Every analyst will admit that even to-day this view has not the sound of a long-discarded error. Nevertheless, alterations in it became essential, as our enquiries advanced from the repressed to the repressing forces, from the object-instincts to the ego. The decisive step forward was the introduction of the concept of narcissism - that is to say, the discovery that the ego itself is cathectered with libido, that the ego, indeed, is the libido's original home, and remains to some extent its headquarters. This narcissistic libido turns towards objects, and thus becomes object-libido; and it can change back into narcissistic libido once more. The concept of narcissism made it possible to obtain an analytic understanding of the traumatic neuroses and of many of the affections bordering on the psychoses, as well as of the latter themselves. It was not necessary to give up our interpretation of the transference neuroses as attempts made by the ego to defend itself against sexuality; but the concept of libido was endangered. Since the ego-instincts, too, were libidinal, it seemed for a time inevitable that we should make libido coincide with instinctual energy in general, as C. G. Jung had already advocated earlier. Nevertheless, there still remained in me a kind of conviction, for which I was not as yet able to find reasons, that the instincts could not all be of the same kind. My next step was taken in Beyond the Pleasure Principle (1920g), when the compulsion to repeat and the conservative character of instinctual life first attracted my attention. Starting from speculations on the beginning of life and from biological parallels, I drew the conclusion that, besides the instinct to preserve living substance and to join it into ever larger units,¹ there must exist another, contrary instinct seeking to dissolve those units and to bring them back to their primaeval, inorganic state. That is to say, as well as Eros there was an instinct of death. The phenomena of life could be explained from the concurrent or mutually opposing action of these two instincts. It was not easy, however, to demonstrate the activities of this supposed death instinct. The manifestations of Eros were conspicuous and noisy enough. It might be assumed that the death instinct operated silently within the organism towards its dissolution, but that, of course, was no proof. A more fruitful idea was that a portion of the instinct is diverted towards the external world and comes to light as an instinct of aggressiveness and destructiveness. In this way the instinct itself could be pressed into the service of Eros, in that the organism was destroying some other thing, whether animate or inanimate, instead of destroying its own self. Conversely, any restriction of this aggressiveness directed outwards would be bound to increase the self-destruction, which is in any case proceeding. At the same time one can suspect from this example that the two kinds of instinct seldom - perhaps never - appear in isolation from each other, but are alloyed with each other in varying and very different proportions and so become unrecognizable to our judgement. In sadism, long since known to us as a component instinct of sexuality, we should have before us a particularly strong alloy of this kind between trends of love and the destructive instinct; while its counterpart, masochism, would be a union between destructiveness directed inwards and sexuality - a union which makes what is otherwise an imperceptible trend into a conspicuous and tangible one.

¹ The opposition which thus emerges between the ceaseless trend by Eros towards extension and the general conservative nature of the instincts is striking, and it may become the starting-point for the study of further problems.

[1930a, 4509]
The name 'libido' can once more be used to denote the manifestations of the power of Eros in order to distinguish them from the energy of the death instinct.¹ It must be confessed that we have much greater difficulty in grasping that instinct; we can only suspect it, as it were, as something in the background behind Eros, and it escapes detection unless its presence is betrayed by its being alloyed with Eros. It is in sadism, where the death instinct twists the erotic aim in its own sense and yet at the same time fully satisfies the erotic urge, that we succeed in obtaining the clearest insight into its nature and its relation to Eros. But even where it emerges without any sexual purpose, in the blindest fury of destructiveness, we cannot fail to recognize that the satisfaction of the instinct is accompanied by an extraordinarily high degree of narcissistic enjoyment, owing to its presenting the ego with a fulfilment of the latter's old wishes for omnipotence. The instinct of destruction, moderated and tamed, and, as it were, inhibited in its aim, must, when it is directed towards objects, provide the ego with the satisfaction of its vital needs and with control over nature. Since the assumption of the existence of the instinct is mainly based on theoretical grounds, we must also admit that it is not entirely proof against theoretical objections. But this is how things appear to us now, in the present state of our knowledge; future research and reflection will no doubt bring further light which will decide the matter.

[1930a, 4511]

In all that follows I adopt the standpoint, therefore, that the inclination to aggression is an original, self-subsisting instinctual disposition in man, and I return to my view that it constitutes the greatest impediment to civilization. At one point in the course of this enquiry I was led to the idea that civilization was a special process which mankind undergoes, and I am still under the influence of that idea. I may now add that civilization is a process in the service of Eros, whose purpose is to combine single human individuals, and after that families, then races, peoples and nations, into one great unity, the unity of mankind. Why this has to happen, we do not know; the work of Eros is precisely this.¹ These collections of men are to be libidinally bound to one another. Necessity alone, the advantages of work in common, will not hold them together. But man's natural aggressive instinct, the hostility of each against all and of all against each, opposes this programme of civilization. This aggressive instinct is the derivative and the main representative of the death instinct which we have found alongside of Eros and which shares world-dominion with it. And now, I think, the meaning of the evolution of civilization is no longer obscure to us. It must present the struggle between Eros and Death, between the instinct of life and the instinct of destruction, as it works itself out in the human species. This struggle is what all life essentially consists of, and the evolution of civilization may therefore be simply described as the struggle for life of the human species.¹ And it is this battle of the giants that our nurse-maids try to appease with their lullaby about Heaven.

[1930a, 4512]
Some readers of this work may further have an impression that they have heard the formula of the struggle between Eros and the death instinct too often. It was alleged to characterize the process of civilization which mankind undergoes but it was also brought into connection with the development of the individual, and, in addition, it was said to have revealed the secret of organic life in general. We cannot, I think, avoid going into the relations of these three processes to one another. The repetition of the same formula is justified by the consideration that both the process of human civilization and of the development of the individual are also vital processes - which is to say that they must share in the most general characteristic of life. On the other hand, evidence of the presence of this general characteristic fails, for the very reason of its general nature, to help us to arrive at any differentiation, so long as it is not narrowed down by special qualifications. We can only be satisfied, therefore, if we assert that the process of civilization is a modification which the vital process experiences under the influence of a task that is set it by Eros and instigated by Ananke - by the exigencies of reality; and that this task is one of uniting separate individuals into a community bound together by libidinal ties. When, however, we look at the relation between the process of human civilization and the developmental or educative process of individual human beings, we shall conclude without much hesitation that the two are very similar in nature, if not the very same process applied to different kinds of object. The process of the civilization of the human species is, of course, an abstraction of a higher order than is the development of the individual and it is therefore harder to apprehend in concrete terms, nor should we pursue analogies to an obsessional extreme; but in view of the similarity between the aims of the two processes - in the one case the integration of a separate individual into a human group, and in the other case the creation of a unified group out of many individuals - we cannot be surprised at the similarity between the means employed and the resultant phenomena.

[1930a, 4527]

The relation to time, which is so hard to describe, is also introduced into the ego by the perceptual system; it can scarcely be doubted that the mode of operation of that system is what provides the origin of the idea of time. But what distinguishes the ego from the id quite especially is a tendency to synthesis in its contents, to a combination and unification in its mental processes which are totally lacking in the id. When presently we come to deal with the instincts in mental life we shall, I hope, succeed in tracing this essential characteristic of the ego back to its source. It alone produces the high degree of organization which the ego needs for its best achievements. The ego develops from perceiving the instincts to controlling them; but this last is only achieved by the representative of the instinct being allotted its proper place in a considerable assemblage, by its being taken up into a coherent context. To adopt a popular mode of speaking, we might say that the ego stands for reason and good sense while the id stands for the untamed passions.

[1933a, 4685]

But how can this conservative characteristic of instincts help us to understand our self-destructiveness? What earlier state of things does an instinct such as this want to restore? Well, the answer is not far to seek and opens wide perspectives. If it is true that - at some immeasurably remote time and in a manner we cannot conceive - life once proceeded out of inorganic matter, then, according to our presumption, an instinct must have arisen which sought to do away with life once more and to re-establish the inorganic state. If we recognize in this instinct the self-destructiveness of our hypothesis, we may regard the self-destructiveness as an expression of a 'death instinct' which cannot fail to be present in every vital process. And now the instincts that we believe in divide themselves into two groups - the erotic instincts, which seek to combine more and more living substance into ever greater unities, and the death instincts, which oppose this effort and lead what is living back into an inorganic state. From the concurrent and opposing action of these two proceed the phenomena of life which are brought to an end by death.

[1933a, 4711]
According to our hypothesis human instincts are of only two kinds: those which seek to preserve and unite - which we call 'erotic', exactly in the sense in which Plato uses the word 'Eros' in his *Symposium*, or 'sexual', with a deliberate extension of the popular conception of 'sexuality' - and those which seek to destroy and kill and which we group together as the aggressive or destructive instinct. As you see, this is in fact no more than a theoretical clarification of the universally familiar opposition between Love and Hate which may perhaps have some fundamental relation to the polarity of attraction and repulsion that plays a part in your own field of knowledge. But we must not be too hasty in introducing ethical judgements of good and evil. Neither of these instincts is any less essential than the other; the phenomena of life arise from the concurrent or mutually opposing action of both. Now it seems as though an instinct of the one sort can scarcely ever operate in isolation; it is always accompanied - or, as we say, alloyed - with a certain quota from the other side, which modifies its aim or is, in some cases, what enables it to achieve that aim. Thus, for instance, the instinct of self-preservation is certainly of an erotic kind, but it must nevertheless have aggressiveness at its disposal if it is to fulfil its purpose. So, too, the instinct of love, when it is directed towards an object, stands in need of some contribution from the instinct for mastery if it is in any way to obtain possession of that object. The difficulty of isolating the two classes of instinct in their actual manifestations is indeed what has so long prevented us from recognizing them.

I fear I may be abusing your interest, which is after all concerned with the prevention of war and not with our theories. Nevertheless I should like to linger for a moment over our destructive instinct, whose popularity is by no means equal to its importance. As a result of a little speculation, we have come to suppose that this instinct is at work in every living creature and is striving to bring it to ruin and to reduce life to its original condition of inanimate matter. Thus it quite seriously deserves to be called a death instinct, while the erotic instincts represent the effort to live. The death instinct turns into the destructive instinct when, with the help of special organs, it is directed outwards, on to objects. The organism preserves its own life, so to say, by destroying an extraneous one. Some portion of the death instinct, however, remains operative within the organism, and we have sought to trace quite a number of normal and pathological phenomena to this internalization of the destructive instinct. We have even been guilty of the heresy of attributing the origin of conscience to this diversion inwards of aggressiveness. You will notice that it is by no means a trivial matter if this process is carried too far: it is positively unhealthy. On the other hand if these forces are turned to destruction in the external world, the organism will be relieved and the effect must be beneficial. This would serve as a biological justification for all the ugly and dangerous impulses against which we are struggling. It must be admitted that they stand nearer to Nature than does our resistance to them for which an explanation also needs to be found. It may perhaps seem to you as though our theories are a kind of mythology and, in the present case, not even an agreeable one. But does not every science come in the end to a kind of mythology like this? Cannot the same be said to-day of your own Physics?

[1933b, 4798]
The forces which we assume to exist behind the tensions caused by the needs of the id are called instincts. They represent the somatic demands upon the mind. Though they are the ultimate cause of all activity, they are of a conservative nature; the state, whatever it may be, which an organism has reached gives rise to a tendency to re-establish that state so soon as it has been abandoned. It is thus possible to distinguish an indeterminate number of instincts, and in common practice this is in fact done. For us, however, the important question arises whether it may not be possible to trace all these numerous instincts back to a few basic ones. We have found that instincts can change their aim (by displacement) and also that they can replace one another - the energy of one instinct passing over to another. This latter process is still insufficiently understood. After long hesitancies and vacillations we have decided to assume the existence of only two basic instincts, Eros and the destructive instinct. (The contrast between the instincts of self-preservation and the preservation of the species, as well as the contrast between ego-love and object-love, fall within Eros.) The aim of the first of these basic instincts is to establish ever greater unities and to preserve them thus - in short, to bind together; the aim of the second is, on the contrary, to undo connections and so to destroy things. In the case of the destructive instinct we may suppose that its final aim is to lead what is living into an inorganic state. For this reason we also call it the death instinct. If we assume that living things came later than inanimate ones and arose from them, then the death instinct fits in with the formula we have proposed to the effect that instincts tend towards a return to an earlier state. In the case of Eros (or the love instinct) we cannot apply this formula. To do so would presuppose that living substance was once a unity which had later been torn apart and was now striving towards reunion.¹

[1940a [1938], 4959]
There is a great deal to be said about this. In the first place, Löwenfeld forces upon my theory an inference which it is not bound to accept. To suppose that in the storing-up of somatic sexual excitation the same thing must be happening as in the accumulation of the stimulus which leads to an epileptic convulsion, is to make a far too detailed hypothesis, and I have given no occasion for it; nor is it the only one that presents itself. I need only assume that the nervous system has the power to master a certain amount of somatic sexual excitation even where the latter is deflected from its aim, and that disturbances only occur when that quantum of excitation receives a sudden increment, and Löwenfeld's claim would be disposed of. I have not ventured to extend my theory in that direction, chiefly because I did not expect to find any solid points of support along that path. I should merely like to indicate that we ought not to think of the production of sexual tension independently of its distribution; that in normal sexual life this production, when it is stimulated by a sexual object, takes on a substantially different form from what it does in a state of psychical quiescence; and so on.

[1895f, 360]

This ego-libido is, however, only conveniently accessible to analytic study when it has been put to the use of cathecting sexual objects, that is, when it has become object-libido. We can then perceive it concentrating upon objects, becoming fixed upon them or abandoning them, moving from one object to another and, from these situations, directing the subject's sexual activity, which leads to the satisfaction, that is, to the partial and temporary extinction, of the libido. The psycho-analysis of what are termed transference neuroses (hysteria and obsessional neurosis) affords us a clear insight at this point.

[1905d, 1531]

Now, however, I must draw your attention to the decisive difference between the symptoms of the 'actual' neuroses and those of the psychoneuroses, the first group of which, the transference neuroses, have occupied us so much hitherto. In both cases the symptoms originate from the libido, and are thus abnormal employments of it, substitutive satisfactions. But the symptoms of the 'actual' neuroses - intracranial pressure, sensations of pain, a state of irritation in an organ, weakening or inhibition of a function - have no 'sense', no psychical meaning. They are not only manifested predominantly in the body (as are hysterical symptoms, for instance, as well), but they are also themselves entirely somatic processes, in the generating of which all the complicated mental mechanisms we have come to know are absent. Thus they really are what psychoneurotic symptoms were so long believed to be. But if so, how can they correspond to employments of the libido, which we have recognized as a force operating in the mind? Well, Gentlemen, that is a very simple matter. Let me remind you of one of the very first objections that were brought up against psycho-analysis. It was said then that it was occupied in finding a purely psychological theory of neurotic phenomena and this was quite hopeless, since psychological theories could never explain an illness. People had chosen to forget that the sexual function is not a purely psychical thing any more than it is a purely somatic one. It influences bodily and mental life alike. If in the symptoms of the psychoneuroses we have become acquainted with manifestations of disturbances in the psychical operation of the sexual function, we shall not be surprised to find in the 'actual' neuroses the direct somatic consequences of sexual disturbances.

[1916-1917, 3439]
Hitherto it has been a premiss of our work that we can distinguish the ego-instincts from the sexual ones by their manifestations. With the transference neuroses this could be done without difficulty. We termed the cathexes of energy which the ego directs towards the objects of its sexual desires 'libido'; all the others, which are sent out by the self-preservative instincts, we termed 'interest'. By tracing the course of the libidinal cathexes, their transformations and final vicissitudes, we were able to obtain a first insight into the machinery of the mental forces. For this purpose the transference neuroses offered us the most favourable material. But the ego, its composition out of various organizations and their construction and mode of functioning, remained hidden from us; and we were driven to suspect that only the analysis of other neurotic disorders would be able to bring us the necessary insight.

Libido is an expression taken from the theory of the emotions. We call by that name the energy, regarded as a quantitative magnitude (though not at present actually measurable), of those instincts which have to do with all that may be comprised under the word 'love'. The nucleus of what we mean by love naturally consists (and this is what is commonly called love, and what the poets sing of) in sexual love with sexual union as its aim. But we do not separate from this - what in any case has a share in the name 'love' - on the one hand, self-love, and on the other, love for parents and children, friendship and love for humanity in general, and also devotion to concrete objects and to abstract ideas. Our justification lies in the fact that psychoanalytic research has taught us that all these tendencies are an expression of the same instinctual impulses; in relations between the sexes these impulses force their way towards sexual union, but in other circumstances they are diverted from this aim or are prevented from reaching it, though always preserving enough of their original nature to keep their identity recognizable (as in such features as the longing for proximity, and self-sacrifice).

Over and over again we find, when we are able to trace instinctual impulses back, that they reveal themselves as derivatives of Eros. If it were not for the considerations put forward in Beyond the Pleasure Principle, and ultimately for the sadistic constituents which have attached themselves to Eros, we should have difficulty in holding to our fundamental dualistic point of view. But since we cannot escape that view, we are driven to conclude that the death instincts are by their nature mute and that the clamour of life proceeds for the most part from Eros.¹

Among the hypothetical concepts which enable the doctor to deal with the analytic material, the first to be mentioned is that of 'libido'. Libido means in psycho-analysis in the first instance the force (thought of as quantitatively variable and measurable) of the sexual instincts directed towards an object - 'sexual' in the extended sense required by analytic theory. Further study showed that it was necessary to set alongside this 'object-libido' a 'narcissistic' or 'ego-libido', directed to the subject's own ego; and the interaction of these two forces has enabled us to account for a great number of normal and abnormal processes in mental life. A rough distinction was soon made between what are known as the 'transference neuroses' and the narcissistic disorders. The former (hysteria and obsessional neurosis) are the objects proper of psychoanalytic treatment, while the others, the narcissistic neuroses, though they can, it is true, be examined by the help of analysis, offer fundamental difficulties to therapeutic influence. It is true that the libido theory of psycho-analysis is by no means complete and that its relation to a general theory of the instincts is not yet clear, for psycho-analysis is a young science, quite unfinished and in a stage of rapid development. Here, however, it should be emphatically pointed out how erroneous the charge of pan-sexualism is which is so often levelled at psycho-analysis. It seeks to show that psycho-analytic theory knows of no mental motive forces other than purely sexual ones and in doing so exploits popular prejudices by using the word 'sexual' not in its analytic but in its vulgar sense.
You see how many of the characteristics and vicissitudes of the instincts still escape our comprehension. A further distinction should be mentioned here which is exhibited between the sexual and self-preserved instincts and which would be of the greatest theoretical importance if it applied to the groups as a whole. The sexual instincts are noticeable to us for their plasticity, their capacity for altering their aims, their replaceability, which admits of one instinctual satisfaction being replaced by another, and their readiness for being deferred, of which we have just given a good example in the aim-inhibited instincts. We should be glad to deny these characteristics to the self-preserved instincts, and to say of them that they are inflexible, admit of no delay, are imperative in a very different sense and have a quite other relation to repression and to anxiety. But a little reflection tells us that this exceptional position applies, not to all the ego-insects, but only to hunger and thirst, and is evidently based on a peculiar character of the sources of those instincts. A good part of the confusing impression made by all this is that we have not given separate consideration to the alterations which the influence of the organized ego makes in the instinctual impulses that belonged originally to the id.

It is not my intention to pursue the further behaviour of femininity through puberty to the period of maturity. Our knowledge, moreover, would be insufficient for the purpose. But I will bring a few features together in what follows. Taking its prehistory as a starting-point, I will only emphasize here that the development of femininity remains exposed to disturbance by the residual phenomena of the early masculine period. Regressions to the fixations of the pre-Oedipus phases very frequently occur; in the course of some women's lives there is a repeated alternation between periods in which masculinity or femininity gains the upper hand. Some portion of what we men call 'the enigma of women' may perhaps be derived from this expression of bisexuality in women's lives. But another question seems to have become ripe for judgement in the course of these researches. We have called the motive force of sexual life 'the libido'. Sexual life is dominated by the polarity of masculine-feminine; thus the notion suggests itself of considering the relation of the libido to this antithesis. It would not be surprising if it were to turn out that each sexuality had its own special libido appropriated to it, so that one sort of libido would pursue the aims of a masculine sexual life and another sort those of a feminine one. But nothing of the kind is true. There is only one libido, which serves both the masculine and the feminine sexual functions. To it itself we cannot assign any sex; if, following the conventional equation of activity and masculinity, we are inclined to describe it as masculine, we must not forget that it also covers trends with a passive aim. Nevertheless the juxtaposition 'feminine libido' is without any justification. Furthermore, it is our impression that more constraint has been applied to the libido when it is pressed into the service of the feminine function, and that - to speak teleologically - Nature takes less careful account of its demands than in the case of masculinity. And the reason for this may lie - thinking once again teleologically - in the fact that the accomplishment of the aim of biology has been entrusted to the aggressiveness of men and has been made to some extent independent of women's consent.

It is hard to say anything of the behaviour of the libido in the id and in the super-ego. All that we know about it relates to the ego, in which at first the whole available quota of libido is stored up. We call this state absolute, primary narcissism. It lasts till the ego begins to cathex the ideas of objects with libido, to transform narcissistic libido into object-libido. Throughout the whole of life the ego remains the great reservoir from which libidinal cathexes are sent out to objects and into which they are also once more withdrawn, just as an amoeba behaves with its pseudopodia. It is only when a person is completely in love that the main quota of libido is transferred on to the object and the object to some extent takes the place of the ego. A characteristic of the libido which is important in life is its mobility, the facility with which it passes from one object to another. This must be contrasted with the fixation of the libido to particular objects, which often persists throughout life.
I will now set out before you what is most definitely known about the sexual life of children. Let me at the same time, for convenience sake, introduce the concept of 'libido'. On the exact analogy of 'hunger', we use 'libido' as the name of the force (in this case that of the sexual instinct, as in the case of hunger that of the nutritive instinct) by which the instinct manifests itself. Other concepts, such as sexual 'excitation' and 'satisfaction', call for no explanation. You yourselves will easily perceive that the sexual activities of infants in arms are mostly a matter of interpretation, or you will probably use that as a ground of objection. These interpretations are arrived at on the basis of analytic examinations made by tracing from the symptoms backwards. In an infant the first impulses of sexuality make their appearance attached to other vital functions. His main interest is, as you know, directed to the intake of nourishment; when children fall asleep after being sated at the breast, they show an expression of blissful satisfaction which will be repeated later in life after the experience of a sexual orgasm. This would be too little on which to base an inference. But we observe how an infant will repeat the action of taking in nourishment without making a demand for further food; here, then, he is not actuated by hunger. We describe this as sensual sucking, and the fact that in doing this he falls asleep once more with a blissful expression shows us that the act of sensual sucking has in itself alone brought him satisfaction. Soon, as we know, things come to a point at which he cannot go to sleep without having sucked. A paediatrician in Budapest, Dr. Lindner, was the first to point out long ago the sexual nature of this activity. Those who are in charge of children, and who have no theoretical views on the subject, seem to form a similar judgement of sucking. They have no doubt of its only purpose being to obtain pleasure, class it as one of a child's 'naughtinesses' and compel him to abandon it by causing him distress, if he will not give it up of his own accord. Thus we learn that infants perform actions which have no purpose other than obtaining pleasure. It is our belief that they first experience this pleasure in connection with taking nourishment but that they soon learn to separate it from that accompanying condition. We can only refer this pleasure to an excitation of the areas of the mouth and lips; we call those parts of the body 'erotogenic zones' and describe the pleasure derived from sucking as a sexual one. We shall no doubt have to discuss further whether this description is justifiable.

Now, however, I must draw your attention to the decisive difference between the symptoms of the 'actual' neuroses and those of the psychoneuroses, the first group of which, the transfERENCE neuroses, have occupied us so much hitherto. In both cases the symptoms originate from the libido, and are thus abnormal employments of it, substitutive satisfactions. But the symptoms of the 'actual' neuroses - intracranial pressure, sensations of pain, a state of irritation in an organ, weakening or inhibition of a function - have no 'sense', no psychical meaning. They are not only manifest predominately in the body (as are hysterical symptoms, for instance, as well), but they are also themselves entirely somatic processes, in the generating of which all the complicated mental mechanisms we have come to know are absent. Thus they really are what psychoneurotic symptoms were so long believed to be. But if so, how can they correspond to employments of the libido, which we have recognized as a force operating in the mind? Well, Gentlemen, that is a very simple matter. Let me remind you of one of the very first objections that were brought up against psycho-analysis. It was said then that it was occupied in finding a purely psychological theory of neurotic phenomena and this was quite hopeless, since psychological theories could never explain an illness. People had chosen to forget that the sexual function is not a purely psychical thing any more than it is a purely somatic one. It influences bodily and mental life alike. If in the symptoms of the psychoneuroses we have become acquainted with manifestations of disturbances in the psychic operation of the sexual function, we shall not be surprised to find in the 'actual' neuroses the direct somatic consequences of sexual disturbances.
Among the hypothetical concepts which enable the doctor to deal with the analytic material, the first to be mentioned is that of 'libido'. Libido means in psycho-analysis in the first instance the force (thought of as quantitatively variable and measurable) of the sexual instincts directed towards an object - 'sexual' in the extended sense required by analytic theory. Further study showed that it was necessary to set alongside this 'object-libido' a 'narcissistic' or 'ego-libido', directed to the subject's own ego: and the interaction of these two forces has enabled us to account for a great number of normal and abnormal processes in mental life. A rough distinction was soon made between what are known as the 'transference neuroses' and the narcissistic disorders. The former (hysteria and obsessional neurosis) are the objects proper of psycho-analytic treatment, while the others, the narcissistic neuroses, though they can, it is true, be examined by the help of analysis, offer fundamental difficulties to therapeutic influence. It is true that the libido theory of psycho-analysis is by no means complete and that its relation to a general theory of the instincts is not yet clear, for psycho-analysis is a young science, quite unfinished and in a stage of rapid development. Here, however, it should be emphatically pointed out how erroneous the charge of pan-sexualism is which is so often levelled at psycho-analysis. It seeks to show that psycho-analytic theory knows of no mental motive forces other than purely sexual ones and in doing so exploits popular prejudices by using the word 'sexual' not in its analytic but in its vulgar sense.

[1924f, 4113]
The conceptual scaffolding which we have set up to help us in dealing with the psychical manifestations of sexual life tallies well with these hypotheses as to the chemical basis of sexual excitation. We have defined the concept of libido as a quantitatively variable force which could serve as a measure of processes and transformations occurring in the field of sexual excitation. We distinguish this libido in respect of its special origin from the energy which must be supposed to underlie mental processes in general, and we thus also attribute a qualitative character to it. In thus distinguishing between libidinal and other forms of psychical energy we are giving expression to the presumption that the sexual processes occurring in the organism are distinguished from the nutritive processes by a special chemistry. The analysis of the perversions and psychoneuroses has shown us that this sexual excitation is derived not from the so-called sexual parts alone, but from all the bodily organs. We thus reach the idea of a quantity of libido, to the mental representation of which we give the name of 'ego-libido', and whose production, increase or diminution, distribution and displacement should afford us possibilities for explaining the psychosexual phenomena observed. [1905d, 1531]

This ego-libido is, however, only conveniently accessible to analytic study when it has been put to the use of cathecting sexual objects, that is, when it has become object-libido. We can then perceive it concentrating upon objects, becoming fixed upon them or abandoning them, moving from one object to another and, from these situations, directing the subject's sexual activity, which leads to the satisfaction, that is, to the partial and temporary extinction, of the libido. The psycho-analysis of what are termed transference neuroses (hysteria and obsessional neurosis) affords us a clear insight at this point. [1905d, 1531]

Nevertheless, we feel a need to modify Spencer's notion, in part to give a more definite form to the ideas contained in it and in part to change them. We should say that laughter arises if a quota of psychical energy which has earlier been used for the cathexis of particular psychical paths has become unusable, so that it can find free discharge. We are well aware what 'evil looks' we are inviting with such a hypothesis; but we will venture to quote in our defence an apposite sentence from Lipps's book *Komik und Humor* (1898, 71), from which illumination is to be derived on more subjects than that of the comic and humour: 'Finally, specific psychological problems always lead fairly deep into psychology, so that at bottom no psychological problem can be treated in isolation.' The concepts of 'psychical energy' and 'discharge' and the treatment of psychical energy as a quantity have become habitual in my thoughts since I began to arrange the facts of psychopathology philosophically; and already in my Interpretation of Dreams (1900a) I tried (in the same sense as Lipps) to establish the fact that what are 'really psychically effective' are psychical processes which are unconscious in themselves, not the contents of consciousness. It is only when I speak of the 'cathexis of psychical paths' that I seem to depart from the analogies commonly used by Lipps. My experiences of the displaceability of psychical energy along certain paths of association, and of the almost indestructible persistence of the traces of psychical processes, have in fact suggested to me an attempt at picturing the unknown in some such way. To avoid misunderstanding, I must add that I am making no attempt to proclaim that the cells and nerve fibres, or the systems of neurones which are taking their place to-day, are these psychical paths, even though it would have to be possible in some manner which cannot yet be indicated to represent such paths by organic elements of the nervous system. [1905c, 1735]
It appears to be far from easy to avoid the endopsychic employment of cathectes that have become superfluous, for in our thought-processes we are constantly in the habit of displacing such cathectes from one path to another without losing any of their energy by discharge. Jokes make use of the following methods with that aim in view. Firstly, they try to keep their expression as short as possible, so as to offer fewer points of attack to the attention. Secondly, they observe the condition of being easy to understand (see above); as soon as they call for intellectual work which would demand a choice between different paths of thought, they would endanger their effect not only by the unavoidable expenditure of thought but also by the awakening of attention. But besides this they employ the device of distracting attention by putting forward something in the joke’s form of expression which catches it, so that in the meantime the liberation of the inhibitory cathexis and its discharge may be completed without interruption. This aim is already fulfilled by the omissions in the joke’s wording; they offer an incitement to filling up the gaps and in that way succeed in withdrawing the joking process from attention. Here the technique of riddles, which attract the attention, is, as it were, brought into the service of the joke-work. Far more effective even are the façades which we have found especially in some groups of tendentious jokes (p. 1699 ff.). The syllogistic façades admirably fulfil the aim of holding the attention by setting it a task. While we are beginning to wonder what was wrong with the reply, we are already laughing; our attention has been caught unawares and the discharge of the liberated inhibitory cathexis has been completed. The same is true of jokes with a comic façade, in which the comic comes to the help of the joke-technique. A comic façade encourages the effectiveness of a joke in more than one way; not only does it make the automatism of the joking process possible, by holding the attention, but it also facilitates the discharge by the joke, by sending on ahead a discharge of a comic kind. The comic is here operating exactly like a bribing fore-pleasure, and we can in this way understand how some jokes are able to renounce entirely the fore-pleasure produced by the ordinary methods of joking and make use only of the comic for fore-pleasure. Among the joke-techniques proper, it is in particular displacement and representation by something absurd which, apart from their other qualifications, give rise, too, to a distraction of the attention which is desirable for the automatic course of the joking process.¹

¹ [1905c, 1739]

The sexual instinct - or, more correctly, the sexual instincts, for analytic investigation teaches us that the sexual instinct is made up of many separate constituents or component instincts - is probably more strongly developed in man than in most of the higher animals; it is certainly more constant, since it has almost entirely overcome the periodicity to which it is tied in animals. It places extraordinarily large amounts of force at the disposal of civilized activity, and it does this in virtue of its especially marked characteristic of being able to displace its aim without materially diminishing in intensity. This capacity to exchange its originally sexual aim for another one, which is no longer sexual but which is psychically related to the first aim, is called the capacity for sublimation. In contrast to this displaceability, in which its value for civilization lies, the sexual instinct may also exhibit a particularly obstinate fixation which renders it unserviceable and which sometimes causes it to degenerate into what are described as abnormalities. The original strength of the sexual instinct probably varies in each individual; certainly the proportion of it which is suitable for sublimation varies. It seems to us that it is the innate constitution of each individual which decides in the first instance how large a part of his sexual instinct it will be possible to sublimate and make use of. In addition to this, the effects of experience and the intellectual influences upon his mental apparatus succeed in bringing about the sublimation of a further portion of it. To extend this process of displacement indefinitely is, however, certainly not possible, any more than is the case with the transformation of heat into mechanical energy in our machines. A certain amount of direct sexual satisfaction seems to be indispensable for most organizations, and a deficiency in this amount, which varies from individual to individual, is visited by phenomena which, on account of their detrimental effects on functioning and their subjective quality of unpleasure, must be regarded as an illness. [1908d, 1952]
Our first reflection will tell us that it cannot be the case that this detachment of the libido occurs exclusively in paranoia; nor can it be that, where it occurs elsewhere, it has such disastrous consequences. It is quite possible that a detachment of the libido is the essential and regular mechanism of every repression. We can have no positive knowledge on that point until the other disorders that are based upon repression have been similarly examined. But it is certain that in normal mental life (and not only in periods of mourning) we are constantly detaching our libido in this way from people or from other objects without falling ill. When Faust freed himself from the world by uttering his curses, the result was not a paranoia or any other neurosis but simply a certain general frame of mind. The detachment of the libido, therefore, cannot in itself be the pathogenic factor in paranoia; there must be some special characteristic which distinguishes a paranoic detachment of the libido from other kinds. It is not difficult to suggest what that characteristic may be. What use is made of the libido after it has been set free by the process of detachment? A normal person will at once begin looking about for a substitute for the lost attachment; and until that substitute has been found the liberated libido will be kept in suspension within his mind, and will there give rise to tensions and colour his mood. In hysteria the liberated libido becomes transformed into somatic innervations or into anxiety. But in paranoia the clinical evidence goes to show that the libido, after it has been withdrawn from the object, is put to a special use. It will be remembered that the majority of cases of paranoia exhibit traces of megalomania, and that megalomania can by itself constitute a paranoia. From this it may be concluded that in paranoia the liberated libido becomes attached to the ego, and is used for the aggrandizement of the ego. A return is thus made to the stage of narcissism (known to us from the development of the libido), in which a person's only sexual object is his own ego. On the basis of this clinical evidence we can suppose that paranoids have brought along with them a fixation at the stage of narcissism, and we can assert that the length of the step back from sublimated homosexuality to narcissism is a measure of the amount of regression characteristic of paranoia.

Libido is an expression taken from the theory of the emotions. We call by that name the energy, regarded as a quantitative magnitude (though not at present actually measurable), of those instincts which have to do with all that may be comprised under the word 'love'. The nucleus of what we mean by love naturally consists (and this is what is commonly called love, and what the poets sing of) in sexual love with sexual union as its aim. But we do not separate from this - what in any case has a share in the name 'love' - on the one hand, self-love, and on the other, love for parents and children, friendship and love for humanity in general, and also devotion to concrete objects and to abstract ideas. Our justification lies in the fact that psycho-analytic research has taught us that all these tendencies are an expression of the same instinctual impulses; in relations between the sexes these impulses force their way towards sexual union, but in other circumstances they are diverted from this aim or are prevented from reaching it, though always preserving enough of their original nature to keep their identity recognizable (as in such features as the longing for proximity, and self-sacrifice).
Among the hypothetical concepts which enable the doctor to deal with the analytic material, the first to be mentioned is that of 'libido'. Libido means in psycho-analysis in the first instance the force (thought of as quantitatively variable and measurable) of the sexual instincts directed towards an object - 'sexual' in the extended sense required by analytic theory. Further study showed that it was necessary to set alongside this 'object-libido' a 'narcissistic' or 'ego-libido', directed to the subject's own ego; and the interaction of these two forces has enabled us to account for a great number of normal and abnormal processes in mental life. A rough distinction was soon made between what are known as the 'transference neuroses' and the narcissistic disorders. The former (hysteria and obsessional neurosis) are the objects proper of psycho-analytic treatment, while the others, the narcissistic neuroses, though they can, it is true, be examined by the help of analysis, offer fundamental difficulties to therapeutic influence. It is true that the libido theory of psycho-analysis is by no means complete and that its relation to a general theory of the instincts is not yet clear, for psycho-analysis is a young science, quite unfinished and in a stage of rapid development. Here, however, it should be emphatically pointed out how erroneous the charge of pan-sexualism is which is so often levelled at psycho-analysis. It seeks to show that psycho-analytic theory knows of no mental motive forces other than purely sexual ones and in doing so exploits popular prejudices by using the word 'sexual' not in its analytic but in its vulgar sense.

[1924f, 4113]
Those philosophers who have become aware that rational and highly complex thought-structures are possible without consciousness playing any part in them have found difficulty in assigning any function to consciousness; it has seemed to them that it can be no more than a superfluous reflected picture of the completed psychical process. We, on the other hand, are rescued from this embarrassment by the analogy between our Cs. system and the perceptual systems. We know that perception by our sense-organs has the result of directing a cathexis of attention to the paths along which the in-coming sensory excitation is spreading; the qualitative excitation of the Pcpt. system acts as a regulator of the discharge of the mobile quantity in the psychical apparatus. We can attribute the same function to the overlying sense-organ of the Cs. system. By perceiving new qualities, it makes a new contribution to directing the mobile quantities of cathexis and distributing them in an expedient fashion. By the help of its perception of pleasure and unpleasure it influences the discharge of the cathexes within what is otherwise an unconscious apparatus operating by means of the displacement of quantities. It seems probable that in the first instance the unpleasure principle regulates the displacement of cathexes automatically. But it is quite possible that consciousness of these qualities may introduce in addition a second and more discriminating regulation, which is even able to oppose the former one, and which perfects the efficiency of the apparatus by enabling it, in contradiction to its original plan, to cathect and work over even what is associated with the release of unpleasure. We learn from the psychology of the neuroses that these processes of regulation carried out by the qualitative excitation of the sense organs play a great part in the functional activity of the apparatus. The automatic domination of the primary unpleasure principle and the consequent restriction imposed upon efficiency are interrupted by the processes of sensory regulation, which are themselves in turn automatic in action. We find that repression (which, though it served a useful purpose to begin with, leads ultimately to a damaging loss of inhibition and mental control) affects memories so much more easily than perceptions because the former can receive no extra cathexis from the excitation of the psychical sense-organs. It is true on the one hand that a thought which has to be warded off cannot become conscious, because it has undergone repression; but on the other hand it sometimes happens that a thought of this kind is only repressed because for other reasons it has been withdrawn from conscious perception. Here are some hints of which we take advantage in our therapeutic procedure in order to undo repressions which have already been effected.

[1900a, 1041]

Now, however, I must draw your attention to the decisive difference between the symptoms of the 'actual' neuroses and those of the psychoneuroses, the first group of which, the transference neuroses, have occupied us so much hitherto. In both cases the symptoms originate from the libido, and are thus abnormal employments of it, substitutive satisfactions. But the symptoms of the 'actual' neuroses - intracranial pressure, sensations of pain, a state of irritation in an organ, weakening or inhibition of a function - have no 'sense', no psychical meaning. They are not only manifested predominantly in the body (as are hysterical symptoms, for instance, as well), but they are also themselves entirely somatic processes, in the generating of which all the complicated mental mechanisms we have come to know are absent. Thus they really are what psychoneurotic symptoms were so long believed to be. But if so, how can they correspond to employments of the libido, which we have recognized as a force operating in the mind? Well, Gentlemen, that is a very simple matter. Let me remind you of one of the very first objections that were brought up against psycho-analysis. It was said then that it was occupied in finding a purely psychological theory of neurotic phenomena and this was quite hopeless, since psychological theories could never explain an illness. People had chosen to forget that the sexual function is not a purely psychical thing any more than it is a purely somatic one. It influences bodily and mental life alike. If in the symptoms of the psychoneuroses we have become acquainted with manifestations of disturbances in the psychical operation of the sexual function, we shall not be surprised to find in the 'actual' neuroses the direct somatic consequences of sexual disturbances.

[1916-1917, 3439]
But I shall resist the temptation of going further here or of discussing other situations which can be understood or pictured if we adopt the hypothesis that the object-libido may withdraw into the ego - for I am obliged to meet two objections which, as I know, are now attracting your attention. In the first place you want to call me to account because in talking of sleep, illness and similar situations I invariably try to separate libido from interest, sexual from ego-instincts, where observations can be fully satisfied by the hypothesis of a single and uniform energy which, being freely mobile, cathects now the object and now the ego, in obedience to one or the other instinct. And in the second place you want to know how I can venture to treat the detaching of the libido from the object as the source of a pathological state, when a transposition of this kind of object-libido into ego-libido (or, more generally, into ego-energy) is among the normal processes of mental dynamics which are repeated daily and every night.

The opposition which he at first offered to religion had three different points of origin. To begin with, there was, in general, his characteristic (which we have seen exemplified already) of fending off all novelties. Any position of the libido which he had once taken up was obstinately defended by him from fear of what he would lose by giving it up and from distrust of the probability of a complete substitute being afforded by the new position that was in view. This is an important and fundamental psychological peculiarity, which I described in my *Three Essays on the Theory of Sexuality* (1905) as a susceptibility to 'fixation'. Under the name of psychical 'inertia' Jung has attempted to erect it into the principal cause of all the failures of neurotics. I think he is wrong in this; for this factor has a far more general application and plays an important part in the lives of the non-neurotic as well. Great mobility or sluggishness of libidinal cathexes (as well as of other kinds of energetic cathexes) are special characteristics which attach to many normal people and by no means to all neurotics, and which have hitherto not been brought into relation with other qualities. They are, as it were, like prime numbers, not further divisible. We only know one thing about them, and that is that mobility of the mental cathexes is a quality which shows striking diminution with the advance of age. This has given us one of the indications of the limits within which psycho-analytic treatment is effective. There are some people, however, who retain this mental plasticity far beyond the usual age-limit, and others who lose it very prematurely. If the latter are neurotics, we make the unwelcome discovery that it is impossible to undo developments in them which, in apparently similar circumstances, have been easily dealt with in other people. So that in considering the conversion of psychical energy no less than of physical, we must make use of the concept of an entropy, which opposes the undoing of what has already occurred.

Thus in our view the individual advances from narcissism to object-love. But we do not believe that the whole of the libido ever passes over from the ego to objects. A certain quantity of libido is always retained in the ego; even when object-love is highly developed, a certain amount of narcissism persists. The ego is a great reservoir from which the libido that is destined for objects flows out and into which it flows back from those objects. Object-libido was at first ego-libido and can be transformed back into ego-libido. For complete health it is essential that the libido should not lose this full mobility. As an illustration of this state of things we may think of an amoeba, whose viscous substance puts out pseudopodia, elongations into which the substance of the body extends but which can be retracted at any time so that the form of the protoplasmic mass is restored.
Among the hypothetical concepts which enable the doctor to deal with the analytic material, the first to be mentioned is that of 'libido'. Libido means in psycho-analysis in the first instance the force (thought of as quantitatively variable and measurable) of the sexual instincts directed towards an object - 'sexual' in the extended sense required by analytic theory. Further study showed that it was necessary to set alongside this 'object-libido' a 'narcissistic' or 'ego-libido', directed to the subject's own ego: and the interaction of these two forces has enabled us to account for a great number of normal and abnormal processes in mental life. A rough distinction was soon made between what are known as the 'transference neuroses' and the narcissistic disorders. The former (hysteria and obsessional neurosis) are the objects proper of psycho-analytic treatment, while the others, the narcissistic neuroses, though they can, it is true, be examined by the help of analysis, offer fundamental difficulties to therapeuetic influence. It is true that the libido theory of psycho-analysis is by no means complete and that its relation to a general theory of the instincts is not yet clear, for psycho-analysis is a young science, quite unfinished and in a stage of rapid development. Here, however, it should be emphatically pointed out how erroneous the charge of pan-sexualism is which is so often levelled at psycho-analysis. It seeks to show that psycho-analytic theory knows of no mental motive forces other than purely sexual ones and in doing so exploits popular prejudices by using the word 'sexual' not in its analytic but in its vulgar sense.
[1924f, 4113]
We can follow the object-libido through still further vicissitudes. When it is withdrawn from objects, it is held in suspense in peculiar conditions of tension and is finally drawn back into the ego, so that it becomes ego-libido once again. In contrast to object-libido, we also describe ego-libido as 'narcissistic' libido. From the vantage-point of psycho-analysis we can look across a frontier, which we may not pass, at the activities of narcissistic libido, and may form some idea of the relation between it and object-libido.¹ Narcissistic or ego-libido seems to be the great reservoir from which the object-cathexes are sent out and into which they are withdrawn once more; the narcissistic libidinal cathexis of the ego is the original state of things, realized in earliest childhood, and is merely covered by the later extrusions of libido, but in essentials persists behind them.

[1905d, 1532]

Although we are not yet in a position to describe with sufficient accuracy the characteristics of this narcissistic stage, at which the hitherto dissociated sexual instincts come together into a single unity and cathect the ego as an object, we suspect already that this narcissistic organization is never wholly abandoned. A human being remains to some extent narcissistic even after he has found external objects for his libido. The cathexes of objects which he effects are as it were emanations of the libido that still remains in his ego and can be drawn back into it once more. The state of being in love, which is psychologically so remarkable and is the normal prototype of the psychoses, shows these emanations at their maximum compared to the level of self-love.

[1912-1913, 2732]

Hitherto it has been a premiss of our work that we can distinguish the ego-instincts from the sexual ones by their manifestations. With the transference neuroses this could be done without difficulty. We termed the cathexes of energy which the ego directs towards the objects of its sexual desires 'libido'; all the others, which are sent out by the self-preservative instincts, we termed 'interest'. By tracing the course of the libidinal cathexes, their transformations and final vicissitudes, we were able to obtain a first insight into the machinery of the mental forces. For this purpose the transference neuroses offered us the most favourable material. But the ego, its composition out of various organizations and their construction and mode of functioning, remained hidden from us; and we were driven to suspect that only the analysis of other neurotic disorders would be able to bring us the necessary insight.

[1916-1917, 3460]

Reflection will quickly suggest that if any such fixation of the libido to the subject's own body and personality, instead of to an object does occur, it cannot be an exception or a trivial event. On the contrary it is probable that this narcissism is the universal and original state of things, from which object-love is only later developed, without the narcissism necessarily disappearing on that account. Indeed we had to recall from the history of the development of object-libido that many sexual instincts begin by finding satisfaction in the subject's own body - auto-erotically, as we say - and that this capacity for auto-erotism is the basis of the lagging-behind of sexuality in the process of education in the reality principle. Auto-erotism would thus be the sexual activity of the narcissistic stage of allocation of the libido.

[1916-1917, 3461]
To put the matter shortly, we pictured the relation of ego-libido to object-libido in a way which I can make plain to you by an analogy from zoology. Think of those simplest of living organisms which consist of a little-differentiated globule of protoplasmic substance. They put out protrusions, known as pseudopodia, into which they cause the substance of their body to flow over. They are able, however, to withdraw the protrusions once more and form themselves again into a globule. We compare the putting-out of these protrusions, then, to the emission of libido on to objects while the main mass of libido can remain in the ego; and we suppose that in normal circumstances ego-libido can be transformed unhindered into object-libido and that this can once more be taken back into the ego.

With the help of these ideas we are now able to explain a whole number of mental states or, to express it more modestly, to describe them in terms of the libido theory - states which we must reckon as belonging to normal life, such as the psychical behaviour of a person in love, during an organic illness or when asleep. As regards the state of sleep, we assumed that it was based on turning-away from the external world and adopting a wish to sleep. The mental activity during the night which is manifested in dreams takes place, we found, in obedience to a wish to sleep and is moreover dominated by purely egoistic motives. We may now add, on the lines of the libido theory, that sleep is a state in which all object-cathexes, libidinal as well as egoistic, are given up and withdrawn into the ego. May not this throw a fresh light on the recuperating effect of sleep and on the nature of fatigue in general? The picture of the blissful isolation of intra-uterine life which a sleeper conjures up once more before us every night is in this way completed on its psychical side as well. In a sleeper the primal state of distribution of the libido is restored - total narcissism, in which libido and ego-interest, still united and indistinguishable, dwell in the self-sufficing ego.

This is the place for two remarks. First, how do we differentiate between the concepts of narcissism and egoism? Well, narcissism, I believe, is the libidinal complement to egoism. When we speak of egoism, we have in view only the individual's advantage; when we talk of narcissism we are also taking his libidinal satisfaction into account. As practical motives the two can be traced separately for quite a distance. It is possible to be absolutely egoistic and yet maintain powerful object-cathexes, in so far as libidinal satisfaction in relation to the object forms part of the ego's needs. In that case, egoism will see to it that striving for the object involves no damage to the ego. It is possible to be egoistic and at the same time to be excessively narcissistic - that is to say, to have very little need for an object, whether, once more, for the purpose of direct sexual satisfaction, or in connection with the higher aspirations, derived from sexual need, which we are occasionally in the habit of contrasting with 'sensuality' under the name of 'love'. In all these connections egoism is what is self-evident and constant, while narcissism is the variable element. The opposite to egoism, altruism, does not, as a concept, coincide with libidinal object-cathexis, but is distinguished from it by the absence of longings for sexual satisfaction. When someone is completely in love, however, altruism converges with libidinal object-cathexis. As a rule the sexual object attracts a portion of the ego's narcissism to itself, and this becomes noticeable as what is known as the 'sexual overvaluation' of the object. If in addition there is an altruistic transposition of egoism on to the sexual object, the object becomes supremely powerful; it has, as it were, absorbed the ego.
Homosexual object-choice originally lies closer to narcissism than does the heterosexual kind. When it is a question, therefore, of repelling an undesirably strong homosexual impulse, the path back to narcissism is made particularly easy. Hitherto I have had very little opportunity of talking to you about the foundations of erotic life so far as we have discovered them, and it is too late now to catch up on the omission. This much, however, I can emphasize to you. Object-choice, the step forward in the development of the libido which is made after the narcissistic stage, can take place according to two different types: either according to the narcissistic type, where the subject's own ego is replaced by another one that is as similar as possible, or according to the attachment type, where people who have become precious through satisfying the other vital needs are chosen as objects by the libido as well. A strong libidinal fixation to the narcissistic type of object-choice is to be included in the predisposition to manifest homosexuality.

[1916-1917, 3470]

During the work of treatment we have to consider the distribution of the patient's libido; we look for the object presentations to which it is bound and free it from them, so as to place it at the disposal of the ego. In the course of this, we have come to form a very curious picture of the original, primal distribution of libido in human beings. We have been driven to assume that at the beginning of the development of the individual all his libido (all his erotic tendencies, all his capacity for love) is tied to himself - that as we say, it cathects his own ego. It is only later that, being attached to the satisfaction of the major vital needs, the libido flows over from the ego on to external objects. Not till then are we able to recognize the libidinal instincts as such and distinguish them from the ego instincts. It is possible for the libido to become detached from these objects and withdrawn again into the ego.

[1917a, 3609]

The next step was taken when psycho-analysis felt its way closer towards the psychological ego, which it had first come to know only as a repressive, censoring agency, capable of erecting protective structures and reactive formations. Critical and far-seeing minds had, it is true, long since objected to the concept of libido being restricted to the energy of the sexual instincts directed towards an object. But they failed to explain how they had arrived at their better knowledge or to derive from it anything of which analysis could make use. Advancing more cautiously, psycho-analysis observed the regularity with which libido is withdrawn from the object and directed on to the ego (the process of introversion); and, by studying the libidinal development of children in its earliest phases, came to the conclusion that the ego is the true and original reservoir of libido, and that it is only from that reservoir that libido is extended on to objects. The ego now found its position among sexual objects and was at once given the foremost place among them. Libido which was in this way lodged in the ego was described as 'narcissistic'.¹ This narcissistic libido was of course also a manifestation of the force of the sexual instinct in the analytical sense of those words, and it had necessarily to be identified with the 'self-preservative instincts' whose existence had been recognized from the first. Thus the original opposition between the ego-instincts and the sexual instincts proved to be inadequate. A portion of the ego-instincts was seen to be libidinal; sexual instincts - probably alongside others - operated in the ego. Nevertheless we are justified in saying that the old formula which lays it down that psychoneuroses are based on a conflict between ego-instincts and sexual instincts contains nothing that we need reject to-day. It is merely that the distinction between the two kinds of instinct, which was originally regarded as in some sort of way qualitative, must now be characterized differently - namely as being topographical. And in particular it is still true that the transference neuroses, the essential subject of psycho-analytic study, are the result of a conflict between the ego and the libidinal cathexis of objects.

[1920g, 3753]
Narcissism. - The most important theoretical advance has certainly been the application of the libido theory to the repressing ego. The ego itself came to be regarded as a reservoir of what was described as narcissistic libido, from which the libidinal cathexes of objects flowed out and into which they could be once more withdrawn. By the help of this conception it became possible to embark upon the analysis of the ego and to make a clinical distinction of the psychoneuroses into transference neuroses and narcissistic disorders. In the former (hysteria and obsessional neurosis) the subject has at his disposal a quantity of libido striving to be transferred on to extraneous objects, and use is made of this in carrying out analytic treatment; on the other hand, the narcissistic disorders (dementia praecox, paranoia, melancholia) are characterized by a withdrawal of the libido from objects and they are therefore scarcely accessible to analytic therapy. But their therapeutic inaccessibility has not prevented analysis from making the most fruitful beginnings in the deeper study of these illnesses, which are counted among the psychoses.

[1923a, 3925]

Narcissism. - A decisive advance was made when the analysis of dementia praecox and other psychotic disorders was ventured upon and thus the examination was begun of the ego itself, which had so far been known only as the agency of repression and opposition. It was found that the pathogenic process in dementia praecox is the withdrawal of the libido from objects and its introduction into the ego, while the clamorous symptoms of the disease arise from the vain struggles of the libido to find a pathway back to objects. It thus turned out to be possible for object-libido to change into cathexis of the ego and vice versa. Further reflection showed that this process must be presumed to occur on the largest scale and that the ego is to be regarded as a great reservoir of libido from which libido is sent out to objects and which is always ready to absorb libido flowing back from objects. Thus the instincts of self-preservation were also of a libidinal nature: they were sexual instincts which, instead of external objects, had taken the subject's own ego as an object. Clinical experience had made us familiar with people who behaved in a striking fashion as though they were in love with themselves and this perversion had been given the name of narcissism. The libido of the self-preservative instincts was now described as narcissistic libido and it was recognized that a high degree of this self-love constituted the primary and normal state of things. The earlier formula laid down for the transference neuroses consequently required to be modified, though not corrected. It was better, instead of speaking of a conflict between sexual instincts and ego instincts, to speak of a conflict between object-libido and ego-libido, or, since the nature of these instincts was the same, between the object-cathexes and the ego.

[1923a, 3933]

¹ Now that we have distinguished between the ego and the id, we must recognize the id as the great reservoir of libido indicated in my paper on narcissism (1914c). The libido which flows into the ego owing to the identifications described above brings about its 'secondary narcissism'.

[1923b, 3964]
In the Oedipus complex the libido was seen to be attached to the image of the parental figures. But earlier there was a period in which there were no such objects. There followed from this fact the concept (of fundamental importance for the libido theory) of a state in which the subject's libido filled his own ego and had that for its object. This state could be called narcissism or self-love. A moment's reflection showed that this state never completely ceases. All through the subject's life his ego remains the great reservoir of his libido, from which object-cathexes are sent out and into which the libido can stream back again from the objects. Thus narcissistic libido is constantly being transformed into object-libido, and vice versa. An excellent instance of the length to which this transformation can go is afforded by the state of being in love, whether in a sexual or sublimated manner, which goes so far as involving a sacrifice of the self. Whereas hitherto in considering the process of repression attention had only been paid to what was repressed, these ideas made it possible to form a correct estimate of the repressing forces too. It had been said that repression was set in action by the instincts of self-preservation operating in the ego (the 'ego-instincts') and that it was brought to bear upon the libidinal instincts. But since the instincts of self-preservation were now recognized as also being of a libidinal nature, as being narcissistic libido, the process of repression was seen to be a process occurring within the libido itself; narcissistic libido was opposed to object-libido, the interest of self-preservation was defending itself against the demands of object-love, and therefore against the demands of sexuality in the narrower sense as well.

[1925d, 4231]
Every analyst will admit that even to-day this view has not the sound of a long-discarded error. Nevertheless, alterations in it became essential, as our enquiries advanced from the repressed to the repressing forces, from the object-instincts to the ego. The decisive step forward was the introduction of the concept of narcissism - that is to say, the discovery that the ego itself is cathected with libido, that the ego, indeed, is the libido's original home, and remains to some extent its headquarters. This narcissistic libido turns towards objects, and thus becomes object-libido; and it can change back into narcissistic libido once more. The concept of narcissism made it possible to obtain an analytic understanding of the traumatic neuroses and of many of the affections bordering on the psychoses, as well as of the latter themselves. It was not necessary to give up our interpretation of the transference neuroses as attempts made by the ego to defend itself against sexuality; but the concept of libido was endangered. Since the ego-instincts, too, were libidinal, it seemed for a time inevitable that we should make libido coincide with instincual energy in general, as C. G. Jung had already advocated earlier. Nevertheless, there still remained in me a kind of conviction, for which I was not as yet able to find reasons, that the instincts could not all be of the same kind. My next step was taken in Beyond the Pleasure Principle (1920), when the compulsion to repeat and the conservative character of instincual life first attracted my attention. Starting from speculations on the beginning of life and from biological parallels, I drew the conclusion that, besides the instinct to preserve living substance and to join it into ever larger units,¹ there must exist another, contrary instinct seeking to dissolve those units and to bring them back to their primaeval, inorganic state. That is to say, as well as Eros there was an instinct of death. The phenomena of life could be explained from the concurrent or mutually opposing action of these two instincts. It was not easy, however, to demonstrate the activities of this supposed death instinct. The manifestations of Eros were conspicuous and noisy enough. It might be assumed that the death instinct operated silently within the organism towards its dissolution, but that, of course, was no proof. A more fruitful idea was that a portion of the instinct is diverted towards the external world and comes to light as an instinct of aggressiveness and destructiveness. In this way the instinct itself could be pressed into the service of Eros, in that the organism was destroying some other thing, whether animate or inanimate, instead of destroying its own self. Conversely, any restriction of this aggressiveness directed outwards would be bound to increase the self-destruction, which is in any case proceeding. At the same time one can suspect from this example that the two kinds of instinct seldom - perhaps never - appear in isolation from each other, but are alloyed with each other in varying and very different proportions and so become unrecognizable to our judgement. In sadism, long since known to us as a component instinct of sexuality, we should have before us a particularly strong alloy of this kind between trends of love and the destructive instinct; while its counterpart, masochism, would be a union between destructiveness directed inwards and sexuality - a union which makes what is otherwise an imperceptible trend into a conspicuous and tangible one.

[1930a, 4509]
It is now time, however, for me to go back both in history and in my subject-matter and once more to take up the most general problems of instinctual life. To begin with, the opposition between the ego-instincts and the sexual instincts lay at the base of our libido theory. When later on we began to study the ego itself more closely and arrived at the conception of narcissism, this distinction itself lost its foundation. In rare cases one can observe that the ego has taken itself as an object and is behaving as though it were in love with itself. Hence the term 'narcissism', borrowed from the Greek myth. But that is only an extreme exaggeration of a normal state of affairs. We came to understand that the ego is always the main reservoir of libido, from which libidinal cathexes of objects go out and into which they return again, while the major part of this libido remains permanently in the ego. Thus ego-libido is being constantly changed into object-libido and object-libido into ego-libido. But in that case they could not be different in their nature and it could have no sense to distinguish the energy of the one from the energy of the other; we could either drop the term 'libido' or use it as synonymous with psychical energy in general. 

[1933a, 4706]

It is hard to say anything of the behaviour of the libido in the id and in the super-ego. All that we know about it relates to the ego, in which at first the whole available quota of libido is stored up. We call this state absolute, primary narcissism. It lasts till the ego begins to cathect the ideas of objects with libido, to transform narcissistic libido into object-libido. Throughout the whole of life the ego remains the great reservoir from which libidinal cathexes are sent out to objects and into which they are also once more withdrawn, just as an amoeba behaves with its pseudopodia. It is only when a person is completely in love that the main quota of libido is transferred on to the object and the object to some extent takes the place of the ego. A characteristic of the libido which is important in life is its mobility, the facility with which it passes from one object to another. This must be contrasted with the fixation of the libido to particular objects, which often persists throughout life.

[1940a [1938], 4961]
I was further made aware of a defect in the account I have given in the text, which, in the interests of lucidity, describes the conceptual distinction between the two phases of auto-erotism and object-love as though it were also a separation in time. But the analyses that I have just mentioned, as well as the findings of Bell quoted on p. 1496 above, show that children between the ages of three and five are capable of very clear object-choice, accompanied by strong affects.

[1905d, 1512]

The characteristics of infantile sexual life which we have hitherto emphasized are the facts that it is essentially auto-erotic (i.e. that it finds its object in the infant's own body) and that its individual component instincts are upon the whole disconnected and independent of one another in their search for pleasure. The final outcome of sexual development lies in what is known as the normal sexual life of the adult, in which the pursuit of pleasure comes under the sway of the reproductive function and in which the component instincts, under the primacy of a single erotogenic zone, form a firm organization directed towards a sexual aim attached to some extraneous sexual object.

[1905d, 1516]

As we all know, it is not until puberty that the sharp distinction is established between the masculine and feminine characters. From that time on, this contrast has a more decisive influence than any other upon the shaping of human life. It is true that the masculine and feminine dispositions are already easily recognizable in childhood. The development of the inhibitions of sexuality (shame, disgust, pity, etc.) takes place in little girls earlier and in the face of less resistance than in boys; the tendency to sexual repression seems in general to be greater; and, where the component instincts of sexuality appear, they prefer the passive form. The auto-erotic activity of the erotogenic zones is, however, the same in both sexes, and owing to this uniformity there is no possibility of a distinction between the two sexes such as arises after puberty. So far as the auto-erotic and masturbatory manifestations of sexuality are concerned, we might lay it down that the sexuality of little girls is of a wholly masculine character. Indeed, if we were able to give a more definite connotation to the concepts of 'masculine' and 'feminine', it would even be possible to maintain that libido is invariably and necessarily of a masculine nature, whether it occurs in men or in women and irrespective of whether its object is a man or a woman.¹

[1905d, 1533]
After having explained the preponderance of perverse tendencies in psychoneurotics by recognizing it as a collateral filling of subsidiary channels when the main current of the instinctual stream has been blocked by 'repression',¹ we proceeded to a consideration of sexual life in childhood. We found it a regrettable thing that the existence of the sexual instinct in childhood has been denied and that the sexual manifestations not infrequently to be observed in children have been described as irregularities. It seemed to us on the contrary that children bring germs of sexual activity with them into the world, that they already enjoy sexual satisfaction when they begin to take nourishment and that they persistently seek to repeat the experience in the familiar activity of 'thumb-sucking'. The sexual activity of children, however, does not, it appeared, develop pari passu with their other functions, but, after a short period of efflorescence from the ages of two to five, enters upon the so-called period of latency. During that period the production of sexual excitation is not by any means stopped but continues and produces a store of energy which is employed to a great extent for purposes other than sexual - namely, on the one hand in contributing the sexual components to social feelings and on the other hand (through repression and reaction-forming) in building up the subsequently developed barriers against sexuality. On this view, the forces destined to retain the sexual instinct upon certain lines are built up in childhood chiefly at the cost of perverse sexual impulses and with the assistance of education. A certain portion of the infantile sexual impulses would seem to evade these uses and succeed in expressing itself as sexual activity. We next found that sexual excitation in children springs from a multiplicity of forces. Satisfaction arises first and foremost from the appropriate sensory excitation of what we have described as erotogenic zones. It seems probable that any part of the skin and any sense-organ - probably, indeed, any organ - can function as an erotogenic zone, though there are some particularly marked erotogenic zones whose excitation would seem to be secured from the very first by certain organic contrivances. It further appears that sexual excitation arises as a by-product, as it were, of a large number of processes that occur in the organism, as soon as they reach a certain degree of intensity, and most especially of any relatively powerful emotion, even though it is of a distressing nature. The excitations from all these sources are not yet combined; but each follows its own separate aim, which is merely the attainment of a certain sort of pleasure. In childhood, therefore, the sexual instinct is not unified and is at first without an object, that is, auto-erotic.  

[1905d, 1543]
I do not know how the case could be better stated, but perhaps I may add a few remarks. It is undoubtedly nothing else but the customary prudishness and their own bad conscience over sexual matters that causes adults to adopt this attitude of 'mystery-making' in front of children; but possibly a part is also played by a piece of theoretical ignorance on their part, which we can counteract by giving the adults some enlightenment. It is commonly believed that the sexual instinct is absent in children and only begins to emerge in them at puberty when the sexual organs mature. This is a gross error, equally serious in its effects both on knowledge and on practice; and it is so easily corrected by observation that one wonders how it could ever have been made. As a matter of fact, the new-born baby brings sexuality with it into the world, certain sexual sensations accompany its development as a suckling and during early childhood, and only very few children would seem to escape sexual activities and sensations before puberty. Anyone who would like to find a detailed exposition of these statements can do so in my *Three Essays on the Theory of Sexuality*, to which I have referred above. There he will learn that the organs of reproduction proper are not the only parts of the body which provide sexual sensations of pleasure, and that nature has even so ordered matters that actual stimulations of the genitals are unavoidable during early childhood. This period of life, during which a certain quota of what is undoubtedly sexual pleasure is produced by the excitation of various parts of the skin (erotogenic zones), by the activity of certain biological instincts and as an accompanying excitation in many affective states, is called the period of *auto-erotism*, to use a term introduced by Havelock Ellis. All that puberty does is to give the genitals primacy among all the other zones and sources which produce pleasure, and thus to force erotism into the service of the function of reproduction. This process can naturally undergo certain inhibitions, and in many people (those who later become perverts and neurotics) it is only incompletely accomplished. On the other hand, the child is capable long before puberty of most of the psychical manifestations of love-tenderness, for example, devotion and jealousy. Often enough, too, an irruption of these mental states is associated with the physical sensations of sexual excitation, so that the child cannot remain in doubt as to the connection between the two. In short, except for his reproductive power, a child has a fully-developed capacity for love long before puberty; and it may be asserted that the 'mystery-making' merely prevents him from being able to gain an intellectual grasp of activities for which he is psychically prepared and physically adjusted.

[1907c, 1914]
Unconscious phantasies have either been unconscious all along and have been formed in the unconscious; or - as is more often the case - they were once conscious phantasies, daydreams, and have since been purposely forgotten and have become unconscious through 'repression'. Their content may afterwards either have remained the same or have undergone alterations, so that the present unconscious phantasies are derivatives of the once conscious ones. Now an unconscious phantasy has a very important connection with the subject's sexual life; for it is identical with the phantasy which served to give him sexual satisfaction during a period of masturbation. At that time the masturbatory act (in the widest sense of the term) was compounded of two parts. One was the evocation of a phantasy and the other some active behaviour for obtaining self-gratification at the height of the phantasy. This compound, as we know, was itself merely soldered together.¹ Originally the action was a purely auto-erotic procedure for the purpose of obtaining pleasure from some particular part of the body, which could be described as erotogenic. Later, this action became merged with a wishful idea from the sphere of object-love and served as a partial realization of the situation in which the phantasy culminated. When, subsequently, the subject renounces this type of satisfaction, composed of masturbation and phantasy, the action is given up, while the phantasy, from being conscious, becomes unconscious. If no other mode of sexual satisfaction supervenes, the subject remains abstinent; and if he does not succeed in sublimating his libido - that is, in deflecting his sexual excitation to higher aims -, the condition is now fulfilled for his unconscious phantasy to be revived and to proliferate, and, at least as regards some part of its content, to put itself into effect, with the whole force of his need for love, in the form of a pathological symptom.
[1908a, 1934]

Further prospects are opened up when we take into consideration the fact that in man the sexual instinct does not originally serve the purposes of reproduction at all, but has as its aim the gaining of particular kinds of pleasure.¹ It manifests itself in this way in human infancy, during which it attains its aim of gaining pleasure not only from the genitals but from other parts of the body (the erotogenic zones), and can therefore disregard any objects other than these convenient ones. We call this stage the stage of auto-erotism, and the child's upbringing has, in our view, the task of restricting it, because to linger in it would make the sexual instinct uncontrollable and unserviceable later on. The development of the sexual instinct then proceeds from auto-erotism to object-love and from the autonomy of the erotogenic zones to their subordination under the primacy of the genitals, which are put at the service of reproduction. During this development a part of the sexual excitation which is provided by the subject's own body is inhibited as being unserviceable for the reproductive function and in favourable cases is brought to sublimation. The forces that can be employed for cultural activities are thus to a great extent obtained through the suppression of what are known as the perverse elements of sexual excitation.
[1908d, 1953]

If we take the second of these stages as an average, we must point out that a number of people are, on account of their organization, not equal to meeting its demands. In whole classes of individuals the development of the sexual instinct, as we have described it above, from auto-erotism to object-love with its aim of uniting the genitals, has not been carried out correctly and sufficiently fully. As a result of these disturbances of development two kinds of harmful deviation from normal sexuality - that is, sexuality which is serviceable to civilization - come about; and the relation between these two is almost that of positive and negative.¹
[1908d, 1953]
In considering the question of abstinence, the distinction is not nearly strictly enough made between two forms of it - namely abstention from any sexual activity whatever and abstention from sexual intercourse with the opposite sex. Many people who boast of succeeding in being abstinent have only been able to do so with the help of masturbation and similar satisfactions which are linked with the auto-erotic sexual activities of early childhood. But precisely because of this connection such substitutive means of sexual satisfaction are by no means harmless; they predispose to the numerous varieties of neuroses and psychoses which are conditional on an involution of sexual life to its infantile forms. Masturbation, moreover, is far from meeting the ideal demands of civilized sexual morality, and consequently drives young people into the same conflicts with the ideals of education which they hoped to escape by abstinence. Furthermore, it vitiates the character through indulgence, and this in more than one way. In the first place, it teaches people to achieve important aims without taking trouble and by easy paths instead of through an energetic exertion of force - that is, it follows the principle that sexuality lays down the pattern of behaviour; secondly, in the phantasies that accompany satisfaction the sexual object is raised to a degree of excellence which is not easily found again in reality. A witty writer (Karl Kraus in the Vienna paper Die Fackel) once expressed this truth in reverse by cynically remarking: 'Copulation is no more than an unsatisfying substitute for masturbation.'

The first of these theories starts out from the neglect of the differences between the sexes on which I laid stress at the beginning of this paper as being characteristic of children. It consists in attributing to everyone, including females, the possession of a penis, such as the boy knows from his own body. It is precisely in what we must regard as the 'normal' sexual constitution that already in childhood the penis is the leading erotogenic zone and the chief auto-erotic sexual object; and the boy's estimate of its value is logically reflected in his inability to imagine a person like himself who is without this essential constituent. When a small boy sees his little sister's genitals, what he says shows that his prejudice is already strong enough to falsify his perception. He does not comment on the absence of a penis, but invariably says, as though by way of consolation and to put things right: 'Her ---'s still quite small. But when she gets bigger it'll grow all right.' The idea of a woman with a penis returns in later life, in the dreams of adults: the dreamer, in a state of nocturnal sexual excitation, will throw a woman down, strip her and prepare for intercourse - and then, in place of the female genitals, he beholds a well-developed penis and breaks off the dream and the excitation. The numerous hermaphrodites of classical antiquity faithfully reproduce this idea, universally held in childhood; one may observe that to most normal people they cause no offence, while the real hermaphroditic formations of the genitals which are permitted to occur by Nature nearly always excite the greatest abhorrence.

Investigation of the childhood history of hysterical patients shows that the hysterical attack is designed to take the place of an auto-erotic satisfaction previously practised and since given up. In a great number of cases this satisfaction (masturbation by contact or by pressure of the thighs, or, again, by movements of the tongue, and so on) recurs during the attack itself, while the subject's consciousness is deflected. Moreover, the onset of an attack that is due to an increase of libido and is in the service of the primary purpose - as a consolation - exactly repeats the conditions under which, at the earlier time, the patient had intentionally sought this auto-erotic satisfaction. The anamnesis of the patient shows the following stages: (a) auto-erotic satisfaction, without ideational content; (b) the same satisfaction, connected with a phantasy which leads to the act of satisfaction; (c) renunciation of the act, with retention of the phantasy; (d) repression of the phantasy, which then comes into effect as a hysterical attack, either in an unchanged form, or in a modified one and adapted to new environmental impressions. Furthermore, (e) the phantasy may even reinstate the act of satisfaction belonging to it which had ostensibly been given up. This is a typical cycle of infantile sexual activity: repression, failure of repression, and return of the repressed.
We should be doing Hans an injustice if we were to trace only the auto-erotic features of his sexual life. His father has detailed information to give us on the subject of his love relationships with other children. From these we can discern the existence of an 'object-choice' just as in the case of an adult; and also, it must be confessed, a very striking degree of inconstancy and a disposition to polygamy.

[1909b, 2010]

The first trait in little Hans which can be regarded as part of his sexual life was a quite peculiarly lively interest in his 'widdler' - an organ deriving its name from that one of its two functions which, scarcely the less important of the two, is not to be eluded in the nursery. This interest aroused in him the spirit of enquiry, and he thus discovered that the presence or absence of a widdler made it possible to differentiate between animate and inanimate objects. He assumed that all animate objects were like himself, and possessed this important bodily organ; he observed that it was present in the larger animals, suspected that this was so too in both his parents, and was not deterred by the evidence of his own eyes from authenticating the fact in his new-born sister. One might almost say that it would have been too shattering a blow to his 'Weltanschauung' if he had had to make up his mind to forgo the presence of this organ in a being similar to him; it would have been as though it were being torn away from himself. It was probably on this account that a threat of his mother's, which was concerned precisely with the loss of his widdler, was hastily dismissed from his thoughts and only succeeded in making its effects apparent at a later period. The reason for his mother's intervention had been that he used to like giving himself feelings of pleasure by touching his member: the little boy had begun to practise the commonest - and most normal - form of auto-erotic sexual activity.

[1909b, 2091]

The pleasure which a person takes in his own sexual organ may become associated with scopophilia (or sexual pleasure in looking) in its active and passive forms, in a manner which has been very aptly described by Alfred Adler (1908) as 'confluence of instincts'. So little Hans began to try to get a sight of other people's widdlers; his sexual curiosity developed, and at the same time he liked to exhibit his own widdler. One of his dreams, dating from the beginning of his period of repression, expressed a wish that one of his little girl friends should assist him in widdling, that is, that she should share the spectacle. The dream shows, therefore, that up till then this wish had subsisted unpressed, and later information confirmed the fact that he had been in the habit of gratifying it. The active side of his sexual scopophilia soon became associated in him with a definite theme. He repeatedly expressed both to his father and his mother his regret that he had never yet seen their widdlers; and it was probably the need for making a comparison which impelled him to do this. The ego is always the standard by which one measures the external world; one learns to understand it by means of a constant comparison with oneself. Hans had observed that large animals had widdlers that were correspondingly larger than his; he consequently suspected that the same was true of his parents, and was anxious to make sure of this. His mother, he thought, must certainly have a widdler 'like a horse'. He was then prepared with the comforting reflection that his widdler would grow with him. It was as though the child's wish to be bigger had been concentrated on his genitals.

[1909b, 2091]
Thus in little Hans's sexual constitution the genital zone was from the outset the one among his erogenous zones which afforded him the most intense pleasure. The only other similar pleasure of which he gave evidence was excretory pleasure, the pleasure attached to the orifices through which micturition and evacuation of the bowels are effected. In his final phantasy of bliss, with which his illness was overcome, he imagined he had children, whom he took to the W.C., whom he made to widdle, whose behinds he wiped - for whom, in short, he did 'everything one can do with children'; it therefore seems impossible to avoid the assumption that during the period when he himself had been looked after as an infant these same performances had been the source of pleasurable sensations for him. He had obtained this pleasure from his erogenous zones with the help of the person who had looked after him - his mother, in fact; and thus the pleasure already pointed the way to object-choice. But it is just possible that at a still earlier date he had been in the habit of giving himself this pleasure auto-erotically - that he had been one of those children who like retaining their excreta till they can derive a voluptuous sensation from their evacuation. I say no more than that it is possible, because the matter was not cleared up in the analysis; the 'making a row with the legs' (kicking about), of which he was so much frightened later on, points in that direction. But in any case these sources of pleasure had no particularly striking importance with Hans, as they so often have with other children. He early became clean in his habits, and neither bed-wetting nor diurnal incontinence played any part during his first years; no trace was observed in him of any inclination to play with his excrement, a propensity which is so revolting in adults, and which commonly makes its reappearance at the termination of processes of psychical involution.

Moreover, this event and the feelings that were revived by it gave a new direction to his wishes. In his triumphant final phantasy he summed up all of his erotic wishes, both those derived from his auto-erotic phase and those connected with his object-love. In that phantasy he was married to his beautiful mother and had innumerable children whom he could look after in his own way.

The arrival of his sister brought into Hans's life many new elements, which from that time on gave him no rest. In the first place he was obliged to submit to a certain degree of privation: to begin with, a temporary separation from his mother, and later a permanent diminution in the amount of care and attention which he had received from her and which thenceforward he had to grow accustomed to sharing with his sister. In the second place, he experienced a revival of the pleasures he had enjoyed when he was looked after as an infant; for they were called up by all that he saw his mother doing for the baby. As a result of these two influences his erotic needs became intensified, while at the same time they began to obtain insufficient satisfaction. He made up for the loss which his sister's arrival had entailed on him by imagining that he had children of his own; and so long as he was at Gmunden - on his second visit there - and could really play with these children, he found a sufficient outlet for his affections. But after his return to Vienna he was once more alone, and set all his hopes upon his mother. He had meanwhile suffered another privation, having been exiled from his parents' bedroom at the age of four and a half. His intensified erotic excitability now found expression in phantasies, by which in his loneliness he conjured up his playmates of the past summer, and in regular auto-erotic satisfaction obtained by a masturbatory stimulation of his genitals.
In psycho-analyses we frequently come across occurrences of this kind, dating back to the earliest years of the patient's childhood, in which his infantile sexual activity appears to reach its climax and often comes to a catastrophic end owing to some misfortune or punishment. Such occurrences are apt to appear in a shadowy way in dreams. Often they will become so clear that the analyst thinks he has a firm hold of them, and will nevertheless evade any final elucidation; and unless he proceeds with the greatest skill and caution he may be compelled to leave it undecided whether the scene in question actually took place or not. It will help to put us upon the right track in interpreting it, if we recognize that more than one version of the scene (each often differing greatly from the other) may be detected in the patient's unconscious phantasies. If we do not wish to go astray in our judgement of their historical reality, we must above all bear in mind that people's 'childhood memories' are only consolidated at a later period, usually at the age of puberty; and that this involves a complicated process of remodelling, analogous in every way to the process by which a nation constructs legends about its early history. It at once becomes evident that in his phantasies about his infancy the individual as he grows up endeavours to efface the recollection of his auto-erotic activities; and this he does by exalting their memory-traces to the level of object-love, just as a real historian will view the past in the light of the present. This explains why these phantasies abound in seductions and assaults, where the facts will have been confined to auto-erotic activities and the caresses or punishments that stimulated them. Furthermore, it becomes clear that in constructing phantasies about his childhood the individual sexualizes his memories; that is, he brings commonplace experiences into relation with his sexual activity, and extends his sexual interest to them - though in doing this he is probably following upon the traces of a really existing connection. No one who remembers my 'Analysis of a Phobia in a Five-Year-Old Boy' will need to be told that it is not my intention in these remarks to detract from the importance which I have hitherto attached to infantile sexuality by reducing it to nothing more than sexual interest at the age of puberty. I merely wish to give some technical advice that may help to clear up a class of phantasy which is calculated to falsify the picture of infantile sexual activity.

The content of the sexual life of infancy consists in auto-erotic activity on the part of the dominant sexual components, in traces of object-love, and in the formation of that complex which deserves to be called the nuclear complex of the neuroses. It is the complex which comprises the child's earliest impulses, alike tender and hostile, towards its parents and brothers and sisters, after its curiosity has been awakened - usually by the arrival of a new baby brother or sister. The uniformity of the content of the sexual life of children, together with the unvarying character of the modifying tendencies which are later brought to bear upon it, will easily account for the constant sameness which as a rule characterizes the phantasies that are constructed around the period of childhood, irrespective of how greatly or how little real experiences have contributed towards them. It is entirely characteristic of the nuclear complex of infancy that the child's father should be assigned the part of a sexual opponent and of an interferer with auto-erotic sexual activities; and real events are usually to a large extent responsible for bringing this about.
Put away your doubts, then, and join me in a consideration of infantile sexuality from the earliest age.¹ A child's sexual instinct turns out to be put together out of a number of factors; it is capable of being divided up into numerous components which originate from various sources. Above all, it is still independent of the reproductive function, into the service of which it will later be brought. It serves for the acquisition of different kinds of pleasurable feeling, which, basing ourselves on analogies and connections, we bring together under the idea of sexual pleasure. The chief source of infantile sexual pleasure is the appropriate excitation of certain parts of the body that are especially susceptible to stimulus: apart from the genitals, these are the oral, anal and urethral orifices, as well as the skin and other sensory surfaces. Since at this first phase of infantile sexual life satisfaction is obtained from the subject's own body and extraneous objects are disregarded, we term this phase (from a word coined by Havelock Ellis) that of auto-erotism. We call the parts of the body that are important in the acquisition of sexual pleasure 'erotogenic zones'. Thumb-sucking (or sensual sucking) in the youngest infants is a good example of this auto-erotic satisfaction from an erotogenic zone. The first scientific observer of this phenomenon, a paediatrician in Budapest named Lindner (1879), already interpreted it correctly as sexual satisfaction and described exhaustively its transition to other and higher forms of sexual activity. Another sexual satisfaction at this period of life is the masturbatory excitation of the genitals, which retains so much importance in later life and by many people is never completely conquered. Alongside these and other auto-erotic activities, we find in children at a very early age manifestations of those instinctual components of sexual pleasure (or, as we like to say, of libido) which presuppose the taking of an extraneous person as an object. These instincts occur in pairs of opposites, active and passive. I may mention as the most important representatives of this group the desire to cause pain (sadism) with its passive counterpart (masochism) and the active and passive desire for looking, from the former of which curiosity branches off later on and from the latter the impulsion to artistic and theatrical display. Others of a child's sexual activities already imply the making of an 'object-choice', where an extraneous person becomes the main feature, a person who owes his importance in the first instance to considerations arising from the self-preservative instinct. But at this early period of childhood difference in sex plays no decisive part as yet. Thus you can attribute some degree of homosexuality to every child without doing him an injustice. This widespread and copious but dissociated sexual life of children, in which each separate instinct pursues its own acquisition of pleasure independently of all the rest, is now brought together and organized in two main directions, so that by the end of puberty the individual's final sexual character is as a rule completely formed. On the one hand, the separate instincts become subordinated to the dominance of the genital zone, so that the whole sexual life enters the service of reproduction, and the satisfaction of the separate instincts retains its importance only as preparing for and encouraging the sexual act proper. On the other hand, object-choice pushes auto-erotism into the background, so that in the subject's erotic life all the components of the sexual instinct now seek satisfaction in relation to the person who is loved. Not all of the original sexual components, however, are admitted to take part in this final establishment of sexuality. Even before puberty extremely energetic repressions of certain instincts have been effected under the influence of education, and mental forces such as shame, disgust and morality have been set up, which, like watchmen, maintain these repressions. So that when at puberty the high tide of sexual demands is reached, it is met by these mental reactive or resistant structures like dams, which direct its flow into what are called normal channels and make it impossible for it to reactivate the instincts that have undergone repression. It is in particular the coprophilic impulses of childhood - that is to say, the desires attaching to the excreta - which are submitted the most rigorously to repression, and the same is true, furthermore, of fixation to the figures to which the child's original object-choice was attached.

[1910a, 2230]
Thus in the case of Schreber we find ourselves once again on the familiar ground of the father-complex.¹ The patient's struggle with Flechsig became revealed to him as a conflict with God, and we must therefore construe it as an infantile conflict with the father whom he loved; the details of that conflict (of which we know nothing) are what determined the content of his delusions. None of the material which in other cases of the sort is brought to light by analysis is absent in the present one: every element is hinted at in one way or another. In infantile experiences such as this the father appears as an interferer with the satisfaction which the child is trying to obtain; this is usually of an auto-erotic character, though at a later date it is often replaced in phantasy by some other satisfaction of a less inglorious kind.² In the final stage of Schreber's delusion a magnificent victory was scored by the infantile sexual urge; for voluptuousness became God-fearing, and God Himself (his father) never tired of demanding it from him. His father's most dreaded threat, castration, actually provided the material for his wishful phantasy (at first resisted but later accepted) of being transformed into a woman. His allusion to an offence covered by the surrogate idea 'soul-murder' could not be more transparent. The chief attendant was discovered to be identical with his neighbour von W., who, according to the voices, had falsely accused him of masturbation (108). The voices said, as though giving grounds for the threat of castration: 'For you are to be represented as being given over to voluptuous excesses.'³ (127-8.) Finally, we come to the enforced thinking (47) to which the patient submitted himself because he supposed that God would believe he had become an idiot and would withdraw from him if he ceased thinking for a moment. This is a reaction (with which we are also familiar in other connections) to the threat or fear of losing one's reason⁴ as a result of indulging in sexual practices and especially in masturbation. Considering the enormous number of delusional ideas of a hypochondriacal nature⁵ which the patient developed, no great importance should perhaps be attached to the fact that some of them coincide word for word with the hypochondriacal fears of masturbators.⁶

I shall now endeavour (and I think the attempt is neither unnecessary nor unjustifiable) to show that the knowledge of psychological processes, which, thanks to psycho-analysis, we now possess, already enables us to understand the part played by a homosexual wish in the development of paranoia. Recent investigations¹ have directed our attention to a stage in the development of the libido which it passes through on the way from auto-erotism to object-love.² This stage has been given the name of narcissism. What happens is this. There comes a time in the development of the individual at which he unifies his sexual instincts (which have hitherto been engaged in auto-erotic activities) in order to obtain a love-object; and he begins by taking himself, his own body, as his love-object, and only subsequently proceeds from this to the choice of some person other than himself as his object. This half-way phase between auto-erotism and object-love may perhaps be indispensable normally; but it appears that many people linger unusually long in this condition, and that many of its features are carried over by them into the later stages of their development. What is of chief importance in the subject's self thus chosen as a love object may already be the genitals. The line of development then leads on to the choice of an external object with similar genitals - that is, to homosexual object-choice - and thence to heterosexuality. People who are manifest homosexuals in later life have, it may be presumed, never emancipated themselves from the binding condition that the object of their choice must possess genitals like their own; and in this connection the infantile sexual theories which attribute the same kind of genitals to both sexes exert much influence.
(3) The supersession of the pleasure principle by the reality principle, with all the psychical consequences involved, which is here schematically condensed into a single sentence, is not in fact accomplished all at once; nor does it take place simultaneously all along the line. For while this development is going on in the ego-instincts, the sexual instincts become detached from them in a very significant way. The sexual instincts behave auto-erotically at first; they obtain their satisfaction in the subject's own body and therefore do not find themselves in the situation of frustration which was what necessitated the institution of the reality principle; and when, later on, the process of finding an object begins, it is soon interrupted by the long period of latency, which delays sexual development until puberty. These two factors - auto-erotism and the latency period - have as their result that the sexual instinct is held up in its psychical development and remains far longer under the dominance of the pleasure principle, from which in many people it is never able to withdraw.

[1911b, 2555]

(7) While the ego goes through its transformation from a pleasure-ego into a reality-ego, the sexual instincts undergo the changes that lead them from their original auto-erotism through various intermediate phases to object-love in the service of procreation. If we are right in thinking that each step in these two courses of development may become the site of a disposition to later neurotic illness, it is plausible to suppose that the form taken by the subsequent illness (the choice of neurosis) will depend on the particular phase of the development of the ego and of the libido in which the dispositional inhibition of development has occurred. Thus unexpected significance attaches to the chronological features of the two developments (which have not yet been studied), and to possible variations in their synchronization.

[1911b, 2556]

A young man who has hitherto satisfied his libido by means of phantasies ending in masturbation, and who now seeks to replace a régime approximating to auto-erotism by the choice of a real object - or a girl who has given her whole affection to her father or brother and who must now, for the sake of a man who is courting her, allow her hitherto unconscious incestuous libidinal wishes to become conscious - or a married woman who would like to renounce her polygamous inclinations and phantasies of prostitution so as to become a faithful consort to her husband and a perfect mother to her child - all of these fall ill from the most laudable efforts, if the earlier fixations of their libido are powerful enough to resist a displacement; and this point will be decided, once again, by the factors of disposition, constitution and infantile experience. All of them, it might be said, meet with the fate of the little tree in the Grimms' fairy tale, which wished it had different leaves. From the hygienic point of view - which, to be sure, is not the only one to be taken into account - one could only wish for them that they had continued to be as undeveloped, as inferior and as useless as they were before they fell ill. The change which the patients strive after, but bring about only imperfectly or not at all, invariably has the value of a step forward from the point of view of real life. It is otherwise if we apply ethical standards: we see people falling ill just as often when they discard an ideal as when they seek to attain it.

[1912c, 2562]
Already a few years back we ventured, with the help of these hypotheses, to approach the problem of choice of neurosis. Our method of work, which aims at discovering normal conditions by studying their disturbances, led us to adopt a very singular and unexpected line of attack. The order in which the main forms of psychoneurosis are usually enumerated - Hysteria, Obsessional Neurosis, Paranoia, Dementia Praecox - corresponds (even though not quite exactly) to the order of the ages at which the onset of these disorders occurs. Hysterical forms of illness can be observed even in earliest childhood; obsessional neurosis usually shows its first symptoms in the second period of childhood (between the ages of six and eight); while the two other psychoneuroses, which I have brought together under the heading of 'paraphrenia', do not appear until after puberty and during adult life. It is these disorders - the last to emerge - which were the first to show themselves accessible to our enquiry into the dispositions that result in the choice of neurosis. The characteristics peculiar to both of them - megalomania, turning away from the world of objects, increased difficulty in transference - have obliged us to conclude that their dispositional fixation is to be looked for in a stage of libidinal development **before** object-choice has been established - that is in the phase of auto-erotism and of narcissism. Thus these forms of illness, which make their appearance so late, go back to very early inhibitions and fixations.

This is the starting-point of the small new fragment of theory which I have formulated. It is of course only in appearance that it is based on this one observation; actually it brings together a large number of earlier impressions, though an understanding of them was only made possible by this last experience. I told myself that my schematic picture of the development of the libidinal function called for an extra insertion in it. To begin with, I had only distinguished, first the phase of auto-erotism during which the subject's component instincts, each on its own account, seek for the satisfaction of their desires in his own body, and then the combination of all the component instincts for the choice of an object, under the primacy of the genitals acting on behalf of reproduction. The analysis of the paraphrenias has, as we know, necessitated the insertion between them of a stage of narcissism, during which the choice of an object has already taken place but that object coincides with the subject's own ego. And now we see the need for yet another stage to be inserted before the final shape is reached - a stage in which the component instincts have already come together for the choice of an object and that object is already something extraneous in contrast to the subject's own self, but in which the **primacy of the genital zones has not yet been established**. On the contrary, the component instincts which dominate this **pregenital organization** of sexual life are the anal-erotic and sadistic ones.

If we trace back the development of libidinal trends as we find them in the individual from their adult forms to the first beginnings in childhood, an important distinction emerges, which I have described in my *Three Essays on the Theory of Sexuality* (1905d). Manifestations of the sexual instincts can be observed from the very first, but to begin with they are not yet directed towards any external object. The separate instinctual components of sexuality work independently of one another to obtain pleasure and find satisfaction in the subject's own body. This stage is known as that of auto-erotism and it is succeeded by one in which an object is chosen.
Further study has shown that it is expedient and indeed indispensable to insert a third stage between these two, or, putting it in another way, to divide the first stage, that of auto-erotism, into two. At this intermediate stage, the importance of which is being made more and more evident by research, the hitherto isolated sexual instincts have already come together into a single whole and have also found an object. But this object is not an external one, extraneous to the subject, but it is his own ego, which has been constituted at about this same time. Bearing in mind pathological fixations of this new stage, which become observable later, we have given it the name of 'narcissism'. The subject behaves as though he were in love with himself; his egoistic instincts and his libidinal wishes are not yet separable under our analysis.

[1912-1913, 2731]

Another product of this sort was the hypothesis of infantile sexuality. This, however, was made at a much later date. In the early days of tentative investigation by analysis no such thing was thought of. At first it was merely observed that the effects of present-day experiences had to be traced back to something in the past. But enquirers often find more than they bargain for. One was drawn further and further back into the past; one hoped at last to be able to stop at puberty, the period in which the sexual impulses are traditionally supposed to awake. But in vain; the tracks led still further back into childhood and into its earlier years. On the way, a mistaken idea had to be overcome which might have been almost fatal to the young science. Influenced by Charcot's view of the traumatic origin of hysteria, one was readily inclined to accept as true and aetiologically significant the statements made by patients in which they ascribed their symptoms to passive sexual experiences in the first years of childhood - to put it bluntly, to seduction. When this aetiology broke down under the weight of its own improbability and contradiction in definitely ascertainable circumstances, the result at first was helpless bewilderment. Analysis had led back to these infantile sexual traumas by the right path, and yet they were not true. The firm ground of reality was gone. At that time I would gladly have given up the whole work, just as my esteemed predecessor, Breuer, had done when he made his unwelcome discovery. Perhaps I persevered only because I no longer had any choice and could not then begin again at anything else. At last came the reflection that, after all, one had no right to despair because one has been deceived in one's expectations; one must revise those expectations. If hysterical subjects trace back their symptoms to traumas that are fictitious, then the new fact which emerges is precisely that they create such scenes in phantasy, and this psychical reality requires to be taken into account alongside practical reality. This reflection was soon followed by the discovery that these phantasies were intended to cover up the auto-erotic activity of the first years of childhood, to embellish it and raise it to a higher plane. And now, from behind the phantasies, the whole range of a child's sexual life came to light.

[1914d, 2886]

Before going any further I must touch on two questions which lead us to the heart of the difficulties of our subject. In the first place, what is the relation of the narcissism of which we are now speaking to auto-erotism, which we have described as an early state of the libido? Secondly, if we grant the ego a primary cathexis of libido, why is there any necessity for further distinguishing a sexual libido from a non-sexual energy of the ego-instincts? Would not the postulation of a single kind of psychical energy save us all the difficulties ofdifferentiating an energy of the ego-instincts from ego-libido, and ego-libido from object-libido?

[1914c, 2934]

As regards the first question, I may point out that we are bound to suppose that a unity comparable to the ego cannot exist in the individual from the start; the ego has to be developed. The auto-erotic instincts, however, are there from the very first; so there must be something added to auto-erotism - a new psychical action - in order to bring about narcissism.

