absurd to marry so early' until they had awakened the old wish to see at long last what happens in marriage. This wish then gave the dream-content its form by replacing marriage by going to the theatre, and the form was that of an earlier wish-fulfilment: 'There! now I may go to the theatre and look at everything that's forbidden, and you mayn't! I'm married and you must wait!' In this way the dreamer's present situation was transformed into its opposite, an old triumph was put in the place of her recent defeat. And, incidentally, a satisfaction of her scopophilia was mixed with a satisfaction of her egoistic competitive sense. This satisfaction then determined the manifest content of the dream, in which the position actually was that she was sitting in the theatre while her friend could not gain admission to it. The portions of the content of the dream behind which the latent dream-thoughts still lay concealed were superimposed on this situation of satisfaction as a misplaced and unintelligible modification of it. The dream's interpretation had to disregard everything that served to represent the wish-fulfilment and to re-establish the distressing latent dream-thoughts from these obscure remaining hints.

[1916-1917, 3312]

There were several conclusions, too, to be drawn from the raw material which had been produced by the patient's first analysis of the dream, and these had to be fitted into the collocation of which we were in search. Behind the mention of the sheep-breeding, evidence was to be expected of his sexual researches, his interest in which he was able to gratify during his visits with his father; but there must also have been allusions to a fear of death, since the greater part of the sheep had died of the epidemic. The most obtrusive thing in the dream, the wolves on the tree, led straight to his grandfather's story; and what was fascinating about this story and capable of provoking the dream can scarcely have been anything but its connection with the theme of castration.

[1918b, 3525]
The most uncompromising attitude on this question is adopted by J. G. E. Maass, the philosopher (1805), quoted by Winterstein (1912): 'Experience confirms our view that we dream most frequently of the things on which our warmest passions are centred. And this shows that our passions must have an influence on the production of our dreams. The ambitious man dreams of the laurels he has won (or imagines he has won) or of those he has still to win; while the lover is busied in his dreams with the object of his sweet hopes. . . . All the sensual desires and repulsions that slumber in the heart can, if anything sets them in motion, cause a dream to arise from the ideas that are associated with them or cause those ideas to intervene in a dream that is already present.'

[1900a, 522]

It will be seen that the emergence of impulses which are foreign to our moral consciousness is merely analogous to what we have already learnt - the fact that dreams have access to ideational material which is absent in our waking state or plays but a small part in it. Thus Benini (1898) writes: 'Certe nostre inclinazioni che si credevano soffocate e spente da un pezzo, si ridestano; passioni vecchie e sepolté rivivono; cose e persone a cui non pensiamo mai, ci vengono dinanzi.' And Volkelt (1875, 105): 'Ideas, too, which have entered waking consciousness almost unnoticed and have perhaps never again been called to memory, very frequently announce their presence in the mind through dreams.' At this point, finally, we may recall Schleiermacher's assertion that the act of falling asleep is accompanied by the appearance of 'involuntary ideas' or images.

[1900a, 578]

The question next arises as to the significance of the appearance of involuntary ideas in dreams, as to the light which the emergence during the night of these morally incompatible impulses throws upon the psychology of the waking and dreaming mind. And here we find a fresh division of opinion and yet another different grouping of the authorities. The line of thought adopted by Hildebrandt and others who share his fundamental position inevitably leads to the view that immoral impulses possess a certain degree of power even in waking life, though it is an inhibited power, unable to force its way into action, and that in sleep something is put out of action which acts like an inhibition in the daytime and has prevented us from being aware of the existence of such impulses. Thus dreams would reveal the true nature of man, though not his whole nature, and they would constitute one means of rendering the hidden interior of the mind accessible to our knowledge. Only upon some such premises as these can Hildebrandt base his attribution to dreams of warning powers, which draw our attention to moral infirmities in our mind, just as physicians admit that dreams can bring unobserved physical illnesses to our conscious notice. So, too, Spitta must be adopting this view when, in speaking of the sources of excitation which impinge upon the mind (at puberty, for instance), he consoles the dreamer with the assurance that he will have done all that lies within his power if he leads a strictly virtuous life in his waking hours, and if he takes care to suppress sinful thoughts whenever they arise and to prevent their maturing and turning into acts. According to this view we might define the 'involuntary ideas' as ideas which had been 'suppressed' during the day, and we should have to regard their emergence as a genuine mental phenomenon.

[1900a, 579]
No one who believes in the capacity of dreams to reveal an immoral tendency of the dreamer's which is really present though suppressed or concealed, could express his view more precisely than in Maury's words: 'En rêve l'homme se révèle donc tout entier à soi-même dans sa nudité et sa misère natives. Dès qu'il suspend l'exercice de sa volonté, il devient le jouet de toutes les passions contre lesquelles, à l'état de veille, la conscience, le sentiment de l'honneur, la crainte nous défendent.' (Ibid., 165.)² In another passage we find these pertinent sentences: 'Dans le songe, c'est surtout l'homme instinctif qui se révèle. . . . L'homme revient pour ainsi dire à l'é'état de nature quand il rêve; mais moins les idées acquises ont pénétré dans son esprit, plus les penchant en désaccord avec elles conservent encore sur lui l'influence dans le rêve.' (Ibid., 462.)³ He goes on to relate by way of example how in his dreams he is not infrequently the victim of the very superstition which he has been attacking in his writings with particular vehemence.