[1914c, 2934]
A third way in which we may approach the study of narcissism is by observing the erotic life of human beings, with its many kinds of differentiation in man and woman. Just as object-libido at first concealed ego-libido from our observation, so too in connection with the object-choice of infants (and of growing children) what we first noticed was that they derived their sexual objects from their experiences of satisfaction. The first auto-erotic sexual satisfactions are experienced in connection with vital functions which serve the purpose of self-preservation. The sexual instincts are at the outset attached to the satisfaction of the ego-instincts; only later do they become independent of these, and even then we have an indication of that original attachment in the fact that the persons who are concerned with a child's feeding, care, and protection become his earliest sexual objects: that is to say, in the first instance his mother or a substitute for her. Side by side, however, with this type and source of object-choice, which may be called the 'anaclitic' or 'attachment' type, psycho-analytic research has revealed a second type, which we were not prepared for finding. We have discovered, especially clearly in people whose libidinal development has suffered some disturbance, such as perverts and homosexuals, that in their later choice of love-objects they have taken as a model not their mother but their own selves. They are plainly seeking themselves as a love-object, and are exhibiting a type of object-choice which must be termed 'narcissistic'. In this observation we have the strongest of the reasons which have led us to adopt the hypothesis of narcissism.

The object [Objekt] of an instinct is the thing in regard to which or through which the instinct is able to achieve its aim. It is what is most variable about an instinct and is not originally connected with it, but becomes assigned to it only in consequence of being peculiarly fitted to make satisfaction possible. The object is not necessarily something extraneous: it may equally well be a part of the subject's own body. It may be changed any number of times in the course of the vicissitudes which the instinct undergoes during its existence; and highly important parts are played by this displacement of instinct. It may happen that the same object serves for the satisfaction of several instincts simultaneously, a phenomenon which Adler has called a 'confluence' of instincts [Triebverschränkung]. A particularly close attachment of the instinct to its object is distinguished by the term 'fixation'. This frequently occurs at very early periods of the development of an instinct and puts an end to its mobility through its intense opposition to detachment.

We have become accustomed to call the early phase of the development of the ego, during which its sexual instincts find auto-erotic satisfaction, 'narcissism', without at once entering on any discussion of the relation between auto-erotism and narcissism. It follows that the preliminary stage of the scopophilic instinct, in which the subject's own body is the object of the scopophilia, must be classed under narcissism, and that we must describe it as a narcissistic formation. The active scopophilic instinct develops from this, by leaving narcissism behind. The passive scopophilic instinct, on the contrary, holds fast to the narcissistic object. Similarly, the transformation of sadism into masochism implies a return to the narcissistic object. And in both these cases the narcissistic subject is, through identification, replaced by another, extraneous ego. If we take into account our constructed preliminary narcissistic stage of sadism, we shall be approaching a more general realization - namely, that the instinctual vicissitudes which consist in the instinct's being turned round upon the subject's own ego and undergoing reversal from activity to passivity are dependent on the narcissistic organization of the ego and bear the stamp of that phase. They perhaps correspond to the attempts at defence which at higher stages of the development of the ego are effected by other means.

[1914c, 2942]

[1915c, 2960]

[1915c, 2968]
At this point we may call to mind that so far we have considered only two pairs of opposite instincts: sadism-masochism and scopophilia-exhibitionism. These are the best known sexual instincts that appear in an ambivalent manner. The other components of the later sexual function are not yet sufficiently accessible to analysis for us to be able to discuss them in a similar way. In general we can assert of them that their activities are auto-erotic; that is to say, their object is negligible in comparison with the organ which is their source, and as a rule coincides with that organ. The object of the scopophilic instinct, however, though it too is in the first instance a part of the subject's own body, is not the eye itself; and in sadism the organic source, which is probably the muscular apparatus with its capacity for action, points unequivocally at an object other than itself, even though that object is part of the subject's own body. In the auto-erotic instincts, the part played by the organic source is so decisive that, according to a plausible suggestion of Federn (1913) and Jekels (1913), the form and function of the organ determine the activity or passivity of the instinctual aim.

The three polarities of the mind are connected with one another in various highly significant ways. There is a primal psychical situation in which two of them coincide. Originally, at the very beginning of mental life, the ego is cathected with instincts and is to some extent capable of satisfying them on itself. We call this condition 'narcissism' and this way of obtaining satisfaction 'auto-erotic'.¹ At this time the external world is not cathected with interest (in a general sense) and is indifferent for purposes of satisfaction. During this period, therefore, the ego-subject coincides with what is pleasurable and the external world with what is indifferent (or possibly unpleasurable, as being a source of stimulation). If for the moment we define loving as the relation of the ego to its sources of pleasure, the situation in which the ego loves itself only and is indifferent to the external world illustrates the first of the opposites which we found to 'loving'.

¹ Some of the sexual instincts are, as we know, capable of this auto-erotic satisfaction, and so are adapted to being the vehicle for the development under the dominance of the pleasure principle which we are about to describe. Those sexual instincts which from the outset require an object, and the needs of the ego-instincts, which are never capable of auto-erotic satisfaction, naturally disturb this state and so pave the way for an advance from it. Indeed, the primal narcissistic state would not be able to follow the development if it were not for the fact that every individual passes through a period during which he is helpless and has to be looked after and during which his pressing needs are satisfied by an external agency and are thus prevented from becoming greater.

In so far as the ego is auto-erotic, it has no need of the external world, but, in consequence of experiences undergone by the instincts of self-preservation, it acquires objects from that world, and, in spite of everything, it cannot avoid feeling internal instinctual stimuli for a time as unpleasurable. Under the dominance of the pleasure principle a further development now takes place in the ego. In so far as the objects which are presented to it are sources of pleasure, it takes them into itself, 'introjects' them (to use Ferenczi's term); and, on the other hand, it expels whatever within itself becomes a cause of unpleasure. (See below, the mechanism of projection.)
It now remains for us to put together what we know of the genesis of love and hate. Love is derived from the capacity of the ego to satisfy some of its instinctual impulses auto-erotically by obtaining organ-pleasure. It is originally narcissistic, then passes on to objects, which have been incorporated into the extended ego, and expresses the motor efforts of the ego towards these objects as sources of pleasure. It becomes intimately linked with the activity of the later sexual instincts and, when these have been completely synthesized, coincides with the sexual impulsion as a whole. Preliminary stages of love emerge as provisional sexual aims while the sexual instincts are passing through their complicated development. As the first of these aims we recognize the phase of incorporating or devouring - a type of love which is consistent with abolishing the object's separate existence and which may therefore be described as ambivalent. At the higher stage of the pregenital sadistic-anal organization, the striving for the object appears in the form of an urge for mastery, to which injury or annihilation of the object is a matter of indifference. Love in this form and at this preliminary stage is hardly to be distinguished from hate in its attitude towards the object. Not until the genital organization is established does love become the opposite of hate.

[1915c, 2973]

You will not be able to escape the resemblance of this example to a joke; and it has in fact often happened that a joke of the dreamer's has been regarded as a joke of the interpreter's. There are other instances in which it has been far from easy to decide whether what we are dealing with is a joke or a dream. But you will recall that the same doubt arose in the case of some parapraxes - slips of the tongue. A man reported as a dream of his that his uncle had given him a kiss while they were sitting in his auto(mobile). He himself very quickly added the interpretation: it meant 'auto-erotism' (a term from the theory of the libido, indicating satisfaction obtained without any outside object). Had the man set out, then, to have some fun with us and was he passing off a joke that had occurred to him as a dream? I think not; I believe he really dreamt it. But what is the origin of this puzzling similarity? This question once led me temporarily aside from my path by compelling me to make jokes themselves the subject of a detailed investigation. It was there shown how jokes originate: a preconscious train of thought is abandoned for a moment to be worked over in the unconscious, and from this it emerges as a joke. Under the influence of the unconscious it is subjected to the effects of the mechanisms that hold sway there - condensation and displacement - the same processes that we have found concerned in the dream-work; and it is to this common feature that is to be ascribed the similarity, when it occurs, between jokes and dreams. But the unintended 'dream-joke' brings none of the yield of pleasure of a true joke. You can learn why if you go more deeply into the study of jokes. A 'dream-joke' strikes us as a bad joke; it does not make us laugh, it leaves us cold.

[1916-1917, 3321]
If an infant could speak, he would no doubt pronounce the act of sucking at his mother's breast by far the most important in his life. He is not far wrong in this, for in this single act he is satisfying at once the two great vital needs. We are therefore not surprised to learn from psycho-analysis how such psychical importance the act retains all through life. Sucking at the mother's breast is the starting-point of the whole of sexual life, the unmatched prototype of every later sexual satisfaction, to which phantasy often enough recurs in times of need. This sucking involves making the mother's breast the first object of the sexual instinct. I can give you no idea of the important bearing of this first object upon the choice of every later object, of the profound effects it has in its transformations and substitutions in even the remotest regions of our sexual life. But at first the infant, in his sucking activity, gives up this object and replaces it by a part of his own body. He begins to suck his thumbs or his own tongue. In this way he makes himself independent of the consent of the external world as regards gaining pleasure, and besides this he increases it by adding the excitation of a second area of his body. The erotogenic zones are not all equally generous in yielding pleasure; it is therefore an important experience when the infant, as Lindner reports, discovers, in the course of feeling around, the specially excitable regions afforded by his genitals and so finds his way from sucking to masturbation.

[1916-1917, 3385]

In forming this opinion of sensual sucking we have already become acquainted with two decisive characteristics of infantile sexuality. It makes its appearance attached to the satisfaction of the major organic needs, and it behaves auto-erotically - that is, it seeks and finds its objects in the infant's own body. What has been shown most clearly in connection with the intake of nourishment is repeated in part with the excretions. We conclude that infants have feelings of pleasure in the process of evacuating urine and faeces and that they soon contrive to arrange those actions in such a way as to bring them the greatest possible yield of pleasure through the corresponding excitations of the erotogenic zones of the mucous membrane. It is here for the first time (as Lou Andreas-Salomé has subtly perceived) that they encounter the external world as an inhibiting power, hostile to their desire for pleasure, and have a glimpse of later conflicts both external and internal. An infant must not produce his excreta at whatever moment he chooses, but when other people decide that he shall. In order to induce him to forgo these sources of pleasure, he is told that everything that has to do with these functions is improper and must be kept secret. This is where he is first obliged to exchange pleasure for social respectability. To begin with, his attitude to his excreta themselves is quite different. He feels no disgust at his faeces, values them as a portion of his own body with which he will not readily part, and makes use of them as his first 'gift', to distinguish people whom he values especially highly. Even after education has succeeded in its aim of making these inclinations alien to him, he carries on his high valuation of faeces in his estimate of 'gifts' and 'money'. On the other hand he seems to regard his achievements in urinating with peculiar pride.

[1916-1917, 3385]
To-day we will follow yet another side of this development namely the relation of the component sexual instincts to their object. Or rather, we will make a hasty survey of this development and dwell somewhat longer on one of its rather late consequences. A few of the components of the sexual instinct, there, have an object from the first and hold fast to it - for instance, the instinct for mastery (sadism) and the scopophilic and epistemophilic instincts. Others, more definitely linked to particular erotogenic zones of the body, have one to begin with only so long as they are still attached to the non-sexual functions, and give it up when they become separated from them. Thus the first object of the oral component of the sexual instinct is the mother's breast which satisfies the infant's need for nourishment. The erotic component, which is satisfied simultaneously during the sucking, makes itself independent with the act of sensual sucking [lutschen]; it gives up the outside object and replaces it by an area of the subject's own body. The oral instinct becomes auto-erotic, as are the anal and other erotogenic instincts from the first. Further development, to put the matter as concisely as possible, has two aims: firstly, the abandonment of auto-erotism, the replacement of the subject's own body once more by an outside object, and secondly, the unification of the various objects of the separate instincts and their replacement by a single object. This can, of course, only be achieved if the object is again a whole body, similar to the subject's own. Nor can it be effected unless a number of the auto-erotic instinctual impulses are left behind as being unserviceable. [1916-1917, 3396]

Now it is a very noteworthy fact that the sexual instincts and the self-preservative instincts do not behave in the same way towards real necessity. The self-preservative instincts, and everything to do with them, are much easier to educate: they learn early to comply with necessity and to arrange their developments in accordance with the instructions of reality. This is intelligible, since they could not otherwise obtain the objects they need in any other way; and without those objects the individual would inevitably perish. The sexual instincts are harder to educate, for at first they have no need of an object. Since they are attached like parasites, as it were, to the other bodily functions, and find their satisfaction auto-erotically on the subject's own body, they are to begin with withdrawn from the educative influence of real necessity, and they retain this characteristic of being self-willed and inaccessible to influence (what we describe as being 'unreasonable') in most people in some respect all through their lives. Moreover, as a rule the educability of a youthful individual is at an end when his sexual needs arise in their full strength. Educators are aware of this and act accordingly; but the findings of psycho-analysis may perhaps also induce them to shift the main impact of education on to the earliest years of childhood, from infancy onwards. The little creature is often completed by the fourth or fifth year of life, and after that merely brings gradually to light what is already within him. [1916-1917, 3415]
It is something else besides that makes symptoms seem strange to us and incomprehensible as a means of libidinal satisfaction. They do not remind us in the very least of anything from which we are in the habit of normally expecting satisfaction. Usually they disregard objects and in so doing abandon their relation to external reality. We can see that this is a consequence of turning away from the reality principle and of returning to the pleasure principle. But it is also a return to a kind of extended auto-erotism, of the sort that offered the sexual instinct its first satisfactions. In place of a change in the external world these substitute a change in the subject's own body: they set an internal act in place of an external one, an adaptation in place of an action - once again, something that corresponds, phylogenetically, to a highly significant regression. We shall only understand this in connection with something new that we have still to learn from the analytic researches into the formation of symptoms. We must further remember that the same processes belonging to the unconscious play a part in the formation of symptoms as in the formation of dreams - namely, condensation and displacement. A symptom, like a dream, represents something as fulfilled: a satisfaction in the infantile manner. But by means of extreme condensation that satisfaction can be compressed into a single sensation or innervation, and by means of extreme displacement it can be restricted to one small detail of the entire libidinal complex. It is not to be wondered at if we, too, often have difficulty in recognizing in a symptom the libidinal satisfaction whose presence we suspect and which is invariably confirmed.

[1916-1917, 3423]
Among the occurrences which recur again and again in the youthful history of neurotics - which are scarcely ever absent - there are a few of particular importance, which also deserve, on that account, I think, to be brought into greater prominence than the rest. As specimens of this class I will enumerate these: observation of parental intercourse, seduction by an adult and threat of being castrated. It would be a mistake to suppose that they are never characterized by material reality; on the contrary, this is often established incontestably through enquiries from older members of the patient's family. It is by no means a rare thing, for instance, for a little boy, who is beginning to play with his penis in a naughty way and is not yet aware that one must conceal such activities, to be threatened by a parent or nurse with having his penis or his sinful hand cut off. Parents will often admit this when they are asked, since they think they have done something useful in making such a threat; a number of people have a correct conscious memory of such a threat, especially if it was made at a somewhat later period. If the threat is delivered by the mother or some other female she usually shifts its performance on to the father or the doctor. In Struwwelpeter, the famous work of the Frankfurt paediatrician Hoffmann (which owes its popularity precisely to an understanding of the sexual and other complexes of childhood), you will find castration softened into a cutting-off of the thumbs as a punishment for obstinate sucking. But it is highly improbable that children are threatened with castration as often as it appears in the analyses of neurotics. We shall be satisfied by realizing that the child puts a threat of this kind together in his imagination on the basis of hints, helped out by a knowledge that auto-erotic satisfaction is forbidden and under the impression of his discovery of the female genitals. Nor is it only in proletarian families that it is perfectly possible for a child, while he is not yet credited with possessing an understanding or a memory, to be a witness of the sexual act between his parents or other grown-up people; and the possibility cannot be rejected that he will be able to understand and react to the impression in retrospect. If, however, the intercourse is described with the most minute details, which would be difficult to observe, or if, as happens most frequently, it turns out to have been intercourse from behind more ferarum [in the manner of animals], there can be no remaining doubt that the phantasy is based on an observation of intercourse between animals (such as dogs) and that its motive was the child's unsatisfied scopophilia during puberty. The extreme achievement on these lines is a phantasy of observing parental intercourse while one is still an unborn baby in the womb. Phantasies of being seduced are of particular interest, because so often they are not phantasies but real memories. Fortunately, however, they are nevertheless not real as often as seemed at first to be shown by the findings of analysis. Seduction by an older child or by one of the same age is even more frequent than by an adult; and if in the case of girls who produce such an event in the story of their childhood their father figures fairly regularly as the seducer, there can be no doubt either of the imaginary nature of the accusation or of the motive that has led to it. A phantasy of being seduced when no seduction has occurred is usually employed by a child to screen the auto-erotic period of his sexual activity. He spares himself shame about masturbation by retrospectively phantasizing a desired object into these earliest times. You must not suppose, however, that sexual abuse of a child by its nearest male relatives belongs entirely to the realm of phantasy. Most analysts will have treated cases in which such events were real and could be unimpeachably established; but even so they related to the later years of childhood and had been transposed into earlier times.

[1916-1917, 3426]
Reflection will quickly suggest that if any such fixation of the libido to the subject's own body and personality, instead of to an object does occur, it cannot be an exception or a trivial event. On the contrary it is probable that this narcissism is the universal and original state of things, from which object-love is only later developed, without the narcissism necessarily disappearing on that account. Indeed we had to recall from the history of the development of object-libido that many sexual instincts begin by finding satisfaction in the subject's own body - auto-erotically, as we say - and that this capacity for auto-erotism is the basis of the lagging-behind of sexuality in the process of education in the reality principle. Auto-erotism would thus be the sexual activity of the narcissistic stage of allocation of the libido.

[1916-1917, 3461]

The Process of Finding an Object, and the Oedipus Complex. - In the first instance the oral component instinct finds satisfaction by attaching itself to the satiating of the desire for nourishment; and its object is the mother's breast. It then detaches itself, becomes independent and at the same time auto-erotic, that is, it finds an object in the child's own body. Others of the component instincts also start by being auto-erotic and are not until later diverted on to an external object. It is a particularly important fact that the component instincts belonging to the genital zone habitually pass through a period of intense auto-erotic satisfaction. The component instincts are not all equally serviceable in the final genital organization of libido; some of them (for instance, the anal components) are consequently left aside and suppressed, or undergo complicated transformations.

[1923a, 3922]

The sexual function, as I found, is in existence from the very beginning of the individual's life, though at first it is attached to the other vital functions and does not become independent of them until later; it has to pass through a long and complicated process of development before it becomes what we are familiar with as the normal sexual life of the adult. It begins by manifesting itself in the activity of a whole number of component instincts. These are dependent upon erogenetic zones in the body; some of them make their appearance in pairs of opposite impulses (such as sadism and masochism or the impulses to look and to be looked at); they operate independently of one another in a search for pleasure, and they find their object for the most part in the subject's own body. Thus at first the sexual function is non-centralized and predominantly auto-erotic. Later, syntheses begin to appear in it; a first stage of organization is reached under the dominance of the oral components, an anal-sadistic stage follows, and it is only after the third stage has at last been reached that the primacy of the genitals is established and that the sexual function begins to serve the ends of reproduction. In the course of this process of development a number of elements of the various component instincts turn out to be unserviceable for this last end and are therefore left on one side or turned to other uses, while others are diverted from their aims and carried over into the genital organization. I gave the name of libido to the energy of the sexual instincts and to that form of energy alone. I was next driven to suppose that the libido does not always pass through its prescribed course of development smoothly. As a result either of the excessive strength of certain of the components or of experiences involving premature satisfaction, fixations of the libido may occur at various points in the course of its development. If subsequently a repression takes place, the libido flows back to these points (a process described as regression), and it is from them that the energy breaks through in the form of a symptom. Later on it further became clear that the localization of the point of fixation is what determines the choice of neurosis, that is, the form in which the subsequent illness makes its appearance.

[1925d, 4211]
COMPONENT INSTINCTS Moreover, the effects of seduction do not help to reveal the early history of the sexual instinct; they rather confuse our view of it by presenting children prematurely with a sexual object for which the infantile sexual instinct at first shows no need. It must, however, be admitted that infantile sexual life, in spite of the preponderating dominance of erotogenic zones, exhibits components which from the very first involve other people as sexual objects. Such are the instincts of scopophilia, exhibitionism and cruelty, which appear in a sense independently of erotogenic zones; these instincts do not enter into intimate relations with genital life until later, but are already to be observed in childhood as independent impulses, distinct in the first instance from erotogenic sexual activity. Small children are essentially without shame, and at some periods of their earliest years show an unmistakable satisfaction in exposing their bodies, with especial emphasis on the sexual parts. The counterpart of this supposedly perverse inclination, curiosity to see other people's genitals, probably, does not become manifest until somewhat later in childhood, when the obstacle set up by a sense of shame has already reached a certain degree of development. Under the influence of seduction the scopophilic perversion can attain great importance in the sexual life of a child. But my researches into the early years of normal people, as well as of neurotic patients, force me to the conclusion that scopophilia can also appear in children as a spontaneous manifestation. Small children whose attention has once been drawn - as a rule by masturbation - to their own genitals usually take the further step without help from outside and develop a lively interest in the genitals of their playmates. Since opportunities for satisfying curiosity of this kind usually occur only in the course of satisfying the two kinds of need for excretion, children of this kind turn into voyeurs, eager spectators of the processes of micturition and defaecation. When repression of these inclinations sets in, the desire to see other people's genitals (whether of their own or the opposite sex) persists as a tormenting compulsion, which in some cases of neurosis later affords the strongest motive force for the formation of symptoms.

A second pregenital phase is that of the sadistic-anal organization. Here the opposition between two currents, which runs through all sexual life, is already developed: they cannot yet, however, be described as 'masculine' and 'feminine', but only as 'active' and 'passive'. The activity is put into operation by the instinct for mastery through the agency of the somatic musculature; the organ which, more than any other, represents the passive sexual aim is the erotogenic mucous membrane of the anus. Both of these currents have objects, which, however, are not identical. Alongside these, other component instincts operate in an auto-erotic manner. In this phase, therefore, sexual polarity and an extraneous object are already observable. But organization and subordination to the reproductive function are still absent.²

¹[1905d, 1511]
²[1905d, 1512]
In order to complete our picture of infantile sexual life, we must also suppose that the choice of an object, such as we have shown to be characteristic of the pubertal phase of development, has already frequently or habitually been effected during the years of childhood: that is to say, the whole of the sexual currents have become directed towards a single person in relation to whom they seek to achieve their aims. This then is the closest approximation possible in childhood to the final form taken by sexual life after puberty. The only difference lies in the fact that in childhood the combination of the component instincts and their subordination under the primacy of the genitals have been effected only very incompletely or not at all. Thus the establishment of that primacy in the service of reproduction is the last phase through which the organization of sexuality passes.¹

[1905d, 1517]

¹ [Footnote added 1924:] At a later date (1923), I myself modified this account by inserting a third phase in the development of childhood, subsequent to the two pregenital organizations. This phase, which already deserves to be described as genital, presents a sexual object and some degree of convergence of the sexual impulses upon that object; but it is differentiated from the final organization of sexual maturity in one essential respect. For it knows only one kind of genital: the male one. For that reason I have named it the 'phallic' stage of organization. (Freud, 1923e.) According to Abraham, it has a biological prototype in the embryo’s undifferentiated genital disposition, which is the same for both sexes.

[1905d, 1517]

DIPHASIC CHOICE OF OBJECT   It may be regarded as typical of the choice of an object that the process is diphasic, that is, that it occurs in two waves. The first of these begins between the ages of two and five, and is brought to a halt or to a retreat by the latency period; it is characterized by the infantile nature of the sexual aims. The second wave sets in with puberty and determines the final outcome of sexual life.

[1905d, 1518]

Although the diphasic nature of object-choice comes down in essentials to no more than the operation of the latency period, it is of the highest importance in regard to disturbances of that final outcome. The resultants of infantile object-choice are carried over into the later period. They either persist as such or are revived at the actual time of puberty. But as a consequence of the repression which has developed between the two phases they prove unutilizable. Their sexual aims have become mitigated and they now represent what may be described as the 'affectionate current' of sexual life. Only psycho-analytic investigation can show that behind this affection, admiration and respect there lie concealed the old sexual longings of the infantile component instincts which have now become unserviceable. The object-choice of the pubertal period is obliged to dispense with the objects of childhood and to start afresh as a 'sensual current'. Should these two currents fail to converge, the result is often that one of the ideals of sexual life, the focusing of all desires upon a single object, will be unattainable.

[1905d, 1518]

¹ [Footnote added 1915:] The schematic picture which I have given in the text aims at emphasizing differences. I have already shown on p. 1517 the extent to which infantile sexuality, owing to its choice of object [added 1924:] and to the development of the phallic phase, approximates to the final sexual organization.

[1905d, 1524]

We were then obliged to recognize, as one of our most surprising findings, that this early efflorescence of infantile sexual life (between the ages of two and five) already gives rise to the choice of an object, with all the wealth of mental activities which such a process involves. Thus, in spite of the lack of synthesis between the different instinctual components and the uncertainty of the sexual aim, the phase of development corresponding to that period must be regarded as an important precursor of the subsequent final sexual organization.

[1905d, 1544]
Further prospects are opened up when we take into consideration the fact that in man the sexual instinct does not originally serve the purposes of reproduction at all, but has as its aim the gaining of particular kinds of pleasure.⁴ It manifests itself in this way in human infancy, during which it attains its aim of gaining pleasure not only from the genitals but from other parts of the body (the erotogenic zones), and can therefore disregard any objects other than these convenient ones. We call this stage the stage of auto-erotism, and the child’s upbringing has, in our view, the task of restricting it, because to linger in it would make the sexual instinct uncontrollable and unserviceable later on. The development of the sexual instinct then proceeds from auto-erotism to object-love and from the autonomy of the erotogenic zones to their subordination under the primacy of the genitals, which are put at the service of reproduction. During this development a part of the sexual excitation which is provided by the subject’s own body is inhibited as being unserviceable for the reproductive function and in favourable cases is brought to sublimation. The forces that can be employed for cultural activities are thus to a great extent obtained through the suppression of what are known as the perverse elements of sexual excitation.

[1908d, 1953]

If we take the second of these stages as an average, we must point out that a number of people are, on account of their organization, not equal to meeting its demands. In whole classes of individuals the development of the sexual instinct, as we have described it above, from auto-erotism to object-love with its aim of uniting the genitals, has not been carried out correctly and sufficiently fully. As a result of these disturbances of development two kinds of harmful deviation from normal sexuality - that is, sexuality which is serviceable to civilization - come about; and the relation between these two is almost that of positive and negative.⁵

[1908d, 1953]

We should be doing Hans an injustice if we were to trace only the auto-erotic features of his sexual life. His father has detailed information to give us on the subject of his love relationships with other children. From these we can discern the existence of an ‘object-choice’ just as in the case of an adult; and also, it must be confessed, a very striking degree of inconstancy and a disposition to polygamy.

[1909b, 2010]
Put away your doubts, then, and join me in a consideration of infantile sexuality from the earliest age.¹ A child's sexual instinct turns out to be put together out of a number of factors; it is capable of being divided up into numerous components which originate from various sources. Above all, it is still independent of the reproductive function, into the service of which it will later be brought. It serves for the acquisition of different kinds of pleasurable feeling, which, basing ourselves on analogies and connections, we bring together under the idea of sexual pleasure. The chief source of infantile sexual pleasure is the appropriate excitation of certain parts of the body that are especially susceptible to stimulus: apart from the genitals, these are the oral, anal and urethral orifices, as well as the skin and other sensory surfaces. Since at this first phase of infantile sexual life satisfaction is obtained from the subject's own body and extraneous objects are disregarded, we term this phase (from a word coined by Havelock Ellis) that of auto-erotism. We call the parts of the body that are important in the acquisition of sexual pleasure 'eroticogenic zones'. Thumb-sucking (or sensual sucking) in the youngest infants is a good example of this auto-erotic satisfaction from an eroticogenic zone. The first scientific observer of this phenomenon, a paediatrician in Budapest named Lindner (1879), already interpreted it correctly as sexual satisfaction and described exhaustively its transition to other and higher forms of sexual activity. Another sexual satisfaction at this period of life is the masturbatory excitation of the genitals, which retains so much importance in later life and by many people is never completely conquered. Alongside these and other auto-erotic activities, we find in children at a very early age manifestations of those instinctual components of sexual pleasure (or, as we like to say, of libido) which presuppose the taking of an extraneous person as an object. These instincts occur in pairs of opposites, active and passive. I may mention as the most important representatives of this group the desire to cause pain (sadism) with its passive counterpart (masochism) and the active and passive desire for looking, from the former of which curiosity branches off later on and from the latter the impulse to artistic and theatrical display. Others of a child's sexual activities already imply the making of an 'object-choice', where an extraneous person becomes the main feature, a person who owes his importance in the first instance to considerations arising from the self-preservative instinct. But at this early period of childhood difference in sex plays no decisive part as yet. Thus you can attribute some degree of homosexuality to every child without doing him an injustice. This widespread and copious but dissociated sexual life of children, in which each separate instinct pursues its own acquisition of pleasure independently of all the rest, is now brought together and organized in two main directions, so that by the end of puberty the individual's final sexual character is as a rule completely formed. On the one hand, the separate instincts become subordinated to the dominance of the genital zone, so that the whole sexual life enters the service of reproduction, and the satisfaction of the separate instincts retains its importance only as preparing for and encouraging the sexual act proper. On the other hand, object-choice pushes auto-eroticism into the background, so that in the subject's erotic life all the components of the sexual instinct now seek satisfaction in relation to the person who is loved. Not all of the original sexual components, however, are admitted to take part in this final establishment of sexuality. Even before puberty extremely energetic repressions of certain instincts have been effected under the influence of education, and mental forces such as shame, disgust and morality have been set up, which, like watchmen, maintain these repressions. So that when at puberty the high tide of sexual demands is reached, it is met by these mental reactive or resistant structures like dams, which direct its flow into what are called normal channels and make it impossible for it to reactivate the instincts that have undergone repression. It is in particular the coprophilic impulses of childhood - that is to say, the desires attaching to the excreta - which are submitted the most rigorously to repression, and the same is true, furthermore, of fixation to the figures to which the child's original object-choice was attached. [1910a, 2230]
Let us return to the sexual development of children. We have some arrears to make up owing to our having paid more attention to the somatic than to the mental phenomena of sexual life. The child's first choice of an object, which derives from its need for help, claims our further interest. Its choice is directed in the first instance to all those who look after it, but these soon give place to its parents. Children's relations to their parents, as we learn alike from direct observations of children and from later analytic examination of adults, are by no means free from elements of accompanying sexual excitation. The child takes both of its parents, and more particularly one of them, as the object of its erotic wishes. In so doing, it usually follows some indication from its parents, whose affection bears the clearest characteristics of a sexual activity, even though of one that is inhibited in its aims. As a rule a father prefers his daughter and a mother her son; the child reacts to this by wishing, if he is a son, to take his father's place, and, if she is a daughter, her mother's. The feelings which are aroused in these relations between parents and children and in the resulting ones between brothers and sisters are not only of a positive or affectionate kind but also of a negative or hostile one. The complex which is thus formed is doomed to early repression; but it continues to exercise a great and lasting influence from the unconscious. It is to be suspected that, together with its extensions, it constitutes the nuclear complex of every neurosis, and we may expect to find it no less actively at work in other regions of mental life. The myth of King Oedipus, who killed his father and took his mother to wife, reveals, with little modification, the infantile wish, which is later opposed and repudiated by the barrier against incest. Shakespeare's Hamlet is equally rooted in the soil of the incest-complex, but under a better disguise.

[1910a, 2232]

The affectionate current is the older of the two. It springs from the earliest years of childhood; it is formed on the basis of the interests of the self-preservative instinct and is directed to the members of the family and those who look after the child. From the very beginning it carries along with it contributions from the sexual instincts - components of erotic interest - which can already be seen more or less clearly even in childhood and in any event are uncovered in neurotics by psycho-analysis later on. It corresponds to the child's primary object-choice. We learn in this way that the sexual instincts find their first objects by attaching themselves to the valuations made by the ego-instincts, precisely in the way in which the first sexual satisfactions are experienced in attachment to the bodily functions necessary for the preservation of life. The 'affection' shown by the child's parents and those who look after him, which seldom fails to betray its erotic nature ('the child is an erotic plaything'), does a very great deal to raise the contributions made by erotism to the cathexes of his ego-instincts, and to increase them to an amount which is bound to play a part in his later development, especially when certain other circumstances lend their support.

[1912d, 2338]
If an infant could speak, he would no doubt pronounce the act of sucking at his mother's breast by far the most important in his life. He is not far wrong in this, for in this single act he is satisfying at once the two great vital needs. We are therefore not surprised to learn from psycho-analysis how such psychical importance the act retains all through life. Sucking at the mother's breast is the starting-point of the whole of sexual life, the unmatched prototype of every later sexual satisfaction, to which phantasy often enough recurs in times of need. This sucking involves making the mother's breast the first object of the sexual instinct. I can give you no idea of the important bearing of this first object upon the choice of every later object, of the profound effects it has in its transformations and substitutions in even the remotest regions of our sexual life. But at first the infant, in his sucking activity, gives up this object and replaces it by a part of his own body. He begins to suck his thumbs or his own tongue. In this way he makes himself independent of the consent of the external world as regards gaining pleasure, and besides this he increases it by adding the excitation of a second area of his body. The erotogenic zones are not all equally generous in yielding pleasure; it is therefore an important experience when the infant, as Lindner reports, discovers, in the course of feeling around, the specially excitable regions afforded by his genitals and so finds his way from sucking to masturbation. [1916-1917, 3385]

To-day we will follow yet another side of this development namely the relation of the component sexual instincts to their object. Or rather, we will make a hasty survey of this development and dwell somewhat longer on one of its rather late consequences. A few of the components of the sexual instinct, there, have an object from the first and hold fast to it - for instance, the instinct for mastery (sadism) and the scopophilic and epistemophilic instincts. Others, more definitely linked to particular erotogenic zones of the body, have one to begin with only so long as they are still attached to the non-sexual functions, and give it up when they become separated from them. Thus the first object of the oral component of the sexual instinct is the mother's breast which satisfies the infant's need for nourishment. The erotic component, which is satisfied simultaneously during the sucking, makes itself independent with the act of sensual sucking (lutschen); it gives up the outside object and replaces it by an area of the subject's own body. The oral instinct becomes auto-erotic, as are the anal and other erotogenic instincts from the first. Further development, to put the matter as concisely as possible, has two aims: firstly, the abandonment of auto-erotism, the replacement of the subject's own body once more by an outside object, and secondly, the unification of the various objects of the separate instincts and their replacement by a single object. This can, of course, only be achieved if the object is again a whole body, similar to the subject's own. Nor can it be effected unless a number of the auto-erotic instinctual impulses are left behind as being unserviceable. [1916-1917, 3396]

The processes of finding an object are fairly complex and no comprehensive account has hitherto been given of them. For our purposes it may be specially pointed out that when, in the years of childhood before puberty, the process has in some respects reached a conclusion, the object that has been found turns out to be almost identical with the first object of the oral pleasure-instinct, which was reached by attachment. Though it is not actually the mother's breast, at least it is the mother. We call the mother the first love-object. For we speak of love when we bring the mental side of the sexual trends into the foreground and want to force back the underlying physical or 'sensual' instinctual demands or to forget them for a moment. At the time at which the child's mother becomes his love-object the psychical work of repression has already begun in him, which is withdrawing from his knowledge awareness of a part of his sexual aims. To his choice of his mother as a love-object everything becomes attached which, under the name of the 'Oedipus complex', has attained so much importance in the psycho-analytic explanation of the neuroses and has played no less a part, perhaps, in the resistance to psycho-analysis. [1916-1917, 3397]
Hitherto it has been a premiss of our work that we can distinguish the ego-instincts from the sexual ones by their manifestations. With the transference neuroses this could be done without difficulty. We termed the cathexes of energy which the ego directs towards the objects of its sexual desires 'libido'; all the others, which are sent out by the self-preservative instincts, we termed 'interest'. By tracing the course of the libidinal cathexes, their transformations and final vicissitudes, we were able to obtain a first insight into the machinery of the mental forces. For this purpose the transference neuroses offered us the most favourable material. But the ego, its composition out of various organizations and their construction and mode of functioning, remained hidden from us; and we were driven to suspect that only the analysis of other neurotic disorders would be able to bring us the necessary insight.

[1916-1917, 3460]

The Process of Finding an Object, and the Oedipus Complex. - In the first instance the oral component instinct finds satisfaction by attaching itself to the satiating of the desire for nourishment; and its object is the mother's breast. It then detaches itself, becomes independent and at the same time auto-erotic, that is, it finds an object in the child's own body. Others of the component instincts also start by being auto-erotic and are not until later diverted on to an external object. It is a particularly important fact that the component instincts belonging to the genital zone habitually pass through a period of intense auto-erotic satisfaction. The component instincts are not all equally serviceable in the final genital organization of libido; some of them (for instance, the anal components) are consequently left aside and suppressed, or undergo complicated transformations.

[1923a, 3922]
The process of arriving at an object, which plays such an important part in mental life, takes place alongside of the organization of the libido. After the stage of auto-eroticism, the first love-object in the case of both sexes is the mother; and it seems probable that to begin with a child does not distinguish its mother's organ of nutrition from its own body. Later, but still in the first years of infancy, the relation known as the Oedipus complex becomes established: boys concentrate their sexual wishes upon their mother and develop hostile impulses against their father as being a rival, while girls adopt an analogous attitude.¹ All of the different variations and consequences of the Oedipus complex are important; and the innately bisexual constitution of human beings makes itself felt and increases the number of simultaneously active tendencies. Children do not become clear for quite a long time about the differences between the sexes; and during this period of sexual researches they produce typical sexual theories which, being circumscribed by the incompleteness of their authors' own physical development, are a mixture of truth and error and fail to solve the problems of sexual life (the riddle of the Sphinx - that is, the question of where babies come from). We see, then, that a child's first object-choice is an incestuous one. The whole course of development that I have described is run through rapidly. For the most remarkable feature of the sexual life of man is its diphasic onset, its onset in two waves, with an interval between them. It reaches a first climax in the fourth or fifth year of a child's life. But thereafter this early efflorescence of sexuality passes off; the sexual impulses which have shown such liveliness are overcome by repression, and a period of latency follows, which lasts until puberty and during which the reaction-formations of morality, shame, and disgust are built up.² Of all living creatures man alone seems to show this diphasic onset of sexual growth, and it may perhaps be the biological determinant of his predisposition to neuroses. At puberty the impulses and object-relations of a child's early years become re-animated, and amongst them the emotional ties of its Oedipus complex. In the sexual life of puberty there is a struggle between the urges of early years and the inhibitions of the latency period. Before this, and while the child is at the highest point of its infantile sexual development, a genital organization of a sort is established; but only the male genitals play a part in it, and the female ones remain undiscovered. (I have described this as the period of phallic primacy.) At this stage the contrast between the sexes is not stated in terms of 'male' or 'female' but of 'possessing a penis' or 'castrated'. The castration complex which arises in this connection is of the profoundest importance in the formation alike of character and of neuroses. [1925d, 4212]
I was further made aware of a defect in the account I have given in the text, which, in the interests of lucidity, describes the conceptual distinction between the two phases of auto-erotism and object-love as though it were also a separation in time. But the analyses that I have just mentioned, as well as the findings of Bell quoted on p. 1496, above, show that children between the ages of three and five are capable of very clear object-choice, accompanied by strong affects.

[1905d, 1512]

If we take the second of these stages as an average, we must point out that a number of people are, on account of their organization, not equal to meeting its demands. In whole classes of individuals the development of the sexual instinct, as we have described it above, from auto-erotism to object-love with its aim of uniting the genitals, has not been carried out correctly and sufficiently fully. As a result of these disturbances of development two kinds of harmful deviation from normal sexuality - that is, sexuality which is serviceable to civilization - come about; and the relation between these two is almost that of positive and negative.¹

[1908d, 1953]

Thus in little Hans's sexual constitution the genital zone was from the outset the one among his erotogenic zones which afforded him the most intense pleasure. The only other similar pleasure of which he gave evidence was excretory pleasure, the pleasure attached to the orifices through which micturition and evacuation of the bowels are effected. In his final phantasy of bliss, with which his illness was overcome, he imagined he had children, whom he took to the W.C., whom he made to widdle, whose behinds he wiped - for whom, in short, he did 'everything one can do with children'; it therefore seems impossible to avoid the assumption that during the period when he himself had been looked after as an infant these same performances had been the source of pleasurable sensations for him. He had obtained this pleasure from his erotogenic zones with the help of the person who had looked after him - his mother, in fact; and thus the pleasure already pointed the way to object-choice. But it is just possible that at a still earlier date he had been in the habit of giving himself this pleasure auto-erotically - that he had been one of those children who like retaining their excreta till they can derive a voluptuous sensation from their evacuation. I say no more than that it is possible, because the matter was not cleared up in the analysis; the 'making a row with the legs' (kicking about), of which he was so much frightened later on, points in that direction. But in any case these sources of pleasure had no particularly striking importance with Hans, as they so often have with other children. He early became clean in his habits, and neither bed-wetting nor diurnal incontinence played any part during his first years; no trace was observed in him of any inclination to play with his excrement, a propensity which is so revolting in adults, and which commonly makes its reappearance at the termination of processes of psychical involution.

[1909b, 2092]

Moreover, this event and the feelings that were revived by it gave a new direction to his wishes. In his triumphant final phantasy he summed up all of his erotic wishes, both those derived from his auto-erotic phase and those connected with his object-love. In that phantasy he was married to his beautiful mother and had innumerable children whom he could look after in his own way.

[1909b, 2098]
The content of the sexual life of infancy consists in auto-erotic activity on the part of the dominant sexual components, in traces of object-love, and in the formation of that complex which deserves to be called the **nuclear complex of the neuroses**. It is the complex which comprises the child's earliest impulses, alike tender and hostile, towards its parents and brothers and sisters, after its curiosity has been awakened - usually by the arrival of a new baby brother or sister. The uniformity of the content of the sexual life of children, together with the unvarying character of the modifying tendencies which are later brought to bear upon it, will easily account for the constant sameness which as a rule characterizes the phantasies that are constructed around the period of childhood, irrespective of how greatly or how little real experiences have contributed towards them. It is entirely characteristic of the nuclear complex of infancy that the child's father should be assigned the part of a sexual opponent and of an interferer with auto-erotic sexual activities; and real events are usually to a large extent responsible for bringing this about.

[1909d, 2162]
Put away your doubts, then, and join me in a consideration of infantile sexuality from the earliest age.¹ A child's sexual instinct turns out to be put together out of a number of factors; it is capable of being divided up into numerous components which originate from various sources. Above all, it is still independent of the reproductive function, into the service of which it will later be brought. It serves for the acquisition of different kinds of pleasurable feeling, which, basing ourselves on analogies and connections, we bring together under the idea of sexual pleasure. The chief source of infantile sexual pleasure is the appropriate excitation of certain parts of the body that are especially susceptible to stimulus: apart from the genitals, these are the oral, anal and urethral orifices, as well as the skin and other sensory surfaces. Since at this first phase of infantile sexual life satisfaction is obtained from the subject's own body and extraneous objects are disregarded, we term this phase (from a word coined by Havelock Ellis) that of auto-erotism. We call the parts of the body that are important in the acquisition of sexual pleasure 'erotogenic zones'. Thumb-sucking (or sensual sucking) in the youngest infants is a good example of this auto-erotic satisfaction from an erotogenic zone. The first scientific observer of this phenomenon, a paediatrician in Budapest named Lindner (1879), already interpreted it correctly as sexual satisfaction and described exhaustively its transition to other and higher forms of sexual activity. Another sexual satisfaction at this period of life is the masturbatory excitation of the genitals, which retains so much importance in later life and by many people is never completely conquered. Alongside these and other auto-erotic activities, we find in children at a very early age manifestations of those instinctual components of sexual pleasure (or, as we like to say, of libido) which presuppose the taking of an extraneous person as an object. These instincts occur in pairs of opposites, active and passive. I may mention as the most important representatives of this group the desire to cause pain (sadism) with its passive counterpart (masochism) and the active and passive desire for looking, from the former of which curiosity branches off later on and from the latter the impulsion to artistic and theatrical display. Others of a child's sexual activities already imply the making of an 'object-choice', where an extraneous person becomes the main feature, a person who owes his importance in the first instance to considerations arising from the self-preservative instinct. But at this early period of childhood difference in sex plays no decisive part as yet. Thus you can attribute some degree of homosexuality to every child without doing him an injustice. This widespread and copious but dissociated sexual life of children, in which each separate instinct pursues its own acquisition of pleasure independently of all the rest, is now brought together and organized in two main directions, so that by the end of puberty the individual's final sexual character is as a rule completely formed. On the one hand, the separate instincts become subordinated to the dominance of the genital zone, so that the whole sexual life enters the service of reproduction, and the satisfaction of the separate instincts retains its importance only as preparing for and encouraging the sexual act proper. On the other hand, object-choice pushes auto-erotism into the background, so that in the subject's erotic life all the components of the sexual instinct now seek satisfaction in relation to the person who is loved. Not all of the original sexual components, however, are admitted to take part in this final establishment of sexuality. Even before puberty extremely energetic repressions of certain instincts have been effected under the influence of education, and mental forces such as shame, disgust and morality have been set up, which, like watchmen, maintain these repressions. So that when at puberty the high tide of sexual demands is reached, it is met by these mental reactive or resistant structures like dams, which direct its flow into what are called normal channels and make it impossible for it to reactivate the instincts that have undergone repression. It is in particular the coprophilic impulses of childhood - that is to say, the desires attaching to the excreta - which are submitted the most rigorously to repression, and the same is true, furthermore, of fixation to the figures to which the child's original object-choice was attached.

[1910a, 2230]
I shall now endeavour (and I think the attempt is neither unnecessary nor unjustifiable) to show that the knowledge of psychological processes, which, thanks to psycho-analysis, we now possess, already enables us to understand the part played by a homosexual wish in the development of paranoia. Recent investigations¹ have directed our attention to a stage in the development of the libido which it passes through on the way from auto-eroticism to object-love.² This stage has been given the name of narcissism. What happens is this. There comes a time in the development of the individual at which he unifies his sexual instincts (which have hitherto been engaged in auto-erotic activities) in order to obtain a love-object; and he begins by taking himself, his own body, as his love-object, and only subsequently proceeds from this to the choice of some person other than himself as his object. This half-way phase between auto-erotism and object-love may perhaps be indispensable normally; but it appears that many people linger unusually long in this condition, and that many of its features are carried over by them into the later stages of their development. What is of chief importance in the subject's self thus chosen as a love object may already be the genitals. The line of development then leads on to the choice of an external object with similar genitals - that is, to homosexual object-choice - and thence to heterosexuality. People who are manifest homosexuals in later life have, it may be presumed, never emancipated themselves from the binding condition that the object of their choice must possess genitals like their own; and in this connection the infantile sexual theories which attribute the same kind of genitals to both sexes exert much influence.

[1911c, 2430]

If an infant could speak, he would no doubt pronounce the act of sucking at his mother's breast by far the most important in his life. He is not far wrong in this, for in this single act he is satisfying at once the two great vital needs. We are therefore not surprised to learn from psycho-analysis how such psychical importance the act retains all through life. Sucking at the mother's breast is the starting-point of the whole of sexual life, the unmatched prototype of every later sexual satisfaction, to which phantasy often enough recurs in times of need. This sucking involves making the mother's breast the first object of the sexual instinct. I can give you no idea of the important bearing of this first object upon the choice of every later object, of the profound effects it has in its transformations and substitutions in even the remotest regions of our sexual life. But at first the infant, in his sucking activity, gives up this object and replaces it by a part of his own body. He begins to suck his thumbs or his own tongue. In this way he makes himself independent of the consent of the external world as regards gaining pleasure, and besides this he increases it by adding the excitation of a second area of his body. The erotogenic zones are not all equally generous in yielding pleasure; it is therefore an important experience when the infant, as Lindner reports, discovers, in the course of feeling around, the specially excitable regions afforded by his genitals and so finds his way from sucking to masturbation.

[1916-1917, 3385]
To-day we will follow yet another side of this development namely the relation of the component sexual instincts to their object. Or rather, we will make a hasty survey of this development and dwell somewhat longer on one of its rather late consequences. A few of the components of the sexual instinct, there, have an object from the first and hold fast to it - for instance, the instinct for mastery (sadism) and the scopophilic and epistemophilic instincts. Others, more definitely linked to particular erogenous zones of the body, have one to begin with only so long as they are still attached to the non-sexual functions, and give it up when they become separated from them. Thus the first object of the oral component of the sexual instinct is the mother's breast which satisfies the infant's need for nourishment. The erotic component, which is satisfied simultaneously during the sucking, makes itself independent with the act of *sensual* sucking [*lutschen*]; it gives up the outside object and replaces it by an area of the subject's own body. The oral instinct becomes *auto-erotic*, as are the anal and other erogenous instincts from the first. Further development, to put the matter as concisely as possible, has two aims: firstly, the abandonment of auto-erotism, the replacement of the subject's own body once more by an outside object, and secondly, the unification of the various objects of the separate instincts and their replacement by a single object. This can, of course, only be achieved if the object is again a whole body, similar to the subject's own. Nor can it be effected unless a number of the auto-erotic instinctual impulses are left behind as being unserviceable.

[1916-1917, 3396]

It is something else besides that makes symptoms seem strange to us and incomprehensible as a means of libidinal satisfaction. They do not remind us in the very least of anything from which we are in the habit of normally expecting satisfaction. Usually they disregard objects and in so doing abandon their relation to external reality. We can see that this is a consequence of turning away from the reality principle and of returning to the pleasure principle. But it is also a return to a kind of extended auto-erotism, of the sort that offered the sexual instinct its first satisfactions. In place of a change in the external world these substitute a change in the subject's own body: they set an internal act in place of an external one, an adaptation in place of an action - once again, something that corresponds, phylogenetically, to a highly significant regression. We shall only understand this in connection with something new that we have still to learn from the analytic researches into the formation of symptoms. We must further remember that the same processes belonging to the unconscious play a part in the formation of dreams - namely, condensation and displacement. A symptom, like a dream, represents something as fulfilled: a satisfaction in the infantile manner. But by means of extreme condensation that satisfaction can be compressed into a single sensation or innervation, and by means of extreme displacement it can be restricted to one small detail of the entire libidinal complex. It is not to be wondered at if we, too, often have difficulty in recognizing in a symptom the libidinal satisfaction whose presence we suspect and which is invariably confirmed.

[1916-1917, 3423]

*The Process of Finding an Object, and the Oedipus Complex.* - In the first instance the oral component instinct finds satisfaction by attaching itself to the satiating of the desire for nourishment; and its object is the mother's breast. It then detaches itself, becomes independent and at the same time *auto-erotic*, that is, it finds an object in the child's own body. Others of the component instincts also start by being auto-erotic and are not until later diverted on to an external object. It is a particularly important fact that the component instincts belonging to the genital zone habitually pass through a period of intense auto-erotic satisfaction. The component instincts are not all equally serviceable in the final genital organization of libido; some of them (for instance, the anal components) are consequently left aside and suppressed, or undergo complicated transformations.

[1923a, 3922]
The process of arriving at an object, which plays such an important part in mental life, takes place alongside of the organization of the libido. After the stage of auto-erotism, the first love-object in the case of both sexes is the mother; and it seems probable that to begin with a child does not distinguish its mother’s organ of nutrition from its own body. Later, but still in the first years of infancy, the relation known as the Oedipus complex becomes established: boys concentrate their sexual wishes upon their mother and develop hostile impulses against their father as being a rival, while girls adopt an analogous attitude.¹ All of the different variations and consequences of the Oedipus complex are important; and the innately bisexual constitution of human beings makes itself felt and increases the number of simultaneously active tendencies. Children do not become clear for quite a long time about the differences between the sexes; and during this period of sexual researches they produce typical sexual theories which, being circumscribed by the incompleteness of their authors’ own physical development, are a mixture of truth and error and fail to solve the problems of sexual life (the riddle of the Sphinx - that is, the question of where babies come from). We see, then, that a child’s first object-choice is an incestuous one. The whole course of development that I have described is run through rapidly. For the most remarkable feature of the sexual life of man is its diphasic onset, its onset in two waves, with an interval between them. It reaches a first climax in the fourth or fifth year of a child’s life. But thereafter this early efflorescence of sexuality passes off; the sexual impulses which have shown such liveliness are overcome by repression, and a period of latency follows, which lasts until puberty and during which the reaction-formations of morality, shame, and disgust are built up.² Of all living creatures man alone seems to show this diphasic onset of sexual growth, and it may perhaps be the biological determinant of his predisposition to neuroses. At puberty the impulses and object-relations of a child’s early years become reanimated, and amongst them the emotional ties of its Oedipus complex. In the sexual life of puberty there is a struggle between the urges of early years and the inhibitions of the latency period. Before this, and while the child is at the highest point of its infantile sexual development, a genital organization of a sort is established; but only the male genitals play a part in it, and the female ones remain undiscovered. (I have described this as the period of phallic primacy.) At this stage the contrast between the sexes is not stated in terms of ‘male’ or ‘female’ but of ‘possessing a penis’ or ‘castrated’. The castration complex which arises in this connection is of the profoundest importance in the formation alike of character and of neuroses.

¹ [1925d, 4212]
This ego-libido is, however, only conveniently accessible to analytic study when it has been put to the use of cathecting sexual objects, that is, when it has become object-libido. We can then perceive it concentrating upon objects, becoming fixed upon them or abandoning them, moving from one object to another and, from these situations, directing the subject’s sexual activity, which leads to the satisfaction, that is, to the partial and temporary extinction, of the libido. The psycho-analysis of what are termed transference neuroses (hysteria and obsessional neurosis) affords us a clear insight at this point.

[1905d, 1531]

We can follow the object-libido through still further vicissitudes. When it is withdrawn from objects, it is held in suspense in peculiar conditions of tension and is finally drawn back into the ego, so that it becomes ego-libido once again. In contrast to object-libido, we also describe ego-libido as ‘narcissistic’ libido. From the vantage-point of psycho-analysis we can look across a frontier, which we may not pass, at the activities of narcissistic libido, and may form some idea of the relation between it and object-libido.¹ Narcissistic or ego-libido seems to be the great reservoir from which the object-cathexes are sent out and into which they are withdrawn once more; the narcissistic libidinal cathexis of the ego is the original state of things, realized in earliest childhood, and is merely covered by the later extrusions of libido, but in essentials persists behind them.

[1905d, 1532]

(1) Our first reflection will tell us that it cannot be the case that this detachment of the libido occurs exclusively in paranoia; nor can it be that, where it occurs elsewhere, it has such disastrous consequences. It is quite possible that a detachment of the libido is the essential and regular mechanism of every repression. We can have no positive knowledge on that point until the other disorders that are based upon repression have been similarly examined. But it is certain that in normal mental life (and not only in periods of mourning) we are constantly detaching our libido in this way from people or from other objects without falling ill. When Faust freed himself from the world by uttering his curses, the result was not a paranoia or any other neurosis but simply a certain general frame of mind. The detachment of the libido, therefore, cannot in itself be the pathogenic factor in paranoia; there must be some special characteristic which distinguishes a paranoic detachment of the libido from other kinds. It is not difficult to suggest what that characteristic may be. What use is made of the libido after it has been set free by the process of detachment? A normal person will at once begin looking about for a substitute for the lost attachment; and until that substitute has been found the liberated libido will be kept in suspension within his mind, and will there give rise to tensions and colour his mood. In hysteria the liberated libido becomes transformed into somatic innervations or into anxiety. But in paranoia the clinical evidence goes to show that the libido, after it has been withdrawn from the object, is put to a special use. It will be remembered that the majority of cases of paranoia exhibit traces of megalomania, and that megalomania can by itself constitute a paranoia. From this it may be concluded that in paranoia the liberated libido becomes attached to the ego, and is used for the aggrandizement of the ego. A return is thus made to the stage of narcissism (known to us from the development of the libido), in which a person’s only sexual object is his own ego. On the basis of this clinical evidence we can suppose that paranoics have brought along with them a fixation at the stage of narcissism, and we can assert that the length of the step back from sublimated homosexuality to narcissism is a measure of the amount of regression characteristic of paranoia.

[1911c, 2438]
Our inquiry into the various vicissitudes which instincts undergo in the process of development and in the course of life must be confined to the sexual instincts, which are the more familiar to us. Observation shows us that an instinct may undergo the following vicissitudes:-

Reversal into its opposite.
Turning round upon the subject's own self.
Repression.
Sublimation.

Since I do not intend to treat of sublimation here and since repression requires a special chapter to itself, it only remains for us to describe and discuss the two first points. Bearing in mind that there are motive forces which work against an instinct's being carried through in an unmodified form, we may also regard these vicissitudes as modes of defence against the instincts.

Reversal of an instinct into its opposite resolves on closer examination into two different processes: a change from activity to passivity, and a reversal of its content. The two processes, being different in their nature, must be treated separately.

Examples of the first process are met with in the two pairs of opposites: sadism-masochism and scopophilia-exhibitionism. The reversal affects only the aims of the instincts. The active aim (to torture, to look at) is replaced by the passive aim (to be tortured, to be looked at). Reversal of content is found in the single instance of the transformation of love into hate.

The turning round of an instinct upon the subject's own self is made plausible by the reflection that masochism is actually sadism turned round upon the subject's own ego, and that exhibitionism includes looking at his own body. Analytic observation, indeed, leaves us in no doubt that the masochist shares in the enjoyment of the assault upon himself, and that the exhibitionist shares in the enjoyment of his exposure. The essence of the process is thus the change of the object, while the aim remains unchanged. We cannot fail to notice, however, that in these examples the turning round upon the subject's self and the transformation from activity to passivity converge or coincide.
With regard to both the instincts which we have just taken as examples, it should be remarked that their transformation by a reversal from activity to passivity and by a turning round upon the subject never in fact involves the whole quota of the instinctual impulse. The earlier active direction of the instinct persists to some degree side by side with its later passive direction, even when the process of its transformation has been very extensive. The only correct statement to make about the scopophilic instinct would be that all the stages of its development, its auto-erotic, preliminary stage as well as its final active or passive form, co-exist alongside one another; and the truth of this becomes obvious if we base our opinion, not on the actions to which the instinct leads, but on the mechanism of its satisfaction. Perhaps, however, it is permissible to look at the matter and represent it in yet another way. We can divide the life of each instinct into a series of separate successive waves, each of which is homogeneous during whatever period of time it may last, and whose relation to one another is comparable to that of successive eruptions of lava. We can then perhaps picture the first, original eruption of the instinct as proceeding in an unchanged form and undergoing no development at all. The next wave would be modified from the outset -(being turned, for instance, from active to passive - and would then, with this new characteristic, be added to the earlier wave, and so on. If we were then to take a survey of the instinctual impulse from its beginning up to a given point, the succession of waves which we have described would inevitably present the picture of a definite development of the instinct.

The fact that, at this later period of development of an instinctual impulse, its (passive) opposite may be observed alongside of it deserves to be marked by the very apt term introduced by Bleuler - 'ambivalence'.

We have become accustomed to call the early phase of the development of the ego, during which its sexual instincts find auto-erotic satisfaction, 'narcissism', without at once entering on any discussion of the relation between auto-erotism and narcissism. It follows that the preliminary stage of the scopophilic instinct, in which the subject's own body is the object of the scopophilia, must be classed under narcissism, and that we must describe it as a narcissistic formation. The active scopophilic instinct develops from this, by leaving narcissism behind. The passive scopophilic instinct, on the contrary, holds fast to the narcissistic object. Similarly, the transformation of sadism into masochism implies a return to the narcissistic object. And in both these cases the narcissistic subject is, through identification, replaced by another, extraneous ego. If we take into account our constructed preliminary narcissistic stage of sadism, we shall be approaching a more general realization - namely, that the instinctual vicissitudes which consist in the instinct's being turned round upon the subject's own ego and undergoing reversal from activity to passivity are dependent on the narcissistic organization of the ego and bear the stamp of that phase. They perhaps correspond to the attempts at defence which at higher stages of the development of the ego are effected by other means.

The change of the content of an instinct into its opposite is observed in a single instance only - the transformation of love into hate. Since it is particularly common to find both these directed simultaneously towards the same object, their co-existence furnishes the most important example of ambivalence of feeling.
Loving admits not merely of one, but of three opposites. In addition to the antithesis 'loving-hating', there is the other one of 'loving-being loved'; and, in addition to these, loving and hating taken together are the opposite of the condition of unconcern or indifference. The second of these three antitheses, loving-being loved, corresponds exactly to the transformation from activity to passivity and may be traced to an underlying situation in the same way as in the case of the scopophilic instinct. This situation is that of loving oneself which we regard as the characteristic feature of narcissism. Then, according as the object or the subject is replaced by an extraneous one, what results is the active aim of loving or the passive one of being loved - the latter remaining near to narcissism.

The instinctual vicissitude of repression will form the subject of an inquiry which follows.

Hitherto it has been a premiss of our work that we can distinguish the ego-instincts from the sexual ones by their manifestations. With the transference neuroses this could be done without difficulty. We termed the cathexes of energy which the ego directs towards the objects of its sexual desires 'libido'; all the others, which are sent out by the self-preservative instincts, we termed 'interest'. By tracing the course of the libidinal cathexes, their transformations and final vicissitudes, we were able to obtain a first insight into the machinery of the mental forces. For this purpose the transference neuroses offered us the most favourable material. But the ego, its composition out of various organizations and their construction and mode of functioning, remained hidden from us; and we were driven to suspect that only the analysis of other neurotic disorders would be able to bring us the necessary insight.

I have now led you into the region in which the next advances in the work of analysis are to be expected. Since we have ventured to operate with the concept of ego-libido the narcissistic neuroses have become accessible to us; the task before us is to arrive at a dynamic elucidation of these disorders and at the same time to complete our knowledge of mental life by coming to understand the ego. The ego-psychology after which we are seeking must not be based on the data of our self-perceptions but (as in the case of the libido) on the analysis of disturbances and disruptions of the ego. It is likely that we shall have a low opinion of our present knowledge of the vicissitudes of the libido, which we have gained from a study of the transference neuroses, when we have achieved this greater task. But hitherto we have not made much progress with it. The narcissistic neuroses can scarcely be attacked with the technique that has served us with the transference neuroses. You will soon learn why. What always happens with them is that, after proceeding for a short distance, we come up against a wall which brings us to a stop. Even with the transference neuroses, as you know, we met with barriers of resistance, but we were able to demolish them bit by bit. In the narcissistic neuroses the resistance is unconquerable; at the most, we are able to cast an inquisitive glance over the top of the wall and spy out what is going on on the other side of it. Our technical methods must accordingly be replaced by others; and we do not know yet whether we shall succeed in finding substitute. Nevertheless, we have no lack of material with these patients either. They make a large number of remarks, even if they do not answer our questions, and for the time being it is our business to interpret these remarks with the help of the understanding we have gained from the symptoms of the transference neuroses. The agreement is great enough to guarantee us some initial advantage. It remains to be seen how far this technique will take us.
It is hard to say anything of the behaviour of the libido in the id and in the super-ego. All that we know about it relates to the ego, in which at first the whole available quota of libido is stored up. We call this state absolute, primary narcissism. It lasts till the ego begins to cathect the ideas of objects with libido, to transform narcissistic libido into object-libido. Throughout the whole of life the ego remains the great reservoir from which libidinal cathexes are sent out to objects and into which they are also once more withdrawn, just as an amoeba behaves with its pseudopodia. It is only when a person is completely in love that the main quota of libido is transferred on to the object and the object to some extent takes the place of the ego. A characteristic of the libido which is important in life is its mobility, the facility with which it passes from one object to another. This must be contrasted with the fixation of the libido to particular objects, which often persists throughout life.

[1940a [1938], 4961]
The conceptual scaffolding which we have set up to help us in dealing with the psychical manifestations of sexual life tallies well with these hypotheses as to the chemical basis of sexual excitation. We have defined the concept of libido as a quantitatively variable force which could serve as a measure of processes and transformations occurring in the field of sexual excitation. We distinguish this libido in respect of its special origin from the energy which must be supposed to underlie mental processes in general, and we thus also attribute a qualitative character to it. In thus distinguishing between libidinal and other forms of psychical energy we are giving expression to the presumption that the sexual processes occurring in the organism are distinguished from the nutritive processes by a special chemistry. The analysis of the perversions and psychoneuroses has shown us that this sexual excitation is derived not from the so-called sexual parts alone, but from all the bodily organs. We thus reach the idea of a quantity of libido, to the mental representation of which we give the name of 'ego-libido', and whose production, increase or diminution, distribution and displacement should afford us possibilities for explaining the psychosexual phenomena observed.

[1905d, 1531]

This ego-libido is, however, only conveniently accessible to analytic study when it has been put to the use of cathecting sexual objects, that is, when it has become object-libido. We can then perceive it concentrating upon objects, becoming fixed upon them or abandoning them, moving from one object to another and, from these situations, directing the subject's sexual activity, which leads to the satisfaction, that is, to the partial and temporary extinction, of the libido. The psycho-analysis of what are termed transference neuroses (hysteria and obsessional neurosis) affords us a clear insight at this point.

[1905d, 1531]

We can follow the object-libido through still further vicissitudes. When it is withdrawn from objects, it is held in suspense in peculiar conditions of tension and is finally drawn back into the ego, so that it becomes ego-libido once again. In contrast to object-libido, we also describe ego-libido as 'narcissistic' libido. From the vantage-point of psycho-analysis we can look across a frontier, which we may not pass, at the activities of narcissistic libido, and may form some idea of the relation between it and object-libido.¹ Narcissistic or ego-libido seems to be the great reservoir from which the object-cathexes are sent out and into which they are withdrawn once more; the narcissistic libidinal cathexis of the ego is the original state of things, realized in earliest childhood, and is merely covered by the later extrusions of libido, but in essentials persists behind them.

[1905d, 1532]

It is of some importance in connection with other parts of the theory of paranoia to notice that we can detect an element of megalomania in most other forms of paranoid disorder. We are justified in assuming that megalomania is essentially of an infantile nature and that, as development proceeds, it is sacrificed to social considerations. Similarly, an individual's megalomania is never so vehemently suppressed as when he is in the grip of an overpowering love:

[1911c, 2433]
This extension of the libido theory - in my opinion, a legitimate one - receives reinforcement from a third quarter, namely, from our observations and views on the mental life of children and primitive peoples. In the latter we find characteristics which, if they occurred singly, might be put down to megalomania: an over-estimation of the power of their wishes and mental acts, the 'omnipotence of thoughts', a belief in the thaumaturgic force of words, and a technique for dealing with the external world - 'magic' - which appears to be a logical application of these grandiose premisses.¹ In the children of to-day, whose development is much more obscure to us, we expect to find an exactly analogous attitude towards the external world.² Thus we form the idea of there being an original libidinal cathexis of the ego, from which some is later given off to objects, but which fundamentally persists and is related to the object-cathexes much as the body of an amoeba is related to the pseudopodia which it puts out. In our researches, taking, as they did, neurotic symptoms for their starting-point, this part of the allocation of libido necessarily remained hidden from us at the outset. All that we noticed were the emanations of this libido - the object-cathexes, which can be sent out and drawn back again. We see also, broadly speaking, an antithesis between ego-libido and object-libido. The more of the one is employed, the more the other becomes depleted. The highest phase of development of which object-libido is capable is seen in the state of being in love, when the subject seems to give up his own personality in favour of an object-cathexis; while we have the opposite condition in the paranoid's phantasy (or self-perception) of the 'end of the world'.³ Finally, as regards the differentiation of psychical energies, we are led to the conclusion that to begin with, during the state of narcissism, they exist together and that our analysis is too coarse to distinguish between them; not until there is object-cathexis is it possible to discriminate a sexual energy - the libido - from an energy of the ego-instincts.

To be asked to give a definite answer to the second question must occasion perceptible uneasiness in every psycho-analyst. One dislikes the thought of abandoning observation for barren theoretical controversy, but nevertheless one must not shirk an attempt at clarification. It is true that notions such as that of an ego-libido, an energy of the ego-instincts, and so on, are neither particularly easy to grasp, nor sufficiently rich in content; a speculative theory of the relations in question would begin by seeking to obtain a sharply defined concept as its basis. But I am of opinion that that is just the difference between a speculative theory and a science erected on empirical interpretation. The latter will not envy speculation its privilege of having a smooth, logically unassailable foundation, but will gladly content itself with nebulous, scarcely imaginable basic concepts, which it hopes to apprehend more clearly in the course of its development, or which it is even prepared to replace by others. For these ideas are not the foundation of science, upon which everything rests: that foundation is observation alone. They are not the bottom but the top of the whole structure, and they can be replaced and discarded without damaging it. The same thing is happening in our day in the science of physics, the basic notions of which as regards matter, centres of force, attraction, etc., are scarcely less debatable than the corresponding notions in psycho-analysis.
In the total absence of any theory of the instincts which would help us to find our bearings, we may be permitted, or rather, it is incumbent upon us, to start off by working out some hypothesis to its logical conclusion, until it either breaks down or is confirmed. There are various points in favour of the hypothesis of there having been from the first a separation between sexual instincts and others, ego-instincts, besides the serviceability of such a hypothesis in the analysis of the transference neuroses. I admit that this latter consideration alone would not be unambiguous, for it might be a question of an indifferent psychical energy which only becomes libido through the act of cathecting an object. But, in the first place, the distinction made in this concept corresponds to the common, popular distinction between hunger and love. In the second place, there are biological considerations in its favour. The individual does actually carry on a twofold existence: one to serve his own purposes and the other as a link in a chain, which he serves against his will, or at least involuntarily. The individual himself regards sexuality as one of his own ends; whereas from another point of view he is an appendage to his germ plasm, at whose disposal he puts his energies in return for a bonus of pleasure. He is the mortal vehicle of a (possibly) immortal substance - like the inheritor of an entailed property, who is only the temporary holder of an estate which survives him. The separation of the sexual instincts from the ego-instincts would simply reflect this twofold function of the individual. Thirdly, we must recollect that all our provisional ideas in psychology will presumably some day be based on an organic substructure. This makes it probable that it is special substances and chemical processes which perform the operations of sexuality and provide for the extension of individual life into that of the species. We are taking this probability into account in replacing the special chemical substances by special psychical forces.

Observation of normal adults shows that their former megalomania has been damped down and that the psychical characteristics from which we inferred their infantile narcissism have been effaced. What has become of their ego-libido? Are we to suppose that the whole amount of it has passed into object-cathexes? Such a possibility is plainly contrary to the whole trend of our argument; but we may find a hint at another answer to the question in the psychology of repression.

Applying our distinction between sexual and ego-instincts, we must recognize that self-regard has a specially intimate dependence on narcissistic libido. Here we are supported by two fundamental facts: that in paraphrenics self-regard is increased, while in the transference neuroses it is diminished; and that in love-relations not being loved lowers the self-regarding feelings, while being loved raises them. As we have indicated, the aim and the satisfaction in a narcissistic object-choice is to be loved.

Further, it is easy to observe that libidinal object-cathexis does not raise self-regard. The effect of dependence upon the loved object is to lower that feeling: a person in love is humble. A person who loves has, so to speak, forfeited a part of his narcissism, and it can only be replaced by his being loved. In all these respects self-regard seems to remain related to the narcissistic element in love.
The relations of self-regard to erotism - that is, to libidinal object-cathexes - may be expressed concisely in the following way. Two cases must be distinguished, according to whether the erotic cathexes are ego-syntonic, or, on the contrary, have suffered repression. In the former case (where the use made of the libido is ego-syntonic), love is assessed like any other activity of the ego. Loving in itself, in so far as it involves longing and deprivation, lowers self-regard; whereas being loved, having one's love returned, and possessing the loved object, raises it once more. When libido is repressed, the erotic cathexis is felt as a severe depletion of the ego, the satisfaction of love is impossible, and the re-enrichment of the ego can be effected only by a withdrawal of libido from its objects. The return of the object-libido to the ego and its transformation into narcissism represents, as it were, a happy love once more; and, on the other hand, it is also true that a real happy love corresponds to the primal condition in which object-libido and ego-libido cannot be distinguished.

At the same time the ego has sent out the libidinal object-cathexes. It becomes impoverished in favour of these cathexes, just as it does in favour of the ego ideal, and it enriches itself once more from its satisfactions in respect of the object, just as it does by fulfilling its ideal.

Being in love consists in a flowing-over of ego-libido on to the object. It has the power to remove repressions and re-instate perversions. It exalts the sexual object into a sexual ideal. Since, with the object type (or attachment type), being in love occurs in virtue of the fulfilment of infantile conditions for loving, we may say that whatever fulfils that condition is idealized.

Mourning over the loss of something that we have loved or admired seems so natural to the layman that he regards it as self-evident. But to psychologists mourning is a great riddle, one of those phenomena which cannot themselves be explained but to which other obscurities can be traced back. We possess, as it seems, a certain amount of capacity for love - what we call libido - which in the earliest stages of development is directed towards our own ego. Later, though still at a very early time, this libido is diverted from the ego on to objects, which are thus in a sense taken into our ego. If the objects are destroyed or if they are lost to us, our capacity for love (our libido) is once more liberated; and it can then either take other objects instead or can temporarily return to the ego. But why it is that this detachment of libido from its objects should be such a painful process is a mystery to us and we have not hitherto been able to frame any hypothesis to account for it. We only see that libido clings to its objects and will not renounce those that are lost even when a substitute lies ready to hand. Such then is mourning.

I may tell you at once that these first explanations of Abraham's have been accepted in psycho-analysis and have become the basis of our attitude to the psychoses. We thus slowly became familiar with the notion that the libido, which we find attached to objects and which is the expression of an effort to obtain satisfaction in connection with those objects, can also leave the objects and set the subject's own ego in their place; and this notion was gradually built up more and more consistently. The name for this way of allocating the libido - 'narcissism' - was borrowed by us from a perversion described by Paul Näcke in which an adult treats his own body with all the caresses that are usually devoted to an outside sexual object.
Reflection will quickly suggest that if any such fixation of the libido to the subject's own body and personality, instead of to an object does occur, it cannot be an exception or a trivial event. On the contrary it is probable that this narcissism is the universal and original state of things, from which object-love is only later developed, without the narcissism necessarily disappearing on that account. Indeed we had to recall from the history of the development of object-libido that many sexual instincts begin by finding satisfaction in the subject's own body - auto-erotically, as we say - and that this capacity for auto-erotism is the basis of the lagging-behind of sexuality in the process of education in the reality principle. Auto-erotism would thus be the sexual activity of the narcissistic stage of allocation of the libido.

To put the matter shortly, we pictured the relation of ego-libido to object-libido in a way which I can make plain to you by an analogy from zoology. Think of those simplest of living organisms which consist of a little-differentiated globule of protoplasmic substance. They put out protrusions, known as pseudopodia, into which they cause the substance of their body to flow over. They are able, however, to withdraw the protrusions once more and form themselves again into a globule. We compare the putting-out of these protrusions, then, to the emission of libido on to objects while the main mass of libido can remain in the ego; and we suppose that in normal circumstances ego-libido can be transformed unhindered into object-libido and that this can once more be taken back into the ego.

With the help of these ideas we are now able to explain a whole number of mental states or, to express it more modestly, to describe them in terms of the libido theory - states which we must reckon as belonging to normal life, such as the psychical behaviour of a person in love, during an organic illness or when asleep. As regards the state of sleep, we assumed that it was based on turning-away from the external world and adopting a wish to sleep. The mental activity during the night which is manifested in dreams takes place, we found, in obedience to a wish to sleep and is moreover dominated by purely egoistic motives. We may now add, on the lines of the libido theory, that sleep is a state in which all object-cathexes, libidinal as well as egoistic, are given up and withdrawn into the ego. May not this throw a fresh light on the recuperating effect of sleep and on the nature of fatigue in general? The picture of the blissful isolation of intra-uterine life which a sleeper conjures up once more before us every night is in this way completed on its psychical side as well. In a sleeper the primal state of distribution of the libido is restored - total narcissism, in which libido and ego-interest, still united and indistinguishable, dwell in the self-sufficing ego.
This is the place for two remarks. First, how do we differentiate between the concepts of narcissism and egoism? Well, narcissism, I believe, is the libidinal complement to egoism. When we speak of egoism, we have in view only the individual's advantage; when we talk of narcissism we are also taking his libidinal satisfaction into account. As practical motives the two can be traced separately for quite a distance. It is possible to be absolutely egoistic and yet maintain powerful object-cathexes, in so far as libidinal satisfaction in relation to the object forms part of the ego's needs. In that case, egoism will see to it that striving for the object involves no damage to the ego. It is possible to be egoistic and at the same time to be excessively narcissistic - that is to say, to have very little need for an object, whether, once more, for the purpose of direct sexual satisfaction, or in connection with the higher aspirations, derived from sexual need, which we are occasionally in the habit of contrasting with 'sensuality' under the name of 'love'. In all these connections egoism is what is self-evident and constant, while narcissism is the variable element. The opposite to egoism, altruism, does not, as a concept, coincide with libidinal object-cathexis, but is distinguished from it by the absence of longings for sexual satisfaction. When someone is completely in love, however, altruism converges with libidinal object-cathexis. As a rule the sexual object attracts a portion of the ego's narcissism to itself, and this becomes noticeable as what is known as the 'sexual overvaluation' of the object. If in addition there is an altruistic transposition of egoism on to the sexual object, the object becomes supremely powerful; it has, as it were, absorbed the ego.

[1916-1917, 3462]

But I shall resist the temptation of going further here or of discussing other situations which can be understood or pictured if we adopt the hypothesis that the object-libido may withdraw into the ego - for I am obliged to meet two objections which, as I know, are now attracting your attention. In the first place you want to call me to account because in talking of sleep, illness and similar situations I invariably try to separate libido from interest, sexual from ego-instincts, where observations can be fully satisfied by the hypothesis of a single and uniform energy which, being freely mobile, cathects now the object and now the ego, in obedience to one or the other instinct. And in the second place you want to know how I can venture to treat the detaching of the libido from the object as the source of a pathological state, when a transposition of this kind of object-libido into ego-libido (or, more generally, into ego-energy) is among the normal processes of mental dynamics which are repeated daily and every night.

[1916-1917, 3465]

Here is my reply. Your first objection sounds well enough. Consideration of the states of sleep, of illness and of being in love in themselves would probably never have led us to distinguish an ego-libido from an object-libido or libido from interest. But there you are neglecting the investigations from which we started and in the light of which we now look at the mental situations under discussion. The differentiation between libido and interest - that is to say, between the sexual and the self-preservative instincts - was forced upon us by our discovery of the conflict out of which the transference neuroses arise. Since then we cannot give it up. The hypothesis that object-libido can be transformed into ego-libido, that we must therefore take an ego-libido into account, seems to us the only one which is able to resolve the enigma of what are termed the narcissistic neuroses - dementia praecox, for instance - and to account for the resemblances and dissimilarities between them and hysteria or obsessions. We are now applying to illness, sleep and being in love what we have elsewhere found inescapably established. We should proceed further with applications of this kind and see where they will take us to. The only thesis which is not an immediate precipitate of our analytic experience is to the effect that libido remains libido, whether it is directed to objects or to one's own ego, and never turns into egoistic interest, and the converse is also true. This thesis, however, is equivalent to the separation between the sexual and ego-instincts which we have already considered critically and to which we shall continue to hold for heuristic reasons until its possible collapse.

[1916-1917, 3465]
Your second observation, too, raises a justifiable question, but it is aimed in the wrong direction. It is true that a withdrawal of the object-libido into the ego is not directly pathogenic; it takes place, as we know, every time before we go to sleep, only to be reversed when we wake up. The amoeba withdraws its protrusions only to send them out again at the first opportunity. But it is quite a different thing when a particular, very energetic process forces a withdrawal of libido from objects. Here the libido that has become narcissistic cannot find its way back to objects, and this interference with the libido's mobility certainly becomes pathogenic. It seems that an accumulation of narcissistic libido beyond a certain amount is not tolerated. We may even imagine that it was for that very reason that object-cathexes originally came about, that the ego was obliged to send out its libido so as not to fall ill as a result of its being dammed up. If it lay within our plan to go more deeply into dementia praecox, I would show you that the process which detaches the libido from objects and cuts off its return to them is closely related to the process of repression and is to be looked at as its counterpart. But you would, first and foremost, find yourselves on familiar ground when you learnt that the determinants of this process are almost identical - so far as we know at present - with those of repression. The conflict seems to be the same and to be carried on between the same forces. If the outcome is so different from, for instance, that in hysteria, the reason can only depend on a difference in innate disposition. The weak spot in the libidinal development of these patients lies in a different phase; the determining fixation, which, as you will recollect, permits the eruption that leads to the formation of symptoms, lies elsewhere, probably in the stage of primitive narcissism to which dementia praecox returns in its final outcome. It is very remarkable that in the case of all the narcissistic neuroses we have to assume fixation points for the libido going back to far earlier phases of development than in hysteria or obsessional neurosis. As you heard, however, the concepts which we arrived at during our study of the transference neuroses are adequate in helping us to find our way about in the narcissistic neuroses which are so much more severe in practice. The conformities go very far; at bottom the field of phenomena is the same. And you can imagine how small a prospect anyone has of explaining these disorders (which belong within the sphere of psychiatry) who is not forearmed for his task with an analytic knowledge of the transference neuroses.

Homosexual object-choice originally lies closer to narcissism than does the heterosexual kind. When it is a question, therefore, of repelling an undesirably strong homosexual impulse, the path back to narcissism is made particularly easy. Hitherto I have had very little opportunity of talking to you about the foundations of erotic life so far as we have discovered them, and it is too late now to catch up on the omission. This much, however, I can emphasize to you. Object-choice, the step forward in the development of the libido which is made after the narcissistic stage, can take place according to two different types: either according to the narcissistic type, where the subject's own ego is replaced by another one that is as similar as possible, or according to the attachment type, where people who have become precious through satisfying the other vital needs are chosen as objects by the libido as well. A strong libidinal fixation to the narcissistic type of object-choice is to be included in the predisposition to manifest homosexuality.

On the basis of our clinical impressions we maintained that these patients' object-cathexes must have been given up and that their object-libido must have been transformed into ego-libido. Through this characteristic we distinguished them from the first group of neurotics (sufferers from hysteria, anxiety-hysteria and obsessional neurosis). This suspicion is now confirmed by their behaviour in our attempts at therapy. They manifest no transference and for that reason are inaccessible to our efforts and cannot be cured by us.
Moreover, a juster appreciation of the process of repression in our present case would lead us to deny that narcissistic masculinity was the sole motive force. The homosexual attitude which came into being during the dream was of such overwhelming intensity that the little boy’s ego found itself unable to cope with it and so defended itself against it by the process of repression. The narcissistic masculinity which attached to his genitals, being opposed to the homosexual attitude, was drawn in, in order to assist the ego in carrying out the task. Merely to avoid misunderstandings, I will add that all narcissistic impulses operate from the ego and have their permanent seat in the ego, and that repressions are directed against libidinal object cathexes.

[1918b, 3587]

During the work of treatment we have to consider the distribution of the patient's libido; we look for the object presentations to which it is bound and free it from them, so as to place it at the disposal of the ego. In the course of this, we have come to form a very curious picture of the original, primal distribution of libido in human beings. We have been driven to assume that at the beginning of the development of the individual all his libido (all his erotic tendencies, all his capacity for love) is tied to himself - that as we say, it cathects his own ego. It is only later that, being attached to the satisfaction of the major vital needs, the libido flows over from the ego on to external objects. Not till then are we able to recognize the libidinal instincts as such and distinguish them from the ego instincts. It is possible for the libido to become detached from these objects and withdrawn again into the ego.

[1917a, 3609]

Thus in our view the individual advances from narcissism to object-love. But we do not believe that the whole of the libido ever passes over from the ego to objects. A certain quantity of libido is always retained in the ego; even when object-love is highly developed, a certain amount of narcissism persists. The ego is a great reservoir from which the libido that is destined for objects flows out and into which it flows back from those objects. Object-libido was at first ego-libido and can be transformed back into ego-libido. For complete health it is essential that the libido should not lose this full mobility. As an illustration of this state of things we may think of an amoeba, whose viscous substance puts out pseudopodia, elongations into which the substance of the body extends but which can be retracted at any time so that the form of the protoplasmic mass is restored.

[1917a, 3610]

It only became possible to extend the libido theory to the narcissistic neuroses after the concept of a ‘narcissistic libido’ had been put forward and applied - a concept, that is, of an amount of sexual energy attached to the ego itself and finding satisfaction in the ego just as satisfaction is usually found only in objects. This entirely legitimate development of the concept of sexuality promises to accomplish as much for the severer neuroses and for the psychoses as can be expected of a theory which is feeling its way forwards on an empirical basis. The traumatic neuroses of peace will also fit into the scheme as soon as a successful outcome has been reached of our investigations into the relations which undoubtedly exist between fright, anxiety and narcissistic libido.

[1919d, 3667]
Let us make a bold attempt at another step forward. It is generally considered that the union of a number of cells into a vital association - the multicellular character of organisms - has become a means of prolonging their life. One cell helps to preserve the life of another, and the community of cells can survive even if individual cells have to die. We have already heard that conjugation, too, the temporary coalescence of two unicellular organisms, has a life-preserving and rejuvenating effect on both of them. Accordingly, we might attempt to apply the libido theory which has been arrived at in psycho-analysis to the mutual relationship of cells. We might suppose that the life instincts or sexual instincts which are active in each cell take the other cells as their object, that they partly neutralize the death instincts (that is, the processes set up by them) in those cells and thus preserve their life; while the other cells do the same for them, and still others sacrifice themselves in the performance of this libidinal function. The germ-cells themselves would behave in a completely 'narcissistic' fashion - to use the phrase that we are accustomed to use in the theory of the neuroses to describe a whole individual who retains his libido in his ego and pays none of it out in object-cathexes. The germ-cells require their libido, the activity of their life instincts, for themselves, as a reserve against their later momentous constructive activity. (The cells of the malignant neoplasms which destroy the organism should also perhaps be described as narcissistic in this same sense: pathology is prepared to regard their germs as innate and to ascribe embryonic attributes to them.) In this way the libido of our sexual instincts would coincide with the Eros of the poets and philosophers which holds all living things together.

[1920g, 3751]

The next step was taken when psycho-analysis felt its way closer towards the psychological ego, which it had first come to know only as a repressive, censoring agency, capable of erecting protective structures and reactive formations. Critical and far-seeing minds had, it is true, long since objected to the concept of libido being restricted to the energy of the sexual instincts directed towards an object. But they failed to explain how they had arrived at their better knowledge or to derive from it anything of which analysis could make use. Advancing more cautiously, psycho-analysis observed the regularity with which libido is withdrawn from the object and directed on to the ego (the process of introversion); and, by studying the libidinal development of children in its earliest phases, came to the conclusion that the ego is the true and original reservoir of libido, and that it is only from that reservoir that libido is extended on to objects. The ego now found its position among sexual objects and was at once given the foremost place among them. Libido which was in this way lodged in the ego was described as 'narcissistic}'.¹ This narcissistic libido was of course also a manifestation of the force of the sexual instinct in the analytical sense of those words, and it had necessarily to be identified with the 'self-preservation instincts' whose existence had been recognized from the first. Thus the original opposition between the ego-instincts and the sexual instincts proved to be inadequate. A portion of the ego-instincts was seen to be libidinal; sexual instincts - probably alongside others - operated in the ego. Nevertheless we are justified in saying that the old formula which lays it down that psychoneuroses are based on a conflict between ego-instincts and sexual instincts contains nothing that we need reject to-day. It is merely that the distinction between the two kinds of instinct, which was originally regarded as in some sort of way qualitative, must now be characterized differently - namely as being topographical. And in particular it is still true that the transference neuroses, the essential subject of psycho-analytic study, are the result of a conflict between the ego and the libidinal cathexis of objects.

[1920g, 3753]
The tendency which falsifies judgement in this respect is that of idealization. But now it is easier for us to find our bearings. We see that the object is being treated in the same way as our own ego, so that when we are in love a considerable amount of narcissistic libido overflows on to the object. It is even obvious, in many forms of love-choice, that the object serves as a substitute for some unattained ego ideal of our own. We love it on account of the perfections which we have striven to reach for our own ego, and which we should now like to procure in this roundabout way as a means of satisfying our narcissism.

Narcissism. - A decisive advance was made when the analysis of dementia praecox and other psychotic disorders was ventured upon and thus the examination was begun of the ego itself, which had so far been known only as the agency of repression and opposition. It was found that the pathogenic process in dementia praecox is the withdrawal of the libido from objects and its introduction into the ego, while the clamorous symptoms of the disease arise from the vain struggles of the libido to find a pathway back to objects. It thus turned out to be possible for object-libido to change into cathexis of the ego and vice versa. Further reflection showed that this process must be presumed to occur on the largest scale and that the ego is to be regarded as a great reservoir of libido from which libido is sent out to objects and which is always ready to absorb libido flowing back from objects. Thus the instincts of self-preservation were also of a libidinal nature: they were sexual instincts which, instead of external objects, had taken the subject's own ego as an object. Clinical experience had made us familiar with people who behaved in a striking fashion as though they were in love with themselves and this perversion had been given the name of narcissism. The libido of the self-preservative instincts was now described as narcissistic libido and it was recognized that a high degree of this self-love constituted the primary and normal state of things. The earlier formula laid down for the transference neuroses consequently required to be modified, though not corrected. It was better, instead of speaking of a conflict between sexual instincts and ego instincts, to speak of a conflict between object-libido and ego-libido, or, since the nature of these instincts was the same, between the object-cathexes and the ego.

Apparent Approach to Jung's Views. - It thus seemed on the face of it as though the slow process of psycho-analytic research was following in the steps of Jung's speculation about a primal libido, especially because the transformation of object-libido into narcissism necessarily carried along with it a certain degree of desexualization, or abandonment of the specifically sexual aims. Nevertheless, it has to be borne in mind that the fact that the self-preservative instincts of the ego are recognized as libidinal does not necessarily prove that there are no other instincts operating in the ego.

The transformation of object-libido into narcissistic libido which thus takes place obviously implies an abandonment of sexual aims, a desexualization - a kind of sublimation, therefore. Indeed, the question arises, and deserves careful consideration, whether this is not the universal road to sublimation, whether all sublimation does not take place though the mediation of the ego, which begins by changing sexual object-libido into narcissistic libido and then, perhaps, goes on to give it another aim.¹ We shall later on have to consider whether other instinctual vicissitudes may not also result from this transformation, whether, for instance, it may not bring about a defusion of the various instincts that are fused together.
This would seem to imply an important amplification of the theory of narcissism. At the very beginning, all the libido is accumulated in the id, while the ego is still in process of formation or is still feeble. The id sends part of this libido out into erotic object-cathexes, whereupon the ego, now grown stronger, tries to get hold of this object-libido and to force itself on the id as a love-object. The narcissism of the ego is thus a secondary one, which has been withdrawn from objects.
[1923b, 3980]

Among the hypothetical concepts which enable the doctor to deal with the analytic material, the first to be mentioned is that of 'libido'. Libido means in psycho-analysis in the first instance the force (thought of as quantitatively variable and measurable) of the sexual instincts directed towards an object - 'sexual' in the extended sense required by analytic theory. Further study showed that it was necessary to set alongside this 'object-libido' a 'narcissistic' or 'ego-libido', directed to the subject's own ego; and the interaction of these two forces has enabled us to account for a great number of normal and abnormal processes in mental life. A rough distinction was soon made between what are known as the 'transference neuroses' and the narcissistic disorders. The former (hysteria and obsessional neurosis) are the objects proper of psycho-analytic treatment, while the others, the narcissistic neuroses, though they can, it is true, be examined by the help of analysis, offer fundamental difficulties to therapeutic influence. It is true that the libido theory of psycho-analysis is by no means complete and that its relation to a general theory of the instincts is not yet clear, for psycho-analysis is a young science, quite unfinished and in a stage of rapid development. Here, however, it should be emphatically pointed out how erroneous the charge of pan-sexualism is which is so often levelled at psycho-analysis. It seeks to show that psycho-analytic theory knows of no mental motive forces other than purely sexual ones and in doing so exploits popular prejudices by using the word 'sexual' not in its analytic but in its vulgar sense.
[1924f, 4113]
The World War, which broke up so many other organizations, could do nothing against our 'International'. The first meeting after the war took place in 1920, at The Hague, on neutral ground. It was moving to see how hospitably the Dutch welcomed the starving and impoverished subjects of the Central European states; and I believe this was the first occasion in a ruined world on which Englishmen and Germans sat at the same table for the friendly discussion of scientific interests. Both in Germany and in the countries of Western Europe the war had actually stimulated interest in psycho-analysis. The observation of war neuroses had at last opened the eyes of the medical profession to the importance of psychogenesis in neurotic disturbances, and some of our psychological conceptions, such as the 'gain from illness' and the 'flight into illness', quickly became popular. The last Congress before the German collapse, which was held at Budapest in 1918, was attended by official representatives of the allied governments of the Central European powers, and they agreed to the establishment of psycho-analytic Centres for the treatment of war neuroses. But this point was never reached. Similarly too the comprehensive plans made by one of our leading members, Dr. Anton von Freund, for establishing in Budapest a centre for analytic study and treatment came to grief as a result of the political upheavals that followed soon afterwards and of the premature death of their irreplaceable author. At a later date some of his ideas were put into execution by Max Eitingon, who in 1920 founded a psycho-analytical clinic in Berlin. During the brief period of Bolshevik rule in Hungary, Ferenczi was still able to carry on a successful course of instruction as the official representative of psycho-analysis at the University of Budapest. After the war our opponents were pleased to announce that events had produced a conclusive argument against the validity of the theses of analysis. The war neuroses, they said, had proved that sexual factors were unnecessary to the aetiology of neurotic disorders. But their triumph was frivolous and premature. For on the one hand no one had been able to carry out a thorough analysis of a case of war neurosis, so that in fact nothing whatever was known for certain as to their motivation and no conclusions could be drawn from this uncertainty; while on the other hand psycho-analysis had long before arrived at the concept of narcissism and of narcissistic neuroses, in which the subject's libido is attached to his own ego instead of to an object. Though on other occasions, therefore, the charge was brought against psycho-analysis of having made an unjustifiable extension of the concept of sexuality, yet, when it became convenient for controversial ends, this crime was forgotten and we were once more held down to the narrowest meaning of the word.

[1925d, 4229]

In the Oedipus complex the libido was seen to be attached to the image of the parental figures. But earlier there was a period in which there were no such objects. There followed from this fact the concept (of fundamental importance for the libido theory) of a state in which the subject's libido filled his own ego and had that for its object. This state could be called narcissism or self-love. A moment's reflection showed that this state never completely ceases. All through the subject's life his ego remains the great reservoir of his libido, from which object-cathexes are sent out and into which the libido can stream back again from the objects. Thus narcissistic libido is constantly being transformed into object-libido, and vice versa. An excellent instance of the length to which this transformation can go is afforded by the state of being in love, whether in a sexual or sublimated manner, which goes so far as involving a sacrifice of the self. Whereas hitherto in considering the process of repression attention had only been paid to what was repressed, these ideas made it possible to form a correct estimate of the repressing forces too. It had been said that repression was set in action by the instincts of self-preservation (the 'ego-instincts') and that it was brought to bear upon the libidinal instincts. But since the instincts of self-preservation were now recognized as also being of a libidinal nature, as being narcissistic libido, the process of repression was seen to be a process occurring within the libido itself; narcissistic libido was opposed to object-libido, the interest of self-preservation was defending itself against the demands of object-love, and therefore against the demands of sexuality in the narrower sense as well.

[1925d, 4231]
There is no more urgent need in psychology than for a securely founded theory of the instincts on which it might then be possible to build further. Nothing of the sort exists, however, and psycho-analysis is driven to making tentative efforts towards some such theory. It began by drawing a contrast between the ego-instincts (the instinct of self-preservation, hunger) and the libidinal instincts (love), but later replaced it by a new contrast between narcissistic and object-libido. This was clearly not the last word on the subject; biological considerations seemed to make it impossible to remain content with assuming the existence of only a single class of instincts.

[1925d, 4232]

If anxiety is a reaction of the ego to danger, we shall be tempted to regard the traumatic neuroses, which so often follow upon a narrow escape from death, as a direct result of a fear of death (or fear for life) and to dismiss from our minds the question of castration and the dependent relationships of the ego. Most of those who observed the traumatic neuroses that occurred during the last war took this line, and triumphantly announced that proof was now forthcoming that a threat to the instinct of self-preservation could by itself produce a neurosis without any admixture of sexual factors and without requiring any of the complicated hypotheses of psycho-analysis. It is in fact greatly to be regretted that not a single analysis of a traumatic neurosis of any value is extant. And it is to be regretted, not because such an analysis would contradict the aetiological importance of sexuality - for any such contradiction has long since been disposed of by the introduction of the concept of narcissism, which brings the libidinal cathexis of the ego into line with the cathexes of objects and emphasizes the libidinal character of the instinct of self-preservation - but because, in the absence of any analyses of this kind, we have lost a most precious opportunity of drawing decisive conclusions about the relations between anxiety and the formation of symptoms. In view of all that we know about the structure of the comparatively simple neuroses of everyday life, it would seem highly improbable that a neurosis could come into being merely because of the objective presence of danger, without any participation of the deeper levels of the mental apparatus. But the unconscious seems to contain nothing that could give any content to our concept of the annihilation of life. Castration can be pictured on the basis of the daily experience of the faeces being separated from the body or on the basis of losing the mother's breast at weaning. But nothing resembling death can ever have been experienced; or if it has, as in fainting, it has left no observable traces behind. I am therefore inclined to adhere to the view that the fear of death should be regarded as analogous to the fear of castration and that the situation to which the ego is reacting is one of being abandoned by the protecting super-ego - the powers of destiny - so that it has no longer any safeguard against all the dangers that surround it. In addition, it must be remembered that in the experiences which lead to a traumatic neurosis the protective shield against external stimuli is broken through and excessive amounts of excitation impinge upon the mental apparatus; so that we have here a second possibility - that anxiety is not only being signalled as an affect but is also being freshly created out of the economic conditions of the situation.

[1926d, 4286]

¹ I feel impelled to point out one at least of the gaps that have been left in the account given above. No discussion of the possibilities of human happiness should omit to take into consideration the relation between narcissism and object libido. We require to know what being essentially self-dependent signifies for the economics of the libido.

[1930a, 4482]
Every analyst will admit that even to-day this view has not the sound of a long-discarded error. Nevertheless, alterations in it became essential, as our enquiries advanced from the repressed to the repressing forces, from the object-instincts to the ego. The decisive step forward was the introduction of the concept of narcissism - that is to say, the discovery that the ego itself is cathected with libido, that the ego, indeed, is the libido's original home, and remains to some extent its headquarters. This narcissistic libido turns towards objects, and thus becomes object-libido; and it can change back into narcissistic libido once more. The concept of narcissism made it possible to obtain an analytic understanding of the traumatic neuroses and of many of the affections bordering on the psychoses, as well as of the latter themselves. It was not necessary to give up our interpretation of the transference neuroses as attempts made by the ego to defend itself against sexuality; but the concept of libido was endangered. Since the ego-instincts, too, were libidinal, it seemed for a time inevitable that we should make libido coincide with instincntual energy in general, as C. G. Jung had already advocated earlier. Nevertheless, there still remained in me a kind of conviction, for which I was not as yet able to find reasons, that the instincts could not all be of the same kind. My next step was taken in Beyond the Pleasure Principle (1920g), when the compulsion to repeat and the conservative character of instinctual life first attracted my attention. Starting from speculations on the beginning of life and from biological parallels, I drew the conclusion that, besides the instinct to preserve living substance and to join it into ever larger units,¹ there must exist another, contrary instinct seeking to dissolve those units and to bring them back to their primaeval, inorganic state. That is to say, as well as Eros there was an instinct of death. The phenomena of life could be explained from the concurrent or mutually opposing action of these two instincts. It was not easy, however, to demonstrate the activities of this supposed death instinct. The manifestations of Eros were conspicuous and noisy enough. It might be assumed that the death instinct operated silently within the organism towards its dissolution, but that, of course, was no proof. A more fruitful idea was that a portion of the instinct is diverted towards the external world and comes to light as an instinct of aggressiveness and destructiveness. In this way the instinct itself could be pressed into the service of Eros, in that the organism was destroying some other thing, whether animate or inanimate, instead of destroying its own self. Conversely, any restriction of this aggressiveness directed outwards would be bound to increase the self-destruction, which is in any case proceeding. At the same time one can suspect from this example that the two kinds of instinct seldom - perhaps never - appear in isolation from each other, but are alloyed with each other in varying and very different proportions and so become unrecognizable to our judgement. In sadism, long since known to us as a component instinct of sexuality, we should have before us a particularly strong alloy of this kind between trends of love and the destructive instinct; while its counterpart, masochism, would be a union between destructiveness directed inwards and sexuality - a union which makes what is otherwise an imperceptible trend into a conspicuous and tangible one. [1930a, 4509]
Just as a planet revolves around a central body as well as rotating on its own axis, so the human individual takes part in the course of development of mankind at the same time as he pursues his own path in life. But to our dull eyes the play of forces in the heavens seems fixed in a never-changing order; in the field of organic life we can still see how the forces contend with one another, and how the effects of the conflict are continually changing. So, also, the two urges, the one towards personal happiness and the other towards union with other human beings, must struggle with each other in every individual; and so, also, the two processes of individual and of cultural development must stand in hostile opposition to each other and mutually dispute the ground. But this struggle between the individual and society is not a derivative of the contradiction - probably an irreconcilable one - between the primal instincts of Eros and death. It is a dispute within the economics of the libido, comparable to the contest concerning the distribution of libido between ego and objects; and it does admit of an eventual accommodation in the individual, as, it may be hoped, it will also do in the future of civilization, however much that civilization may oppress the life of the individual to-day.

[1930a, 4529]

In order to remain faithful to our customary phraseology, we shall have to speak, not of transposing the psychical accent, but of displacing large amounts of cathexis. The question then is whether we are entitled to picture extensive displacements like this from one agency of the mental apparatus to another. It looks like a new hypothesis constructed ad hoc. Yet we may remind ourselves that we have repeatedly (even though not sufficiently often) taken a factor of this kind into account in our attempts at a metapsychological picture of mental events. Thus, for instance, we supposed that the difference between an ordinary erotic object-cathexis and the state of being in love is that in the latter incomparably more cathexis passes over to the object and that the ego empties itself as it were in favour of the object. In studying some cases of paranoia I was able to establish the fact that ideas of persecution are formed early and exist for a long time without any perceptible effect, until, as the result of some particular precipitating event, they receive sufficient amounts of cathexis to cause them to become dominant. The cure, too, of such paranoic attacks would lie not so much in a resolution and correction of the delusional ideas as in a withdrawal from them of the cathexis which has been lent to them. The alternations between melancholia and mania, between a cruel suppression of the ego by the super-ego and a liberation of the ego after that pressure, suggests a shift of cathexis of this kind; such a shift, moreover, would have to be brought in to explain a whole number of phenomena belonging to normal mental life. If this has been done hitherto only to a very limited extent, that is on account of our usual caution - something which deserves only praise. The region in which we feel secure is that of the pathology of mental life; it is here that we make our observations and acquire our convictions. For the present we venture to form a judgement on the normal mind only in so far as we can discern what is normal in the isolations and distortions of the pathological material. When once we have overcome this hesitancy we shall recognize what a large contribution is made to the understanding of mental processes by the static conditions as well as by the dynamic changes in the \textit{quantity} of energetic cathexis.

[1927d, 4544]
It is now time, however, for me to go back both in history and in my subject-matter and once more to take up the most general problems of instinctual life. To begin with, the opposition between the ego-instincts and the sexual instincts lay at the base of our libido theory. When later on we began to study the ego itself more closely and arrived at the conception of narcissism, this distinction itself lost its foundation. In rare cases one can observe that the ego has taken itself as an object and is behaving as though it were in love with itself. Hence the term 'narcissism', borrowed from the Greek myth. But that is only an extreme exaggeration of a normal state of affairs. We came to understand that the ego is always the main reservoir of libido, from which libidinal cathexes of objects go out and into which they return again, while the major part of this libido remains permanently in the ego. Thus ego-libido is being constantly changed into object-libido and object-libido into ego-libido. But in that case they could not be different in their nature and it could have no sense to distinguish the energy of the one from the energy of the other; we could either drop the term 'libido' or use it as synonymous with psychical energy in general.

The forces which we assume to exist behind the tensions caused by the needs of the id are called **instincts**. They represent the somatic demands upon the mind. Though they are the ultimate cause of all activity, they are of a conservative nature; the state, whatever it may be, which an organism has reached gives rise to a tendency to re-establish that state so soon as it has been abandoned. It is thus possible to distinguish an indeterminate number of instincts, and in common practice this is in fact done. For us, however, the important question arises whether it may not be possible to trace all these numerous instincts back to a few basic ones. We have found that instincts can change their aim (by displacement) and also that they can replace one another - the energy of one instinct passing over to another. This latter process is still insufficiently understood. After long hesitancies and vacillations we have decided to assume the existence of only two basic instincts, **Eros** and the **destructive instinct**. (The contrast between the instincts of self-preservation and the preservation of the species, as well as the contrast between ego-love and object-love, fall within Eros.) The aim of the first of these basic instincts is to establish ever greater unities and to preserve them thus - in short, to bind together; the aim of the second is, on the contrary, to undo connections and so to destroy things. In the case of the destructive instinct we may suppose that its final aim is to lead what is living into an inorganic state. For this reason we also call it the **death instinct**. If we assume that living things came later than inanimate ones and arose from them, then the death instinct fits in with the formula we have proposed to the effect that instincts tend towards a return to an earlier state. In the case of Eros (or the love instinct) we cannot apply this formula. To do so would presuppose that living substance was once a unity which had later been torn apart and was now striving towards reunion.¹

It is hard to say anything of the behaviour of the libido in the id and in the super-ego. All that we know about it relates to the ego, in which at first the whole available quota of libido is stored up. We call this state absolute, primary **narcissism**. It lasts till the ego begins to cathect the ideas of objects with libido, to transform narcissistic libido into object-libido. Throughout the whole of life the ego remains the great reservoir from which libidinal cathexes are sent out to objects and into which they are also once more withdrawn, just as an amoeba behaves with its pseudopodia. It is only when a person is completely in love that the main quota of libido is transferred on to the object and the object to some extent takes the place of the ego. A characteristic of the libido which is important in life is its **mobility**, the facility with which it passes from one object to another. This must be contrasted with the **fixation** of the libido to particular objects, which often persists throughout life.
I was further made aware of a defect in the account I have given in the text, which, in the interests of lucidity, describes the conceptual distinction between the two phases of auto-erotism and object-love as though it were also a separation in time. But the analyses that I have just mentioned, as well as the findings of Bell quoted on p. 1496 n., above, show that children between the ages of three and five are capable of very clear object-choice, accompanied by strong affects.

[1905d, 1512]
Put away your doubts, then, and join me in a consideration of infantile sexuality from the earliest age.¹ A child's sexual instinct turns out to be put together out of a number of factors; it is capable of being divided up into numerous components which originate from various sources. Above all, it is still independent of the reproductive function, into the service of which it will later be brought. It serves for the acquisition of different kinds of pleasurable feeling, which, basing ourselves on analogies and connections, we bring together under the idea of sexual pleasure. The chief source of infantile sexual pleasure is the appropriate excitation of certain parts of the body that are especially susceptible to stimulus: apart from the genitals, these are the oral, anal and urethral orifices, as well as the skin and other sensory surfaces. Since at this first phase of infantile sexual life satisfaction is obtained from the subject's own body and extraneous objects are disregarded, we term this phase (from a word coined by Havelock Ellis) that of auto-erotism. We call the parts of the body that are important in the acquisition of sexual pleasure 'erogenetic zones'. Thumb-sucking (or sensual sucking) in the youngest infants is a good example of this auto-erotic satisfaction from an erogenetic zone. The first scientific observer of this phenomenon, a paediatrician in Budapest named Lindner (1879), already interpreted it correctly as sexual satisfaction and described exhaustively its transition to other and higher forms of sexual activity. Another sexual satisfaction at this period of life is the masturbatory excitation of the genitals, which retains so much importance in later life and by many people is never completely conquered. Alongside these and other auto-erotic activities, we find in children at a very early age manifestations of those instinctual components of sexual pleasure (or, as we like to say, of libido) which presuppose the taking of an extraneous person as an object. These instincts occur in pairs of opposites, active and passive. I may mention as the most important representatives of this group the desire to cause pain (sadism) with its passive counterpart (masochism) and the active and passive desire for looking, from the former of which curiosity branches off later on and from the latter the impulsion to artistic and theatrical display. Others of a child's sexual activities already imply the making of an 'object-choice', where an extraneous person becomes the main feature, a person who owes his importance in the first instance to considerations arising from the self-preservative instinct. But at this early period of childhood difference in sex plays no decisive part as yet. Thus you can attribute some degree of homosexuality to every child without doing him an injustice. This widespread and copious but dissociated sexual life of children, in which each separate instinct pursues its own acquisition of pleasure independently of all the rest, is now brought together and organized in two main directions, so that by the end of puberty the individual's final sexual character is as a rule completely formed. On the one hand, the separate instincts become subordinated to the dominance of the genital zone, so that the whole sexual life enters the service of reproduction, and the satisfaction of the separate instincts retains its importance only as preparing for and encouraging the sexual act proper. On the other hand, object-choice pushes auto-erotism into the background, so that in the subject's erotic life all the components of the sexual instinct now seek satisfaction in relation to the person who is loved. Not all of the original sexual components, however, are admitted to take part in this final establishment of sexuality. Even before puberty extremely energetic repressions of certain instincts have been effected under the influence of education, and mental forces such as shame, disgust and morality have been set up, which, like watchmen, maintain these repressions. So that when at puberty the high tide of sexual demands is reached, it is met by these mental reactive or resistant structures like dams, which direct its flow into what are called normal channels and make it impossible for it to reactivate the instincts that have undergone repression. It is in particular the coprophilic impulses of childhood - that is to say, the desires attaching to the excreta - which are submitted the most rigorously to repression, and the same is true, furthermore, of fixation to the figures to which the child's original object-choice was attached. [1910a, 2230]
The affectionate current is the older of the two. It springs from the earliest years of childhood; it is formed on the basis of the interests of the self-preservation instinct and is directed to the members of the family and those who look after the child. From the very beginning it carries along with it contributions from the sexual instincts - components of erotic interest - which can already be seen more or less clearly even in childhood and in any event are uncovered in neurotics by psycho-analysis later on. It corresponds to the child's primary object-choice. We learn in this way that the sexual instincts find their first objects by attaching themselves to the valuations made by the ego-instincts, precisely in the way in which the first sexual satisfactions are experienced in attachment to the bodily functions necessary for the preservation of life. The 'affection' shown by the child's parents and those who look after him, which seldom fails to betray its erotic nature ('the child is an erotic plaything'), does a very great deal to raise the contributions made by erotism to the cathexes of his ego-instincts, and to increase them to an amount which is bound to play a part in his later development, especially when certain other circumstances lend their support.

[1912d, 2338]

A third way in which we may approach the study of narcissism is by observing the erotic life of human beings, with its many kinds of differentiation in man and woman. Just as object-libido at first concealed ego-libido from our observation, so too in connection with the object-choice of infants (and of growing children) what we first noticed was that they derived their sexual objects from their experiences of satisfaction. The first auto-erotic sexual satisfactions are experienced in connection with vital functions which serve the purpose of self-preservation. The sexual instincts are at the outset attached to the satisfaction of the ego-instincts; only later do they become independent of these, and even then we have an indication of that original attachment in the fact that the persons who are concerned with a child's feeding, care, and protection become his earliest sexual objects: that is to say, in the first instance his mother or a substitute for her. Side by side, however, with this type and source of object-choice, which may be called the 'anaclitic' or 'attachment' type, psycho-analytic research has revealed a second type, which we were not prepared for finding. We have discovered, especially clearly in people whose libidinal development has suffered some disturbance, such as perverts and homosexuals, that in their later choice of love-objects they have taken as a model not their mother but their own selves. They are plainly seeking themselves as a love-object, and are exhibiting a type of object-choice which must be termed 'narcissistic'. In this observation we have the strongest of the reasons which have led us to adopt the hypothesis of narcissism.

[1914c, 2942]

From the economic standpoint psycho-analysis supposes that the mental representatives of the instincts have a charge (cathexis) of definite quantities of energy, and that it is the purpose of the mental apparatus to hinder any damming-up of these energies and to keep as low as possible the total amount of the excitations with which it is loaded. The course of mental processes is automatically regulated by the 'pleasure-unpleasure principle'; and unpleasure is thus in some way related to an increase of excitation and pleasure to a decrease. In the course of development the original pleasure principle undergoes a modification with reference to the external world, giving place to the 'reality principle', in accordance with which the mental apparatus learns to postpone the pleasure of satisfaction and to tolerate temporarily feelings of unpleasure.

[1926f, 4404]
In order to remain faithful to our customary phraseology, we shall have to speak, not of transposing the psychical accent, but of displacing large amounts of cathexis. The question then is whether we are entitled to picture extensive displacements like this from one agency of the mental apparatus to another. It looks like a new hypothesis constructed ad hoc. Yet we may remind ourselves that we have repeatedly (even though not sufficiently often) taken a factor of this kind into account in our attempts at a metapsychological picture of mental events. Thus, for instance, we supposed that the difference between an ordinary erotic object-cathexis and the state of being in love is that in the latter incomparably more cathexis passes over to the object and that the ego emptied itself as it were in favour of the object. In studying some cases of paranoia I was able to establish the fact that ideas of persecution are formed early and exist for a long time without any perceptible effect, until, as the result of some particular precipitating event, they receive sufficient amounts of cathexis to cause them to become dominant. The cure, too, of such paranoic attacks would lie not so much in a resolution and correction of the delusional ideas as in a withdrawal from them of the cathexis which has been lent to them. The alternations between melancholia and mania, between a cruel suppression of the ego by the super-ego and a liberation of the ego after that pressure, suggests a shift of cathexis of this kind; such a shift, moreover, would have to be brought in to explain a whole number of phenomena belonging to normal mental life. If this has been done hitherto only to a very limited extent, that is on account of our usual caution - something which deserves only praise. The region in which we feel secure is that of the pathology of mental life; it is here that we make our observations and acquire our convictions. For the present we venture to form a judgement on the normal mind only in so far as we can discern what is normal in the isolations and distortions of the pathological material. When once we have overcome this hesitancy we shall recognize what a large contribution is made to the understanding of mental processes by the static conditions as well as by the dynamic changes in the quantity of energetic cathexis.

[1927d, 4544]

It is hard to say anything of the behaviour of the libido in the id and in the super-ego. All that we know about it relates to the ego, in which at first the whole available quota of libido is stored up. We call this state absolute, primary narcissism. It lasts till the ego begins to cathect the ideas of objects with libido, to transform narcissistic libido into object-libido. Throughout the whole of life the ego remains the great reservoir from which libidinal cathexes are sent out to objects and into which they are also once more withdrawn, just as an amoeba behaves with its pseudopodia. It is only when a person is completely in love that the main quota of libido is transferred on to the object and the object to some extent takes the place of the ego. A characteristic of the libido which is important in life is its mobility, the facility with which it passes from one object to another. This must be contrasted with the fixation of the libido to particular objects, which often persists throughout life.

[1940a [1938], 4961]

But of that we know nothing. And the profound obscurity of the background of our ignorance is scarcely illuminated by a few glimmers of insight. Here we have approached the still shrouded secret of the nature of the psychical. We assume, as other natural sciences have led us to expect, that in mental life some kind of energy is at work; but we have nothing to go upon which will enable us to come nearer to a knowledge of it by analogies with other forms of energy. We seem to recognize that nervous or psychical energy occurs in two forms, one freely mobile and another, by comparison, bound; we speak of cathexes and hypercathexes of psychical material, and even venture to suppose that a hypercathexis brings about a kind of synthesis of different processes - a synthesis in the course of which free energy is transformed into bound energy. Further than this we have not advanced. At any rate, we hold firmly to the view that the distinction between the unconscious and the preconscious state lies in dynamic relations of this kind, which would explain how it is that, whether spontaneously or with our assistance, the one can be changed into the other.

[1940a [1938], 4973]
This ego-libido is, however, only conveniently accessible to analytic study when it has been put to the use of cathecting sexual objects, that is, when it has become object-libido. We can then perceive it concentrating upon objects, becoming fixed upon them or abandoning them, moving from one object to another and, from these situations, directing the subject’s sexual activity, which leads to the satisfaction, that is, to the partial and temporary extinction, of the libido. The psycho-analysis of what are termed transference neuroses (hysteria and obsessional neurosis) affords us a clear insight at this point.

[1905d, 1531]

We can follow the object-libido through still further vicissitudes. When it is withdrawn from objects, it is held in suspense in peculiar conditions of tension and is finally drawn back into the ego, so that it becomes ego-libido once again. In contrast to object-libido, we also describe ego-libido as ‘narcissistic’ libido. From the vantage-point of psycho-analysis we can look across a frontier, which we may not pass, at the activities of narcissistic libido, and may form some idea of the relation between it and object-libido.¹ Narcissistic or ego-libido seems to be the great reservoir from which the object-cathexes are sent out and into which they are withdrawn once more; the narcissistic libidinal cathexis of the ego is the original state of things, realized in earliest childhood, and is merely covered by the later extrusions of libido, but in essentials persists behind them.

[1905d, 1532]

(1) Our first reflection will tell us that it cannot be the case that this detachment of the libido occurs exclusively in paranoia; nor can it be that, where it occurs elsewhere, it has such disastrous consequences. It is quite possible that a detachment of the libido is the essential and regular mechanism of every repression. We can have no positive knowledge on that point until the other disorders that are based upon repression have been similarly examined. But it is certain that in normal mental life (and not only in periods of mourning) we are constantly detaching our libido in this way from people or from other objects without falling ill. When Faust freed himself from the world by uttering his curses, the result was not a paranoia or any other neurosis but simply a certain general frame of mind. The detachment of the libido, therefore, cannot in itself be the pathogenic factor in paranoia; there must be some special characteristic which distinguishes a paranoic detachment of the libido from other kinds. It is not difficult to suggest what that characteristic may be. What use is made of the libido after it has been set free by the process of detachment? A normal person will at once begin looking about for a substitute for the lost attachment; and until that substitute has been found the liberated libido will be kept in suspension within his mind, and will there give rise to tensions and colour his mood. In hysteria the liberated libido becomes transformed into somatic innervations or into anxiety. But in paranoia the clinical evidence goes to show that the libido, after it has been withdrawn from the object, is put to a special use. It will be remembered that the majority of cases of paranoia exhibit traces of megalomania, and that megalomania can by itself constitute a paranoia. From this it may be concluded that in paranoia the liberated libido becomes attached to the ego, and is used for the aggrandizement of the ego. A return is thus made to the stage of narcissism (known to us from the development of the libido), in which a person’s only sexual object is his own ego. On the basis of this clinical evidence we can suppose that paranoics have brought along with them a fixation at the stage of narcissism, and we can assert that the length of the step back from sublimated homosexuality to narcissism is a measure of the amount of regression characteristic of paranoia.

[1911c, 2438]
Although we are not yet in a position to describe with sufficient accuracy the characteristics of this narcissistic stage, at which the hitherto dissociated sexual instincts come together into a single unity and cathect the ego as an object, we suspect already that this narcissistic organization is never wholly abandoned. A human being remains to some extent narcissistic even after he has found external objects for his libido. The cathexes of objects which he effects are as it were emanations of the libido that still remains in his ego and can be drawn back into it once more. The state of being in love, which is psychologically so remarkable and is the normal prototype of the psychoses, shows these emanations at their maximum compared to the level of self-love.

[1912-1913, 2732]

This extension of the libido theory - in my opinion, a legitimate one - receives reinforcement from a third quarter, namely, from our observations and views on the mental life of children and primitive peoples. In the latter we find characteristics which, if they occurred singly, might be put down to megalomania: an over-estimation of the power of their wishes and mental acts, the 'omnipotence of thoughts', a belief in the thaumaturgic force of words, and a technique for dealing with the external world - 'magic' - which appears to be a logical application of these grandiose premisses.¹ In the children of to-day, whose development is much more obscure to us, we expect to find an exactly analogous attitude towards the external world.² Thus we form the idea of there being an original libidinal cathexis of the ego, from which some is later given off to objects, but which fundamentally persists and is related to the object-cathexes much as the body of an amoeba is related to the pseudopodia which it puts out. In our researches, taking, as they did, neurotic symptoms for their starting-point, this part of the allocation of libido necessarily remained hidden from us at the outset. All that we noticed were the emanations of this libido - the object-cathexes, which can be sent out and drawn back again. We see also, broadly speaking, an antithesis between ego-libido and object-libido. The more of the one is employed, the more the other becomes depleted. The highest phase of development of which object-libido is capable is seen in the state of being in love, when the subject seems to give up his own personality in favour of an object-cathexis; while we have the opposite condition in the paranoic's phantasy (or self-perception) of the 'end of the world'.³ Finally, as regards the differentiation of psychic energies, we are led to the conclusion that to begin with, during the state of narcissism, they exist together and that our analysis is too coarse to distinguish between them; not until there is object-cathexis is it possible to discriminate a sexual energy - the libido - from an energy of the ego-instincts.

[1914c, 2933]

The value of the concepts 'ego-libido' and 'object-libido' lies in the fact that they are derived from the study of the intimate characteristics of neurotic and psychotic processes. A differentiation of libido into a kind which is proper to the ego and one which is attached to objects is an unavoidable corollary to an original hypothesis which distinguished between sexual instincts and ego-instincts. At any rate, analysis of the pure transference neuroses (hysteria and obsessional neurosis) compelled me to make this distinction and I only know that all attempts to account for these phenomena by other means have been completely unsuccessful.

[1914c, 2934]
In estimating the influence of organic disease upon the distribution of libido, I follow a suggestion made to me orally by Sándor Ferenczi. It is universally known, and we take it as a matter of course, that a person who is tormented by organic pain and discomfort gives up his interest in the things of the external world, in so far as they do not concern his suffering. Closer observation teaches us that he also withdraws libidinal interest from his love-objects: so long as he suffers, he ceases to love. The commonplace nature of this fact is no reason why we should be deterred from translating it into terms of the libido theory. We should then say: (the sick man withdraws his libidinal cathexes back upon his own ego, and sends them out again when he recovers. 'Concentrated is his soul', says Wilhelm Busch of the poet suffering from toothache, 'in his molar's narrow hole.' Here libido and ego-interest share the same fate and are once more indistinguishable from each other. The familiar egoism of the sick person covers both. We find it so natural because we are certain that in the same situation we should behave in just the same way. The way in which a lover's feelings, however strong, are banished by bodily ailments, and suddenly replaced by complete indifference, is a theme which has been exploited by comic writers to an appropriate extent.

[1914c, 2938]

Mourning over the loss of something that we have loved or admired seems so natural to the layman that he regards it as self-evident. But to psychologists mourning is a great riddle, one of those phenomena which cannot themselves be explained but to which other obscurities can be traced back. We possess, as it seems, a certain amount of capacity for love - what we call libido - which in the earliest stages of development is directed towards our own ego. Later, though still at a very early time, this libido is diverted from the ego on to objects, which are thus in a sense taken into our ego. If the objects are destroyed or if they are lost to us, our capacity for love (our libido) is once more liberated; and it can then either take other objects instead or can temporarily return to the ego. But why it is that this detachment of libido from its objects should be such a painful process is a mystery to us and we have not hitherto been able to frame any hypothesis to account for it. We only see that libido clings to its objects and will not renounce those that are lost even when a substitute lies ready to hand. Such then is mourning.

[1916a, 3096]

Hitherto it has been a premiss of our work that we can distinguish the ego-instincts from the sexual ones by their manifestations. With the transference neuroses this could be done without difficulty. We termed the cathexes of energy which the ego directs towards the objects of its sexual desires 'libido'; all the others, which are sent out by the self-preservative instincts, we termed 'interest'. By tracing the course of the libidinal cathexes, their transformations and final vicissitudes, we were able to obtain a first insight into the machinery of the mental forces. For this purpose the transference neuroses offered us the most favourable material. But the ego, its composition out of various organizations and their construction and mode of functioning, remained hidden from us; and we were driven to suspect that only the analysis of other neurotic disorders would be able to bring us the necessary insight.

[1916-1917, 3460]

To put the matter shortly, we pictured the relation of ego-libido to object-libido in a way which I can make plain to you by an analogy from zoology. Think of those simplest of living organisms which consist of a little-differentiated globule of protoplastic substance. They put out protrusions, known as pseudopodia, into which they cause the substance of their body to flow over. They are able, however, to withdraw the protrusions once more and form themselves again into a globule. We compare the putting-out of these protrusions, then, to the emission of libido on to objects while the main mass of libido can remain in the ego; and we suppose that in normal circumstances ego-libido can be transformed unhindered into object-libido and that this can once more be taken back into the ego.

[1916-1917, 3461]
Organic illness, painful stimulation or inflammation of an organ, creates a condition which clearly results in a detachment of the libido from its objects. The libido which is withdrawn is found in the ego once more, as an increased cathexis of the diseased part of the body. One may venture to assert, indeed, that the withdrawal of the libido from its objects in these circumstances is more striking than the diversion of egoistic interest from the external world. This seems to offer us a path to an understanding of hypochondria, in which an organ excites the ego's attention in the same way, without being ill so far as we can perceive.

But I shall resist the temptation of going further here or of discussing other situations which can be understood or pictured if we adopt the hypothesis that the object-libido may withdraw into the ego - for I am obliged to meet two objections which, as I know, are now attracting your attention. In the first place you want to call me to account because in talking of sleep, illness and similar situations I invariably try to separate libido from interest, sexual from ego-instincts, where observations can be fully satisfied by the hypothesis of a single and uniform energy which, being freely mobile, cathects now the object and now the ego, in obedience to one or the other instinct. And in the second place you want to know how I can venture to treat the detaching of the libido from the object as the source of a pathological state, when a transposition of this kind of object-libido into ego-libido (or, more generally, into ego-energy) is among the normal processes of mental dynamics which are repeated daily and every night.

Your second observation, too, raises a justifiable question, but it is aimed in the wrong direction. It is true that a withdrawal of the object-libido into the ego is not directly pathogenic; it takes place, indeed, as we know, every time before we go to sleep, only to be reversed when we wake up. The amoeba withdraws its protrusions only to send them out again at the first opportunity. But it is quite a different thing when a particular, very energetic process forces a withdrawal of libido from objects. Here the libido that has become narcissistic cannot find its way back to objects, and this interference with the libido's mobility certainly becomes pathogenic. It seems that an accumulation of narcissistic libido beyond a certain amount is not tolerated. We may even imagine that it was for that very reason that object-cathexes originally came about, that the ego was obliged to send out its libido so as not to fall ill as a result of its being dammed up. If it lay within our plan to go more deeply into dementia praecox, I would show you that the process which detaches the libido from objects and cuts off its return to them is closely related to the process of repression and is to be looked at as its counterpart. But you would, first and foremost, find yourselves on familiar ground when you learnt that the determinants of this process are almost identical - so far as we know at present - with those of repression. The conflict seems to be the same and to be carried on between the same forces. If the outcome is so different from, for instance, that in hysteria, the reason can only depend on a difference in innate disposition. The weak spot in the libidinal development of these patients lies in a different phase; the determining fixation, which, as you will recollect, permits the irruption that leads to the formation of symptoms, lies elsewhere, probably in the stage of primitive narcissism to which dementia praecox returns in its final outcome. It is very remarkable that in the case of all the narcissistic neuroses we have to assume fixation points for the libido going back to far earlier phases of development than in hysteria or obsessional neurosis. As you heard, however, the concepts which we arrived at during our study of the transference neuroses are adequate in helping us to find our way about in the narcissistic neuroses which are so much more severe in practice. The conformities go very far; at bottom the field of phenomena is the same. And you can imagine how small a prospect anyone has of explaining these disorders (which belong within the sphere of psychiatry) who is not forearmed for his task with an analytic knowledge of the transference neuroses.

[1916-1917, 3464]

[1916-1917, 3465]

[1916-1917, 3466]
Homosexual object-choice originally lies closer to narcissism than does the heterosexual kind. When it is a question, therefore, of repelling an undesirably strong homosexual impulse, the path back to narcissism is made particularly easy. Hitherto I have had very little opportunity of talking to you about the foundations of erotic life so far as we have discovered them, and it is too late now to catch up on the omission. This much, however, I can emphasize to you. Object-choice, the step forward in the development of the libido which is made after the narcissistic stage, can take place according to two different types: either according to the narcissistic type, where the subject's own ego is replaced by another one that is as similar as possible, or according to the attachment type, where people who have become precious through satisfying the other vital needs are chosen as objects by the libido as well. A strong libidinal fixation to the narcissistic type of object-choice is to be included in the predisposition to manifest homosexuality.

[1916-1917, 3470]

During the work of treatment we have to consider the distribution of the patient's libido; we look for the object presentations to which it is bound and free it from them, so as to place it at the disposal of the ego. In the course of this, we have come to form a very curious picture of the original, primal distribution of libido in human beings. We have been driven to assume that at the beginning of the development of the individual all his libido (all his erotic tendencies, all his capacity for love) is tied to himself - that as we say, it cathetics his own ego. It is only later that, being attached to the satisfaction of the major vital needs, the libido flows over from the ego on to external objects. Not till then are we able to recognize the libidinal instincts as such and distinguish them from the ego instincts. It is possible for the libido to become detached from these objects and withdrawn again into the ego.

[1917a, 3609]

Thus in our view the individual advances from narcissism to object-love. But we do not believe that the whole of the libido ever passes over from the ego to objects. A certain quantity of libido is always retained in the ego; even when object-love is highly developed, a certain amount of narcissism persists. The ego is a great reservoir from which the libido that is destined for objects flows out and into which it flows back from those objects. Object-libido was at first ego-libido and can be transformed back into ego-libido. For complete health it is essential that the libido should not lose this full mobility. As an illustration of this state of things we may think of an amoeba, whose viscous substance puts out pseudopodia, elongations into which the substance of the body extends but which can be retracted at any time so that the form of the protoplasmic mass is restored.

[1917a, 3610]

Narcissism. - The most important theoretical advance has certainly been the application of the libido theory to the repressing ego. The ego itself came to be regarded as a reservoir of what was described as narcissistic libido, from which the libidinal cathexes of objects flowed out and into which they could be once more withdrawn. By the help of this conception it became possible to embark upon the analysis of the ego and to make a clinical distinction of the psychoneuroses into transference neuroses and narcissistic disorders. In the former (hysteria and obsessional neurosis) the subject has at his disposal a quantity of libido striving to be transferred on to extraneous objects, and use is made of this in carrying out analytic treatment; on the other hand, the narcissistic disorders (dementia praecox, paranoia, melancholia) are characterized by a withdrawal of the libido from objects and they are therefore scarcely accessible to analytic therapy. But their therapeutic inaccessibility has not prevented analysis from making the most fruitful beginnings in the deeper study of these illnesses, which are counted among the psychoses.

[1923a, 3925]
This would seem to imply an important amplification of the theory of narcissism. At the very beginning, all the libido is accumulated in the id, while the ego is still in process of formation or is still feeble. The id sends part of this libido out into erotic object-cathexes, whereupon the ego, now grown stronger, tries to get hold of this object-libido and to force itself on the id as a love-object. The narcissism of the ego is thus a secondary one, which has been withdrawn from objects.

[1923b, 3980]

Among the hypothetical concepts which enable the doctor to deal with the analytic material, the first to be mentioned is that of 'libido'. Libido means in psycho-analysis in the first instance the force (thought of as quantitatively variable and measurable) of the sexual instincts directed towards an object - 'sexual' in the extended sense required by analytic theory. Further study showed that it was necessary to set alongside this 'object-libido' a 'narcissistic' or 'ego-libido', directed to the subject's own ego; and the interaction of these two forces has enabled us to account for a great number of normal and abnormal processes in mental life. A rough distinction was soon made between what are known as the 'transference neuroses' and the narcissistic disorders. The former (hysteria and obsessional neurosis) are the objects proper of psychoanalytic treatment, while the others, the narcissistic neuroses, though they can, it is true, be examined by the help of analysis, offer fundamental difficulties to therapeutic influence. It is true that the libido theory of psycho-analysis is by no means complete and that its relation to a general theory of the instincts is not yet clear, for psycho-analysis is a young science, quite unfinished and in a stage of rapid development. Here, however, it should be emphatically pointed out how erroneous the charge of pan-sexualism is which is so often levelled at psycho-analysis. It seeks to show that psycho-analytic theory knows of no mental motive forces other than purely sexual ones and in doing so exploits popular prejudices by using the word 'sexual' not in its analytic but in its vulgar sense.

[1924f, 4113]

In the Oedipus complex the libido was seen to be attached to the image of the parental figures. But earlier there was a period in which there were no such objects. There followed from this fact the concept (of fundamental importance for the libido theory) of a state in which the subject's libido filled his own ego and had that for its object. This state could be called narcissism or self-love. A moment's reflection showed that this state never completely ceases. All through the subject's life his ego remains the great reservoir of his libido, from which object-cathexes are sent out and into which the libido can stream back again from the objects. Thus narcissistic libido is constantly being transformed into object-libido, and vice versa. An excellent instance of the length to which this transformation can go is afforded by the state of being in love, whether in a sexual or sublimated manner, which goes so far as involving a sacrifice of the self. Whereas hitherto in considering the process of repression attention had only been paid to what was repressed, these ideas made it possible to form a correct estimate of the repressing forces too. It had been said that repression was set in action by the instincts of self-preservation operating in the ego (the 'ego-instincts') and that it was brought to bear upon the libidinal instincts. But since the instincts of self-preservation were now recognized as also being of a libidinal nature, as being narcissistic libido, the process of repression was seen to be a process occurring within the libido itself; narcissistic libido was opposed to object-libido, the interest of self-preservation was defending itself against the demands of object-love, and therefore against the demands of sexuality in the narrower sense as well.

[1925d, 4231]
In the course of these struggles we come across two activities of the ego which form symptoms and which deserve special attention because they are obviously surrogates of repression and therefore well calculated to illustrate its purpose and technique. The fact that such auxiliary and substitutive techniques emerge may argue that true repression has met with difficulties in its functioning. If one considers how much more the ego is the scene of action of symptom-formation in obsessional neurosis than it is in hysteria and with what tenacity the ego clings to its relations to reality and to consciousness, employing all its intellectual faculties to that end - and indeed how the very process of thinking becomes hypercathected and erotized - then one may perhaps come to a better understanding of these variations of repression.

[1926d, 4278]

From the economic standpoint psycho-analysis supposes that the mental representatives of the instincts have a charge (cathexis) of definite quantities of energy, and that it is the purpose of the mental apparatus to hinder any damming-up of these energies and to keep as low as possible the total amount of the excitations with which it is loaded. The course of mental processes is automatically regulated by the 'pleasure-unpleasure principle'; and unpleasure is thus in some way related to an increase of excitation and pleasure to a decrease. In the course of development the original pleasure principle undergoes a modification with reference to the external world, giving place to the 'reality principle', in accordance with which the mental apparatus learns to postpone the pleasure of satisfaction and to tolerate temporarily feelings of unpleasure.

[1926f, 4404]

In order to remain faithful to our customary phraseology, we shall have to speak, not of transposing the psychical accent, but of displacing large amounts of cathexis. The question then is whether we are entitled to picture extensive displacements like this from one agency of the mental apparatus to another. It looks like a new hypothesis constructed ad hoc. Yet we may remind ourselves that we have repeatedly (even though not sufficiently often) taken a factor of this kind into account in our attempts at a metapsychological picture of mental events. Thus, for instance, we supposed that the difference between an ordinary erotic object-cathexis and the state of being in love is that in the latter incomparably more cathexis passes over to the object and that the ego empties itself as it were in favour of the object. In studying some cases of paranoia I was able to establish the fact that ideas of persecution are formed early and exist for a long time without any perceptible effect, until, as the result of some particular precipitating event, they receive sufficient amounts of cathexis to cause them to become dominant. The cure, too, of such paranoid attacks would lie not so much in a resolution and correction of the delusional ideas as in a withdrawal from them of the cathexis which has been lent to them. The alternations between melancholia and mania, between a cruel suppression of the ego by the super-ego and a liberation of the ego after that pressure, suggests a shift of cathexis of this kind; such a shift, moreover, would have to be brought in to explain a whole number of phenomena belonging to normal mental life. If this has been done hitherto only to a very limited extent, that is on account of our usual caution - something which deserves only praise. The region in which we feel secure is that of the pathology of mental life; it is here that we make our observations and acquire our convictions. For the present we venture to form a judgement on the normal mind only in so far as we can discern what is normal in the isolations and distortions of the pathological material. When once we have overcome this hesitancy we shall recognize what a large contribution is made to the understanding of mental processes by the static conditions as well as by the dynamic changes in the quantity of energetic cathexis.

[1927d, 4544]
All of this may appear to be far from simple. But when one has grown reconciled to this unusual spatial view of the mental apparatus, it can present no particular difficulties to the imagination. I will add the further comment that the psychical topography that I have developed here has nothing to do with the anatomy of the brain, and actually only touches it at one point. What is unsatisfactory in this picture - and I am aware of it as clearly as anyone - is due to our complete ignorance of the dynamic nature of the mental processes. We tell ourselves that what distinguishes a conscious idea from a preconscious one, and the latter from an unconscious one, can only be a modification, or perhaps a different distribution, of psychical energy. We talk of cathexes and hypercathexes, but beyond this we are without any knowledge on the subject or even any starting-point for a serviceable working hypothesis. Of the phenomenon of consciousness we can at least say that it was originally attached to perception. All sensations which originate from the perception of painful, tactile, auditory or visual stimuli are what are most readily conscious. Thought-processes, and whatever may be analogous to them in the id, are in themselves unconscious and obtain access to consciousness by becoming linked to the mnemonic residues of visual and auditory perceptions along the path of the function of speech. In animals, which lack speech, these conditions must be of a simpler kind.

[1939a, 4919]

It is hard to say anything of the behaviour of the libido in the id and in the super-ego. All that we know about it relates to the ego, in which at first the whole available quota of libido is stored up. We call this state absolute, primary narcissism. It lasts till the ego begins to cathect the ideas of objects with libido, to transform narcissistic libido into object-libido. Throughout the whole of life the ego remains the great reservoir from which libidinal cathexes are sent out to objects and into which they are also once more withdrawn, just as an amoeba behaves with its pseudopodia. It is only when a person is completely in love that the main quota of libido is transferred on to the object and the object to some extent takes the place of the ego. A characteristic of the libido which is important in life is its mobility, the facility with which it passes from one object to another. This must be contrasted with the fixation of the libido to particular objects, which often persists throughout life.

[1940a [1938], 4961]

But of that we know nothing. And the profound obscurity of the background of our ignorance is scarcely illuminated by a few glimmers of insight. Here we have approached the still shrouded secret of the nature of the psychical. We assume, as other natural sciences have led us to expect, that in mental life some kind of energy is at work; but we have nothing to go upon which will enable us to come nearer to a knowledge of it by analogies with other forms of energy. We seem to recognize that nervous or psychical energy occurs in two forms, one freely mobile and another, by comparison, bound; we speak of cathexes and hypercathexes of psychical material, and even venture to suppose that a hypercathexis brings about a kind of synthesis of different processes - a synthesis in the course of which free energy is transformed into bound energy. Further than this we have not advanced. At any rate, we hold firmly to the view that the distinction between the unconscious and the preconscious state lies in dynamic relations of this kind, which would explain how it is that, whether spontaneously or with our assistance, the one can be changed into the other.

[1940a [1938], 4973]
I shall refrain from describing more complicated instances of the sexual process in a similar way. I will only state that in essentials this formula is applicable to women as well, in spite of the confusion introduced into the problem by all the artificial retarding and stunting of the female sexual instinct. In women too we must postulate a somatic sexual excitation and a state in which this excitation becomes a psychical stimulus - libido - and provokes the urge to the specific action to which voluptuous feeling is attached. Where women are concerned, however, we are not in a position to say what the process analogous to the relaxation of tension of the seminal vesicles may be.
[1895b, 345]

The conceptual scaffolding which we have set up to help us in dealing with the psychical manifestations of sexual life tallies well with these hypotheses as to the chemical basis of sexual excitation. We have defined the concept of libido as a quantitatively variable force which could serve as a measure of processes and transformations occurring in the field of sexual excitation. We distinguish this libido in respect of its special origin from the energy which must be supposed to underlie mental processes in general, and we thus also attribute a qualitative character to it. In thus distinguishing between libidinal and other forms of psychical energy we are giving expression to the presumption that the sexual processes occurring in the organism are distinguished from the nutritive processes by a special chemistry. The analysis of the perversions and psychoneuroses has shown us that this sexual excitation is derived not from the so-called sexual parts alone, but from all the bodily organs. We thus reach the idea of a quantity of libido, to the mental representation of which we give the name of 'ego-libido', and whose production, increase or diminution, distribution and displacement should afford us possibilities for explaining the psychosexual phenomena observed.
[1905d, 1531]

From the first of these standpoints, the dynamic one, psycho-analysis derives all mental processes (apart from the reception of external stimuli) from the interplay of forces, which assist or inhibit one another, combine with one another, enter into compromises with one another, etc. All of these forces are originally in the nature of instincts; thus they have an organic origin. They are characterized by possessing an immense (somatic) store of power ('the compulsion to repeat'); and they are represented mentally as images or ideas with an affective charge. In psycho-analysis, no less than in other sciences, the theory of the instincts is an obscure subject. An empirical analysis leads to the formulation of two groups of instincts: the so-called 'ego-instincts', which are directed towards self-preservation, and the 'object-instincts', which are concerned with relations to an external object. The social instincts are not regarded as elementary or irreducible. Theoretical speculation leads to the suspicion that there are two fundamental instincts which lie concealed behind the manifest ego-instincts and object-instincts: namely (a) Eros, the instinct which strives for ever closer union, and (b) the instinct of destruction, which leads towards the dissolution of what is living. In psycho-analysis the manifestation of the force of Eros is given the name 'libido'.
[1926f, 4403]
The question arises: What happens to the libido which has been withdrawn from external objects in schizophrenia? The megalomania characteristic of these states points the way. This megalomania has no doubt come into being at the expense of object-libido. The libido that has been withdrawn from the external world has been directed to the ego and thus gives rise to an attitude which may be called narcissism. But the megalomania itself is no new creation; on the contrary, it is, as we know, a magnification and plainer manifestation of a condition which had already existed previously. This leads us to look upon the narcissism which arises through the drawing in of object-cathexes as a secondary one, superimposed upon a primary narcissism that is obscured by a number of different influences.

The form of disease known as paranoia, chronic systematic insanity, occupies an unsettled position in the attempts at classification made by present-day psychiatry. There is, however, no doubt of its close affinity to dementia praecox. I once ventured to suggest that paranoia and dementia praecox should be brought together under the common designation of 'paraphrenia'. The forms of paranoia are described according to their content as megalomania, persecution mania, erotomania, delusions of jealousy, and so on. We shall not expect anything much in the way of an attempt at an explanation from psychiatry. Here is an example of one, though, it is true, one that is out of date and does not carry much weight - an attempt to derive one symptom from another by means of an intellectual rationalization: it is suggested that the patient, who, owing to a primary disposition, believes that he is being persecuted, infers from his persecution that he must be someone of quite particular importance and so develops megalomania. According to our analytic view the megalomania is the direct result of a magnification of the ego due to the drawing in of the libidinal object-cathexes - a secondary narcissism which is a return of the original early infantile one. We have, however, made a few observations of persecution mania which have induced us to follow a particular track. The first thing that struck us was that in the large majority of cases the persecutor was of the same sex as the persecuted patient. This was still open to an innocent explanation; but in a few cases that were thoroughly studied it was clear that the person of the same sex whom the patient loved most had, since his illness, been turned into his persecutor. This made a further development possible: namely, the replacement of the beloved person, along the line of familiar resemblances, by someone else - for instance, a father by a schoolmaster or by some superior. Experiences of this kind in ever increasing numbers led us to conclude that paranoia persecutoria is the form of the disease in which a person is defending himself against a homosexual impulse which has become too powerful. The change over from affection to hatred, which, it is well known, may become a serious threat to the life of the loved and hated object, corresponds in such cases to the transformation of libidinal impulses into anxiety which is a regular outcome of the process of repression. Listen, for instance, to what is, once again, the most recent instance of my observations in this connection.

During the work of treatment we have to consider the distribution of the patient's libido; we look for the object presentations to which it is bound and free it from them, so as to place it at the disposal of the ego. In the course of this, we have come to form a very curious picture of the original, primal distribution of libido in human beings. We have been driven to assume that at the beginning of the development of the individual all his libido (all his erotic tendencies, all his capacity for love) is tied to himself - that as we say, it cathects his own ego. It is only later that, being attached to the satisfaction of the major vital needs, the libido flows over from the ego on to external objects. Not till then are we able to recognize the libidinal instincts as such and distinguish them from the ego instincts. It is possible for the libido to become detached from these objects and withdrawn again into the ego.
Now that we have distinguished between the ego and the id, we must recognize the id as the great reservoir of libido indicated in my paper on narcissism (1914c). The libido which flows into the ego owing to the identifications described above brings about its 'secondary narcissism'.

This would seem to imply an important amplification of the theory of narcissism. At the very beginning, all the libido is accumulated in the id, while the ego is still in process of formation or is still feeble. The id sends part of this libido out into erotic object-cathexes, whereupon the ego, now grown stronger, tries to get hold of this object-libido and to force itself on the id as a love-object. The narcissism of the ego is thus a secondary one, which has been withdrawn from objects.

Thus we have said repeatedly that the ego is formed to a great extent out of identifications which take the place of abandoned cathexes by the id; that the first of these identifications always behave as a special agency in the ego and stand apart from the ego in the form of a super-ego, while later on, as it grows stronger, the ego may become more resistant to the influences of such identifications. The super-ego owes its special position in the ego, or in relation to the ego, to a factor which must be considered from two sides: on the one hand it was the first identification and one which took place while the ego was still feeble, and on the other hand it is the heir to the Oedipus complex and has thus introduced the most momentous objects into the ego. The super-ego's relation to the later alterations of the ego is roughly similar to that of the primary sexual phase of childhood to later sexual life after puberty. Although it is accessible to all later influences, it nevertheless preserves throughout life the character given to it by its derivation from the father-complex - namely, the capacity to stand apart from the ego and to master it. It is a memorial of the former weakness and dependence of the ego, and the mature ego remains subject to its domination. As the child was once under a compulsion to obey its parents, so the ego submits to the categorical imperative of its super-ego.
The first of these is the oral or, as it might be called, cannibalistic pregenital sexual organization. Here sexual activity has not yet been separated from the ingestion of food; nor are opposite currents within the activity differentiated. The object of both activities is the same; the sexual aim consists in the incorporation of the object - the prototype of a process which, in the form of identification, is later to play such an important psychological part. A relic of this constructed phase of organization, which is forced upon our notice by pathology, may be seen in thumb-sucking, in which the sexual activity, detached from the nutritive activity, has substituted for the extraneous object one situated in the subject's own body.¹

¹ It is worth emphasizing that his flight into illness was made possible by his identifying himself with his father. The identification enabled his affects to regress on to the residue of his childhood.

From the precipitating cause of the patient's illness in his adult years there was a thread leading back to his childhood. He had found himself in a situation similar to that in which, as he knew or suspected, his father had been before his marriage; and he had thus been able to identify himself with his father. But his dead father was involved in his recent attack in yet another way. The conflict at the root of his illness was in essentials a struggle between the persisting influence of his father's wishes and his own amatory predilections. If we take into consideration what the patient reported in the course of the first hours of his treatment, we shall not be able to avoid a suspicion that this struggle was a very ancient one and had arisen as far back as in his childhood.

In my description I shall, as I have already said, content myself with the briefest possible summary of the circumstances. Obviously the first problem to be solved was why the two speeches of the Czech captain - his rat story, and his request to the patient that he should pay back the money to Lieutenant A. - should have had such an agitating effect on him and should have provoked such violently pathological reactions. The presumption was that it was a question of 'complexive sensitiveness', and that the speeches had jarred upon certain hyperaesthetic spots in his unconscious. And so it proved to be. As always happened with the patient in connection with military matters, he had been in a state of unconscious identification with his father, who had seen many years' service and had been full of stories of his soldiering days. Now it happened by chance - for chance may play a part in the formation of a symptom, just as the wording may help in the making of a joke - that one of his father's little adventures had an important element in common with the captain's request. His father, in his capacity as non-commissioned officer, had control over a small sum of money and had on one occasion lost it at cards. (Thus he had been a 'Spielratte'.) He would have found himself in a serious position if one of his comrades had not advanced him the amount. After he had left the army and become well-off, he had tried to find this friend in need so as to pay him back the money, but had not managed to trace him. The patient was uncertain whether he had ever succeeded in returning the money. The recollection of this sin of his father's youth was painful to him, for, in spite of appearances, his unconscious was filled with hostile strictures upon his father's character. The captain's words, 'You must pay back the 3.80 kronen to Lieutenant A.', had sounded to his ears like an allusion to this unpaid debt of his father's.
But the information that the young lady at the post office at Z-- had herself paid the charges due upon the packet, with a complimentary remark about himself,¹ had intensified his identification with his father in quite another direction. At this stage in the analysis he brought out some new information, to the effect that the landlord of the inn at the little place where the post office was had had a pretty daughter. She had been decidedly encouraging to the smart young officer, so that he had thought of returning there after the manoeuvres were over and of trying his luck with her. Now, however, she had a rival in the shape of the young lady at the post office. Like his father in the tale of his marriage, he could afford now to hesitate upon which of the two he should bestow his favours when he had finished his military service. We can see at once that his singular indecision whether he should travel to Vienna or go back to the place where the post office was, and the constant temptation he felt to turn back while he was on the journey (p. 2140), were not so senseless as they seemed to us at first. To his conscious mind, the attraction exercised upon him by Z--, the place where the post office was, was explained by the necessity of seeing Lieutenant A. and fulfilling the vow with his assistance. But in reality what was attracting him was the young lady at the post office, and the lieutenant was merely a good substitute for her, since he had lived at the same place and had himself been in charge of the military postal service. And when subsequently he heard that it was not Lieutenant A. but another officer B., who had been on duty at the post office that day, he drew him into his combination as well; and he was then able to reproduce in his deliria in connection with the two officers the hesitation he felt between the two girls who were so kindly disposed towards him.²

After this preliminary stage a transformation sets in whose mechanism is known to us but whose motive forces we do not yet understand. The child's love for his mother cannot continue to develop consciously any further; it succumbs to repression. The boy represses his love for his mother: he puts himself in her place, identifies himself with her, and takes his own person as a model in whose likeness he chooses the new objects of his love. In this way he has become a homosexual. What he has in fact done is to slip back to auto-erotism: for the boys whom he now loves as he grows up are after all only substitutive figures and revivals of himself in childhood - boys whom he loves in the way in which his mother loved him when he was a child. He finds the objects of his love along the path of narcissism, as we say; for Narcissus, according to the Greek legend, was a youth who preferred his own reflection to everything else and who was changed into the lovely flower of that name.

¹ [1909d, 2165]
² [1910c, 2274]
Lying partly undressed on the sofa beside her lover, she heard a noise like a click or beat. She did not know its cause, but she arrived at an interpretation of it after meeting two men on the staircase, one of whom was carrying something that looked like a covered box. She became convinced that someone acting on instructions from her lover had watched and photographed her during their intimate tête à tête. I do not for a moment imagine, of course, that if the unlucky noise had not occurred the delusion would not have been formed; on the contrary, something inevitable is to be seen behind this accidental circumstance, something which was bound to assert itself compulsively in the patient, just as when she supposed that there was a liaison between her lover and the elderly superior, her mother-substitute. Among the store of unconscious phantasies of all neurotics, and probably of all human beings, there is one which is seldom absent and which can be disclosed by analysis: this is the phantasy of watching sexual intercourse between the parents. I call such phantasies - of the observation of sexual intercourse between the parents, of seduction, of castration, and others - "primal phantasies"; and I shall discuss in detail elsewhere their origin and their relation to individual experience. The accidental noise was thus merely playing the part of a provoking factor which activated the typical phantasy of overhearing which is a component of the parental complex. Indeed, it is doubtful whether we can rightly call the noise 'accidental'. As Otto Rank has remarked to me, such noises are on the contrary an indispensable part of the phantasy of listening, and they reproduce either the sounds which betray parental intercourse or those by which the listening child fears to betray itself. But now we know at once where we stand. The patient's lover was still her father, but she herself had taken her mother's place. The part of the listener had then to be allotted to a third person. We can see by what means the girl had freed herself from her homosexual dependence on her mother. It was by means of a small piece of regression: instead of choosing her mother as a love-object, she identified herself with her - she herself became her mother. The possibility of this regression points to the narcissistic origin of her homosexual object-choice and thus to the paranoic disposition in her. One might sketch a train of thought which would bring about the same result as this identification: 'If my mother does it, I may do it too; I've just as good a right as she has.'

What we have learned from these three sources may be summarized as follows. First, identification is the original form of emotional tie with an object; secondly, in a regressive way it becomes a substitute for a libidinal object-tie, as it were by means of introjection of the object into the ego; and thirdly, it may arise with any new perception of a common quality shared with some other person who is not an object of the sexual instinct. The more important this common quality is, the more successful may this partial identification become, and it may thus represent the beginning of a new tie.
The genesis of male homosexuality in a large class of cases is as follows. A young man has been unusually long and intensely fixated upon his mother in the sense of the Oedipus complex. But at last, after the end of puberty, the time comes for exchanging his mother for some other sexual object. Things take a sudden turn: the young man does not abandon his mother, but identifies himself with her; he transforms himself into her, and now looks about for objects which can replace his ego for him, and on which he can bestow such love and care as he has experienced from his mother. This is a frequent process, which can be confirmed as often as one likes, and which is naturally quite independent of any hypothesis that may be made as to the organic driving force and the motives of the sudden transformation. A striking thing about this identification is its ample scale; it remoulds the ego in one of its important features - in its sexual character - upon the model of what has hitherto been the object. In this process the object itself is renounced - whether entirely or in the sense of being preserved only in the unconscious is a question outside the present discussion. Identification with an object that is renounced or lost, as a substitute for that object - introjection of it into the ego - is indeed no longer a novelty to us. A process of the kind may sometimes be directly observed in small children. A short time ago an observation of this sort was published in the *Internationale Zeitschrift für Psychoanalyse*. A child who was unhappy over the loss of a kitten declared straight out that now he himself was the kitten, and accordingly crawled about on all fours, would not eat at table, etc.¹

¹ It is by no means rare for a love-relation to be broken off through a process of identification on the part of the lover with the loved object, a process equivalent to a kind of regression to narcissism. After this has been accomplished, it is easy in making a fresh choice of object to direct the libido to a member of the sex opposite to that of the earlier choice.

At this point we must widen our range a little. We succeeded in explaining the painful disorder of melancholia by supposing that an object which was lost has been set up again inside the ego - that is, that an object-cathexis has been replaced by an identification.³ At that time, however, we did not appreciate the full significance of this process and did not know how common and how typical it is. Since then we have come to understand that this kind of substitution has a great share in determining the form taken by the ego and that it makes an essential contribution towards building up what is called its ‘character’.

When it happens that a person has to give up a sexual object, there quite often ensues an alteration of his ego which can only be described as a setting up of the object inside the ego, as it occurs in melancholia; the exact nature of this substitution is as yet unknown to us. It may be that by this introjection, which is a kind of regression to the mechanism of the oral phase, the ego makes it easier for the object to be given up or renders that process possible. It may be that this identification is the sole condition under which the id can give up its objects. At any rate the process, especially in the early phases of development, is a very frequent one, and it makes it possible to suppose that the character of the ego is a precipitate of abandoned object-cathexes and that it contains the history of those object-choices. It must, of course, be admitted from the outset that there are varying degrees of capacity for resistance, which decide the extent to which a person’s character fends off or accepts the influences of the history of his erotic object-choices. In women who have had many experiences in love there seems to be no difficulty in finding vestiges of their object-cathexes in the traits of their character. We must also take into consideration cases of simultaneous object-cathexis and identification - cases, that is, in which the alteration in character occurs before the object has been given up. In such cases the alteration in character has been able to survive the object-relation and in a certain sense to conserve it.
¹ An interesting parallel to the replacement of object-choice by identification is to be found in the belief of primitive peoples, and in the prohibitions based upon it, that the attributes of animals which are incorporated as nourishment persist as part of the character of those who eat them. As is well known, this belief is one of the roots of cannibalism and its effects have continued through the series of usages of the totem meal down to Holy Communion. The consequences ascribed by this belief to oral mastery of the object do in fact follow in the case of the later sexual object-choice.
[1923b, 3963]

From another point of view it may be said that this transformation of an erotic object-choice into an alteration of the ego is also a method by which the ego can obtain control over the id and deepen its relations with it - at the cost, it is true, of acquiescing to a large extent in the id's experiences. When the ego assumes the features of the object, it is forcing itself, so to speak, upon the id as a love-object and is trying to make good the id's loss by saying: 'Look, you can love me too - I am so like the object.'
[1923b, 3964]

The transformation of object-libido into narcissistic libido which thus takes place obviously implies an abandonment of sexual aims, a desexualization - a kind of sublimation, therefore. Indeed, the question arises, and deserves careful consideration, whether this is not the universal road to sublimation, whether all sublimation does not take place though the mediation of the ego, which begins by changing sexual object-libido into narcissistic libido and then, perhaps, goes on to give it another aim.¹ We shall later on have to consider whether other instinctual vicissitudes may not also result from this transformation, whether, for instance, it may not bring about a defusion of the various instincts that are fused together.
[1923b, 3964]

¹ Now that we have distinguished between the ego and the id, we must recognize the id as the great reservoir of libido indicated in my paper on narcissism (1914c). The libido which flows into the ego owing to the identifications described above brings about its 'secondary narcissism'.
[1923b, 3964]

Here we arrive again at the possibility which has already been discussed that sublimation may take place regularly, through the mediation of the ego. The other case will be recollected, in which the ego deals with the first object-cathexes of the id (and certainly with later ones too) by taking over the libido from them into itself and binding it to the alteration of the ego produced by means of identification. The transformation into ego-libido of course involves an abandonment of sexual aims, a desexualization. In any case this throws light upon an important function of the ego in its relation to Eros. By thus getting hold of the libido from the object-cathexes, setting itself up as sole love-object, and desexualizing or sublimating the libido of the id, the ego is working in opposition to the purposes of Eros and placing itself at the service of the opposing instinctual impulses. It has to acquiesce in some of the other object-cathexes of the id; it has, so to speak, to participate in them. We shall come back later to another possible consequence of this activity of the ego.
[1923b, 3979]

This would seem to imply an important amplification of the theory of narcissism. At the very beginning, all the libido is accumulated in the id, while the ego is still in process of formation or is still feeble. The id sends part of this libido out into erotic object-cathexes, whereupon the ego, now grown stronger, tries to get hold of this object-libido and to force itself on the id as a love-object. The narcissism of the ego is thus a secondary one, which has been withdrawn from objects.
[1923b, 3980]
The description we have given applies to the most extreme instances of this state of affairs, but in a lesser measure this factor has to be reckoned with in very many cases, perhaps in all comparatively severe cases of neurosis. In fact it may be precisely this element in the situation, the attitude of the ego ideal, that determines the severity of a neurotic illness. We shall not hesitate, therefore, to discuss rather more fully the way in which the sense of guilt expresses itself under different conditions.

[1923b, 3984]

Our ideas about the ego are beginning to clear, and its various relationships are gaining distinctness. We now see the ego in its strength and in its weaknesses. It is entrusted with important functions. By virtue of its relation to the perceptual system it gives mental processes an order in time and submits them to 'reality-testing'. By interposing the processes of thinking, it secures a postponement of motor discharges and controls the access to motility. This last power is, to be sure, a question more of form than of fact; in the matter of action the ego's position is like that of a constitutional monarch, without whose sanction no law can be passed but who hesitates long before imposing his veto on any measure put forward by Parliament. All the experiences of life that originate from without enrich the ego; the id, however, is its second external world, which it strives to bring into subjection to itself. It withdraws libido from the id and transforms the object-cathexes of the id into ego-structures. With the aid of the super-ego, in a manner that is still obscure to us, it draws upon the experiences of past ages stored in the id.

[1923b, 3989]

Towards the two classes of instincts the ego's attitude is not impartial. Through its work of identification and sublimation it gives the death instincts in the id assistance in gaining control over the libido, but in so doing it runs the risk of becoming the object of the death instincts and of itself perishing. In order to be able to help in this way it has had itself to become filled with libido; it thus itself becomes the representative of Eros and henceforward desires to live and to be loved.

[1923b, 3990]

I have described elsewhere how this turning away takes place. The object-cathexes are given up and replaced by identifications. The authority of the father or the parents is introjected into the ego, and there it forms the nucleus of the super-ego, which takes over the severity of the father and perpetuates his prohibition against incest, and so secures the ego from the return of the libidinal object-cathexis. The libidinal trends belonging to the Oedipus complex are in part desexualized and sublimated (a thing which probably happens with every transformation into an identification) and in part inhibited in their aim and changed into impulses of affection. The whole process has, on the one hand, preserved the genital organ - has averted the danger of its loss - and, on the other, has paralysed it - has removed its function. This process ushers in the latency period, which now interrupts the child's sexual development.

[1924d, 4088]
The basis of the process is what is called an 'identification' - that is to say, the assimilation of one ego to another one, as a result of which the first ego behaves like the second in certain respects, imitates it and in a sense takes it up into itself. Identification has been not unsuitably compared with the oral, cannibalistic incorporation of the other person. It is a very important form of attachment to someone else, probably the very first, and not the same thing as the choice of an object. The difference between the two can be expressed in some such way as this. If a boy identifies himself with his father, he wants to be like his father; if he makes him the object of his choice, he wants to have him, to possess him. In the first case his ego is altered on the model of his father; in the second case that is not necessary. Identification and object-choice are to a large extent independent of each other; it is however possible to identify oneself with someone whom, for instance, one has taken as a sexual object, and to alter one's ego on his model. It is said that the influencing of the ego by the sexual object occurs particularly often with women and is characteristic of femininity. I must already have spoken to you in my earlier lectures of what is by far the most instructive relation between identification and object-choice. It can be observed equally easily in children and adults, in normal as in sick people. If one has lost an object or has been obliged to give it up, one often compensates oneself by identifying oneself with it and by setting it up once more in one's ego, so that here object-choice regresses, as it were, to identification.

[1933a, 4672]

I myself am far from satisfied with these remarks on identification; but it will be enough if you can grant me that the installation of the super-ego can be described as a successful instance of identification with the parental agency. The fact that speaks decisively for this view is that this new creation of a superior agency within the ego is most intimately linked with the destiny of the Oedipus complex, so that the super-ego appears as the heir of that emotional attachment which is of such importance for childhood. With his abandonment of the Oedipus complex a child must, as we can see, renounce the intense object-cathexes which he has deposited with his parents, and it is as a compensation for this loss of objects that there is such a strong intensification of the identifications with his parents which have probably long been present in his ego. Identifications of this kind as precipitates of object-cathexes that have been given up will be repeated often enough later in the child's life; but it is entirely in accordance with the emotional importance of this first instance of such a transformation that a special place in the ego should be found for its outcome. Close investigation has shown us, too, that the super-ego is stunted in its strength and growth if the surmounting of the Oedipus complex is only incompletely successful. In the course of development the super-ego also takes on the influences of those who have stepped into the place of parents - educators, teachers, people chosen as ideal models. Normally it departs more and more from the original parental figures; it becomes, so to say, more impersonal. Nor must it be forgotten that a child has a different estimate of its parents at different periods of its life. At the time at which the Oedipus complex gives place to the super-ego they are something quite magnificent; but later they lose much of this. Identifications then come about with these later parents as well, and indeed they regularly make important contributions to the formation of character; but in that case they only affect the ego, they no longer influence the super-ego, which has been determined by the earliest parental imagos.

[1933a, 4673]
So far we have allowed ourselves to be impressed by the merits and capabilities of the ego; it is now time to consider the other side as well. The ego is after all only a portion of the id, a portion that has been expediently modified by the proximity of the external world with its threat of danger. From a dynamic point of view it is weak, it has borrowed its energies from the id, and we are not entirely without insight into the methods - we might call them dodges - by which it extracts further amounts of energy from the id. One such method, for instance, is by identifying itself with actual or abandoned objects. The object-cathexes spring from the instinctual demands of the id. The ego has in the first instance to take note of them. But by identifying itself with the object it recommends itself to the id in place of the object and seeks to divert the id's libido on to itself. We have already seen that in the course of its life the ego takes into itself a large number of precipitates like this of former object-cathexes. The ego must on the whole carry out the id's intentions, it fulfils its task by finding out the circumstances in which those intentions can best be achieved. The ego's relation to the id might be compared with that of a rider to his horse. The horse supplies the locomotive energy, while the rider has the privilege of deciding on the goal and of guiding the powerful animal's movement. But only too often there arises between the ego and the id the not precisely ideal situation of the rider being obliged to guide the horse along the path by which it itself wants to go.

[1933a, 4685]

Incidentally, here is a point on which we may dwell for a moment. You yourselves have no doubt assumed that what is known as 'character', a thing so hard to define, is to be ascribed entirely to the ego. We have already made out a little of what it is that creates character. First and foremost there is the incorporation of the former parental agency as a super-ego, which is no doubt its most important and decisive portion, and, further, identifications with the two parents of the later period and with other influential figures, and similar identifications formed as precipitates of abandoned object-relations. And we may now add as contributions to the construction of character which are never absent the reaction-formations which the ego acquires - to begin with in making its repressions and later, by a more normal method, when it rejects unwished-for instinctual impulses.

[1933a, 4698]

If a little girl persists in her first wish - to grow into a boy - in extreme cases she will end as a manifest homosexual, and otherwise she will exhibit markedly masculine traits in the conduct of her later life, will choose a masculine vocation, and so on. The other path leads by way of abandoning the mother she has loved: the daughter, under the influence of her envy for the penis, cannot forgive her mother for having sent her into the world so insufficiently equipped. In her resentment over this she gives up her mother and puts someone else in her place as the object of her love - her father. If one has lost a love-object, the most obvious reaction is to identify oneself with it, to replace it from within, as it were, by identification. This mechanism now comes to the little girl's help. Identification with her mother can take the place of attachment to her mother. The little daughter puts herself in her mother's place, as she has always done in her games; she tries to take her mother's place with her father, and begins to hate the mother she used to love, and from two motives: from jealousy as well as from mortification over the penis she has been denied. Her new relation to her father may start by having as its content a wish to have his penis at her disposal, but it culminates in another wish - to have a baby from him as a gift. The wish for a baby has thus taken the place of the wish for a penis, or has at all events split off from it.

[1940a [1938], 5000]
Here is one instance. It is well known that at all periods there have been, as there still are, people who can take as their sexual objects members of their own sex as well as of the opposite one, without the one trend interfering with the other. We call such people bisexuals, and we accept their existence without feeling much surprise about it. We have come to learn, however, that every human being is bisexual in this sense and that his libido is distributed, either in a manifest or a latent fashion, over objects of both sexes. But we are struck by the following point. Whereas in the first class of people the two trends have got on together without clashing, in the second and more numerous class they are in a state of irreconcilable conflict. A man's heterosexuality will not put up with any homosexuality, and vice versa. If the former is the stronger it succeeds in keeping the latter latent and forcing it away from satisfaction in reality. On the other hand, there is no greater danger for a man's heterosexual function than its being disturbed by his latent homosexuality. We might attempt to explain this by saying that each individual only has a certain quota of libido at his disposal, for which the two rival trends have to struggle. But it is not clear why the rivals do not always divide up the available quota of libido between them according to their relative strength, since they are able to do so in a number of cases. We are forced to the conclusion that the tendency to a conflict is something special, something which is newly added to the situation, irrespective of the quantity of libido. An independently-emerging tendency to conflict of this sort can scarcely be attributed to anything but the intervention of an element of free aggressiveness. [1937c, 5038]
This ego-libido is, however, only conveniently accessible to analytic study when it has been put to the use of cathecting sexual objects, that is, when it has become object-libido. We can then perceive it concentrating upon objects, becoming fixed upon them or abandoning them, moving from one object to another and, from these situations, directing the subject's sexual activity, which leads to the satisfaction, that is, to the partial and temporary extinction, of the libido. The psycho-analysis of what are termed transference neuroses (hysteria and obsessional neurosis) affords us a clear insight at this point.

The object [Objekt] of an instinct is the thing in regard to which or through which the instinct is able to achieve its aim. It is what is most variable about an instinct and is not originally connected with it, but becomes assigned to it only in consequence of being peculiarly fitted to make satisfaction possible. The object is not necessarily something extraneous: it may equally well be a part of the subject's own body. It may be changed any number of times in the course of the vicissitudes which the instinct undergoes during its existence; and highly important parts are played by this displacement of instinct. It may happen that the same object serves for the satisfaction of several instincts simultaneously, a phenomenon which Adler has called a 'confluence' of instincts [Triebverschränkung]. A particularly close attachment of the instinct to its object is distinguished by the term 'fixation'. This frequently occurs at very early periods of the development of an instinct and puts an end to its mobility through its intense opposition to detachment.

The tenacity with which the libido adheres to particular trends and objects - what may be described as the 'adhesiveness' of the libido - makes its appearance as an independent factor, varying from individual to individual, whose determinants are quite unknown to us, but whose significance for the aetiology of the neuroses we shall certainly no longer underestimate. We should not, on the other hand, over-estimate the intimacy of this connection. For a similar 'adhesiveness' of the libido occurs (for unknown reasons) under numerous conditions in normal people, and it is found as a determining factor in people who are in one sense the contrary of neurotics - in perverts. It was known even before the days of psycho-analysis (cf. Binet) that in the anamnesis of perverts a very early impression of an abnormal instinctual trend or choice of object was quite often found, to which the subject's libido remained attached all through his life. It is often impossible to say what it is that enabled this impression to exercise such an intense attraction on the libido. I will describe a case of this sort which I myself observed.

With this as a starting-point we go on to make our first important discovery. We learn that, when we try to understand neurotic disorders, by far the greater significance attaches to the sexual instincts; that in fact neuroses are the specific disorders, so to speak, of the sexual function; that in general whether or not a person develops a neurosis depends on the quantity of his libido, and on the possibility of satisfying it and of discharging it through satisfaction; that the form taken by the disease is determined by the way in which the individual passes through the course of development of his sexual function, or, as we put it, by the fixations his libido has undergone in the course of its development; and, further, that by a special, not very simple technique for influencing the mind we are able to throw light on the nature of some groups of neuroses and at the same time to do away with them. Our therapeutic efforts have their greatest success with a certain class of neuroses which proceed from a conflict between the ego-instincts and the sexual instincts. For in human beings it may happen that the demands of the sexual instincts, whose reach of course extends far beyond the individual, seem to the ego to constitute a danger which threatens its self-preservation or its self-esteem. The ego then assumes the defensive, denies the sexual instincts the satisfaction they desire and forces them into those by-paths of substitutive satisfaction which become manifest as nervous symptoms.
The Development of the Libido. - The sexual instinct, the dynamic manifestation of which in mental life we shall call 'libido', is made up of component instincts into which it may once more break up and which are only gradually united into well-defined organizations. The sources of these component instincts are the organs of the body and in particular certain specially marked erotogenic zones; but contributions are made to libido from every important functional process in the body. At first the individual component instincts strive for satisfaction independently of one another, but in the course of development they become more and more convergent and concentrated. The first (pregenital) stage of organization to be discerned is the oral one, in which - in conformity with the suckling's predominant interest - the oral zone plays the leading part. This is followed by the sadistic-anal organization, in which the anal zone and the component instinct of sadism are particularly prominent; at this stage the difference between the sexes is represented by the contrast between active and passive. The third and final stage of organization is that in which the majority of the component instincts converge under the primacy of the genital zones. As a rule this development is passed through swiftly and unobtrusively; but some individual portions of the instincts remain behind at the prodromal stages of the process and thus give rise to fixations of libido, which are important as constituting predispositions for subsequent eruptions of repressed impulses and which stand in a definite relation to the later development of neuroses and perversions. (See the article on 'The Libido Theory'.)

[1923a, 3921]

The sexual function, as I found, is in existence from the very beginning of the individual's life, though at first it is attached to the other vital functions and does not become independent of them until later; it has to pass through a long and complicated process of development before it becomes what we are familiar with as the normal sexual life of the adult. It begins by manifesting itself in the activity of a whole number of component instincts. These are dependent upon erotogenic zones in the body; some of them make their appearance in pairs of opposite impulses (such as sadism and masochism or the impulses to look and to be looked at); they operate independently of one another in a search for pleasure, and they find their object for the most part in the subject's own body. Thus at first the sexual function is non-centralized and predominantly auto-erotic. Later, syntheses begin to appear in it; a first stage of organization is reached under the dominance of the oral components, an anal-sadistic stage follows, and it is only after the third stage has at last been reached that the primacy of the genitals is established and that the sexual function begins to serve the ends of reproduction. In the course of this process of development a number of elements of the various component instincts turn out to be unserviceable for this last end and are therefore left on one side or turned to other uses, while others are diverted from their aims and carried over into the genital organization. I gave the name of libido to the energy of the sexual instincts and to that form of energy alone. I was next driven to suppose that the libido does not always pass through its prescribed course of development smoothly. As a result either of the excessive strength of certain of the components or of experiences involving premature satisfaction, fixations of the libido may occur at various points in the course of its development. If subsequently a repression takes place, the libido flows back to these points (a process described as regression), and it is from them that the energy breaks through in the form of a symptom. Later on it further became clear that the localization of the point of fixation is what determines the choice of neurosis, that is, the form in which the subsequent illness makes its appearance.

[1925d, 4211]
It is hard to say anything of the behaviour of the libido in the id and in the super-ego. All that we know about it relates to the ego, in which at first the whole available quota of libido is stored up. We call this state absolute, primary narcissism. It lasts till the ego begins to cathect the ideas of objects with libido, to transform narcissistic libido into object-libido. Throughout the whole of life the ego remains the great reservoir from which libidinal cathexes are sent out to objects and into which they are also once more withdrawn, just as an amoeba behaves with its pseudopodia. It is only when a person is completely in love that the main quota of libido is transferred on to the object and the object to some extent takes the place of the ego. A characteristic of the libido which is important in life is its mobility, the facility with which it passes from one object to another. This must be contrasted with the fixation of the libido to particular objects, which often persists throughout life.

[1940a [1938], 4961]

This process is not always performed faultlessly. Inhibitions in its development manifest themselves as the many sorts of disturbance in sexual life. When this is so, we find fixations of the libido to conditions in earlier phases, whose urge, which is independent of the normal sexual aim, is described as perversion. One such developmental inhibition, for instance, is homosexuality when it is manifest. Analysis shows that in every case a homosexual object-tie was present and in most cases persisted in a latent condition. The situation is complicated by the fact that as a rule the processes necessary for bringing about a normal outcome are not completely present or absent, but partially present, so that the final result remains dependent on these quantitative relations. In these circumstances the genital organization is, it is true, attained, but it lacks those portions of the libido which have not advanced with the rest and have remained fixated to pregenital objects and aims. This weakening shows itself in a tendency, if there is an absence of genital satisfaction or if there are difficulties in the real external world, for the libido to hark back to its earlier pregenital cathexes (regression).

[1940a [1938], 4966]
In my *Three Essays on the Theory of Sexuality* I have expressed the opinion that each stage in the development of psychosexuality affords a possibility of 'fixation', and thus of a dispositional point. People who have not freed themselves completely from the stage of narcissism - who, that is to say, have at that point a fixation which may operate as a disposition to a later illness - are exposed to the danger that some unusually intense wave of libido, finding no other outlet, may lead to a sexualization of their social instincts and so undo the sublimations which they had achieved in the course of their development. This result may be produced by anything that causes the libido to flow backwards (i.e. that causes a 'regression'): whether, on the one hand, the libido becomes collaterally reinforced owing to some disappointment over a woman, or is directly dammed up owing to a mishap in social relations with other men - both of these being instances of 'frustration'; or whether, on the other hand, there is a general intensification of the libido, so that it becomes too powerful to find an outlet along the channels which are already open to it, and consequently bursts through its banks at the weakest spot.

Since our analyses show that paranoics *endeavour to protect themselves against any such sexualization of their social instinctual cathexes*, we are driven to suppose that the weak spot in their development is to be looked for somewhere between the stages of auto-erotism, narcissism and homosexuality, and that their disposition to illness (which may perhaps be susceptible of more precise definition) must be located in that region. A similar disposition would have to be assigned to patients suffering from Kraepelin's dementia praecox or (as Bleuler has named it) *schizophrenia*; and we shall hope later on to find clues which will enable us to trace back the differences between the two disorders (as regards both the form they take and the course they run) to corresponding differences in the patients’ dispositional fixations.

Your second observation, too, raises a justifiable question, but it is aimed in the wrong direction. It is true that a withdrawal of the object-libido into the ego is not directly pathogenic; it takes place, indeed, as we know, every time before we go to sleep, only to be reversed when we wake up. The amoeba withdraws its protrusions only to send them out again at the first opportunity. But it is quite a different thing when a particular, very energetic process forces a withdrawal of libido from objects. Here the libido that has become narcissistic cannot find its way back to objects, and this interference with the libido's mobility certainly becomes pathogenic. It seems that an accumulation of narcissistic libido beyond a certain amount is not tolerated. We may even imagine that it was for that very reason that object-cathexes originally came about, that the ego was obliged to send out its libido so as not to fall ill as a result of its being dammed up. If it lay within our plan to go more deeply into dementia praecox, I would show you that the process which detaches the libido from objects and cuts off its return to them is closely related to the process of repression and is to be looked at as its counterpart. But you would, first and foremost, find yourselves on familiar ground when you learnt that the determinants of this process are almost identical - so far as we know at present - with those of repression. The conflict seems to be the same and to be carried on between the same forces. If the outcome is so different from, for instance, that in hysteria, the reason can only depend on a difference in innate disposition. The weak spot in the libidinal development of these patients lies in a different phase; the determining fixation, which, as you will recollect, permits the irruption that leads to the formation of symptoms, lies elsewhere, probably in the stage of primitive narcissism to which dementia praecox returns in its final outcome. It is very remarkable that in the case of all the narcissistic neuroses we have to assume fixation points for the libido going back to far earlier phases of development than in hysteria or obsessional neurosis. As you heard, however, the concepts which we arrived at during our study of the transference neuroses are adequate in helping us to find our way about in the narcissistic neuroses which are so much more severe in practice. The conformities go very far; at bottom the field of phenomena is the same. And you can imagine how small a prospect anyone has of explaining these disorders (which belong within the sphere of psychiatry) who is not forarmed for his task with an analytic knowledge of the transference neuroses.

[1916-1917, 3466]
It is hard to say anything of the behaviour of the libido in the id and in the super-ego. All that we know about it relates to the ego, in which at first the whole available quota of libido is stored up. We call this state absolute, primary narcissism. It lasts till the ego begins to cathect the ideas of objects with libido, to transform narcissistic libido into object-libido. Throughout the whole of life the ego remains the great reservoir from which libidinal cathexes are sent out to objects and into which they are also once more withdrawn, just as an amoeba behaves with its pseudopodia. It is only when a person is completely in love that the main quota of libido is transferred on to the object and the object to some extent takes the place of the ego. A characteristic of the libido which is important in life is its mobility, the facility with which it passes from one object to another. This must be contrasted with the fixation of the libido to particular objects, which often persists throughout life.

[1940a [1938], 4961]
This ego-libido is, however, only conveniently accessible to analytic study when it has been put to the use of cathecting sexual objects, that is, when it has become object-libido. We can then perceive it concentrating upon objects, becoming fixed upon them or abandoning them, moving from one object to another and, from these situations, directing the subject's sexual activity, which leads to the satisfaction, that is, to the partial and temporary extinction, of the libido. The psycho-analysis of what are termed transference neuroses (hysteria and obsessional neurosis) affords us a clear insight at this point.

We can follow the object-libido through still further vicissitudes. When it is withdrawn from objects, it is held in suspense in peculiar conditions of tension and is finally drawn back into the ego, so that it becomes ego-libido once again. In contrast to object-libido, we also describe ego-libido as 'narcissistic' libido. From the vantage-point of psycho-analysis we can look across a frontier, which we may not pass, at the activities of narcissistic libido, and may form some idea of the relation between it and object-libido.¹ Narcissistic or ego-libido seems to be the great reservoir from which the object-cathexes are sent out and into which they are withdrawn once more; the narcissistic libidinal cathexis of the ego is the original state of things, realized in earliest childhood, and is merely covered by the later extrusions of libido, but in essentials persists behind them.

It should be the task of a libido theory of neurotic and psychotic disorders to express all the observed phenomena and inferred processes in terms of the economics of the libido. It is easy to guess that the vicissitudes of the ego-libido will have the major part to play in this connection, especially when it is a question of explaining the deeper psychotic disturbances. We are then faced by the difficulty that our method of research, psycho-analysis, for the moment affords us assured information only on the transformations that take place in the object-libido,² but is unable to make any immediate distinction between the ego-libido and the other forms of energy operating in the ego.³

The value of the concepts 'ego-libido' and 'object-libido' lies in the fact that they are derived from the study of the intimate characteristics of neurotic and psychotic processes. A differentiation of libido into a kind which is proper to the ego and one which is attached to objects is an unavoidable corollary to an original hypothesis which distinguished between sexual instincts and ego-instincts. At any rate, analysis of the pure transference neuroses (hysteria and obsessional neurosis) compelled me to make this distinction and I only know that all attempts to account for these phenomena by other means have been completely unsuccessful.

Certain special difficulties seem to me to lie in the way of a direct study of narcissism. Our chief means of access to it will probably remain the analysis of the paraphrenias. Just as the transference neuroses have enabled us to trace the libidinal instinctual impulses, so dementia praecox and paranoia will give us an insight into the psychology of the ego. Once more, in order to arrive at an understanding of what seems so simple in normal phenomena, we shall have to turn to the field of pathology with its distortions and exaggerations. At the same time, other means of approach remain open to us, by which we may obtain a better knowledge of narcissism. These I shall now discuss in the following order: the study of organic disease, of hypochondria and of the erotic life of the sexes.
Since a study of instinctual life from the direction of consciousness presents almost insuperable difficulties, the principal source of our knowledge remains the psycho-analytic investigation of mental disturbances. Psycho-analysis, however, in consequence of the course taken by its development, has hitherto been able to give us information of a fairly satisfactory nature only about the sexual instincts; for it is precisely that group which alone can be observed in isolation, as it were, in the psychoneuroses. With the extension of psycho-analysis to the other neurotic affections, we shall no doubt find a basis for our knowledge of the ego-instincts as well, though it would be rash to expect equally favourable conditions for observation in this further field of research.
[1915c, 2963]

Hitherto it has been a premiss of our work that we can distinguish the ego-instincts from the sexual ones by their manifestations. With the transference neuroses this could be done without difficulty. We termed the cathexes of energy which the ego directs towards the objects of its sexual desires 'libido'; all the others, which are sent out by the self-preservative instincts, we termed 'interest'. By tracing the course of the libidinal cathexes, their transformations and final vicissitudes, we were able to obtain a first insight into the machinery of the mental forces. For this purpose the transference neuroses offered us the most favourable material. But the ego, its composition out of various organizations and their construction and mode of functioning, remained hidden from us; and we were driven to suspect that only the analysis of other neurotic disorders would be able to bring us the necessary insight.
[1916-1917, 3460]

Your second observation, too, raises a justifiable question, but it is aimed in the wrong direction. It is true that a withdrawal of the object-libido into the ego is not directly pathogenic; it takes place, indeed, as we know, every time before we go to sleep, only to be reversed when we wake up. The amoeba withdraws its protrusions only to send them out again at the first opportunity. But it is quite a different thing when a particular, very energetic process forces a withdrawal of libido from objects. Here the libido that has become narcissistic cannot find its way back to objects, and this interference with the libido's mobility certainly becomes pathogenic. It seems that an accumulation of narcissistic libido beyond a certain amount is not tolerated. We may even imagine that it was for that very reason that object-cathexes originally came about, that the ego was obliged to send out its libido so as not to fall ill as a result of its being dammed up. If it lay within our plan to go more deeply into dementia praecox, I would show you that the process which detaches the libido from objects and cuts off its return to them is closely related to the process of repression and is to be looked at as its counterpart. But you would, first and foremost, find yourselves on familiar ground when you learnt that the determinants of this process are almost identical - so far as we know at present - with those of repression. The conflict seems to be the same and to be carried on between the same forces. If the outcome is so different from, for instance, that in hysteria, the reason can only depend on a difference in innate disposition. The weak spot in the libidinal development of these patients lies in a different phase; the determining fixation, which, as you will recollect, permits the irritation that leads to the formation of symptoms, lies elsewhere, probably in the stage of primitive narcissism to which dementia praecox returns in its final outcome. It is very remarkable that in the case of all the narcissistic neuroses we have to assume fixation points for the libido going back to far earlier phases of development than in hysteria or obsessional neurosis. As you heard, however, the concepts which we arrived at during our study of the transference neuroses are adequate in helping us to find our way about in the narcissistic neuroses which are so much more severe in practice. The conformities go very far; at bottom the field of phenomena is the same. And you can imagine how small a prospect anyone has of explaining these disorders (which belong within the sphere of psychiatry) who is not forarmed for his task with an analytic knowledge of the transference neuroses.
[1916-1917, 3466]
I have now led you into the region in which the next advances in the work of analysis are to be expected. Since we have ventured to operate with the concept of ego-libido the narcissistic neuroses have become accessible to us; the task before us is to arrive at a dynamic elucidation of these disorders and at the same time to complete our knowledge of mental life by coming to understand the ego. The ego-psychology after which we are seeking must not be based on the data of our self-perceptions but (as in the case of the libido) on the analysis of disturbances and disruptions of the ego. It is likely that we shall have a low opinion of our present knowledge of the vicissitudes of the libido, which we have gained from a study of the transference neuroses, when we have achieved this greater task. But hitherto we have not made much progress with it. The narcissistic neuroses can scarcely be attacked with the technique that has served us with the transference neuroses. You will soon learn why. What always happens with them is that, after proceeding for a short distance, we come up against a wall which brings us to a stop. Even with the transference neuroses, as you know, we met with barriers of resistance, but we were able to demolish them bit by bit. In the narcissistic neuroses the resistance is unconquerable; at the most, we are able to cast an inquisitive glance over the top of the wall and spy out what is going on on the other side of it. Our technical methods must accordingly be replaced by others; and we do not know yet whether we shall succeed in finding substitute. Nevertheless, we have no lack of material with these patients either. They make a large number of remarks, even if they do not answer our questions, and for the time being it is our business to interpret these remarks with the help of the understanding we have gained from the symptoms of the transference neuroses. The agreement is great enough to guarantee us some initial advantage. It remains to be seen how far this technique will take us.

[1916-1917, 3467]

There can be no question but that the libido has somatic sources, that it streams to the ego from various organs and parts of the body. This is most clearly seen in the case of that portion of the libido which, from its instinctual aim, is described as sexual excitation. The most prominent of the parts of the body from which this libido arises are known by the name of 'erotogenic zones', though in fact the whole body is an erotogenic zone of this kind. The greater part of what we know about Eros - that is to say, about its exponent, the libido - has been gained from a study of the sexual function, which, indeed, on the prevailing view, even if not according to our theory, coincides with Eros. We have been able to form a picture of the way in which the sexual urge, which is destined to exercise a decisive influence on our life, gradually develops out of successive contributions from a number of component instincts, which represent particular erotogenic zones.

[1940a [1938], 4962]
This ego-libido is, however, only conveniently accessible to analytic study when it has been put to the use of cathecting sexual objects, that is, when it has become object-libido. We can then perceive it concentrating upon objects, becoming fixed upon them or abandoning them, moving from one object to another and, from these situations, directing the subject's sexual activity, which leads to the satisfaction, that is, to the partial and temporary extinction, of the libido. The psycho-analysis of what are termed transference neuroses (hysteria and obsessional neurosis) affords us a clear insight at this point.

[1905d, 1531]

We can follow the object-libido through still further vicissitudes. When it is withdrawn from objects, it is held in suspense in peculiar conditions of tension and is finally drawn back into the ego, so that it becomes ego-libido once again. In contrast to object-libido, we also describe ego-libido as 'narcissistic' libido. From the vantage-point of psycho-analysis we can look across a frontier, which we may not pass, at the activities of narcissistic libido, and may form some idea of the relation between it and object-libido.¹ Narcissistic or ego-libido seems to be the great reservoir from which the object-cathexes are sent out and into which they are withdrawn once more; the narcissistic libidinal cathexis of the ego is the original state of things, realized in earliest childhood, and is merely covered by the later extrusions of libido, but in essentials persists behind them.