[1900a, 580]

I hope that the foregoing examples will be enough (till the next objection is raised) to make it seem plausible that even dreams with a distressing content are to be construed as wish-fulfillments. Nor will anyone regard it as a chance coincidence that the interpretation of these dreams has brought us up each time against topics about which people are loth to speak or to think. The distressing feeling aroused by these dreams is no doubt identical with the repugnance which tends (usually with success) to restrain us from discussing or mentioning such topics, and which each of us has to overcome if we nevertheless find ourselves compelled to embark on them. But the unpleasurable feeling which thus recurs in dreams does not disprove the existence of a wish. Everyone has wishes that he would prefer not to disclose to other people, and wishes that he will not admit even to himself. On the other hand, we are justified in linking the unpleasurable character of all these dreams with the fact of dream-distortion. And we are justified in concluding that these dreams are distorted and the wish-fulfilment contained in them disguised to the point of being unrecognizable precisely owing to the repugnance felt for the topic of the dream or for the wish derived from it and to an intention to repress them. The distortion in the dream is thus shown in fact to be an act of the censorship. We shall be taking into account everything that has been brought to light by our analysis of unpleasurable dreams if we make the following modification in the formula in which we have sought to express the nature of dreams: a dream is a (disguised) fulfilment of a (suppressed or repressed) wish.¹

[1900a, 653]

I should like, further, to draw special attention to the fact that the analysis of this dream has given us access to certain details of the pathogenically operative events which had otherwise been inaccessible to memory, or at all events to reproduction. The recollection of the bed-wetting in childhood had, as we have seen, already been repressed. And Dora had never mentioned the details of her persecution by Herr K.; they had never occurred to her mind.

[1905e, 1424]

Here then we seem to have finished off the interpretation of this second dream as well. Both of them have been made intelligible to us on the presupposition that a dreamer knows in his unconscious thoughts all that he has forgotten in his conscious ones, and that in the former he judges correctly what in the latter he misunderstands in a delusion. In the course of our arguments we have no doubt been obliged to make some assertions which have seemed strange to the reader because of their unfamiliarity; and we have probably often roused a suspicion that what we pretended was the author's meaning was in fact only our own. I am anxious to do all I can to dissipate this suspicion, and for that reason I will gladly enter into more detail over one of the most delicate points - I mean the use of ambiguous words and phrases, such as: 'Somewhere in the Sun Gradiva was sitting.'

[1907a, 1877]
My second remark is a supplement to the theory of dreams. We cannot explain the origin of dreams unless we adopt the hypothesis that the repressed unconscious has achieved some degree of independence of the ego, so that it does not acquiesce in the wish to sleep and retains its cathexes even when all the object-cathexes depending on the ego have been withdrawn in order to encourage sleep. Only if that is so can we understand how the unconscious can make use of the lifting or reduction of the censorship which occurs at night, and can succeed in obtaining control over the day's residues so as to construct a forbidden dream-wish out of their material. On the other hand, it may be that these day's residues have to thank an already existing connection with the repressed unconscious for some of their resistance to the withdrawal of libido commanded by the wish to sleep. We will, then, insert this dynamically important feature into our view of the formation of dreams by way of supplement.

For a time psycho-analysis seemed fated to merge into psychology without being able to show why the psychology of the sick differed from that of the normal. In the course of its advance, however, it came up against the problem of dreams, which are abnormal products of the mind created by normal men under regularly recurrent physiological conditions. When psycho-analysis had solved the problem of dreams, it had discovered in unconscious psychical processes the common ground in which the highest and the lowest of mental impulses have their roots and from which spring the most normal as well as the most morbid and erratic of mental productions. The new picture of the workings of the mind began to grow ever clearer and more complete. It was a picture of obscure instinctual forces organic in origin, striving towards inborn aims, and, above them, of an agency comprising more highly organized mental structures - acquisitions of human evolution made under the impact of human history -, an agency which has taken over portions of the instinctual impulses, has developed them further or has even directed them towards higher aims, but which in any case binds them firmly and manipulates their energy to suit its own purposes. This higher organization, however, which is known to us as the ego, has rejected another portion of these same elementary instinctual impulses as being unserviceable because they cannot be fitted into the organic unity of the individual or because they rebel against the individual's cultural aims. The ego is not in a position to exterminate these unsubdued mental powers, but it turns its back on them, lets them remain at the lowest psychological level, defends itself from their demands by the energetic erection of protective and antithetical barriers or seeks to come to terms with them by means of substitutive satisfactions. These instincts which have fallen victim to repression - untamed and indestructible, yet inhibited from any kind of activity - together with their primitive mental representatives, constitute the mental underworld, the nucleus of the true unconscious, and are at every moment ready to assert their demands and, by hook or by crook, to force their way forward to satisfaction. To this is due the instability of the proud superstructure of the mind, the emergence at night of the proscribed and repressed material in the form of dreams, and the tendency to fall ill with neuroses and psychoses as soon as the balance of power between the ego and the repressed shifts to the disadvantage of the ego.