[1905d, 1532]

¹ [Footnote added 1924:] Since neuroses other than the transference neuroses have become to a greater extent accessible to psycho-analysis, this limitation has lost its earlier validity.

[1905d, 1532]

Certain special difficulties seem to me to lie in the way of a direct study of narcissism. Our chief means of access to it will probably remain the analysis of the paraphrenias. Just as the transference neuroses have enabled us to trace the libidinal instinctual impulses, so dementia praecox and paranoia will give us an insight into the psychology of the ego. Once more, in order to arrive at an understanding of what seems so simple in normal phenomena, we shall have to turn to the field of pathology with its distortions and exaggerations. At the same time, other means of approach remain open to us, by which we may obtain a better knowledge of narcissism. These I shall now discuss in the following order: the study of organic disease, of hypochondria and of the erotic life of the sexes.

[1914c, 2938]
I have now led you into the region in which the next advances in the work of analysis are to be expected. Since we have ventured to operate with the concept of ego-libido the narcissistic neuroses have become accessible to us; the task before us is to arrive at a dynamic elucidation of these disorders and at the same time to complete our knowledge of mental life by coming to understand the ego. The ego-psychology after which we are seeking must not be based on the data of our self-perceptions but (as in the case of the libido) on the analysis of disturbances and disruptions of the ego. It is likely that we shall have a low opinion of our present knowledge of the vicissitudes of the libido, which we have gained from a study of the transference neuroses, when we have achieved this greater task. But hitherto we have not made much progress with it. The narcissistic neuroses can scarcely be attacked with the technique that has served us with the transference neuroses. You will soon learn why. What always happens with them is that, after proceeding for a short distance, we come up against a wall which brings us to a stop. Even with the transference neuroses, as you know, we met with barriers of resistance, but we were able to demolish them bit by bit. In the narcissistic neuroses the resistance is unconquerable; at the most, we are able to cast an inquisitive glance over the top of the wall and spy out what is going on on the other side of it. Our technical methods must accordingly be replaced by others; and we do not know yet whether we shall succeed in finding substitute. Nevertheless, we have no lack of material with these patients either. They make a large number of remarks, even if they do not answer our questions, and for the time being it is our business to interpret these remarks with the help of the understanding we have gained from the symptoms of the transference neuroses. The agreement is great enough to guarantee us some initial advantage. It remains to be seen how far this technique will take us.

[1916-1917, 3467]
This is the place for two remarks. First, how do we differentiate between the concepts of narcissism and egoism? Well, narcissism, I believe, is the libidinal complement to egoism. When we speak of egoism, we have in view only the individual's advantage; when we talk of narcissism we are also taking his libidinal satisfaction into account. As practical motives the two can be traced separately for quite a distance. It is possible to be absolutely egoistic and yet maintain powerful object-cathexes, in so far as libidinal satisfaction in relation to the object forms part of the ego's needs. In that case, egoism will see to it that striving for the object involves no damage to the ego. It is possible to be egoistic and at the same time to be excessively narcissistic - that is to say, to have very little need for an object, whether, once more, for the purpose of direct sexual satisfaction, or in connection with the higher aspirations, derived from sexual need, which we are occasionally in the habit of contrasting with 'sensuality' under the name of 'love'. In all these connections egoism is what is self-evident and constant, while narcissism is the variable element. The opposite to egoism, altruism, does not, as a concept, coincide with libidinal object-cathexis, but is distinguished from it by the absence of longings for sexual satisfaction. When someone is completely in love, however, altruism converges with libidinal object-cathexis. As a rule the sexual object attracts a portion of the ego's narcissism to itself, and this becomes noticeable as what is known as the 'sexual overvaluation' of the object. If in addition there is an altruistic transposition of egoism on to the sexual object, the object becomes supremely powerful; it has, as it were, absorbed the ego.

[1916-1917, 3462]

It only became possible to extend the libido theory to the narcissistic neuroses after the concept of a 'narcissistic libido' had been put forward and applied - a concept, that is, of an amount of sexual energy attached to the ego itself and finding satisfaction in the ego just as satisfaction is usually found only in objects. This entirely legitimate development of the concept of sexuality promises to accomplish as much for the severer neuroses and for the psychoses as can be expected of a theory which is feeling its way forwards on an empirical basis. The traumatic neuroses of peace will also fit into the scheme as soon as a successful outcome has been reached of our investigations into the relations which undoubtedly exist between fright, anxiety and narcissistic libido.

[1919d, 3667]

People will be only too readily inclined to include among the psychical assets of a culture its ideals - its estimates of what achievements are the highest and the most to be striven after. It will seem at first as though these ideals would determine the achievements of the cultural unit; but the actual course of events would appear to be that the ideals are based on the first achievements which have been made possible by a combination of the culture's internal gifts and external circumstances, and that these first achievements are then held on to by the ideal as something to be carried further. The satisfaction which the ideal offers to the participants in the culture is thus of a narcissistic nature; it rests on their pride in what has already been successfully achieved. To make this satisfaction complete calls for a comparison with other cultures which have aimed at different achievements and have developed different ideals. On the strength of these differences every culture claims the right to look down on the rest. In this way cultural ideals become a source of discord and enmity between different cultural units, as can be seen most clearly in the case of nations.

[1927c, 4425]
The narcissistic satisfaction provided by the cultural ideal is also among the forces which are successful in combating the hostility to culture within the cultural unit. This satisfaction can be shared in not only by the favoured classes, which enjoy the benefits of the culture, but also by the suppressed ones, since the right to despise the people outside it compensates them for the wrongs they suffer within their own unit. No doubt one is a wretched plebeian, harassed by debts and military service; but, to make up for it, one is a Roman citizen, one has one's share in the task of ruling other nations and dictating their laws. This identification of the suppressed classes with the class who rules and exploits them is, however, only part of a larger whole. For, on the other hand, the suppressed classes can be emotionally attached to their masters; in spite of their hostility to them they may see in them their ideals; unless such relations of a fundamentally satisfying kind subsisted, it would be impossible to understand how a number of civilizations have survived so long in spite of the justifiable hostility of large human masses.

A different kind of satisfaction is afforded by art to the participants in a cultural unit, though as a rule it remains inaccessible to the masses, who are engaged in exhausting work and have not enjoyed any personal education. As we discovered long since, art offers substitutive satisfactions for the oldest and still most deeply felt cultural renunciations, and for that reason it serves as nothing else does to reconcile a man to the sacrifices he has made on behalf of civilization. On the other hand, the creations of art heighten his feelings of identification, of which every cultural unit stands in so much need, by providing an occasion for sharing highly valued emotional experiences. And when those creations picture the achievements of his particular culture and bring to his mind its ideals in an impressive manner, they also minister to his narcissistic satisfaction.

¹ I feel impelled to point out one at least of the gaps that have been left in the account given above. No discussion of the possibilities of human happiness should omit to take into consideration the relation between narcissism and object libido. We require to know what being essentially self-dependent signifies for the economics of the libido.

[1927c, 4425]

[1927c, 4426]
The cultural super-ego has developed its ideals and set up its demands. Among the latter, those which deal with the relations of human beings to one another are comprised under the heading of ethics. People have at all times set the greatest value on ethics, as though they expected that it in particular would produce especially important results. And it does in fact deal with a subject which can easily be recognized as the sorest spot in every civilization. Ethics is thus to be regarded as a therapeutic attempt - as an endeavour to achieve, by means of a command of the super-ego, something which has so far not been achieved by means of any other cultural activities. As we already know, the problem before us is how to get rid of the greatest hindrance to civilization - namely, the constitutional inclination of human beings to be aggressive towards one another; and for that very reason we are especially interested in what is probably the most recent of the cultural commands of the super-ego, the commandment to love one's neighbour as oneself. In our research into, and therapy of, a neurosis, we are led to make two reproaches against the super-ego of the individual. In the severity of its commands and prohibitions it troubles itself too little about the happiness of the ego, in that it takes insufficient account of the resistances against obeying them - of the instinctual strength of the id, and of the difficulties presented by the real external environment. Consequently we are very often obliged, for therapeutic purposes, to oppose the super-ego, and we endeavour to lower its demands. Exactly the same objections can be made against the ethical demands of the cultural super-ego. It, too, does not trouble itself enough about the facts of the mental constitution of human beings. It issues a command and does not ask whether it is possible for people to obey it. On the contrary, it assumes that a man's ego is psychologically capable of anything that is required of it, that his ego has unlimited mastery over his id. This is a mistake; and even in what are known as normal people the id cannot be controlled beyond certain limits. If more is demanded of a man, a revolt will be produced in him or a neurosis, or he will be made unhappy. The commandment, 'Love thy neighbour as thyself', is the strongest defence against human aggressiveness and an excellent example of the unpsychological proceedings of the cultural super-ego. The commandment is impossible to fulfil; such an enormous inflation of love can only lower its value, not get rid of the difficulty. Civilization pays no attention to all this; it merely admonishes us that the harder it is to obey the precept the more meritorious it is to do so. But anyone who follows such a precept in present-day civilization only puts himself at a disadvantage vis-à-vis the person who disregards it. What a potent obstacle to civilization aggressiveness must be, if the defence against it can cause as much unhappiness as aggressiveness itself! 'Natural' ethics, as it is called, has nothing to offer here except the narcissistic satisfaction of being able to think oneself better than others. At this point the ethics based on religion introduces its promises of a better after-life. But so long as virtue is not rewarded here on earth, ethics will, I fancy, preach in vain. I too think it quite certain that a real change in the relations of human beings to possessions would be of more help in this direction than any ethical commands; but the recognition of this fact among socialists has been obscured and made useless for practical purposes by a fresh idealistic misconception of human nature. [1930a, 4530]
THE INSTINCT FOR KNOWLEDGE   At about the same time as the sexual life of children reaches its first peak, between the ages of three and five, they also begin to show signs of the activity which may be ascribed to the instinct for knowledge or research. This instinct cannot be counted among the elementary instincitual components, nor can it be classed as exclusively belonging to sexuality. Its activity corresponds on the one hand to a sublimated manner of obtaining mastery, while on the other hand it makes use of the energy of scopophilia. Its relations to sexual life, however, are of particular importance, since we have learnt from psycho-analysis that the instinct for knowledge in children is attracted unexpectedly early and intensively to sexual problems and is in fact possibly first aroused by them.

After having explained the preponderance of perverse tendencies in psychoneurotics by recognizing it as a collateral filling of subsidiary channels when the main current of the instinctual stream has been blocked by 'repression';¹ we proceeded to a consideration of sexual life in childhood. We found it a regrettable thing that the existence of the sexual instinct in childhood has been denied and that the sexual manifestations not infrequently to be observed in children have been described as irregularities. It seemed to us on the contrary that children bring germs of sexual activity with them into the world, that they already enjoy sexual satisfaction when they begin to take nourishment and that they persistently seek to repeat the experience in the familiar activity of 'thumb-sucking'. The sexual activity of children, however, does not, it appeared, develop pari passu with their other functions, but, after a short period of efflorescence from the ages of two to five, enters upon the so-called period of latency. During that period the production of sexual excitation is not by any means stopped but continues and produces a store of energy which is employed to a great extent for purposes other than sexual - namely, on the one hand in contributing the sexual components to social feelings and on the other hand (through repression and reaction-forming) in building up the subsequently developed barriers against sexuality. On this view, the forces destined to retain the sexual instinct upon certain lines are built up in childhood chiefly at the cost of perverse sexual impulses and with the assistance of education. A certain portion of the infantile sexual impulses would seem to evade these uses and succeed in expressing itself as sexual activity. We next found that sexual excitation in children springs from a multiplicity of forces. Satisfaction arises first and foremost from the appropriate sensory excitation of what we have described as erotogenic zones. It seems probable that any part of the skin and any sense-organ - probably, indeed, any organ - can function as an erotogenic zone, though there are some particularly marked erotogenic zones whose excitation would seem to be secured from the very first by certain organic contrivances. It further appears that sexual excitation arises as a by-product, as it were, of a large number of processes that occur in the organism, as soon as they reach a certain degree of intensity, and most especially of any relatively powerful emotion, even though it is of a distressing nature. The excitations from all these sources are not yet combined; but each follows its own separate aim, which is merely the attainment of a certain sort of pleasure. In childhood, therefore, the sexual instinct is not unified and is at first without an object, that is, auto-erotic.

¹[1905d, 1513]
By a lucky chance I am in a position to call a witness in favour of my assertions from your very midst. I have here in my hand a paper written by a Dr. Sanford Bell, which was published in The American Journal of Psychology in 1902. The author is a Fellow of Clark University, of the very institution in whose lecture-room we are now assembled. In this work, which is entitled 'A Preliminary Study of the Emotion of Love between the Sexes', and which appeared three years before my Three Essays on the Theory of Sexuality, the author says exactly what I have just told you: 'The emotion of sex-love . . . does not make its appearance for the first time at the period of adolescence, as has been thought.' He carried out his work in what we in Europe would call 'the American manner', collecting no fewer than 2,500 positive observations in the course of fifteen years, among them 800 of his own. Concerning the signs by which these instances of falling in love are revealed he writes as follows: 'The unprejudiced mind in observing these manifestations in hundreds of couples of children cannot escape referring them to sex origin. The most exacting mind is satisfied when to these observations are added the confessions of those who have, as children, experienced the emotion to a marked degree of intensity and whose memories of childhood are relatively distinct.' But those of you who do not wish to believe in infantile sexuality will be most of all surprised to hear that not a few of these children who have fallen in love so early are of the tender age of three, four and five.

[1910a, 2229]

It would not astonish me if you were to attach more credence to these observations made by one of your closest neighbours than to mine. I myself have recently been fortunate enough to obtain a fairly complete picture of the somatic instinctual manifestations and mental products at an early stage of a child’s erotic life from the analysis of a five-year-old boy, suffering from anxiety - an analysis carried out with a correct technique by his own father.¹ And I may remind you that only a few hours ago, in this same room, my friend Dr. C. G. Jung reported an observation to you made on a still younger girl who, with a precipitating cause similar to my patient’s (the birth of a younger child in the family), made it possible to infer with certainty the presence of almost the same sensual impulses, wishes and complexes. I do not despair, therefore, of your becoming reconciled to what seems at first sight the strange idea of infantile sexuality. And I should like to quote to you the praiseworthy example of the Zurich psychiatrist, Dr. E. Bleuler, who declared publicly not many years ago that he was ‘unable to comprehend my theories of sexuality’, and who has since then confirmed the existence of infantile sexuality to its full extent from his own observations. (Cf. Bleuler, 1908.)

[1910a, 2229]

It is only too easy to explain why most people (whether medical observers or others) will hear nothing of the sexual life of children. They have forgotten their own infantile sexual activity under the pressure of their education to a civilized life, and they do not wish to be reminded of what has been repressed. They would arrive at other convictions if they were to begin their enquiry with a self-analysis, a revision and interpretation of their childhood memories.

[1910a, 2229]
Put away your doubts, then, and join me in a consideration of infantile sexuality from the earliest age.¹ A child's sexual instinct turns out to be put together out of a number of factors; it is capable of being divided up into numerous components which originate from various sources. Above all, it is still independent of the reproductive function, into the service of which it will later be brought. It serves for the acquisition of different kinds of pleasurable feeling, which, basing ourselves on analogies and connections, we bring together under the idea of sexual pleasure. The chief source of infantile sexual pleasure is the appropriate excitation of certain parts of the body that are especially susceptible to stimulus: apart from the genitals, these are the oral, anal and urethral orifices, as well as the skin and other sensory surfaces. Since at this first phase of infantile sexual life satisfaction is obtained from the subject's own body and extraneous objects are disregarded, we term this phase (from a word coined by Havelock Ellis) that of auto-eroticism. We call the parts of the body that are important in the acquisition of sexual pleasure 'erotogenic zones'. Thumb-sucking (or sensual sucking) in the youngest infants is a good example of this auto-erotic satisfaction from an erotogenic zone. The first scientific observer of this phenomenon, a paediatrician in Budapest named Lindner (1879), already interpreted it correctly as sexual satisfaction and described exhaustively its transition to other and higher forms of sexual activity. Another sexual satisfaction at this period of life is the masturbatory excitation of the genitals, which retains so much importance in later life and by many people is never completely conquered. Alongside these and other auto-erotic activities, we find in children at a very early age manifestations of those instinctual components of sexual pleasure (or, as we like to say, of libido) which presuppose the taking of an extraneous person as an object. These instincts occur in pairs of opposites, active and passive. I may mention as the most important representatives of this group the desire to cause pain (sadism) with its passive counterpart (masochism) and the active and passive desire for looking, from the former of which curiosity branches off later on and from the latter the impulse to artistic and theatrical display. Others of a child's sexual activities already imply the making of an 'object-choice', where an extraneous person becomes the main feature, a person who owes his importance in the first instance to considerations arising from the self-preservative instinct. But at this early period of childhood difference in sex plays no decisive part as yet. Thus you can attribute some degree of homosexuality to every child without doing him an injustice. This widespread and copious but dissociated sexual life of children, in which each separate instinct pursues its own acquisition of pleasure independently of all the rest, is now brought together and organized in two main directions, so that by the end of puberty the individual's final sexual character is as a rule completely formed. On the one hand, the separate instincts become subordinated to the dominance of the genital zone, so that the whole sexual life enters the service of reproduction, and the satisfaction of the separate instincts retains its importance only as preparing for and encouraging the sexual act proper. On the other hand, object-choice pushes auto-eroticism into the background, so that in the subject's erotic life all the components of the sexual instinct now seek satisfaction in relation to the person who is loved. Not all of the original sexual components, however, are admitted to take part in this final establishment of sexuality. Even before puberty extremely energetic repressions of certain instincts have been effected under the influence of education, and mental forces such as shame, disgust and morality have been set up, which, like watchmen, maintain these repressions. So that when at puberty the high tide of sexual demands is reached, it is met by these mental reactive or resistant structures like dams, which direct its flow into what are called normal channels and make it impossible for it to reactivate the instincts that have undergone repression. It is in particular the coprophilic impulses of childhood - that is to say, the desires attaching to the excreta - which are submitted the most rigorously to repression, and the same is true, furthermore, of fixation to the figures to which the child's original object-choice was attached.

[1910a, 2230]
Let us return to the sexual development of children. We have some arrears to make up owing to our having paid more attention to the somatic than to the mental phenomena of sexual life. The child's first choice of an object, which derives from its need for help, claims our further interest. Its choice is directed in the first instance to all those who look after it, but these soon give place to its parents. Children's relations to their parents, as we learn alike from direct observations of children and from later analytic examination of adults, are by no means free from elements of accompanying sexual excitation. The child takes both of its parents, and more particularly one of them, as the object of its erotic wishes. In so doing, it usually follows some indication from its parents, whose affection bears the clearest characteristics of a sexual activity, even though of one that is inhibited in its aims. As a rule a father prefers his daughter and a mother her son; the child reacts to this by wishing, if he is a son, to take his father's place, and, if she is a daughter, her mother's. The feelings which are aroused in these relations between parents and children and in the resulting ones between brothers and sisters are not only of a positive or affectionate kind but also of a negative or hostile one. The complex which is thus formed is doomed to early repression; but it continues to exercise a great and lasting influence from the unconscious. It is to be suspected that, together with its extensions, it constitutes the nuclear complex of every neurosis, and we may expect to find it no less actively at work in other regions of mental life. The myth of King Oedipus, who killed his father and took his mother to wife, reveals, with little modification, the infantile wish, which is later opposed and repudiated by the barrier against incest. Shakespeare's Hamlet is equally rooted in the soil of the incest-complex, but under a better disguise.

I shall now endeavour (and I think the attempt is neither unnecessary nor unjustifiable) to show that the knowledge of psychological processes, which, thanks to psycho-analysis, we now possess, already enables us to understand the part played by a homosexual wish in the development of paranoia. Recent investigations¹ have directed our attention to a stage in the development of the libido which it passes through on the way from auto-erotism to object-love.² This stage has been given the name of narcissism. What happens is this. There comes a time in the development of the individual at which he unifies his sexual instincts (which have hitherto been engaged in auto-erotic activities) in order to obtain a love-object; and he begins by taking himself, his own body, as his love-object, and only subsequently proceeds from this to the choice of some person other than himself as his object. This half-way phase between auto-erotism and object-love may perhaps be indispensable normally; but it appears that many people linger unusually long in this condition, and that many of its features are carried over by them into the later stages of their development. What is of chief importance in the subject's self thus chosen as a love object may already be the genitals. The line of development then leads on to the choice of an external object with similar genitals - that is, to homosexual object-choice - and thence to heterosexuality. People who are manifest homosexuals in later life have, it may be presumed, never emancipated themselves from the binding condition that the object of their choice must possess genitals like their own; and in this connection the infantile sexual theories which attribute the same kind of genitals to both sexes exert much influence.

¹ [1910a, 2232]
² [1911c, 2430]
This is the starting-point of the small new fragment of theory which I have formulated. It is of course only in appearance that it is based on this one observation; actually it brings together a large number of earlier impressions, though an understanding of them was only made possible by this last experience. I told myself that my schematic picture of the development of the libidinal function called for an extra insertion in it. To begin with, I had only distinguished, first the phase of auto-erotism during which the subject's component instincts, each on its own account, seek for the satisfaction of their desires in his own body, and then the combination of all the component instincts for the choice of an object, under the primacy of the genitals acting on behalf of reproduction. The analysis of the paraphrenias has, as we know, necessitated the insertion between them of a stage of narcissism, during which the choice of an object has already taken place but that object coincides with the subject's own ego. And now we see the need for yet another stage to be inserted before the final shape is reached - a stage in which the component instincts have already come together for the choice of an object and that object is already something extraneous in contrast to the subject's own self, but in which the primacy of the genital zones has not yet been established. On the contrary, the component instincts which dominate this pregenital organization of sexual life are the anal-erotic and sadistic ones.

I will now set out before you what is most definitely known about the sexual life of children. Let me at the same time, for convenience sake, introduce the concept of 'libido'. On the exact analogy of 'hunger', we use 'libido' as the name of the force (in this case that of the sexual instinct, as in the case of hunger that of the nutritive instinct) by which the instinct manifests itself. Other concepts, such as sexual 'excitation' and 'satisfaction', call for no explanation. You yourselves will easily perceive that the sexual activities of infants in arms are mostly a matter of interpretation, or you will probably use that as a ground of objection. These interpretations are arrived at on the basis of analytic examinations made by tracing from the symptoms backwards. In an infant the first impulses of sexuality make their appearance attached to other vital functions. His main interest is, as you know, directed to the intake of nourishment; when children fall asleep after being sated at the breast, they show an expression of blissful satisfaction which will be repeated later in life after the experience of a sexual orgasm. This would be too little on which to base an inference. But we observe how an infant will repeat the action of taking in nourishment without making a demand for further food; here, then, he is not actuated by hunger. We describe this as sensual sucking, and the fact that in doing this he falls asleep once more with a blissful expression shows us that the act of sensual sucking has in itself alone brought him satisfaction. Soon, as we know, things come to a point at which he cannot go to sleep without having sucked. A paediatrician in Budapest, Dr. Lindner, was the first to point out long ago the sexual nature of this activity. Those who are in charge of children, and who have no theoretical views on the subject, seem to form a similar judgement of sucking. They have no doubt of its only purpose being to obtain pleasure, class it as one of a child's 'naughtinesses' and compel him to abandon it by causing him distress, if he will not give it up of his own accord. Thus we learn that infants perform actions which have no purpose other than obtaining pleasure. It is our belief that they first experience this pleasure in connection with taking nourishment but that they soon learn to separate it from that accompanying condition. We can only refer this pleasure to an excitation of the areas of the mouth and lips; we call those parts of the body 'erotic zones' and describe the pleasure derived from sucking as a sexual one. We shall no doubt have to discuss further whether this description is justifiable.

[1913i, 2626]

[1916-1917, 3384]
I know you have been wanting for a long time to interrupt me and exclaim: 'Enough of these atrocities! You tell us that defaecating is a source of sexual satisfaction, and already exploited in infancy! that faeces is a valuable substance and that the anus is a kind of genital! We don't believe all that but we do understand why paediatricians and educationists have given a wide berth to psycho-analysis and its findings.' No, Gentlemen. You have merely forgotten that I have been trying to introduce the facts of infantile sexual life to you in connection with the facts of the sexual perversions. Why should you not be aware that for a large number of adults, homosexual and heterosexual alike, the anus does really take over the role of the vagina in sexual intercourse? And that there are many people who retain a voluptuous feeling in defaecating all through their lives and describe it as being far from small? As regards interest in the act of defaecation and enjoyment in watching someone else defaecating, you can get children themselves to confirm the fact when they are a few years older and able to tell you about it. Of course, you must not have systematically intimidated them beforehand, or they will quite understand that they must be silent on the subject. And as to the other things that you are anxious not to believe, I will refer you to the findings of analysis and of the direct observation of children and will add that it calls for real ingenuity not to see all this or to see it differently. Nor do I complain if you find the kinship between infantile sexual activity and sexual perversions something very striking. But it is in fact self-evident: if a child has a sexual life at all it is bound to be of a perverse kind; for, except for a few obscure hints, children are without what makes sexuality into the reproductive function. On the other hand, the abandonment of the reproductive function is the common feature of all perversions. We actually describe a sexual activity as perverse if it has given up the aim of reproduction and pursues the attainment of pleasure as an aim independent of it. So, as you will see, the breach and turning-point in the development of sexual life lies in its becoming subordinate to the purposes of reproduction. Everything that happens before this turn of events and equally everything that disregards it and that aims solely at obtaining pleasure is given the uncomplimentary name of 'perverse' and as such is proscribed. [1916-1917, 3386]
Thus forearmed we can proceed to the consideration of a suggestion which we shall certainly not be spared. 'Why', we shall be asked, 'are you so obstinate in describing as being already sexuality what on your own evidence are indefinable manifestations in childhood out of which sexual life will later develop? Why should you not be content instead with giving them a physiological description and simply say that in an infant at the breast we already observe activities, such as sensual sucking or holding back the excreta, which show us that he is striving for "organ-pleasure"? In that way you would have avoided the hypothesis, so repugnant to every feeling, of the smallest babies having a sexual life.' - Indeed, Gentlemen, I have no objection at all to organ-pleasure. I know that even the supreme pleasure of sexual union is only an organ-pleasure attached to the activity of the genitals. But can you tell me when this originally indifferent organ-pleasure acquires the sexual character which it undoubtedly possesses in the later phases of development? Do we know any more about 'organ-pleasure' than about sexuality? You will reply that it gains its sexual character precisely when the genitals begin to play their part; 'sexual' coincides with 'genital'. You will even reject the objection raised by the perversions by pointing out to me that in the majority of perversions a genital orgasm is after all aimed at, even if it is arrived at by a method other than the union of the genitals. You are certainly taking up a much stronger position in determining the characteristics of what is sexual if you knock out of it the relation to reproduction which is made untenable by the perversions and put genital activity in its place. But, if so, we are no longer far apart: it is only a question of the genital organs versus the other organs. What are you going to do, however, about the numerous experiences which show you that the genitals can be represented as regards their yield of pleasure by other organs, as in the case of kissing or of the perverse practices of voluptuaries or of the symptoms of hysteria? In that neurosis it is quite usual for signs of stimulation, sensations and innervations, and even the processes of erection, which belong properly to the genitals, to be displaced on to other, remote regions of the body - as, for instance, by transposition upwards, to the head and face. Being thus convinced that you have nothing to catch hold of for your characterization of what is sexual, you will no doubt have to make up your minds to follow my example and extend the description of being 'sexual' to the activities of early childhood, too, which strive for organ-pleasure.

From the third year of life a child's sexual life shows much agreement with an adult's. It differs from the latter, as we already know, in lacking a firm organization under the primacy of the genitals, in its inevitable traits of perversion and also, of course, in the far lesser intensity of the whole trend. But from the point of view of theory the most interesting phases of sexual, or, as we will say, of libidinal, development lie earlier than this point of time. This course of development takes place so rapidly that we should probably never have succeeded in getting a firm hold of its fleeting pictures by direct observation. It was only with the help of the psycho-analytic investigation of the neuroses that it became possible to discern the still earlier phases of the development of the libido. These are nothing but constructions, to be sure, but, if you carry out psycho-analyses in practice, you will find that they are necessary and useful constructions. You will soon learn how it comes about that pathology can here put us in possession of conditions which we should inevitably overlook in a normal subject.
With this as a starting-point we go on to make our first important discovery. We learn that, when we try to understand neurotic disorders, by far the greater significance attaches to the sexual instincts; that in fact neuroses are the specific disorders, so to speak, of the sexual function; that in general whether or not a person develops a neurosis depends on the quantity of his libido, and on the possibility of satisfying it and of discharging it through satisfaction; that the form taken by the disease is determined by the way in which the individual passes through the course of development of his sexual function, or, as we put it, by the fixations his libido has undergone in the course of its development; and, further, that by a special, not very simple technique for influencing the mind we are able to throw light on the nature of some groups of neuroses and at the same time to do away with them. Our therapeutic efforts have their greatest success with a certain class of neuroses which proceed from a conflict between the ego-instincts and the sexual instincts. For in human beings it may happen that the demands of the sexual instincts, whose reach of course extends far beyond the individual, seem to the ego to constitute a danger which threatens its self-preservation or its self-esteem. The ego then assumes the defensive, denies the sexual instincts the satisfaction they desire and forces them into those by-paths of substitutive satisfaction which become manifest as nervous symptoms.

[1917a, 3609]

It is almost humiliating that, after working so long, we should still be having difficulty in understanding the most fundamental facts. But we have made up our minds to simplify nothing and to hide nothing. If we cannot see things clearly we will at least see clearly what the obscurities are. What is hampering us here is evidently some hitch in the development of our theory of the instincts. We began by tracing the organization of the libido through its successive stages - from the oral through the sadistic-anal to the genital - and in doing so placed all the components of the sexual instinct on the same footing. Later it appeared that sadism was the representative of another instinct, which was opposed to Eros. This new view, that the instincts fall into two groups, seems to explode the earlier construction of the successive stages of libidinal organization. But we do not have to break fresh ground in order to find a way out of the difficulty. The solution has been at hand for a long time and lies in the fact that what we are concerned with are scarcely ever pure instinctual impulses but mixtures in various proportions of the two groups of instincts. If this is so, there is no need to revise our view of the organizations of the libido. A sadistic cathexis of an object may also legitimately claim to be treated as a libidinal one; and an aggressive impulse against the father can just as well be subjected to repression as a tender impulse towards the mother. Nevertheless we shall bear in mind for future consideration the possibility that repression is a process which has a special relation to the genital organization of the libido and that the ego resorts to other methods of defence when it has to secure itself against the libido on other levels of organization. To continue: a case like 'Little Hans's' does not enable us to come to any clear conclusion. It is true that in him an aggressive impulse was disposed of by repression, but this happened after the genital organization had been reached.

[1926d, 4282]
Then I will pursue the subject further; in any case it is not easy for me to get away from it. I will tell you, then, that the most remarkable thing about the sexual life of children seems to me that it passes through the whole of its very far-reaching development in the first five years of life. From then onwards until puberty there stretches what is known as the period of latency. During it sexuality normally advances no further; on the contrary, the sexual urges diminish in strength and many things are given up and forgotten which the child did and knew. During that period of life, after the early efflorescence of sexuality has withered, such attitudes of the ego as shame, disgust and morality arise, which are destined to stand up against the later tempest of puberty and to lay down the path of the freshly awakening sexual desires. This 'diphasic onset', as it is named, of sexual life has a great deal to do with the genesis of neurotic illnesses. It seems to occur only in human beings, and it is perhaps one of the determinants of the human privilege of becoming neurotic. The prehistory of sexual life was just as much overlooked before psycho-analysis as, in another department, the background to conscious mental life. You will rightly suspect that the two are intimately connected. [1926e, 4353]
You will be glad to hear that the analysis of phobias has not much more that is new to teach us. For the same thing happens with them as with children's anxiety: unemployable libido is being constantly transformed into an apparently realistic anxiety and thus a tiny external danger is introduced to represent the claims of the libido. There is nothing to be wondered at in this agreement, for the infantile phobias are not only the prototype of the later ones which we class as 'anxiety hysteria' but are actually their precondition and the prelude to them. Every hysterical phobia goes back to an infantile anxiety and is a continuation of it, even if it has a different content and must thus be given another name. The difference between the two disorders lies in their mechanism. In order that libido shall be changed into anxiety, it no longer suffices in the case of adults for the libido to have become momentarily unemployable in the form of a longing. Adults have long since learnt how to hold such libido in suspense or to employ it in some other way. If, however, the libido belongs to a psychical impulse which has been subjected to repression, then circumstances are re-established similar to those in the case of a child in whom there is still no distinction between conscious and unconscious; and by mean of regression to the infantile phobia a passage is opened, as it were, through which the transformation of libido into anxiety can be comfortably accomplished.

[1916-1917, 3455]

At the very beginning, in the individual's primitive oral phase, object-cathexis and identification are no doubt indistinguishable from each other. We can only suppose that later on object-cathexes proceed from the id, which feels erotic trends as needs. The ego, which to begin with is still feeble, becomes aware of the object-cathexes, and either acquiesces in them or tries to fend them off by the process of repression.¹

[1923b, 3963]
Further study has shown that it is expedient and indeed indispensable to insert a third stage between these two, or, putting it in another way, to divide the first stage, that of auto-erotism, into two. At this intermediate stage, the importance of which is being made more and more evident by research, the hitherto isolated sexual instincts have already come together into a single whole and have also found an object. But this object is not an external one, extraneous to the subject, but it is his own ego, which has been constituted at about this same time. Bearing in mind pathological fixations of this new stage, which become observable later, we have given it the name of 'narcissism'. The subject behaves as though he were in love with himself; his egoistic instincts and his libidinal wishes are not yet separable under our analysis.

¹ I assume that at this early narcissistic stage cathexes arising from libidinal and from other sources of excitation may still be indistinguishable from one another.

Reflection will quickly suggest that if any such fixation of the libido to the subject's own body and personality, instead of to an object does occur, it cannot be an exception or a trivial event. On the contrary it is probable that this narcissism is the universal and original state of things, from which object-love is only later developed, without the narcissism necessarily disappearing on that account. Indeed we had to recall from the history of the development of object-libido that many sexual instincts begin by finding satisfaction in the subject's own body - auto-erotically, as we say - and that this capacity for auto-erotism is the basis of the lagging-behind of sexuality in the process of education in the reality principle. Auto-erotism would thus be the sexual activity of the narcissistic stage of allocation of the libido.

With the help of these ideas we are now able to explain a whole number of mental states or, to express it more modestly, to describe them in terms of the libido theory - states which we must reckon as belonging to normal life, such as the psychical behaviour of a person in love, during an organic illness or when asleep. As regards the state of sleep, we assumed that it was based on turning-away from the external world and adopting a wish to sleep. The mental activity during the night which is manifested in dreams takes place, we found, in obedience to a wish to sleep and is moreover dominated by purely egoistic motives. We may now add, on the lines of the libido theory, that sleep is a state in which all object-cathexes, libidinal as well as egoistic, are given up and withdrawn into the ego. May not this throw a fresh light on the recuperating effect of sleep and on the nature of fatigue in general? The picture of the blissful isolation of intra-uterine life which a sleeper conjures up once more before us every night is in this way completed on its psychical side as well. In a sleeper the primal state of distribution of the libido is restored - total narcissism, in which libido and ego-interest, still united and indistinguishable, dwell in the self-sufficing ego.
This is the place for two remarks. First, how do we differentiate between the concepts of narcissism and egoism? Well, narcissism, I believe, is the libidinal complement to egoism. When we speak of egoism, we have in view only the individual's advantage; when we talk of narcissism we are also taking his libidinal satisfaction into account. As practical motives the two can be traced separately for quite a distance. It is possible to be absolutely egoistic and yet maintain powerful object-cathexes, in so far as libidinal satisfaction in relation to the object forms part of the ego's needs. In that case, egoism will see to it that striving for the object involves no damage to the ego. It is possible to be egoistic and at the same time to be excessively narcissistic - that is to say, to have very little need for an object, whether, once more, for the purpose of direct sexual satisfaction, or in connection with the higher aspirations, derived from sexual need, which we are occasionally in the habit of contrasting with 'sensuality' under the name of 'love'. In all these connections egoism is what is self-evident and constant, while narcissism is the variable element. The opposite to egoism, altruism, does not, as a concept, coincide with libidinal object-cathexis, but is distinguished from it by the absence of longings for sexual satisfaction. When someone is completely in love, however, altruism converges with libidinal object-cathexis. As a rule the sexual object attracts a portion of the ego's narcissism to itself, and this becomes noticeable as what is known as the 'sexual overvaluation' of the object. If in addition there is an altruistic transposition of egoism on to the sexual object, the object becomes supremely powerful; it has, as it were, absorbed the ego.

Homosexual object-choice originally lies closer to narcissism than does the heterosexual kind. When it is a question, therefore, of repelling an undesirably strong homosexual impulse, the path back to narcissism is made particularly easy. Hitherto I have had very little opportunity of talking to you about the foundations of erotic life so far as we have discovered them, and it is too late now to catch up on the omission. This much, however, I can emphasize to you. Object-choice, the step forward in the development of the libido which is made after the narcissistic stage, can take place according to two different types: either according to the narcissistic type, where the subject's own ego is replaced by another one that is as similar as possible, or according to the attachment type, where people who have become precious through satisfying the other vital needs are chosen as objects by the libido as well. A strong libidinal fixation to the narcissistic type of object-choice is to be included in the predisposition to manifest homosexuality.

During the work of treatment we have to consider the distribution of the patient's libido; we look for the object presentations to which it is bound and free it from them, so as to place it at the disposal of the ego. In the course of this, we have come to form a very curious picture of the original, primal distribution of libido in human beings. We have been driven to assume that at the beginning of the development of the individual all his libido (all his erotic tendencies, all his capacity for love) is tied to himself - that as we say, it cathects his own ego. It is only later that, being attached to the satisfaction of the major vital needs, the libido flows over from the ego on to external objects. Not till then are we able to recognize the libidinal instincts as such and distinguish them from the ego instincts. It is possible for the libido to become detached from these objects and withdrawn again into the ego.
What I have been trying to describe in this outline is the \textit{libido theory} of the neuroses, upon which are founded all our conceptions of the nature of these morbid states, together with our therapeutic measures for relieving them. We naturally regard the premises of the libido theory as valid for normal behaviour as well. We speak of the narcissism of small children, and it is to the excessive narcissism of primitive man that we ascribe his belief in the omnipotence of his thoughts and his consequent attempts to influence the course of events in the external world by the technique of magic.

[1917a, 3610]

This would seem to imply an important amplification of the theory of narcissism. At the very beginning, all the libido is accumulated in the id, while the ego is still in process of formation or is still feeble. The id sends part of this libido out into erotic object-cathexes, whereupon the ego, now grown stronger, tries to get hold of this object-libido and to force itself on the id as a love-object. The narcissism of the ego is thus a secondary one, which has been withdrawn from objects.

[1923b, 3980]

In the Oedipus complex the libido was seen to be attached to the image of the parental figures. But earlier there was a period in which there were no such objects. There followed from this fact the concept (of fundamental importance for the libido theory) of a state in which the subject's libido filled his own ego and had that for its object. This state could be called \textit{narcissism} or self-love. A moment's reflection showed that this state never completely ceases. All through the subject's life his ego remains the great reservoir of his libido, from which object-cathexes are sent out and into which the libido can stream back again from the objects. Thus narcissistic libido is constantly being transformed into object-libido, and \textit{vice versa}. An excellent instance of the length to which this transformation can go is afforded by the state of being in love, whether in a sexual or sublimated manner, which goes so far as involving a sacrifice of the self. Whereas hitherto in considering the process of repression attention had only been paid to what was repressed, these ideas made it possible to form a correct estimate of the repressing forces too. It had been said that repression was set in action by the instincts of self-preservation operating in the ego (the 'ego-instincts') and that it was brought to bear upon the libidinal instincts. But since the instincts of self-preservation were now recognized as also being of a libidinal nature, as being narcissistic libido, the process of repression was seen to be a process occurring within the libido itself; narcissistic libido was opposed to object-libido, the interest of self-preservation was defending itself against the demands of object-love, and therefore against the demands of sexuality in the narrower sense as well.

[1925d, 4231]

There can be no question of restricting one or the other of the basic instincts to one of the provinces of the mind. They must necessarily be met with everywhere. We may picture an initial state as one in which the total available energy of Eros, which henceforward we shall speak of as 'libido', is present in the still undifferentiated ego-id and serves to neutralize the destructive tendencies which are simultaneously present. (We are without a term analogous to 'libido' for describing the energy of the destructive instinct.) At a later stage it becomes relatively easy for us to follow the vicissitudes of the libido, but this is more difficult with the destructive instinct.

[1940a [1938], 4960]
The less repellent of the so-called sexual perversions are very widely diffused among the whole population, as every one knows except medical writers upon the subject. Or, I should rather say, they know it too; only they take care to forget it at the moment when they take up their pens to write about it. So it is not to be wondered at that this hysterical girl of nearly nineteen, who had heard of the occurrence of such a method of sexual intercourse (sucking at the male organ), should have developed an unconscious phantasy of this sort and should have given it expression by an irritation in her throat and by coughing. Nor would it have been very extraordinary if she had arrived at such a phantasy even without having had any enlightenment from external sources - an occurrence which I have quite certainly observed in other patients. For in her case a noteworthy fact afforded the necessary somatic prerequisite for this independent creation of a phantasy which would coincide with the practices of perverts. She remembered very well that in her childhood she had been a thumb-sucker. Her father, too recollected breaking her of the habit after it had persisted into her fourth or fifth year. Dora herself had a clear picture of a scene from her early childhood in which she was sitting on the floor in a corner sucking her left thumb and at the same time tugging with her right hand at the lobe of her brother's ear as he sat quietly beside her. Here we have an instance of the complete form of self-gratification by sucking, as it has also been described to me by other patients, who had subsequently become anaesthetic and hysterical.

[1905e, 1388]

One of these patients gave me a piece of information which sheds a clear light on the origin of this curious habit. This young woman had never broken herself of the habit of sucking. She retained a memory of her childhood, dating back, according to her, to the first half of her second year, in which she saw herself sucking at her nurse's breast and at the same time pulling rhythmically at the lobe of her nurse's ear. No one will feel inclined to dispute, I think, that the mucous membrane of the lips and mouth is to be regarded as a primary 'erotogenic zone', since it preserves this earlier significance in the act of kissing, which is looked upon as normal. An intense activity of this erotogenic zone at an early age thus determines the subsequent presence of a somatic compliance on the part of the tract of mucous membrane which begins at the lips. Thus, at a time when the sexual object proper, that is, the male organ, has already become known, circumstances may arise which once more increase the excitation of the oral zone, whose erotogenic character has, as we have seen, been retained. It then needs very little creative power to substitute the sexual object of the moment (the penis) for the original object (the nipple) or for the finger which does duty for it, and to place the current sexual object in the situation in which gratification was originally obtained. So we see that this excessively repulsive and perverted phantasy of sucking at a penis has the most innocent origin. It is a new version of what may be described as a prehistoric impression of sucking at the mother's or nurse's breast - an impression which has usually been revived by contact with children who are being nursed. In most instances a cow's udder has aptly played the part of an image intermediate between a nipple and a penis.

[1905e, 1389]

We found from the study of neurotic disorders that beginnings of an organization of the sexual instinctual components can be detected in the sexual life of children from its very beginning. During a first, very early phase, oral erotism occupies most of the picture. A second of these pregenital organizations is characterized by the predominance of sadism and anal erotism. It is not until a third phase has been reached that the genital zones proper contribute their share in determining sexual life, and in children this last phase is developed only so far as to a primacy of the phallus.

[1905d, 1544]
I do not know how the case could be better stated, but perhaps I may add a few remarks. It is undoubtedly nothing else but the customary prudishness and their own bad conscience over sexual matters that causes adults to adopt this attitude of 'mystery-making' in front of children; but possibly a part is also played by a piece of theoretical ignorance on their part, which we can counteract by giving the adults some enlightenment. It is commonly believed that the sexual instinct is absent in children and only begins to emerge in them at puberty when the sexual organs mature. This is a gross error, equally serious in its effects both on knowledge and on practice; and it is so easily corrected by observation that one wonders how it could ever have been made. As a matter of fact, the new-born baby brings sexuality with it into the world, certain sexual sensations accompany its development as a suckling and during early childhood, and only very few children would seem to escape sexual activities and sensations before puberty. Anyone who would like to find a detailed exposition of these statements can do so in my Three Essays on the Theory of Sexuality, to which I have referred above. There he will learn that the organs of reproduction proper are not the only parts of the body which provide sexual sensations of pleasure, and that nature has even so ordered matters that actual stimulations of the genitals are unavoidable during early childhood. This period of life, during which a certain quota of what is undoubtedly sexual pleasure is produced by the excitation of various parts of the skin (erotogenic zones), by the activity of certain biological instincts and as an accompanying excitation in many affective states, is called the period of auto-erotism, to use a term introduced by Havelock Ellis. All that puberty does is to give the genitals primacy among all the other zones and sources which produce pleasure, and thus to force erotism into the service of the function of reproduction. This process can naturally undergo certain inhibitions, and in many people (those who later become perverts and neurotics) it is only incompletely accomplished. On the other hand, the child is capable long before puberty of most of the psychical manifestations of love-tenderness, for example, devotion and jealousy. Often enough, too, an irruption of these mental states is associated with the physical sensations of sexual excitation, so that the child cannot remain in doubt as to the connection between the two. In short, except for his reproductive power, a child has a fully-developed capacity for love long before puberty; and it may be asserted that the 'mystery-making' merely prevents him from being able to gain an intellectual grasp of activities for which he is psychically prepared and physically adjusted.

[1907c, 1914]

Infantile sexuality exhibits two other characteristics which are of importance from a biological point of view. It turns out to be put together from a number of component instincts which seem to be attached to certain regions of the body ('erotogenic zones') and some of which emerge from the beginning in pairs of opposites - instincts with an active and a passive aim. Just as in later life what is loved is not merely the object's sexual organs but his whole body, so from the very first it is not merely the genitals but many other parts of the body which are the seat of sexual excitation and respond to appropriate stimuli with sexual pleasure. This fact is closely related to the second characteristic of infantile sexuality - namely that to start with it is attached to the functions of nutrition and excretion, and, in all probability, of muscular excitation and sensory activity.

[1913j, 2817]
It now remains for us to put together what we know of the genesis of love and hate. Love is derived from the capacity of the ego to satisfy some of its instinctual impulses auto-erotically by obtaining organ-pleasure. It is originally narcissistic, then passes over on to objects, which have been incorporated into the extended ego, and expresses the motor efforts of the ego towards these objects as sources of pleasure. It becomes intimately linked with the activity of the later sexual instincts and, when these have been completely synthesized, coincides with the sexual impulsion as a whole. Preliminary stages of love emerge as provisional sexual aims while the sexual instincts are passing through their complicated development. As the first of these aims we recognize the phase of incorporating or devouring - a type of love which is consistent with abolishing the object's separate existence and which may therefore be described as ambivalent. At the higher stage of the pregenital sadistic-anal organization, the striving for the object appears in the form of an urge for mastery, to which injury or annihilation of the object is a matter of indifference. Love in this form and at this preliminary stage is hardly to be distinguished from hate in its attitude towards the object. Not until the genital organization is established does love become the opposite of hate.

[1915c, 2973]

Thus forearmed we can proceed to the consideration of a suggestion which we shall certainly not be spared. 'Why', we shall be asked, 'are you so obstinate in describing as being already sexuality what on your own evidence are indefinable manifestations in childhood out of which sexual life will later develop? Why should you not be content instead with giving them a physiological description and simply say that in an infant at the breast we already observe activities, such as sensual sucking or holding back the excreta, which show us that he is striving for "organ-pleasure"? In that way you would have avoided the hypothesis, so repugnant to every feeling, of the smallest babies having a sexual life.' - Indeed, Gentlemen, I have no objection at all to organ-pleasure. I know that even the supreme pleasure of sexual union is only an organ-pleasure attached to the activity of the genitals. But can you tell me when this originally indifferent organ-pleasure acquires the sexual character which it undoubtedly possesses in the later phases of development? Do we know any more about 'organ-pleasure' than about sexuality? You will reply that it gains its sexual character precisely when the genitals begin to play their part; 'sexual' coincides with 'genital'. You will even reject the objection raised by the perversions by pointing out to me that in the majority of perversions a genital orgasm is after all aimed at, even if it is arrived at by a method other than the union of the genitals. You are certainly taking up a much stronger position in determining the characteristics of what is sexual if you knock out of it the relation to reproduction which is made untenable by the perversions and put genital activity in its place. But, if so, we are no longer far apart: it is only a question of the genital organs versus the other organs. What are you going to do, however, about the numerous experiences which show you that the genitals can be represented as regards their yield of pleasure by other organs, as in the case of kissing or of the perverse practices of voluptuaries or of the symptoms of hysteria? In that neurosis it is quite usual for signs of stimulation, sensations and innervations, and even the processes of erection, which belong properly to the genitals, to be displaced on to other, remote regions of the body - as, for instance, by transposition upwards, to the head and face. Being thus convinced that you have nothing to catch hold of for your characterization of what is sexual, you will no doubt have to make up your minds to follow my example and extend the description of being 'sexual' to the activities of early childhood, too, which strive for organ-pleasure.

[1916-1917, 3392]
Accordingly, I can now describe to you the form taken by a child's sexual life before the establishment of the primacy of the genitals, preparations for which are made in the first period of infancy preceding the latency period and which is permanently organized from puberty onwards. A kind of loose organization which may be called 'pregenital' exists during this early period. During this phase what stand in the forefront are not the genital component instincts but the sadistic and anal ones. The contrast between 'masculine' and 'feminine' plays no part here as yet. Its place is taken by the contrast between 'active' and 'passive', which may be described as a precursor of the sexual polarity and which later on is soldered to that polarity. What appears to us as masculine in the activities of this phase, when we look at it from the point of view of the genital phase, turns out to be an expression of an instinct for mastery which easily passes over into cruelty. Trends with a passive aim are attached to the erotogenic zone of the anal orifice, which is very important at this period. The instincts for looking and for gaining knowledge are powerfully at work; the genitals actually play a part in sexual life only as organs for the excretion of urine. The component instincts of this phase are not without objects, but those objects do not necessarily converge into a single object. The sadistic-anal organization is the immediate forerunner of the phase of genital primacy. Detailed study shows how much of it is retained in the later definitive shape of things and shows too the way in which its component instincts are compelled to take their place in the new genital organization. Behind the sadistic-anal phase of libidinal development we get a glimpse of a still earlier and more primitive stage of organization, in which the erotogenic zone of the mouth plays the chief part. As you will guess, the sexual activity of sensual sucking belongs to it. We must admire the understanding of the Ancient Egyptians who, in their art, represented children, including the God Horus, with a finger in their mouth. Only recently Abraham has given examples of the traces which this primitive oral phase leaves behind it in later sexual life.

I shall now attempt to sketch out a synthetic survey of my patient's sexual development, beginning from its earliest indications. The first that we hear of it is in the disturbance of his appetite; for, taking other observations into account, I am inclined, though with due reservations, to regard that as a result of some process in the sphere of sexuality. I have been driven to regard as the earliest recognizable sexual organization the so-called 'cannibalistic' or 'oral' phase, during which the original attachment of sexual excitation to the nutritional instinct still dominates the scene. It is not to be expected that we should come upon direct manifestations of this phase, but only upon indications of it where disturbances have been set up. Impairment of the nutritional instinct (though this can of course have other causes) draws our attention to a failure on the part of the organism to master its sexual excitation. In this phase the sexual aim could only be cannibalism - devouring; it makes its appearance with our present patient through regression from a higher stage, in the form of fear of 'being eaten by the wolf'. We were, indeed, obliged to translate this into a fear of being copulated with by his father. It is well known that there is a neurosis in girls which occurs at a much later age, at the time of puberty or soon afterwards, and which expresses aversion to sexuality by means of anorexia. This neurosis will have to be brought into relation with the oral phase of sexual life. The erotic aim of the oral organization further makes its appearance at the height of a lover's paroxysm (in such phrases as 'I could eat you up with love') and in affectionate relations with children, when the grown-up person is pretending to be a child himself. I have elsewhere given voice to a suspicion that the father of our present patient used himself to indulge in 'affectionate abuse', and may have played at wolf or dog with the little boy and have threatened as a joke to gobble him up (p. 3524). The patient confirmed this suspicion by his curious behaviour in the transference. Whenever he shrank back on to the transference from the difficulties of the treatment, he used to threaten me with eating me up and later with all kinds of other ill-treatment - all of which was merely an expression of affection.

[1916-1917, 3395]

[1918b, 3583]
Permanent marks have been left by this oral phase of sexuality upon the usages of language. People commonly speak for instance, of an 'appetizing' love-object, and describe persons they are fond of as 'sweet'. It will be remembered, too, that our little patient would only eat sweet things. In dreams sweet things and sweetmeats stand regularly for caresses or sexual gratifications.

[1918b, 3583]

The Development of the Libido. - The sexual instinct, the dynamic manifestation of which in mental life we shall call 'libido', is made up of component instincts into which it may once more break up and which are only gradually united into well-defined organizations. The sources of these component instincts are the organs of the body and in particular certain specially marked erogenous zones; but contributions are made to libido from every important functional process in the body. At first the individual component instincts strive for satisfaction independently of one another, but in the course of development they become more and more convergent and concentrated. The first (pregenital) stage of organization to be discerned is the oral one, in which - in conformity with the suckling's predominant interest - the oral zone plays the leading part. This is followed by the sadistic-anal organization, in which the anal zone and the component instinct of sadism are particularly prominent; at this stage the difference between the sexes is represented by the contrast between active and passive. The third and final stage of organization is that in which the majority of the component instincts converge under the primacy of the genital zones. As a rule this development is passed through swiftly and unobtrusively; but some individual portions of the instincts remain behind at the prodromal stages of the process and thus give rise to fixations of libido, which are important as constituting predispositions for subsequent irruptions of repressed impulses and which stand in a definite relation to the later development of neuroses and perversions. (See the article on 'The Libido Theory'.)

[1923a, 3921]

At the very beginning, in the individual's primitive oral phase, object-cathexis and identification are no doubt indistinguishable from each other. We can only suppose that later on object-cathexes proceed from the id, which feels erotic trends as needs. The ego, which to begin with is still feeble, becomes aware of the object-cathexes, and either acquiesces in them or tries to fend them off by the process of repression.¹

[1923b, 3963]

The function of judgement is concerned in the main with two sorts of decisions. It affirms or disaffirms the possession by a thing of a particular attribute; and it asserts or disputes that a presentation has an existence in reality. The attribute to be decided about may originally have been good or bad, useful or harmful. Expressed in the language of the oldest - the oral - instinctual impulses, the judgement is: 'I should like to eat this', or 'I should like to spit it out'; and, put more generally: 'I should like to take this into myself and to keep that out.' That is to say: 'It shall be inside me' or 'it shall be outside me'. As I have shown elsewhere, the original pleasure-ego wants to introject into itself everything that is good and to eject from itself everything that is bad. What is bad, what is alien to the ego and what is external are, to begin with, identical.²

[1925h, 4141]
The sexual function, as I found, is in existence from the very beginning of the individual's life, though at first it is attached to the other vital functions and does not become independent of them until later; it has to pass through a long and complicated process of development before it becomes what we are familiar with as the normal sexual life of the adult. It begins by manifesting itself in the activity of a whole number of component instincts. These are dependent upon erogenous zones in the body; some of them make their appearance in pairs of opposite impulses (such as sadism and masochism or the impulses to look and to be looked at); they operate independently of one another in a search for pleasure, and they find their object for the most part in the subject's own body. Thus at first the sexual function is non-centralized and predominantly auto-erotic. Later, syntheses begin to appear in it; a first stage of organization is reached under the dominance of the oral components, an anal-sadistic stage follows, and it is only after the third stage has at last been reached that the primacy of the genitals is established and that the sexual function begins to serve the ends of reproduction. In the course of this process of development a number of elements of the various component instincts turn out to be unserviceable for this last end and are therefore left on one side or turned to other uses, while others are diverted from their aims and carried over into the genital organization. I gave the name of libido to the energy of the sexual instincts and to that form of energy alone. I was next driven to suppose that the libido does not always pass through its prescribed course of development smoothly. As a result either of the excessive strength of certain of the components or of experiences involving premature satisfaction, fixations of the libido may occur at various points in the course of its development. If subsequently a repression takes place, the libido flows back to these points (a process described as regression), and it is from them that the energy breaks through in the form of a symptom. Later on it further became clear that the localization of the point of fixation is what determines the choice of neurosis, that is, the form in which the subsequent illness makes its appearance.

[1925d, 4211]

The first sexual and sexually coloured experiences which a child has in relation to its mother are naturally of a passive character. It is suckled, fed, cleaned, and dressed by her, and taught to perform all its functions. A part of its libido goes on clinging to those experiences and enjoys the satisfactions bound up with them; but another part strives to turn them into activity. In the first place, being suckled at the breast gives place to active sucking. As regards the other experiences the child contents itself either with becoming self-sufficient - that is, with itself successfully carrying out what had hitherto been done for it - or with repeating its passive experiences in an active form in play; or else it actually makes its mother into the object and behaves as the active subject towards her. For a long time I was unable to credit this last behaviour, which takes place in the field of real action, until my observations removed all doubts on the matter.

[1931b, 4600]
We find ourselves on firmer ground when we investigate the manner in which the life of the instincts serves the sexual function. Here we have acquired quite definite knowledge, with which you too are already familiar. It is not the case, then, that we recognize a sexual instinct which is from the first the vehicle of an urge towards the aim of the sexual function - the union of the two sex-cells. What we see is a great number of component instincts arising from different areas and regions of the body, which strive for satisfaction fairly independently of one another and find that satisfaction in something that we may call ‘organ-pleasure’. The genitals are the latest of these ‘erotogenic zones’ and the name of ‘sexual’ pleasure cannot be withheld from their organ-pleasure. These impulses which strive for pleasure are not all taken up into the final organization of the sexual function. A number of them are set aside as unserviceable, by repression or some other means; a few of them are diverted from their aim in the remarkable manner I have mentioned and used to strengthen other impulses; yet others persist in minor roles, and serve for the performance of introductory acts, for the production of fore-pleasure. You have heard how in the course of this long-drawn-out development several phases of preliminary organization can be recognized and also how this history of the sexual function explains its aberrations and atrophies. The first of these 'pregenital' phases is known to us as the oral one because, in conformity with the way in which an infant in arms is nourished, the erotogenic zone of the mouth dominates what may be called the sexual activity of that period of life. At a second level the sadistic and anal impulses come to the fore, undoubtedly in connection with the appearance of the teeth, the strengthening of the muscular apparatus and the control of the sphincter functions. We have learnt a number of interesting details about this remarkable stage of development in particular. Thirdly comes the phallic phase in which in both sexes the male organ (and what corresponds to it in girls) attains an importance which can no longer be overlooked. We have reserved the name of genital phase for the definitive sexual organization which is established after puberty and in which the female genital organ for the first time meets with the recognition which the male one acquired long before.
[1933a, 4703]

So far all this is trite repetition. And you must not suppose that the many things I have not mentioned this time no longer hold good. This repetition was necessary so that I might use it as the starting-point for a report on the advances in our knowledge. We can boast of having learnt much that is new, particularly about the early organizations of the libido, and of having obtained a clearer grasp of the significance of what is old; and I will give you at least a few examples to demonstrate this. Abraham showed in 1924 that two stages can be distinguished in the sadistic-anal phase. The earlier of these is dominated by the destructive trends of destroying and losing, the later one by trends friendly towards objects - those of keeping and possessing. It is in the middle of this phase, therefore, that consideration for the object makes its first appearance as a precursor of a later erotic cathexis. We are equally justified in making a similar subdivision in the first, oral phase. In the first sub-stage what is in question is only oral incorporation, there is no ambivalence at all in the relation to the object - the mother's breast. The second stage, characterized by the emergence of the biting activity, may be described as the 'oral-sadistic' one; it exhibits for the first time the phenomena of ambivalence, which become so much clearer afterwards, in the following sadistic-anal phase. The value of these new distinctions is to be seen especially if we look for the dispositional points in the development of the libido in the case of particular neuroses, such as obsessional neurosis or melancholia. You must here recall to mind what we have learnt about the connection between fixation of the libido, disposition and regression.
[1933a, 4704]
The first organ to emerge as an erotogenic zone and to make libidinal demands on the mind is, from the time of birth onwards, the mouth. To begin with, all psychical activity is concentrated on providing satisfaction for the needs of that zone. Primarily, of course, this satisfaction serves the purpose of self-preservation by means of nourishment; but physiology should not be confused with psychology. The baby's obstinate persistence in sucking gives evidence at an early stage of a need for satisfaction which, though it originates from and is instigated by the taking of nourishment, nevertheless strives to obtain pleasure independently of nourishment and for that reason may and should be termed sexual.

(1940a [1938], 4965)

During this oral phase sadistic impulses already occur sporadically along with the appearance of the teeth. Their extent is far greater in the second phase, which we describe as the sadistic-anal one, because satisfaction is then sought in aggression and in the excretory function. Our justification for including aggressive urges under the libido is based on the view that sadism is an instinctual fusion of purely libidinal and purely destructive urges, a fusion which thenceforward persists uninterruptedly.¹

(1940a [1938], 4965)
It is worth remarking that we have here three symptoms - the disgust, the sensation of pressure on the upper part of the body, and the avoidance of men engaged in affectionate conversation - all of them derived from a single experience, and that it is only by taking into account the interrelation of these three phenomena that we can understand the way in which the formation of the symptoms came about. The disgust is the symptom of repression in the erotogenic oral zone, which, as we shall hear, had been over-indulged in Dora's infancy by the habit of sensual sucking. The pressure of the erect member probably led to an analogous change in the corresponding female organ, the clitoris; and the excitation of this second erotogenic zone was referred by a process of displacement to the simultaneous pressure against the thorax and became fixed there. Her avoidance of men who might possibly be in a state of sexual excitement follows the mechanism of a phobia, its purpose being to safeguard her against any revival of the repressed perception.

Furthermore, it is clear that the behaviour of a child who indulges in thumb-sucking is determined by a search for some pleasure which has already been experienced and is now remembered. In the simplest case he proceeds to find this satisfaction by sucking rhythmically at some part of the skin or mucous membrane. It is also easy to guess the occasions on which the child had his first experiences of the pleasure which he is now striving to renew. It was the child's first and most vital activity, his sucking at his mother's breast, or at substitutes for it, that must have familiarized him with this pleasure. The child's lips, in our view, behave like an erotogenic zone, and no doubt stimulation by the warm flow of milk is the cause of the pleasurable sensation. The satisfaction of the erotogenic zone is associated, in the first instance, with the satisfaction of the need for nourishment. To begin with, sexual activity attaches itself to functions serving the purpose of self-preservation and does not become independent of them until later. No one who has seen a baby sinking back satiated from the breast and falling asleep with flushed cheeks and a blissful smile can escape the reflection that this picture persists as a prototype of the expression of sexual satisfaction in later life. The need for repeating the sexual satisfaction now becomes detached from the need for taking nourishment - a separation which becomes inevitable when the teeth appear and food is no longer taken in only by sucking, but is also chewed up. The child does not make use of an extraneous body for his sucking, but prefers a part of his own skin because it is more convenient, because it mikes him independent of the external world, which he is not yet able to control, and because in that way he provides himself, as it were, with a second erotogenic zone, though one of an inferior kind. The inferiority of this second region is among the reasons why at a later date he seeks the corresponding part - the lips - of another person. ('It's a pity I can't kiss myself', he seems to be saying.)

It is not every child who sucks in this way. It may be assumed that those children do so in whom there is a constitutional intensification of the erotogenic significance of the labial region. If that significance persists, these same children when they are grown up will become epicures in kissing, will be inclined to perverse kissing, or, if males, will have a powerful motive for drinking and smoking. If, however, repression ensues, they will feel disgust at food and will produce hysterical vomiting. The repression extends to the nutritional instinct owing to the dual purpose served by the labial zone. Many of my women patients who suffer from disturbances of eating, globus hystericus, constriction of the throat and vomiting, have indulged energetically in sucking during their childhood.
It must come as a great relief to find that, when once we have understood the nature of the instinct arising from a single one of the erotogenic zones, we shall have very little more to learn of the sexual activity of children. The clearest distinctions as between one zone and another concern the nature of the contrivance necessary for satisfying the instinct; in the case of the labial zone it consisted of sucking, and this has to be replaced by other muscular actions according to the position and nature of the other zones.

These seem to be the most important of the typical sexual theories that children produce spontaneously in early childhood, under the sole influence of the components of the sexual instinct. I know that I have not succeeded in making my material complete or in establishing an unbroken connection between it and the rest of infantile life. But I may add one or two supplementary observations, whose absence would otherwise be noticed by any well-informed person. Thus, for instance, there is the significant theory that a baby is got by a kiss - a theory which obviously betrays the predominance of the erotogenic zone of the mouth. In my experience this theory is exclusively feminine and is sometimes found to be pathogenic in girls whose sexual researches have been subjected to exceedingly strong inhibitions in childhood. Again, through an accidental observation, one of my women patients happened upon the theory of the 'couvade', which, as is well known, is a general custom among some races and is probably intended to contradict the doubts as to paternity which can never be entirely overcome. A rather eccentric uncle of this patient's stayed at home for days after the birth of his child and received visitors in his dressing-gown, from which she concluded that both parents took part in the birth of their children and had to go to bed.

The inclination to take a man's sexual organ into the mouth and suck at it, which in respectable society is considered a loathsome sexual perversion, is nevertheless found with great frequency among women of to-day - and of earlier times as well, as ancient sculptures show - and in the state of being in love it appears completely to lose its repulsive character. Phantasies derived from this inclination are found by doctors even in women who have not become aware of the possibilities of obtaining sexual satisfaction in this way by reading Krafft Ebing's *Psychopathia Sexualis* or from other sources of information. Women, it seems, find no difficulty in producing this kind of wishful phantasy spontaneously.¹ Further investigation in forms us that this situation, which morality condemns with such severity, may be traced to an origin of the most innocent kind. It only repeats in a different form a situation in which we all once felt comfortable - when we were still in our suckling days ('essendo io in culla')² and took our mother's (or wet-nurse's) nipple into our mouth and sucked at it. The organic impression of this experience - the first source of pleasure in our life - doubtless remains indelibly printed on us; and when at a later date the child becomes familiar with the cow's udder whose function is that of a nipple, but whose shape and position under the belly make it resemble a penis, the preliminary stage has been reached which will later enable him to form the repellent sexual phantasy.

---

² See chapter on 'The Orgasm of the Udder'.
We have no information about the circumstances of his heredity; on the other hand we have seen that the accidental conditions of his childhood had a profound and disturbing effect on him. His illegitimate birth deprived him of his father's influence until perhaps his fifth year, and left him open to the tender seductions of a mother whose only solace he was. After being kissed by her into precocious sexual maturity, he must no doubt have embarked on a phase of infantile sexual activity of which only one single manifestation is definitely attested - the intensity of his infantile sexual researches. The instinct to look and the instinct to know were those most strongly excited by the impressions of his early childhood; the erotogenic zone of the mouth was given an emphasis which it never afterwards surrendered. From his later behaviour in the contrary direction, such as his exaggerated sympathy for animals, we can conclude that there was no lack of strong sadistic traits in this period of his childhood.

I will now set out before you what is most definitely known about the sexual life of children. Let me at the same time, for convenience sake, introduce the concept of 'libido'. On the exact analogy of 'hunger', we use 'libido' as the name of the force (in this case that of the sexual instinct, as in the case of hunger that of the nutritive instinct) by which the instinct manifests itself. Other concepts, such as sexual 'excitation' and 'satisfaction', call for no explanation. You yourselves will easily perceive that the sexual activities of infants in arms are mostly a matter of interpretation, or you will probably use that as a ground of objection. These interpretations are arrived at on the basis of analytic examinations made by tracing from the symptoms backwards. In an infant the first impulses of sexuality make their appearance attached to other vital functions. His main interest is, as you know, directed to the intake of nourishment; when children fall asleep after being sated at the breast, they show an expression of blissful satisfaction which will be repeated later in life after the experience of a sexual orgasm. This would be too little on which to base an inference. But we observe how an infant will repeat the action of taking in nourishment without making a demand for further food; here, then, he is not actuated by hunger. We describe this as sensual sucking, and the fact that in doing this he falls asleep once more with a blissful expression shows us that the act of sensual sucking has in itself alone brought him satisfaction. Soon, as we know, things come to a point at which he cannot go to sleep without having sucked. A paediatrician in Budapest, Dr. Lindner, was the first to point out long ago the sexual nature of this activity. Those who are in charge of children, and who have no theoretical views on the subject, seem to form a similar judgement of sucking. They have no doubt of its only purpose being to obtain pleasure, class it as one of a child's 'naughtinesses' and compel him to abandon it by causing him distress, if he will not give it up of his own accord. Thus we learn that infants perform actions which have no purpose other than obtaining pleasure. It is our belief that they first experience this pleasure in connection with taking nourishment but that they soon learn to separate it from that accompanying condition. We can only refer this pleasure to an excitation of the areas of the mouth and lips; we call those parts of the body 'erotogenic zones' and describe the pleasure derived from sucking as a sexual one. We shall no doubt have to discuss further whether this description is justifiable.
The Development of the Libido. - The sexual instinct, the dynamic manifestation of which in mental life we shall call 'libido', is made up of component instincts into which it may once more break up and which are only gradually united into well-defined organizations. The sources of these component instincts are the organs of the body and in particular certain specially marked erotogenic zones; but contributions are made to libido from every important functional process in the body. At first the individual component instincts strive for satisfaction independently of one another, but in the course of development they become more and more convergent and concentrated. The first (pregenital) stage of organization to be discerned is the oral one, in which - in conformity with the suckling's predominant interest - the oral zone plays the leading part. This is followed by the sadistic-anal organization, in which the anal zone and the component instinct of sadism are particularly prominent; at this stage the difference between the sexes is represented by the contrast between active and passive. The third and final stage of organization is that in which the majority of the component instincts converge under the primacy of the genital zones. As a rule this development is passed through swiftly and unobtrusively; but some individual portions of the instincts remain behind at the prodromal stages of the process and thus give rise to fixations of libido, which are important as constituting predispositions for subsequent eruptions of repressed impulses and which stand in a definite relation to the later development of neuroses and perversions. (See the article on 'The Libido Theory'.) [1923a, 3921]

We find ourselves on firmer ground when we investigate the manner in which the life of the instincts serves the sexual function. Here we have acquired quite definite knowledge, with which you too are already familiar. It is not the case, then, that we recognize a sexual instinct which is from the first the vehicle of an urge towards the aim of the sexual function - the union of the two sex-cells. What we see is a great number of component instincts arising from different areas and regions of the body, which strive for satisfaction fairly independently of one another and find that satisfaction in something that we may call 'organ-pleasure'. The genitals are the latest of these 'erotogenic zones' and the name of 'sexual' pleasure cannot be withheld from their organ-pleasure. These impulses which strive for pleasure are not all taken up into the final organization of the sexual function. A number of them are set aside as unserviceable, by repression or some other means; a few of them are diverted from their aim in the remarkable manner I have mentioned and used to strengthen other impulses; yet others persist in minor roles, and serve for the performance of introductory acts, for the production of fore-pleasure. You have heard how in the course of this long-drawn-out development several phases of preliminary organization can be recognized and also how this history of the sexual function explains its aberrations and atrophies. The first of these 'pregenital' phases is known to us as the oral one because, in conformity with the way in which an infant in arms is nourished, the erotogenic zone of the mouth dominates what may be called the sexual activity of that period of life. At a second level the sadistic and anal impulses come to the fore, undoubtedly in connection with the appearance of the teeth, the strengthening of the muscular apparatus and the control of the sphincter functions. We have learnt a number of interesting details about this remarkable stage of development in particular. Thirdly comes the phallic phase in which in both sexes the male organ (and what corresponds to it in girls) attains an importance which can no longer be overlooked. We have reserved the name of genital phase for the definitive sexual organization which is established after puberty and in which the female genital organ for the first time meets with the recognition which the male one acquired long before. [1933a, 4703]
The first organ to emerge as an erotogenic zone and to make libidinal demands on the mind is, from the time of birth onwards, the mouth. To begin with, all psychical activity is concentrated on providing satisfaction for the needs of that zone. Primarily, of course, this satisfaction serves the purpose of self-preservation by means of nourishment; but physiology should not be confused with psychology. The baby's obstinate persistence in sucking gives evidence at an early stage of a need for satisfaction which, though it originates from and is instigated by the taking of nourishment, nevertheless strives to obtain pleasure independently of nourishment and for that reason may and should be termed sexual.
We found from the study of neurotic disorders that beginnings of an organization of the sexual instinctual components can be detected in the sexual life of children from its very beginning. During a first, very early phase, oral erotism occupies most of the picture. A second of these pregenital organizations is characterized by the predominance of sadism and anal erotism. It is not until a third phase has been reached that the genital zones proper contribute their share in determining sexual life, and in children this last phase is developed only so far as to a primacy of the phallus.

[1905d, 1544]

I shall now attempt to sketch out a synthetic survey of my patient's sexual development, beginning from its earliest indications. The first that we hear of it is in the disturbance of his appetite; for, taking other observations into account, I am inclined, though with due reservations, to regard that as a result of some process in the sphere of sexuality. I have been driven to regard as the earliest recognizable sexual organization the so-called 'cannibalistic' or 'oral' phase, during which the original attachment of sexual excitation to the nutritional instinct still dominates the scene. It is not to be expected that we should come upon direct manifestations of this phase, but only upon indications of it where disturbances have been set up. Impairment of the nutritional instinct (though this can of course have other causes) draws our attention to a failure on the part of the organism to master its sexual excitation. In this phase the sexual aim could only be cannibalism - devouring; it makes its appearance with our present patient through regression from a higher stage, in the form of fear of 'being eaten by the wolf'. We were, indeed, obliged to translate this into a fear of being copulated with by his father. It is well known that there is a neurosis in girls which occurs at a much later age, at the time of puberty or soon afterwards, and which expresses aversion to sexuality by means of anorexia. This neurosis will have to be brought into relation with the oral phase of sexual life. The erotic aim of the oral organization further makes its appearance at the height of a lover's paroxysm (in such phrases as 'I could eat you up with love') and in affectionate relations with children, when the grown-up person is pretending to be a child himself. I have elsewhere given voice to a suspicion that the father of our present patient used himself to indulge in 'affectionate abuse', and may have played at wolf or dog with the little boy and have threatened as a joke to gobble him up (p. 3524). The patient confirmed this suspicion by his curious behaviour in the transference. Whenever he shrank back on to the transference from the difficulties of the treatment, he used to threaten me with eating me up and later with all kinds of other ill-treatment - all of which was merely an expression of affection.

[1918b, 3583]

Erotogenic masochism accompanies the libido through all its developmental phases and derives from them its changing psychical coatings. The fear of being eaten up by the totem animal (the father) originates from the primitive oral organization; the wish to be beaten by the father comes from the sadistic-anal phase which follows it; castration, although it is later disavowed, enters into the content of masochistic phantasies as a precipitate of the phallic stage or organization;¹ and from the final genital organization there arise, of course, the situations of being copulated with and of giving birth, which are characteristic of femaleness. The part played in masochism by the nates, too, is easily understandable, apart from its obvious basis in reality. The nates are the part of the body which is given erotogenic preference in the sadistic-anal phase, like the breast in the oral phase and the penis in the genital phase.

[1924c, 4077]
We have been able to study transformations of instinct and similar processes particularly in anal erotism, the excitations arising from the sources of the erotogenic anal zone, and we were surprised at the multiplicity of uses to which these instinctual impulses are put. It may not be easy, perhaps, to get free from the contempt into which this particular zone has fallen in the course of evolution. Let us therefore allow ourselves to be reminded by Abraham that embryologically the anus corresponds to the primitive mouth, which has migrated down to the end of the bowel. We have learnt, then, that after a person's own faeces, his excrement, has lost its value for him, this instinctual interest derived from the anal source passes over on to objects that can be presented as gifts. And this is rightly so, for faeces were the first gift that an infant could make, something he could part with out of love for whoever was looking after him. After this, corresponding exactly to analogous changes of meaning that occur in linguistic development, this ancient interest in faeces is transformed into the high valuation of gold and money but also makes a contribution to the affective cathexis of baby and penis. It is a universal conviction among children, who long retain the cloaca theory, that babies are born from the bowel like a piece of faeces: defaecation is the model of the act of birth. But the penis too has its fore-runner in the column of faeces which fills and stimulates the mucous membrane of the bowel. When a child, unwillingly enough, comes to realize that there are human creatures who do not possess a penis, that organ appears to him as something detachable from the body and becomes unmistakably analogous to the excrement, which was the first piece of bodily material that had to be renounced. A great part of anal erotism is thus carried over into a cathexis of the penis. But the interest in that part of the body has, in addition to its anal-erotic root, an oral one which is perhaps more powerful still: for when sucking has come to an end, the penis also becomes heir of the mother’s nipple.

[1933a, 4705]
It is worth remarking that we have here three symptoms - the disgust, the sensation of pressure on the upper part of the body, and the avoidance of men engaged in affectionate conversation - all of them derived from a single experience, and that it is only by taking into account the interrelation of these three phenomena that we can understand the way in which the formation of the symptoms came about. The disgust is the symptom of repression in the erotogenic oral zone, which, as we shall hear, had been over-indulged in Dora's infancy by the habit of sensual sucking. The pressure of the erect member probably led to an analogous change in the corresponding female organ, the clitoris; and the excitation of this second erotogenic zone was referred by a process of displacement to the simultaneous pressure against the thorax and became fixed there. Her avoidance of men who might possibly be in a state of sexual excitement follows the mechanism of a phobia, its purpose being to safeguard her against any revival of the repressed perception.

One of these patients gave me a piece of information which sheds a clear light on the origin of this curious habit. This young woman had never broken herself of the habit of sucking. She retained a memory of her childhood, dating back, according to her, to the first half of her second year, in which she saw herself sucking at her nurse's breast and at the same time pulling rhythmically at the lobe of her nurse's ear. No one will feel inclined to dispute, I think, that the mucous membrane of the lips and mouth is to be regarded as a primary 'erotogenic zone', since it preserves this earlier significance in the act of kissing, which is looked upon as normal. An intense activity of this erotogenic zone at an early age thus determines the subsequent presence of a somatic compliance on the part of the tract of mucous membrane which begins at the lips. Thus, at a time when the sexual object proper, that is, the male organ, has already become known, circumstances may arise which once more increase the excitation of the oral zone, whose erotogenic character has, as we have seen, been retained. It then needs very little creative power to substitute the sexual object of the moment (the penis) for the original object (the nipple) or for the finger which does duty for it, and to place the current sexual object in the situation in which gratification was originally obtained. So we see that this excessively repulsive and perverted phantasy of sucking at a penis has the most innocent origin. It is a new version of what may be described as a prehistoric impression of sucking at the mother's or nurse's breast - an impression which has usually been revived by contact with children who are being nursed. In most instances a cow's udder has aptly played the part of an image intermediate between a nipple and a penis.

THUMB-SUCKING For reasons which will appear later, I shall take thumb-sucking (or sensual sucking) as a sample of the sexual manifestations of childhood. (An excellent study of this subject has been made by the Hungarian paediatrician, Lindner, 1879.)

Thumb-sucking appears already in early infancy and may continue into maturity, or even persist all through life. It consists in the rhythmic repetition of a sucking contact by the mouth (or lips). There is no question of the purpose of this procedure being the taking of nourishment. A portion of the lip itself, the tongue, or any other part of the skin within reach - even the big toe - may be taken as the object upon which this sucking is carried out. In this connection a grasping-instinct may appear and may manifest itself as a simultaneous rhythmic tugging at the lobes of the ears or a catching hold of some part of another person (as a rule the ear) for the same purpose. Sensual sucking involves a complete absorption of the attention and leads either to sleep or even to a motor reaction in the nature of an orgasm.¹ It is not infrequently combined with rubbing some sensitive part of the body such as the breast or the external genitalia. Many children proceed by this path from sucking to masturbation.
Lindner himself clearly recognized the sexual nature of this activity and emphasized it without qualification. In the nursery, sucking is often classed along with the other kinds of sexual 'naughtiness' of children. This view has been most energetically repudiated by numbers of paediatricians and nerve-specialists, though this is no doubt partly due to a confusion between 'sexual' and 'genital'. Their objection raises a difficult question and one which cannot be evaded: what is the general characteristic which enables us to recognize the sexual manifestations of children? The concatenation of phenomena into which we have been given an insight by psycho-analytic investigation justifies us, in my opinion, in regarding thumb-sucking as a sexual manifestation and in choosing it for our study of the essential features of infantile sexual activity.¹

¹ [Footnote added 1920:] In 1919, a Dr. Galant published, under the title of 'Das Lutscherli', the confession of a grown-up girl who had never given up this infantile sexual activity and who represents the satisfaction to be gained from sucking as something completely analogous to sexual satisfaction, particularly when this is obtained from a lover's kiss: 'Not every kiss is equal to a "Lutscherli" - no, no, not by any means! It is impossible to describe what a lovely feeling goes through your whole body when you suck; you are right away from this world. You are absolutely satisfied, and happy beyond desire. It is a wonderful feeling; you long for nothing but peace - uninterrupted peace. It is just unspeakably lovely: you feel no pain and no sorrow, and ah! you are carried into another world.'

AUTO-EROTISM We are in duty bound to make a thorough examination of this example. It must be insisted that the most striking feature of this sexual activity is that the instinct is not directed towards other people, but obtains satisfaction from the subject's own body. It is 'auto-erotic', to call it by a happily chosen term introduced by Havelock Ellis (1910).¹

¹ [Footnote added 1920:] In 1919, a Dr. Galant published, under the title of 'Das Lutscherli', the confession of a grown-up girl who had never given up this infantile sexual activity and who represents the satisfaction to be gained from sucking as something completely analogous to sexual satisfaction, particularly when this is obtained from a lover's kiss: 'Not every kiss is equal to a "Lutscherli" - no, no, not by any means! It is impossible to describe what a lovely feeling goes through your whole body when you suck; you are right away from this world. You are absolutely satisfied, and happy beyond desire. It is a wonderful feeling; you long for nothing but peace - uninterrupted peace. It is just unspeakably lovely: you feel no pain and no sorrow, and ah! you are carried into another world.'

Furthermore, it is clear that the behaviour of a child who indulges in thumb-sucking is determined by a search for some pleasure which has already been experienced and is now remembered. In the simplest case he proceeds to find this satisfaction by sucking rhythmically at some part of the skin or mucous membrane. It is also easy to guess the occasions on which the child had his first experiences of the pleasure which he is now striving to renew. It was the child's first and most vital activity, his sucking at his mother's breast, or at substitutes for it, that must have familiarized him with this pleasure. The child's lips, in our view, behave like an erotogenic zone, and no doubt stimulation by the warm flow of milk is the cause of the pleasurable sensation. The satisfaction of the erotogenic zone is associated, in the first instance, with the satisfaction of the need for nourishment. To begin with, sexual activity attaches itself to functions serving the purpose of self-preservation and does not become independent of them until later. No one who has seen a baby sinking back satiated from the breast and falling asleep with flushed cheeks and a blissful smile can escape the reflection that this picture persists as a prototype of the expression of sexual satisfaction in later life. The need for repeating the sexual satisfaction now becomes detached from the need for taking nourishment - a separation which becomes inevitable when the teeth appear and food is no longer taken in only by sucking, but is also chewed up. The child does not make use of an extraneous body for his sucking, but prefers a part of his own skin because it is more convenient, because it makes him independent of the external world, which he is not yet able to control, and because in that way he provides himself, as it were, with a second erotogenic zone, though one of an inferior kind. The inferiority of this second region is among the reasons why at a later date he seeks the corresponding part - the lips - of another person. ('It's a pity I can't kiss myself', he seems to be saying.)
It is not every child who sucks in this way. It may be assumed that those children do so in whom there is a constitutional intensification of the erotogenic significance of the labial region. If that significance persists, these same children when they are grown up will become epicures in kissing, will be inclined to perverse kissing, or, if males, will have a powerful motive for drinking and smoking. If, however, repression ensues, they will feel disgust at food and will produce hysterical vomiting. The repression extends to the nutritional instinct owing to the dual purpose served by the labial zone. Many of my women patients who suffer from disturbances of eating, globus hystericus, constriction of the throat and vomiting, have indulged energetically in sucking during their childhood.

Our study of thumb-sucking or sensual sucking has already given us the three essential characteristics of an infantile sexual manifestation. At its origin it attaches itself to one of the vital somatic functions; it has as yet no sexual object, and is thus auto-erotic; and its sexual aim is dominated by an erotogenic zone. It is to be anticipated that these characteristics will be found to apply equally to most of the other activities of the infantile sexual instincts.

CHARACTERISTICS OF EROTOGENIC ZONES The example of thumb-sucking shows us still more about what constitutes an erotogenic zone. It is a part of the skin or mucous membrane in which stimuli of a certain sort evoke a feeling of pleasure possessing a particular quality. There can be no doubt that the stimuli which produce the pleasure are governed by special conditions, though we do not know what those are. A rhythmic character must play a part among them and the analogy of tickling is forced upon our notice. It seems less certain whether the character of the pleasurable feeling evoked by the stimulus should be described as a 'specific' one - a 'specific' quality in which the sexual factor would precisely lie. Psychology is still so much in the dark in questions of pleasure and unpleasure that the most cautious assumption is the one most to be recommended. We may later come upon reasons which seem to support the idea that the pleasurable feeling does in fact possess a specific quality.

The character of erotogenicity can be attached to some parts of the body in a particularly marked way. There are predestined erotogenic zones, as is shown by the example of sucking. The same example, however, also shows us that any other part of the skin or mucous membrane can take over the functions of an erotogenic zone, and must therefore have some aptitude in that direction. Thus the quality of the stimulus has more to do with producing the pleasurable feeling than has the nature of the part of the body concerned. A child who is indulging in sensual sucking searches about his body and chooses some part of it to suck - a part which is afterwards preferred by him from force of habit; if he happens to hit upon one of the predestined regions (such as the nipples or genitals) no doubt it retains the preference. A precisely analogous tendency to displacement is also found in the symptomatology of hysteria. In that neurosis repression affects most of all the actual genital zones and these transmit their susceptibility to stimulation to other erotogenic zones (normally neglected in adult life), which then behave exactly like genitals. But besides this, precisely as in the case of sucking, any other part of the body can acquire the same susceptibility to stimulation as is possessed by the genitals and can become an erotogenic zone. Erotogenic and hysterogenic zones show the same characteristics.¹
THE INFANTILE SEXUAL AIM  

The sexual aim of the infantile instinct consists in obtaining satisfaction by means of an appropriate stimulation of the erotogenic zone which has been selected in one way or another. This satisfaction must have been previously experienced in order to have left behind a need for its repetition; and we may expect that Nature will have made safe provisions so that this experience of satisfaction shall not be left to chance.¹ We have already learnt what the contrivance is that fulfills this purpose in the case of the labial zone: it is the simultaneous connection which links this part of the body with the taking in of food. We shall come across other, similar contrivances as sources of sexuality. The state of being in need of a repetition of the satisfaction reveals itself in two ways: by a peculiar feeling of tension, possessing, rather, the character of unpleasure, and by a sensation of itching or stimulation which is centrally conditioned and projected on to the peripheral erotogenic zone. We can therefore formulate a sexual aim in another way: it consists in replacing the projected sensation of stimulation in the erotogenic zone by an external stimulus which removes that sensation by producing a feeling of satisfaction. This external stimulus will usually consist in some kind of manipulation that is analogous to the sucking. [1905d, 1505]

It must come as a great relief to find that, when once we have understood the nature of the instinct arising from a single one of the erotogenic zones, we shall have very little more to learn of the sexual activity of children. The clearest distinctions as between one zone and another concern the nature of the contrivance necessary for satisfying the instinct; in the case of the labial zone it consisted of sucking, and this has to be replaced by other muscular actions according to the position and nature of the other zones. [1905d, 1506]

The first of these is the oral or, as it might be called, cannibalistic pregenital sexual organization. Here sexual activity has not yet been separated from the ingestion of food; nor are opposite currents within the activity differentiated. The object of both activities is the same; the sexual aim consists in the incorporation of the object - the prototype of a process which, in the form of identification, is later to play such an important psychological part. A relic of this constructed phase of organization, which is forced upon our notice by pathology, may be seen in thumb-sucking, in which the sexual activity, detached from the nutritive activity, has substituted for the extraneous object one situated in the subject’s own body.¹ [1905d, 1516]
After having explained the preponderance of perverse tendencies in psychoneurotics by recognizing it as a collateral filling of subsidiary channels when the main current of the instinctual stream has been blocked by 'repression',¹ we proceeded to a consideration of sexual life in childhood. We found it a regrettable thing that the existence of the sexual instinct in childhood has been denied and that the sexual manifestations not infrequently to be observed in children have been described as irregularities. It seemed to us on the contrary that children bring germs of sexual activity with them into the world, that they already enjoy sexual satisfaction when they begin to take nourishment and that they persistently seek to repeat the experience in the familiar activity of 'thumb-sucking'. The sexual activity of children, however, does not, it appeared, develop pari passu with their other functions, but, after a short period of efflorescence from the ages of two to five, enters upon the so-called period of latency. During that period the production of sexual excitation is not by any means stopped but continues and produces a store of energy which is employed to a great extent for purposes other than sexual - namely, on the one hand in contributing the sexual components to social feelings and on the other hand (through repression and reaction-forming) in building up the subsequently developed barriers against sexuality. On this view, the forces destined to retain the sexual instinct upon certain lines are built up in childhood chiefly at the cost of perverse sexual impulses and with the assistance of education. A certain portion of the infantile sexual impulses would seem to evade these uses and succeed in expressing itself as sexual activity. We next found that sexual excitation in children springs from a multiplicity of forces. Satisfaction arises first and foremost from the appropriate sensory excitation of what we have described as erotogenic zones. It seems probable that any part of the skin and any sense-organ - probably, indeed, any organ - can function as an erotogenic zone, though there are some particularly marked erotogenic zones whose excitation would seem to be secured from the very first by certain organic contrivances. It further appears that sexual excitation arises as a by-product, as it were, of a large number of processes that occur in the organism, as soon as they reach a certain degree of intensity, and most especially of any relatively powerful emotion, even though it is of a distressing nature. The excitations from all these sources are not yet combined; but each follows its own separate aim, which is merely the attainment of a certain sort of pleasure. In childhood, therefore, the sexual instinct is not unified and is at first without an object, that is, auto-erotic.

[1905d, 1543]
I do not know how the case could be better stated, but perhaps I may add a few remarks. It is undoubtedly nothing else but the customary prudishness and their own bad conscience over sexual matters that causes adults to adopt this attitude of 'mystery-making' in front of children; but possibly a part is also played by a piece of theoretical ignorance on their part, which we can counteract by giving the adults some enlightenment. It is commonly believed that the sexual instinct is absent in children and only begins to emerge in them at puberty when the sexual organs mature. This is a gross error, equally serious in its effects both on knowledge and on practice; and it is so easily corrected by observation that one wonders how it could ever have been made. As a matter of fact, the new-born baby brings sexuality with it into the world, certain sexual sensations accompany its development as a suckling and during early childhood, and only very few children would seem to escape sexual activities and sensations before puberty. Anyone who would like to find a detailed exposition of these statements can do so in my *Three Essays on the Theory of Sexuality*, to which I have referred above. There he will learn that the organs of reproduction proper are not the only parts of the body which provide sexual sensations of pleasure, and that nature has even so ordered matters that actual stimulations of the genitals are unavoidable during early childhood. This period of life, during which a certain quota of what is undoubtedly sexual pleasure is produced by the excitation of various parts of the skin (erogenous zones), by the activity of certain biological instincts and as an accompanying excitation in many affective states, is called the period of auto-erotism, to use a term introduced by Havelock Ellis. All that puberty does is to give the genitals primacy among all the other zones and sources which produce pleasure, and thus to force erotism into the service of the function of reproduction. This process can naturally undergo certain inhibitions, and in many people (those who later become perverts and neurotics) it is only incompletely accomplished. On the other hand, the child is capable long before puberty of most of the psychical manifestations of love-tenderness, for example, devotion and jealousy. Often enough, too, an irruption of these mental states is associated with the physical sensations of sexual excitation, so that the child cannot remain in doubt as to the connection between the two. In short, except for his reproductive power, a child has a fully-developed capacity for love long before puberty; and it may be asserted that the 'mystery-making' merely prevents him from being able to gain an intellectual grasp of activities for which he is psychically prepared and physically adjusted.

[1907c, 1914]
I will now set out before you what is most definitely known about the sexual life of children. Let me at the same time, for convenience sake, introduce the concept of 'libido'. On the exact analogy of 'hunger', we use 'libido' as the name of the force (in this case that of the sexual instinct, as in the case of hunger that of the nutritive instinct) by which the instinct manifests itself. Other concepts, such as sexual 'excitation' and 'satisfaction', call for no explanation. You yourselves will easily perceive that the sexual activities of infants in arms are mostly a matter of interpretation, or you will probably use that as a ground of objection. These interpretations are arrived at on the basis of analytic examinations made by tracing from the symptoms backwards. In an infant the first impulses of sexuality make their appearance attached to other vital functions. His main interest is, as you know, directed to the intake of nourishment; when children fall asleep after being sated at the breast, they show an expression of blissful satisfaction which will be repeated later in life after the experience of a sexual orgasm. This would be too little on which to base an inference. But we observe how an infant will repeat the action of taking in nourishment without making a demand for further food; here, then, he is not actuated by hunger. We describe this as sensual sucking, and the fact that in doing this he falls asleep once more with a blissful expression shows us that the act of sensual sucking has in itself alone brought him satisfaction. Soon, as we know, things come to a point at which he cannot go to sleep without having sucked. A paediatrician in Budapest, Dr. Lindner, was the first to point out long ago the sexual nature of this activity. Those who are in charge of children, and who have no theoretical views on the subject, seem to form a similar judgement of sucking. They have no doubt of its only purpose being to obtain pleasure, class it as one of a child's 'naughtinesses' and compel him to abandon it by causing him distress, if he will not give it up of his own accord. Thus we learn that infants perform actions which have no purpose other than obtaining pleasure. It is our belief that they first experience this pleasure in connection with taking nourishment but that they soon learn to separate it from that accompanying condition. We can only refer this pleasure to an excitation of the areas of the mouth and lips; we call those parts of the body 'erotogenic zones' and describe the pleasure derived from sucking as a sexual one. We shall no doubt have to discuss further whether this description is justifiable.

If an infant could speak, he would no doubt pronounce the act of sucking at his mother's breast by far the most important in his life. He is not far wrong in this, for in this single act he is satisfying at once the two great vital needs. We are therefore not surprised to learn from psycho-analysis how such psychical importance the act retains all through life. Sucking at the mother's breast is the starting-point of the whole of sexual life, the unmatched prototype of every later sexual satisfaction, to which phantasy often enough recurs in times of need. This sucking involves making the mother's breast the first object of the sexual instinct. I can give you no idea of the important bearing of this first object upon the choice of every later object, of the profound effects it has in its transformations and substitutions in even the remotest regions of our sexual life. But at first the infant, in his sucking activity, gives up this object and replaces it by a part of his own body. He begins to suck his thumbs or his own tongue. In this way he makes himself independent of the consent of the external world as regards gaining pleasure, and besides this he increases it by adding the excitation of a second area of his body. The erotogenic zones are not all equally generous in yielding pleasure; it is therefore an important experience when the infant, as Lindner reports, discovers, in the course of feeling around, the specially excitable regions afforded by his genitals and so finds his way from sucking to masturbation.
In forming this opinion of sensual sucking we have already become acquainted with two decisive characteristics of infantile sexuality. It makes its appearance attached to the satisfaction of the major organic needs, and it behaves auto-erotically - that is, it seeks and finds its objects in the infant's own body. What has been shown most clearly in connection with the intake of nourishment is repeated in part with the excretions. We conclude that infants have feelings of pleasure in the process of evacuating urine and faeces and that they soon contrive to arrange those actions in such a way as to bring them the greatest possible yield of pleasure through the corresponding excitations of the erogenous zones of the mucous membrane. It is here for the first time (as Lou Andreas-Salomé has subtly perceived) that they encounter the external world as an inhibiting power, hostile to their desire for pleasure, and have a glimpse of later conflicts both external and internal. An infant must not produce his excreta at whatever moment he chooses, but when other people decide that he shall. In order to induce him to forgo these sources of pleasure, he is told that everything that has to do with these functions is improper and must be kept secret. This is where he is first obliged to exchange pleasure for social respectability. To begin with, his attitude to his excreta themselves is quite different. He feels no disgust at his faeces, values them as a portion of his own body with which he will not readily part, and makes use of them as his first 'gift', to distinguish people whom he values especially highly. Even after education has succeeded in its aim of making these inclinations alien to him, he carries on his high valuation of faeces in his estimate of 'gifts' and 'money'. On the other hand he seems to regard his achievements in urinating with peculiar pride.

Accordingly, I can now describe to you the form taken by a child's sexual life before the establishment of the primacy of the genitals, preparations for which are made in the first period of infancy preceding the latency period and which is permanently organized from puberty onwards. A kind of loose organization which may be called 'pregenital' exists during this early period. During this phase what stand in the forefront are not the genital component instincts but the sadistic and anal ones. The contrast between 'masculine' and 'feminine' plays no part here as yet. Its place is taken by the contrast between 'active' and 'passive', which may be described as a precursor of the sexual polarity and which later on is soldered to that polarity. What appears to us as masculine in the activities of this phase, when we look at it from the point of view of the genital phase, turns out to be an expression of an instinct for mastery which easily passes over into cruelty. Trends with a passive aim are attached to the erogenous zone of the anal orifice, which is very important at this period. The instincts for looking and for gaining knowledge are powerfully at work; the genitals actually play a part in sexual life only as organs for the excretion of urine. The component instincts of this phase are not without objects, but those objects do not necessarily converge into a single object. The sadistic-anal organization is the immediate forerunner of the phase of genital primacy. Detailed study shows how much of it is retained in the later definitive shape of things and shows too the way in which its component instincts are compelled to take their place in the new genital organization. Behind the sadistic-anal phase of libidinal development we get a glimpse of a still earlier and more primitive stage of organization, in which the erogenous zone of the mouth plays the chief part. As you will guess, the sexual activity of sensual sucking belongs to it. We must admire the understanding of the Ancient Egyptians who, in their art, represented children, including the God Horus, with a finger in their mouth. Only recently Abraham has given examples of the traces which this primitive oral phase leaves behind it in later sexual life.
To-day we will follow yet another side of this development namely the relation of the component sexual instincts to their object. Or rather, we will make a hasty survey of this development and dwell somewhat longer on one of its rather late consequences. A few of the components of the sexual instinct, there, have an object from the first and hold fast to it - for instance, the instinct for mastery (sadism) and the scopophilic and epistemophilic instincts. Others, more definitely linked to particular erotogenic zones of the body, have one to begin with only so long as they are still attached to the non-sexual functions, and give it up when they become separated from them. Thus the first object of the oral component of the sexual instinct is the mother's breast which satisfies the infant's need for nourishment. The erotic component, which is satisfied simultaneously during the sucking, makes itself independent with the act of sensual sucking [lutschen]; it gives up the outside object and replaces it by an area of the subject's own body. The oral instinct becomes auto-erotic, as are the anal and other erotogenic instincts from the first. Further development, to put the matter as concisely as possible, has two aims: firstly, the abandonment of auto-erotism, the replacement of the subject's own body once more by an outside object, and secondly, the unification of the various objects of the separate instincts and their replacement by a single object. This can, of course, only be achieved if the object is again a whole body, similar to the subject's own. Nor can it be effected unless a number of the auto-erotic instinctual impulses are left behind as being unserviceable.

We may disregard the fact that it is unrecognizable to the subject, who, on the contrary, feels the alleged satisfaction as suffering and complains of it. This transformation is a function of the psychical conflict under pressure of which the symptom had to be formed. What was once a satisfaction to the subject is, indeed, bound to arouse his resistance or his disgust to-day. We are familiar with a trivial but instructive model of this change of mind. The same child who once eagerly sucked the milk from his mother's breast is likely a few years later to display a strong dislike to drinking milk, which his upbringing has difficulties in overcoming. This dislike increases to disgust if a skin forms on the milk or the drink containing it. We cannot exclude the possibility, perhaps, that the skin conjures up a memory of the mother's breast, once so ardently desired. Between the two situations, however, there lies the experience of weaning, with its traumatic effects.

The Process of Finding an Object, and the Oedipus Complex. - In the first instance the oral component instinct finds satisfaction by attaching itself to the satiating of the desire for nourishment; and its object is the mother's breast. It then detaches itself, becomes independent and at the same time auto-erotic, that is, it finds an object in the child's own body. Others of the component instincts also start by being auto-erotic and are not until later diverted on to an external object. It is a particularly important fact that the component instincts belonging to the genital zone habitually pass through a period of intense auto-erotic satisfaction. The component instincts are not all equally serviceable in the final genital organization of libido; some of them (for instance, the anal components) are consequently left aside and suppressed, or undergo complicated transformations.

The first organ to emerge as an erotogenic zone and to make libidinal demands on the mind is, from the time of birth onwards, the mouth. To begin with, all psychical activity is concentrated on providing satisfaction for the needs of that zone. Primarily, of course, this satisfaction serves the purpose of self-preservation by means of nourishment; but physiology should not be confused with psychology. The baby's obstinate persistence in sucking gives evidence at an early stage of a need for satisfaction which, though it originates from and is instigated by the taking of nourishment, nevertheless strives to obtain pleasure independently of nourishment and for that reason may and should be termed sexual.
During this oral phase sadistic impulses already occur sporadically along with the appearance of the teeth. Their extent is far greater in the second phase, which we describe as the sadistic-anal one, because satisfaction is then sought in aggression and in the excretory function. Our justification for including aggressive urges under the libido is based on the view that sadism is an instinctual fusion of purely libidinal and purely destructive urges, a fusion which thenceforward persists uninterruptedly.¹

[1940a [1938], 4965]
Furthermore, it is clear that the behaviour of a child who indulges in thumb-sucking is determined by a search for some pleasure which has already been experienced and is now remembered. In the simplest case he proceeds to find this satisfaction by sucking rhythmically at some part of the skin or mucous membrane. It is also easy to guess the occasions on which the child had his first experiences of the pleasure which he is now striving to renew. It was the child's first and most vital activity, his sucking at his mother's breast, or at substitutes for it, that must have familiarized him with this pleasure. The child's lips, in our view, behave like an erotogenic zone, and no doubt stimulation by the warm flow of milk is the cause of the pleasurable sensation. The satisfaction of the erotogenic zone is associated, in the first instance, with the satisfaction of the need for nourishment. To begin with, sexual activity attaches itself to functions serving the purpose of self-preservation and does not become independent of them until later. No one who has seen a baby sinking back satiated from the breast and falling asleep with flushed cheeks and a blissful smile can escape the reflection that this picture persists as a prototype of the expression of sexual satisfaction in later life. The need for repeating the sexual satisfaction now becomes detached from the need for taking nourishment - a separation which becomes inevitable when the teeth appear and food is no longer taken in only by sucking, but is also chewed up. The child does not make use of an extraneous body for his sucking, but prefers a part of his own skin because it is more convenient, because it mikes him independent of the external world, which he is not yet able to control, and because in that way he provides himself, as it were, with a second erotogenic zone, though one of an inferior kind. The inferiority of this second region is among the reasons why at a later date he seeks the corresponding part - the lips - of another person. ('It's a pity I can't kiss myself', he seems to be saying.)

Our study of thumb-sucking or sensual sucking has already given us the three essential characteristics of an infantile sexual manifestation. At its origin it attaches itself to one of the vital somatic functions; it has as yet no sexual object, and is thus auto-erotic; and its sexual aim is dominated by an erotogenic zone. It is to be anticipated that these characteristics will be found to apply equally to most of the other activities of the infantile sexual instincts.

¹ [Footnote added 1920:] Havelock Ellis, it is true, uses the word 'auto-erotic' in a somewhat different sense, to describe an excitation which is not provoked from outside but arises internally. What psychoanalysis regards as the essential point is not the genesis of the excitation, but the question of its relation to an object.

THE INFANTILE SEXUAL AIM  The sexual aim of the infantile instinct consists in obtaining satisfaction by means of an appropriate stimulation of the erotogenic zone which has been selected in one way or another. This satisfaction must have been previously experienced in order to have left behind a need for its repetition; and we may expect that Nature will have made safe provisions so that this experience of satisfaction shall not be left to chance.¹ We have already learnt what the contrivance is that fulfills this purpose in the case of the labial zone: it is the simultaneous connection which links this part of the body with the taking in of food. We shall come across other, similar contrivances as sources of sexuality. The state of being in need of a repetition of the satisfaction reveals itself in two ways: by a peculiar feeling of tension, possessing, rather, the character of unpleasure, and by a sensation of itching or stimulation which is centrally conditioned and projected on to the peripheral erotogenic zone. We can therefore formulate a sexual aim in another way: it consists in replacing the projected sensation of stimulation in the erotogenic zone by an external stimulus which removes that sensation by producing a feeling of satisfaction. This external stimulus will usually consist in some kind of manipulation that is analogous to the sucking.
The processes at puberty thus establish the primacy of the genital zones; and, in a man, the penis, which has now become capable of erection, presses forward insistently towards the new sexual aim - penetration into a cavity in the body which excites his genital zone. Simultaneously on the psychical side the process of finding an object, for which preparations have been made from earliest childhood, is completed. At a time at which the first beginnings of sexual satisfaction are still linked with the taking of nourishment, the sexual instinct has a sexual object outside the infant's own body in the shape of his mother's breast. It is only later that the instinct loses that object, just at the time, perhaps, when the child is able to form a total idea of the person to whom the organ that is giving him satisfaction belongs. As a rule the sexual instinct then becomes auto-erotic, and not until the period of latency has been passed through is the original relation restored. There are thus good reasons why a child sucking at his mother's breast has become the prototype of every relation of love. The finding of an object is in fact a refinding of it.¹

THE SEXUAL OBJECT DURING EARLY INFANCY  But even after sexual activity has become detached from the taking of nourishment, an important part of this first and most significant of all sexual relations is left over, which helps to prepare for the choice of an object and thus to restore the happiness that has been lost. All through the period of latency children learn to feel for other people who help them in their helplessness and satisfy their needs a love which is on the model of, and a continuation of, their relation as sucklings to their nursing mother. There may perhaps be an inclination to dispute the possibility of identifying a child's affection and esteem for those who look after him with sexual love. I think, however, that a closer psychological examination may make it possible to establish this identity beyond any doubt. A child's intercourse with anyone responsible for his care affords him an unending source of sexual excitation and satisfaction from his erotogenic zones. This is especially so since the person in charge of him, who, after all, is as a rule his mother, herself regards him with feelings that are derived from her own sexual life: she strokes him, kisses him, rocks him and quite clearly treats him as a substitute for a complete sexual object.¹ A mother would probably be horrified if she were made aware that all her marks of affection were rousing her child's sexual instinct and preparing for its later intensity. She regards what she does as asexual, 'pure' love, since, after all, she carefully avoids applying more excitations to the child's genitals than are unavoidable in nursery care. As we know, however, the sexual instinct is not aroused only by direct excitation of the genital zone. What we call affection will unfailingly show its effects one day on the genital zones as well. Moreover, if the mother understood more of the high importance of the part played by instincts in mental life as a whole - in all its ethical and psychical achievements - she would spare herself any self-reproaches even after her enlightenment. She is only fulfilling her task in teaching the child to love. After all, he is meant to grow up into a strong and capable person with vigorous sexual needs and to accomplish during his life all the things that human beings are urged to do by their instincts. It is true that an excess of parental affection does harm by causing precocious sexual maturity and also because, by spoiling the child, it makes him incapable in later life of temporarily doing without love or of being content with a smaller amount of it. One of the clearest indications that a child will later become neurotic is to be seen in an insatiable demand for his parents' affection. And on the other hand neuropathic parents, who are inclined as a rule to display excessive affection, are precisely those who are most likely by their caresses to arouse the child's disposition to neurotic illness. Incidentally, this example shows that there are ways more direct than inheritance by which neurotic parents can hand their disorder on to their children.

¹ [1905d, 1535]
In his subsequent development, however, it was not to homosexuality that our young libertine proceeded, but to an energetic masculinity with traits of polygamy; he knew how to vary his behaviour, too, with his varying feminine objects - audaciously aggressive in one case, languishing and bashful in another. His affection had moved from his mother on to other objects of love, but at a time when there was a scarcity of these it returned to her, only to break down in a neurosis. It was not until this happened that it became evident to what a pitch of intensity his love for his mother had developed and through what vicissitudes it had passed. The sexual aim which he pursued with his girl playmates, of sleeping with them, had originated in relation to his mother. It was expressed in words which might be retained in maturity, though they would then bear a richer connotation.¹ The boy had found his way to object-love in the usual manner from the care he had received when he was an infant; and a new pleasure had now become the most important for him - that of sleeping beside his mother. I should like to emphasize the importance of pleasure derived from cutaneous contact as a component in this new aim of Hans's, which, according to the nomenclature (artificial to my mind) of Moll, would have to be described as satisfaction of the instinct of contrectation.¹¹

Let us return to the sexual development of children. We have some arrears to make up owing to our having paid more attention to the somatic than to the mental phenomena of sexual life. The child's first choice of an object, which derives from its need for help, claims our further interest. Its choice is directed in the first instance to all those who look after it, but these soon give place to its parents. Children's relations to their parents, as we learn alike from direct observations of children and from later analytic examination of adults, are by no means free from elements of accompanying sexual excitation. The child takes both of its parents, and more particularly one of them, as the object of its erotic wishes. In so doing, it usually follows some indication from its parents, whose affection bears the clearest characteristics of a sexual activity, even though of one that is inhibited in its aims. As a rule a father prefers his daughter and a mother her son; the child reacts to this by wishing, if he is a son, to take his father's place, and, if she is a daughter, her mother's. The feelings which are aroused in these relations between parents and children and in the resulting ones between brothers and sisters are not only of a positive or affectionate kind but also of a negative or hostile one. The complex which is thus formed is doomed to early repression; but it continues to exercise a great and lasting influence from the unconscious. It is to be suspected that, together with its extensions, it constitutes the nuclear complex of every neurosis, and we may expect to find it no less actively at work in other regions of mental life. The myth of King Oedipus, who killed his father and took his mother to wife, reveals, with little modification, the infantile wish, which is later opposed and repudiated by the barrier against incest. Shakespeare's Hamlet is equally rooted in the soil of the incest-complex, but under a better disguise.

¹¹ [1909b, 2095] [1910a, 2232]
The inclination to take a man's sexual organ into the mouth and suck at it, which in respectable society is considered a loathsome sexual perversion, is nevertheless found with great frequency among women of to-day - and of earlier times as well, as ancient sculptures show -, and in the state of being in love it appears completely to lose its repulsive character. Phantasies derived from this inclination are found by doctors even in women who have not become aware of the possibilities of obtaining sexual satisfaction in this way by reading Krafft Ebing's *Psychopathia Sexualis* or from other sources of information. Women, it seems, find no difficulty in producing this kind of wishful phantasy spontaneously.¹ Further investigation in forms us that this situation, which morality condemns with such severity, may be traced to an origin of the most innocent kind. It only repeats in a different form a situation in which we all once felt comfortable - when we were still in our suckling days ('essendo io in culla')² and took our mother's (or wet-nurse's) nipple into our mouth and sucked at it. The organic impression of this experience - the first source of pleasure in our life - doubtless remains indelibly printed on us; and when at a later date the child becomes familiar with the cow's udder whose function is that of a nipple, but whose shape and position under the belly make it resemble a penis, the preliminary stage has been reached which will later enable him to form the repellent sexual phantasy.

[1910c, 2262]

The affectionate current is the older of the two. It springs from the earliest years of childhood; it is formed on the basis of the interests of the self-preservative instinct and is directed to the members of the family and those who look after the child. From the very beginning it carries along with it contributions from the sexual instincts - components of erotic interest - which can already be seen more or less clearly even in childhood and in any event are uncovered in neurotics by psycho-analysis later on. It corresponds to the child's primary object-choice. We learn in this way that the sexual instincts find their first objects by attaching themselves to the valuations made by the ego-instincts, precisely in the way in which the first sexual satisfactions are experienced in attachment to the bodily functions necessary for the preservation of life. The 'affection' shown by the child's parents and those who look after him, which seldom fails to betray its erotic nature ('the child is an erotic plaything'), does a very great deal to raise the contributions made by erotism to the cathexes of his ego-instincts, and to increase them to an amount which is bound to play a part in his later development, especially when certain other circumstances lend their support.

[1912d, 2338]

A third way in which we may approach the study of narcissism is by observing the erotic life of human beings, with its many kinds of differentiation in man and woman. Just as object-libido at first concealed ego-libido from our observation, so too in connection with the object-choice of infants (and of growing children) what we first noticed was that they derived their sexual objects from their experiences of satisfaction. The first auto-erotic sexual satisfactions are experienced in connection with vital functions which serve the purpose of self-preservation. The sexual instincts are at the outset attached to the satisfaction of the ego-instincts; only later do they become independent of these, and even then we have an indication of that original attachment in the fact that the persons who are concerned with a child's feeding, care, and protection become his earliest sexual objects: that is to say, in the first instance his mother or a substitute for her. Side by side, however, with this type and source of object-choice, which may be called the 'anacritic' or 'attachment' type, psycho-analytic research has revealed a second type, which we were not prepared for finding. We have discovered, especially clearly in people whose libidinal development has suffered some disturbance, such as perverts and homosexuals, that in their later choice of love-objects they have taken as a model not their mother but their own selves. They are plainly seeking themselves as a love-object, and are exhibiting a type of object-choice which must be termed 'narcissistic'. In this observation we have the strongest of the reasons which have led us to adopt the hypothesis of narcissism.

[1914c, 2942]
If an infant could speak, he would no doubt pronounce the act of sucking at his mother's breast by far the most important in his life. He is not far wrong in this, for in this single act he is satisfying at once the two great vital needs. We are therefore not surprised to learn from psycho-analysis how such psychical importance the act retains all through life. Sucking at the mother's breast is the starting-point of the whole of sexual life, the unmatched prototype of every later sexual satisfaction, to which phantasy often enough recurs in times of need. This sucking involves making the mother's breast the first object of the sexual instinct. I can give you no idea of the important bearing of this first object upon the choice of every later object, of the profound effects it has in its transformations and substitutions in even the remotest regions of our sexual life. But at first the infant, in his sucking activity, gives up this object and replaces it by a part of his own body. He begins to suck his thumbs or his own tongue. In this way he makes himself independent of the consent of the external world as regards gaining pleasure, and besides this he increases it by adding the excitation of a second area of his body. The erotogenic zones are not all equally generous in yielding pleasure; it is therefore an important experience when the infant, as Lindner reports, discovers, in the course of feeling around, the specially excitable regions afforded by his genitals and so finds his way from sucking to masturbation.

In forming this opinion of sensual sucking we have already become acquainted with two decisive characteristics of infantile sexuality. It makes its appearance attached to the satisfaction of the major organic needs, and it behaves *auto-erotically* - that is, it seeks and finds its objects in the infant's own body. What has been shown most clearly in connection with the intake of nourishment is repeated in part with the excretions. We conclude that infants have feelings of pleasure in the process of evacuating urine and faeces and that they soon contrive to arrange those actions in such a way as to bring them the greatest possible yield of pleasure through the corresponding excitations of the erotogenic zones of the mucous membrane. It is here for the first time (as Lou Andreas-Salomé has subtly perceived) that they encounter the external world as an inhibiting power, hostile to their desire for pleasure, and have a glimpse of later conflicts both external and internal. An infant must not produce his excreta at whatever moment he chooses, but when other people decide that he shall. In order to induce him to forgo these sources of pleasure, he is told that everything that has to do with these functions is improper and must be kept secret. This is where he is first obliged to exchange pleasure for social respectability. To begin with, his attitude to his excreta themselves is quite different. He feels no disgust at his faeces, values them as a portion of his own body with which he will not readily part, and makes use of them as his first 'gift', to distinguish people whom he values especially highly. Even after education has succeeded in its aim of making these inclinations alien to him, he carries on his high valuation of faeces in his estimate of 'gifts' and 'money'. On the other hand he seems to regard his achievements in urinating with peculiar pride.
To-day we will follow yet another side of this development namely the relation of the component sexual instincts to their object. Or rather, we will make a hasty survey of this development and dwell somewhat longer on one of its rather late consequences. A few of the components of the sexual instinct, there, have an object from the first and hold fast to it - for instance, the instinct for mastery (sadism) and the scopophilic and epistemophilic instincts. Others, more definitely linked to particular erotogenic zones of the body, have one to begin with only so long as they are still attached to the non-sexual functions, and give it up when they become separated from them. Thus the first object of the oral component of the sexual instinct is the mother's breast which satisfies the infant's need for nourishment. The erotic component, which is satisfied simultaneously during the sucking, makes itself independent with the act of sensual sucking [lutschen]; it gives up the outside object and replaces it by an area of the subject's own body. The oral instinct becomes auto-erotic, as are the anal and other erotogenic instincts from the first. Further development, to put the matter as concisely as possible, has two aims: firstly, the abandonment of auto-erotism, the replacement of the subject's own body once more by an outside object, and secondly, the unification of the various objects of the separate instincts and their replacement by a single object. This can, of course, only be achieved if the object is again a whole body, similar to the subject's own. Nor can it be effected unless a number of the auto-erotic instinctual impulses are left behind as being unserviceable.

[1916-1917, 3396]

The processes of finding an object are fairly complex and no comprehensive account has hitherto been given of them. For our purposes it may be specially pointed out that when, in the years of childhood before puberty, the process has in some respects reached a conclusion, the object that has been found turns out to be almost identical with the first object of the oral pleasure-instinct, which was reached by attachment. Though it is not actually the mother's breast, at least it is the mother. We call the mother the first love-object. For we speak of love when we bring the mental side of the sexual trends into the foreground and want to force back the underlying physical or 'sensual' instinctual demands or to forget them for a moment. At the time at which the child's mother becomes his love-object the psychical work of repression has already begun in him, which is withdrawing from his knowledge awareness of a part of his sexual aims. To his choice of his mother as a love-object everything becomes attached which, under the name of the 'Oedipus complex', has attained so much importance in the psycho-analytic explanation of the neuroses and has played no less a part, perhaps, in the resistance to psycho-analysis.

[1916-1917, 3397]

We may disregard the fact that it is unrecognizable to the subject, who, on the contrary, feels the alleged satisfaction as suffering and complains of it. This transformation is a function of the psychical conflict under pressure of which the symptom had to be formed. What was once a satisfaction to the subject is, indeed, bound to arouse his resistance or his disgust to-day. We are familiar with a trivial but instructive model of this change of mind. The same child who once eagerly sucked the milk from his mother's breast is likely a few years later to display a strong dislike to drinking milk, which his upbringing has difficulties in overcoming. This dislike increases to disgust if a skin forms on the milk or the drink containing it. We cannot exclude the possibility, perhaps, that the skin conjures up a memory of the mother's breast, once so ardently desired. Between the two situations, however, there lies the experience of weaning, with its traumatic effects.

[1916-1917, 3423]
Homosexual object-choice originally lies closer to narcissism than does the heterosexual kind. When it is a question, therefore, of repelling an undesirably strong homosexual impulse, the path back to narcissism is made particularly easy. Hitherto I have had very little opportunity of talking to you about the foundations of erotic life so far as we have discovered them, and it is too late now to catch up on the omission. This much, however, I can emphasize to you. Object-choice, the step forward in the development of the libido which is made after the narcissistic stage, can take place according to two different types: either according to the narcissistic type, where the subject's own ego is replaced by another one that is as similar as possible, or according to the attachment type, where people who have become precious through satisfying the other vital needs are chosen as objects by the libido as well. A strong libidinal fixation to the narcissistic type of object-choice is to be included in the predisposition to manifest homosexuality.

[1916-1917, 3470]

During the work of treatment we have to consider the distribution of the patient's libido; we look for the object presentations to which it is bound and free it from them, so as to place it at the disposal of the ego. In the course of this, we have come to form a very curious picture of the original, primal distribution of libido in human beings. We have been driven to assume that at the beginning of the development of the individual all his libido (all his erotic tendencies, all his capacity for love) is tied to himself - that as we say, it cathects his own ego. It is only later that, being attached to the satisfaction of the major vital needs, the libido flows over from the ego on to external objects. Not till then are we able to recognize the libidinal instincts as such and distinguish them from the ego instincts. It is possible for the libido to become detached from these objects and withdrawn again into the ego.

[1917a, 3609]

But when a group is formed the whole of this intolerance vanishes, temporarily or permanently, within the group. So long as a group formation persists or so far as it extends, individuals in the group behave as though they were uniform, tolerate the peculiarities of its other members, equate themselves with them, and have no feeling of aversion towards them. Such a limitation of narcissism can, according to our theoretical views, only be produced by one factor, a libidinal tie with other people. Love for oneself knows only one barrier - love for others, love for objects.² The question will at once be raised whether community of interest in itself, without any addition of libido, must not necessarily lead to the toleration of other people and to considerateness for them. This objection may be met by the reply that nevertheless no lasting limitation of narcissism is effected in this way, since this tolerance does not persist longer than the immediate advantage gained from the other people's collaboration. But the practical importance of this discussion is less than might be supposed, for experience has shown that in cases of collaboration libidinal ties are regularly formed between the fellow-workers which prolong and solidify the relation between them to a point beyond what is merely profitable. The same thing occurs in men's social relations as has become familiar to psycho-analytic research in the course of the development of the individual libido. The libido attaches itself to the satisfaction of the great vital needs, and chooses as its first objects the people who have a share in that process. And in the development of mankind as a whole, just as in individuals, love alone acts as the civilizing factor in the sense that it brings a change from egoism to altruism. And this is true both of sexual love for women, with all the obligations which it involves of not harming the things that are dear to women, and also of desexualized, sublimated homosexual love for other men, which springs from work in common.

[1921c, 3795]
The Process of Finding an Object, and the Oedipus Complex. - In the first instance the oral component instinct finds satisfaction by attaching itself to the satiety of the desire for nourishment; and its object is the mother's breast. It then detaches itself, becomes independent and at the same time *auto-erotic*, that is, it finds an object in the child's own body. Others of the component instincts also start by being auto-erotic and are not until later diverted on to an external object. It is a particularly important fact that the component instincts belonging to the genital zone habitually pass through a period of intense auto-erotic satisfaction. The component instincts are not all equally serviceable in the final genital organization of libido; some of them (for instance, the anal components) are consequently left aside and suppressed, or undergo complicated transformations.

Erotogenic masochism accompanies the libido through all its developmental phases and derives from them its changing psychical coatings. The fear of being eaten up by the totem animal (the father) originates from the primitive oral organization; the wish to be beaten by the father comes from the sadistic-anal phase which follows it; castration, although it is later disavowed, enters into the content of masochistic phantasies as a precipitate of the phallic stage or organization;¹ and from the final genital organization there arise, of course, the situations of being copulated with and of giving birth, which are characteristic of femaleness. The part played in masochism by the nates, too, is easily understandable, apart from its obvious basis in reality. The nates are the part of the body which is given erotogenic preference in the sadistic-anal phase, like the breast in the oral phase and the penis in the genital phase.

The sexual function, as I found, is in existence from the very beginning of the individual's life, though at first it is attached to the other vital functions and does not become independent of them until later; it has to pass through a long and complicated process of development before it becomes what we are familiar with as the normal sexual life of the adult. It begins by manifesting itself in the activity of a whole number of *component instincts*. These are dependent upon *erotogenic zones* in the body; some of them make their appearance in pairs of opposite impulses (such as sadism and masochism or the impulses to look and to be looked at); they operate independently of one another in a search for pleasure, and they find their object for the most part in the subject's own body. Thus at first the sexual function is non-centralized and predominantly *auto-erotic*. Later, syntheses begin to appear in it; a first stage of organization is reached under the dominance of the *oral components*, an *anal-sadistic* stage follows, and it is only after the third stage has at last been reached that the primacy of the *genitals* is established and that the sexual function begins to serve the ends of reproduction. In the course of this process of development a number of elements of the various component instincts turn out to be unserviceable for this last end and are therefore left on one side or turned to other uses, while others are diverted from their aims and carried over into the genital organization. I gave the name of *libido* to the energy of the sexual instincts and to that form of energy alone. I was next driven to suppose that the libido does not always pass through its prescribed course of development smoothly. As a result either of the excessive strength of certain of the components or of experiences involving premature satisfaction, *fixations* of the libido may occur at various points in the course of its development. If subsequently a repression takes place, the libido flows back to these points (a process described as *regression*), and it is from them that the energy breaks through in the form of a symptom. Later on it further became clear that the localization of the point of fixation is what determines the *choice of neurosis*, that is, the form in which the subsequent illness makes its appearance.

¹ [1923a, 3922]

[1924c, 4077]

[1925d, 4211]
The process of arriving at an object, which plays such an important part in mental life, takes place alongside of the organization of the libido. After the stage of auto-erotism, the first love-object in the case of both sexes is the mother; and it seems probable that to begin with a child does not distinguish its mother's organ of nutrition from its own body. Later, but still in the first years of infancy, the relation known as the Oedipus complex becomes established: boys concentrate their sexual wishes upon their mother and develop hostile impulses against their father as being a rival, while girls adopt an analogous attitude.¹ All of the different variations and consequences of the Oedipus complex are important; and the innately bisexual constitution of human beings makes itself felt and increases the number of simultaneously active tendencies. Children do not become clear for quite a long time about the differences between the sexes; and during this period of sexual researches they produce typical sexual theories which, being circumscribed by the incompleteness of their authors’ own physical development, are a mixture of truth and error and fail to solve the problems of sexual life (the riddle of the Sphinx - that is, the question of where babies come from). We see, then, that a child's first object-choice is an incestuous one. The whole course of development that I have described is run through rapidly. For the most remarkable feature of the sexual life of man is its diphasic onset, its onset in two waves, with an interval between them. It reaches a first climax in the fourth or fifth year of a child's life. But thereafter this early efflorescence of sexuality passes off; the sexual impulses which have shown such liveliness are overcome by repression, and a period of latency follows, which lasts until puberty and during which the reaction-formations of morality, shame, and disgust are built up.² Of all living creatures man alone seems to show this diphasic onset of sexual growth, and it may perhaps be the biological determinant of his predisposition to neuroses. At puberty the impulses and object-relations of a child's early years become reanimated, and amongst them the emotional ties of its Oedipus complex. In the sexual life of puberty there is a struggle between the urges of early years and the inhibitions of the latency period. Before this, and while the child is at the highest point of its infantile sexual development, a genital organization of a sort is established; but only the male genitals play a part in it, and the female ones remain undiscovered. (I have described this as the period of phallic primacy.) At this stage the contrast between the sexes is not stated in terms of 'male' or 'female' but of 'possessing a penis' or 'castrated'. The castration complex which arises in this connection is of the profoundest importance in the formation alike of character and of neuroses. [1925d, 4212]

The biological factor is the long period of time during which the young of the human species is in a condition of helplessness and dependence. Its intra-uterine existence seems to be short in comparison with that of most animals, and it is sent into the world in a less finished state. As a result, the influence of the real external world upon it is intensified and an early differentiation between the ego and the id is promoted. Moreover, the dangers of the external world have a greater importance for it, so that the value of the object which can alone protect it against them and take the place of its former intra-uterine life is enormously enhanced. The biological factor, then, establishes the earliest situations of danger and creates the need to be loved which will accompany the child through the rest of its life. [1926d, 4308]
These connections are not hard to find. They consist in the relation of the child's helplessness to the helplessness of the adult which continues it. So that, as was to be expected, the motives for the formation of religion which psycho-analysis revealed now turn out to be the same as the infantile contribution to the manifest motives. Let us transport ourselves into the mental life of a child. You remember the choice of object according to the anaclitic type, which psycho-analysis talks of? The libido there follows the paths of narcissistic needs and attaches itself to the objects which ensure the satisfaction of those needs. In this way the mother, who satisfies the child's hunger, becomes its first love-object and certainly also its first protection against all the undefined dangers which threaten it in the external world - its first protection against anxiety, we may say.

[1927c, 4435]

Further reflection tells us that the adult's ego-feeling cannot have been the same from the beginning. It must have gone through a process of development, which cannot, of course, be demonstrated but which admits of being constructed with a fair degree of probability.¹ An infant at the breast does not as yet distinguish his ego from the external world as the source of the sensations flowing in upon him. He gradually learns to do so, in response to various promptings. He must be very strongly impressed by the fact that some sources of excitation, which he will later recognize as his own bodily organs, can provide him with sensations at any moment, whereas other sources evade him from time to time - among them what he desires most of all, his mother's breast - and only reappear as a result of his screaming for help. In this way there is for the first time set over against the ego an 'object', in the form of something which exists 'outside' and which is only forced to appear by a special action. A further incentive to a disengagement of the ego from the general mass of sensations - that is, to the recognition of an 'outside', an external world - is provided by the frequent, manifold and unavoidable sensations of pain and unpleasure the removal and avoidance of which is enjoined by the pleasure principle, in the exercise of its unrestricted domination. A tendency arises to separate from the ego everything that can become a source of such unpleasure, to throw it outside and to create a pure pleasure-ego which is confronted by a strange and threatening 'outside'. The boundaries of this primitive pleasure-ego cannot escape rectification through experience. Some of the things that one is unwilling to give up, because they give pleasure, are nevertheless not ego but object; and some sufferings that one seeks to expel turn out to be inseparable from the ego in virtue of their internal origin. One comes to learn a procedure by which, through a deliberate direction of one's sensory activities and through suitable muscular action, one can differentiate between what is internal - what belongs to the ego - and what is external - what emanates from the outer world. In this way one makes the first step towards the introduction of the reality principle which is to dominate future development. This differentiation, of course, serves the practical purpose of enabling one to defend oneself against sensations of unpleasure which one actually feels or with which one is threatened. In order to fend off certain unpleasurable excitations arising from within, the ego can use no other methods than those which it uses against unpleasure coming from without, and this is the starting-point of important pathological disturbances.

[1930a, 4467]
We shall return to the part played by the clitoris; let us now turn to the second task with which a girl's development is burdened. A boy's mother is the first object of his love, and she remains so too during the formation of his Oedipus complex and, in essence, all through his life. For a girl too her first object must be her mother (and the figures of wet-nurses and foster-mothers that merge into her). The first object-cathexes occur in attachment to the satisfaction of the major and simple vital needs, and the circumstances of the care of children are the same for both sexes. But in the Oedipus situation the girl's father has become her love-object, and we expect that in the normal course of development she will find her way from this paternal object to her final choice of an object. In the course of time, therefore, a girl has to change her erogenous zone and her object - both of which a boy retains. The question then arises of how this happens: in particular, how does a girl pass from her mother to an attachment to her father? or, in other words, how does she pass from her masculine phase to the feminine one to which she is biologically destined?

A child's first erotic object is the mother's breast that nourishes it; love has its origin in attachment to the satisfied need for nourishment. There is no doubt that, to begin with, the child does not distinguish between the breast and its own body; when the breast has to be separated from the body and shifted to the 'outside' because the child so often finds it absent, it carries with it as an 'object' a part of the original narcissistic libidinal cathexis. This first object is later completed into the person of the child's mother, who not only nourishes it but also looks after it and thus arouses in it a number of other physical sensations, pleasurable and unpleasurable. By her care of the child's body she becomes its first seducer. In these two relations lies the root of a mother's importance, unique, without parallel, established unalterably for a whole lifetime as the first and strongest love-object and as the prototype of all later love-relations - for both sexes. In all this the phylogenetic foundation has so much the upper hand over personal accidental experience that it makes no difference whether a child has really sucked at the breast or has been brought up on the bottle and never enjoyed the tenderness of a mother's care. In both cases the child's development takes the same path; it may be that in the second case its later longing grows all the greater. And for however long it is fed at its mother's breast, it will always be left with a conviction after it has been weaned that its feeding was too short and too little.

It is an interesting thing that the relation between the Oedipus complex and the castration complex should take such a different shape - an opposite one, in fact - in the case of females as compared to that of males. In males, as we have seen, the threat of castration brings the Oedipus complex to an end; in females we find that, on the contrary, it is their lack of a penis that forces them into their Oedipus complex. It does little harm to a woman if she remains in her feminine Oedipus attitude. (The term 'Electra complex' has been proposed for it.) She will in that case choose her husband for his paternal characteristics and be ready to recognize his authority. Her longing to possess a penis, which is in fact unappeasable, may find satisfaction if she can succeed in completing her love for the organ by extending it to the bearer of the organ, just as happened earlier when she progressed from her mother's breast to her mother as a whole person.
Furthermore, it is clear that the behaviour of a child who indulges in thumb-sucking is determined by a search for some pleasure which has already been experienced and is now remembered. In the simplest case he proceeds to find this satisfaction by sucking rhythmically at some part of the skin or mucous membrane. It is also easy to guess the occasions on which the child had his first experiences of the pleasure which he is now striving to renew. It was the child's first and most vital activity, his sucking at his mother's breast, or at substitutes for it, that must have familiarized him with this pleasure. The child's lips, in our view, behave like an erotogenic zone, and no doubt stimulation by the warm flow of milk is the cause of the pleasurable sensation. The satisfaction of the erotogenic zone is associated, in the first instance, with the satisfaction of the need for nourishment. To begin with, sexual activity attaches itself to functions serving the purpose of self-preservation and does not become independent of them until later. No one who has seen a baby sinking back satiated from the breast and falling asleep with flushed cheeks and a blissful smile can escape the reflection that this picture persists as a prototype of the expression of sexual satisfaction in later life. The need for repeating the sexual satisfaction now becomes detached from the need for taking nourishment - a separation which becomes inevitable when the teeth appear and food is no longer taken in only by sucking, but is also chewed up. The child does not make use of an extraneous body for his sucking, but prefers a part of his own skin because it is more convenient, because it makes him independent of the external world, which he is not yet able to control, and because in that way he provides himself, as it were, with a second erotogenic zone, though one of an inferior kind. The inferiority of this second region is among the reasons why at a later date he seeks the corresponding part - the lips - of another person. ('It's a pity I can't kiss myself', he seems to be saying.)

[1905d, 1503]

The processes at puberty thus establish the primacy of the genital zones; and, in a man, the penis, which has now become capable of erection, presses forward insistently towards the new sexual aim - penetration into a cavity in the body which excites his genital zone. Simultaneously on the psychical side the process of finding an object, for which preparations have been made from earliest childhood, is completed. At a time at which the first beginnings of sexual satisfaction are still linked with the taking of nourishment, the sexual instinct has a sexual object outside the infant's own body in the shape of his mother's breast. It is only later that the instinct loses that object, just at the time, perhaps, when the child is able to form a total idea of the person to whom the organ that is giving him satisfaction belongs. As a rule the sexual instinct then becomes auto-erotic, and not until the period of latency has been passed through is the original relation restored. There are thus good reasons why a child sucking at his mother's breast has become the prototype of every relation of love. The finding of an object is in fact a refinding of it.¹

[1905d, 1535]
The inclination to take a man's sexual organ into the mouth and suck at it, which in respectable society is considered a loathsome sexual perversion, is nevertheless found with great frequency among women of to-day - and of earlier times as well, as ancient sculptures show -, and in the state of being in love it appears completely to lose its repulsive character. Phantasies derived from this inclination are found by doctors even in women who have not become aware of the possibilities of obtaining sexual satisfaction in this way by reading Krafft Ebing's *Psychopathia Sexualis* or from other sources of information. Women, it seems, find no difficulty in producing this kind of wishful phantasy spontaneously.¹ Further investigation in forms us that this situation, which morality condemns with such severity, may be traced to an origin of the most innocent kind. It only repeats in a different form a situation in which we all once felt comfortable - when we were still in our suckling days ('essendo io in culla')² and took our mother's (or wet-nurse's) nipple into our mouth and sucked at it. The organic impression of this experience - the first source of pleasure in our life - doubtless remains indelibly printed on us; and when at a later date the child becomes familiar with the cow's udder whose function is that of a nipple, but whose shape and position under the belly make it resemble a penis, the preliminary stage has been reached which will later enable him to form the repellent sexual phantasy.

[1910c, 2262]

The affectionate current is the older of the two. It springs from the earliest years of childhood; it is formed on the basis of the interests of the self-preservative instinct and is directed to the members of the family and those who look after the child. From the very beginning it carries along with it contributions from the sexual instincts - components of erotic interest - which can already be seen more or less clearly even in childhood and in any event are uncovered in neurotics by psycho-analysis later on. It corresponds to the child's primary object-choice. We learn in this way that the sexual instincts find their first objects by attaching themselves to the valuations made by the ego-instincts, precisely in the way in which the first sexual satisfactions are experienced in attachment to the bodily functions necessary for the preservation of life. The 'affection' shown by the child's parents and those who look after him, which seldom fails to betray its erotic nature ('the child is an erotic plaything'), does a very great deal to raise the contributions made by erotism to the cathexes of his ego-instincts, and to increase them to an amount which is bound to play a part in his later development, especially when certain other circumstances lend their support.

[1912d, 2338]
I will now set out before you what is most definitely known about the sexual life of children. Let me at the same time, for convenience sake, introduce the concept of 'libido'. On the exact analogy of 'hunger', we use 'libido' as the name of the force (in this case that of the sexual instinct, as in the case of hunger that of the nutritive instinct) by which the instinct manifests itself. Other concepts, such as sexual 'excitation' and 'satisfaction', call for no explanation. You yourselves will easily perceive that the sexual activities of infants in arms are mostly a matter of interpretation, or you will probably use that as a ground of objection. These interpretations are arrived at on the basis of analytic examinations made by tracing from the symptoms backwards. In an infant the first impulses of sexuality make their appearance attached to other vital functions. His main interest is, as you know, directed to the intake of nourishment; when children fall asleep after being sated at the breast, they show an expression of blissful satisfaction which will be repeated later in life after the experience of a sexual orgasm. This would be too little on which to base an inference. But we observe how an infant will repeat the action of taking in nourishment without making a demand for further food; here, then, he is not actuated by hunger. We describe this as sensual sucking, and the fact that in doing this he falls asleep once more with a blissful expression shows us that the act of sensual sucking has in itself alone brought him satisfaction. Soon, as we know, things come to a point at which he cannot go to sleep without having sucked. A paediatrician in Budapest, Dr. Lindner, was the first to point out long ago the sexual nature of this activity. Those who are in charge of children, and who have no theoretical views on the subject, seem to form a similar judgement of sucking. They have no doubt of its only purpose being to obtain pleasure, class it as one of a child's 'naughtinesses' and compel him to abandon it by causing him distress, if he will not give it up of his own accord. Thus we learn that infants perform actions which have no purpose other than obtaining pleasure. It is our belief that they first experience this pleasure in connection with taking nourishment but that they soon learn to separate it from that accompanying condition. We can only refer this pleasure to an excitation of the areas of the mouth and lips; we call those parts of the body 'erotogenic zones' and describe the pleasure derived from sucking as a sexual one. We shall no doubt have to discuss further whether this description is justifiable.

[1916-1917, 3384]

If an infant could speak, he would no doubt pronounce the act of sucking at his mother's breast by far the most important in his life. He is not far wrong in this, for in this single act he is satisfying at once the two great vital needs. We are therefore not surprised to learn from psycho-analysis how such psychical importance the act retains all through life. Sucking at the mother's breast is the starting-point of the whole of sexual life, the unmatched prototype of every later sexual satisfaction, to which phantasy often enough recurs in times of need. This sucking involves making the mother's breast the first object of the sexual instinct. I can give you no idea of the important bearing of this first object upon the choice of every later object, of the profound effects it has in its transformations and substitutions in even the remotest regions of our sexual life. But at first the infant, in his sucking activity, gives up this object and replaces it by a part of his own body. He begins to suck his thumbs or his own tongue. In this way he makes himself independent of the consent of the external world as regards gaining pleasure, and besides this he increases it by adding the excitation of a second area of his body. The erotogenic zones are not all equally generous in yielding pleasure; it is therefore an important experience when the infant, as Lindner reports, discovers, in the course of feeling around, the specially excitable regions afforded by his genitals and so finds his way from sucking to masturbation.

[1916-1917, 3385]
At the very beginning, in the individual's primitive oral phase, object-cathexis and identification are no doubt indistinguishable from each other. We can only suppose that later on object-cathexes proceed from the id, which feels erotic trends as needs. The ego, which to begin with is still feeble, becomes aware of the object-cathexes, and either acquiesces in them or tries to fend them off by the process of repression.¹

[1923b, 3963]

The biological factor is the long period of time during which the young of the human species is in a condition of helplessness and dependence. Its intra-uterine existence seems to be short in comparison with that of most animals, and it is sent into the world in a less finished state. As a result, the influence of the real external world upon it is intensified and an early differentiation between the ego and the id is promoted. Moreover, the dangers of the external world have a greater importance for it, so that the value of the object which can alone protect it against them and take the place of its former intra-uterine life is enormously enhanced. The biological factor, then, establishes the earliest situations of danger and creates the need to be loved which will accompany the child through the rest of its life.

[1926d, 4308]

As regards the other point - the specific instinctual factor - we come upon an interesting discrepancy between theory and experience. Theoretically there is no objection to supposing that any sort of instinctual demand might occasion the same repressions and their consequences; but our observation shows us invariably, so far as we can judge, that the excitations that play this pathogenic part arise from the component instincts of sexual life. The symptoms of neuroses are, it might be said, without exception either a substitutive satisfaction of some sexual urge or measures to prevent such a satisfaction; and as a rule they are compromises between the two, of the kind that come about in accordance with the laws operating between contraries in the unconscious. The gap in our theory cannot at present be filled; our decision is made more difficult by the fact that most of the urges of sexual life are not of a purely erotic nature but have arisen from alloys of the erotic instinct with portions of the destructive instinct. But it cannot be doubted that the instincts which manifest themselves physiologically as sexuality play a prominent, unexpectedly large part in the causation of the neuroses - whether it is an exclusive one remains to be decided. It must also be borne in mind that in the course of cultural development no other function has been so energetically and extensively repudiated as precisely the sexual one. Theory must rest satisfied with a few hints that betray a deeper connection: the fact that the first period of childhood, during which the ego begins to be differentiated from the id, is also the period of the early sexual efflorescence which is brought to an end by the period of latency; that it can hardly be a matter of chance that this momentous early period subsequently falls a victim to infantile amnesia; and lastly, that biological changes in sexual life (such as the function's diphasic onset which we have already mentioned, the disappearance of the periodic character of sexual excitement and the transformation in the relation between female menstruation and male excitation) - that these innovations in sexuality must have been of high importance in the evolution of animals into man. It is left for the science of the future to bring these still isolated data together into a new understanding. It is not in psychology but in biology that there is a gap here. We shall not be wrong, perhaps, in saying that the weak point in the ego's organization seems to lie in its attitude to the sexual function, as though the biological antithesis between self-preservation and the preservation of the species had found a psychological expression at that point.

[1940a [1938], 4994]
The first of these is the oral or, as it might be called, cannibalistic pregenital sexual organization. Here sexual activity has not yet been separated from the ingestion of food; nor are opposite currents within the activity differentiated. The object of both activities is the same; the sexual aim consists in the incorporation of the object - the prototype of a process which, in the form of identification, is later to play such an important psychological part. A relic of this constructed phase of organization, which is forced upon our notice by pathology, may be seen in thumb-sucking, in which the sexual activity, detached from the nutritive activity, has substituted for the extraneous object one situated in the subject's own body.¹

[1905d, 1516]

We found from the study of neurotic disorders that beginnings of an organization of the sexual instinctual components can be detected in the sexual life of children from its very beginning. During a first, very early phase, oral erotism occupies most of the picture. A second of these pregenital organizations is characterized by the predominance of sadism and anal erotism. It is not until a third phase has been reached that the genital zones proper contribute their share in determining sexual life, and in children this last phase is developed only so far as to a primacy of the phallus. [1905d, 1544]

I shall now attempt to sketch out a synthetic survey of my patient's sexual development, beginning from its earliest indications. The first that we hear of it is in the disturbance of his appetite; for, taking other observations into account, I am inclined, though with due reservations, to regard that as a result of some process in the sphere of sexuality. I have been driven to regard as the earliest recognizable sexual organization the so-called 'cannibalistic' or 'oral' phase, during which the original attachment of sexual excitation to the nutritional instinct still dominates the scene. It is not to be expected that we should come upon direct manifestations of this phase, but only upon indications of it where disturbances have been set up. Impairment of the nutritional instinct (though this can of course have other causes) draws our attention to a failure on the part of the organism to master its sexual excitation. In this phase the sexual aim could only be cannibalism - devouring; it makes its appearance with our present patient through regression from a higher stage, in the form of fear of 'being eaten by the wolf'. We were, indeed, obliged to translate this into a fear of being copulated with by his father. It is well known that there is a neurosis in girls which occurs at a much later age, at the time of puberty or soon afterwards, and which expresses aversion to sexuality by means of anorexia. This neurosis will have to be brought into relation with the oral phase of sexual life. The erotic aim of the oral organization further makes its appearance at the height of a lover's paroxysm (in such phrases as 'I could eat you up with love') and in affectionate relations with children, when the grown-up person is pretending to be a child himself. I have elsewhere given voice to a suspicion that the father of our present patient used himself to indulge in 'affectionate abuse', and may have played at wolf or dog with the little boy and have threatened as a joke to gobble him up (p. 3524). The patient confirmed this suspicion by his curious behaviour in the transference. Whenever he shrank back on to the transference from the difficulties of the treatment, he used to threaten me with eating me up and later with all kinds of other ill-treatment - all of which was merely an expression of affection. [1918b, 3583]

Permanent marks have been left by this oral phase of sexuality upon the usages of language. People commonly speak for instance, of an 'appetizing' love-object, and describe persons they are fond of as 'sweet'. It will be remembered, too, that our little patient would only eat sweet things. In dreams sweet things and sweetmeats stand regularly for caresses or sexual gratifications. [1918b, 3583]
In the obscurity that reigns at present in the theory of the instincts, it would be unwise to reject any idea that promises to throw light on it. We started out from the great opposition between the life and death instincts. Now object-love itself presents us with a second example of a similar polarity - that between love (or other affection) and hate (or aggressiveness). If only we could succeed in relating these two polarities to each other and in deriving one from the other! From the very first we recognized the presence of a sadistic component in the sexual instinct.¹ As we know, it can make itself independent and can, in the form of a perversion, dominate an individual's entire sexual activity. It also emerges as a predominant component instinct in one of the 'pregenital organizations', as I have named them. But how can the sadistic instinct, whose aim it is to injure the object, be derived from Eros, the preserver of life? Is it not plausible to suppose that this sadism is in fact a death instinct which, under the influence of the narcissistic libido, has been forced away from the ego and has consequently only emerged in relation to the object? It now enters the service of the sexual function. During the oral stage of organization of the libido, the act of obtaining erotic mastery over an object coincides with that object's destruction; later, the sadistic instinct separates off, and finally, at the stage of genital primacy, it takes on, for the purposes of reproduction, the function of overpowering the sexual object to the extent necessary for carrying out the sexual act. It might indeed be said that the sadism which has been forced out of the ego has pointed the way for the libidinal components of the sexual instinct, and that these follow after it to the object. Wherever the original sadism has undergone no mitigation or intermixture, we find the familiar ambivalence of love and hate in erotic life.

[1920g, 3755]

At the same time as this identification with his father, or a little later, the boy has begun to develop a true object-cathexis towards his mother according to the attachment type. He then exhibits, therefore, two psychologically distinct ties: a straightforward sexual object-cathexis towards his mother and an identification with his father which takes him as his model. The two subsist side by side for a time without any mutual influence or interference. In consequence of the irresistible advance towards a unification of mental life, they come together at last; and the normal Oedipus complex originates from their confluence. The little boy notices that his father stands in his way with his mother. His identification with his father then takes on a hostile colouring and becomes identical with the wish to replace his father in regard to his mother as well. Identification, in fact, is ambivalent from the very first; it can turn into an expression of tenderness as easily as into a wish for someone's removal. It behaves like a derivative of the first, oral phase of the organization of the libido, in which the object that we long for and prize is assimilated by eating and is in that way annihilated as such. The cannibal, as we know, has remained at this standpoint; he has a devouring affection for his enemies and only devours people of whom he is fond.

[1921c, 3797]
The Development of the Libido. - The sexual instinct, the dynamic manifestation of which in mental life we shall call 'libido', is made up of component instincts into which it may once more break up and which are only gradually united into well-defined organizations. The sources of these component instincts are the organs of the body and in particular certain specially marked erotogenic zones; but contributions are made to libido from every important functional process in the body. At first the individual component instincts strive for satisfaction independently of one another, but in the course of development they become more and more convergent and concentrated. The first (pregenital) stage of organization to be discerned is the oral one, in which - in conformity with the suckling's predominant interest - the oral zone plays the leading part. This is followed by the sadistic-anal organization, in which the anal zone and the component instinct of sadism are particularly prominent; at this stage the difference between the sexes is represented by the contrast between active and passive. The third and final stage of organization is that in which the majority of the component instincts converge under the primacy of the genital zones. As a rule this development is passed through swiftly and unobtrusively; but some individual portions of the instincts remain behind at the prodromal stages of the process and thus give rise to fixations of libido, which are important as constituting predispositions for subsequent irruptions of repressed impulses and which stand in a definite relation to the later development of neuroses and perversions. (See the article on 'The Libido Theory'.)

Erotogenic masochism accompanies the libido through all its developmental phases and derives from them its changing psychical coatings. The fear of being eaten up by the totem animal (the father) originates from the primitive oral organization; the wish to be beaten by the father comes from the sadistic-anal phase which follows it; castration, although it is later disavowed, enters into the content of masochistic phantasies as a precipitate of the phallic stage or organization;¹ and from the final genital organization there arise, of course, the situations of being copulated with and of giving birth, which are characteristic of femaleness. The part played in masochism by the nates, too, is easily understandable, apart from its obvious basis in reality. The nates are the part of the body which is given erotogenic preference in the sadistic-anal phase, like the breast in the oral phase and the penis in the genital phase.

[1923a, 3921]

[1924c, 4077]
These are unwelcome complications, considering that we only set out to study simple cases of symptom-formation due to repression, and with that intention selected the earliest and to all appearances, most transparent neuroses of childhood. Instead of a single repression we have found a collection of them and have become involved with regression into the bargain. Perhaps we have added to the confusion by treating the two cases of animal phobia at our disposal - 'Little Hans' and the 'Wolf Man' - as though they were cast in the same mould. As a matter of fact, certain differences between them stand out. It is only with regard to 'Little Hans' that we can say with certainty that what his phobia disposed of were the two main impulses of the Oedipus complex - his aggressiveness towards his father and his over-fondness for his mother. A tender feeling for his father was undoubtedly there too and played a part in repressing the opposite feeling; but we can prove neither that it was strong enough to draw repression upon itself nor that it disappeared afterwards. 'Hans' seems, in fact, to have been a normal boy with what is called a 'positive' Oedipus complex. It is possible that the factors which we do not find were actually at work in him, but we cannot demonstrate their existence. Even the most exhaustive analysis has gaps in its data and is insufficiently documented. In the case of the Russian the deficiency lies elsewhere. His attitude to female objects had been disturbed by an early seduction and his passive, feminine side was strongly developed. The analysis of his wolf-dream revealed very little intentional aggressiveness towards his father, but it brought forward unmistakable proof that what repression overtook was his passive tender attitude to his father. In his case, too, the other factors may have been operative as well; but they were not in evidence. How is it that, in spite of these differences in the two cases, almost amounting to an antithesis, the final outcome - a phobia - was approximately the same? The answer must be sought in another quarter. I think it will be found in the second fact which emerges from our brief comparative examination. It seems to me that in both cases we can detect what the motive force of the repression was and can substantiate our view of its nature from the line of development which the two children subsequently pursued. This motive force was the same in both of them. It was the fear of impending castration. 'Little Hans' gave up his aggressiveness towards his father from fear of being castrated. His fear that a horse would bite him can, without any forcing, be given the full sense of a fear that a horse would bite off his genitals, would castrate him. But it was from fear of being castrated, too, that the little Russian relinquished his wish to be loved by his father, for he thought that a relation of that sort presupposed a sacrifice of his genitals - of the organ which distinguished him from a female. As we see, both forms of the Oedipus complex, the normal, active form and the inverted one, came to grief through the castration complex. The Russian boy's anxiety-idea of being devoured by a wolf contained, it is true, no suggestion of castration, for the oral regression it had undergone had removed it too far from the phallic stage. But the analysis of his dream rendered further proof superfluous. It was a triumph of repression that the form in which his phobia was expressed should no longer have contained any allusion to castration.

[1926d, 4267]
1 [Footnote added 1920:] Lou Andreas-Salomé (1916), in a paper which has given us a very much deeper understanding of the significance of anal erotism, has shown how the history of the first prohibition which a child comes across - the prohibition against getting pleasure from anal activity and its products - has a decisive effect on his whole development. This must be the first occasion on which the infant has a glimpse of an environment hostile to his instinctual impulses, on which he learns to separate his own entity from this alien one and on which he carries out the first 'repression' of his possibilities for pleasure. From that time on, what is 'anal' remains the symbol of everything that is to be repudiated and excluded from life. The clear-cut distinction between anal and genital processes which is later insisted upon is contradicted by the close anatomical and functional analogies and relations which hold between them. The genital apparatus remains the neighbour of the cloaca, and actually 'in the case of women is only taken from it on lease'.

[1905d, 1507]

The cruel component of the sexual instinct develops in childhood even more independently of the sexual activities that are attached to erotogenic zones. Cruelty in general comes easily to the childish nature, since the obstacle that brings the instinct for mastery to a halt at another person's pain - namely a capacity for pity - is developed relatively late. The fundamental psychological analysis of this instinct has, as we know, not yet been satisfactorily achieved. It may be assumed that the impulse of cruelty arises from the instinct for mastery and appears at a period of sexual life at which the genitals have not yet taken over their later role. It then dominates a phase of sexual life which we shall later describe as a pregenital organization. Children who distinguish themselves by special cruelty towards animals and playmates usually give rise to a just suspicion of an intense and precocious sexual activity arising from erotogenic zones; and, though all the sexual instincts may display simultaneous precocity, erotogenic sexual activity seems, nevertheless, to be the primary one. The absence of the barrier of pity brings with it a danger that the connection between the cruel and the erotogenic instincts, thus established in childhood, may prove unbreakable in later life. Ever since Jean Jacques Rousseau's *Confessions*, it has been well known to all educationalists that the painful stimulation of the skin of the buttocks is one of the erotogenic roots of the passive instinct of cruelty (masochism). The conclusion has rightly been drawn by them that corporal punishment, which is usually applied to this part of the body, should not be inflicted upon any children whose libido is liable to be forced into collateral channels by the later demands of cultural education.¹

[1905d, 1512]

We found from the study of neurotic disorders that beginnings of an organization of the sexual instinctual components can be detected in the sexual life of children from its very beginning. During a first, very early phase, oral erotism occupies most of the picture. A second of these pregenital organizations is characterized by the predominance of sadism and anal erotism. It is not until a third phase has been reached that the genital zones proper contribute their share in determining sexual life, and in children this last phase is developed only so far as to a primacy of the phallus.

[1905d, 1544]
Their ignorance of the vagina also makes it possible for children to believe in the second of their sexual theories. If the baby grows in the mother's body and is then removed from it, this can only happen along the one possible pathway -the anal aperture. The baby must be evacuated like a piece of excrement, like a stool. When, in later childhood, the same question is the subject of solitary reflection or of a discussion between two children, the explanations probably arrived at are that the baby emerges from the navel, which comes open, or that the abdomen is slit up and the baby taken out - which was what happened to the wolf in the story of Little Red Riding-Hood. These theories are expressed aloud and also consciously remembered later on; they no longer contain anything objectionable. These same children have by then completely forgotten that in earlier years they believed in another theory of birth, which is now obstructed by the repression of the anal sexual components that has meanwhile occurred. At that time a motion was something which could be talked about in the nursery without shame. The child was still not so distant from his constitutional coprophilic inclinations. There was nothing degraded about coming into the world like a heap of faeces, which had not yet been condemned by feelings of disgust. The cloacal theory, which, after all, is valid for so many animals, was the most natural theory, and it alone could obtrude upon the child as being a probable one.

This is the starting-point of the small new fragment of theory which I have formulated. It is of course only in appearance that it is based on this one observation; actually it brings together a large number of earlier impressions, though an understanding of them was only made possible by this last experience. I told myself that my schematic picture of the development of the libidinal function called for an extra insertion in it. To begin with, I had only distinguished, first the phase of auto-erotism during which the subject's component instincts, each on its own account, seek for the satisfaction of their desires in his own body, and then the combination of all the component instincts for the choice of an object, under the primacy of the genitals acting on behalf of reproduction. The analysis of the paraphrenias has, as we know, necessitated the insertion between them of a stage of narcissism, during which the choice of an object has already taken place but that object coincides with the subject's own ego. And now we see the need for yet another stage to be inserted before the final shape is reached - a stage in which the component instincts have already come together for the choice of an object and that object is already something extraneous in contrast to the subject's own self, but in which the primacy of the genital zones has not yet been established. On the contrary, the component instincts which dominate this pregenital organization of sexual life are the anal-erotic and sadistic ones.

(a) The extraordinary part played by impulses of hatred and anal erotism in the symptomatology of obsessional neurosis has already struck many observers and has recently been emphasized with particular clarity by Ernest Jones (1913). This follows directly from our hypothesis if we suppose that in that neurosis the component instincts in question have once more taken over the representation of the genital instincts, whose forerunners they were in the process of development.

[1908c, 1973]
(b) If we wish to bring our hypothesis into contact with biological lines of thought, we must not forget that the antithesis between male and female, which is introduced by the reproductive function, cannot be present as yet at the stage of pregenital object-choice. We find in its place the antithesis between trends with an active and with a passive aim, an antithesis which later becomes firmly attached to that between the sexes. Activity is supplied by the common instinct of mastery, which we call sadism when we find it in the service of the sexual function; and even in fully developed normal sexual life it has important subsidiary services to perform. The passive trend is fed by anal erotism, whose erotogenic zone corresponds to the old, undifferentiated cloaca. A stressing of this anal erotism in the pregenital stage of organization leaves behind a significant predisposition to homosexuality in men when the next stage of the sexual function, the primacy of the genitals, is reached. The way in which this last phase is erected upon the preceding one and the accompanying remoulding of the libidinal cathexes present analytic research with the most interesting problems.

[1913], 2628

Infantile sexuality exhibits two other characteristics which are of importance from a biological point of view. It turns out to be put together from a number of component instincts which seem to be attached to certain regions of the body ('erotogenic zones') and some of which emerge from the beginning in pairs of opposites - instincts with an active and a passive aim. Just as in later life what is loved is not merely the object's sexual organs but his whole body, so from the very first it is not merely the genitals but many other parts of the body which are the seat of sexual excitation and respond to appropriate stimuli with sexual pleasure. This fact is closely related to the second characteristic of infantile sexuality - namely that to start with it is attached to the functions of nutrition and excretion, and, in all probability, of muscular excitation and sensory activity.

[1913], 2817

It now remains for us to put together what we know of the genesis of love and hate. Love is derived from the capacity of the ego to satisfy some of its instinctual impulses auto-erotically by obtaining organ-pleasure. It is originally narcissistic, then passes over on to objects, which have been incorporated into the extended ego, and expresses the motor efforts of the ego towards these objects as sources of pleasure. It becomes intimately linked with the activity of the later sexual instincts and, when these have been completely synthesized, coincides with the sexual impulsion as a whole. Preliminary stages of love emerge as provisional sexual aims while the sexual instincts are passing through their complicated development. As the first of these aims we recognize the phase of incorporating or devouring - a type of love which is consistent with abolishing the object's separate existence and which may therefore be described as ambivalent. At the higher stage of the pregenital sadistic-anal organization, the striving for the object appears in the form of an urge for mastery, to which injury or annihilation of the object is a matter of indifference. Love in this form and at this preliminary stage is hardly to be distinguished from hate in its attitude towards the object. Not until the genital organization is established does love become the opposite of hate.

[1915c], 2973

Hate, as a relation to objects, is older than love. It derives from the narcissistic ego's primordial repudiation of the external world with its outpouring of stimuli. As an expression of the reaction of unpleasure evoked by objects, it always remains in an intimate relation with the self-preservation instincts; so that sexual and ego-instincts can readily develop an antithesis which repeats that of love and hate. When the ego-instincts dominate the sexual function, as is the case at the stage of the sadistic-anal organization, they impart the qualities of hate to the instinctual aim as well.

[1915c], 2974
In forming this opinion of sensual sucking we have already become acquainted with two decisive characteristics of infantile sexuality. It makes its appearance attached to the satisfaction of the major organic needs, and it behaves auto-erotically - that is, it seeks and finds its objects in the infant's own body. What has been shown most clearly in connection with the intake of nourishment is repeated in part with the excretions. We conclude that infants have feelings of pleasure in the process of evacuating urine and faeces and that they soon contrive to arrange those actions in such a way as to bring them the greatest possible yield of pleasure through the corresponding excitations of the erogenous zones of the mucous membrane. It is here for the first time (as Lou Andreas-Salomé has subtly perceived) that they encounter the external world as an inhibiting power, hostile to their desire for pleasure, and have a glimpse of later conflicts both external and internal. An infant must not produce his excreta at whatever moment he chooses, but when other people decide that he shall. In order to induce him to forgo these sources of pleasure, he is told that everything that has to do with these functions is improper and must be kept secret. This is where he is first obliged to exchange pleasure for social respectability. To begin with, his attitude to his excreta themselves is quite different. He feels no disgust at his faeces, values them as a portion of his own body with which he will not readily part, and makes use of them as his first 'gift', to distinguish people whom he values especially highly. Even after education has succeeded in its aim of making these inclinations alien to him, he carries on his high valuation of faeces in his estimate of 'gifts' and 'money'. On the other hand he seems to regard his achievements in urinating with peculiar pride.

Thus forearmed we can proceed to the consideration of a suggestion which we shall certainly not be spared. 'Why', we shall be asked, 'are you so obstinate in describing as being already sexuality what on your own evidence are indefinable manifestations in childhood out of which sexual life will later develop? Why should you not be content instead with giving them a physiological description and simply say that in an infant at the breast we already observe activities, such as sensual sucking or holding back the excreta, which show us that he is striving for "organ-pleasure"? In that way you would have avoided the hypothesis, so repugnant to every feeling, of the smallest babies having a sexual life.' - Indeed, Gentlemen, I have no objection at all to organ-pleasure. I know that even the supreme pleasure of sexual union is only an organ-pleasure attached to the activity of the genitals. But can you tell me when this originally indifferent organ-pleasure acquires the sexual character which it undoubtedly possesses in the later phases of development? Do we know any more about 'organ-pleasure' than about sexuality? You will reply that it gains its sexual character precisely when the genitals begin to play their part; 'sexual' coincides with 'genital'. You will even reject the objection raised by the perversions by pointing out to me that in the majority of perversions a genital orgasm is after all aimed at, even if it is arrived at by a method other than the union of the genitals. You are certainly taking up a much stronger position in determining the characteristics of what is sexual if you knock out of it the relation to reproduction which is made untenable by the perversions and put genital activity in its place. But, if so, we are no longer far apart: it is only a question of the genital organs versus the other organs. What are you going to do, however, about the numerous experiences which show you that the genitals can be represented as regards their yield of pleasure by other organs, as in the case of kissing or of the perverse practices of voluptuaries or of the symptoms of hysteria? In that neurosis it is quite usual for signs of stimulation, sensations and innervations, and even the processes of erection, which belong properly to the genitals, to be displaced on to other, remote regions of the body - as, for instance, by transposition upwards, to the head and face. Being thus convinced that you have nothing to catch hold of for your characterization of what is sexual, you will no doubt have to make up your minds to follow my example and extend the description of being 'sexual' to the activities of early childhood, too, which strive for organ-pleasure.
Accordingly, I can now describe to you the form taken by a child's sexual life before the establishment of the primacy of the genitals, preparations for which are made in the first period of infancy preceding the latency period and which is permanently organized from puberty onwards. A kind of loose organization which may be called 'pregenital' exists during this early period. During this phase what stand in the forefront are not the genital component instincts but the sadistic and anal ones. The contrast between 'masculine' and 'feminine' plays no part here as yet. Its place is taken by the contrast between 'active' and 'passive', which may be described as a precursor of the sexual polarity and which later on is soldered to that polarity. What appears to us as masculine in the activities of this phase, when we look at it from the point of view of the genital phase, turns out to be an expression of an instinct for mastery which easily passes over into cruelty. Trends with a passive aim are attached to the erotogenic zone of the anal orifice, which is very important at this period. The instincts for looking and for gaining knowledge are powerfully at work; the genitals actually play a part in sexual life only as organs for the excretion of urine. The component instincts of this phase are not without objects, but those objects do not necessarily converge into a single object. The sadistic-anal organization is the immediate forerunner of the phase of genital primacy. Detailed study shows how much of it is retained in the later definitive shape of things and shows too the way in which its component instincts are compelled to take their place in the new genital organization. Behind the sadistic-anal phase of libidinal development we get a glimpse of a still earlier and more primitive stage of organization, in which the erotogenic zone of the mouth plays the chief part. As you will guess, the sexual activity of sensual sucking belongs to it. We must admire the understanding of the Ancient Egyptians who, in their art, represented children, including the God Horus, with a finger in their mouth. Only recently Abraham has given examples of the traces which this primitive oral phase leaves behind it in later sexual life.

To-day we will follow yet another side of this development namely the relation of the component sexual instincts to their object. Or rather, we will make a hasty survey of this development and dwell somewhat longer on one of its rather late consequences. A few of the components of the sexual instinct, there, have an object from the first and hold fast to it - for instance, the instinct for mastery (sadism) and the scopophilic and epistemophilic instincts. Others, more definitely linked to particular erotogenic zones of the body, have one to begin with only so long as they are still attached to the non-sexual functions, and give it up when they become separated from them. Thus the first object of the oral component of the sexual instinct is the mother's breast which satisfies the infant's need for nourishment. The erotic component, which is satisfied simultaneously during the sucking, makes itself independent with the act of sensual sucking [lutschen]; it gives up the outside object and replaces it by an area of the subject's own body. The oral instinct becomes auto-erotic, as are the anal and other erotogenic instincts from the first. Further development, to put the matter as concisely as possible, has two aims: firstly, the abandonment of auto-erotism, the replacement of the subject's own body once more by an outside object, and secondly, the unification of the various objects of the separate instincts and their replacement by a single object. This can, of course, only be achieved if the object is again a whole body, similar to the subject's own. Nor can it be effected unless a number of the auto-erotic instinctual impulses are left behind as being unserviceable.
The sadistic-anal organization can easily be regarded as a continuation and development of the oral one. The violent muscular activity, directed upon the object, by which it is characterized, is to be explained as an action preparatory to eating. The eating then ceases to be a sexual aim, and the preparatory action becomes a sufficient aim in itself. The essential novelty, as compared with the previous stage, is that the receptive passive function becomes disengaged from the oral zone and attached to the anal zone. In this connection we can hardly fail to think of biological parallels or of the theory that the pregenital organizations in man should be regarded as vestiges of conditions which have been permanently retained in several classes of animals. The building up of the instinct for research out of its various components is another characteristic feature of this stage of development.

The boy's anal erotism was not particularly noticeable. Under the influence of his sadism the affectionate significance of faeces gave place to an aggressive one. A part was played in the transformation of his sadism into masochism by a sense of guilt, the presence of which points to developmental processes in spheres other than the sexual one.

The Development of the Libido. - The sexual instinct, the dynamic manifestation of which in mental life we shall call 'libido', is made up of component instincts into which it may once more break up and which are only gradually united into well-defined organizations. The sources of these component instincts are the organs of the body and in particular certain specially marked erotogenic zones; but contributions are made to libido from every important functional process in the body. At first the individual component instincts strive for satisfaction independently of one another, but in the course of development they become more and more convergent and concentrated. The first (pregenital) stage of organization to be discerned is the oral one, in which - in conformity with the suckling's predominant interest - the oral zone plays the leading part. This is followed by the sadistic-anal organization, in which the anal zone and the component instinct of sadism are particularly prominent; at this stage the difference between the sexes is represented by the contrast between active and passive. The third and final stage of organization is that in which the majority of the component instincts converge under the primacy of the genital zones. As a rule this development is passed through swiftly and unobtrusively; but some individual portions of the instincts remain behind at the prodromal stages of the process and thus give rise to fixations of libido, which are important as constituting predispositions for subsequent irruptions of repressed impulses and which stand in a definite relation to the later development of neuroses and perversions. (See the article on 'The Libido Theory'.)

It is not unimportant to bear in mind what transformations are undergone, during the sexual development of childhood, by the polarity of sex with which we are familiar. A first antithesis is introduced with the choice of object, which, of course, presupposes a subject and an object. At the stage of the pregenital sadistic-anal organization, there is as yet no question of male and female; the antithesis between active and passive is the dominant one.¹ At the following stage of infantile genital organization, which we now know about, maleness exists, but not femaleness. The antithesis here is between having a male genital and being castrated. It is not until development has reached its completion at puberty that the sexual polarity coincides with male and female. Maleness combines subject, activity and possession of the penis; femaleness takes over object and passivity. The vagina is now valued as a place of shelter for the penis; it enters into the heritage of the womb.
Erotogenic masochism accompanies the libido through all its developmental phases and derives from them its changing psychical coatings. The fear of being eaten up by the totem animal (the father) originates from the primitive oral organization; the wish to be beaten by the father comes from the sadistic-anal phase which follows it; castration, although it is later disavowed, enters into the content of masochistic phantasies as a precipitate of the phallic stage or organization;¹ and from the final genital organization there arise, of course, the situations of being copulated with and of giving birth, which are characteristic of femaleness. The part played in masochism by the nates, too, is easily understandable, apart from its obvious basis in reality. The nates are the part of the body which is given erotogenic preference in the sadistic-anal phase, like the breast in the oral phase and the penis in the genital phase.

The sexual function, as I found, is in existence from the very beginning of the individual's life, though at first it is attached to the other vital functions and does not become independent of them until later; it has to pass through a long and complicated process of development before it becomes what we are familiar with as the normal sexual life of the adult. It begins by manifesting itself in the activity of a whole number of component instincts. These are dependent upon erotogenic zones in the body; some of them make their appearance in pairs of opposite impulses (such as sadism and masochism or the impulses to look and to be looked at); they operate independently of one another in a search for pleasure, and they find their object for the most part in the subject's own body. Thus at first the sexual function is non-centralized and predominantly auto-erotic. Later, syntheses begin to appear in it; a first stage of organization is reached under the dominance of the oral components, an anal-sadistic stage follows, and it is only after the third stage has at last been reached that the primacy of the genitals is established and that the sexual function begins to serve the ends of reproduction. In the course of this process of development a number of elements of the various component instincts turn out to be unserviceable for this last end and are therefore left on one side or turned to other uses, while others are diverted from their aims and carried over into the genital organization. I gave the name of libido to the energy of the sexual instincts and to that form of energy alone. I was next driven to suppose that the libido does not always pass through its prescribed course of development smoothly. As a result either of the excessive strength of certain of the components or of experiences involving premature satisfaction, fixations of the libido may occur at various points in the course of its development. If subsequently a repression takes place, the libido flows back to these points (a process described as regression), and it is from them that the energy breaks through in the form of a symptom. Later on it further became clear that the localization of the point of fixation is what determines the choice of neurosis, that is, the form in which the subsequent illness makes its appearance.

It is also characteristic of children that their two excretory needs are cathected with sexual interest. Later on, education draws a sharp distinction here, which is once more obliterated in the practice of joking. It may seem to us an unsavoury fact, but it takes quite a long time for children to develop feelings of disgust. This is not disputed even by people who insist otherwise on the seraphic purity of the child's mind.
A social factor is also unmistakably present in the cultural trend towards cleanliness, which has received \textit{ex post facto} justification in hygienic considerations but which manifested itself before their discovery. The incitement to cleanliness originates in an urge to get rid of the excreta, which have become disagreeable to the sense perceptions. We know that in the nursery things are different. The excreta arouse no disgust in children. They seem valuable to them as being a part of their own body which has come away from it. Here upbringing insists with special energy on hastening the course of development which lies ahead, and which should make the excreta worthless, disgusting, abhorrent and abominable. Such a reversal of values would scarcely be possible if the substances that are expelled from the body were not doomed by their strong smells to share the fate which overtook olfactory stimuli after man adopted the erect posture. Anal erotism, therefore, succumbs in the first instance to the ‘organic repression’ which paved the way to civilization. The existence of the social factor which is responsible for the further transformation of anal erotism is attested by the circumstance that, in spite of all man’s developmental advances, he scarcely finds the smell of his own excreta repulsive, but only that of other people’s. Thus a person who is not clean - who does not hide his excreta - is offending other people; he is showing no consideration for them. And this is confirmed by our strongest and commonest terms of abuse. It would be incomprehensible, too, that man should use the name of his most faithful friend in the animal world - the dog - as a term of abuse if that creature had not incurred his contempt through two characteristics: that it is an animal whose dominant sense is that of smell and one which has no horror of excrement, and that it is not ashamed of its sexual functions. [1930a, 4495]

We find ourselves on firmer ground when we investigate the manner in which the life of the instincts serves the sexual function. Here we have acquired quite definite knowledge, with which you too are already familiar. It is not the case, then, that we recognize a sexual instinct which is from the first the vehicle of an urge towards the aim of the sexual function - the union of the two sex-cells. What we see is a great number of component instincts arising from different areas and regions of the body, which strive for satisfaction fairly independently of one another and find that satisfaction in something that we may call ‘organ-pleasure’. The genitals are the latest of these ‘erotogenic zones’ and the name of ‘sexual’ pleasure cannot be withheld from their organ-pleasure. These impulses which strive for pleasure are not all taken up into the final organization of the sexual function. A number of them are set aside as unserviceable, by repression or some other means; a few of them are diverted from their aim in the remarkable manner I have mentioned and used to strengthen other impulses; yet others persist in minor roles, and serve for the performance of introductory acts, for the production of fore-pleasure. You have heard how in the course of this long-drawn-out development several phases of preliminary organization can be recognized and also how this history of the sexual function explains its aberrations and atrophies. The first of these 'pregenital' phases is known to us as the \textit{oral} one because, in conformity with the way in which an infant in arms is nourished, the erotogenic zone of the mouth dominates what may be called the sexual activity of that period of life. At a second level the \textit{sadistic} and \textit{anal} impulses come to the fore, undoubtedly in connection with the appearance of the teeth, the strengthening of the muscular apparatus and the control of the sphincter functions. We have learnt a number of interesting details about this remarkable stage of development in particular. Thirdly comes the \textit{phallic} phase in which in both sexes the male organ (and what corresponds to it in girls) attains an importance which can no longer be overlooked. We have reserved the name of \textit{genital} phase for the definitive sexual organization which is established after puberty and in which the female genital organ for the first time meets with the recognition which the male one acquired long before. [1933a, 4703]
So far all this is trite repetition. And you must not suppose that the many things I have not mentioned this time no longer hold good. This repetition was necessary so that I might use it as the starting-point for a report on the advances in our knowledge. We can boast of having learnt much that is new, particularly about the early organizations of the libido, and of having obtained a clearer grasp of the significance of what is old; and I will give you at least a few examples to demonstrate this. Abraham showed in 1924 that two stages can be distinguished in the sadistic-anal phase. The earlier of these is dominated by the destructive trends of destroying and losing, the later one by trends friendly towards objects - those of keeping and possessing. It is in the middle of this phase, therefore, that consideration for the object makes its first appearance as a precursor of a later erotic cathexis. We are equally justified in making a similar subdivision in the first, oral phase. In the first sub-stage what is in question is only oral incorporation, there is no ambivalence at all in the relation to the object - the mother's breast. The second stage, characterized by the emergence of the biting activity, may be described as the 'oral-sadistic' one; it exhibits for the first time the phenomena of ambivalence, which become so much clearer afterwards, in the following sadistic-anal phase. The value of these new distinctions is to be seen especially if we look for the dispositional points in the development of the libido in the case of particular neuroses, such as obsessional neurosis or melancholia. You must here recall to mind what we have learnt about the connection between fixation of the libido, disposition and regression.

[1933a, 4704]

We approach the investigation of the sexual development of women with two expectations. The first is that here once more the constitution will not adapt itself to its function without a struggle. The second is that the decisive turning-points will already have been prepared for or completed before puberty. Both expectations are promptly confirmed. Furthermore, a comparison with what happens with boys tells us that the development of a little girl into a normal woman is more difficult and more complicated, since it includes two extra tasks, to which there is nothing corresponding in the development of a man. Let us follow the parallel lines from their beginning. Undoubtedly the material is different to start with in boys and girls: it did not need psycho-analysis to establish that. The difference in the structure of the genitals is accompanied by other bodily differences which are too well known to call for mention. Differences emerge too in the instinctual disposition which give a glimpse of the later nature of women. A little girl is as a rule less aggressive, defiant and self-sufficient; she seems to have a greater need for being shown affection and on that account to be more dependent and pliant. It is probably only as a result of this pliancy that she can be taught more easily and quicker to control her excretions: urine and faeces are the first gifts that children make to those who look after them, and controlling them is the first concession to which the instinctual life of children can be induced. One gets an impression, too, that little girls are more intelligent and livelier than boys of the same age; they go out more to meet the external world and at the same time form stronger object-cathexes. I cannot say whether this lead in development has been confirmed by exact observations, but in any case there is no question that girls cannot be described as intellectually backward. These sexual differences are not, however, of great consequence: they can be outweighed by individual variations. For our immediate purposes they can be disregarded.

[1933a, 4719]
Both sexes seem to pass through the early phases of libidinal development in the same manner. It might have been expected that in girls there would already have been some lag in aggressiveness in the sadistic-anal phase, but such is not the case. Analysis of children's play has shown our women analysts that the aggressive impulses of little girls leave nothing to be desired in the way of abundance and violence. With their entry into the phallic phase the differences between the sexes are completely eclipsed by their agreements. We are now obliged to recognize that the little girl is a little man. In boys, as we know, this phase is marked by the fact that they have learnt how to derive pleasurable sensations from their small penis and connect its excited state with their ideas of sexual intercourse. Little girls do the same thing with their still smaller clitoris. It seems that with them all their masturbatory acts are carried out on this penis-equivalent, and that the truly feminine vagina is still undiscovered by both sexes. It is true that there are a few isolated reports of early vaginal sensations as well, but it could not be easy to distinguish these from sensations in the anus or vestibulum; in any case they cannot play a great part. We are entitled to keep to our view that in the phallic phase of girls the clitoris is the leading erotogenic zone. But it is not, of course, going to remain so. With the change to femininity the clitoris should wholly or in part hand over its sensitivity, and at the same time its importance, to the vagina. This would be one of the two tasks which a woman has to perform in the course of her development, whereas the more fortunate man has only to continue at the time of his sexual maturity the activity that he has previously carried out at the period of the early efflorescence of his sexuality.

[1933a, 4720]

During this oral phase sadistic impulses already occur sporadically along with the appearance of the teeth. Their extent is far greater in the second phase, which we describe as the sadistic-anal one, because satisfaction is then sought in aggression and in the excretory function. Our justification for including aggressive urges under the libido is based on the view that sadism is an instinctual fusion of purely libidinal and purely destructive urges, a fusion which thenceforward persists uninterruptedly.¹

[1940a [1938], 4965]
ACTIVITY OF THE ANAL ZONE  Like the labial zone, the anal zone is well suited by its position to act as a medium through which sexuality may attach itself to other somatic functions. It is to be presumed that the erotogenic significance of this part of the body is very great from the first. We learn with some astonishment from psycho-analysis of the transmutations normally undergone by the sexual excitations arising from this zone and of the frequency with which it retains a considerable amount of susceptibility to genital stimulation throughout life.² The intestinal disturbances which are so common in childhood see to it that the zone shall not lack intense excitations. Intestinal catarrhs at the tenderest age make children 'nervy', as people say, and in cases of later neurotic illness they have a determining influence on the symptoms in which the neurosis is expressed, and they put at its disposal the whole range of intestinal disturbances. If we bear in mind the erotogenic significance of the outlet of the intestinal canal, which persists, at all events in a modified form, we shall not be inclined to scoff at the influence of haemorrhoids, to which old-fashioned medicine used to attach so much importance in explaining neurotic conditions.

Children who are making use of the susceptibility to erotogenic stimulation of the anal zone betray themselves by holding back their stool till its accumulation brings about violent muscular contractions and, as it passes through the anus, is able to produce powerful stimulation of the mucous membrane. In so doing it must no doubt cause not only painful but also highly pleasurable sensations. One of the clearest signs of subsequent eccentricity or nervousness is to be seen when a baby obstinately refuses to empty his bowels when he is put on the pot - that is, when his nurse wants him to - and holds back that function till he himself chooses to exercise it. He is naturally not concerned with dirtying the bed, he is only anxious not to miss the subsidiary pleasure attached to defaecating. Educators are once more right when they describe children who keep the process back as 'naughty'.

The contents of the bowels, which act as a stimulating mass upon a sexually sensitive portion of mucous membrane, behave like forerunners of another organ, which is destined to come into action after the phase of childhood. But they have other important meanings for the infant. They are clearly treated as a part of the infant's own body and represent his first 'gift': by producing them he can express his active compliance with his environment and, by withholding them, his disobedience. From being a 'gift' they later come to acquire the meaning of 'baby' - for babies, according to one of the sexual theories of children, are acquired by eating and are born through the bowels.

The retention of the faecal mass, which is thus carried out intentionally by the child to begin with, in order to serve, as it were, as a masturbatory stimulus upon the anal zone or to be employed in his relation to the people looking after him, is also one of the roots of the constipation which is so common among neurpaths. Further, the whole significance of the anal zone is reflected in the fact that few neurotics are to be found without their special scatological practices, ceremonies, and so on, which they carefully keep secret.¹

Actual masturbatory stimulation of the anal zone by means of the finger, provoked by a centrally determined or peripherally maintained sensation of itching, is by no means rare among older children.
A second pregenital phase is that of the sadistic-anal organization. Here the opposition between two currents, which runs through all sexual life, is already developed: they cannot yet, however, be described as ‘masculine’ and ‘feminine’, but only as ‘active’ and ‘passive’. The activity is put into operation by the instinct for mastery through the agency of the somatic musculature; the organ which, more than any other, represents the passive sexual aim is the erotogenic mucous membrane of the anus. Both of these currents have objects, which, however, are not identical. Alongside these, other component instincts operate in an auto-erotic manner. In this phase, therefore, sexual polarity and an extraneous object are already observable. But organization and subordination to the reproductive function are still absent.²

Their ignorance of the vagina also makes it possible for children to believe in the second of their sexual theories. If the baby grows in the mother's body and is then removed from it, this can only happen along the one possible pathway -the anal aperture. The baby must be evacuated like a piece of excrement, like a stool. When, in later childhood, the same question is the subject of solitary reflection or of a discussion between two children, the explanations probably arrived at are that the baby emerges from the navel, which comes open, or that the abdomen is slit up and the baby taken out - which was what happened to the wolf in the story of Little Red Riding-Hood. These theories are expressed aloud and also consciously remembered later on; they no longer contain anything objectionable. These same children have by then completely forgotten that in earlier years they believed in another theory of birth, which is now obstructed by the repression of the anal sexual components that has meanwhile occurred. At that time a motion was something which could be talked about in the nursery without shame. The child was still not so distant from his constitutional coprophilic inclinations. There was nothing degraded about coming into the world like a heap of faeces, which had not yet been condemned by feelings of disgust. The cloacal theory, which, after all, is valid for so many animals, was the most natural theory, and it alone could obtrude upon the child as being a probable one.

After the admission afforded by this phantasy, it will scarcely be possible to dispute the fact that in Hans's mind there was pleasure attached to the excretory functions.
Thus in little Hans’s sexual constitution the genital zone was from the outset the one among his erotogenic zones which afforded him the most intense pleasure. The only other similar pleasure of which he gave evidence was excretory pleasure, the pleasure attached to the orifices through which micturition and evacuation of the bowels are effected. In his final phantasy of bliss, with which his illness was overcome, he imagined he had children, whom he took to the W.C., whom he made to widdle, whose behinds he wiped - for whom, in short, he did ‘everything one can do with children’; it therefore seems impossible to avoid the assumption that during the period when he himself had been looked after as an infant these same performances had been the source of pleasurable sensations for him. He had obtained this pleasure from his erotogenic zones with the help of the person who had looked after him - his mother, in fact; and thus the pleasure already pointed the way to object-choice. But it is just possible that at a still earlier date he had been in the habit of giving himself this pleasure auto-erotically - that he had been one of those children who like retaining their excreta till they can derive a voluptuous sensation from their evacuation. I say no more than that it is possible, because the matter was not cleared up in the analysis; the ‘making a row with the legs’ (kicking about), of which he was so much frightened later on, points in that direction. But in any case these sources of pleasure had no particularly striking importance with Hans, as they so often have with other children. He early became clean in his habits, and neither bed-wetting nor diurnal incontinence played any part during his first years; no trace was observed in him of any inclination to play with his excrement, a propensity which is so revolting in adults, and which commonly makes its reappearance at the termination of processes of psychical involution.

² This confession to a pleasure in the excretory processes, which we have learnt to recognize as one of the auto-erotic components of infantile sexuality, may be compared with the remarks made by little Hans in my ‘Analysis of a Phobia in a Five-year-old Boy’.

Accordingly, I can now describe to you the form taken by a child’s sexual life before the establishment of the primacy of the genitals, preparations for which are made in the first period of infancy preceding the latency period and which is permanently organized from puberty onwards. A kind of loose organization which may be called ‘pregenital’ exists during this early period. During this phase what stand in the forefront are not the genital component instincts but the sadistic and anal ones. The contrast between ‘masculine’ and ‘feminine’ plays no part here as yet. Its place is taken by the contrast between ‘active’ and ‘passive’, which may be described as a precursor of the sexual polarity and which later on is soldered to that polarity. What appears to us as masculine in the activities of this phase, when we look at it from the point of view of the genital phase, turns out to be an expression of an instinct for mastery which easily passes over into cruelty. Trends with a passive aim are attached to the erotogenic zone of the anal orifice, which is very important at this period. The instincts for looking and for gaining knowledge are powerfully at work; the genitals actually play a part in sexual life only as organs for the excretion of urine. The component instincts of this phase are not without objects, but those objects do not necessarily converge into a single object. The sadistic-anal organization is the immediate forerunner of the phase of genital primacy. Detailed study shows how much of it is retained in the later definitive shape of things and shows too the way in which its component instincts are compelled to take their place in the new genital organization. Behind the sadistic-anal phase of libidinal development we get a glimpse of a still earlier and more primitive stage of organization, in which the erotogenic zone of the mouth plays the chief part. As you will guess, the sexual activity of sensual sucking belongs to it. We must admire the understanding of the Ancient Egyptians who, in their art, represented children, including the God Horus, with a finger in their mouth. Only recently Abraham has given examples of the traces which this primitive oral phase leaves behind it in later sexual life.

[1909b, 2092]

[1911c, 2402]

[1916-1917, 3395]
Erotogenic masochism accompanies the libido through all its developmental phases and derives from them its changing psychical coatings. The fear of being eaten up by the totem animal (the father) originates from the primitive oral organization; the wish to be beaten by the father comes from the sadistic-anal phase which follows it; castration, although it is later disavowed, enters into the content of masochistic phantasies as a precipitate of the phallic stage or organization;¹ and from the final genital organization there arise, of course, the situations of being copulated with and of giving birth, which are characteristic of femaleness. The part played in masochism by the nates, too, is easily understandable, apart from its obvious basis in reality. The nates are the part of the body which is given erotogenic preference in the sadistic-anal phase, like the breast in the oral phase and the penis in the genital phase.

[1924c, 4077]

During this oral phase sadistic impulses already occur sporadically along with the appearance of the teeth. Their extent is far greater in the second phase, which we describe as the sadistic-anal one, because satisfaction is then sought in aggression and in the excretory function. Our justification for including aggressive urges under the libido is based on the view that sadism is an instinctual fusion of purely libidinal and purely destructive urges, a fusion which thenceforward persists uninterruptedly.¹

[1940a [1938], 4965]
We found from the study of neurotic disorders that beginnings of an organization of the sexual instinctual components can be detected in the sexual life of children from its very beginning. During a first, very early phase, oral erotism occupies most of the picture. A second of these pregenital organizations is characterized by the predominance of sadism and anal erotism. It is not until a third phase has been reached that the genital zones proper contribute their share in determining sexual life, and in children this last phase is developed only so far as to a primacy of the phallus.

[1905d, 1544]

It is easy to gather from these people's early childhood history that they took a comparatively long time to overcome their infantile incontinentia alvi [faecal incontinence], and that even in later childhood they suffered from isolated failures of this function. As infants, they seem to have belonged to the class who refuse to empty their bowels when they are put on the pot because they derive a subsidiary pleasure from defaecating;¹ for they tell us that even in somewhat later years they enjoyed holding back their stool, and they remember - though more readily about their brothers and sisters than about themselves - doing all sorts of unseemly things with the faeces that had been passed. From these indications we infer that such people are born with a sexual constitution in which the erotogenicity of the anal zone is exceptionally strong. But since none of these weaknesses and idiosyncrasies are to be found in them once their childhood has been passed, we must conclude that the anal zone had lost its erotogenic significance in the course of development; and it is to be suspected that the regularity with which this triad of properties is present in their character may be brought into relation with the disappearance of their anal erotism.

[1908b, 1943]

I know that no one is prepared to believe in a state of things so long as it appears to be unintelligible and to offer no angle from which an explanation can be attempted. But we can at least bring the underlying factors nearer to our understanding by the help of the postulates I laid down in my Three Essays on the Theory of Sexuality in 1905. I there attempted to show that the sexual instinct of man is highly complex and is put together from contributions made by numerous constituents and component instincts. Important contributions to 'sexual excitation' are furnished by the peripheral excitations of certain specially designated parts of the body (the genitals, mouth, anus, urethra), which therefore deserve to be described as 'erotogenic zones'. But the amounts of excitation coming in from these parts of the body do not all undergo the same vicissitudes, nor is the fate of all of them the same at every period of life. Generally speaking, only a part of them is made use of in sexual life; another part is deflected from sexual aims and directed towards others - a process which deserves the name of 'sublimation'. During the period of life which may be called the period of 'sexual latency' - i.e. from the completion of the fifth year to the first manifestations of puberty (round about the eleventh year) - reaction-formations, or counter-forces, such as shame, disgust and morality, are created in the mind. They are actually formed at the expense of the excitations proceeding from the erotogenic zones, and they rise like dams to oppose the later activity of the sexual instincts. Now anal erotism is one of the components of the instinct which, in the course of development and in accordance with the education demanded by our present civilization, have become unserviceable for sexual aims. It is therefore plausible to suppose that these character-traits of orderliness, parsimony and obstinacy, which are so often prominent in people who were formerly anal erotics, are to be regarded as the first and most constant results of the sublimation of anal erotism.²

[1908b, 1943]
Since it is precisely the remarks in my *Three Essays on the Theory of Sexuality* about the anal erotism of infants that have particularly scandalized uncomprehending readers, I venture at this point to interpolate an observation for which I have to thank a very intelligent patient. 'A friend of mine', he told me, 'who has read your *Three Essays on the Theory of Sexuality*, was talking about the book. He entirely agreed with it, but there was one passage, which - though of course he accepted and understood its meaning like that of the rest - struck him as so grotesque and comic that he sat down and laughed over it for a quarter of an hour. This passage ran: "One of the clearest signs of subsequent eccentricity or nervousness is to be seen when a baby obstinately refuses to empty his bowels when he is put on the pot - that is, when his nurse wants him to - and holds back that function till he himself chooses to exercise it. He is naturally not concerned with dirtying the bed, he is only anxious not to miss the subsidiary pleasure attached to defaecating." The picture of this baby sitting on the pot and deliberating whether he would put up with a restriction of this kind upon his personal freedom of will, and feeling anxious, too, not to miss the pleasure attached to defaecating, - this caused my friend the most intense amusement. About twenty minutes afterwards, as we were having some cocoa, he suddenly remarked without any preliminary: "I say, seeing the cocoa in front of me has suddenly made me think of an idea that I always had when I was a child. I used always to pretend to myself that I was the cocoa-manufacturer Van Houten" (he pronounced the name Van "Hauten") "and that I possessed a great secret for the manufacture of this cocoa. Everybody was trying to get hold of this secret that was a boon to humanity but I kept it carefully to myself. I don't know why I should have hit specially upon Van Houten. Probably his advertisements impressed me more than any others." Laughing, and without thinking at the time that my words had any deep meaning, I said: "Wann haut'n die Mutter?" ['When does mother smack?' The first two words in the German phrase are pronounced exactly like 'Van Houten'.] It was only later that I realized that my pun in fact contained the key to the whole of my friend's sudden childhood recollection, and I then recognized it as a brilliant example of a screen-phantasy. My friend's phantasy, while keeping to the situation, actually involved (the nutritional process) and making use of phonetic associations ("Kakao" ['cocoa'. - 'Kaka' is the common German nursery word for 'faeces'] and "Wann haut'n"), pacified his sense of guilt by making a complete reversal in the content of his recollection: there was a displacement from the back of the body to the front, excreting food became taking food in, and something that was shameful and had to be concealed became a secret that was a boon to humanity. I was interested to see how, only a quarter of an hour after my friend had fended the phantasy off (though, it is true, in the comparatively mild form of raising an objection on formal grounds) - he was, quite involuntarily, presented with the most convincing evidence by his own unconscious.' [1908b, 1943]

Their ignorance of the vagina also makes it possible for children to believe in the second of their sexual theories. If the baby grows in the mother's body and is then removed from it, this can only happen along the one possible pathway -the anal aperture. *The baby must be evacuated like a piece of excrement, like a stool.* When, in later childhood, the same question is the subject of solitary reflection or of a discussion between two children, the explanations probably arrived at are that the baby emerges from the navel, which comes open, or that the abdomen is slit up and the baby taken out - which was what happened to the wolf in the story of Little Red Riding-Hood. These theories are expressed aloud and also consciously remembered later on; they no longer contain anything objectionable. These same children have by then completely forgotten that in earlier years they believed in another theory of birth, which is now obstructed by the repression of the anal sexual components that has meanwhile occurred. At that time a motion was something which could be talked about in the nursery without shame. The child was still not so distant from his constitutional coprophilic inclinations. There was nothing degraded about coming into the world like a heap of faeces, which had not yet been condemned by feelings of disgust. The cloacal theory, which, after all, is valid for so many animals, was the most natural theory, and it alone could obtrude upon the child as being a probable one. [1908c, 1973]
This being so, however, it was only logical that the child should refuse to grant women the painful prerogative of giving birth to children. If babies are born through the anus, then a man can give birth just as well as a woman. It is therefore possible for a boy to imagine that he, too, has children of his own, without there being any need to accuse him on that account of having feminine inclinations. He is merely giving evidence in this of the anal erotism which is still alive in him.
[1908c, 1973]

After the admission afforded by this phantasy, it will scarcely be possible to dispute the fact that in Hans's mind there was pleasure attached to the excretory functions.
[1909b, 2083]

Thus in little Hans's sexual constitution the genital zone was from the outset the one among his erotogenic zones which afforded him the most intense pleasure. The only other similar pleasure of which he gave evidence was excretory pleasure, the pleasure attached to the orifices through which micturition and evacuation of the bowels are effected. In his final phantasy of bliss, with which his illness was overcome, he imagined he had children, whom he took to the W.C., whom he made to widdle, whose behinds he wiped - for whom, in short, he did 'everything one can do with children'; it therefore seems impossible to avoid the assumption that during the period when he himself had been looked after as an infant these same performances had been the source of pleasurable sensations for him. He had obtained this pleasure from his erotogenic zones with the help of the person who had looked after him - his mother, in fact; and thus the pleasure already pointed the way to object-choice. But it is just possible that at a still earlier date he had been in the habit of giving himself this pleasure auto-erotically - that he had been one of those children who like retaining their excreta till they can derive a voluptuous sensation from their evacuation. I say no more than that it is possible, because the matter was not cleared up in the analysis; the 'making a row with the legs' (kicking about), of which he was so much frightened later on, points in that direction. But in any case these sources of pleasure had no particularly striking importance with Hans, as they so often have with other children. He early became clean in his habits, and neither bed-wetting nor diurnal incontinence played any part during his first years; no trace was observed in him of any inclination to play with his excrement, a propensity which is so revolting in adults, and which commonly makes its reappearance at the termination of processes of psychical involution.
[1909b, 2092]
There are two points upon which I should principally like to insist. When all is said and done, the erotic quips and comic anecdotes that you have collected and published in *Anthropophyteia* have only been produced and repeated because they gave pleasure both to their narrators and their hearers. It is not difficult to guess which components of the sexual instinct (compounded as it is from so many elements) find satisfaction in this manner. These tales give us direct information as to which of the component instincts of sexuality are retained in a given group of people as particularly efficient in producing pleasure; and in this way they give the neatest confirmation of the findings reached by the psycho-analytic examination of neurotics. Allow me to indicate the most important example of this kind. Psycho-analysis has led us to assert that the anal region - normally and not only in perverse individuals - is the site of an erotogenic sensitivity, and that in certain ways it behaves exactly like a genital organ. Doctors and psychologists, when told of there being an anal erotism and an anal character derived from it, have been highly indignant. At this point *Anthropophyteia* comes to the help of psycho-analysis by showing how universally people dwell with pleasure upon this part of the body, its performances and indeed the product of its function. If this were not so, all these anecdotes would be bound to give rise to disgust in their hearers or else the whole mass of the population would have to be ‘perverse’ in the sense in which the word is used in works dealing with ‘psychopathia sexualis’ in a moralizing tone. It would not be hard to give other instances of how the material collected by the authors of *Anthropophyteia* has been of value for the researches of sexual psychology. Its value may even be increased, perhaps, by the circumstance (not in itself an advantage) that the collectors know nothing of the theoretical findings of psycho-analysis and have brought together the material without any guiding principles.

² This confession to a pleasure in the excretory processes, which we have learnt to recognize as one of the auto-erotic components of infantile sexuality, may be compared with the remarks made by little Hans in my ‘Analysis of a Phobia in a Five-year-old Boy’.

³ Psycho-analysis has taught us that in the very earliest period of childhood faeces is a highly prized substance, in relation to which coprophilic instincts find satisfaction. With the repression of these instincts, which is accelerated as much as possible by up-bringing, this substance falls into contempt and then serves conscious purposes as a means of expressing disdain and scorn. Certain forms of mental activity such as joking are still able to make the obstructed source of pleasure accessible for a brief moment, and thus show how much of the esteem in which human beings once held their faeces still remains preserved in the unconscious. The most important residue of this former esteem is, however, that all the interest which the child has had in faeces is transferred in the adult on to another material which he learns in life to set above almost everything else - gold.¹ How old this connection between excrement and gold is can be seen from an observation by Jeremias:² gold, according to ancient oriental mythology, is the excrement of hell.

¹ For psycho-analysts I need hardly emphasize the fact that in this little experience of the child's we have before us one of those extremely common cases in which early anal erotism persists into later erotic life. Even her desire to paint the eggs with colours derived from the same source.
Nevertheless, psycho-analysis and folklore have not allowed themselves to be deterred from transgressing these prohibitions and have been able as a result to teach us all kinds of things that are indispensable for an understanding of human nature. If we limit ourselves here to what has been learnt about the excretory functions, it may be said that the chief finding from psycho-analytic research has been the fact that the human infant is obliged to recapitulate during the early part of his development the changes in the attitude of the human race towards excremental matters which probably had their start when homo sapiens first raised himself off Mother Earth. In the earliest years of infancy there is as yet no trace of shame about the excretory functions or of disgust at excreta. Small children show great interest in these, just as they do in others of their bodily secretions; they like occupying themselves with them and can derive many kinds of pleasure from doing so. Excreta, regarded as parts of a child's own body and as products of his own organism, have a share in the esteem - the narcissistic esteem, as we should call it - with which he regards everything relating to his self. Children are, indeed, proud of their own excretions and make use of them to help in asserting themselves against adults. Under the influence of its upbringing, the child's coprophilic instincts and inclinations gradually succumb to repression; it learns to keep them secret, to be ashamed of them and to feel disgust at their objects. Strictly speaking, however, the disgust never goes so far as to apply to a child's own excretions, but is content with repudiating them when they are the products of other people. The interest which has hitherto been attached to excrement is carried over on to other objects - for instance, from faeces on to money, which is, of course, late in acquiring significance for children. Important constituents in the formation of character are developed, or strengthened, from the repression of coprophilic inclinations.

[1913k, 2640]

The overmastering interest which must be felt in psycho-analysis by the theory of education is based upon a fact which has become evident. Only someone who can feel his way into the minds of children can be capable of educating them; and we grown-up people cannot understand children because we no longer understand our own childhood. Our infantile amnesia proves that we have grown estranged from our childhood. Psycho-analysis has brought to light the wishes, the thought structures and the developmental processes of childhood. All earlier attempts in this direction have been in the highest degree incomplete and misleading because they have entirely overlooked the inestimably important factor of sexuality in its physical and mental manifestations. The incredulous astonishment which meets the most certainly established findings of psycho-analysis on the subject of childhood - the Oedipus complex, self-love (or 'narcissism'), the disposition to perversions, anal erotism, sexual curiosity - is a measure of the gulf which separates our mental life, our judgements of value and, indeed, our processes of thought from those of even normal children.

[1913j, 2825]
This class of perverts at any rate behave to their sexual objects in approximately the same way as normal people do to theirs. But we now come to a long series of abnormal people whose sexual activity diverges more and more widely from what seems desirable to a sensible person. In their multiplicity and strangeness they can only be compared to the grotesque monsters painted by Breughel for the temptation of St. Anthony or to the long procession of vanished gods and believers which Flaubert heads past, before the eyes of his pious penitent. Such a medley calls for some kind of arrangement if it is not to confuse our senses. We accordingly divide them into those in whom, like the homosexuals, the sexual object has been changed, and others in whom the sexual aim is what has primarily been altered. The first group includes those who have renounced the union of the two genitals and who replace the genitals of one of the couple engaged in the sexual act by some other part or region of the body; in this they disregard the lack of suitable organic arrangements as well as any impediment offered by feelings of disgust. (They replace the vulva, for instance, by the mouth or anus.) Others follow, who, it is true, still retain the genitals as an object - not, however, on account of their sexual function but of other functions in which the genital plays a part either for anatomical reasons or because of its propinquity. We find from them that the excretory functions, which have been put aside as improper during the upbringing of children, retain the ability to attract the whole of sexual interest. Then come others again, who have abandoned the genital as an object altogether, and have taken some other part of the body as the object they desire - a woman's breast, a foot or a plait of hair. After them come others for whom parts of the body are of no importance but whose every wish is satisfied by a piece of clothing, a shoe, a piece of underclothing - the fetishists. Later in the procession come people who require the whole object indeed, but make quite definite demands of it - strange or horrible - even that it must have become a defenceless corpse, and who, using criminal violence, make it into one so that they may enjoy it. But enough of this kind of horror!

In forming this opinion of sensual sucking we have already become acquainted with two decisive characteristics of infantile sexuality. It makes its appearance attached to the satisfaction of the major organic needs, and it behaves auto-erotically - that is, it seeks and finds its objects in the infant's own body. What has been shown most clearly in connection with the intake of nourishment is repeated in part with the excretions. We conclude that infants have feelings of pleasure in the process of evacuating urine and faeces and that they soon contrive to arrange those actions in such a way as to bring them the greatest possible yield of pleasure through the corresponding excitations of the erotogenic zones of the mucous membrane. It is here for the first time (as Lou Andreas-Salomé has subtly perceived) that they encounter the external world as an inhibiting power, hostile to their desire for pleasure, and have a glimpse of later conflicts both external and internal. An infant must not produce his excreta at whatever moment he chooses, but when other people decide that he shall. In order to induce him to forgo these sources of pleasure, he is told that everything that has to do with these functions is improper and must be kept secret. This is where he is first obliged to exchange pleasure for social respectability. To begin with, his attitude to his excreta themselves is quite different. He feels no disgust at his faeces, values them as a portion of his own body with which he will not readily part, and makes use of them as his first 'gift', to distinguish people whom he values especially highly. Even after education has succeeded in its aim of making these inclinations alien to him, he carries on his high valuation of faeces in his estimate of 'gifts' and 'money'. On the other hand he seems to regard his achievements in urinating with peculiar pride.
Accordingly, I can now describe to you the form taken by a child's sexual life before the establishment of the primacy of the genitals, preparations for which are made in the first period of infancy preceding the latency period and which is permanently organized from puberty onwards. A kind of loose organization which may be called 'pregenital' exists during this early period. During this phase what stand in the forefront are not the genital component instincts but the sadistic and anal ones. The contrast between 'masculine' and 'feminine' plays no part here as yet. Its place is taken by the contrast between 'active' and 'passive', which may be described as a precursor of the sexual polarity and which later on is soldered to that polarity. What appears to us as masculine in the activities of this phase, when we look at it from the point of view of the genital phase, turns out to be an expression of an instinct for mastery which easily passes over into cruelty. Trends with a passive aim are attached to the erotogenic zone of the anal orifice, which is very important at this period. The instincts for looking and for gaining knowledge are powerfully at work; the genitals actually play a part in sexual life only as organs for the excretion of urine. The component instincts of this phase are not without objects, but those objects do not necessarily converge into a single object. The sadistic-anal organization is the immediate forerunner of the phase of genital primacy. Detailed study shows how much of it is retained in the later definitive shape of things and shows too the way in which its component instincts are compelled to take their place in the new genital organization. Behind the sadistic-anal phase of libidinal development we get a glimpse of a still earlier and more primitive stage of organization, in which the erotogenic zone of the mouth plays the chief part. As you will guess, the sexual activity of sensual sucking belongs to it. We must admire the understanding of the Ancient Egyptians who, in their art, represented children, including the God Horus, with a finger in their mouth. Only recently Abraham has given examples of the traces which this primitive oral phase leaves behind it in later sexual life.

I must beg the reader to bear in mind that I obtained this history of an infantile neurosis as a by-product, so to speak, during the analysis of an illness in mature years. I have therefore been obliged to put it together from even smaller fragments than are usually at one's disposal for purposes of synthesis. This task, which is not difficult in other respects, finds a natural limit when it is a question of forcing a structure which is itself in many dimensions on to the two-dimensional descriptive plane. I must therefore content myself with bringing forward fragmentary portions, which the reader can then put together into a living whole. The obsessional neurosis that has been described grew up, as has been repeatedly emphasized, on the basis of a sadistic-anal constitution. But we have hitherto discussed only one of the two chief factors - the patient's sadism and its transformations. Everything that concerns his anal erotism has intentionally been left on one side so that it might be brought together and discussed at this later stage.

Analysts have long been agreed that the multifarious instinctual impulses which are comprised under the name of anal erotism play an extraordinarily important part, which it would be quite impossible to over-estimate, in building up sexual life and mental activity in general. It is equally agreed that one of the most important manifestations of the transformed erotism derived from this source is to be found in the treatment of money, for in the course of life this precious material attracts on to itself the psychical interest which was originally proper to faeces, the product of the anal zone. We are accustomed to trace back interest in money, in so far as it is of a libidinal and not of a rational character, to excretory pleasure, and we expect normal people to keep their relations to money entirely free from libidinal influences and regulate them according to the demands of reality.
Intestinal disorders set in very early with him, and especially in the form which is the most frequent and, among children, the most normal - namely, incontinence. We shall certainly be right, however, in rejecting a pathological explanation of these earliest occurrences, and in regarding them only as evidence of the patient's intention not to let himself be disturbed or checked in the pleasure attached to the function of evacuation. He found a great deal of enjoyment (such as would tally with the natural coarseness of many classes of society, though not of his) in anal jokes and exhibitions, and this enjoyment had been retained by him until after the beginning of his later illness.

[1918b, 3558]

¹ I believe these can be no difficulty in substantiating the statement that infants only soil with their excrement people whom they know and are fond of; they do not consider strangers worthy of this distinction. In my Three Essays on the Theory of Sexuality (1905d) I mentioned the very first purpose to which faeces are put - namely, the auto-erotic stimulation of the intestinal mucous membrane. We now reach a further stage, at which a decisive part in the process of defaecation is played by the child's attitude to some object to whom he thus shows himself obedient or agreeable. This relation is one that persists; for even older children will only allow themselves to be assisted in defaecating and urinating by particular privileged persons, though in this connection the prospect of other forms of satisfaction is also involved.

[1918b, 3563]

Since the column of faeces stimulates the erotogenic mucous membrane of the bowel, it plays the part of an active organ in regard to it; it behaves just as the penis does to the vaginal mucous membrane, and acts as it were as its forerunner during the cloacal epoch. The handing over of faeces for the sake of (out of love for) some one else becomes a prototype of castration; it is the first occasion upon which an individual parts with a piece of his own body¹ in order to gain the favour of some other person whom he loves. So that a person's love of his own penis, which is in other respects narcissistic, is not without an element of anal erotism. 'Faeces', 'baby' and 'penis' thus form a unity, an unconscious concept (sit venia verbo) - the concept, namely, of 'a little one' that can become separated from one's body. Along these paths of association the libidinal cathexis may become displaced or intensified in ways which are pathologically important and which are revealed by analysis.

[1918b, 3566]

The sadistic-anal organization can easily be regarded as a continuation and development of the oral one. The violent muscular activity, directed upon the object, by which it is characterized, is to be explained as an action preparatory to eating. The eating then ceases to be a sexual aim, and the preparatory action becomes a sufficient aim in itself. The essential novelty, as compared with the previous stage, is that the receptive passive function becomes disengaged from the oral zone and attached to the anal zone. In this connection we can hardly fail to think of biological parallels or of the theory that the pregenital organizations in man should be regarded as vestiges of conditions which have been permanently retained in several classes of animals. The building up of the instinct for research out of its various components is another characteristic feature of this stage of development.

[1918b, 3584]

From that moment we had to face the problem of the later history of the anal-erotic instinctual impulses. What becomes of them when, owing to the establishment of a definitive genital organization, they have lost their importance in sexual life? Do they preserve their original nature, but in a state of repression? Are they sublimated or assimilated by transformation into character-traits? Or do they find a place within the new organization of sexuality characterized by genital primacy? Or, since none of these vicissitudes of anal erotism is likely to be the only one, to what extent and in what way does each of them share in deciding its fate? For the organic sources of anal erotism cannot of course be buried as a result of the emergence of the genital organization.

[1917c, 3599]
Along another path, a part of the erotism of the pregenital phase, too, becomes available for use in the phase of genital primacy. The baby is regarded as 'lumf' (cf. the analysis of 'Little Hans'), as something which becomes detached from the body by passing through the bowel. A certain amount of libidinal cathexis which originally attached to the contents of the bowel can thus be extended to the baby born through it. Linguistic evidence of this identity of baby and faeces is contained in the expression 'to give someone a baby'. For its faeces are the infant's first gift, a part of his body which he will give up only on persuasion by someone he loves, to whom indeed, he will make a spontaneous gift of it as a token of affection; for, as a rule, infants do not dirty strangers. (There are similar if less intense reactions with urine.) Defaecation affords the first occasion on which the child must decide between a narcissistic and an object-loving attitude. He either parts obediently with his faeces, 'sacrifices' them to his love, or else retains them for purposes of auto-erotic satisfaction and later as a means of asserting his own will. If he makes the latter choice we are in the presence of defiance (obstinacy) which, accordingly, springs from a narcissistic clinging to anal erotism.

[1917c, 3602]

By allowing common feeling to be our guide in deciding what features of human life are to be regarded as civilized, we have obtained a clear impression of the general picture of civilization; but it is true that so far we have discovered nothing that is not universally known. At the same time we have been careful not to fall in with the prejudice that civilization is synonymous with perfecting, that it is the road to perfection pre-ordained for men. But now a point of view presents itself which may lead in a different direction. The development of civilization appears to us as a peculiar process which mankind undergoes, and in which several things strike us as familiar. We may characterize this process with reference to the changes which it brings about in the familiar instinctual dispositions of human beings, to satisfy which is, after all, the economic task of our lives. A few of these instincts are used up in such a manner that something appears in their place which, in an individual, we describe as a character-trait. The most remarkable example of such a process is found in the anal erotism of young human beings. Their original interest in the excretory function, its organs and products, is changed in the course of their growth into a group of traits which are familiar to us as parsimony, a sense of order and cleanliness - qualities which, though valuable and welcome in themselves, may be intensified till they become markedly dominant and produce what is called the anal character. How this happens we do not know, but there is no doubt about the correctness of the finding.¹ Now we have seen that order and cleanliness are important requirements of civilization, although their vital necessity is not very apparent, any more than their suitability as sources of enjoyment. At this point we cannot fail to be struck by the similarity between the process of civilization and the libidinal development of the individual. Other instincts are induced to displace the conditions for their satisfaction, to lead them into other paths. In most cases this process coincides with that of the sublimation (of instinctual aims) with which we are familiar, but in some it can be differentiated from it. Sublimation of instinct is an especially conspicuous feature of cultural development; it is what makes it possible for higher psychic activities, scientific, artistic or ideological, to play such an important part in civilized life. If one were to yield to a first impression, one would say that sublimation is a vicissitude which has been forced upon the instincts entirely by civilization. But it would be wiser to reflect upon this a little longer. In the third place, finally, and this seems the most important of all, it is impossible to overlook the extent to which civilization is built up upon a renunciation of instinct, how much it presupposes precisely the non-satisfaction (by suppression, repression or some other means?) of powerful instincts. This 'cultural frustration' dominates the large field of social relationships between human beings. As we already know, it is the cause of the hostility against which all civilizations have to struggle. It will also make severe demands on our scientific work, and we shall have much to explain here. It is not easy to understand how it can become possible to deprive an instinct of satisfaction. Nor is doing so without danger. If the loss is not compensated for economically, one can be certain that serious disorders will ensue.

[1930a, 4494]
A social factor is also unmistakably present in the cultural trend towards cleanliness, which has received *ex post facto* justification in hygienic considerations but which manifested itself before their discovery. The incitement to cleanliness originates in an urge to get rid of the excreta, which have become disagreeable to the sense perceptions. We know that in the nursery things are different. The excreta arouse no disgust in children. They seem valuable to them as being a part of their own body which has come away from it. Here upbringing insists with special energy on hastening the course of development which lies ahead, and which should make the excreta worthless, disgusting, abhorrent and abominable. Such a reversal of values would scarcely be possible if the substances that are expelled from the body were not doomed by their strong smells to share the fate which overtook olfactory stimuli after man adopted the erect posture. Anal erotism, therefore, succumbs in the first instance to the 'organic repression' which paved the way to civilization. The existence of the social factor which is responsible for the further transformation of anal erotism is attested by the circumstance that, in spite of all man's developmental advances, he scarcely finds the smell of *his own* excreta repulsive, but only that of other people's. Thus a person who is not clean - who does not hide his excreta - is offending other people; he is showing no consideration for them. And this is confirmed by our strongest and commonest terms of abuse. It would be incomprehensible, too, that man should use the name of his most faithful friend in the animal world - the dog - as a term of abuse if that creature had not incurred his contempt through two characteristics: that it is an animal whose dominant sense is that of smell and one which has no horror of excrement, and that it is not ashamed of its sexual functions.

[1930a, 4495]

We have been able to study transformations of instinct and similar processes particularly in anal erotism, the excitations arising from the sources of the erotogenic anal zone, and we were surprised at the multiplicity of uses to which these instinctual impulses are put. It may not be easy, perhaps, to get free from the contempt into which this particular zone has fallen in the course of evolution. Let us therefore allow ourselves to be reminded by Abraham that embryologically the anus corresponds to the primitive mouth, which has migrated down to the end of the bowel. We have learnt, then, that after a person's own faeces, his excrement, has lost its value for him, this instinctual interest derived from the anal source passes over on to objects that can be presented as *gifts*. And this is rightly so, for faeces were the first gift that an infant could make, something he could part with out of love for whoever was looking after him. After this, corresponding exactly to analogous changes of meaning that occur in linguistic development, this ancient interest in faeces is transformed into the high valuation of *gold* and *money* but also makes a contribution to the affective cathexis of *baby* and *penis*. It is a universal conviction among children, who long retain the cloaca theory, that babies are born from the bowel like a piece of faeces: defaecation is the model of the act of birth. But the penis too has its fore-runner in the column of faeces which fills and stimulates the mucous membrane of the bowel. When a child, unwillingly enough, comes to realize that there are human creatures who do not possess a penis, that organ appears to him as something detachable from the body and becomes unmistakably analogous to the excrement, which was the first piece of bodily material that had to be renounced. A great part of anal erotism is thus carried over into a cathexis of the penis. But the interest in that part of the body has, in addition to its anal-erotic root, an oral one which is perhaps more powerful still: for when sucking has come to an end, the penis also becomes heir of the mother's nipple.

[1933a, 4705]
The processes at puberty thus establish the primacy of the genital zones; and, in a man, the penis, which has now become capable of erection, presses forward insistently towards the new sexual aim - penetration into a cavity in the body which excites his genital zone. Simultaneously on the psychical side the process of finding an object, for which preparations have been made from earliest childhood, is completed. At a time at which the first beginnings of sexual satisfaction are still linked with the taking of nourishment, the sexual instinct has a sexual object outside the infant's own body in the shape of his mother's breast. It is only later that the instinct loses that object, just at the time, perhaps, when the child is able to form a total idea of the person to whom the organ that is giving him satisfaction belongs. As a rule the sexual instinct then becomes auto-erotic, and not until the period of latency has been passed through is the original relation restored. There are thus good reasons why a child sucking at his mother's breast has become the prototype of every relation of love. The finding of an object is in fact a refinding of it.¹

THE SEXUAL OBJECT DURING EARLY INFANCY  But even after sexual activity has become detached from the taking of nourishment, an important part of this first and most significant of all sexual relations is left over, which helps to prepare for the choice of an object and thus to restore the happiness that has been lost. All through the period of latency children learn to feel for other people who help them in their helplessness and satisfy their needs a love which is on the model of, and a continuation of, their relation as sucklings to their nursing mother. There may perhaps be an inclination to dispute the possibility of identifying a child's affection and esteem for those who look after him with sexual love. I think, however, that a closer psychological examination may make it possible to establish this identity beyond any doubt. A child's intercourse with anyone responsible for his care affords him an unending source of sexual excitation and satisfaction from his erogenous zones. This is especially so since the person in charge of him, who, after all, is as a rule his mother, herself regards him with feelings that are derived from her own sexual life: she strokes him, kisses him, rocks him and quite clearly treats him as a substitute for a complete sexual object.¹ A mother would probably be horrified if she were made aware that all her marks of affection were rousing her child's sexual instinct and preparing for its later intensity. She regards what she does as asexual, 'pure' love, since, after all, she carefully avoids applying more excitations to the child's genitals than are unavoidable in nursery care. As we know, however, the sexual instinct is not aroused only by direct excitation of the genital zone. What we call affection will unfailingly show its effects one day on the genital zones as well. Moreover, if the mother understood more of the high importance of the part played by instincts in mental life as a whole - in all its ethical and psychical achievements - she would spare herself any self-reproaches even after her enlightenment. She is only fulfilling her task in teaching the child to love. After all, he is meant to grow up into a strong and capable person with vigorous sexual needs and to accomplish during his life all the things that human beings are urged to do by their instincts. It is true that an excess of parental affection does harm by causing precocious sexual maturity and also because, by spoiling the child, it makes him incapable in later life of temporarily doing without love or of being content with a smaller amount of it. One of the clearest indications that a child will later become neurotic is to be seen in an insatiable demand for his parents' affection. And on the other hand neuropathic parents, who are inclined as a rule to display excessive affection, are precisely those who are most likely by their caresses to arouse the child's disposition to neurotic illness. Incidentally, this example shows that there are ways more direct than inheritance by which neurotic parents can hand their disorder on to their children.

[1905d, 1536]
To-day we will follow yet another side of this development namely the relation of the component sexual instincts to their object. Or rather, we will make a hasty survey of this development and dwell somewhat longer on one of its rather late consequences. A few of the components of the sexual instinct, there, have an object from the first and hold fast to it - for instance, the instinct for mastery (sadism) and the scopophilic and epistemophilic instincts. Others, more definitely linked to particular erotogenic zones of the body, have one to begin with only so long as they are still attached to the non-sexual functions, and give it up when they become separated from them. Thus the first object of the oral component of the sexual instinct is the mother's breast which satisfies the infant's need for nourishment. The erotic component, which is satisfied simultaneously during the sucking, makes itself independent with the act of sensual sucking [lutschen]; it gives up the outside object and replaces it by an area of the subject's own body. The oral instinct becomes auto-erotic, as are the anal and other erotogenic instincts from the first. Further development, to put the matter as concisely as possible, has two aims: firstly, the abandonment of auto-erotism, the replacement of the subject's own body once more by an outside object, and secondly, the unification of the various objects of the separate instincts and their replacement by a single object. This can, of course, only be achieved if the object is again a whole body, similar to the subject's own. Nor can it be effected unless a number of the auto-erotic instinctual impulses are left behind as being unserviceable.

[1916-1917, 3396]

The Process of Finding an Object, and the Oedipus Complex. - In the first instance the oral component instinct finds satisfaction by attaching itself to the satiating of the desire for nourishment; and its object is the mother's breast. It then detaches itself, becomes independent and at the same time auto-erotic, that is, it finds an object in the child's own body. Others of the component instincts also start by being auto-erotic and are not until later diverted on to an external object. It is a particularly important fact that the component instincts belonging to the genital zone habitually pass through a period of intense auto-erotic satisfaction. The component instincts are not all equally serviceable in the final genital organization of libido; some of them (for instance, the anal components) are consequently left aside and suppressed, or undergo complicated transformations.

[1923a, 3922]
Children who are making use of the susceptibility to erotogenic stimulation of the anal zone betray themselves by holding back their stool till its accumulation brings about violent muscular contractions and, as it passes through the anus, is able to produce powerful stimulation of the mucous membrane. In so doing it must no doubt cause not only painful but also highly pleasurable sensations. One of the clearest signs of subsequent eccentricity or nervousness is to be seen when a baby obstinately refuses to empty his bowels when he is put on the pot - that is, when his nurse wants him to - and holds back that function till he himself chooses to exercise it. He is naturally not concerned with dirtying the bed, he is only anxious not to miss the subsidiary pleasure attached to defaecating. Educators are once more right when they describe children who keep the process back as 'naughty'.

[1905d, 1507]

The contents of the bowels, which act as a stimulating mass upon a sexually sensitive portion of mucous membrane, behave like forerunners of another organ, which is destined to come into action after the phase of childhood. But they have other important meanings for the infant. They are clearly treated as a part of the infant's own body and represent his first 'gift': by producing them he can express his active compliance with his environment and, by withholding them, his disobedience. From being a 'gift' they later come to acquire the meaning of 'baby' - for babies, according to one of the sexual theories of children, are acquired by eating and are born through the bowels.

[1905d, 1507]

The retention of the faecal mass, which is thus carried out intentionally by the child to begin with, in order to serve, as it were, as a masturbatory stimulus upon the anal zone or to be employed in his relation to the people looking after him, is also one of the roots of the constipation which is so common among neuropaths. Further, the whole significance of the anal zone is reflected in the fact that few neurotics are to be found without their special scatological practices, ceremonies, and so on, which they carefully keep secret.¹

[1905d, 1507]

Actual masturbatory stimulation of the anal zone by means of the finger, provoked by a centrally determined or peripherally maintained sensation of itching, is by no means rare among older children.

[1905d, 1507]

¹ [Footnote added 1920:] Lou Andreas-Salomé (1916), in a paper which has given us a very much deeper understanding of the significance of anal erotism, has shown how the history of the first prohibition which a child comes across - the prohibition against getting pleasure from anal activity and its products - has a decisive effect on his whole development. This must be the first occasion on which the infant has a glimpse of an environment hostile to his instinctual impulses, on which he learns to separate his own entity from this alien one and on which he carries out the first 'repression' of his possibilities for pleasure. From that time on, what is 'anal' remains the symbol of everything that is to be repudiated and excluded from life. The clear-cut distinction between anal and genital processes which is later insisted upon is contradicted by the close anatomical and functional analogies and relations which hold between them. The genital apparatus remains the neighbour of the cloaca, and actually 'in the case of women is only taken from it on lease'.

[1905d, 1507]
Thus in little Hans's sexual constitution the genital zone was from the outset the one among his erotogenic zones which afforded him the most intense pleasure. The only other similar pleasure of which he gave evidence was excretory pleasure, the pleasure attached to the orifices through which micturition and evacuation of the bowels are effected. In his final phantasy of bliss, with which his illness was overcome, he imagined he had children, whom he took to the W.C., whom he made to widdle, whose behinds he wiped - for whom, in short, he did 'everything one can do with children'; it therefore seems impossible to avoid the assumption that during the period when he himself had been looked after as an infant these same performances had been the source of pleasurable sensations for him. He had obtained this pleasure from his erotogenic zones with the help of the person who had looked after him - his mother, in fact; and thus the pleasure already pointed the way to object-choice. But it is just possible that at a still earlier date he had been in the habit of giving himself this pleasure auto-erotically - that he had been one of those children who like retaining their excreta till they can derive a voluptuous sensation from their evacuation. I say no more than that it is possible, because the matter was not cleared up in the analysis; the 'making a row with the legs' (kicking about), of which he was so much frightened later on, points in that direction. But in any case these sources of pleasure had no particularly striking importance with Hans, as they so often have with other children. He early became clean in his habits, and neither bed-wetting nor diurnal incontinence played any part during his first years; no trace was observed in him of any inclination to play with his excrement, a propensity which is so revolting in adults, and which commonly makes its reappearance at the termination of processes of psychical involution.

[1909b, 2092]

Thus forearmed we can proceed to the consideration of a suggestion which we shall certainly not be spared. 'Why', we shall be asked, 'are you so obstinate in describing as being already sexuality what on your own evidence are indefinable manifestations in childhood out of which sexual life will later develop? Why should you not be content instead with giving them a physiological description and simply say that in an infant at the breast we already observe activities, such as sensual sucking or holding back the excreta, which show us that he is striving for "organ-pleasure"? In that way you would have avoided the hypothesis, so repugnant to every feeling, of the smallest babies having a sexual life.' - Indeed, Gentlemen, I have no objection at all to organ-pleasure. I know that even the supreme pleasure of sexual union is only an organ-pleasure attached to the activity of the genitals. But can you tell me when this originally indifferent organ-pleasure acquires the sexual character which it undoubtedly possesses in the later phases of development? Do we know any more about 'organ-pleasure' than about sexuality? You will reply that it gains its sexual character precisely when the genitals begin to play their part; 'sexual' coincides with 'genital'. You will even reject the objection raised by the perversions by pointing out to me that in the majority of perversions a genital orgasm is after all aimed at, even if it is arrived at by a method other than the union of the genitals. You are certainly taking up a much stronger position in determining the characteristics of what is sexual if you knock out of it the relation to reproduction which is made untenable by the perversions and put genital activity in its place. But, if so, we are no longer far apart: it is only a question of the genital organs versus the other organs. What are you going to do, however, about the numerous experiences which show you that the genitals can be represented as regards their yield of pleasure by other organs, as in the case of kissing or of the perverse practices of voluptuaries or of the symptoms of hysteria? In that neurosis it is quite usual for signs of stimulation, sensations and innervations, and even the processes of erection, which belong properly to the genitals, to be displaced on to other, remote regions of the body - as, for instance, by transposition upwards, to the head and face. Being thus convinced that you have nothing to catch hold of for your characterization of what is sexual, you will no doubt have to make up your minds to follow my example and extend the description of being 'sexual' to the activities of early childhood, too, which strive for organ-pleasure.

[1916-1917, 3392]
The cruel component of the sexual instinct develops in childhood even more independently of
the sexual activities that are attached to erotogenic zones. Cruelty in general comes easily to
the childish nature, since the obstacle that brings the instinct for mastery to a halt at another
person's pain - namely a capacity for pity - is developed relatively late. The fundamental
psychological analysis of this instinct has, as we know, not yet been satisfactorily achieved. It
may be assumed that the impulse of cruelty arises from the instinct for mastery and appears at
a period of sexual life at which the genitals have not yet taken over their later role. It then
dominates a phase of sexual life which we shall later describe as a pregenital organization.
Children who distinguish themselves by special cruelty towards animals and playmates usually
give rise to a just suspicion of an intense and precocious sexual activity arising from erotogenic
zones; and, though all the sexual instincts may display simultaneous precocity, erotogenic
sexual activity seems, nevertheless, to be the primary one. The absence of the barrier of pity
brings with it a danger that the connection between the cruel and the erotogenic instincts, thus
established in childhood, may prove unbreakable in later life. Ever since Jean Jacques
Rousseau's *Confessions*, it has been well known to all educationalists that the painful
stimulation of the skin of the buttocks is one of the erotogenic roots of the passive instinct of
cruelty (masochism). The conclusion has rightly been drawn by them that corporal punishment,
which is usually applied to this part of the body, should not be inflicted upon any children whose
libido is liable to be forced into collateral channels by the later demands of cultural education.¹

We found from the study of neurotic disorders that beginnings of an organization of the sexual
instinctual components can be detected in the sexual life of children from its very beginning.
During a first, very early phase, oral erotism occupies most of the picture. A second of these
pregenital organizations is characterized by the predominance of sadism and anal erotism. It is
not until a third phase has been reached that the genital zones proper contribute their share in
determining sexual life, and in children this last phase is developed only so far as to a primacy
of the phallus.

The boy's anal erotism was not particularly noticeable. Under the influence of his sadism the
affectionate significance of faeces gave place to an aggressive one. A part was played in the
transformation of his sadism into masochism by a sense of guilt, the presence of which points to
developmental processes in spheres other than the sexual one.

His seduction continued to make its influence felt, by maintaining the passivity of his sexual
aim. It transformed his sadism to a great extent into the masochism which was its passive
counterpart. But it is questionable whether the seduction can be made entirely responsible for
this characteristic of passivity, for the child's reaction to his observation of intercourse at the age
of one and a half was already preponderantly a passive one. His sympathetic sexual excitement
expressed itself by his passing a stool, though it is true that in this behaviour an active element
is also to be distinguished. Side by side with the masochism which dominated his sexual
impulsions and also found expression in phantasies, his sadism, too, persisted and was
directed against small animals. His sexual researches had set in from the time of the seduction
and had been concerned, in essence, with two problems: the origin of children and the
possibility of losing the genitals. These researches wove themselves into the manifestations of
his instinctual impulses, and directed his sadistic propensities on to small animals as being
representatives of small children.
Unfortunately we can describe this state of things only as it affects the male child; the corresponding processes in the little girl are not known to us. The small boy undoubtedly perceives the distinction between men and women, but to begin with he has no occasion to connect it with a difference in their genitals. It is natural for him to assume that all other living beings, humans and animals, possess a genital like his own; indeed, we know that he looks for an organ analogous to his own in inanimate things as well.¹ This part of the body, which is easily excitable, prone to changes and so rich in sensations, occupies the boy’s interest to a high degree and is constantly setting new tasks to his instinct for research. He wants to see it in other people as well, so as to compare it with his own; and he behaves as though he had a vague idea that this organ could and should be bigger. The driving force which this male portion of the body will develop later at puberty expresses itself at this period of life mainly as an urge to investigate, as sexual curiosity. Many of the acts of exhibitionism and aggression which children commit, and which in later years would be judged without hesitation to be expressions of lust, prove in analysis to be experiments undertaken in the service of sexual research.

The communists believe that they have found the path to deliverance from our evils. According to them, man is wholly good and is well-disposed to his neighbour; but the institution of private property has corrupted his nature. The ownership of private wealth gives the individual power, and with it the temptation to ill-treat his neighbour; while the man who is excluded from possession is bound to rebel in hostility against his oppressor. If private property were abolished, all wealth held in common, and everyone allowed to share in the enjoyment of it, ill-will and hostility would disappear among men. Since everyone’s needs would be satisfied, no one would have any reason to regard another as his enemy; all would willingly undertake the work that was necessary. I have no concern with any economic criticisms of the communist system; I cannot enquire into whether the abolition of private property is expedient or advantageous.¹ But I am able to recognize that the psychological premises on which the system is based are an untenable illusion. In abolishing private property we deprive the human love of aggression of one of its instruments, certainly a strong one, though certainly not the strongest; but we have in no way altered the differences in power and influence which are misused by aggressiveness, nor have we altered anything in its nature. Aggressiveness was not created by property. It reigned almost without limit in primitive times, when property was still very scanty, and it already shows itself in the nursery almost before property has given up its primal, anal form; it forms the basis of every relation of affection and love among people (with the single exception, perhaps, of the mother’s relation to her male child). If we do away with personal rights over material wealth, there still remains prerogative in the field of sexual relationships, which is bound to become the source of the strongest dislike and the most violent hostility among men who in other respects are on an equal footing. If we were to remove this factor, too, by allowing complete freedom of sexual life and thus abolishing the family, the germ-cell of civilization, we cannot, it is true, easily foresee what new paths the development of civilization could take; but one thing we can expect, and that is that this indestructible feature of human nature will follow it there.

During this oral phase sadistic impulses already occur sporadically along with the appearance of the teeth. Their extent is far greater in the second phase, which we describe as the sadistic-anal one, because satisfaction is then sought in aggression and in the excretory function. Our justification for including aggressive urges under the libido is based on the view that sadism is an instinctual fusion of purely libidinal and purely destructive urges, a fusion which thenceforward persists uninterruptedly.¹

[1930a, 4505]

[1940a [1938], 4965]
The cruel component of the sexual instinct develops in childhood even more independently of the sexual activities that are attached to erogenous zones. Cruelty in general comes easily to the childish nature, since the obstacle that brings the instinct for mastery to a halt at another person's pain - namely a capacity for pity - is developed relatively late. The fundamental psychological analysis of this instinct has, as we know, not yet been satisfactorily achieved. It may be assumed that the impulse of cruelty arises from the instinct for mastery and appears at a period of sexual life at which the genitals have not yet taken over their later role. It then dominates a phase of sexual life which we shall later describe as a pregenital organization.

Children who distinguish themselves by special cruelty towards animals and playmates usually give rise to a just suspicion of an intense and precocious sexual activity arising from erogenous zones; and, though all the sexual instincts may display simultaneous precocity, erogenous sexual activity seems, nevertheless, to be the primary one. The absence of the barrier of pity brings with it a danger that the connection between the cruel and the erogenous instincts, thus established in childhood, may prove unbreakable in later life. Ever since Jean Jacques Rousseau's *Confessions*, it has been well known to all educationalists that the painful stimulation of the skin of the buttocks is one of the erogenous roots of the passive instinct of cruelty (masochism). The conclusion has rightly been drawn by them that corporal punishment, which is usually applied to this part of the body, should not be inflicted upon any children whose libido is liable to be forced into collateral channels by the later demands of cultural education.¹

But Hans was not by any means a bad character; he was not even one of those children who at his age still give free play to the propensity towards cruelty and violence which is a constituent of human nature. On the contrary, he had an unusually kind-hearted and affectionate disposition; his father reported that the transformation of aggressive tendencies into feelings of pity took place in him at a very early age. Long before the phobia he had become uneasy when he saw the horses in a merry-go-round being beaten; and he was never unmoved if any one wept in his presence. At one stage in the analysis a piece of suppressed sadism made its appearance in a particular context:¹ but it was suppressed sadism, and we shall presently have to discover from the content what it stood for and what it was meant to replace. And Hans deeply loved the father against whom he cherished these death-wishes; and while his intellect demurred to such a contradiction,² he could not help demonstrating the fact of its existence, by hitting his father and immediately afterwards kissing the place he had hit. We ourselves, too, must guard against making a difficulty of such a contradiction.³ Indeed, if it were not so, repressions and neuroses would perhaps never come about. In the adult these pairs of contrary emotions do not as a rule become simultaneously conscious except at the climaxes of passionate love; at other times they usually go on suppressing each other until one of them succeeds in keeping the other altogether out of sight. But in children they can exist peaceably side by side for quite a considerable time.

¹ [1905d, 1512]
² [1909b, 2097]
An important element in the theory of repression is the view that repression is not an event that occurs once but that it requires a permanent expenditure. If this expenditure were to cease, the repressed impulse, which is being fed all the time from its sources, would on the next occasion flow along the channels from which it had been forced away, and the repression would either fail in its purpose or would have to be repeated an indefinite number of times. Thus it is because instincts are continuous in their nature that the ego has to make its defensive action secure by a permanent expenditure. This action undertaken to protect repression is observable in analytic treatment as *resistance*. Resistance presupposes the existence of what I have called *anticathexis*. An anticathexis of this kind is clearly seen in obsessional neurosis. It appears there in the form of an alteration of the ego, as a reaction-formation in the ego, and is effected by the reinforcement of the attitude which is the opposite of the instinctual trend that has to be repressed - as, for instance, in pity, conscientiousness and cleanliness. These reaction-formations of obsessional neurosis are essentially exaggerations of the normal traits of character which develop during the latency period. The presence of an anticathexis in hysteria is much more difficult to detect, though theoretically it is equally dispensable. In hysteria, too, a certain amount of alteration of the ego through reaction-formation is unmistakable and in some circumstances becomes so marked that it forces itself on our attention as the principal symptom. The conflict due to ambivalence, for instance, is resolved in hysteria by this means. The subject's hatred of a person whom he loves is kept down by an exaggerated amount of tenderness for him and apprehensiveness about him. But the difference between reaction-formations in obsessional neurosis and in hysteria is that in the latter they do not have the universality of a character-trait but are confined to particular relationships. A hysterical woman, for instance, may be specially affectionate with her own children whom at bottom she hates; but she will not on that account be more loving in general than other women or even more affectionate to other children. The reaction-formation of hysteria clings tenaciously to a particular object and never spreads over into a general disposition of the ego, whereas what is characteristic of obsessional neurosis is precisely a spreading-over of this kind - a loosening of relations to the object and a facilitation of displacement in the choice of object.

[1926d, 4310]
A second pregenital phase is that of the sadistic-anal organization. Here the opposition between two currents, which runs through all sexual life, is already developed: they cannot yet, however, be described as 'masculine' and 'feminine', but only as 'active' and 'passive'. The activity is put into operation by the instinct for mastery through the agency of the somatic musculature; the organ which, more than any other, represents the passive sexual aim is the erotogenic mucous membrane of the anus. Both of these currents have objects, which, however, are not identical. Alongside these, other component instincts operate in an auto-erotic manner. In this phase, therefore, sexual polarity and an extraneous object are already observable. But organization and subordination to the reproductive function are still absent.²

AMBIVALENCE This form of sexual organization can persist throughout life and can permanently attract a large portion of sexual activity to itself. The predominance in it of sadism and the cloacal part played by the anal zone give it a quite peculiarly archaic colouring. It is further characterized by the fact that in it the opposing pairs of instincts are developed to an approximately equal extent, a state of affairs described by Bleuler's happily chosen term 'ambivalence'.

We found from the study of neurotic disorders that beginnings of an organization of the sexual instinctual components can be detected in the sexual life of children from its very beginning. During a first, very early phase, oral erotism occupies most of the picture. A second of these pregenital organizations is characterized by the predominance of sadism and anal erotism. It is not until a third phase has been reached that the genital zones proper contribute their share in determining sexual life, and in children this last phase is developed only so far as to a primacy of the phallus.

In men a high degree of this trend persists as a portion of their libido, and it serves to introduce the sexual act. When this urge makes itself felt at the first approach to a woman, it must make use of words, for two reasons; firstly, to announce itself to her, and secondly, because if the idea is aroused by speech it may induce a corresponding excitement in the woman herself and may awaken an inclination in her to passive exhibitionism. A wooing speech like this is not yet smut, but it passes over into it. If the woman's readiness emerges quickly the obscene speech has a short life; it yields at once to a sexual action. It is otherwise if quick readiness on the woman's part is not to be counted on, and if in place of it defensive reactions appear. In that case the sexually exciting speech becomes an aim in itself in the shape of smut. Since the sexual aggressiveness is held up in its advance towards the act, it pauses at the evocation of the excitement and derives pleasure from the signs of it in the woman. In so doing, the aggressiveness is no doubt altering its character as well, just as any libidinal impulse will if it is met by an obstacle. It becomes positively hostile and cruel, and it thus summons to its help against the obstacle the sadistic components of the sexual instinct.³
But it is precisely in the field of character-development that we come across a good analogy with the case we have been describing - a confirmation, that is, of the occurrence of the pregenital sadistic anal-erotic sexual organization. It is a well-known fact, and one that has given much ground for complaint, that after women have lost their genital function their character often undergoes a peculiar alteration. They become quarrelsome, vexatious and overbearing, petty and stingy; that is to say, they exhibit typically sadistic and anal-erotic traits which they did not possess earlier, during their period of womanliness. Writers of comedy and satirists have in all ages directed their invectives against the 'old dragon' into which the charming girl, the loving wife and the tender mother have been transformed. We can see that this alteration of character corresponds to a regression of sexual life to the pregenital sadistic and anal-erotic stage, in which we have discovered the disposition to obsessional neurosis. It seems, then, to be not only the precursor of the genital phase but often enough its successor as well, its termination after the genitals have fulfilled their function.

[1913i, 2629]

Accordingly, I can now describe to you the form taken by a child's sexual life before the establishment of the primacy of the genitals, preparations for which are made in the first period of infancy preceding the latency period and which is permanently organized from puberty onwards. A kind of loose organization which may be called 'pregenital' exists during this early period. During this phase what stand in the forefront are not the genital component instincts but the sadistic and anal ones. The contrast between 'masculine' and 'feminine' plays no part here as yet. Its place is taken by the contrast between 'active' and 'passive', which may be described as a precursor of the sexual polarity and which later on is soldered to that polarity. What appears to us as masculine in the activities of this phase, when we look at it from the point of view of the genital phase, turns out to be an expression of an instinct for mastery which easily passes over into cruelty. Trends with a passive aim are attached to the erotogenic zone of the anal orifice, which is very important at this period. The instincts for looking and for gaining knowledge are powerfully at work; the genitals actually play a part in sexual life only as organs for the excretion of urine. The component instincts of this phase are not without objects, but those objects do not necessarily converge into a single object. The sadistic-anal organization is the immediate forerunner of the phase of genital primacy. Detailed study shows how much of it is retained in the later definitive shape of things and shows too the way in which its component instincts are compelled to take their place in the new genital organization. Behind the sadistic-anal phase of libidinal development we get a glimpse of a still earlier and more primitive stage of organization, in which the erotogenic zone of the mouth plays the chief part. As you will guess, the sexual activity of sensual sucking belongs to it. We must admire the understanding of the Ancient Egyptians who, in their art, represented children, including the God Horus, with a finger in their mouth. Only recently Abraham has given examples of the traces which this primitive oral phase leaves behind it in later sexual life.

[1916-1917, 3395]
One of the patient's pieces of information will make it easier for us to understand the alteration in his character which appeared during his parents' absence as a somewhat indirect consequence of his seduction. He said that he gave up masturbating very soon after his Nanya's refusal and threat. *His sexual life, therefore, which was beginning to come under the sway of the genital zone, gave way before an external obstacle, and was thrown back by its influence into an earlier phase of pregenital organization.* As a result of the suppression of his masturbation, the boy's sexual life took on a sadistic-anal character. He became irritable and a tormentor, and gratified himself in this way at the expense of animals and humans. His principal object was his beloved Nanya, and he knew how to torment her till she burst into tears. In this way he revenged himself on her for the refusal he had met with, and at the same time gratified his sexual lust in the form which corresponded to his present regressive phase. He began to be cruel to small animals, to catch flies and pull off their wings, to crush beetles underfoot; in his imagination he liked beating large animals (horses) as well. All of these, then, were active and sadistic proceedings; we shall discuss his anal impulses at this period in a later connection.

[1918b, 3516]

The sadistic-anal organization can easily be regarded as a continuation and development of the oral one. The violent muscular activity, directed upon the object, by which it is characterized, is to be explained as an action preparatory to eating. The eating then ceases to be a sexual aim, and the preparatory action becomes a sufficient aim in itself. The essential novelty, as compared with the previous stage, is that the receptive passive function becomes disengaged from the oral zone and attached to the anal zone. In this connection we can hardly fail to think of biological parallels or of the theory that the pregenital organizations in man should be regarded as vestiges of conditions which have been permanently retained in several classes of animals. The building up of the instinct for research out of its various components is another characteristic feature of this stage of development.

[1918b, 3584]

Thus the sadistic-anal organization continued to exist during the phase of the animal phobia which now set in, only it suffered an admixture of anxiety-phenomena. The child persisted in his sadistic as well as in his masochistic activities, but he reacted with anxiety to a portion of them; the conversion of his sadism into its opposite probably made further progress.

[1918b, 3585]

As a result of numerous impressions, and in particular of one specially cogent analytical observation, I came to the conclusion a few years later that in the development of the libido in man the phase of genital primacy must be preceded by a 'pregenital organization' in which sadism and anal erotism play the leading parts.

[1917c, 3599]

From that moment we had to face the problem of the later history of the anal-erotic instinctual impulses. What becomes of them when, owing to the establishment of a definitive genital organization, they have lost their importance in sexual life? Do they preserve their original nature, but in a state of repression? Are they sublimated or assimilated by transformation into character-traits? Or do they find a place within the new organization of sexuality characterized by genital primacy? Or, since none of these vicissitudes of anal erotism is likely to be the only one, to what extent and in what way does each of them share in deciding its fate? For the organic sources of anal erotism cannot of course be buried as a result of the emergence of the genital organization.

[1917c, 3599]
In the obscurity that reigns at present in the theory of the instincts, it would be unwise to reject any idea that promises to throw light on it. We started out from the great opposition between the life and death instincts. Now object-love itself presents us with a second example of a similar polarity - that between love (or other affection) and hate (or aggressiveness). If only we could succeed in relating these two polarities to each other and in deriving one from the other! From the very first we recognized the presence of a sadistic component in the sexual instinct.¹ As we know, it can make itself independent and can, in the form of a perversion, dominate an individual's entire sexual activity. It also emerges as a predominant component instinct in one of the 'pregenital organizations', as I have named them. But how can the sadistic instinct, whose aim it is to injure the object, be derived from Eros, the preserver of life? Is it not plausible to suppose that this sadism is in fact a death instinct which, under the influence of the narcissistic libido, has been forced away from the ego and has consequently only emerged in relation to the object? It now enters the service of the sexual function. During the oral stage of organization of the libido, the act of obtaining erotic mastery over an object coincides with that object's destruction; later, the sadistic instinct separates off, and finally, at the stage of genital primacy, it takes on, for the purposes of reproduction, the function of overpowering the sexual object to the extent necessary for carrying out the sexual act. It might indeed be said that the sadism which has been forced out of the ego has pointed the way for the libidinal components of the sexual instinct, and that these follow after it to the object. Wherever the original sadism has undergone no mitigation or intermixture, we find the familiar ambivalence of love and hate in erotic life.

The Development of the Libido. - The sexual instinct, the dynamic manifestation of which in mental life we shall call 'libido', is made up of component instincts into which it may once more break up and which are only gradually united into well-defined organizations. The sources of these component instincts are the organs of the body and in particular certain specially marked erotogenic zones; but contributions are made to libido from every important functional process in the body. At first the individual component instincts strive for satisfaction independently of one another, but in the course of development they become more and more convergent and concentrated. The first (pregenital) stage of organization to be discerned is the oral one, in which - in conformity with the sucking's predominant interest - the oral zone plays the leading part. This is followed by the sadistic-anal organization, in which the anal zone and the component instinct of sadism are particularly prominent; at this stage the difference between the sexes is represented by the contrast between active and passive. The third and final stage of organization is that in which the majority of the component instincts converge under the primacy of the genital zones. As a rule this development is passed through swiftly and unobtrusively; but some individual portions of the instincts remain behind at the prodromal stages of the process and thus give rise to fixations of libido, which are important as constituting predispositions for subsequent irruptions of repressed impulses and which stand in a definite relation to the later development of neuroses and perversions. (See the article on 'The Libido Theory'.)

It is not unimportant to bear in mind what transformations are undergone, during the sexual development of childhood, by the polarity of sex with which we are familiar. A first antithesis is introduced with the choice of object, which, of course, presupposes a subject and an object. At the stage of the pregenital sadistic-anal organization, there is as yet no question of male and female; the antithesis between active and passive is the dominant one.¹ At the following stage of infantile genital organization, which we now know about, maleness exists, but not femaleness. The antithesis here is between having a male genital and being castrated. It is not until development has reached its completion at puberty that the sexual polarity coincides with male and female. Maleness combines subject, activity and possession of the penis; femaleness takes over object and passivity. The vagina is now valued as a place of shelter for the penis; it enters into the heritage of the womb.
Erotogenic masochism accompanies the libido through all its developmental phases and derives from them its changing psychical coatings. The fear of being eaten up by the totem animal (the father) originates from the primitive oral organization; the wish to be beaten by the father comes from the sadistic-anal phase which follows it; castration, although it is later disavowed, enters into the content of masochistic phantasies as a precipitate of the phallic stage or organization;¹ and from the final genital organization there arise, of course, the situations of being copulated with and of giving birth, which are characteristic of femaleness. The part played in masochism by the nates, too, is easily understandable, apart from its obvious basis in reality. The nates are the part of the body which is given erotogenic preference in the sadistic-anal phase, like the breast in the oral phase and the penis in the genital phase. [1924c, 4077]

As regards the metapsychological explanation of regression, I am inclined to find it in a 'defusion of instinct', in a detachment of the erotic components which, with the onset of the genital stage, had joined the destructive cathexes belonging to the sadistic phase. [1926d, 4273]
AMBIVALENCE   This form of sexual organization can persist throughout life and can permanently attract a large portion of sexual activity to itself. The predominance in it of sadism and the cloacal part played by the anal zone give it a quite peculiarly archaic colouring. It is further characterized by the fact that in it the opposing pairs of instincts are developed to an approximately equal extent, a state of affairs described by Bleuler's happily chosen term 'ambivalence'.
[1905d, 1517]

So far all this is trite repetition. And you must not suppose that the many things I have not mentioned this time no longer hold good. This repetition was necessary so that I might use it as the starting-point for a report on the advances in our knowledge. We can boast of having learnt much that is new, particularly about the early organizations of the libido, and of having obtained a clearer grasp of the significance of what is old; and I will give you at least a few examples to demonstrate this. Abraham showed in 1924 that two stages can be distinguished in the sadistic-anal phase. The earlier of these is dominated by the destructive trends of destroying and losing, the later one by trends friendly towards objects - those of keeping and possessing. It is in the middle of this phase, therefore, that consideration for the object makes its first appearance as a precursor of a later erotic cathexis. We are equally justified in making a similar subdivision in the first, oral phase. In the first sub-stage what is in question is only oral incorporation, there is no ambivalence at all in the relation to the object - the mother's breast. The second stage, characterized by the emergence of the biting activity, may be described as the 'oral-sadistic' one; it exhibits for the first time the phenomena of ambivalence, which become so much clearer afterwards, in the following sadistic-anal phase. The value of these new distinctions is to be seen especially if we look for the dispositional points in the development of the libido in the case of particular neuroses, such as obsessional neurosis or melancholia. You must here recall to mind what we have learnt about the connection between fixation of the libido, disposition and regression.
[1933a, 4704]
I shall now endeavour (and I think the attempt is neither unnecessary nor unjustifiable) to show that the knowledge of psychological processes, which, thanks to psycho-analysis, we now possess, already enables us to understand the part played by a homosexual wish in the development of paranoia. Recent investigations¹ have directed our attention to a stage in the development of the libido which it passes through on the way from auto-erotism to object-love.² This stage has been given the name of narcissism. What happens is this. There comes a time in the development of the individual at which he unifies his sexual instincts (which have hitherto been engaged in auto-erotic activities) in order to obtain a love-object; and he begins by taking himself, his own body, as his love-object, and only subsequently proceeds from this to the choice of some person other than himself as his object. This half-way phase between auto-erotism and object-love may perhaps be indispensable normally; but it appears that many people linger unusually long in this condition, and that many of its features are carried over by them into the later stages of their development. What is of chief importance in the subject's self thus chosen as a love object may already be the genitals. The line of development then leads on to the choice of an external object with similar genitals - that is, to homosexual object-choice - and thence to heterosexuality. People who are manifest homosexuals in later life have, it may be presumed, never emancipated themselves from the binding condition that the object of their choice must possess genitals like their own; and in this connection the infantile sexual theories which attribute the same kind of genitals to both sexes exert much influence.

¹[1911c, 2430]
²(1) Our first reflection will tell us that it cannot be the case that this detachment of the libido occurs exclusively in paranoia; nor can it be that, where it occurs elsewhere, it has such disastrous consequences. It is quite possible that a detachment of the libido is the essential and regular mechanism of every repression. We can have no positive knowledge on that point until the other disorders that are based upon repression have been similarly examined. But it is certain that in normal mental life (and not only in periods of mourning) we are constantly detaching our libido in this way from people or from other objects without falling ill. When Faust freed himself from the world by uttering his curses, the result was not a paranoia or any other neurosis but simply a certain general frame of mind. The detachment of the libido, therefore, cannot in itself be the pathogenic factor in paranoia; there must be some special characteristic which distinguishes a paranoic detachment of the libido from other kinds. It is not difficult to suggest what that characteristic may be. What use is made of the libido after it has been set free by the process of detachment? A normal person will at once begin looking about for a substitute for the lost attachment; and until that substitute has been found the liberated libido will be kept in suspension within his mind, and will there give rise to tensions and colour his mood. In hysteria the liberated libido becomes transformed into somatic innervations or into anxiety. But in paranoia the clinical evidence goes to show that the libido, after it has been withdrawn from the object, is put to a special use. It will be remembered that the majority of cases of paranoia exhibit traces of megalomania, and that megalomania can by itself constitute a paranoia. From this it may be concluded that in paranoia the liberated libido becomes attached to the ego, and is used for the aggrandizement of the ego. A return is thus made to the stage of narcissism (known to us from the development of the libido), in which a person's only sexual object is his own ego. On the basis of this clinical evidence we can suppose that paranoics have brought along with them a fixation at the stage of narcissism, and we can assert that the length of the step back from sublimated homosexuality to narcissism is a measure of the amount of regression characteristic of paranoia.

²[1911c, 2438]
This is the starting-point of the small new fragment of theory which I have formulated. It is of course only in appearance that it is based on this one observation; actually it brings together a large number of earlier impressions, though an understanding of them was only made possible by this last experience. I told myself that my schematic picture of the development of the libidinal function called for an extra insertion in it. To begin with, I had only distinguished, first the phase of auto-erotism during which the subject's component instincts, each on its own account, seek for the satisfaction of their desires in his own body, and then the combination of all the component instincts for the choice of an object, under the primacy of the genitals acting on behalf of reproduction. The analysis of the paraphrenias has, as we know, necessitated the insertion between them of a stage of narcissism, during which the choice of an object has already taken place but that object coincides with the subject's own ego. And now we see the need for yet another stage to be inserted before the final shape is reached - a stage in which the component instincts have already come together for the choice of an object and that object is already something extraneous in contrast to the subject's own self, but in which the primacy of the genital zones has not yet been established. On the contrary, the component instincts which dominate this pregential organization of sexual life are the anal-erotic and sadistic ones.

Further study has shown that it is expedient and indeed indispensable to insert a third stage between these two, or, putting it in another way, to divide the first stage, that of auto-erotism, into two. At this intermediate stage, the importance of which is being made more and more evident by research, the hitherto isolated sexual instincts have already come together into a single whole and have also found an object. But this object is not an external one, extraneous to the subject, but it is his own ego, which has been constituted at about this same time. Bearing in mind pathological fixations of this new stage, which become observable later, we have given it the name of 'narcissism'. The subject behaves as though he were in love with himself; his egoistic instincts and his libidinal wishes are not yet separable under our analysis.

Although we are not yet in a position to describe with sufficient accuracy the characteristics of this narcissistic stage, at which the hitherto dissociated sexual instincts come together into a single unity and cathect the ego as an object, we suspect already that this narcissistic organization is never wholly abandoned. A human being remains to some extent narcissistic even after he has found external objects for his libido. The cathexes of objects which he effects are as it were emanations of the libido that still remains in his ego and can be drawn back into it once more. The state of being in love, which is psychologically so remarkable and is the normal prototype of the psychoses, shows these emanations at their maximum compared to the level of self-love.

Primitive men and neurotics, as we have seen, attach a high valuation - in our eyes an over-valuation - to psychical acts. This attitude may plausibly be brought into relation with narcissism and regarded as an essential component of it. It may be said that in primitive men the process of thinking is still to a great extent sexualized. This is the origin of their belief in the omnipotence of thoughts, their unshakable confidence in the possibility of controlling the world and their inaccessibility to the experiences, so easily obtainable, which could teach them man's true position in the universe. As regards neurotics, we find that on the one hand a considerable part of this primitive attitude has survived in their constitution, and on the other hand that the sexual repression that has occurred in them has brought about a further sexualization of their thinking processes. The psychological results must be the same in both cases, whether the libidinal hypercathexis of thinking is an original one or has been produced by regression: intellectual narcissism and the omnipotence of thoughts.¹
If we may regard the existence among primitive races of the omnipotence of thoughts as evidence in favour of narcissism, we are encouraged to attempt a comparison between the phases in the development of men's view of the universe and the stages of an individual's libidinal development. The animistic phase would correspond to narcissism both chronologically and in its content; the religious phase would correspond to the stage of object-choice of which the characteristic is a child's attachment to his parents; while the scientific phase would have an exact counterpart in the stage at which an individual has reached maturity, has renounced the pleasure principle, adjusted himself to reality and turned to the external world for the object of his desires.¹

¹ I will only briefly allude here to the fact that the original narcissism of children has a decisive influence upon our view of the development of their character and excludes the possibility of their having any primary sense of inferiority.

¹ I assume that at this early narcissistic stage cathexes arising from libidinal and from other sources of excitation may still be indistinguishable from one another.

The overmastering interest which must be felt in psycho-analysis by the theory of education is based upon a fact which has become evident. Only someone who can feel his way into the minds of children can be capable of educating them; and we grown-up people cannot understand children because we no longer understand our own childhood. Our infantile amnesia proves that we have grown estranged from our childhood. Psycho-analysis has brought to light the wishes, the thought structures and the developmental processes of childhood. All earlier attempts in this direction have been in the highest degree incomplete and misleading because they have entirely overlooked the inestimably important factor of sexuality in its physical and mental manifestations. The incredulous astonishment which meets the most certainly established findings of psycho-analysis on the subject of childhood - the Oedipus complex, self-love (or 'narcissism'), the disposition to perversions, anal erotism, sexual curiosity - is a measure of the gulf which separates our mental life, our judgements of value and, indeed, our processes of thought from those of even normal children.

The term narcissism is derived from clinical description and was chosen by Paul Näcke in 1899 to denote the attitude of a person who treats his own body in the same way in which the body of a sexual object is ordinarily treated - who looks at it, that is to say, strokes it and fondles it till he obtains complete satisfaction through these activities. Developed to this degree, narcissism has the significance of a perversion that has absorbed the whole of the subject's sexual life, and it will consequently exhibit the characteristics which we expect to meet with in the study of all perversions.

Psycho-analytic observers were subsequently struck by the fact that individual features of the narcissistic attitude are found in many people who suffer from other disorders - for instance, as Sadger has pointed out, in homosexuals - and finally it seemed probable that an allocation of the libido such as deserved to be described as narcissism might be present far more extensively, and that it might claim a place in the regular course of human sexual development.¹ Difficulties in psycho-analytic work upon neurotics led to the same supposition, for it seemed as though this kind of narcissistic attitude in them constituted one of the limits to their susceptibility to influence. Narcissism in this sense would not be a perversion, but the libidinal complement to the egoism of the instinct of self-preservation, a measure of which may justifiably be attributed to every living creature.
A pressing motive for occupying ourselves with the conception of a primary and normal narcissism arose when the attempt was made to subsume what we know of dementia praecox (Kraepelin) or schizophrenia (Bleuler) under the hypothesis of the libido theory. Patients of this kind, whom I have proposed to term paraphrenics, display two fundamental characteristics: megalomania and diversion of their interest from the external world - from people and things. In consequence of the latter change, they become inaccessible to the influence of psycho-analysis and cannot be cured by our efforts. But the paraphrenic's turning away from the external world needs to be more precisely characterized. A patient suffering from hysteria or obsessional neurosis has also, as far as his illness extends, given up his relation to reality. But analysis shows that he has by no means broken off his erotic relations to people and things. He still retains them in phantasy; i.e. he has, on the one hand, substituted for real objects imaginary ones from his memory, or has mixed the latter with the former; and on the other hand, he has renounced the initiation of motor activities for the attainment of his aims in connection with those objects. Only to this condition of the libido may we legitimately apply the term 'introversion' of the libido which is used by Jung indiscriminately. It is otherwise with the paraphrenic. He seems really to have withdrawn his libido from people and things in the external world, without replacing them by others in phantasy. When he does so replace them, the process seems to be a secondary one and to be part of an attempt at recovery, designed to lead the libido back to objects.¹

[1914c, 2932]

The question arises: What happens to the libido which has been withdrawn from external objects in schizophrenia? The megalomania characteristic of these states points the way. This megalomania has no doubt come into being at the expense of object-libido. The libido that has been withdrawn from the external world has been directed to the ego and thus gives rise to an attitude which may be called narcissism. But the megalomania itself is no new creation; on the contrary, it is, as we know, a magnification and plainer manifestation of a condition which had already existed previously. This leads us to look upon the narcissism which arises through the drawing in of object-cathexes as a secondary one, superimposed upon a primary narcissism that is obscured by a number of different influences.

[1914c, 2932]
This extension of the libido theory - in my opinion, a legitimate one - receives reinforcement from a third quarter, namely, from our observations and views on the mental life of children and primitive peoples. In the latter we find characteristics which, if they occurred singly, might be put down to megalomania: an over-estimation of the power of their wishes and mental acts, the 'omnipotence of thoughts', a belief in the thaumaturgic force of words, and a technique for dealing with the external world - 'magic' - which appears to be a logical application of these grandiose premisses.¹ In the children of to-day, whose development is much more obscure to us, we expect to find an exactly analogous attitude towards the external world.² Thus we form the idea of there being an original libidinal cathexis of the ego, from which some is later given off to objects, but which fundamentally persists and is related to the object-cathexes much as the body of an amoeba is related to the pseudopodia which it puts out. In our researches, taking, as they did, neurotic symptoms for their starting-point, this part of the allocation of libido necessarily remained hidden from us at the outset. All that we noticed were the emanations of this libido - the object-cathexes, which can be sent out and drawn back again. We see also, broadly speaking, an antithesis between ego-libido and object-libido. The more of the one is employed, the more the other becomes depleted. The highest phase of development of which object-libido is capable is seen in the state of being in love, when the subject seems to give up his own personality in favour of an object-cathexis; while we have the opposite condition in the paranoid's phantasy (or self-perception) of the 'end of the world'.³ Finally, as regards the differentiation of psychical energies, we are led to the conclusion that to begin with, during the state of narcissism, they exist together and that our analysis is too coarse to distinguish between them; not until there is object-cathexis is it possible to discriminate a sexual energy - the libido - from an energy of the ego-instincts.

[1914c, 2933]

Before going any further I must touch on two questions which lead us to the heart of the difficulties of our subject. In the first place, what is the relation of the narcissism of which we are now speaking to auto-erotism, which we have described as an early state of the libido? Secondly, if we grant the ego a primary cathexis of libido, why is there any necessity for further distinguishing a sexual libido from a non-sexual energy of the ego-instincts? Would not the postulation of a single kind of psychical energy save us all the difficulties of differentiating an energy of the ego-instincts from ego-libido, and ego-libido from object-libido?

[1914c, 2934]

Certain special difficulties seem to me to lie in the way of a direct study of narcissism. Our chief means of access to it will probably remain the analysis of the paraphrenias. Just as the transference neuroses have enabled us to trace the libidinal instinctual impulses, so dementia praecox and paranoia will give us an insight into the psychology of the ego. Once more, in order to arrive at an understanding of what seems so simple in normal phenomena, we shall have to turn to the field of pathology with its distortions and exaggerations. At the same time, other means of approach remain open to us, by which we may obtain a better knowledge of narcissism. These I shall now discuss in the following order: the study of organic disease, of hypochondria and of the erotic life of the sexes.

[1914c, 2938]
In estimating the influence of organic disease upon the distribution of libido, I follow a suggestion made to me orally by Sándor Ferenczi. It is universally known, and we take it as a matter of course, that a person who is tormented by organic pain and discomfort gives up his interest in the things of the external world, in so far as they do not concern his suffering. Closer observation teaches us that he also withdraws *libidinal* interest from his love-objects: so long as he suffers, he ceases to love. The commonplace nature of this fact is no reason why we should be deterred from translating it into terms of the libido theory. We should then say: (the sick man withdraws his libidinal cathexes back upon his own ego, and sends them out again when he recovers. 'Concentrated is his soul', says Wilhelm Busch of the poet suffering from toothache, 'in his molar's narrow hole.' Here libido and ego-interest share the same fate and are once more indistinguishable from each other. The familiar egoism of the sick person covers both. We find it so natural because we are certain that in the same situation we should behave in just the same way. The way in which a lover's feelings, however strong, are banished by bodily ailments, and suddenly replaced by complete indifference, is a theme which has been exploited by comic writers to an appropriate extent.

[1914c, 2938]

We have, however, not concluded that human beings are divided into two sharply differentiated groups, according as their object-choice conforms to the anaclitic or to the narcissistic type; we assume rather that both kinds of object-choice are open to each individual, though he may show a preference for one or the other. We say that a human being has originally two sexual objects - himself and the woman who nurses him - and in doing so we are postulating a primary narcissism in everyone, which may in some cases manifest itself in a dominating fashion in his object-choice.

[1914c, 2943]
A comparison of the male and female sexes then shows that there are fundamental differences between them in respect of their type of object-choice, although these differences are of course not universal. Complete object-love of the attachment type is, properly speaking, characteristic of the male. It displays the marked sexual overvaluation which is doubtless derived from the child's original narcissism and thus corresponds to a transference of that narcissism to the sexual object. This sexual overvaluation is the origin of the peculiar state of being in love, a state suggestive of a neurotic compulsion, which is thus traceable to an impoverishment of the ego as regards libido in favour of the love-object. A different course is followed in the type of female most frequently met with, which is probably the purest and truest one. With the onset of puberty the maturing of the female sexual organs, which up till then have been in a condition of latency, seems to bring about an intensification of the original narcissism, and this is unfavourable to the development of a true object-choice with its accompanying sexual overvaluation. Women, especially if they grow up with good looks, develop a certain self-contentment which compensates them for the social restrictions that are imposed upon them in their choice of object. Strictly speaking, it is only themselves that such women love with an intensity comparable to that of the man's love for them. Nor does their need lie in the direction of loving, but of being loved; and the man who fulfils this condition is the one who finds favour with them. The importance of this type of woman for the erotic life of mankind is to be rated very high. Such women have the greatest fascination for men, not only for aesthetic reasons, since as a rule they are the most beautiful, but also because of a combination of interesting psychological factors. For it seems very evident that another person's narcissism has a great attraction for those who have renounced part of their own narcissism and are in search of object-love. The charm of a child lies to a great extent in his narcissism, his self-contentment and inaccessibility, just as does the charm of certain animals which seem not to concern themselves about us, such as cats and the large beasts of prey. Indeed, even great criminals and humorists, as they are represented in literature, compel our interest by the narcissistic consistency with which they manage to keep away from their ego anything that would diminish it. It is as if we envied them for maintaining a blissful state of mind - an unassailable libidinal position which we ourselves have since abandoned. The great charm of narcissistic women has, however, its reverse side; a large part of the lover's dissatisfaction, of his doubts of the woman's love, of his complaints of her enigmatic nature, has its root in this incongruity between the types of object-choice. [1914c, 2943]
The primary narcissism of children which we have assumed and which forms one of the postulates of our theories of the libido, is less easy to grasp by direct observation than to confirm by inference from elsewhere. If we look at the attitude of affectionate parents towards their children, we have to recognize that it is a revival and reproduction of their own narcissism, which they have long since abandoned. The trustworthy pointer constituted by overvaluation, which we have already recognized as a narcissistic stigma in the case of object-choice, dominates, as we all know, their emotional attitude. Thus they are under a compulsion to ascribe every perfection to the child - which sober observation would find no occasion to do - and to conceal and forget all his shortcomings. (Incidentally, the denial of sexuality in children is connected with this.) Moreover, they are inclined to suspend in the child's favour the operation of all the cultural acquisitions which their own narcissism has been forced to respect, and to renew on his behalf the claims to privileges which were long ago given up by themselves. The child shall have a better time than his parents; he shall not be subject to the necessities which they have recognized as paramount in life. Illness, death, renunciation of enjoyment, restrictions on his own will, shall not touch him; the laws of nature and of society shall be abrogated in his favour; he shall once more really be the centre and core of creation - 'His Majesty the Baby',¹ as we once fancied ourselves. The child shall fulfil those wishful dreams of the parents which they never carried out - the boy shall become a great man and a hero in his father's place, and the girl shall marry a prince as a tardy compensation for her mother. At the most touchy point in the narcissistic system, the immortality of the ego, which is so hard pressed by reality, security is achieved by taking refuge in the child. Parental love, which is so moving and at bottom so childish, is nothing but the parents' narcissism born again, which, transformed into object-love, unmistakably reveals its former nature.

The disturbances to which a child's original narcissism is exposed, the reactions with which he seeks to protect himself from them and the paths into which he is forced in doing so - these are themes which I propose to leave on one side, as an important field of work which still awaits exploration. The most significant portion of it, however, can be singled out in the shape of the 'castration complex' (in boys, anxiety about the penis - in girls, envy for the penis) and treated in connection with the effect of early deterrence from sexual activity. Psycho-analytic research ordinarily enables us to trace the vicissitudes undergone by the libidinal instincts when these, isolated from the ego-instincts, are placed in opposition to them; but in the particular field of the castration complex, it allows us to infer the existence of an epoch and a psychical situation in which the two groups of instincts, still operating in unison and inseparably mingled, make their appearance as narcissistic interests. It is from this context that Adler has derived his concept of the 'masculine protest', which he has elevated almost to the position of the sole motive force in the formation of character and neurosis alike and which he bases not on a narcissistic, and therefore still a libidinal, trend, but on a social valuation. Psycho-analytic research has from the very beginning recognized the existence and importance of the 'masculine protest', but it has regarded it, in opposition to Adler, as narcissistic in nature and derived from the castration complex. The 'masculine protest' is concerned in the formation of character, into the genesis of which it enters along with many other factors, but it is completely unsuited for explaining the problems of the neuroses, with regard to which Adler takes account of nothing but the manner in which they serve the ego-instincts. I find it quite impossible to place the genesis of neurosis upon the narrow basis of the castration complex, however powerfully it may come to the fore in men among their resistances to the cure of a neurosis. Incidentally, I know of cases of neurosis in which the 'masculine protest', or, as we regard it, the castration complex, plays no pathogenic part, and even fails to appear at all.

¹[1914c, 2945]
Observation of normal adults shows that their former megalomania has been damped down and that the psychical characteristics from which we inferred their infantile narcissism have been effaced. What has become of their ego-libido? Are we to suppose that the whole amount of it has passed into object-cathexes? Such a possibility is plainly contrary to the whole trend of our argument; but we may find a hint at another answer to the question in the psychology of repression.
[1914c, 2947]

This ideal ego is now the target of the self-love which was enjoyed in childhood by the actual ego. The subject's narcissism makes its appearance displaced on to this new ideal ego, which, like the infantile ego, finds itself possessed of every perfection that is of value. As always where the libido is concerned, man has here again shown himself incapable of giving up a satisfaction he had once enjoyed. He is not willing to forgo the narcissistic perfection of his childhood; and when, as he grows up, he is disturbed by the admonitions of others and by the awakening of his own critical judgement, so that he can no longer retain that perfection, he seeks to recover it in the new form of an ego ideal. What he projects before him as his ideal is the substitute for the lost narcissism of his childhood in which he was his own ideal.
[1914c, 2948]

The formation of an ego ideal is often confused with the sublimation of instinct, to the detriment of our understanding of the facts. A man who has exchanged his narcissism for homage to a high ego ideal has not necessarily on that account succeeded in sublimating his libidinal instincts. It is true that the ego ideal demands such sublimation, but it cannot enforce it; sublimation remains a special process which may be prompted by the ideal but the execution of which is entirely independent of any such prompting. It is precisely in neurotics that we find the highest differences of potential between the development of their ego ideal and the amount of sublimation of their primitive libidinal instincts; and in general it is far harder to convince an idealist of the inexpedient location of his libido than a plain man whose pretensions have remained more moderate. Further, the formation of an ego ideal and sublimation are quite differently related to the causation of neurosis. As we have learnt, the formation of an ideal heightens the demands of the ego and is the most powerful factor favouring repression; sublimation is a way out, a way by which those demands can be met *without* involving repression.
[1914c, 2948]

Applying our distinction between sexual and ego-instincts, we must recognize that self-regard has a specially intimate dependence on narcissistic libido. Here we are supported by two fundamental facts: that in paraphrenics self-regard is increased, while in the transference neuroses it is diminished; and that in love-relations not being loved lowers the self-regarding feelings, while being loved raises them. As we have indicated, the aim and the satisfaction in a narcissistic object-choice is to be loved.
[1914c, 2951]

Further, it is easy to observe that libidinal object-cathexis does not raise self-regard. The effect of dependence upon the loved object is to lower that feeling: a person in love is humble. A person who loves has, so to speak, forfeited a part of his narcissism, and it can only be replaced by his being loved. In all these respects self-regard seems to remain related to the narcissistic element in love.
[1914c, 2951]
The relations of self-regard to erotism - that is, to libidinal object-cathexes - may be expressed concisely in the following way. Two cases must be distinguished, according to whether the erotic cathexes are ego-syntonic, or, on the contrary, have suffered repression. In the former case (where the use made of the libido is ego-syntonic), love is assessed like any other activity of the ego. Loving in itself, in so far as it involves longing and deprivation, lowers self-regard; whereas being loved, having one's love returned, and possessing the loved object, raises it once more. When libido is repressed, the erotic cathexis is felt as a severe depletion of the ego, the satisfaction of love is impossible, and the re-enrichment of the ego can be effected only by a withdrawal of libido from its objects. The return of the object-libido to the ego and its transformation into narcissism represents, as it were, a happy love once more; and, on the other hand, it is also true that a real happy love corresponds to the primal condition in which object-libido and ego-libido cannot be distinguished.

[1914c, 2952]

The development of the ego consists in a departure from primary narcissism and gives rise to a vigorous attempt to recover that state. This departure is brought about by means of the displacement of libido on to an ego ideal imposed from without; and satisfaction is brought about from fulfilling this ideal.

[1914c, 2953]

The sexual ideal may enter into an interesting auxiliary relation to the ego ideal. It may be used for substitutive satisfaction where narcissistic satisfaction encounters real hindrances. In that case a person will love in conformity with the narcissistic type of object-choice, will love what he once was and no longer is, or else what possesses the excellences which he never had at all (cf. (c)). The formula parallel to the one there stated runs thus: what possesses the excellence which the ego lacks for making it an ideal, is loved. This expedient is of special importance for the neurotic, who, on account of his excessive object-cathexes, is impoverished in his ego and is incapable of fulfilling his ego ideal. He then seeks a way back to narcissism from his prodigal expenditure of libido upon objects, by choosing a sexual ideal after the narcissistic type which possesses the excellences to which he cannot attain. This is the cure by love, which he generally prefers to cure by analysis. Indeed, he cannot believe in any other mechanism of cure; he usually brings expectations of this sort with him to the treatment and directs them towards the person of the physician. The patient's incapacity for love, resulting from his extensive repressions, naturally stands in the way of a therapeutic plan of this kind. An unintended result is often met with when, by means of the treatment, he has been partially freed from his repressions: he withdraws from further treatment in order to choose a love-object, leaving his cure to be continued by a life with someone he loves. We might be satisfied with this result, if it did not bring with it all the dangers of a crippling dependence upon his helper in need.

[1914c, 2954]
We have become accustomed to call the early phase of the development of the ego, during which its sexual instincts find auto-erotic satisfaction, 'narcissism', without at once entering on any discussion of the relation between auto-erotism and narcissism. It follows that the preliminary stage of the scopophilic instinct, in which the subject's own body is the object of the scopophilia, must be classed under narcissism, and that we must describe it as a narcissistic formation. The active scopophilic instinct develops from this, by leaving narcissism behind. The passive scopophilic instinct, on the contrary, holds fast to the narcissistic object. Similarly, the transformation of sadism into masochism implies a return to the narcissistic object. And in both these cases the narcissistic subject is, through identification, replaced by another, extraneous ego. If we take into account our constructed preliminary narcissistic stage of sadism, we shall be approaching a more general realization - namely, that the instinctual vicissitudes which consist in the instinct's being turned round upon the subject's own ego and undergoing reversal from activity to passivity are dependent on the narcissistic organization of the ego and bear the stamp of that phase. They perhaps correspond to the attempts at defence which at higher stages of the development of the ego are effected by other means.

[1915c, 2968]

Loving admits not merely of one, but of three opposites. In addition to the antithesis 'loving-hating', there is the other one of 'loving-being loved'; and, in addition to these, loving and hating taken together are the opposite of the condition of unconcern or indifference. The second of these three antitheses, loving-being loved, corresponds exactly to the transformation from activity to passivity and may be traced to an underlying situation in the same way as in the case of the scopophilic instinct. This situation is that of loving oneself which we regard as the characteristic feature of narcissism. Then, according as the object or the subject is replaced by an extraneous one, what results is the active aim of loving or the passive one of being loved - the latter remaining near to narcissism.

[1915c, 2969]

The three polarities of the mind are connected with one another in various highly significant ways. There is a primal psychical situation in which two of them coincide. Originally, at the very beginning of mental life, the ego is cathected with instincts and is to some extent capable of satisfying them on itself. We call this condition 'narcissism' and this way of obtaining satisfaction 'auto-erotic'.¹ At this time the external world is not cathected with interest (in a general sense) and is indifferent for purposes of satisfaction. During this period, therefore, the ego-subject coincides with what is pleasurable and the external world with what is indifferent (or possibly unpleasurable, as being a source of stimulation). If for the moment we define loving as the relation of the ego to its sources of pleasure, the situation in which the ego loves itself only and is indifferent to the external world illustrates the first of the opposites which we found to 'loving'.

[1915c, 2970]

¹ Some of the sexual instincts are, as we know, capable of this auto-erotic satisfaction, and so are adapted to being the vehicle for the development under the dominance of the pleasure principle which we are about to describe. Those sexual instincts which from the outset require an object, and the needs of the ego-instincts, which are never capable of auto-erotic satisfaction, naturally disturb this state and so pave the way for an advance from it. Indeed, the primal narcissistic state would not be able to follow the development if it were not for the fact that every individual passes through a period during which he is helpless and has to be looked after and during which his pressing needs are satisfied by an external agency and are thus prevented from becoming greater.

[1915c, 2970]
In so far as the ego is auto-erotic, it has no need of the external world, but, in consequence of experiences undergone by the instincts of self-preservation, it acquires objects from that world, and, in spite of everything, it cannot avoid feeling internal instinctual stimuli for a time as unpleasurable. Under the dominance of the pleasure principle a further development now takes place in the ego. In so far as the objects which are presented to it are sources of pleasure, it takes them into itself, 'introjects' them (to use Ferenczi's term); and, on the other hand, it expels whatever within itself becomes a cause of unpleasure. (See below, the mechanism of projection.)

When, during the stage of primary narcissism, the object makes its appearance, the second opposite to loving, namely hating, also attains its development.

It now remains for us to put together what we know of the genesis of love and hate. Love is derived from the capacity of the ego to satisfy some of its instinctual impulses auto-erotically by obtaining organ-pleasure. It is originally narcissistic, then passes over on to objects, which have been incorporated into the extended ego, and expresses the motor efforts of the ego towards these objects as sources of pleasure. It becomes intimately linked with the activity of the later sexual instincts and, when these have been completely synthesized, coincides with the sexual impulsion as a whole. Preliminary stages of love emerge as provisional sexual aims while the sexual instincts are passing through their complicated development. As the first of these aims we recognize the phase of incorporating or devouring - a type of love which is consistent with abolishing the object's separate existence and which may therefore be described as ambivalent. At the higher stage of the pregenital sadistic-anal organization, the striving for the object appears in the form of an urge for mastery, to which injury or annihilation of the object is a matter of indifference. Love in this form and at this preliminary stage is hardly to be distinguished from hate in its attitude towards the object. Not until the genital organization is established does love become the opposite of hate.

It is, of course, the study of dreams which has taught us what we know of the psychical characteristics of the state of sleep. It is true that dreams only show us the dreamer in so far as he is not sleeping; nevertheless they are bound to reveal at the same time characteristics of sleep itself. We have come to know from observation some peculiarities of dreams which we could not at first understand, but which we can now fit into the picture without difficulty. Thus, we know that dreams are completely egoistic and that the person who plays the chief part in their scenes is always to be recognized as the dreamer. This is now easily to be accounted for by the narcissism of the state of sleep. Narcissism and egoism, indeed, coincide; the word 'narcissism' is only intended to emphasize the fact that egoism is a libidinal phenomenon as well; or, to put it in another way, narcissism may be described as the libidinal complement of egoism. The 'diagnostic' capacity of dreams - a phenomenon which is generally acknowledged, but regarded as puzzling - becomes equally comprehensible, too. In dreams, incipient physical disease is often detected earlier and more clearly than in waking life, and all the current bodily sensations assume gigantic proportions. This magnification is hypochondriacal in character; it is conditional upon the withdrawal of all psychical cathexes from the external world back on to the ego, and it makes possible early recognition of bodily changes which in waking life would still for a time have remained unobserved.
Mourning over the loss of something that we have loved or admired seems so natural to the layman that he regards it as self-evident. But to psychologists mourning is a great riddle, one of those phenomena which cannot themselves be explained but to which other obscurities can be traced back. We possess, as it seems, a certain amount of capacity for love - what we call libido - which in the earliest stages of development is directed towards our own ego. Later, though still at a very early time, this libido is diverted from the ego on to objects, which are thus in a sense taken into our ego. If the objects are destroyed or if they are lost to us, our capacity for love (our libido) is once more liberated; and it can then either take other objects instead or can temporarily return to the ego. But why it is that this detachment of libido from its objects should be such a painful process is a mystery to us and we have not hitherto been able to frame any hypothesis to account for it. We only see that libido clings to its objects and will not renounce those that are lost even when a substitute lies ready to hand. Such then is mourning.

[1916a, 3096]

What I have been trying to describe in this outline is the libido theory of the neuroses, upon which are founded all our conceptions of the nature of these morbid states, together with our therapeutic measures for relieving them. We naturally regard the premises of the libido theory as valid for normal behaviour as well. We speak of the narcissism of small children, and it is to the excessive narcissism of primitive man that we ascribe his belief in the omnipotence of his thoughts and his consequent attempts to influence the course of events in the external world by the technique of magic.

[1917a, 3610]

After this introduction I propose to describe how the universal narcissism of men, their self-love, has up to the present suffered three severe blows from the researches of science.

[1917a, 3610]

Among the hypothetical concepts which enable the doctor to deal with the analytic material, the first to be mentioned is that of 'libido'. Libido means in psycho-analysis in the first instance the force (thought of as quantitatively variable and measurable) of the sexual instincts directed towards an object - 'sexual' in the extended sense required by analytic theory. Further study showed that it was necessary to set alongside this 'object-libido' a 'narcissistic' or 'ego-libido', directed to the subject's own ego; and the interaction of these two forces has enabled us to account for a great number of normal and abnormal processes in mental life. A rough distinction was soon made between what are known as the 'transference neuroses' and the narcissistic disorders. The former (hysteria and obsessional neurosis) are the objects proper of psycho-analytic treatment, while the others, the narcissistic neuroses, though they can, it is true, be examined by the help of analysis, offer fundamental difficulties to therapeutic influence. It is true that the libido theory of psycho-analysis is by no means complete and that its relation to a general theory of the instincts is not yet clear, for psycho-analysis is a young science, quite unfinished and in a stage of rapid development. Here, however, it should be emphatically pointed out how erroneous the charge of pan-sexualism is which is so often levelled at psycho-analysis. It seeks to show that psycho-analytic theory knows of no mental motive forces other than purely sexual ones and in doing so exploits popular prejudices by using the word 'sexual' not in its analytic but in its vulgar sense.

[1924f, 4113]
At a later date (1923), I myself modified this account by inserting a third phase in the development of childhood, subsequent to the two pregenital organizations. This phase, which already deserves to be described as genital, presents a sexual object and some degree of convergence of the sexual impulses upon that object; but it is differentiated from the final organization of sexual maturity in one essential respect. For it knows only one kind of genital: the male one. For that reason I have named it the ‘phallic’ stage of organization. (Freud, 1923e.) According to Abraham, it has a biological prototype in the embryo's undifferentiated genital disposition, which is the same for both sexes. [1905d, 1517]

The schematic picture which I have given in the text aims at emphasizing differences. I have already shown on p. 1517 the extent to which infantile sexuality, owing to its choice of object [added 1924:] and to the development of the phallic phase, approximates to the final sexual organization. [1905d, 1524]

We found from the study of neurotic disorders that beginnings of an organization of the sexual instinctual components can be detected in the sexual life of children from its very beginning. During a first, very early phase, oral erotism occupies most of the picture. A second of these pregenital organizations is characterized by the predominance of sadism and anal erotism. It is not until a third phase has been reached that the genital zones proper contribute their share in determining sexual life, and in children this last phase is developed only so far as to a primacy of the phallus. [1905d, 1544]

In spite of the gaps in our knowledge of infantile sexual life, we had to proceed to an attempt at examining the alterations brought about in it by the arrival of puberty. We selected two of these as being the decisive ones: the subordination of all the other sources of sexual excitation under the primacy of the genital zones and the process of finding an object. Both of these are already adumbrated in childhood. The first is accomplished by the mechanism of exploiting fore-pleasure: what were formerly self-contained sexual acts, attended by pleasure and excitation, become acts preparatory to the new sexual aim (the discharge of the sexual products), the attainment of which, enormously pleasurable, brings the sexual excitation to an end. In this connection we had to take into account the differentiation of sexuality into masculine and feminine; and we found that in order to become a woman a further stage of repression is necessary, which discards a portion of infantile masculinity and prepares the woman for changing her leading genital zone. As regards object-choice, we found that it is given its direction by the childhood hints (revived at puberty) of the child's sexual inclination towards his parents and others in charge of him, but that it is diverted away from them, on to other people who resemble them, owing to the barrier against incest which has meanwhile been erected. Finally it must be added that during the transition period of puberty the processes of somatic and of psychical development continue for a time side by side independently, until the irruption of an intense mental erotic impulse, leading to the innervation of the genitals, brings about the unity of the erotic function which is necessary for normality. [1905d, 1545]
There is absolutely no justification for distinguishing a special homosexual instinct. What constitutes a homosexual is a peculiarity not in his instinctual life but in his choice of an object. Let me recall what I have said in my Three Essays to the effect that we have mistakenly imagined the bond between instinct and object in sexual life as being more intimate than it really is. A homosexual may have normal instincts, but he is unable to disengage them from a class of objects defined by a particular determinant. And in his childhood, since at that period this determinant is taken for granted as being of universal application, he is able to behave like little Hans, who showed his affection to little boys and girls indiscriminately, and once described his friend Fritzl as 'the girl he was fondest of'. Hans was a homosexual (as all children may very well be), quite consistently with the fact, which must always be kept in mind, that he was acquainted with only one kind of genital organ - a genital organ like his own.¹

¹ [Footnote added 1923:] I have subsequently (1923e) drawn attention to the fact that the period of sexual development which our little patient was passing through is universally characterized by acquaintance with only one sort of genital organ, namely, the male one. In contrast to the later period of maturity, this period is marked not by a genital primacy but by a primacy of the phallus.
[1909b, 2094]

Phallic phase, which is contemporaneous with the Oedipus complex, does not develop further to the definitive genital organization, but is submerged, and is succeeded by the latency period. Its termination, however, takes place in a typical manner and in conjunction with events that are of regular recurrence.
[1924d, 4086]
Now it is my view that what brings about the destruction of the child's phallic genital organization is this threat of castration. Not immediately, it is true, and not without other influences being brought to bear as well. For to begin with the boy does not believe in the threat or obey it in the least. Psycho-analysis has recently attached importance to two experiences which all children go through and which, it is suggested, prepare them for the loss of highly valued parts of the body. These experiences are the withdrawal of the mother's breast - at first intermittently and later for good - and the daily demand on them to give up the contents of the bowel. But there is no evidence to show that, when the threat of castration takes place, those experiences have any effect. It is not until a fresh experience comes his way that the child begins to reckon with the possibility of being castrated, and then only hesitatingly and unwillingly, and not without making efforts to depreciate the significance of something he has himself observed.

[1924d, 4087]

In boys the situation of the Oedipus complex is the first stage that can be recognized with certainty. It is easy to understand, because at that stage a child retains the same object which he previously cathected with his libido - not as yet a genital one - during the preceding period while he was being suckled and nursed. The fact, too, that in this situation he regards his father as a disturbing rival and would like to get rid of him and take his place is a straightforward consequence of the actual state of affairs. I have shown elsewhere¹ how the Oedipus attitude in little boys belongs to the phallic phase, and how its destruction is brought about by the fear of castration - that is, by narcissistic interest in their genitals. The matter is made more difficult to grasp by the complicating circumstance that even in boys the Oedipus complex has a double orientation, active and passive, in accordance with their bisexual constitution; a boy also wants to take his mother's place as the love-object of his father - a fact which we describe as the feminine attitude.

[1925j, 4147]

The old paediatrician Lindner once remarked that a child discovers the genital zones (the penis or the clitoris) as a source of pleasure while indulging in sensual sucking (thumb sucking).¹ I shall leave it an open question whether it is really true that the child takes the newly found source of pleasure in exchange for the recent loss of the mother's nipple - a possibility to which later phantasies (fellatio) seem to point. Be that as it may, the genital zone is discovered at some time or other, and there seems no justification for attributing any psychical content to the first activities in connection with it. But the first step in the phallic phase which begins in this way is not the linking-up of the masturbation with the object-cathexes of the Oedipus complex, but a momentous discovery which little girls are destined to make. They notice the penis of a brother or playmate, strikingly visible and of large proportions, at once recognize it as the superior counterpart of their own small and inconspicuous organ, and from that time forward fall a victim to envy for the penis.

[1925j, 4149]
The detaching of sexuality from the genitals has the advantage of allowing us to bring the sexual activities of children and of perverts into the same scope as those of normal adults. The sexual activities of children have hitherto been entirely neglected and though those of perverts have been recognized it has been with moral indignation and without understanding. Looked at from the psycho-analytic standpoint, even the most eccentric and repellent perversions are explicable as manifestations of component instincts of sexuality which have freed themselves from the primacy of the genitals and are now in pursuit of pleasure on their own account as they were in the very early days of the libido's development. The most important of these perversions, homosexuality, scarcely deserves the name. It can be traced back to the constitutional bisexuality of all human beings and to the after-effects of the phallic primacy. Psycho-analysis enables us to point to some trace or other of a homosexual object-choice in everyone. If I have described children as 'polymorphously perverse', I was only using a terminology that was generally current; no moral judgement was implied by the phrase. Psycho-analysis has no concern whatever with such judgements of value.

We find ourselves on firmer ground when we investigate the manner in which the life of the instincts serves the sexual function. Here we have acquired quite definite knowledge, with which you too are already familiar. It is not the case, then, that we recognize a sexual instinct which is from the first the vehicle of an urge towards the aim of the sexual function - the union of the two sex-cells. What we see is a great number of component instincts arising from different areas and regions of the body, which strive for satisfaction fairly independently of one another and find that satisfaction in something that we may call 'organ-pleasure'. The genitals are the latest of these 'erotogenic zones' and the name of 'sexual' pleasure cannot be withheld from their organ-pleasure. These impulses which strive for pleasure are not all taken up into the final organization of the sexual function. A number of them are set aside as unserviceable, by repression or some other means; a few of them are diverted from their aim in the remarkable manner I have mentioned and used to strengthen other impulses; yet others persist in minor roles, and serve for the performance of introductory acts, for the production of fore-pleasure. You have heard how in the course of this long-drawn-out development several phases of preliminary organization can be recognized and also how this history of the sexual function explains its aberrations and atrophies. The first of these 'pregenital' phases is known to us as the oral one because, in conformity with the way in which an infant in arms is nourished, the erotogenic zone of the mouth dominates what may be called the sexual activity of that period of life. At a second level the sadistic and anal impulses come to the fore, undoubtedly in connection with the appearance of the teeth, the strengthening of the muscular apparatus and the control of the sphincter functions. We have learnt a number of interesting details about this remarkable stage of development in particular. Thirdly comes the phallic phase in which in both sexes the male organ (and what corresponds to it in girls) attains an importance which can no longer be overlooked. We have reserved the name of genital phase for the definitive sexual organization which is established after puberty and in which the female genital organ for the first time meets with the recognition which the male one acquired long before.
Both sexes seem to pass through the early phases of libidinal development in the same manner. It might have been expected that in girls there would already have been some lag in aggressiveness in the sadistic-anal phase, but such is not the case. Analysis of children's play has shown our women analysts that the aggressive impulses of little girls leave nothing to be desired in the way of abundance and violence. With their entry into the phallic phase the differences between the sexes are completely eclipsed by their agreements. We are now obliged to recognize that the little girl is a little man. In boys, as we know, this phase is marked by the fact that they have learnt how to derive pleasurable sensations from their small penis and connect its excited state with their ideas of sexual intercourse. Little girls do the same thing with their still smaller clitoris. It seems that with them all their masturbatory acts are carried out on this penis-equivalent, and that the truly feminine vagina is still undiscovered by both sexes. It is true that there are a few isolated reports of early vaginal sensations as well, but it could not be easy to distinguish these from sensations in the anus or vestibulum; in any case they cannot play a great part. We are entitled to keep to our view that in the phallic phase of girls the clitoris is the leading erotogenic zone. But it is not, of course, going to remain so. With the change to femininity the clitoris should wholly or in part pass over its sensitivity, and at the same time its importance, to the vagina. This would be one of the two tasks which a woman has to perform in the course of her development, whereas the more fortunate man has only to continue at the time of his sexual maturity the activity that he has previously carried out at the period of the early efflorescence of his sexuality.

[1933a, 4720]

We shall be glad, then, to know the nature of the girl's libidinal relations to her mother. The answer is that they are of very many different kinds. Since they persist through all three phases of infantile sexuality, they also take on the characteristics of the different phases and express themselves by oral, sadistic-anal and phallic wishes. These wishes represent active as well as passive impulses; if we relate them to the differentiation of the sexes which is to appear later - though we should avoid doing so as far as possible - we may call them masculine and feminine. Besides this, they are completely ambivalent, both affectionate and of a hostile and aggressive nature. The latter often only come to light after being changed into anxiety ideas. It is not always easy to point to a formulation of these early sexual wishes; what is most clearly expressed is a wish to get the mother with child and the corresponding wish to bear her a child - both belonging to the phallic period and sufficiently surprising, but established beyond doubt by analytic observation. The attractiveness of these investigations lies in the surprising detailed findings which they bring us. Thus, for instance, we discover the fear of being murdered or poisoned, which may later form the core of a paranoid illness, already present in this pre-Oedipus period, in relation to the mother. Or another case: you will recall an interesting episode in the history of analytic research which caused me many distressing hours. In the period in which the main interest was directed to discovering infantile sexual traumas, almost all my women patients told me that they had been seduced by their father. I was driven to recognize in the end that these reports were untrue and so came to understand that hysterical symptoms are derived from phantasies and not from real occurrences. It was only later that I was able to recognize in this phantasy of being seduced by the father the expression of the typical Oedipus complex in women. And now we find the phantasy of seduction once more in the pre-Oedipus prehistory of girls; but the seducer is regularly the mother. Here, however, the phantasy touches the ground of reality, for it was really the mother who by her activities over the child's bodily hygiene inevitably stimulated, and perhaps even roused for the first time, pleasurable sensations in her genitals.

[1933a, 4722]
An abundant source of a child's hostility to its mother is provided by its multifarious sexual wishes, which alter according to the phase of the libido and which cannot for the most part be satisfied. The strongest of these frustrations occur at the phallic period, if the mother forbids pleasurable activity with the genitals - often with severe threats and every sign of displeasure - activity to which, after all, she herself had introduced the child. One would think these were reasons enough to account for a girl's turning away from her mother. One would judge, if so, that the estrangement follows inevitably from the nature of children's sexuality, from the immoderate character of their demand for love and the impossibility of fulfilling their sexual wishes. It might be thought indeed that this first love-relation of the child's is doomed to dissolution for the very reason that it is the first, for these early object-cathexes are regularly ambivalent to a high degree. A powerful tendency to aggressiveness is always present beside a powerful love, and the more passionately a child loves its object the more sensitive does it become to disappointments and frustrations from that object; and in the end the love must succumb to the accumulated hostility. Or the idea that there is an original ambivalence such as this in erotic cathexes may be rejected, and it may be pointed out that it is the special nature of the mother-child relation that leads, with equal inevitability, to the destruction of the child's love; for even the mildest upbringing cannot avoid using compulsion and introducing restrictions, and any such intervention in the child's liberty must provoke as a reaction an inclination to rebelliousness and aggressiveness. A discussion of these possibilities might, I think, be most interesting; but an objection suddenly emerges which forces our interest in another direction. All these factors - the slights, the disappointments in love, the jealousy, the seduction followed by prohibition - are, after all, also in operation in the relation of a boy to his mother and are yet unable to alienate him from the maternal object. Unless we can find something that is specific for girls and is not present or not in the same way present in boys, we shall not have explained the termination of the attachment of girls to their mother.

One cannot very well doubt the importance of envy for the penis. You may take it as an instance of male injustice if I assert that envy and jealousy play an even greater part in the mental life of women than of men. It is not that I think these characteristics are absent in men or that I think they have no other roots in women than envy for the penis; but I am inclined to attribute their greater amount in women to this latter influence. Some analysts, however, have shown an inclination to depreciate the importance of this first instalment of penis-envy in the phallic phase. They are of opinion that what we find of this attitude in women is in the main a secondary structure which has come about on the occasion of later conflicts by regression to this early infantile impulse. This, however, is a general problem of depth psychology. In many pathological - or even unusual - instinctual attitudes (for instance, in all sexual perversions) the question arises of how much of their strength is to be attributed to early infantile fixations and how much to the influence of later experiences and developments. In such cases it is almost always a matter of complemental series such as we put forward in our discussion of the aetiology of the neuroses. Both factors play a part in varying amounts in the causation; a less on the one side is balanced by a more on the other. The infantile factor sets the pattern in all cases but does not always determine the issue, though it often does. Precisely in the case of penis-envy I should argue decidedly in favour of the preponderance of the infantile factor.

[1933a, 4726]

[1933a, 4727]
The essential content of the first is as follows: the little girl has hitherto lived in a masculine way, has been able to get pleasure by the excitation of her clitoris and has brought this activity into relation with her sexual wishes directed towards her mother, which are often active ones; now, owing to the influence of her penis-envy, she loses her enjoyment in her phallic sexuality. Her self-love is mortified by the comparison with the boy's far superior equipment and in consequence she renounces her masturbatory satisfaction from her clitoris, repudiates her love for her mother and at the same time not infrequently represses a good part of her sexual trends in general. No doubt her turning away from her mother does not occur all at once, for to begin with the girl regards her castration as an individual misfortune, and only gradually extends it to other females and finally to her mother as well. Her love was directed to her phallic mother; with the discovery that her mother is castrated it becomes possible to drop her as an object, so that the motives for hostility, which have long been accumulating, gain the upper hand. This means, therefore, that as a result of the discovery of women's lack of a penis they are debased in value for girls just as they are for boys and later perhaps for men.

Along with the abandonment of clitoral masturbation a certain amount of activity is renounced. Passivity now has the upper hand, and the girl's turning to her father is accomplished principally with the help of passive instinctual impulses. You can see that a wave of development like this, which clears the phallic activity out of the way, smoothes the ground for femininity. If too much is not lost in the course of it through repression, this femininity may turn out to be normal. The wish with which the girl turns to her father is no doubt originally the wish for the penis which her mother has refused her and which she now expects from her father. The feminine situation is only established, however, if the wish for a penis is replaced by one for a baby, if, that is, a baby takes the place of a penis in accordance with an ancient symbolic equivalence. It has not escaped us that the girl has wished for a baby earlier, in the undisturbed phallic phase: that, of course, was the meaning of her playing with dolls. But that play was not in fact an expression of her femininity; it served as an identification with her mother with the intention of substituting activity for passivity. She was playing the part of her mother and the doll was herself: now she could do with the baby everything that her mother used to do with her. Not until the emergence of the wish for a penis does the doll-baby become a baby from the girl's father, and thereafter the aim of the most powerful feminine wish. Her happiness is great if later on this wish for a baby finds fulfilment in reality, and quite especially so if the baby is a little boy who brings the longed-for penis with him. Often enough in her combined picture of 'a baby from her father' the emphasis is laid on the baby and her father left unstressed. In this way the ancient masculine wish for the possession of a penis is still faintly visible through the femininity now achieved. But perhaps we ought rather to recognize this wish for a penis as being par excellence a feminine one.
With the transference of the wish for a penis-baby on to her father, the girl has entered the situation of the Oedipus complex. Her hostility to her mother, which did not need to be freshly created, is now greatly intensified, for she becomes the girl’s rival, who receives from her father everything that she desires from him. For a long time the girl’s Oedipus complex concealed her pre-Oedipus attachment to her mother from our view, though it is nevertheless so important and leaves such lasting fixations behind it. For girls the Oedipus situation is the outcome of a long and difficult development; it is a kind of preliminary solution, a position of rest which is not soon abandoned, especially as the beginning of the latency period is not far distant. And we are now struck by a difference between the two sexes, which is probably momentous, in regard to the relation of the Oedipus complex to the castration complex. In a boy the Oedipus complex, in which he desires his mother and would like to get rid of his father as being a rival, develops naturally from the phase of his phallic sexuality. The threat of castration compels him, however, to give up that attitude. Under the impression of the danger of losing his penis, the Oedipus complex is abandoned, repressed and, in the most normal cases, entirely destroyed, and a severe super-ego is set up as its heir. What happens with a girl is almost the opposite. The castration complex prepares for the Oedipus complex instead of destroying it; the girl is driven out of her attachment to her mother through the influence of her envy for the penis and she enters the Oedipus situation as though into a haven of refuge. In the absence of fear of castration the chief motive is lacking which leads boys to surmount the Oedipus complex. Girls remain in it for an indeterminate length of time; they demolish it late and, even so, incompletely. In these circumstances the formation of the super-ego must suffer; it cannot attain the strength and independence which give it its cultural significance, and feminists are not pleased when we point out to them the effects of this factor upon the average feminine character.

[1933a, 4731]

The third phase is that known as the phallic one, which is, as it were, a forerunner of the final form taken by sexual life and already much resembles it. It is to be noted that it is not the genitals of both sexes that play a part at this stage, but only the male ones (the phallus). The female genitals long remain unknown: in children’s attempts to understand the sexual processes they pay homage to the venerable cloacal theory - a theory which has a genetic justification.

[1940a [1938], 4965]

With the phallic phase and in the course of it the sexuality of early childhood reaches its height and approaches its dissolution. Thereafter boys and girls have different histories. Both have begun to put their intellectual activity at the service of sexual researches; both start off from the premiss of the universal presence of the penis. But now the paths of the sexes diverge. The boy enters the Oedipus phase; he begins to manipulate his penis and simultaneously has phantasies of carrying out some sort of activity with it in relation to his mother, till, owing to the combined effect of a threat of castration and the sight of the absence of a penis in females, he experiences the greatest trauma of his life and this introduces the period of latency with all its consequences. The girl, after vainly attempting to do the same as the boy, comes to recognize her lack of a penis or rather the inferiority of her clitoris, with permanent effects on the development of her character; as a result of this first disappointment in rivalry, she often begins by turning away altogether from sexual life.

[1940a [1938], 4965]

² The occurrence of early vaginal excitations is often asserted. But it is most probable that what is in question are excitations in the clitoris - that is, in an organ analogous to the penis. This does not invalidate our right to describe the phase as phallic.

[1940a [1938], 4965]
It would be a mistake to suppose that these three phases succeed one another in a clear-cut fashion. One may appear in addition to another; they may overlap one another, may be present alongside of one another. In the early phases the different component instincts set about their pursuit of pleasure independently of one another; in the phallic phase there are the beginnings of an organization which subordinates the other urges to the primacy of the genitals and signifies the start of a co-ordination of the general urge towards pleasure into the sexual function. The complete organization is only achieved at puberty, in a fourth, genital phase. A state of things is then established in which (1) some earlier libidinal cathexes are retained, (2) others are taken into the sexual function as preparatory, auxiliary acts, the satisfaction of which produces what is known as fore-pleasure, and (3) other urges are excluded from the organization, and are either suppressed altogether (repressed) or are employed in the ego in another way, forming character-traits or undergoing sublimation with a displacement of their aims.

[1940a [1938], 4966]

In trying to introduce this factor into the structure of our theory, we must not overlook the fact that it cannot, by its very nature, occupy the same position in both sexes. In males the striving to be masculine is completely ego-syntonic from the first; the passive attitude, since it presupposes an acceptance of castration, is energetically repressed, and often its presence is only indicated by excessive overcompensations. In females, too, the striving to be masculine is ego-syntonic at a certain period - namely in the phallic phase, before the development to femininity has set in. But it then succumbs to the momentous process of repression whose outcome, as has so often been shown, determines the fortunes of a woman's femininity. A great deal depends on whether a sufficient amount of her masculinity complex escapes repression and exercises a permanent influence on her character. Normally, large portions of the complex are transformed and contribute to the construction of her femininity: the appeased wish for a penis is destined to be converted into a wish for a baby and for a husband, who possesses a penis. It is strange, however, how often we find that the wish for masculinity has been retained in the unconscious and, from out of its state of repression, exercises a disturbing influence.

[1937c, 5044]
ACTIVITY OF THE GENITAL ZONES

Among the erotogenic zones that form part of the child's body there is one which certainly does not play the opening part, and which cannot be the vehicle of the oldest sexual impulses, but which is destined to great things in the future. In both male and female children it is brought into connection with micturition (in the glans and clitoris) and in the former is enclosed in a pouch of mucous membrane, so that there can be no lack of stimulation of it by secretions which may give an early start to sexual excitation. The sexual activities of this erotogenic zone, which forms part of the sexual organs proper, are the beginning of what is later to become 'normal' sexual life. The anatomical situation of this region, the secretions in which it is bathed, the washing and rubbing to which it is subjected in the course of a child's toilet, as well as accidental stimulation (such as the movement of intestinal worms in the case of girls), make it inevitable that the pleasurable feeling which this part of the body is capable of producing should be noticed by children even during their earliest infancy, and should give rise to a need for its repetition. If we consider this whole range of contrivances and bear in mind that both making a mess and measures for keeping clean are bound to operate in much the same way, it is scarcely possible to avoid the conclusion that the foundations for the future primacy over sexual activity exercised by this erotogenic zone are established by early infantile masturbation, which scarcely a single individual escapes. The action which disposes of the stimulus and brings about satisfaction consists in a rubbing movement with the hand or in the application of pressure (no doubt on the lines of a pre-existing reflex) either from the hand or by bringing the thighs together. This last method is by far the more common in the case of girls. The preference for the hand which is shown by boys is already evidence of the important contribution which the instinct for mastery is destined to make to masculine sexual activity.¹

[1905d, 1508]

The erotogenic zone of the genitals begins to make itself noticeable, it seems, even during the years of childhood. This may happen in two ways. Either, like any other erotogenic zone, it yields satisfaction in response to appropriate sensory stimulation; or, in a manner which is not quite understandable, when satisfaction is derived from other sources, a sexual excitation is simultaneously produced which has a special relation to the genital zone. We were reluctantly obliged to admit that we could not satisfactorily explain the relation between sexual satisfaction and sexual excitation, or that between the activity of the genital zone and the activity of the other sources of sexuality.

[1905d, 1544]

We found from the study of neurotic disorders that beginnings of an organization of the sexual instinctual components can be detected in the sexual life of children from its very beginning. During a first, very early phase, oral erotism occupies most of the picture. A second of these pregenital organizations is characterized by the predominance of sadism and anal erotism. It is not until a third phase has been reached that the genital zones proper contribute their share in determining sexual life, and in children this last phase is developed only so far as to a primacy of the phallus.

[1905d, 1544]
The first of these theories starts out from the neglect of the differences between the sexes on which I laid stress at the beginning of this paper as being characteristic of children. It consists in attributing to everyone, including females, the possession of a penis, such as the boy knows from his own body. It is precisely in what we must regard as the 'normal' sexual constitution that already in childhood the penis is the leading erotogenic zone and the chief auto-erotic sexual object; and the boy's estimate of its value is logically reflected in his inability to imagine a person like himself who is without this essential constituent. When a small boy sees his little sister's genitals, what he says shows that his prejudice is already strong enough to falsify his perception. He does not comment on the absence of a penis, but invariably says, as though by way of consolation and to put things right: 'Her ---'s still quite small. But when she gets bigger it'll grow all right.' The idea of a woman with a penis returns in later life, in the dreams of adults: the dreamer, in a state of nocturnal sexual excitation, will throw a woman down, strip her and prepare for intercourse - and then, in place of the female genitals, he beholds a well-developed penis and breaks off the dream and the excitation. The numerous hermaphrodites of classical antiquity faithfully reproduce this idea, universally held in childhood; one may observe that to most normal people they cause no offence, while the real hermaphroditic formations of the genitals which are permitted to occur by Nature nearly always excite the greatest abhorrence.

If this idea of a woman with a penis becomes 'fixated' in an individual when he is a child, resisting all the influences of later life and making him as a man unable to do without a penis in his sexual object, then, although in other respects he may lead a normal sexual life, he is bound to become a homosexual, and will seek his sexual object among men who, owing to some other physical and mental characteristics, remind him of women. Real women, when he comes to know them later, remain impossible as sexual objects for him, because they lack the essential sexual attraction; indeed, in connection with another impression of his childhood life, they may even become abhorrent to him. The child, having been mainly dominated by excitations in the penis, will usually have obtained pleasure by stimulating it with his hand; he will have been detected in this by his parents or nurse and terrorized by the threat of having his penis cut off. The effect of this 'threat of castration' is proportionate to the value set upon that organ and is quite extraordinarily deep and persistent. Legends and myths testify to the upheaval in the child's emotional life and to the horror which is linked with the castration complex - a complex which is subsequently remembered by consciousness with corresponding reluctance. The woman's genitalia, when seen later on, are regarded as a mutilated organ and recall this threat, and they therefore arouse horror instead of pleasure in the homosexual. This reaction cannot be altered in any way when the homosexual comes to learn from science that his childish assumption that women had a penis too was not so far wrong after all. Anatomy has recognized the clitoris within the female pudenda as being an organ that is homologous to the penis; and the physiology of the sexual processes has been able to add that this small penis which does not grow any bigger behaves in fact during childhood like a real and genuine penis - that it becomes the seat of excitations which lead to its being touched, that its excitability gives the little girl's sexual activity a masculine character and that a wave of repression in the years of puberty is needed in order for this masculine sexuality to be discarded and the woman to emerge. Since the sexual function of many women is crippled, whether by their obstinate clinging on to this excitability of the clitoris so that they remain anaesthetic in intercourse, or by such excessive repression occurring that its operation is partly replaced by hysterical compensatory formations - all this seems to show that there is some truth in the infantile sexual theory that women, like men, possess a penis.
The third of the typical sexual theories arises in children if, through some chance domestic occurrence, they become witnesses of sexual intercourse between their parents. Their perceptions of what is happening are bound, however, to be only very incomplete. Whatever detail it may be that comes under their observation - whether it is the relative positions of the two people, or the noises they make, or some accessory circumstance - children arrive in every case at the same conclusion. They adopt what may be called a sadistic view of coition. They see it as something that the stronger participant is forcibly inflicting on the weaker, and they (especially boys) compare it to the romping familiar to them from their childish experience - romping which, incidentally, is not without a dash of sexual excitation. I have not been able to ascertain that children recognize this behaviour which they have witnessed between their parents as the missing link needed for solving the problem of babies; it appears more often that the connection is overlooked by them for the very reason that they have interpreted the act of love as an act of violence. But this view of it itself gives an impression of being a return of the obscure impulse towards cruel behaviour which became attached to the excitations of the child's penis when he first began to think about the problem of where babies came from. The possibility, too, cannot be excluded that this premature sadistic impulse, which might so nearly have led to the discovery of coition, itself first emerged under the influence of extremely obscure memories of parental intercourse, for which the child had obtained the material - though at the time he made no use of it - while he was still in his first years and was sharing his parents' bedroom.

The first trait in little Hans which can be regarded as part of his sexual life was a quite peculiarly lively interest in his 'widdler' - an organ deriving its name from that one of its two functions which, scarcely the less important of the two, is not to be eluded in the nursery. This interest aroused in him the spirit of enquiry, and he thus discovered that the presence or absence of a widdler made it possible to differentiate between animate and inanimate objects. He assumed that all animate objects were like himself, and possessed this important bodily organ; he observed that it was present in the larger animals, suspected that this was so too in both his parents, and was not deterred by the evidence of his own eyes from authenticating the fact in his new-born sister. One might almost say that it would have been too shattering a blow to his 'Weltanschauung' if he had had to make up his mind to forgo the presence of this organ in a being similar to him; it would have been as though it were being torn away from himself. It was probably on this account that a threat of his mother's, which was concerned precisely with the loss of his widdler, was hastily dismissed from his thoughts and only succeeded in making its effects apparent at a later period. The reason for his mother's intervention had been that he used to like giving himself feelings of pleasure by touching his member: the little boy had begun to practise the commonest - and most normal - form of auto-erotic sexual activity.
Thus in little Hans's sexual constitution the genital zone was from the outset the one among his erotogenic zones which afforded him the most intense pleasure. The only other similar pleasure of which he gave evidence was excretory pleasure, the pleasure attached to the orifices through which micturition and evacuation of the bowels are effected. In his final phantasy of bliss, with which his illness was overcome, he imagined he had children, whom he took to the W.C., whom he made to widdle, whose behinds he wiped - for whom, in short, he did 'everything one can do with children'; it therefore seems impossible to avoid the assumption that during the period when he himself had been looked after as an infant these same performances had been the source of pleasurable sensations for him. He had obtained this pleasure from his erotogenic zones with the help of the person who had looked after him - his mother, in fact; and thus the pleasure already pointed the way to object-choice. But it is just possible that at a still earlier date he had been in the habit of giving himself this pleasure auto-erotically - that he had been one of those children who like retaining their excreta till they can derive a voluptuous sensation from their evacuation. I say no more than that it is possible, because the matter was not cleared up in the analysis; the 'making a row with the legs' (kicking about), of which he was so much frightened later on, points in that direction. But in any case these sources of pleasure had no particularly striking importance with Hans, as they so often have with other children. He early became clean in his habits, and neither bed-wetting nor diurnal incontinence played any part during his first years; no trace was observed in him of any inclination to play with his excrement, a propensity which is so revolting in adults, and which commonly makes its reappearance at the termination of processes of psychical involution.

[1909b, 2092]

If an infant could speak, he would no doubt pronounce the act of sucking at his mother's breast by far the most important in his life. He is not far wrong in this, for in this single act he is satisfying at once the two great vital needs. We are therefore not surprised to learn from psycho-analysis how such psychical importance the act retains all through life. Sucking at the mother's breast is the starting-point of the whole of sexual life, the unmatched prototype of every later sexual satisfaction, to which phantasy often enough recurs in times of need. This sucking involves making the mother's breast the first object of the sexual instinct. I can give you no idea of the important bearing of this first object upon the choice of every later object, of the profound effects it has in its transformations and substitutions in even the remotest regions of our sexual life. But at first the infant, in his sucking activity, gives up this object and replaces it by a part of his own body. He begins to suck his thumbs or his own tongue. In this way he makes himself independent of the consent of the external world as regards gaining pleasure, and besides this he increases it by adding the excitation of a second area of his body. The erotogenic zones are not all equally generous in yielding pleasure; it is therefore an important experience when the infant, as Lindner reports, discovers, in the course of feeling around, the specially excitable regions afforded by his genitals and so finds his way from sucking to masturbation.

[1916-1917, 3385]

The Process of Finding an Object, and the Oedipus Complex. - In the first instance the oral component instinct finds satisfaction by attaching itself to the satiating of the desire for nourishment; and its object is the mother's breast. It then detaches itself, becomes independent and at the same time auto-erotic, that is, it finds an object in the child's own body. Others of the component instincts also start by being auto-erotic and are not until later diverted on to an external object. It is a particularly important fact that the component instincts belonging to the genital zone habitually pass through a period of intense auto-erotic satisfaction. The component instincts are not all equally serviceable in the final genital organization of libido; some of them (for instance, the anal components) are consequently left aside and suppressed, or undergo complicated transformations.

[1923a, 3922]
Unfortunately we can describe this state of things only as it affects the male child; the corresponding processes in the little girl are not known to us. The small boy undoubtedly perceives the distinction between men and women, but to begin with he has no occasion to connect it with a difference in their genitals. It is natural for him to assume that all other living beings, humans and animals, possess a genital like his own; indeed, we know that he looks for an organ analogous to his own in inanimate things as well.¹ This part of the body, which is easily excitable, prone to changes and so rich in sensations, occupies the boy's interest to a high degree and is constantly setting new tasks to his instinct for research. He wants to see it in other people as well, so as to compare it with his own; and he behaves as though he had a vague idea that this organ could and should be bigger. The driving force which this male portion of the body will develop later at puberty expresses itself at this period of life mainly as an urge to investigate, as sexual curiosity. Many of the acts of exhibitionism and aggression which children commit, and which in later years would be judged without hesitation to be expressions of lust, prove in analysis to be experiments undertaken in the service of sexual research.

Erotogenic masochism accompanies the libido through all its developmental phases and derives from them its changing psychical coatings. The fear of being eaten up by the totem animal (the father) originates from the primitive oral organization; the wish to be beaten by the father comes from the sadistic-anal phase which follows it; castration, although it is later disavowed, enters into the content of masochistic phantasies as a precipitate of the phallic stage or organization;¹ and from the final genital organization there arise, of course, the situations of being copulated with and of giving birth, which are characteristic of femaleness. The part played in masochism by the nates, too, is easily understandable, apart from its obvious basis in reality. The nates are the part of the body which is given erotogenic preference in the sadistic-anal phase, like the breast in the oral phase and the penis in the genital phase.

When the (male) child's interest turns to his genitals he betrays the fact by manipulating them frequently; and he then finds that the adults do not approve of this behaviour. More or less plainly, more or less brutally, a threat is pronounced that this part of him which he values so highly will be taken away from him. Usually it is from women that the threat emanates; very often they seek to strengthen their authority by a reference to the father or the doctor, who, so they say, will carry out the punishment. In a number of cases the women will themselves mitigate the threat in a symbolic manner by telling the child that what is to be removed is not his genital, which actually plays a passive part, but his hand, which is the active culprit. It happens particularly often that the little boy is threatened with castration, not because he plays with his penis with his hand, but because he wets his bed every night and cannot be got to be clean. Those in charge of him behave as if this nocturnal incontinence was the result and the proof of his being unduly concerned with his penis, and they are probably right. In any case, long-continued bed-wetting is to be equated with the emissions of adults. It is an expression of the same excitation of the genitals which has impelled the child to masturbate at this period.
The old paediatrician Lindner once remarked that a child discovers the genital zones (the penis or the clitoris) as a source of pleasure while indulging in sensual sucking (thumb sucking).¹ I shall leave it an open question whether it is really true that the child takes the newly found source of pleasure in exchange for the recent loss of the mother's nipple - a possibility to which later phantasies (fellatio) seem to point. Be that as it may, the genital zone is discovered at some time or other, and there seems no justification for attributing any psychical content to the first activities in connection with it. But the first step in the phallic phase which begins in this way is not the linking-up of the masturbation with the object-cathexes of the Oedipus complex, but a momentous discovery which little girls are destined to make. They notice the penis of a brother or playmate, strikingly visible and of large proportions, at once recognize it as the superior counterpart of their own small and inconspicuous organ, and from that time forward fall a victim to envy for the penis. [1925j, 4149]
Psycho-analytic research is most decidedly opposed to any attempt at separating off homosexuals from the rest of mankind as a group of a special character. By studying sexual excitations other than those that are manifestly displayed, it has found that all human beings are capable of making a homosexual object-choice and have in fact made one in their unconscious. Indeed, libidinal attachments to persons of the same sex play no less a part as factors in normal mental life, and a greater part as a motive force for illness, than do similar attachments to the opposite sex. On the contrary, psycho-analysis considers that a choice of an object independently of its sex - freedom to range equally over male and female objects - as it is found in childhood, in primitive states of society and early periods of history, is the original basis from which, as a result of restriction in one direction or the other, both the normal and the inverted types develop. Thus from the point of view of psycho-analysis the exclusive sexual interest felt by men for women is also a problem that needs elucidating and is not a self-evident fact based upon an attraction that is ultimately of a chemical nature. A person's final sexual attitude is not decided until after puberty and is the result of a number of factors, not all of which are yet known; some are of a constitutional nature but others are accidental. No doubt a few of these factors may happen to carry so much weight that they influence the result in their sense. But in general the multiplicity of determining factors is reflected in the variety of manifest sexual attitudes in which they find their issue in mankind. In inverted types, a predominance of archaic constitutions and primitive psychical mechanisms is regularly to be found. Their most essential characteristics seem to be a coming into operation of narcissistic object-choice and a retention of the erotic significance of the anal zone. There is nothing to be gained, however, by separating the most extreme types of inversion from the rest on the basis of constitutional peculiarities of that kind. What we find as an apparently sufficient explanation of these types can be equally shown to be present, though less strongly, in the constitution of transitional types and of those whose manifest attitude is normal. The differences in the end-products may be of a qualitative nature, but analysis shows that the differences between their determinants are only quantitative. Among the accidental factors that influence object-choice we have found that frustration (in the form of an early deterrence, by fear, from sexual activity) deserves attention, and we have observed that the presence of both parents plays an important part. The absence of a strong father in childhood not infrequently favours the occurrence of inversion. Finally, it may be insisted that the concept of inversion in respect of the sexual object should be sharply distinguished from that of the occurrence in the subject of a mixture of sexual characters. In the relation between these two factors, too, a certain degree of reciprocal independence is unmistakably present.

THE RIDDLE OF THE SPHINX

It is not by theoretical interests but by practical ones that activities of research are set going in children. The threat to the bases of a child's existence offered by the discovery or the suspicion of the arrival of a new baby and the fear that he may, as a result of it, cease to be cared for and loved, make him thoughtful and clear-sighted. And this history of the instinct's origin is in line with the fact that the first problem with which it deals is not the question of the distinction between the sexes but the riddle of where babies come from. (This, in a distorted form which can easily be rectified, is the same riddle that was propounded by the Theban Sphinx.) On the contrary, the existence of two sexes does not to begin with arouse any difficulties or doubts in children. It is self-evident to a male child that a genital like his own is to be attributed to everyone he knows, and he cannot make its absence tally with his picture of these other people.
If we could divest ourselves of our corporeal existence, and could view the things of this earth with a fresh eye as purely thinking beings, from another planet for instance, nothing perhaps would strike our attention more forcibly than the fact of the existence of two sexes among human beings, who, though so much alike in other respects, yet mark the difference between them with such obvious external signs. But it does not seem that children choose this fundamental fact in the same way as the starting-point of their researches into sexual problems. Since they have known a father and mother as far back as they can remember in life, they accept their existence as a reality which needs no further enquiry, and a boy has the same attitude towards a little sister from whom he is separated by only a slight difference of age of one or two years. A child's desire for knowledge on this point does not in fact awaken spontaneously, prompted perhaps by some inborn need for established causes; it is aroused under the goad of the self-seeking instincts that dominate him, when - perhaps after the end of his second year - he is confronted with the arrival of a new baby. And a child whose own nursery has received no such addition is able, from observations made in other homes, to put himself in the same situation. The loss of his parents' care, which he actually experiences or justly fears, and the presentiment that from now on he must for evermore share all his possessions with the newcomer, have the effect of awakening his emotions and sharpening his capacities for thought. The elder child expresses unconcealed hostility towards his rival, which finds vent in unfriendly criticisms of it, in wishes that 'the stork should take it away again' and occasionally even in small attacks upon the creature lying helpless in the cradle. A wider difference in age usually softens the expression of this primary hostility. In the same way, at a rather later age, if no small brother or sister has appeared, the child's wish for a playmate, such as he has seen in other families, may gain the upper hand.  

[1908c, 1968]

These false sexual theories, which I shall now discuss, all have one very curious characteristic. Although they go astray in a grotesque fashion, yet each one of them contains a fragment of real truth; and in this they are analogous to the attempts of adults, which are looked at as strokes of genius, at solving the problems of the universe which are too hard for human comprehension. What is correct and hits the mark in such theories is to be explained by their origin from the components of the sexual instinct which are already stirring in the childish organism. For it is not owing to any arbitrary mental act or to chance impressions that those notions arise, but to the necessities of the child's psychosexual constitution; and this is why we can speak of sexual theories in children as being typical, and why we find the same mistaken beliefs in every child whose sexual life is accessible to us.  

[1908c, 1970]
The first of these theories starts out from the neglect of the differences between the sexes on which I laid stress at the beginning of this paper as being characteristic of children. It consists in attributing to everyone, including females, the possession of a penis, such as the boy knows from his own body. It is precisely in what we must regard as the 'normal' sexual constitution that already in childhood the penis is the leading erotogenic zone and the chief auto-erotic sexual object; and the boy's estimate of its value is logically reflected in his inability to imagine a person like himself who is without this essential constituent. When a small boy sees his little sister's genitals, what he says shows that his prejudice is already strong enough to falsify his perception. He does not comment on the absence of a penis, but invariably says, as though by way of consolation and to put things right: 'Her ---'s still quite small. But when she gets bigger it'll grow all right.' The idea of a woman with a penis returns in later life, in the dreams of adults: the dreamer, in a state of nocturnal sexual excitation, will throw a woman down, strip her and prepare for intercourse - and then, in place of the female genitals, he beholds a well-developed penis and breaks off the dream and the excitation. The numerous hermaphrodites of classical antiquity faithfully reproduce this idea, universally held in childhood; one may observe that to most normal people they cause no offence, while the real hermaphroditic formations of the genitals which are permitted to occur by Nature nearly always excite the greatest abhorrence.

[1908c, 1971]

If children could follow the hints given by the excitation of the penis they would get a little nearer to the solution of their problem. That the baby grows inside the mother's body is obviously not a sufficient explanation. How does it get inside? What starts its development? That the father has something to do with it seems likely; he says that the baby is *his* baby as well.¹ Again, the penis certainly has a share, too, in these mysterious happenings; the excitation in it which accompanies all these activities of the child's thoughts bears witness to this. Attached to this excitation are impulsions which the child cannot account for - obscure urges to do something violent, to press in, to knock to pieces, to tear open a hole somewhere. But when the child thus seems to be well on the way to postulating the existence of the vagina and to concluding that an incursion of this kind by his father's penis into his mother is the act by means of which the baby is created in his mother's body - at this juncture his enquiry is broken off in helpless perplexity. For standing in its way is his theory that his mother possesses a penis just as a man does, and the existence of the cavity which receives the penis remains undiscovered by him. It is not hard to guess that the lack of success of his intellectual efforts makes it easier for him to reject and forget them. This brooding and doubting, however, becomes the prototype of all later intellectual work directed towards the solution of problems, and the first failure has a crippling effect on the child's whole future.

[1908c, 1972]
Their ignorance of the vagina also makes it possible for children to believe in the second of their sexual theories. If the baby grows in the mother's body and is then removed from it, this can only happen along the one possible pathway - the anal aperture. *The baby must be evacuated like a piece of excrement, like a stool.* When, in later childhood, the same question is the subject of solitary reflection or of a discussion between two children, the explanations probably arrived at are that the baby emerges from the navel, which comes open, or that the abdomen is slit up and the baby taken out - which was what happened to the wolf in the story of Little Red Riding-Hood. These theories are expressed aloud and also consciously remembered later on; they no longer contain anything objectionable. These same children have by then completely forgotten that in earlier years they believed in another theory of birth, which is now obstructed by the repression of the anal sexual components that has meanwhile occurred. At that time a motion was something which could be talked about in the nursery without shame. The child was still not so distant from his constitutional coprophilic inclinations. There was nothing degraded about coming into the world like a heap of faeces, which had not yet been condemned by feelings of disgust. The cloacal theory, which, after all, is valid for so many animals, was the most natural theory, and it alone could obtrude upon the child as being a probable one.

[1908c, 1973]

'A little later Hans was watching his seven-day-old sister being given a bath. "But her widdler's still quite small," he remarked; and then added, as though by way of consolation: "When she grows up it'll get bigger all right."²

[1909b, 2007]

² Two other boys were reported to me as having made the same judgement, expressed in identical words and followed by the same anticipation, when they were allowed to satisfy their curiosity and look at their baby sister's body for the first time. One might well feel horrified at such signs of the premature decay of a child's intellect. Why was it that these young enquirers did not report what they really saw - namely, that there was no widdler there? In little Hans's case, at all events, we can account completely for the faulty perception. We are aware that by a process of careful induction he had arrived at the general proposition that every animate object, in contradistinction to inanimate ones, possesses a widdler. His mother had confirmed him in this conviction by giving him corroborative information in regard to persons inaccessible to his own observation. He was now utterly incapable of surrendering what he had achieved merely on the strength of this single observation made upon his little sister. He therefore made a judgement that in that instance also there was a widdler present, only that it was still very small, but that it would grow till it was as big as a horse's.

[1909b, 2007]

A five-year-old boy cousin came to visit Hans, who had by then reached the age of four. Hans was constantly putting his arms round him, and once, as he was giving him one of these tender embraces, said: 'I am so fond of you.'

[1909b, 2010]

This is the first trace of homosexuality that we have come across in him, but it will not be the last. Little Hans seems to be a positive paragon of all the vices.

[1909b, 2010]
"Hans obtained some companionship of this kind when, shortly afterwards (he was by then four and a half), we moved to Gmunden for the summer holidays. In our house there his playmates were our landlord's children: Franzl (about twelve years old), Fritzl (eight), Olga (seven), and Berta (five). Besides these there were the neighbour's children, Anna (ten), and two other little girls of nine and seven whose names I have forgotten. Hans's favourite was Fritzl; he often hugged him and made protestations of his love. Once when he was asked: "Which of the girls are you fondest of?" he answered: "Fritzl!" At the same time he treated the girls in a most aggressive, masculine and arrogant way, embracing them and kissing them heartily - a process to which Berta in particular offered no objection. When Berta was coming out of the room one evening he put his arms round her neck and said in the fondest tones: "Berta, you are a dear!" This, by the way, did not prevent his kissing the others as well and assuring them of his love. He was fond, too, of the fourteen-year-old Mariedl - another of our landlord's daughters - who used to play with him. One evening as he was being put to bed he said: "I want Mariedl to sleep with me." On being told that would not do, he said: "Then she shall sleep with Mummy or with Daddy." He was told that would not do either, but that Mariedl must sleep with her own father and mother. Upon which the following dialogue took place:

There is absolutely no justification for distinguishing a special homosexual instinct. What constitutes a homosexual is a peculiarity not in his instinctual life but in his choice of an object. Let me recall what I have said in my Three Essays to the effect that we have mistakenly imagined the bond between instinct and object in sexual life as being more intimate than it really is. A homosexual may have normal instincts, but he is unable to disengage them from a class of objects defined by a particular determinant. And in his childhood, since at that period this determinant is taken for granted as being of universal application, he is able to behave like little Hans, who showed his affection to little boys and girls indiscriminately, and once described his friend Fritzl as 'the girl he was fondest of'. Hans was a homosexual (as all children may very well be), quite consistently with the fact, which must always be kept in mind, that he was acquainted with only one kind of genital organ - a genital organ like his own."
Put away your doubts, then, and join me in a consideration of infantile sexuality from the earliest age.¹ A child's sexual instinct turns out to be put together out of a number of factors; it is capable of being divided up into numerous components which originate from various sources. Above all, it is still independent of the reproductive function, into the service of which it will later be brought. It serves for the acquisition of different kinds of pleasurable feeling, which, basing ourselves on analogies and connections, we bring together under the idea of sexual pleasure. The chief source of infantile sexual pleasure is the appropriate excitation of certain parts of the body that are especially susceptible to stimulus: apart from the genitals, these are the oral, anal and urethral orifices, as well as the skin and other sensory surfaces. Since at this first phase of infantile sexual life satisfaction is obtained from the subject's own body and extraneous objects are disregarded, we term this phase (from a word coined by Havelock Ellis) that of auto-erotism. We call the parts of the body that are important in the acquisition of sexual pleasure 'erotogenic zones'. Thumb-sucking (or sensual sucking) in the youngest infants is a good example of this auto-erotic satisfaction from an erotogenic zone. The first scientific observer of this phenomenon, a paediatrician in Budapest named Lindner (1879), already interpreted it correctly as sexual satisfaction and described exhaustively its transition to other and higher forms of sexual activity. Another sexual satisfaction at this period of life is the masturbatory excitation of the genitals, which retains so much importance in later life and by many people is never completely conquered. Alongside these and other auto-erotic activities, we find in children at a very early age manifestations of those instinctual components of sexual pleasure (or, as we like to say, of libido) which presuppose the taking of an extraneous person as an object. These instincts occur in pairs of opposites, active and passive. I may mention as the most important representatives of this group the desire to cause pain (sadism) with its passive counterpart (masochism) and the active and passive desire for looking, from the former of which curiosity branches off later on and from the latter the impulsion to artistic and theatrical display. Others of a child's sexual activities already imply the making of an 'object-choice', where an extraneous person becomes the main feature, a person who owes his importance in the first instance to considerations arising from the self-preservative instinct. But at this early period of childhood difference in sex plays no decisive part as yet. Thus you can attribute some degree of homosexuality to every child without doing him an injustice. This widespread and copious but dissociated sexual life of children, in which each separate instinct pursues its own acquisition of pleasure independently of all the rest, is now brought together and organized in two main directions, so that by the end of puberty the individual's final sexual character is as a rule completely formed. On the one hand, the separate instincts become subordinated to the dominance of the genital zone, so that the whole sexual life enters the service of reproduction, and the satisfaction of the separate instincts retains its importance only as preparing for and encouraging the sexual act proper. On the other hand, object-choice pushes auto-erotism into the background, so that in the subject's erotic life all the components of the sexual instinct now seek satisfaction in relation to the person who is loved. Not all of the original sexual components, however, are admitted to take part in this final establishment of sexuality. Even before puberty extremely energetic repressions of certain instincts have been effected under the influence of education, and mental forces such as shame, disgust and morality have been set up, which, like watchmen, maintain these repressions. So that when at puberty the high tide of sexual demands is reached, it is met by these mental reactive or resistant structures like dams, which direct its flow into what are called normal channels and make it impossible for it to reactivate the instincts that have undergone repression. It is in particular the coprophilic impulses of childhood - that is to say, the desires attaching to the excreta - which are submitted the most rigorously to repression, and the same is true, furthermore, of fixation to the figures to which the child's original object-choice was attached.

[1910a, 2230]
In connection with the attempt, which psycho-analysis has made necessary, to correlate the fundamental principle of its theory with the mental life of children, Adler exhibits the most serious departures from actual observation and the most fundamental confusion in his concepts. The biological, social and psychological meanings of 'masculine' and 'feminine' are here hopelessly mixed. It is impossible, and is disproved by observation, that a child, whether male or female, should found the plan of its life on an original depreciation of the female sex and take the wish to be a real man as its 'guiding line'. Children have, to begin with, no idea of the significance of the distinction between the sexes; on the contrary, they start with the assumption that the same genital organ (the male one) is possessed by both sexes; they do not begin their sexual researches with the problem of the distinction between the sexes, while the social underestimation of women is completely foreign to them. There are women in whose neurosis the wish to be a man has played no part. Whatever in the nature of a masculine protest can be shown to exist is easily traceable to a disturbance in primary narcissism due to threats of castration or to the earliest interferences with sexual activities. All disputes about the psychogenesis of the neuroses must eventually be decided in the field of the neuroses of childhood. Careful dissection of a neurosis in early childhood puts an end to all misapprehensions about the aetiology of the neuroses and to all doubts about the part played by the sexual instincts in them. That is why, in his criticism of Jung's paper 'Conflicts in the Mind of the Child', Adler was obliged to resort to the imputation that the facts of the case had been one-sidedly arranged, 'no doubt by the father'.

Though I am anxious to cut short this discussion still further, I must nevertheless tell you a little about the sexual researches of children: they are too characteristic of infantile sexuality and of too great significance for the symptomatology of the neuroses to be passed over. Infantile sexual researches begin very early, sometimes before the third year of life. They do not relate to the distinction between the sexes, for this means nothing to children, since they (or at any rate boys) attribute the same male genital to both sexes. If, afterwards, a boy makes the discovery of the vagina from seeing his little sister or a girl playmate, he tries, to begin with, to disavow the evidence of his senses, for he cannot imagine a human creature like himself who is without such a precious portion. Later on, he takes fright at the possibility thus presented to him; and any threats that may have been made to him earlier, because he took too intense an interest in his little organ, now produce a deferred effect. He comes under the sway of the castration complex, the form taken by which plays a great part in the construction of his character if he remains normal, in his neurosis if he falls ill, and in his resistances if he comes into analytic treatment. As regards little girls, we can say of them that they feel greatly at a disadvantage owing to their lack of a big, visible penis, that they envy boys for possessing one and that, in the main for this reason, they develop a wish to be a man - a wish that re-emerges later on, in any neurosis that may arise if they meet with a mishap in playing a feminine part. In her childhood, moreover, a girl's clitoris takes on the role of a penis entirely: it is characterized by special excitability and is the area in which auto-erotic satisfaction is obtained. The process of a girl's becoming a woman depends very much on the clitoris passing on this sensitivity to the vaginal orifice in good time and completely. In cases of what is known as sexual anaesthesia in women the clitoris has obstinately retained its sensitivity.

¹ Perhaps it would be safer to say 'with the parents': for before a child has arrived at definite knowledge of the difference between the sexes, the lack of a penis, it does not distinguish in value between its father and its mother. I recently came across the instance of a young married woman whose story showed that, after noticing the lack of a penis in herself, she had supposed it to be absent not in all women, but only in those whom she regarded as inferior, and had still supposed that her mother possessed one. In order to simplify my presentation I shall discuss only identification with the father.

[1914d, 2918]

[1916-1917, 3387]

[1923b, 3965]
But why should his father, after being reduced to the status of a Devil, bear this physical mark of a woman? The feature seems at first hard to interpret; but soon we find two explanations which compete with each other without being mutually exclusive. A boy's feminine attitude to his father undergoes repression as soon as he understands that his rivalry with a woman for his father's love has as a precondition the loss of his own male genitals - in other words, castration. Repudiation of the feminine attitude is thus the result of a revolt against castration. It regularly finds its strongest expression in the converse phantasy of castrating the father, of turning him into a woman. Thus the Devil's breasts would correspond to a projection of the subject's own femininity on to the father-substitute. The second explanation of these female additions to the Devil's body no longer has a hostile meaning but an affectionate one. It sees in the adoption of this shape an indication that the child's tender feelings towards his mother have been displaced on to his father; and this suggests that there has previously been a strong fixation on the mother, which, in its turn, is responsible for part of the child's hostility towards his father. Large breasts are the positive sexual characteristics of the mother even at a time when the negative characteristic of the female - her lack of a penis - is as yet unknown to the child.¹

Unfortunately we can describe this state of things only as it affects the male child; the corresponding processes in the little girl are not known to us. The small boy undoubtedly perceives the distinction between men and women, but to begin with he has no occasion to connect it with a difference in their genitals. It is natural for him to assume that all other living beings, humans and animals, possess a genital like his own; indeed, we know that he looks for an organ analogous to his own in inanimate things as well.¹ This part of the body, which is easily excitable, prone to changes and so rich in sensations, occupies the boy's interest to a high degree and is constantly setting new tasks to his instinct for research. He wants to see it in other people as well, so as to compare it with his own; and he behaves as though he had a vague idea that this organ could and should be bigger. The driving force which this male portion of the body will develop later at puberty expresses itself at this period of life mainly as an urge to investigate, as sexual curiosity. Many of the acts of exhibitionism and aggression which children commit, and which in later years would be judged without hesitation to be expressions of lust, prove in analysis to be experiments undertaken in the service of sexual research.²

We have lately been made more clearly aware than before that a child's sexual development advances to a certain phase at which the genital organ has already taken over the leading role. But this genital is the male one only, or, more correctly, the penis; the female genital has remained undiscovered. This phallic phase, which is contemporaneous with the Oedipus complex, does not develop further to the definitive genital organization, but is submerged, and is succeeded by the latency period. Its termination, however, takes place in a typical manner and in conjunction with events that are of regular recurrence.
We should not be as short-sighted as the person in charge of the child who threatens him with castration, and we must not overlook the fact that at this time masturbation by no means represents the whole of his sexual life. As can be clearly shown, he stands in the Oedipus attitude to his parents; his masturbation is only a genital discharge of the sexual excitation belonging to the complex, and throughout his later years will owe its importance to that relationship. The Oedipus complex offered the child two possibilities of satisfaction, an active and a passive one. He could put himself in his father's place in a masculine fashion and have intercourse with his mother as his father did, in which case he would soon have felt the latter as a hindrance; or he might want to take the place of his mother and be loved by his father, in which case his mother would become superfluous. The child may have had only very vague notions as to what constitutes a satisfying erotic intercourse; but certainly the penis must play a part in it, for the sensations in his own organ were evidence of that. So far he had had no occasion to doubt that women possessed a penis. But now his acceptance of the possibility of castration, his recognition that women were castrated, made an end of both possible ways of obtaining satisfaction from the Oedipus complex. For both of them entailed the loss of his penis - the masculine one as a resulting punishment and the feminine one as a precondition. If the satisfaction of love in the field of the Oedipus complex is to cost the child his penis, a conflict is bound to arise between his narcissistic interest in that part of his body and the libidinal cathexis of his parental objects. In this conflict the first of these forces normally triumphs: the child's ego turns away from the Oedipus complex.

The process of arriving at an object, which plays such an important part in mental life, takes place alongside of the organization of the libido. After the stage of auto-erotism, the first love-object in the case of both sexes is the mother; and it seems probable that to begin with a child does not distinguish its mother's organ of nutrition from its own body. Later, but still in the first years of infancy, the relation known as the Oedipus complex becomes established: boys concentrate their sexual wishes upon their mother and develop hostile impulses against their father as being a rival, while girls adopt an analogous attitude. All of the different variations and consequences of the Oedipus complex are important; and the innately bisexual constitution of human beings makes itself felt and increases the number of simultaneously active tendencies. Children do not become clear for quite a long time about the differences between the sexes; and during this period of sexual researches they produce typical sexual theories which, being circumscribed by the incompleteness of their authors' own physical development, are a mixture of truth and error and fail to solve the problems of sexual life (the riddle of the Sphinx - that is, the question of where babies come from). We see, then, that a child's first object-choice is an incestuous one. The whole course of development that I have described is run through rapidly. For the most remarkable feature of the sexual life of man is its diphasic onset, its onset in two waves, with an interval between them. It reaches a first climax in the fourth or fifth year of a child's life. But thereafter this early efflorescence of sexuality passes off; the sexual impulses which have shown such liveliness are overcome by repression, and a period of latency follows, which lasts until puberty and during which the reaction-formations of morality, shame, and disgust are built up. Of all living creatures man alone seems to show this diphasic onset of sexual growth, and it may perhaps be the biological determinant of his predisposition to neuroses. At puberty the impulses and object-relations of a child's early years become re-energised, and amongst him the emotional ties of its Oedipus complex. In the sexual life of puberty there is a struggle between the urges of early years and the inhibitions of the latency period. Before this, and while the child is at the highest point of its infantile sexual development, a genital organization of a sort is established; but only the male genitals play a part in it, and the female ones remain undiscovered. (I have described this as the period of phallic primacy.) At this stage the contrast between the sexes is not stated in terms of 'male' or 'female' but of 'possessing a penis' or 'castrated'. The castration complex which arises in this connection is of the profoundest importance in the formation alike of character and of neuroses.
Another characteristic of early infantile sexuality is that the female sexual organ proper as yet plays no part in it: the child has not yet discovered it. Stress falls entirely on the male organ, all the child's interest is directed towards the question of whether it is present or not. We know less about the sexual life of little girls than of boys. But we need not feel ashamed of this distinction; after all, the sexual life of adult women is a 'dark continent' for psychology. But we have learnt that girls feel deeply their lack of a sexual organ that is equal in value to the male one; they regard themselves on that account as inferior, and this 'envy for the penis' is the origin of a whole number of characteristic feminine reactions.

[1926e, 4355]

The third phase is that known as the phallic one, which is, as it were, a forerunner of the final form taken by sexual life and already much resembles it. It is to be noted that it is not the genitals of both sexes that play a part at this stage, but only the male ones (the phallus). The female genitals long remain unknown: in children's attempts to understand the sexual processes they pay homage to the venerable cloacal theory - a theory which has a genetic justification.²

[1940a [1938], 4965]

With the phallic phase and in the course of it the sexuality of early childhood reaches its height and approaches its dissolution. Thereafter boys and girls have different histories. Both have begun to put their intellectual activity at the service of sexual researches: both start off from the premiss of the universal presence of the penis. But now the paths of the sexes diverge. The boy enters the Oedipus phase; he begins to manipulate his penis and simultaneously has phantasies of carrying out some sort of activity with it in relation to his mother, till, owing to the combined effect of a threat of castration and the sight of the absence of a penis in females, he experiences the greatest trauma of his life and this introduces the period of latency with all its consequences. The girl, after vainly attempting to do the same as the boy, comes to recognize her lack of a penis or rather the inferiority of her clitoris, with permanent effects on the development of her character; as a result of this first disappointment in rivalry, she often begins by turning away altogether from sexual life.

[1940a [1938], 4965]
We found from the study of neurotic disorders that beginnings of an organization of the sexual instinctual components can be detected in the sexual life of children from its very beginning. During a first, very early phase, oral erotism occupies most of the picture. A second of these pregenital organizations is characterized by the predominance of sadism and anal erotism. It is not until a third phase has been reached that the genital zones proper contribute their share in determining sexual life, and in children this last phase is developed only so far as to a primacy of the phallus.

[1905d, 1544]

Thus in little Hans's sexual constitution the genital zone was from the outset the one among his erotogenic zones which afforded him the most intense pleasure. The only other similar pleasure of which he gave evidence was excretory pleasure, the pleasure attached to the orifices through which micturition and evacuation of the bowels are effected. In his final phantasy of bliss, with which his illness was overcame, he imagined he had children, whom he took to the W.C., whom he made to widdle, whose behinds he wiped - for whom, in short, he did 'everything one can do with children'; it therefore seems impossible to avoid the assumption that during the period when he himself had been looked after as an infant these same performances had been the source of pleasurable sensations for him. He had obtained this pleasure from his erotogenic zones with the help of the person who had looked after him - his mother, in fact; and thus the pleasure already pointed the way to object-choice. But it is just possible that at a still earlier date he had been in the habit of giving himself this pleasure auto-erotically - that he had been one of those children who like retaining their excreta till they can derive a voluptuous sensation from their evacuation. I say no more than that it is possible, because the matter was not cleared up in the analysis; the 'making a row with the legs' (kicking about), of which he was so much frightened later on, points in that direction. But in any case these sources of pleasure had no particularly striking importance with Hans, as they so often have with other children. He early became clean in his habits, and neither bed-wetting nor diurnal incontinence played any part during his first years; no trace was observed in him of any inclination to play with his excrement, a propensity which is so revolting in adults, and which commonly makes its reappearance at the termination of processes of psychical involution.

[1909b, 2092]

The Process of Finding an Object, and the Oedipus Complex. - In the first instance the oral component instinct finds satisfaction by attaching itself to the satiating of the desire for nourishment; and its object is the mother's breast. It then detaches itself, becomes independent and at the same time auto-erotic, that is, it finds an object in the child's own body. Others of the component instincts also start by being auto-erotic and are not until later diverted on to an external object. It is a particularly important fact that the component instincts belonging to the genital zone habitually pass through a period of intense auto-erotic satisfaction. The component instincts are not all equally serviceable in the final genital organization of libido; some of them (for instance, the anal components) are consequently left aside and suppressed, or undergo complicated transformations.

[1923a, 3922]
ACTIVITY OF THE GENITAL ZONES

Among the erotogenic zones that form part of the child's body there is one which certainly does not play the opening part, and which cannot be the vehicle of the oldest sexual impulses, but which is destined to great things in the future. In both male and female children it is brought into connection with micturition (in the glans and clitoris) and in the former is enclosed in a pouch of mucous membrane, so that there can be no lack of stimulation of it by secretions which may give an early start to sexual excitation. The sexual activities of this erotogenic zone, which forms part of the sexual organs proper, are the beginning of what is later to become 'normal' sexual life. The anatomical situation of this region, the secretions in which it is bathed, the washing and rubbing to which it is subjected in the course of a child's toilet, as well as accidental stimulation (such as the movement of intestinal worms in the case of girls), make it inevitable that the pleasurable feeling which this part of the body is capable of producing should be noticed by children even during their earliest infancy, and should give rise to a need for its repetition. If we consider this whole range of contrivances and bear in mind that both making a mess and measures for keeping clean are bound to operate in much the same way, it is scarcely possible to avoid the conclusion that the foundations for the future primacy over sexual activity exercised by this erotogenic zone are established by early infantile masturbation, which scarcely a single individual escapes. The action which disposes of the stimulus and brings about satisfaction consists in a rubbing movement with the hand or in the application of pressure (no doubt on the lines of a pre-existing reflex) either from the hand or by bringing the thighs together. This last method is by far the more common in the case of girls. The preference for the hand which is shown by boys is already evidence of the important contribution which the instinct for mastery is destined to make to masculine sexual activity.¹

It will be in the interests of clarity if I say at once that three phases of infantile masturbation are to be distinguished. The first of these belongs to early infancy, and the second to the brief efflorescence of sexual activity about the fourth year of life; only the third phase corresponds to pubertal masturbation, which is often the only kind taken into account.

SECOND PHASE OF INFANTILE MASTURBATION

The masturbation of early infancy seems to disappear after a short time; but it may persist uninterruptedly until puberty, and this would constitute the first great deviation from the course of development laid down for civilized men. At some point of childhood after early infancy, as a rule before the fourth year, the sexual instinct belonging to the genital zone usually revives and persists again for a time until it is once more suppressed, or it may continue without interruption. This second phase of infantile sexual activity may assume a variety of different forms which can only be determined by a precise analysis of individual cases. But all its details leave behind the deepest (unconscious) impressions in the subject's memory, determine the development of his character, if he is to remain healthy, and the symptomatology of his neurosis, if he is to fall ill after puberty.¹ In the latter case we find that this sexual period has been forgotten and that the conscious memories that bear witness to it have been displaced. (I have already mentioned that I am also inclined to relate normal infantile amnesia to this infantile sexual activity.) Psychoanalytic investigation enables us to make what has been forgotten conscious and thus do away with a compulsion that arises from the unconscious psychical material.

¹ [Footnote added 1915:] Unusual techniques in carrying out masturbation in later years seem to point to the influence of a prohibition against masturbation which has been overcome.
If this idea of a woman with a penis becomes 'fixated' in an individual when he is a child, resisting all the influences of later life and making him as a man unable to do without a penis in his sexual object, then, although in other respects he may lead a normal sexual life, he is bound to become a homosexual, and will seek his sexual object among men who, owing to some other physical and mental characteristics, remind him of women. Real women, when he comes to know them later, remain impossible as sexual objects for him, because they lack the essential sexual attraction; indeed, in connection with another impression of his childhood life, they may even become abhorrent to him. The child, having been mainly dominated by excitations in the penis, will usually have obtained pleasure by stimulating it with his hand; he will have been detected in this by his parents or nurse and terrorized by the threat of having his penis cut off. The effect of this 'threat of castration' is proportionate to the value set upon that organ and is quite extraordinarily deep and persistent. Legends and myths testify to the upheaval in the child's emotional life and to the horror which is linked with the castration complex - a complex which is subsequently remembered by consciousness with corresponding reluctance. The woman's genitalia, when seen later on, are regarded as a mutilated organ and recall this threat, and they therefore arouse horror instead of pleasure in the homosexual. This reaction cannot be altered in any way when the homosexual comes to learn from science that his childish assumption that women had a penis too was not so far wrong after all. Anatomy has recognized the clitoris within the female pudenda as being an organ that is homologous to the penis; and the physiology of the sexual processes has been able to add that this small penis which does not grow any bigger behaves in fact during childhood like a real and genuine penis - that it becomes the seat of excitations which lead to its being touched, that its excitability gives the little girl's sexual activity a masculine character and that a wave of repression in the years of puberty is needed in order for this masculine sexuality to be discarded and the woman to emerge. Since the sexual function of many women is crippled, whether by their obstinate clinging on to this excitability of the clitoris so that they remain anaesthetic in intercourse, or by such excessive repression occurring that its operation is partly replaced by hysterical compensatory formations - all this seems to show that there is some truth in the infantile sexual theory that women, like men, possess a penis.

[1908c, 1971]

Speaking as a whole, hysterical attacks, like hysteria in general, revive a piece of sexual activity in women which existed during their childhood and at that time revealed an essentially masculine character. It can often be observed that girls who have shown a boyish nature and inclinations up to the years before puberty are precisely those who become hysterical from puberty onwards. In a whole number of cases the hysterical neurosis merely represents an excessive accentuation of the typical wave of repression which, by doing away with her masculine sexuality, allows the woman to emerge.²

[1909a, 1984]
The first trait in little Hans which can be regarded as part of his sexual life was a quite peculiarly lively interest in his 'widdler' - an organ deriving its name from that one of its two functions which, scarcely the less important of the two, is not to be eluded in the nursery. This interest aroused in him the spirit of enquiry, and he thus discovered that the presence or absence of a widdler made it possible to differentiate between animate and inanimate objects. He assumed that all animate objects were like himself, and possessed this important bodily organ; he observed that it was present in the larger animals, suspected that this was so too in both his parents, and was not deterred by the evidence of his own eyes from authenticating the fact in his new-born sister. One might almost say that it would have been too shattering a blow to his 'Weltanschauung' if he had had to make up his mind to forgo the presence of this organ in a being similar to him; it would have been as though it were being torn away from himself. It was probably on this account that a threat of his mother's, which was concerned precisely with the loss of his widdler, was hastily dismissed from his thoughts and only succeeded in making its effects apparent at a later period. The reason for his mother's intervention had been that he used to like giving himself feelings of pleasure by touching his member: the little boy had begun to practise the commonest - and most normal - form of auto-erotic sexual activity.

The arrival of his sister brought into Hans's life many new elements, which from that time on gave him no rest. In the first place he was obliged to submit to a certain degree of privation: to begin with, a temporary separation from his mother, and later a permanent diminution in the amount of care and attention which he had received from her and which thenceforward he had to grow accustomed to sharing with his sister. In the second place, he experienced a revival of the pleasures he had enjoyed when he was looked after as an infant; for they were called up by all that he saw his mother doing for the baby. As a result of these two influences his erotic needs became intensified, while at the same time they began to obtain insufficient satisfaction. He made up for the loss which his sister's arrival had entailed on him by imagining that he had children of his own; and so long as he was at Gmunden - on his second visit there - and could really play with these children, he found a sufficient outlet for his affections. But after his return to Vienna he was once more alone, and set all his hopes upon his mother. He had meanwhile suffered another privation, having been exiled from his parents' bedroom at the age of four and a half. His intensified erotic excitability now found expression in phantasies, by which in his loneliness he conjured up his playmates of the past summer, and in regular auto-erotic satisfaction obtained by a masturbatory stimulation of his genitals.

I have, as you know, divided masturbation according to the subject's age into (1) masturbation in infants, which includes all auto-erotic activities serving the purpose of sexual satisfaction, (2) masturbation in children, which arises directly out of the preceding kind and has already become fixed to certain erotogenic zones, and (3) masturbation at puberty, which is either continuous with childhood masturbation or is separated from it by the period of latency. In some of the accounts which I have heard you give, full justice has not quite been done to this temporal division. The ostensible unity of masturbation, which is fostered by the customary medical terminology, has given rise to some generalizations where a differentiation according to the three periods of life would have been better justified. It has been a matter for regret, too, that we have not been able to pay as much attention to female as to male masturbation; female masturbation, I believe, is deserving of a special study and in its case it is particularly true that a special emphasis lies on the modifications in it that arise in relation to the subject's age.
I come now to the objections raised by Reitler to my teleological argument in favour of the ubiquity of masturbation in infancy. I admit that this argument must be abandoned. If one more edition of my *Three Essays on the Theory of Sexuality* is called for, it will not contain the sentence under attack. I will renounce my attempt at guessing the purposes of Nature and will content myself with describing the facts.

[1912f, 2569]

There is another question that I might draw your attention to, which has been dealt with too little in our discussions: that of 'unconscious' masturbation. I mean masturbation during sleep, during abnormal states, or fits. You will recall the many hysterical fits in which masturbatory acts recur in a disguised or unrecognizable way, after the subject has renounced that form of satisfaction, and the many symptoms in obsessional neurosis which seek to replace and repeat this kind of sexual activity, which has formerly been forbidden. We may also speak of a therapeutic return of masturbation. A number of you will have found on occasion, as I have, that it represents a great advance if during the treatment the patient ventures to take up masturbation once more, though he may have no intention of making a permanent stop at that infantile halting-place. In this connection I may remind you that a considerable number of precisely the most severe sufferers from neurosis have avoided all recollection of masturbation during historic times, while psycho-analysis is able to prove that that species of sexual activity had by no means been strange to them during the forgotten earliest period of their lives.

[1912f, 2574]

If an infant could speak, he would no doubt pronounce the act of sucking at his mother's breast by far the most important in his life. He is not far wrong in this, for in this single act he is satisfying at once the two great vital needs. We are therefore not surprised to learn from psycho-analysis how such psychical importance the act retains all through life. Sucking at the mother's breast is the starting-point of the whole of sexual life, the unmatched prototype of every later sexual satisfaction, to which phantasy often enough recurs in times of need. This sucking involves making the mother's breast the first object of the sexual instinct. I can give you no idea of the important bearing of this first object upon the choice of every later object, of the profound effects it has in its transformations and substitutions in even the remotest regions of our sexual life. But at first the infant, in his sucking activity, gives up this object and replaces it by a part of his own body. He begins to suck his thumbs or his own tongue. In this way he makes himself independent of the consent of the external world as regards gaining pleasure, and besides this he increases it by adding the excitement of a second area of his body. The erotogenic zones are not all equally generous in yielding pleasure; it is therefore an important experience when the infant, as Lindner reports, discovers, in the course of feeling around, the specially excitable regions afforded by his genitals and so finds his way from sucking to masturbation.

[1916-1917, 3385]
In forming this opinion of sensual sucking we have already become acquainted with two decisive characteristics of infantile sexuality. It makes its appearance attached to the satisfaction of the major organic needs, and it behaves *auto-erotically* - that is, it seeks and finds its objects in the infant's own body. What has been shown most clearly in connection with the intake of nourishment is repeated in part with the excretions. We conclude that infants have feelings of pleasure in the process of evacuating urine and faeces and that they soon contrive to arrange those actions in such a way as to bring them the greatest possible yield of pleasure through the corresponding excitations of the erotogenic zones of the mucous membrane. It is here for the first time (as Lou Andreas-Salomé has subtly perceived) that they encounter the external world as an inhibiting power, hostile to their desire for pleasure, and have a glimpse of later conflicts both external and internal. An infant must not produce his excreta at whatever moment he chooses, but when other people decide that he shall. In order to induce him to forgo these sources of pleasure, he is told that everything that has to do with these functions is improper and must be kept secret. This is where he is first obliged to exchange pleasure for social respectability. To begin with, his attitude to his excreta themselves is quite different. He feels no disgust at his faeces, values them as a portion of his own body with which he will not readily part, and makes use of them as his first 'gift', to distinguish people whom he values especially highly. Even after education has succeeded in its aim of making these inclinations alien to him, he carries on his high valuation of faeces in his estimate of 'gifts' and 'money'. On the other hand he seems to regard his achievements in urinating with peculiar pride.

[1916-1917, 3385]

Allow me, therefore, to proceed with my brief account of infantile sexuality. What I have already reported of two systems of organs might be confirmed in reference to the others. A child's sexual life is indeed made up entirely of the activities of a number of component instincts which seek, independently of one another, to obtain pleasure, in part from the subject's own body and in part already from an external object. Among these organs the genitals come into prominence very soon. There are people in whom obtaining pleasure from their own genitals, without the assistance of any other genitals or of an object, continues uninterruptedly from infantile masturbation to the unavoidable masturbation of puberty and persists for an indefinite length of time afterwards. Incidentally, the topic of masturbation is not one that can be so easily disposed of: it is something that calls for examination from many angles.

[1916-1917, 3386]

And one thing more! On the whole you will have gained very little for what you want to assert - the sexual purity of children - even if you succeed in convincing me that it would be better to regard the activities of infants-in-arms as non-sexual. For the sexual life of children is already free from all these doubts from the third year of life onwards: at about that time the genitals already begin to stir, a period of infantile masturbation - of genital satisfaction, therefore - sets in, regularly perhaps. The mental and social phenomena of sexual life need no longer be absent; the choice of an object, an affectionate preference for particular people, a decision, even, in favour of one of the two sexes, jealousy - all these have been established by impartial observations made independently of psycho-analysis and before its time, and they can be confirmed by any observer who cares to see them. You will object that you have never doubted the early awakening of affection; you have only doubted whether this affection bears a 'sexual' character. It is true that children have already learnt to conceal this between the ages of three and eight. But if you are attentive you will be able nevertheless to collect enough evidence of the 'sensual' aims of this affection, and whatever you still lack after that can easily be supplied in plenty by the investigations of analysis. The sexual aims at this period of life are intimately connected with the child's contemporary sexual researches, of which I have given you some instances. The perverse character of some of these aims is of course dependent on the child's constitutional immaturity, for he has not yet discovered the aim that consists in the act of copulation.

[1916-1917, 3393]
Among the occurrences which recur again and again in the youthful history of neurotics - which are scarcely ever absent - there are a few of particular importance, which also deserve, on that account, I think, to be brought into greater prominence than the rest. As specimens of this class I will enumerate these: observation of parental intercourse, seduction by an adult and threat of being castrated. It would be a mistake to suppose that they are never characterized by material reality; on the contrary, this is often established incontestably through enquiries from older members of the patient’s family. It is by no means a rare thing, for instance, for a little boy, who is beginning to play with his penis in a naughty way and is not yet aware that one must conceal such activities, to be threatened by a parent or nurse with having his penis or his sinful hand cut off. Parents will often admit this when they are asked, since they think they have done something useful in making such a threat; a number of people have a correct conscious memory of such a threat, especially if it was made at a somewhat later period. If the threat is delivered by the mother or some other female she usually shifts its performance on to the father or the doctor. In Struwwelpeter, the famous work of the Frankfurt paediatrician Hoffmann (which owes its popularity precisely to an understanding of the sexual and other complexes of childhood), you will find castration softened into a cutting-off of the thumbs as a punishment for obstinate sucking. But it is highly improbable that children are threatened with castration as often as it appears in the analyses of neurotics. We shall be satisfied by realizing that the child puts a threat of this kind together in his imagination on the basis of hints, helped out by a knowledge that auto-erotic satisfaction is forbidden and under the impression of his discovery of the female genitals. Nor is it only in proletarian families that it is perfectly possible for a child, while he is not yet credited with possessing an understanding or a memory, to be a witness of the sexual act between his parents or other grown-up people; and the possibility cannot be rejected that he will be able to understand and react to the impression in retrospect. If, however, the intercourse is described with the most minute details, which would be difficult to observe, or if, as happens most frequently, it turns out to have been intercourse from behind more ferarum [in the manner of animals], there can be no remaining doubt that the phantasy is based on an observation of intercourse between animals (such as dogs) and that its motive was the child’s unsatisfied scopophilia during puberty. The extreme achievement on these lines is a phantasy of observing parental intercourse while one is still an unborn baby in the womb. Phantasies of being seduced are of particular interest, because so often they are not phantasies but real memories. Fortunately, however, they are nevertheless not real as often as seemed at first to be shown by the findings of analysis. Seduction by an older child or by one of the same age is even more frequent than by an adult; and if in the case of girls who produce such an event in the story of their childhood their father figures fairly regularly as the seducer, there can be no doubt either of the imaginary nature of the accusation or of the motive that has led to it. A phantasy of being seduced when no seduction has occurred is usually employed by a child to screen the auto-erotic period of his sexual activity. He spares himself shame about masturbation by retrospectively phantasying a desired object into these earliest times. You must not suppose, however, that sexual abuse of a child by its nearest male relatives belongs entirely to the realm of phantasy. Most analysts will have treated cases in which such events were real and could be unimpeachably established; but even so they related to the later years of childhood and had been transposed into earlier times.

[1916-1917, 3426]
Unfortunately we can describe this state of things only as it affects the male child; the corresponding processes in the little girl are not known to us. The small boy undoubtedly perceives the distinction between men and women, but to begin with he has no occasion to connect it with a difference in their genitals. It is natural for him to assume that all other living beings, humans and animals, possess a genital like his own; indeed, we know that he looks for an organ analogous to his own in inanimate things as well.¹ This part of the body, which is easily excitable, prone to changes and so rich in sensations, occupies the boy's interest to a high degree and is constantly setting new tasks to his instinct for research. He wants to see it in other people as well, so as to compare it with his own; and he behaves as though he had a vague idea that this organ could and should be bigger. The driving force which this male portion of the body will develop later at puberty expresses itself at this period of life mainly as an urge to investigate, as sexual curiosity. Many of the acts of exhibitionism and aggression which children commit, and which in later years would be judged without hesitation to be expressions of lust, prove in analysis to be experiments undertaken in the service of sexual research.

When the (male) child's interest turns to his genitals he betrays the fact by manipulating them frequently; and he then finds that the adults do not approve of this behaviour. More or less plainly, more or less brutally, a threat is pronounced that this part of him which he values so highly will be taken away from him. Usually it is from women that the threat emanates; very often they seek to strengthen their authority by a reference to the father or the doctor, who, so they say, will carry out the punishment. In a number of cases the women will themselves mitigate the threat in a symbolic manner by telling the child that what is to be removed is not his genital, which actually plays a passive part, but his hand, which is the active culprit. It happens particularly often that the little boy is threatened with castration, not because he plays with his penis with his hand, but because he wets his bed every night and cannot be got to be clean. Those in charge of him behave as if this nocturnal incontinence was the result and the proof of his being unduly concerned with his penis, and they are probably right. In any case, long-continued bed-wetting is to be equated with the emissions of adults. It is an expression of the same excitation of the genitals which has impelled the child to masturbate at this period.

We should not be as short-sighted as the person in charge of the child who threatens him with castration, and we must not overlook the fact that at this time masturbation by no means represents the whole of his sexual life. As can be clearly shown, he stands in the Oedipus attitude to his parents; his masturbation is only a genital discharge of the sexual excitation belonging to the complex, and throughout his later years will owe its importance to that relationship. The Oedipus complex offered the child two possibilities of satisfaction, an active and a passive one. He could put himself in his father's place in a masculine fashion and have intercourse with his mother as his father did, in which case he would soon have felt the latter as a hindrance; or he might want to take the place of his mother and be loved by his father, in which case his mother would become superfluous. The child may have had only very vague notions as to what constitutes a satisfying erotic intercourse; but certainly the penis must play a part in it, for the sensations in his own organ were evidence of that. So far he had had no occasion to doubt that women possessed a penis. But now his acceptance of the possibility of castration, his recognition that women were castrated, made an end of both possible ways of obtaining satisfaction from the Oedipus complex. For both of them entailed the loss of his penis - the masculine one as a resulting punishment and the feminine one as a precondition. If the satisfaction of love in the field of the Oedipus complex is to cost the child his penis, a conflict is bound to arise between his narcissistic interest in that part of his body and the libidinal cathexis of his parental objects. In this conflict the first of these forces normally triumphs: the child's ego turns away from the Oedipus complex.
As regards the prehistory of the Oedipus complex in boys we are far from complete clarity. We know that that period includes an identification of an affectionate sort with the boy's father, an identification which is still free from any sense of rivalry in regard to his mother. Another element of that stage is invariably, I believe, a masturbatory activity in connection with the genitals, the masturbation of early childhood, the more or less violent suppression of which by those in charge of the child sets the castration complex in action. It is to be assumed that this masturbation is attached to the Oedipus complex and serves as a discharge for the sexual excitation belonging to it. It is, however, uncertain whether the masturbation has this character from the first, or whether on the contrary it makes its first appearance spontaneously as an activity of a bodily organ and is only brought into relation with the Oedipus complex at some later date; this second possibility is by far the more probable. Another doubtful question is the part played by bed-wetting and by the breaking of that habit through the intervention of training measures. We are inclined to make the simple connection that continued bed-wetting is a result of masturbation and that its suppression is regarded by boys as an inhibition of their genital activity - that is, as having the meaning of a threat of castration; but whether we are always right in supposing this remains to be seen. Finally, analysis shows us in a shadowy way how the fact of a child at a very early age listening to his parents copulating may set up his first sexual excitation, and how that event may, owing to its after-effects, act as a starting-point for the child's whole sexual development. Masturbation, as well as the two attitudes in the Oedipus complex, later on become attached to this early experience, the child having subsequently interpreted its meaning. It is impossible, however, to suppose that these observations of coitus are of universal occurrence, so that at this point we are faced with the problem of 'primal phantasies'. Thus the prehistory of the Oedipus complex, even in boys, raises all of these questions for sifting and explanation; and there is the further problem of whether we are to suppose that the process invariably follows the same course, or whether a great variety of different preliminary stages may not converge upon the same terminal situation.

Every analyst has come across certain women who cling with especial intensity and tenacity to the bond with their father and to the wish in which it culminates of having a child by him. We have good reason to suppose that the same wishful phantasy was also the motive force of their infantile masturbation, and it is easy to form an impression that at this point we have been brought up against an elementary and unanalysable fact of infantile sexual life. But a thorough analysis of these very cases brings something different to light - namely, that here the Oedipus complex has a long prehistory and is in some respects a secondary formation.

It is an odd thing that the regular and essential part of this sexual activity was not overlooked. Or rather, it is by no means odd; for it was impossible to overlook it. Children's sexual impulses find their main expressions in self-gratification by friction of their own genitals, or, more precisely, of the male portion of them. The extraordinarily wide distribution of this form of childish 'naughtiness' was always known to adults, and it was regarded as a grave sin and severely punished. But please do not ask me how people could reconcile these observations of the immoral inclinations of children - for children do it, as they themselves say, because it gives them pleasure - with the theory of their innate purity and non-sensuality. You must get our opponents to solve this riddle. We have a more important problem before us. What attitude should we adopt towards the sexual activity of early childhood? We know the responsibility we are incurring if we suppress it; but we do not venture to let it take its course without restriction. Among races at a low level of civilization, and among the lower strata of civilized races, the sexuality of children seems to be given free rein. This probably provides a powerful protection against the subsequent development of neuroses in the individual. But does it not at the same time involve an extraordinary loss of the aptitude for cultural achievements? There is a good deal to suggest that here we are faced by a new Scylla and Charybdis.

[1925j, 4148]

[1926e, 4359]
The brilliantly told, faultlessly motivated story is of course complete in itself and is certain to make a deep effect upon the reader. But analysis shows us that its invention is based fundamentally upon a wishful phantasy belonging to the period of puberty, which a number of people actually remember consciously. The phantasy embodies a boy's wish that his mother should herself initiate him into sexual life in order to save him from the dreaded injuries caused by masturbation. (The numerous creative works that deal with the theme of redemption have the same origin.) The 'vice' of masturbation is replaced by the addiction to gambling; and the emphasis laid upon the passionate activity of the hands betrays this derivation. Indeed, the passion for play is an equivalent of the old compulsion to masturbate; 'playing' is the actual word used in the nursery to describe the activity of the hands upon the genitals. The irresistible nature of the temptation, the solemn resolutions, which are nevertheless invariably broken, never to do it again, the stupefying pleasure and the bad conscience which tells the subject that he is ruining himself (committing suicide) - all these elements remain unaltered in the process of substitution. It is true that Zweig's story is told by the mother, not by the son. It must flatter the son to think: 'if my mother only knew what dangers masturbation involves me in, she would certainly save me from them by allowing me to lavish all my tenderness on her own body'. The equation of the mother with a prostitute, which is made by the young man in the story, is linked up with the same phantasy. It brings the unattainable woman within easy reach. The bad conscience which accompanies the phantasy brings about the unhappy ending of the story. It is also interesting to notice how the façade given to the story by its author seeks to disguise its analytic meaning. For it is extremely questionable whether the erotic life of women is dominated by sudden and mysterious impulses. On the contrary, analysis reveals an adequate motivation for the surprising behaviour of this woman who had hitherto turned away from love. Faithful to the memory of her dead husband, she had armed herself against all similar attractions; but - and here the son's phantasy is right - she did not, as a mother, escape her quite unconscious transference of love on to her son, and Fate was able to catch her at this undefended spot.

If the addiction to gambling, with the unsuccessful struggles to break the habit and the opportunities it affords for self-punishment, is a repetition of the compulsion to masturbate, we shall not be surprised to find that it occupied such a large space in Dostoevsky's life. After all, we find no cases of severe neurosis in which the auto-erotic satisfaction of early childhood and of puberty has not played a part; and the relation between efforts to suppress it and fear of the father are too well known to need more than a mention.¹

Little girls usually discover for themselves their characteristic phallic activity - masturbation of the clitoris; and to begin with this is no doubt unaccompanied by phantasy. The part played in starting it by nursery hygiene is reflected in the very common phantasy which makes the mother or nurse into a seducer. Whether little girls masturbate less frequently and from the first less energetically than little boys is not certain; quite possibly it is so. Actual seduction, too, is common enough; it is initiated either by other children or by someone in charge of the child who wants to soothe it, or send it to sleep or make it dependent on them. Where seduction intervenes it invariably disturbs the natural course of the developmental processes, and it often leaves behind extensive and lasting consequences.
A prohibition of masturbation, as we have seen, becomes an incentive for giving it up; but it also becomes a motive for rebelling against the person who prohibits it - that is to say, the mother, or the mother-substitute who later regularly merges with her. A defiant persistence in masturbation appears to open the way to masculinity. Even where the girl has not succeeded in suppressing her masturbation, the effect of the apparently vain prohibition is seen in her later efforts to free herself at all costs from a satisfaction which has been spoilt for her. When she reaches maturity her object-choice may still be influenced by this persisting purpose. Her resentment at being prevented from free sexual activity plays a big part in her detachment from her mother. The same motive comes into operation again after puberty, when her mother takes up her duty of guarding her daughter's chastity. We shall, of course, not forget that the mother is similarly opposed to a boy's masturbating and thus provides him, too, with a strong motive for rebellion.

[1931b, 4596]

This account of how girls respond to the impression of castration and the prohibition against masturbation will very probably strike the reader as confused and contradictory. This is not entirely the author's fault. In truth, it is hardly possible to give a description which has general validity. We find the most different reactions in different individuals, and in the same individual the contrary attitudes exist side by side. With the first intervention of the prohibition, the conflict is there, and from now on it will accompany the development of the sexual function. Insight into what takes place is made particularly difficult by the fact of its being so hard to distinguish the mental processes of this first phase from later ones by which they are overlaid and are distorted in memory. Thus, for instance, a girl may later construe the fact of castration as a punishment for her masturbatory activity, and she will attribute the carrying out of this punishment to her father, but neither of these ideas can have been a primary one. Similarly, boys regularly fear castration from their father, although in their case, too, the threat most usually comes from their mother.

[1931b, 4597]

Lastly, intense active wishful impulses directed towards the mother also arise during the phallic phase. The sexual activity of this period culminates in clitoridal masturbation. This is probably accompanied by ideas of the mother, but whether the child attaches a sexual aim to the idea, and what that aim is, I have not been able to discover from my observations. It is only when all her interests have received a fresh impetus through the arrival of a baby brother or sister that we can clearly recognize such an aim. The little girl wants to believe that she has given her mother the new baby, just as the boy wants to; and her reaction to this event and her behaviour to the baby is exactly the same as his. No doubt this sounds quite absurd, but perhaps that is only because it sounds so unfamiliar.

[1931b, 4603]

The turning-away from her mother is an extremely important step in the course of a little girl's development. It is more than a mere change of object. We have already described what takes place in it and the many motives put forward for it; we may now add that hand in hand with it there is to be observed a marked lowering of the active sexual impulses and a rise of the passive ones. It is true that the active trends have been affected by frustration more strongly; they have proved totally unrealizable and are therefore abandoned by the libido more readily. But the passive trends have not escaped disappointment either. With the turning-away from the mother clitoridal masturbation frequently ceases as well; and often enough when the small girl represses her previous masculinity a considerable portion of her sexual trends in general is permanently injured too. The transition to the father-object is accomplished with the help of the passive trends in so far as they have escaped the catastrophe. The path to the development of femininity now lies open to the girl, to the extent to which it is not restricted by the remains of the pre-Oedipus attachment to her mother which she has surmounted.

[1931b, 4603]
But we have not made any mention at all so far of what the real danger is that the child is afraid of as a result of being in love with his mother. The danger is the punishment of being castrated, of losing his genital organ. You will of course object that after all that is not a real danger. Our boys are not castrated because they are in love with their mothers during the phase of the Oedipus complex. But the matter cannot be dismissed so simply. Above all, it is not a question of whether castration is really carried out; what is decisive is that the danger is one that threatens from outside and that the child believes in it. He has some ground for this, for people threaten him often enough with cutting off his penis during the phallic phase, at the time of his early masturbation, and hints at that punishment must regularly find a phylogenetic reinforcement in him. It is our suspicion that during the human family's primaeval period castration used actually to be carried out by a jealous and cruel father upon growing boys, and that circumcision, which so frequently plays a part in puberty rites among primitive peoples, is a clearly recognizable relic of it. We are aware that here we are diverging widely from the general opinion; but we must hold fast to the view that fear of castration is one of the commonest and strongest motives for repression and thus for the formation of neuroses. The analysis of cases in which circumcision, though not, it is true, castration, has been carried out on boys as a cure or punishment for masturbation (a far from rare occurrence in Anglo-American society) has given our conviction a last degree of certainty. It is very tempting at this point to go more deeply into the castration complex, but I will stick to our subject.

Both sexes seem to pass through the early phases of libidinal development in the same manner. It might have been expected that in girls there would already have been some lag in aggressiveness in the sadistic-anal phase, but such is not the case. Analysis of children's play has shown our women analysts that the aggressive impulses of little girls leave nothing to be desired in the way of abundance and violence. With their entry into the phallic phase the differences between the sexes are completely eclipsed by their agreements. We are now obliged to recognize that the little girl is a little man. In boys, as we know, this phase is marked by the fact that they have learnt how to derive pleasurable sensations from their small penis and connect its excited state with their ideas of sexual intercourse. Little girls do the same thing with their still smaller clitoris. It seems that with them all their masturbatory acts are carried out on this penis-equivalent, and that the truly feminine vagina is still undiscovered by both sexes. It is true that there are a few isolated reports of early vaginal sensations as well, but it could not be easy to distinguish these from sensations in the anus or vestibulum; in any case they cannot play a great part. We are entitled to keep to our view that in the phallic phase of girls the clitoris is the leading erotogenic zone. But it is not, of course, going to remain so. With the change to femininity the clitoris should wholly or in part hand over its sensitivity, and at the same time its importance, to the vagina. This would be one of the two tasks which a woman has to perform in the course of her development, whereas the more fortunate man has only to continue at the time of his sexual maturity the activity that he has previously carried out at the period of the early efflorescence of his sexuality.
The essential content of the first is as follows: the little girl has hitherto lived in a masculine way, has been able to get pleasure by the excitation of her clitoris and has brought this activity into relation with her sexual wishes directed towards her mother, which are often active ones; now, owing to the influence of her penis-envy, she loses her enjoyment in her phallic sexuality. Her self-love is mortified by the comparison with the boy's far superior equipment and in consequence she renounces her masturbatory satisfaction from her clitoris, repudiates her love for her mother and at the same time not infrequently represses a good part of her sexual trends in general. No doubt her turning away from her mother does not occur all at once, for to begin with the girl regards her castration as an individual misfortune, and only gradually extends it to other females and finally to her mother as well. Her love was directed to her phallic mother; with the discovery that her mother is castrated it becomes possible to drop her as an object, so that the motives for hostility, which have long been accumulating, gain the upper hand. This means, therefore, that as a result of the discovery of women's lack of a penis they are debased in value for girls just as they are for boys and later perhaps for men.

[1933a, 4728]

You all know the immense aetiological importance attributed by our neurotic patients to their masturbation. They make it responsible for all their troubles and we have the greatest difficulty in persuading them that they are mistaken. In fact, however, we ought to admit to them that they are right, for masturbation is the executive agent of infantile sexuality, from the faulty development of which they are indeed suffering. But what neurotics mostly blame is the masturbation of the period of puberty; they have mostly forgotten that of early infancy, which is what is really in question. I wish I might have an opportunity some time of explaining to you at length how important all the factual details of early masturbation become for the individual's subsequent neurosis or character: whether or not it was discovered, how the parents struggled against it or permitted it, or whether he succeeded in suppressing it himself. All of this leaves permanent traces on his development. But I am on the whole glad that I need not do this. It would be a hard and tedious task and at the end of it you would put me in an embarrassing situation by quite certainly asking me to give you some practical advice as to how a parent or educator should deal with the masturbation of small children. From the development of girls, which is what my present lecture is concerned with, I can give you the example of a child herself trying to get free from masturbating. She does not always succeed in this. If envy for the penis has provoked a powerful impulse against clitoridal masturbation but this nevertheless refuses to give way, a violent struggle for liberation ensues in which the girl, as it were, herself takes over the role of her deposed mother and gives expression to her entire dissatisfaction with her inferior clitoris in her efforts against obtaining satisfaction from it. Many years later, when her masturbatory activity has long since been suppressed, an interest still persists which we must interpret as a defence against a temptation that is still dreaded. It manifests itself in the emergence of sympathy for those to whom similar difficulties are attributed, it plays a part as a motive in contracting a marriage and, indeed, it may determine the choice of a husband or lover. Disposing of early infantile masturbation is truly no easy or indifferent business.

[1933a, 4729]
Along with the abandonment of clitoridal masturbation a certain amount of activity is renounced. Passivity now has the upper hand, and the girl's turning to her father is accomplished principally with the help of passive instinctual impulses. You can see that a wave of development like this, which clears the phallic activity out of the way, smooths the ground for femininity. If too much is not lost in the course of it through repression, this femininity may turn out to be normal. The wish with which the girl turns to her father is no doubt originally the wish for the penis which her mother has refused her and which she now expects from her father. The feminine situation is only established, however, if the wish for a penis is replaced by one for a baby, if, that is, a baby takes the place of a penis in accordance with an ancient symbolic equivalence. It has not escaped us that the girl has wished for a baby earlier, in the undisturbed phallic phase: that, of course, was the meaning of her playing with dolls. But that play was not in fact an expression of her femininity; it served as an identification with her mother with the intention of substituting activity for passivity. She was playing the part of her mother and the doll was herself: now she could do with the baby everything that her mother used to do with her. Not until the emergence of the wish for a penis does the doll-baby become a baby from the girl's father, and thereafter the aim of the most powerful feminine wish. Her happiness is great if later on this wish for a baby finds fulfilment in reality, and quite especially so if the baby is a little boy who brings the longed-for penis with him. Often enough in her combined picture of 'a baby from her father' the emphasis is laid on the baby and her father left unstressed. In this way the ancient masculine wish for the possession of a penis is still faintly visible through the femininity now achieved. But perhaps we ought rather to recognize this wish for a penis as being par excellence a feminine one.

With the phallic phase and in the course of it the sexuality of early childhood reaches its height and approaches its dissolution. Thereafter boys and girls have different histories. Both have begun to put their intellectual activity at the service of sexual researches; both start off from the premiss of the universal presence of the penis. But now the paths of the sexes diverge. The boy enters the Oedipus phase; he begins to manipulate his penis and simultaneously has phantasies of carrying out some sort of activity with it in relation to his mother, till, owing to the combined effect of a threat of castration and the sight of the absence of a penis in females, he experiences the greatest trauma of his life and this introduces the period of latency with all its consequences. The girl, after vainly attempting to do the same as the boy, comes to recognize her lack of a penis or rather the inferiority of her clitoris, with permanent effects on the development of her character; as a result of this first disappointment in rivalry, she often begins by turning away altogether from sexual life.

² The occurrence of early vaginal excitations is often asserted. But it is most probable that what is in question are excitations in the clitoris - that is, in an organ analogous to the penis. This does not invalidate our right to describe the phase as phallic.
This preface is not superfluous, for it can heighten our realization of the intensity of the Oedipus complex. When a boy (from the age of two or three) has entered the phallic phrase of his libidinal development, is feeling pleasurable sensations in his sexual organ and has learnt to procure these at will by manual stimulation, he becomes his mother's lover. He wishes to possess her physically in such ways as he has divined from his observations and intuitions about sexual life, and he tries to seduce her by showing her the male organ which he is proud to own. In a word, his early awakened masculinity seeks to take his father's place with her; his father has hitherto in any case been an envied model to the boy, owing to the physical strength he perceives in him and the authority with which he finds him clothed. His father now becomes a rival who stands in his way and whom he would like to get rid of. If while his father is away he is allowed to share his mother's bed and if when his father returns he is once more banished from it, his satisfaction when his father disappears and his disappointment when he emerges again are deeply felt experiences. This is the subject of the Oedipus complex, which the Greek legend has translated from the world of a child's phantasy into pretended reality. Under the conditions of our civilization it is invariably doomed to a frightening end.

The boy's mother has understood quite well that his sexual excitation relates to herself. Sooner or later she reflects that it is not right to allow it to continue. She thinks she is doing the correct thing in forbidding him to handle his genital organ. Her prohibition has little effect; at the most it brings about some modification in his method of obtaining satisfaction. At last his mother adopts the severest measures; she threatens to take away from him the thing he is defying her with. Usually, in order to make the threat more frightening and more credible, she delegates its execution to the boy's father, saying that she will tell him and that he will cut the penis off. Strange to say, this threat operates only if another condition is fulfilled before or afterwards. In itself it seems too inconceivable to the boy that such a thing could happen. But if at the time of the threat he can recall the appearance of female genitals or if shortly afterwards he has a sight of them - of genitals, that is to say, which really lack this supremely valued part, then he takes what he has heard seriously and, coming under the influence of the castration complex, experiences the severest trauma of his young life.¹

¹[1940a [1938], 4997]
The results of the threat of castration are multifarious and incalculable; they affect the whole of a boy's relations with his father and mother and subsequently with men and women in general. As a rule the child's masculinity is unable to stand up to this first shock. In order to preserve his sexual organ he renounces the possession of his mother more or less completely; his sexual life often remains permanently encumbered by the prohibition. If a strong feminine component, as we call it, is present in him, its strength is increased by this intimidation of his masculinity. He falls into a passive attitude to his father, such as he attributes to his mother. It is true that as a result of the threat he has given up masturbation, but not the activities of his imagination accompanying it. On the contrary, since these are now the only form of sexual satisfaction remaining to him, he indulges in them more than before and in these phantasies, though he still continues to identify himself with his father, he also does so, simultaneously and perhaps predominantly, with his mother. Derivatives and modified products of these early masturbatory phantasies usually make their way into his later ego and play a part in the formation of his character. Apart from this encouragement of his femininity, fear and hatred of his father gain greatly in intensity. The boy's masculinity withdraws, as it were, into a defiant attitude towards his father, which will dominate his later behaviour in human society in a compulsive fashion. A residue of his erotic fixation to his mother is often left in the form of an excessive dependence on her, and this persists as a kind of bondage to women. He no longer ventures to love his mother, but he cannot risk not being loved by her, for in that case he would be in danger of being betrayed by her to his father and handed over to castration. The whole experience, with all its antecedents and consequences, of which my account has only been able to give a selection, is subjected to a highly energetic repression, and, as is made possible by the laws operating in the unconscious id, all the mutually contending emotional impulses and reactions which are set going at that time are preserved in the unconscious and ready to disturb the later development of the ego after puberty. When the somatic process of sexual maturation puts fresh life into the old libidinal fixations which had apparently been surmounted, sexual life will turn out to be inhibited, without homogeneity and fallen apart into mutually conflicting urges.

[1940a [1938], 4998]

The effects of the castration complex in little girls are more uniform and no less profound. A female child has, of course, no need to fear the loss of a penis; she must, however, react to the fact of not having received one. From the very first she envies boys its possession; her whole development may be said to take place under the colours of envy for the penis. She begins by making vain attempts to do the same as boys and later, with greater success, makes efforts to compensate for her defect - efforts which may lead in the end to a normal feminine attitude. If during the phallic phase she tries to get pleasure like a boy by the manual stimulation of her genitals, it often happens that she fails to obtain sufficient satisfaction and extends her judgement of inferiority from her stunted penis to her whole self. As a rule she soon gives up masturbating, since she has no wish to be reminded of the superiority of her brother or playmate, and turns away from sexuality altogether.

[1940a [1938], 5000]
It is worth remarking that we have here three symptoms - the disgust, the sensation of pressure on the upper part of the body, and the avoidance of men engaged in affectionate conversation - all of them derived from a single experience, and that it is only by taking into account the interrelation of these three phenomena that we can understand the way in which the formation of the symptoms came about. The disgust is the symptom of repression in the erotogenic oral zone, which, as we shall hear, had been over-indulged in Dora's infancy by the habit of sensual sucking. The pressure of the erect member probably led to an analogous change in the corresponding female organ, the clitoris; and the excitation of this second erotogenic zone was referred by a process of displacement to the simultaneous pressure against the thorax and became fixed there. Her avoidance of men who might possibly be in a state of sexual excitement follows the mechanism of a phobia, its purpose being to safeguard her against any revival of the repressed perception. [1905e, 1370]

ACTIVITY OF THE GENITAL ZONES Among the erotogenic zones that form part of the child's body there is one which certainly does not play the opening part, and which cannot be the vehicle of the oldest sexual impulses, but which is destined to great things in the future. In both male and female children it is brought into connection with micturition (in the glans and clitoris) and in the former is enclosed in a pouch of mucous membrane, so that there can be no lack of stimulation of it by secretions which may give an early start to sexual excitation. The sexual activities of this erotogenic zone, which forms part of the sexual organs proper, are the beginning of what is later to become 'normal' sexual life. The anatomical situation of this region, the secretions in which it is bathed, the washing and rubbing to which it is subjected in the course of a child's toilet, as well as accidental stimulation (such as the movement of intestinal worms in the case of girls), make it inevitable that the pleasurable feeling which this part of the body is capable of producing should be noticed by children even during their earliest infancy, and should give rise to a need for its repetition. If we consider this whole range of contrivances and bear in mind that both making a mess and measures for keeping clean are bound to operate in much the same way, it is scarcely possible to avoid the conclusion that the foundations for the future primacy over sexual activity exercised by this erotogenic zone are established by early infantile masturbation, which scarcely a single individual escapes. The action which disposes of the stimulus and brings about satisfaction consists in a rubbing movement with the hand or in the application of pressure (no doubt on the lines of a pre-existing reflex) either from the hand or by bringing the thighs together. This last method is by far the more common in the case of girls. The preference for the hand which is shown by boys is already evidence of the important contribution which the instinct for mastery is destined to make to masculine sexual activity.¹ [1905d, 1508]

¹ [Footnote added 1924:] At a later date (1923), I myself modified this account by inserting a third phase in the development of childhood, subsequent to the two pregenital organizations. This phase, which already deserves to be described as genital, presents a sexual object and some degree of convergence of the sexual impulses upon that object; but it is differentiated from the final organization of sexual maturity in one essential respect. For it knows only one kind of genital: the male one. For that reason I have named it the 'phallic' stage of organization. (Freud, 1923e.) According to Abraham, it has a biological prototype in the embryo's undifferentiated genital disposition, which is the same for both sexes. [1905d, 1517]

¹ [Footnote added 1915:] The schematic picture which I have given in the text aims at emphasizing differences. I have already shown on p. 1517 the extent to which infantile sexuality, owing to its choice of object [added 1924:] and to the development of the phallic phase, approximates to the final sexual organization. [1905d, 1524]
We found from the study of neurotic disorders that beginnings of an organization of the sexual instinctual components can be detected in the sexual life of children from its very beginning. During a first, very early phase, oral erotism occupies most of the picture. A second of these pregenital organizations is characterized by the predominance of sadism and anal erotism. It is not until a third phase has been reached that the genital zones proper contribute their share in determining sexual life, and in children this last phase is developed only so far as to a primacy of the phallus. [1905d, 1544]

In spite of the gaps in our knowledge of infantile sexual life, we had to proceed to an attempt at examining the alterations brought about in it by the arrival of puberty. We selected two of these as being the decisive ones: the subordination of all the other sources of sexual excitation under the primacy of the genital zones and the process of finding an object. Both of these are already adumbrated in childhood. The first is accomplished by the mechanism of exploiting fore-pleasure: what were formerly self-contained sexual acts, attended by pleasure and excitation, become acts preparatory to the new sexual aim (the discharge of the sexual products), the attainment of which, enormously pleasurable, brings the sexual excitation to an end. In this connection we had to take into account the differentiation of sexuality into masculine and feminine; and we found that in order to become a woman a further stage of repression is necessary, which discards a portion of infantile masculinity and prepares the woman for changing her leading genital zone. As regards object-choice, we found that it is given its direction by the childhood hints (revived at puberty) of the child's sexual inclination towards his parents and others in charge of him, but that it is diverted away from them, on to other people who resemble them, owing to the barrier against incest which has meanwhile been erected. Finally it must be added that during the transition period of puberty the processes of somatic and of psychical development continue for a time side by side independently, until the irruption of an intense mental erotic impulse, leading to the innervation of the genitals, brings about the unity of the erotic function which is necessary for normality. [1905d, 1545]

If we take the second of these stages as an average, we must point out that a number of people are, on account of their organization, not equal to meeting its demands. In whole classes of individuals the development of the sexual instinct, as we have described it above, from auto-erotism to object-love with its aim of uniting the genitals, has not been carried out correctly and sufficiently fully. As a result of these disturbances of development two kinds of harmful deviation from normal sexuality - that is, sexuality which is serviceable to civilization - come about; and the relation between these two is almost that of positive and negative.¹ [1908d, 1953]

There is absolutely no justification for distinguishing a special homosexual instinct. What constitutes a homosexual is a peculiarity not in his instinctual life but in his choice of an object. Let me recall what I have said in my Three Essays to the effect that we have mistakenly imagined the bond between instinct and object in sexual life as being more intimate than it really is. A homosexual may have normal instincts, but he is unable to disengage them from a class of objects defined by a particular determinant. And in his childhood, since at that period this determinant is taken for granted as being of universal application, he is able to behave like little Hans, who showed his affection to little boys and girls indiscriminately, and once described his friend Fritzl as 'the girl he was fondest of'. Hans was a homosexual (as all children may very well be), quite consistently with the fact, which must always be kept in mind, that he was acquainted with only one kind of genital organ - a genital organ like his own.¹ [1909b, 2094]
¹ [Footnote added 1923:] I have subsequently (1923e) drawn attention to the fact that the period of sexual development which our little patient was passing through is universally characterized by acquaintance with only one sort of genital organ, namely, the male one. In contrast to the later period of maturity, this period is marked not by a genital primacy but by a primacy of the phallus.
[1909b, 2094]

There is something else that I must add in order to complete our view of sexual perversions. However infamous they may be, however sharply they may be contrasted with normal sexual activity, quiet consideration will show that some perverse trait or other is seldom absent from the sexual life of normal people. Even a kiss can claim to be described as a perverse act, since it consists in the bringing together of two oral erotogenic zones instead of the two genitals. Yet no one rejects it as perverse; on the contrary, it is permitted in theatrical performances as a softened hint at the sexual act. But precisely kissing can easily turn into a complete perversion - if, that is to say, it becomes so intense that a genital discharge and orgasm follow upon it directly, an event that is far from rare. We can learn, too, that for one person feeling and looking at the object are indispensable preconditions of sexual enjoyment, that another person will pinch or bite at the climax of sexual excitation, that the highest pitch of excitement in lovers is not always provoked by the genitals but by some other region of the object's body, and any number of similar things besides. There is no sense in excluding people with individual traits of this kind from the class of the normal and putting them among the perverts. On the contrary, we shall recognize more and more clearly that the essence of the perversions lies not in the extension of the sexual aim, not in the replacement of the genitals, not even always in the variant choice of the object, but solely in the exclusiveness with which these deviations are carried out and as a result of which the sexual act serving the purpose of reproduction is put on one side. In so far as the perverse actions are inserted in the performance of the normal sexual act as preparatory or intensifying contributions, they are in reality not perversions at all. The gulf between normal and perverse sexuality is of course very much narrowed by facts of this kind. It is an easy conclusion that normal sexuality has emerged out of something that was in existence before it, by weeding out certain features of that material as unserviceable and collecting together the rest in order to subordinate them to a new aim, that of reproduction.
[1916-1917, 3391]
Accordingly, I can now describe to you the form taken by a child's sexual life before the establishment of the primacy of the genitals, preparations for which are made in the first period of infancy preceding the latency period and which is permanently organized from puberty onwards. A kind of loose organization which may be called 'pregenital' exists during this early period. During this phase what stand in the forefront are not the genital component instincts but the sadistic and anal ones. The contrast between 'masculine' and 'feminine' plays no part here as yet. Its place is taken by the contrast between 'active' and 'passive', which may be described as a precursor of the sexual polarity and which later on is soldered to that polarity. What appears to us as masculine in the activities of this phase, when we look at it from the point of view of the genital phase, turns out to be an expression of an instinct for mastery which easily passes over into cruelty. Trends with a passive aim are attached to the erotogenic zone of the anal orifice, which is very important at this period. The instincts for looking and for gaining knowledge are powerfully at work; the genitals actually play a part in sexual life only as organs for the excretion of urine. The component instincts of this phase are not without objects, but those objects do not necessarily converge into a single object. The sadistic-anal organization is the immediate forerunner of the phase of genital primacy. Detailed study shows how much of it is retained in the later definitive shape of things and shows too the way in which its component instincts are compelled to take their place in the new genital organization. Behind the sadistic-anal phase of libidinal development we get a glimpse of a still earlier and more primitive stage of organization, in which the erotogenic zone of the mouth plays the chief part. As you will guess, the sexual activity of sensual sucking belongs to it. We must admire the understanding of the Ancient Egyptians who, in their art, represented children, including the God Horus, with a finger in their mouth. Only recently Abraham has given examples of the traces which this primitive oral phase leaves behind it in later sexual life.

[1916-1917, 3395]

The Development of the Libido. - The sexual instinct, the dynamic manifestation of which in mental life we shall call 'libido', is made up of component instincts into which it may once more break up and which are only gradually united into well-defined organizations. The sources of these component instincts are the organs of the body and in particular certain specially marked erotogenic zones; but contributions are made to libido from every important functional process in the body. At first the individual component instincts strive for satisfaction independently of one another, but in the course of development they become more and more convergent and concentrated. The first (pregenital) stage of organization to be discerned is the oral one, in which - in conformity with the suckling's predominant interest - the oral zone plays the leading part. This is followed by the sadistic-anal organization, in which the anal zone and the component instinct of sadism are particularly prominent; at this stage the difference between the sexes is represented by the contrast between active and passive. The third and final stage of organization is that in which the majority of the component instincts converge under the primacy of the genital zones. As a rule this development is passed through swiftly and unobtrusively; but some individual portions of the instincts remain behind at the prodromal stages of the process and thus give rise to fixations of libido, which are important as constituting predispositions for subsequent irruptions of repressed impulses and which stand in a definite relation to the later development of neuroses and perversions. (See the article on 'The Libido Theory'.)

[1923a, 3921]
The Process of Finding an Object, and the Oedipus Complex. - In the first instance the oral component instinct finds satisfaction by attaching itself to the sating of the desire for nourishment; and its object is the mother's breast. It then detaches itself, becomes independent and at the same time *auto-erotic*, that is, it finds an object in the child's own body. Others of the component instincts also start by being auto-erotic and are not until later diverted on to an external object. It is a particularly important fact that the component instincts belonging to the genital zone habitually pass through a period of intense auto-erotic satisfaction. The component instincts are not all equally serviceable in the final genital organization of libido; some of them (for instance, the anal components) are consequently left aside and suppressed, or undergo complicated transformations.

[1923a, 3922]

In that volume *(p. 1400)* I wrote that 'the choice of an object, such as we have shown to be characteristic of the pubertal phase of development, has already frequently or habitually been effected during the years of childhood: that is to say, the whole of the sexual currents have become directed towards a single person in relation to whom they seek to achieve their aims. This then is the closest approximation possible in childhood to the final form taken by sexual life after puberty. The only difference lies in the fact that in childhood the combination of the component instincts and their subordination under the primacy of the genitals have been effected only very incompletely or not at all. Thus the establishment of that primacy in the service of reproduction is the last phase through which the organization of sexuality passes.'

[1923e, 4058]

To-day I should no longer be satisfied with the statement that in the early period of childhood the primacy of the genitals has been effected only very incompletely or not at all. The approximation of the child's sexual life to that of the adult goes much further and is not limited solely to the coming into being of the choice of an object. Even if a proper combination of the component instincts under the primacy of the genitals is not effected, nevertheless, at the height of the course of development of infantile sexuality, interest in the genitals and in their activity acquires a dominating significance which falls little short of that reached in maturity. At the same time, the main characteristic of this 'infantile genital organization' is its *difference* from the final genital organization of the adult. This consists in the fact that, for both sexes, only one genital, namely the male one, comes into account. What is present, therefore, is not a primacy of the genitals, but a primacy of the *phallus*.

[1923e, 4059]

Erotogenic masochism accompanies the libido through all its developmental phases and derives from them its changing psychical coatings. The fear of being eaten up by the totem animal (the father) originates from the primitive oral organization; the wish to be beaten by the father comes from the sadistic-anal phase which follows it; castration, although it is later disavowed, enters into the content of masochistic phantasies as a precipitate of the phallic stage or organization;¹ and from the final genital organization there arise, of course, the situations of being copulated with and of giving birth, which are characteristic of femaleness. The part played in masochism by the nates, too, is easily understandable, apart from its obvious basis in reality. The nates are the part of the body which is given erotogenic preference in the sadistic-anal phase, like the breast in the oral phase and the penis in the genital phase.

[1924c, 4077]
Now it is my view that what brings about the destruction of the child's phallic genital organization is this threat of castration. Not immediately, it is true, and not without other influences being brought to bear as well. For to begin with the boy does not believe in the threat or obey it in the least. Psycho-analysis has recently attached importance to two experiences which all children go through and which, it is suggested, prepare them for the loss of highly valued parts of the body. These experiences are the withdrawal of the mother's breast - at first intermittently and later for good - and the daily demand on them to give up the contents of the bowel. But there is no evidence to show that, when the threat of castration takes place, those experiences have any effect. It is not until a fresh experience comes his way that the child begins to reckon with the possibility of being castrated, and then only hesitatingly and unwillingly, and not without making efforts to depreciate the significance of something he has himself observed.

At this point our material - for some incomprehensible reason - becomes far more obscure and full of gaps. The female sex, too, develops an Oedipus complex, a super-ego and a latency period. May we also attribute a phallic organization and a castration complex to it? The answer is in the affirmative; but these things cannot be the same as they are in boys. Here the feminist demand for equal rights for the sexes does not take us far, for the morphological distinction is bound to find expression in differences of psychical development. 'Anatomy is Destiny', to vary a saying of Napoleon's. The little girl's clitoris behaves just like a penis to begin with; but, when she makes a comparison with a playfellow of the other sex, she perceives that she has 'come off badly' and she feels this as a wrong done to her and as a ground for inferiority. For a while still she consoles herself with the expectation that later on, when she grows older, she will acquire just as big an appendage as the boy's. Here the masculinity complex of women branches off. A female child, however, does not understand her lack of a penis as being a sex character; she explains it by assuming that at some earlier date she had possessed an equally large organ and had then lost it by castration. She seems not to extend this inference from herself to other, adult females, but, entirely on the lines of the phallic phase, to regard them as possessing large and complete - that is to say, male - genitals. The essential difference thus comes about that the girl accepts castration as an accomplished fact, whereas the boy fears the possibility of its occurrence.
The sexual function, as I found, is in existence from the very beginning of the individual's life, though at first it is attached to the other vital functions and does not become independent of them until later; it has to pass through a long and complicated process of development before it becomes what we are familiar with as the normal sexual life of the adult. It begins by manifesting itself in the activity of a whole number of component instincts. These are dependent upon erotogenic zones in the body; some of them make their appearance in pairs of opposite impulses (such as sadism and masochism or the impulses to look and to be looked at); they operate independently of one another in a search for pleasure, and they find their object for the most part in the subject's own body. Thus at first the sexual function is non-centralized and predominantly auto-erotic. Later, syntheses begin to appear in it; a first stage of organization is reached under the dominance of the oral components, an anal-sadistic stage follows, and it is only after the third stage has at last been reached that the primacy of the genitals is established and that the sexual function begins to serve the ends of reproduction. In the course of this process of development a number of elements of the various component instincts turn out to be unserviceable for this last end and are therefore left on one side or turned to other uses, while others are diverted from their aims and carried over into the genital organization. I gave the name of libido to the energy of the sexual instincts and to that form of energy alone. I was next driven to suppose that the libido does not always pass through its prescribed course of development smoothly. As a result either of the excessive strength of certain of the components or of experiences involving premature satisfaction, fixations of the libido may occur at various points in the course of its development. If subsequently a repression takes place, the libido flows back to these points (a process described as regression), and it is from them that the energy breaks through in the form of a symptom. Later on it further became clear that the localization of the point of fixation is what determines the choice of neurosis, that is, the form in which the subsequent illness makes its appearance.
[1925d, 4211]
The process of arriving at an object, which plays such an important part in mental life, takes place alongside of the organization of the libido. After the stage of auto-erotism, the first love-object in the case of both sexes is the mother; and it seems probable that to begin with a child does not distinguish its mother's organ of nutrition from its own body. Later, but still in the first years of infancy, the relation known as the Oedipus complex becomes established: boys concentrate their sexual wishes upon their mother and develop hostile impulses against their father as being a rival, while girls adopt an analogous attitude.¹ All of the different variations and consequences of the Oedipus complex are important; and the innately bisexual constitution of human beings makes itself felt and increases the number of simultaneously active tendencies. Children do not become clear for quite a long time about the differences between the sexes; and during this period of sexual researches they produce typical sexual theories which, being circumscribed by the incompleteness of their authors’ own physical development, are a mixture of truth and error and fail to solve the problems of sexual life (the riddle of the Sphinx - that is, the question of where babies come from). We see, then, that a child's first object-choice is an incestuous one. The whole course of development that I have described is run through rapidly. For the most remarkable feature of the sexual life of man is its diphasic onset, its onset in two waves, with an interval between them. It reaches a first climax in the fourth or fifth year of a child's life. But thereafter this early efflorescence of sexuality passes off; the sexual impulses which have shown such liveliness are overcome by repression, and a period of latency follows, which lasts until puberty and during which the reaction-formations of morality, shame, and disgust are built up.² Of all living creatures man alone seems to show this diphasic onset of sexual growth, and it may perhaps be the biological determinant of his predisposition to neuroses. At puberty the impulses and object-relations of a child's early years become re-animated, and amongst them the emotional ties of its Oedipus complex. In the sexual life of puberty there is a struggle between the urges of early years and the inhibitions of the latency period. Before this, and while the child is at the highest point of its infantile sexual development, a genital organization of a sort is established; but only the male genitals play a part in it, and the female ones remain undiscovered. (I have described this as the period of phallic primacy.) At this stage the contrast between the sexes is not stated in terms of 'male' or 'female' but of 'possessing a penis' or 'castrated'. The castration complex which arises in this connection is of the profoundest importance in the formation alike of character and of neuroses.

[1925d, 4212]
The case of the 'Wolf Man' and the somewhat less complicated one of 'Little Hans' raise a number of further considerations. But we have already made two unexpected discoveries. There can be no doubt that the instinctual impulse which was repressed in both phobias was a hostile one against the father. One might say that that impulse had been repressed by the process of being transformed into its opposite. Instead of aggressiveness on the part of the subject towards his father, there appeared aggressiveness (in the shape of revenge) on the part of his father towards the subject. Since this aggressiveness is in any case rooted in the sadistic phase of the libido, only a certain amount of degradation is needed to reduce it to the oral stage. This stage, while only hinted at in 'Little Hans's' fear of being bitten, was blatantly exhibited in the 'Wolf Man's' terror of being devoured. But, besides this, the analysis has demonstrated, beyond a shadow of doubt, the presence of another instinctual impulse of an opposite nature which had succumbed to repression. This was a tender, passive impulse directed towards the father, which had already reached the genital (phallic) level of libidinal organization. As regards the final outcome of the process of repression, this impulse seems, indeed, to have been the more important of the two; it underwent a more far-reaching regression and had a decisive influence upon the content of the phobia. In following up a single instinctual repression we have thus had to recognize a convergence of two such processes. The two instinctual impulses that have been overtaken by repression - sadistic aggressiveness towards the father and a tender passive attitude to him - form a pair of opposites. Furthermore, a full appreciation of 'Little Hans's' case shows that the formation of his phobia had had the effect of abolishing his affectionate object-cathexis of his mother as well, though the actual content of his phobia betrayed no sign of this. The process of repression had attacked almost all the components of his Oedipus complex - both his hostile and his tender impulses towards his father and his tender impulses towards his mother. In my Russian patient this state of affairs was much less obvious. [1926d, 4266]
These are unwelcome complications, considering that we only set out to study simple cases of symptom-formation due to repression, and with that intention selected the earliest and to all appearances, most transparent neuroses of childhood. Instead of a single repression we have found a collection of them and have become involved with regression into the bargain. Perhaps we have added to the confusion by treating the two cases of animal phobia at our disposal - 'Little Hans' and the 'Wolf Man' - as though they were cast in the same mould. As a matter of fact, certain differences between them stand out. It is only with regard to 'Little Hans' that we can say with certainty that what his phobia disposed of were the two main impulses of the Oedipus complex - his aggressiveness towards his father and his over-fondness for his mother. A tender feeling for his father was undoubtedly there too and played a part in repressing the opposite feeling; but we can prove neither that it was strong enough to draw repression upon itself nor that it disappeared afterwards. 'Hans' seems, in fact, to have been a normal boy with what is called a 'positive' Oedipus complex. It is possible that the factors which we do not find were actually at work in him, but we cannot demonstrate their existence. Even the most exhaustive analysis has gaps in its data and is insufficiently documented. In the case of the Russian the deficiency lies elsewhere. His attitude to female objects had been disturbed by an early seduction and his passive, feminine side was strongly developed. The analysis of his wolf-dream revealed very little intentional aggressiveness towards his father, but it brought forward unmistakable proof that what repression overtook was his passive tender attitude to his father. In his case, too, the other factors may have been operative as well; but they were not in evidence. How is it that, in spite of these differences in the two cases, almost amounting to an antithesis, the final outcome - a phobia - was approximately the same? The answer must be sought in another quarter. I think it will be found in the second fact which emerges from our brief comparative examination. It seems to me that in both cases we can detect what the motive force of the repression was and can substantiate our view of its nature from the line of development which the two children subsequently pursued. This motive force was the same in both of them. It was the fear of impending castration. 'Little Hans' gave up his aggressiveness towards his father from fear of being castrated. His fear that a horse would bite him can, without any forcing, be given the full sense of a fear that a horse would bite off his genitals, would castrate him. But it was from fear of being castrated, too, that the little Russian relinquished his wish to be loved by his father, for he thought that a relation of that sort presupposed a sacrifice of his genitals - of the organ which distinguished him from a female. As we see, both forms of the Oedipus complex, the normal, active form and the inverted one, came to grief through the castration complex. The Russian boy's anxiety-idea of being devoured by a wolf contained, it is true, no suggestion of castration, for the oral regression it had undergone had removed it too far from the phallic stage. But the analysis of his dream rendered further proof superfluous. It was a triumph of repression that the form in which his phobia was expressed should no longer have contained any allusion to castration.

[1926d, 4267]

It would be a mistake to suppose that these three phases succeed one another in a clear-cut fashion. One may appear in addition to another; they may overlap one another, may be present alongside of one another. In the early phases the different component instincts set about their pursuit of pleasure independently of one another; in the phallic phase there are the beginnings of an organization which subordinates the other urges to the primacy of the genitals and signifies the start of a co-ordination of the general urge towards pleasure into the sexual function. The complete organization is only achieved at puberty, in a fourth, genital phase. A state of things is then established in which (1) some earlier libidinal cathexes are retained, (2) others are taken into the sexual function as preparatory, auxiliary acts, the satisfaction of which produces what is known as fore-pleasure, and (3) other urges are excluded from the organization, and are either suppressed altogether (repressed) or are employed in the ego in another way, forming character-traits or undergoing sublimation with a displacement of their aims.

[1940a [1938], 4966]
To-day I should no longer be satisfied with the statement that in the early period of childhood the primacy of the genitals has been effected only very incompletely or not at all. The approximation of the child's sexual life to that of the adult goes much further and is not limited solely to the coming into being of the choice of an object. Even if a proper combination of the component instincts under the primacy of the genitals is not effected, nevertheless, at the height of the course of development of infantile sexuality, interest in the genitals and in their activity acquires a dominating significance which falls little short of that reached in maturity. At the same time, the main characteristic of this 'infantile genital organization' is its **difference** from the final genital organization of the adult. This consists in the fact that, for both sexes, only one genital, namely the male one, comes into account. What is present, therefore, is not a primacy of the genitals, but a primacy of the **phallus**.

[1923e, 4059]

And now, as a third point, psycho-analysis has shown us, to our growing astonishment, the enormously important part played by what is known as the 'Oedipus complex' - that is, the emotional relation of a child to its two parents - in the mental life of human beings. Our astonishment diminishes when we realize that the Oedipus complex is the psychical correlate of two fundamental biological facts: the long period of the human child's dependence, and the remarkable way in which its sexual life reaches a first climax in the third to fifth years of life, and then, after a period of inhibition, sets in again at puberty. And here, the discovery was made that a third and extremely serious part of human intellectual activity, the part which has created the great institutions of religion, law, ethics, and all forms of civic life, has as its fundamental aim the enabling of the individual to master his Oedipus complex and to divert his libido from its infantile attachments into the social ones that are ultimately desired. The applications of psycho-analysis to the science of religion and sociology (e.g. by the present writer, Theodor Reik and Oskar Pfister), which have led to these findings, are still young and insufficiently appreciated; but it cannot be doubted that further studies will only confirm the certainty of these important conclusions.

[1924f, 4117]

By its theory of the instincts psycho-analysis offended the feelings of individuals in so far as they regarded themselves as members of the social community; another branch of its theory was calculated to hurt every single person at the tenderest point of his own psychological development. Psycho-analysis disposed once and for all of the fairy tale of an asexual childhood. It demonstrated the fact that sexual interests and activities occur in small children from the beginning of their lives. It showed what transformations those activities pass through, how at about the age of five they succumb to inhibition and how from puberty onwards they enter the service of the reproductive function. It recognized that early infantile sexual life reaches its peak in what is known as the Oedipus complex (an emotional attachment of the child to the parent of the opposite sex accompanied by an attitude of rivalry to the parent of the same sex) and that at that period of life this impulsion extends uninhibited into a straightforward sexual desire. This can be confirmed so easily that only the greatest efforts could make it possible to overlook it. Every individual has in fact gone through this phase but has afterwards energetically repressed its purport and succeeded in forgetting it. A horror of incest and an enormous sense of guilt are left over from this prehistoric epoch of the individual's existence. It may be that something quite similar occurred in the prehistoric epoch of the human species as a whole and that the beginnings of morality, religion and social order were intimately connected with the surmounting of that primaeval era. To adults their prehistory seems so inglorious that they refuse to allow themselves to be reminded of it: they were infuriated when psycho-analysis tried to lift the veil of amnesia from their years of childhood. There was only one way out: what psycho-analysis asserted must be false and what posed as a new science must be a tissue of fancies and distortions.

[1925e, 4128]
The process of arriving at an object, which plays such an important part in mental life, takes place alongside of the organization of the libido. After the stage of auto-erotism, the first love-object in the case of both sexes is the mother; and it seems probable that to begin with a child does not distinguish its mother's organ of nutrition from its own body. Later, but still in the first years of infancy, the relation known as the Oedipus complex becomes established: boys concentrate their sexual wishes upon their mother and develop hostile impulses against their father as being a rival, while girls adopt an analogous attitude.¹ All of the different variations and consequences of the Oedipus complex are important; and the innately bisexual constitution of human beings makes itself felt and increases the number of simultaneously active tendencies. Children do not become clear for quite a long time about the differences between the sexes; and during this period of sexual researches they produce typical sexual theories which, being circumscribed by the incompleteness of their authors' own physical development, are a mixture of truth and error and fail to solve the problems of sexual life (the riddle of the Sphinx - that is, the question of where babies come from). We see, then, that a child's first object-choice is an incestuous one. The whole course of development that I have described is run through rapidly. For the most remarkable feature of the sexual life of man is its diphasic onset, its onset in two waves, with an interval between them. It reaches a first climax in the fourth or fifth year of a child's life. But thereafter this early efflorescence of sexuality passes off; the sexual impulses which have shown such liveliness are overcome by repression, and a period of latency follows, which lasts until puberty and during which the reaction-formations of morality, shame, and disgust are built up.² Of all living creatures man alone seems to show this diphasic onset of sexual growth, and it may perhaps be the biological determinant of his predisposition to neuroses. At puberty the impulses and object-relations of a child's early years become reanimated, and amongst them the emotional ties of its Oedipus complex. In the sexual life of puberty there is a struggle between the urges of early years and the inhibitions of the latency period. Before this, and while the child is at the highest point of its infantile sexual development, a genital organization of a sort is established; but only the male genitals play a part in it, and the female ones remain undiscovered. (I have described this as the period of phallic primacy.) At this stage the contrast between the sexes is not stated in terms of 'male' or 'female' but of 'possessing a penis' or 'castrated'. The castration complex which arises in this connection is of the profoundest importance in the formation alike of character and of neuroses.

I must begin by adding that increasing experience showed more and more plainly that the Oedipus complex was the nucleus of the neurosis. It was at once the climax of infantile sexual life and the point of junction from which all of its later developments proceeded. But if so, it was no longer possible to expect analysis to discover a factor that was specific in the aetiology of the neuroses. It must be true, as Jung expressed it so well in the early days when he was still an analyst, that neuroses have no peculiar content which belongs exclusively to them but that neurotics break down at the same difficulties that are successfully overcome by normal people. This discovery was very far from being a disappointment. It was in complete harmony with another one: that the depth-psychology revealed by psycho-analysis was in fact the psychology of the normal mind. Our path had been like that of chemistry: the great qualitative differences between substances were traced back to quantitative variations in the proportions in which the same elements were combined.
(2) For cultural reasons the most intense repression falls upon the sexual instincts; but it is precisely in connection with them that repression most easily miscarries, so that neurotic symptoms are found to be substitutive satisfactions of repressed sexuality. The belief that in man sexual life begins only at puberty is incorrect. On the contrary, signs of it can be detected from the beginning of extra-uterine existence; it reaches a first culminating point at or before the fifth year ('early period'), after which it is inhibited or interrupted ('latency period') until the age of puberty, which is the second climax of its development. This diphasic onset of sexual development seems to be distinctive of the genus Homo. All experiences during the first period of childhood are of the greatest importance to the individual, and in combination with his inherited sexual constitution form the dispositions for the subsequent development of character and disease. It is wrong to make sexuality coincide with 'genitality'. The sexual instincts pass through a complicated course of development, and it is only at the end of it that the 'primacy of the genital zones' is attained. Before this there are a number of 'pregenital' organizations of the libido - points at which it may become 'fixated' and to which, in the event of subsequent repression, it will return ('regression'). The infantile fixations of the libido are what determine the form of any later neurosis. Thus the neuroses are to be regarded as inhibitions in the development of the libido. There are no specific causes of nervous disorders; the question whether a conflict finds a healthy solution or leads to a neurotic inhibition of function depends upon quantitative considerations.

[1926f, 4405]

With the phallic phase and in the course of it the sexuality of early childhood reaches its height and approaches its dissolution. Thereafter boys and girls have different histories. Both have begun to put their intellectual activity at the service of sexual researches; both start off from the premiss of the universal presence of the penis. But now the paths of the sexes diverge. The boy enters the Oedipus phase; he begins to manipulate his penis and simultaneously has phantasies of carrying out some sort of activity with it in relation to his mother, till, owing to the combined effect of a threat of castration and the sight of the absence of a penis in females, he experiences the greatest trauma of his life and this introduces the period of latency with all its consequences. The girl, after vainly attempting to do the same as the boy, comes to recognize her lack of a penis or rather the inferiority of her clitoris, with permanent effects on the development of her character; as a result of this first disappointment in rivalry, she often begins by turning away altogether from sexual life.

[1940a [1938], 4965]
At this point our material - for some incomprehensible reason - becomes far more obscure and full of gaps. The female sex, too, develops an Oedipus complex, a super-ego and a latency period. May we also attribute a phallic organization and a castration complex to it? The answer is in the affirmative; but these things cannot be the same as they are in boys. Here the feminist demand for equal rights for the sexes does not take us far, for the morphological distinction is bound to find expression in differences of psychical development. 'Anatomy is Destiny', to vary a saying of Napoleon's. The little girl's clitoris behaves just like a penis to begin with; but, when she makes a comparison with a playfellow of the other sex, she perceives that she has 'come off badly' and she feels this as a wrong done to her and as a ground for inferiority. For a while still she consoles herself with the expectation that later on, when she grows older, she will acquire just as big an appendage as the boy's. Here the masculinity complex of women branches off. A female child, however, does not understand her lack of a penis as being a sex character; she explains it by assuming that at some earlier date she had possessed an equally large organ and had then lost it by castration. She seems not to extend this inference from herself to other, adult females, but, entirely on the lines of the phallic phase, to regard them as possessing large and complete - that is to say, male - genitals. The essential difference thus comes about that the girl accepts castration as an accomplished fact, whereas the boy fears the possibility of its occurrence.

[1924d, 4090]

With the phallic phase and in the course of it the sexuality of early childhood reaches its height and approaches its dissolution. Thereafter boys and girls have different histories. Both have begun to put their intellectual activity at the service of sexual researches; both start off from the premiss of the universal presence of the penis. But now the paths of the sexes diverge. The boy enters the Oedipus phase; he begins to manipulate his penis and simultaneously has phantasies of carrying out some sort of activity with it in relation to his mother, till, owing to the combined effect of a threat of castration and the sight of the absence of a penis in females, he experiences the greatest trauma of his life and this introduces the period of latency with all its consequences. The girl, after vainly attempting to do the same as the boy, comes to recognize her lack of a penis or rather the inferiority of her clitoris, with permanent effects on the development of her character; as a result of this first disappointment in rivalry, she often begins by turning away altogether from sexual life.

[1940a [1938], 4965]
In order to complete our picture of infantile sexual life, we must also suppose that the choice of an object, such as we have shown to be characteristic of the pubertal phase of development, has already frequently or habitually been effected during the years of childhood: that is to say, the whole of the sexual currents have become directed towards a single person in relation to whom they seek to achieve their aims. This then is the closest approximation possible in childhood to the final form taken by sexual life after puberty. The only difference lies in the fact that in childhood the combination of the component instincts and their subordination under the primacy of the genitals have been effected only very incompletely or not at all. Thus the establishment of that primacy in the service of reproduction is the last phase through which the organization of sexuality passes.¹

[1905d, 1517]
Put away your doubts, then, and join me in a consideration of infantile sexuality from the earliest age.¹ A child's sexual instinct turns out to be put together out of a number of factors; it is capable of being divided up into numerous components which originate from various sources. Above all, it is still independent of the reproductive function, into the service of which it will later be brought. It serves for the acquisition of different kinds of pleasurable feeling, which, basing ourselves on analogies and connections, we bring together under the idea of sexual pleasure. The chief source of infantile sexual pleasure is the appropriate excitation of certain parts of the body that are especially susceptible to stimulus: apart from the genitals, these are the oral, anal and urethral orifices, as well as the skin and other sensory surfaces. Since at this first phase of infantile sexual life satisfaction is obtained from the subject's own body and extraneous objects are disregarded, we term this phase (from a word coined by Havelock Ellis) that of auto-erotism. We call the parts of the body that are important in the acquisition of sexual pleasure 'erotogenic zones'. Thumb-sucking (or sensual sucking) in the youngest infants is a good example of this auto-erotic satisfaction from an erotogenic zone. The first scientific observer of this phenomenon, a paediatrician in Budapest named Lindner (1879), already interpreted it correctly as sexual satisfaction and described exhaustively its transition to other and higher forms of sexual activity. Another sexual satisfaction at this period of life is the masturbatory excitation of the genitals, which retains so much importance in later life and by many people is never completely conquered. Alongside these and other auto-erotic activities, we find in children at a very early age manifestations of those instinctual components of sexual pleasure (or, as we like to say, of libido) which presuppose the taking of an extraneous person as an object. These instincts occur in pairs of opposites, active and passive. I may mention as the most important representatives of this group the desire to cause pain (sadism) with its passive counterpart (masochism) and the active and passive desire for looking, from the former of which curiosity branches off later on and from the latter the impulse to artistic and theatrical display. Others of a child's sexual activities already imply the making of an 'object-choice', where an extraneous person becomes the main feature, a person who owes his importance in the first instance to considerations arising from the self-preservative instinct. But at this early period of childhood difference in sex plays no decisive part as yet. Thus you can attribute some degree of homosexuality to every child without doing him an injustice. This widespread and copious but dissociated sexual life of children, in which each separate instinct pursues its own acquisition of pleasure independently of all the rest, is now brought together and organized in two main directions, so that by the end of puberty the individual's final sexual character is as a rule completely formed. On the one hand, the separate instincts become subordinated to the dominance of the genital zone, so that the whole sexual life enters the service of reproduction, and the satisfaction of the separate instincts retains its importance only as preparing for and encouraging the sexual act proper. On the other hand, object-choice pushes auto-erotism into the background, so that in the subject's erotic life all the components of the sexual instinct now seek satisfaction in relation to the person who is loved. Not all of the original sexual components, however, are admitted to take part in this final establishment of sexuality. Even before puberty extremely energetic repressions of certain instincts have been effected under the influence of education, and mental forces such as shame, disgust and morality have been set up, which, like watchmen, maintain these repressions. So that when at puberty the high tide of sexual demands is reached, it is met by these mental reactive or resistant structures like dams, which direct its flow into what are called normal channels and make it impossible for it to reactivate the instincts that have undergone repression. It is in particular the coprophilic impulses of childhood - that is to say, the desires attaching to the excreta - which are submitted the most rigorously to repression, and the same is true, furthermore, of fixation to the figures to which the child's original object-choice was attached.

[1910a, 2230]
These, then, must be the oldest and most powerful of human desires. We cannot hope to understand this or test our hypothesis on these two examples, so long as we are totally ignorant of the meaning and origin of the totemic system. But the wording of these two taboos and the fact of their concurrence will remind anyone acquainted with the findings of psycho-analytic investigations on individuals of something quite definite, which psycho-analysts regard as the centre-point of childhood wishes and as the nucleus of neuroses.¹

[1912-1913, 2680]

The overmastering interest which must be felt in psycho-analysis by the theory of education is based upon a fact which has become evident. Only someone who can feel his way into the minds of children can be capable of educating them; and we grown-up people cannot understand children because we no longer understand our own childhood. Our infantile amnesia proves that we have grown estranged from our childhood. Psycho-analysis has brought to light the wishes, the thought structures and the developmental processes of childhood. All earlier attempts in this direction have been in the highest degree incomplete and misleading because they have entirely overlooked the inestimably important factor of sexuality in its physical and mental manifestations. The incredulous astonishment which meets the most certainly established findings of psycho-analysis on the subject of childhood - the Oedipus complex, self-love (or 'narcissism'), the disposition to perversions, anal erotism, sexual curiosity - is a measure of the gulf which separates our mental life, our judgements of value and, indeed, our processes of thought from those of even normal children.

[1913j, 2825]

For psycho-analysis has taught us that the individual's emotional attitudes to other people, which are of such extreme importance to his later behaviour, are already established at an unexpectedly early age. The nature and quality of the human child's relations to people of his own and the opposite sex have already been laid down in the first six years of his life. He may afterwards develop and transform them in certain directions but he can no longer get rid of them. The people to whom he is in this way fixed are his parents and his brothers and sisters. All those whom he gets to know later become substitute figures for these first objects of his feelings. (We should perhaps add to his parents any other people, such as nurses, who cared for him in his infancy.) These substitute figures can be classified from his point of view according as they are derived from what we call the 'imagos' of his father, his mother, his brothers and sisters, and so on. His later acquaintances are thus obliged to take over a kind of emotional heritage; they encounter sympathies and antipathies to the production of which they themselves have contributed little. All of his later choices of friendship and love follow upon the basis of the memory-traces left behind by these first prototypes.

[1914f, 2873]
What I have in mind is rivalry in love, with a clear emphasis on the subject's sex. While he is still a small child, a son will already begin to develop a special affection for his mother, whom he regards as belonging to him; he begins to feel his father as a rival who disputes his sole possession. And in the same way a little girl looks on her mother as a person who interferes with her affectionate relation to her father and who occupies a position which she herself could very well fill. Observation shows us to what early years these attitudes go back. We refer to them as the 'Oedipus complex', because the legend of Oedipus realizes, with only a slight softening, the two extreme wishes that arise from the son's situation - to kill his father and take his mother to wife. I do not wish to assert that the Oedipus complex exhausts the relation of children to their parents: it can easily be far more complicated. The Oedipus complex can, moreover, be developed to a greater or less strength, it can even be reversed; but it is a regular and very important factor in a child's mental life, and there is more danger of our underestimating rather than over-estimating its influence and that of the developments which proceed from it. Incidentally, children often react in their Oedipus attitude to a stimulus coming from their parents, who are frequently led in their preferences by difference of sex, so that the father will choose his daughter and the mother her son as a favourite, or, in case of a cooling-off in the marriage, as a substitute for a love-object that has lost its value.

[1916-1917, 3295]

It cannot be said that the world has shown much gratitude to psycho-analytic research for its revelation of the Oedipus complex. On the contrary, the discovery has provoked the most violent opposition among adults; and those who had neglected to take part in the repudiation of this proscribed and tabooed emotional relationship made up for their fault later by depriving the complex of its value through twisted re-interpretations. It is my unaltered conviction that there is nothing in this to be disavowed or glossed over. We must reconcile ourselves to the fact which was recognized by the Greek legend itself as an inevitable fate. It is once again an interesting fact that the Oedipus complex, which has been rejected from real life, has been left to imaginative writing, has been placed freely, as it were, at its disposal. Otto Rank has shown in a careful study how the Oedipus complex has provided dramatic authors with a wealth of themes in endless modifications, softens and disguises - in distortions, that is to say, of the kind which we are already familiar with as the work of a censorship. We may therefore also ascribe this Oedipus complex to dreamers who have been fortunate enough to escape conflicts with their parents in later life. And, intimately linked with it, we find what we call the 'castration complex', the reaction to the threats against the child aimed at putting a stop to his early sexual activities and attributed to his father.

[1916-1917, 3296]
First and foremost, it is an untenable error to deny that children have a sexual life and to suppose that sexuality only begins at puberty with the maturation of the genitals. On the contrary, from the very first children have a copious sexual life, which differs at many points from what is later regarded as normal. What in adult life is described as ‘perverse’ differs from the normal in these respects: first, by disregarding the barrier of species (the gulf between men and animals), secondly, by overstepping the barrier against disgust, thirdly that against incest (the prohibition against seeking sexual satisfaction from near blood-relations), fourthly that against members of one's own sex and fifthly the transferring of the part played by the genitals to other organs and areas of the body. None of these barriers existed from the beginning; they were only gradually erected in the course of development and education. Small children are free from them. They recognize no frightful gulf between human beings and animals; the arrogance with which men separate themselves from animals does not emerge until later. To begin with, children exhibit no disgust at excreta but acquire this slowly under the pressure of education; they attach no special importance to the distinction between the sexes, but attribute the same conformation of the genitals to both; they direct their first sexual lusts and their curiosity to those who are nearest and for other reasons dearest to them - parents, brothers and sisters, or nurses; and finally, they show (what later on breaks through once again at the climax of a love-relation) that they expect to derive pleasure not only from their sexual organs, but that many other parts of the body lay claim to the same sensitivity, afford them analogous feelings of pleasure and can accordingly play the part of genitals. Children may thus be described as 'polymorphously perverse', and if these impulses only show traces of activity, that is because on the one hand they are of less intensity compared with those in later life and on the other hand all a child's sexual manifestations are at once energetically suppressed by education. This suppression is, as it were, extended into theory; for adults endeavour to overlook one portion of the sexual manifestations of children and to disguise another portion by misinterpreting its sexual nature, so that they can then disavow the whole of them. It is often the very same people who in the nursery are furious with any sexual naughtinesses of children and afterwards at their writing-tables defend the sexual purity of the same children. When children are left to themselves, or under the influence of seduction, they often bring about quite considerable achievements in the way of perverse sexual activity. Adults are of course right not to take this too seriously and to regard it as 'childishness', or 'playfulness', for children are not to be condemned as fully capable or fully responsible either before the judgement-seat of morals or before the law; but nonetheless these things exist. They have their importance both as indications of a child's innate constitution and as causes and encouragements of later developments in him; they give us information on the sexual life of children and so on human sexual life in general. If, therefore, we once more find all these perverse wishful impulses behind our distorted dreams, that only means that in this field too dreams have taken a step backwards into the state of infancy.

[1916-1917, 3297]
Among these forbidden wishes special emphasis deserves to be further laid on the incestuous ones - that is, on those aiming at sexual intercourse with parents and brothers and sisters. You know what horror is felt, or at least professed, in human society at such intercourse, and what stress is laid on the prohibitions directed against it. Tremendous efforts have been made to explain this horror of incest. Some people have supposed that breeding considerations on the part of Nature have found psychical representation in this prohibition, since inbreeding would impair racial characters. Others have maintained that, as a result of living together from early childhood onwards, sexual desire has been diverted from the people in question. In both these cases, it may be remarked, an avoidance of incest would be secured automatically, and it would not be clear why such severe prohibitions were called for, which would point rather to the presence of a strong desire for it. Psycho-analytic researches have shown unmistakably that the choice of an incestuous love-object is, on the contrary, the first and invariable one, and that it is not until later that resistance to it sets in; it is no doubt impossible to trace back this resistance to individual psychology.

Let us now bring together what our researches into child psychology have contributed to our understanding of dreams. We have not only found that the material of the forgotten experiences of childhood is accessible to dreams, but we have also seen that the mental life of children with all its characteristics, its egoism, its incestuous choice of love-objects, and so on, still persists in dreams - that is, in the unconscious, and that dreams carry us back every night to this infantile level. The fact is thus confirmed that what is unconscious in mental life is also what is infantile.

The strange impression of there being so much evil in people begins to diminish. This frightful evil is simply the initial, primitive, infantile part of mental life, which we can find in actual operation in children, but which, in part, we overlook in them on account of their small size, and which in part we do not take seriously since we do not expect any high ethical standard from children. Since dreams regress to this level, they give the appearance of having brought to light the evil in us. But this is a deceptive appearance, by which we have allowed ourselves to be scared. We are not so evil as we were inclined to suppose from the interpretation of dreams.

The processes of finding an object are fairly complex and no comprehensive account has hitherto been given of them. For our purposes it may be specially pointed out that when, in the years of childhood before puberty, the process has in some respects reached a conclusion, the object that has been found turns out to be almost identical with the first object of the oral pleasure-instinct, which was reached by attachment. Though it is not actually the mother's breast, at least it is the mother. We call the mother the first love-object. For we speak of love when we bring the mental side of the sexual trends into the foreground and want to force back the underlying physical or 'sensual' instinctual demands or to forget them for a moment. At the time at which the child's mother becomes his love-object the psychical work of repression has already begun in him, which is withdrawing from his knowledge awareness of a part of his sexual aims. To his choice of his mother as a love-object everything becomes attached which, under the name of the 'Oedipus complex', has attained so much importance in the psycho-analytic explanation of the neuroses and has played no less a part, perhaps, in the resistance to psycho-analysis.
It is a surprising thing that the tragedy of Sophocles does not call up indignant repudiation in his audience - a reaction similar to that of our simple-minded army doctor but far better justified. For fundamentally it is an amoral work: it absolves men from moral responsibility, exhibits the gods as promoters of crime and shows the impotence of the moral impulses of men which struggle against crime. It might easily be supposed that the material of the legend had in view an indictment of the gods and of fate; and in the hands of Euripides, the critic and enemy of the gods, it would probably have become such an indictment. But with the devout Sophocles there is no question of an application of that kind. The difficulty is overcome by the pious sophistry that to bow to the will of the gods is the highest morality even when it promotes crime. I cannot think that this morality is a strong point of the play, but it has no influence on its effect. It is not to it that the auditor reacts but to the secret sense and content of the legend. He reacts as though by self-analysis he had recognized the Oedipus complex in himself and had unveiled the will of the gods and the oracle as exalted disguises of his own unconscious. It is as though he was obliged to remember the two wishes - to do away with his father and in place of him to take his mother to wife - and to be horrified at them. And he understands the dramatist's voice as though it were saying to him: 'You are struggling in vain against your responsibility and are protesting in vain of what you have done in opposition to these criminal intentions. You are guilty, for you have not been able to destroy them; they still persist in you unconsciously.' And there is psychological truth contained in this. Even if a man has repressed his evil impulses into the unconscious and would like to tell himself afterwards that he is not responsible for them, he is nevertheless bound to be aware of this responsibility as a sense of guilt whose basis is unknown to him. [1916-1917, 3398]

What, then, can be gathered about the Oedipus complex from the direct observation of children at the time of their making their choice of an object before the latency period? Well, it is easy to see that the little man wants to have his mother all to himself, that he feels the presence of his father as a nuisance, that he is resentful if his father indulges in any signs of affection towards his mother and that he shows satisfaction when his father has gone on a journey or is absent. He will often express his feelings directly in words and promise his mother to marry her. It will be thought that this amounts to little compared to the deeds of Oedipus; but in fact it is enough, it is the same thing at root. Observation is often obscured by the circumstance that on other occasions the same child will simultaneously give evidence of great affection for his father. But contrary - or, as it is better to say, 'ambivalent' - emotional attitudes, which in adults would lead to a conflict, remain compatible with each other for a long time in children, just as later they find a permanent place beside each other in the unconscious. It will also be objected that the little boy's conduct arises from egoistic motives and gives no grounds for postulating an erotic complex: the child's mother attends to all his needs, so that he has an interest in preventing her from looking after anyone else. This also is true; but it will soon become clear that in this situation as in similar ones the egoistic interest is merely affording a point of support to which the erotic trend is attached. The little boy may show the most undisguised sexual curiosity about his mother, he may insist upon sleeping beside her at night, he may force his presence on her while she is dressing or may even make actual attempts at seducing her, as his mother will often notice and report with amusement - all of which puts beyond doubt the erotic nature of his tie with his mother. Nor must it be forgotten that the mother devotes the same attention to her little daughter without producing the same result and that the father often competes with her in looking after the boy and yet fails to gain the same significance as she does. In short, the factor of sexual preference cannot be eliminated from the situation by any criticism. From the standpoint of egoistic interest it would be simply foolish of the little man not to prefer to put up with having two people in his service rather than only one of them. [1916-1917, 3399]
This and very much else of a similar nature will be shown to you by the direct observation of children and by the consideration of clearly retained memories from childhood uninfluenced by analysis. From this you will conclude among other things that the position of a child in the family order is a factor of extreme importance in determining the shape of his later life and should deserve consideration in every life-history. But, what is more important, in view of this information which can be so easily obtained, you will not be able to recall without a smile the pronouncements of science in explanation of the prohibition of incest. There is no end to what has been invented on the subject. It has been said that sexual inclination is diverted from members of the same family who are of the opposite sex by the fact of having lived together from childhood; or, again, that a biological purpose of avoiding inbreeding is represented psychically by an innate horror of incest. In all this the fact is entirely overlooked that such an inexorable prohibition of it in law and custom would not be needed if there were any reliable natural barriers against the temptation to incest. The truth is just the opposite. A human being's first choice of an object is regularly an incestuous one, aimed, in the case of the male, at his mother and sister; and it calls for the severest prohibitions to deter this persistent infantile tendency from realization. Among the primitive races still living to-day, among savages, the prohibitions against incest are even very much stricter than among ourselves, and Theodor Reik has only recently shown in a brilliant work that the puberty rites of savages, which represent a re-birth, have the sense of releasing the boy from his incestuous bond with his mother and of reconciling him with his father.

[1916-1917, 3400]

We know from psycho-analytic experience, however, that the fear of damaging or losing one's eyes is a terrible one in children. Many adults retain their apprehensiveness in this respect, and no physical injury is so much dreaded by them as an injury to the eye. We are accustomed to say, too, that we will treasure a thing as the apple of our eye. A study of dreams, phantasies and myths has taught us that anxiety about one's eyes, the fear of going blind, is often enough a substitute for the dread of being castrated. The self-blinding of the mythical criminal, Oedipus, was simply a mitigated form of the punishment of castration - the only punishment that was adequate for him by the *lex talionis*. We may try on rationalistic grounds to deny that fears about the eye are derived from the fear of castration, and may argue that it is very natural that so precious an organ as the eye should be guarded by a proportionate dread. Indeed, we might go further and say that the fear of castration itself contains no other significance and no deeper secret than a justifiable dread of this rational kind. But this view does not account adequately for the substitutive relation between the eye and the male organ which is seen to exist in dreams and myths and phantasies; nor can it dispel the impression that the threat of being castrated in especial excites a peculiarly violent and obscure emotion, and that this emotion is what first gives the idea of losing other organs its intense colouring. All further doubts are removed when we learn the details of their 'castration complex' from the analysis of neurotic patients, and realize its immense importance in their mental life.

[1919h, 3684]
This first configuration of the child’s love, which in typical cases takes the shape of the Oedipus complex, succumbs, as we know, from the beginning of the period of latency onwards to a wave of repression. Such of it as is left over shows itself as a purely affectionate emotional tie, relating to the same people, but no longer to be described as ‘sexual’. Psycho-analysis, which illuminates the depths of mental life, has no difficulty in showing that the sexual ties of the earliest years of childhood also persist, though repressed and unconscious. It gives us courage to assert that wherever we come across an affectionate feeling it is successor to a completely ‘sensual’ object-tie with the person in question or rather with that person’s prototype (or imago).

It cannot indeed disclose to us without a special investigation whether in a given case this former complete sexual current still exists under repression or whether it has already been exhausted. To speak still more precisely: it is quite certain that this current is still there as a form and possibility, and can always be cathected and put into activity again by means of regression; the only question is (and it cannot always be answered) what degree of cathexis and operative force it still has at the present moment. Equal care must be taken in this connection to avoid two sources of error - the Scylla of underestimating the importance of the repressed unconscious, and the Charybdis of judging the normal entirely by the standards of the pathological.

[1921c, 3829]

There is not much to be said from the analytic point of view. It is easy to see that essentially it is compounded of grief, the pain caused by the thought of losing the loved object, and of the narcissistic wound, in so far as this is distinguishable from the other wound; further, of feelings of enmity against the successful rival, and of a greater or lesser amount of self-criticism which tries to hold the subject’s own ego accountable for his loss. Although we may call it normal, this jealousy is by no means completely rational, that is, derived from the actual situation, proportionate to the real circumstances and under the complete control of the conscious ego; for it is rooted deep in the unconscious, it is a continuation of the earliest stirrings of the child’s affective life, and it originates in the Oedipus or brother-and-sister complex of the first sexual period. Moreover, it is noteworthy that in some people it is experienced bisexually. That is to say, a man will not only feel pain about the woman he loves and hatred of the man who is his rival, but also grief about the man, whom he loves unconsciously, and hatred of the woman as his rival; and this latter set of feelings will add to the intensity of his jealousy. I even know of a man who suffered exceedingly during his attacks of jealousy and who, according to his own account, went through unendurable torments by consciously imagining himself in the position of the faithless woman. The sensation of helplessness which then came over him and the images he used to describe his condition - exposed to the vulture’s beak like Prometheus, or thrown bound into a nest of serpents - were referred by him to impressions received during several homosexual acts of aggression to which he had been subjected as a boy.

[1922b, 3900]

In the very earliest years of childhood (approximately between the ages of two and five) a convergence of the sexual impulses occurs of which, in the case of boys, the object is the mother. This choice of an object, in conjunction with a corresponding attitude of rivalry and hostility towards the father, provides the content of what is known as the Oedipus complex, which in every human being is of the greatest importance in determining the final shape of his erotic life. It has been found to be characteristic of a normal individual that he learns to master his Oedipus complex, whereas the neurotic subject remains involved in it.

[1923a, 3922]
But the derivation of the super-ego from the first object-cathexes of the id, from the Oedipus complex, signifies even more for it. This derivation, as we have already shown, brings it into relation with the phylogenetic acquisitions of the id and makes it a reincarnation of former ego-structures which have left their precipitates behind in the id. Thus the super-ego is always close to the id and can act as its representative vis-à-vis the ego. It reaches deep down into the id and for that reason is farther from consciousness than the ego is.¹

[1923b, 3982]

One may go further and venture the hypothesis that a great part of the sense of guilt must normally remain unconscious, because the origin of conscience is intimately connected with the Oedipus complex, which belongs to the unconscious. If anyone were inclined to put forward the paradoxical proposition that the normal man is not only far more immoral than he believes but also far more moral than he knows, psycho-analysis, on whose findings the first half of the assertion rests, would have no objection to raise against the second half.¹

[1923b, 3986]

To an ever-increasing extent the Oedipus complex reveals its importance as the central phenomenon of the sexual period of early childhood. After that, its dissolution takes place; it succumbs to repression, as we say, and is followed by the latency period. It has not yet become clear, however, what it is that brings about its destruction. Analyses seem to show that it is the experience of painful disappointments. The little girl likes to regard herself as what her father loves above all else; but the time comes when she has to endure a harsh punishment from him and she is cast out of her fool's paradise. The boy regards his mother as his own property; but he finds one day that she has transferred her love and solicitude to a new arrival. Reflection must deepen our sense of the importance of those influences, for it will emphasize the fact that distressing experiences of this sort, which act in opposition to the content of the complex, are inevitable. Even when no special events occur, like those we have mentioned as examples, the absence of the satisfaction hoped for, the continued denial of the desired baby, must in the end lead the small lover to turn away from his hopeless longing. In this way the Oedipus complex would go to its destruction from its lack of success, from the effects of its internal impossibility. [1924d, 4085]

And now, as a third point, psycho-analysis has shown us, to our growing astonishment, the enormously important part played by what is known as the 'Oedipus complex' - that is, the emotional relation of a child to its two parents - in the mental life of human beings. Our astonishment diminishes when we realize that the Oedipus complex is the psychical correlate of two fundamental biological facts: the long period of the human child's dependence, and the remarkable way in which its sexual life reaches a first climax in the third to fifth years of life, and then, after a period of inhibition, sets in again at puberty. And here, the discovery was made that a third and extremely serious part of human intellectual activity, the part which has created the great institutions of religion, law, ethics, and all forms of civic life, has as its fundamental aim the enabling of the individual to master his Oedipus complex and to divert his libido from its infantile attachments into the social ones that are ultimately desired. The applications of psycho-analysis to the science of religion and sociology (e. g. by the present writer, Theodor Reik and Oskar Pfister), which have led to these findings, are still young and insufficiently appreciated; but it cannot be doubted that further studies will only confirm the certainty of these important conclusions.

[1924f, 4117]
By its theory of the instincts psycho-analysis offended the feelings of individuals in so far as they regarded themselves as members of the social community; another branch of its theory was calculated to hurt every single person at the tenderest point of his own psychical development. Psycho-analysis disposed once and for all of the fairy tale of an asexual childhood. It demonstrated the fact that sexual interests and activities occur in small children from the beginning of their lives. It showed what transformations those activities pass through, how at about the age of five they succumb to inhibition and how from puberty onwards they enter the service of the reproductive function. It recognized that early infantile sexual life reaches its peak in what is known as the Oedipus complex (an emotional attachment of the child to the parent of the opposite sex accompanied by an attitude of rivalry to the parent of the same sex) and that at that period of life this impulsion extends uninhibited into a straightforward sexual desire. This can be confirmed so easily that only the greatest efforts could make it possible to overlook it. Every individual has in fact gone through this phase but has afterwards energetically repressed its purport and succeeded in forgetting it. A horror of incest and an enormous sense of guilt are left over from this prehistoric epoch of the individual's existence. It may be that something quite similar occurred in the prehistoric epoch of the human species as a whole and that the beginnings of morality, religion and social order were intimately connected with the surmounting of that praeval era. To adults their prehistory seems so inglorious that they refuse to allow themselves to be reminded of it: they were infuriated when psycho-analysis tried to lift the veil of amnesia from their years of childhood. There was only one way out: what psycho-analysis asserted must be false and what posed as a new science must be a tissue of fancies and distortions.

The Oedipus complex, however, is such an important thing that the manner in which one enters and leaves it cannot be without its effects. In boys (as I have shown at length in the paper to which I have just referred and to which all of my present remarks are closely related) the complex is not simply repressed, it is literally smashed to pieces by the shock of threatened castration. Its libidinal cathexes are abandoned, desexualized and in part sublimated; its objects are incorporated into the ego, where they form the nucleus of the super-ego and give that new structure its characteristic qualities. In normal, or, it is better to say, in ideal cases, the Oedipus complex exists no longer, even in the unconscious; the super-ego has become its heir. Since the penis (to follow Ferenczi) owes its extraordinarily high narcissistic cathexis to its organic significance for the propagation of the species, the catastrophe to the Oedipus complex (the abandonment of incest and the institution of conscience and morality) may be regarded as a victory of the race over the individual. This is an interesting point of view when one considers that neurosis is based upon a struggle of the ego against the demands of the sexual function. But to leave the standpoint of individual psychology is not of any immediate help in clarifying this complicated situation.

Since Dr. de Saussure has said in his preface that I have corrected his work, I must add a qualification; my influence has only made itself felt in a few corrections and comments and I have in no way sought to encroach upon the author's independence. In the first, theoretical part of this work, I should have expounded a number of things differently from him: for instance, the difficult topic of the preconscious and the unconscious. And above all, I should have treated the Oedipus complex far more exhaustively.
The process of arriving at an object, which plays such an important part in mental life, takes place alongside of the organization of the libido. After the stage of auto-erotism, the first love-object in the case of both sexes is the mother; and it seems probable that to begin with a child does not distinguish its mother's organ of nutrition from its own body. Later, but still in the first years of infancy, the relation known as the Oedipus complex becomes established: boys concentrate their sexual wishes upon their mother and develop hostile impulses against their father as being a rival, while girls adopt an analogous attitude.¹ All of the different variations and consequences of the Oedipus complex are important; and the innately bisexual constitution of human beings makes itself felt and increases the number of simultaneously active tendencies. Children do not become clear for quite a long time about the differences between the sexes; and during this period of sexual researches they produce typical sexual theories which, being circumscribed by the incompleteness of their authors' own physical development, are a mixture of truth and error and fail to solve the problems of sexual life (the riddle of the Sphinx - that is, the question of where babies come from). We see, then, that a child's first object-choice is an incestuous one. The whole course of development that I have described is run through rapidly. For the most remarkable feature of the sexual life of man is its diphasic onset, its onset in two waves, with an interval between them. It reaches a first climax in the fourth or fifth year of a child's life. But thereafter this early efflorescence of sexuality passes off; the sexual impulses which have shown such liveliness are overcome by repression, and a period of latency follows, which lasts until puberty and during which the reaction-formations of morality, shame, and disgust are built up.² Of all living creatures man alone seems to show this diphasic onset of sexual growth, and it may perhaps be the biological determinant of his predisposition to neuroses. At puberty the impulses and object-relations of a child's early years become re-animated, and amongst them the emotional ties of its Oedipus complex. In the sexual life of puberty there is a struggle between the urges of early years and the inhibitions of the latency period. Before this, and while the child is at the highest point of its infantile sexual development, a genital organization of a sort is established; but only the male genitals play a part in it, and the female ones remain undiscovered. (I have described this as the period of phallic primacy.) At this stage the contrast between the sexes is not stated in terms of 'male' or 'female' but of 'possessing a penis' or 'castrated'. The castration complex which arises in this connection is of the profoundest importance in the formation alike of character and of neuroses.

¹ (Footnote added 1935:) The information about infantile sexuality was obtained from the study of men and the theory deduced from it was concerned with male children. It was natural enough to expect to find a complete parallel between the two sexes; but this turned out not to hold. Further investigations and reflections revealed profound differences between the sexual development of men and women. The first sexual object of a baby girl (just as of a baby boy) is her mother; and before a woman can reach the end of her normal development she has to change not only her sexual object but also her leading genital zone. From this circumstance difficulties arise and possibilities of inhibition which are not present in the case of men.

² [1925d, 4212]
I must begin by adding that increasing experience showed more and more plainly that the Oedipus complex was the nucleus of the neurosis. It was at once the climax of infantile sexual life and the point of junction from which all of its later developments proceeded. But if so, it was no longer possible to expect analysis to discover a factor that was specific in the aetiology of the neuroses. It must be true, as Jung expressed it so well in the early days when he was still an analyst, that neuroses have no peculiar content which belongs exclusively to them but that neurotics break down at the same difficulties that are successfully overcome by normal people. This discovery was very far from being a disappointment. It was in complete harmony with another one: that the depth-psychology revealed by psycho-analysis was in fact the psychology of the normal mind. Our path had been like that of chemistry: the great qualitative differences between substances were traced back to quantitative variations in the proportions in which the same elements were combined.

In the Oedipus complex the libido was seen to be attached to the image of the parental figures. But earlier there was a period in which there were no such objects. There followed from this fact the concept (of fundamental importance for the libido theory) of a state in which the subject's libido filled his own ego and had that for its object. This state could be called narcissism or self-love. A moment's reflection showed that this state never completely ceases. All through the subject's life his ego remains the great reservoir of his libido, from which object-cathexes are sent out and into which the libido can stream back again from the objects. Thus narcissistic libido is constantly being transformed into object-libido, and vice versa. An excellent instance of the length to which this transformation can go is afforded by the state of being in love, whether in a sexual or sublimated manner, which goes so far as involving a sacrifice of the self. Whereas hitherto in considering the process of repression attention had only been paid to what was repressed, these ideas made it possible to form a correct estimate of the repressing forces too. It had been said that repression was set in action by the instincts of self-preservation operating in the ego (the 'ego-instincts') and that it was brought to bear upon the libidinal instincts. But since the instincts of self-preservation were now recognized as also being of a libidinal nature, as being narcissistic libido, the process of repression was seen to be a process occurring within the libido itself; narcissistic libido was opposed to object-libido, the interest of self-preservation was defending itself against the demands of object-love, and therefore against the demands of sexuality in the narrower sense as well.

But let us first summon history to our aid. When Caius Julius Caesar landed in Egypt, he found the young Queen Cleopatra (who was soon to become so important to him) married to her still younger brother Ptolemy. In an Egyptian dynasty there was nothing peculiar in this; the Ptolemies, who were of Greek origin, had merely carried on the custom which had been practised by their predecessors, the ancient Pharaohs, for a few thousand years. This, however, was merely brother-and-sister incest, which even at the present time is not judged so harshly. So let us turn to our chief witness in matters concerning primateval times - mythology. It informs us that the myths of every people, and not only of the Greeks, are filled with examples of love-affairs between fathers and daughters and even between mothers and sons. Cosmology, no less than the genealogy of royal races, is founded upon incest. For what purpose do you suppose these legends were created? To brand gods and kings as criminals? to fasten on them the abhorrence of the human race? Rather, surely, because incestuous wishes are a primordial human heritage and have never been fully overcome, so that their fulfilment was still granted to gods and their descendants when the majority of common humans were already obliged to renounce them. It is in complete harmony with these lessons of history and mythology that we find incestuous wishes still present and operative in the childhood of the individual.
I think that Goethe would not have rejected psycho-analysis in an unfriendly spirit, as so many of our contemporaries have done. He himself approached it at a number of points, recognized much through his own insight that we have since been able to confirm, and some views, which have brought criticism and mockery down upon us, were expounded by him as self-evident. Thus he was familiar with the incomparable strength of the first affective ties of human creatures. He celebrated them in the Dedication to his *Faust* poem, in words which we could repeat for each of our analyses:

[1930, 4579]

Thus he does not deny that these perennial first inclinations take figures from one's own family circle as their object.

[1930, 4579]

But you must not expect to hear the glad tidings that the struggle about analysis is over and has ended in its recognition as a science and its admission as a subject for instruction at universities. There is no question of that. The struggle continues, though in more polite forms. What is also new is that a sort of buffer-layer has formed in scientific society between analysis and its opponents. This consists of people who allow the validity of some portions of analysis and admit as much, subject to the most entertaining qualifications, but who on the other hand reject other portions of it, a fact which they cannot proclaim too loudly. It is not easy to divine what determines their choice in this. It seems to depend on personal sympathies. One person will take objection to sexuality, another to the unconscious; what seems particularly unpopular is the fact of symbolism. Though the structure of psycho-analysis is unfinished, it nevertheless presents, even to-day, a unity from which elements cannot be broken off at the caprice of whoever comes along; but these eclectics seem to disregard this. I have never had the impression that these half- or quarter-adherents based their rejection on an examination of the facts. Some distinguished men, too, are included in this category. They, to be sure, are excused by the fact that their time and their interest belong to other things - to those things, namely, in mastering which they have achieved so much. But in that case would they not do better to suspend their judgement instead of taking sides so decisively? With one of these great men I once succeeded in effecting a rapid conversion. He was a world-famous critic, who had followed the spiritual currents of the time with benevolent understanding and prophetic penetration. I only came to know him when he was past his eightieth year; but he was still enchanting in his talk. You will easily guess whom I mean. Nor was it I who introduced the subject of psycho-analysis. It was he who did so, by comparing himself with me in the most modest fashion. 'I am only a literary man,' he said, 'but you are a natural scientist and discoverer. However, there is one thing I must say to you: I have never had sexual feelings towards my mother.' 'But there is no need at all for you to have known them,' was my reply; 'to grown-up people those are unconscious feelings.' 'Oh! so that's what you think!' he said with relief, and pressed my hand. We went on talking together on the best of terms for another few hours. I heard later that in the few remaining years of his life he often spoke of analysis in a friendly way and was pleased at being able to use a word that was new to him - 'repression'.

[1933a, 4740]
This preface is not superfluous, for it can heighten our realization of the intensity of the Oedipus complex. When a boy (from the age of two or three) has entered the phallic phrase of his libidinal development, is feeling pleasurable sensations in his sexual organ and has learnt to procure these at will by manual stimulation, he becomes his mother's lover. He wishes to possess her physically in such ways as he has divined from his observations and intuitions about sexual life, and he tries to seduce her by showing her the male organ which he is proud to own. In a word, his early awakened masculinity seeks to take his father's place with her; his father has hitherto in any case been an envied model to the boy, owing to the physical strength he perceives in him and the authority with which he finds him clothed. His father now becomes a rival who stands in his way and whom he would like to get rid of. If while his father is away he is allowed to share his mother's bed and if when his father returns he is once more banished from it, his satisfaction when his father disappears and his disappointment when he emerges again are deeply felt experiences. This is the subject of the Oedipus complex, which the Greek legend has translated from the world of a child's phantasy into pretended reality. Under the conditions of our civilization it is invariably doomed to a frightening end.

[1940a [1938], 4997]
I have learnt to look upon unconscious love relations like this (which are marked by their abnormal consequences) - between a father and a daughter, or between a mother and a son - as a revival of germs of feeling in infancy. I have shown at length elsewhere¹ at what an early age sexual attraction makes itself felt between parents and children, and I have explained that the legend of Oedipus is probably to be regarded as a poetical rendering of what is typical in these relations. Distinct traces are probably to be found in most people of an early partiality of this kind - on the part of a daughter for her father, or on the part of a son for his mother; but it must be assumed to be more intense from the very first in the case of those children whose constitution marks them down for a neurosis, who develop prematurely and have a craving for love. At this point certain other influences, which need not be discussed here, come into play, and lead to a fixation of this rudimentary feeling of love or to a reinforcement of it; so that it turns into something (either while the child is still young or not until it has reached the age of puberty) which must be put on a par with a sexual inclination and which, like the latter, has the forces of the libido at its command.² The nature of her disposition had always drawn her towards her father, and his numerous illnesses were bound to have increased her affection for him. In some of these illnesses he would allow no one but her to discharge the lighter duties of nursing. He had been so proud of the early growth of her intelligence that he had made her his confidante while she was still a child. It was really she and not her mother whom Frau K.'s appearance had driven out of more than one position.

[1905e, 1393]

What I have in mind is rivalry in love, with a clear emphasis on the subject's sex. While he is still a small child, a son will already begin to develop a special affection for his mother, whom he regards as belonging to him; he begins to feel his father as a rival who disputes his sole possession. And in the same way a little girl looks on her mother as a person who interferes with her affectionate relation to her father and who occupies a position which she herself could very well fill. Observation shows us to what early years these attitudes go back. We refer to them as the 'Oedipus complex', because the legend of Oedipus realizes, with only a slight softening, the two extreme wishes that arise from the son's situation - to kill his father and take his mother to wife. I do not wish to assert that the Oedipus complex exhausts the relation of children to their parents: it can easily be far more complicated. The Oedipus complex can, moreover, be developed to a greater or less strength, it can even be reversed; but it is a regular and very important factor in a child's mental life, and there is more danger of our underestimating rather than over-estimating its influence and that of the developments which proceed from it. Incidentally, children often react in their Oedipus attitude to a stimulus coming from their parents, who are frequently led in their preferences by difference of sex, so that the father will choose his daughter and the mother her son as a favourite, or, in case of a cooling-off in the marriage, as a substitute for a love-object that has lost its value.

[1916-1917, 3295]
Nothing, however, deserves more notice than the fact that children regularly direct their sexual wishes towards their nearest relatives - in the first place, therefore, towards their father and mother, and afterwards towards their brothers and sisters. The first object of a boy's love is his mother, and of a girl's her father (except in so far as an innate bisexual disposition favours the simultaneous presence of the contrary attitude). The other parent is felt as a disturbing rival and not infrequently viewed with strong hostility. You must understand me aright. What I mean to say is not that the child wants to be treated by its favourite parent merely with the kind of affection which we adults like to regard as the essence of the parent-child relation. No, analysis leaves us in no doubt that the child's wishes extend beyond such affection to all that we understand by sensual satisfaction - so far, that is, as the child's powers of imagination allow. It is easy to see that the child never guesses the actual facts of sexual intercourse; he replaces them by other notions derived from his own experience and feelings. As a rule his wishes culminate in the intention to bear, or in some in definable way, to procreate a baby. Boys, too, in their ignorance, do not exclude themselves from the wish to bear a baby. We give the whole of this mental structure the name of 'Oedipus complex', after the familiar Greek legend. With the end of the early sexual period it should normally be given up, should radically disintegrate and become transformed; and the results of this transformation are destined for important functions in later mental life. But as a rule this is not effected radically enough, in which case puberty brings about a revival of the complex, which may have serious consequences.

[1926e, 4355]

However instructive cases of this kind may be, a still higher degree of interest must attach to the influence of a situation which every child is destined to pass through and which follows inevitably from the factor of the prolonged period during which a child is cared for by other people and lives with his parents. I am thinking of the Oedipus complex, so named because its essential substance is to be found in the Greek legend of King Oedipus, which has fortunately been preserved for us in a version by a great dramatist. The Greek hero killed his father and took his mother to wife. That he did so unwittingly, since he did not know them as his parents, is a deviation from the analytic facts which we can easily understand and which, indeed, we shall recognize as inevitable.

[1940a [1938], 4995]
This discovery is confirmed by a legend that has come down to us from classical antiquity: a legend whose profound and universal power to move can only be understood if the hypothesis I have put forward in regard to the psychology of children has an equally universal validity. What I have in mind is the legend of King Oedipus and Sophocles' drama which bears his name. [1900a, 740]

The action of the play consists in nothing other than the process of revealing, with cunning delays and ever-mounting excitement - a process that can be likened to the work of a psycho-analysis - that Oedipus himself is the murderer of Laius, but further that he is the son of the murdered man and of Jocasta. Appalled at the abomination which he has unwittingly perpetrated, Oedipus blinds himself and forsakes his home. The oracle has been fulfilled. [1900a, 740]

_Oedipus Rex_ is what is known as a tragedy of destiny. Its tragic effect is said to lie in the contrast between the supreme will of the gods and the vain attempts of mankind to escape the evil that threatens them. The lesson which, it is said, the deeply moved spectator should learn from the tragedy is submission to the divine will and realization of his own impotence. Modern dramatists have accordingly tried to achieve a similar tragic effect by weaving the same contrast into a plot invented by themselves. But the spectators have looked on unmoved while a curse or an oracle was fulfilled in spite of all the efforts of some innocent man: later tragedies of destiny have failed in their effect. [1900a, 741]

There is an unmistakable indication in the text of Sophocles' tragedy itself that the legend of Oedipus sprang from some primaeval dream-material which had as its content the distressing disturbance of a child's relation to his parents owing to the first stirrings of sexuality. At a point when Oedipus, though he is not yet enlightened, has begun to feel troubled by his recollection of the oracle, Jocasta consoles him by referring to a dream which many people dream, though, as she thinks, it has no meaning:

[1900a, 742]

¹ [Footnote added 1911:] I have published elsewhere a typical example of a disguised Oedipus dream of this kind. [Reprinted below.] Another example, with a detailed analysis, has been published by Otto Rank (1911a). - [Added 1914:] For some other disguised Oedipus dreams, in which eye-symbolism is prominent, see Rank (1913). Other papers on eye-dreams and eye-symbolism, by Eder, Ferenczi and Reitler will be found in the same place. The blinding in the legend of Oedipus, as well as elsewhere, stands for castration. - [Added 1911:] Incidentally, the symbolic interpretation of undisguised Oedipus dreams was not unknown to the ancients. Rank (1910, 534) writes: 'Thus Julius Caesar is reported to have had a dream of sexual intercourse with his mother which was explained by the dream-interpreters as a favourable augury for his taking possession of the earth (Mother Earth). The oracle given to the Tarquins was equally well known, which prophesied that the conquest of Rome would fall to that one of them who should first kiss his mother ("osculum matri tulent"). This was interpreted by Brutus as referring to Mother Earth. ("Terram osculo contigit, scilicet quod ea communis mater omnium mortalium esset" Livy, I, 56.)' - [Added 1914:] Compare in this connection the dream of Hippias reported by Herodotus (VI, 107): 'As for the Persians, they were guided to Marathon by Hippias son of Pisistratus. Hippias in the past night had seen a vision in his sleep wherein he thought that he lay with his own mother; he interpreted this dream to signify that he should return to Athens and recover his power, and so die an old man in his own mother-country.' - [Added 1911:] These myths and interpretations reveal a true psychological insight. I have found that people who know that they are preferred or favoured by the mother give evidence in their lives of a peculiar self-reliance and an unshakeable optimism which often seem like heroic attributes and bring actual success to their possessors. [1900a, 855]
Let us return to the sexual development of children. We have some arrears to make up owing
to our having paid more attention to the somatic than to the mental phenomena of sexual life.
The child's first choice of an object, which derives from its need for help, claims our further
interest. Its choice is directed in the first instance to all those who look after it, but these soon
give place to its parents. Children's relations to their parents, as we learn alike from direct
observations of children and from later analytic examination of adults, are by no means free
from elements of accompanying sexual excitation. The child takes both of its parents, and more
particularly one of them, as the object of its erotic wishes. In so doing, it usually follows some
indication from its parents, whose affection bears the clearest characteristics of a sexual
activity, even though of one that is inhibited in its aims. As a rule a father prefers his daughter
and a mother her son; the child reacts to this by wishing, if he is a son, to take his father's place,
and, if she is a daughter, her mother's. The feelings which are aroused in these relations
between parents and children and in the resulting ones between brothers and sisters are not
only of a positive or affectionate kind but also of a negative or hostile one. The complex which is
thus formed is doomed to early repression; but it continues to exercise a great and lasting
influence from the unconscious. It is to be suspected that, together with its extensions, it
constitutes the nuclear complex of every neurosis, and we may expect to find it no less actively
at work in other regions of mental life. The myth of King Oedipus, who killed his father and took
his mother to wife, reveals, with little modification, the infantile wish, which is later opposed and
repudiated by the barrier against incest. Shakespeare's Hamlet is equally rooted in the soil of
the incest-complex, but under a better disguise.

[1910a, 2232]

¹ For the substitution of blinding for castration - a substitution that occurs, too, in the myth of Oedipus -
see Reitler (1913), Ferenczi (1913b), Rank (1913) and Eder (1913).

[1912-1913, 2770]

The first consequence of our substitution is most remarkable. If the totem animal is the father,
then the two principal ordinances of totemism, the two taboo prohibitions which constitute its
core - not to kill the totem and not to have sexual relations with a woman of the same totem -
coincide in their content with the two crimes of Oedipus, who killed his father and married his
mother, as well as with the two primal wishes of children, the insufficient repression or the re-
awakening of which forms the nucleus of perhaps every psychoneurosis. If this equation is
anything more than a misleading trick of chance, it must enable us to throw a light upon the
origin of totemism in the inconceivably remote past. In other words, it would enable us to make
it probable that the totemic system - like little Hans's animal phobia and little Árpád's poultry
perversion - was a product of the conditions involved in the Oedipus complex. In order to pursue
this possibility, we shall have, in the following pages, to study a feature of the totemic system
(or, as we might say, of the totemic religion) which I have hitherto scarcely found an opportunity
of mentioning.

[1912-1913, 2772]
Of all the imagos of a childhood which, as a rule, is no longer remembered, none is more important for a youth or a man than that of his father. Organic necessity introduces into a man's relation to his father an emotional ambivalence which we have found most strikingly expressed in the Greek myth of King Oedipus. A little boy is bound to love and admire his father, who seems to him the most powerful, the kindest and the wisest creature in the world. God himself is after all only an exaltation of this picture of a father as he is represented in the mind of early childhood. But soon the other side of this emotional relationship emerges. One's father is recognized as the paramount disturber of one's instinctual life; he becomes a model not only to imitate but also to get rid of, in order to take his place. Thenceforward affectionate and hostile impulses towards him persist side by side, often to the end of one's life, without either of them being able to do away with the other. It is in this existence of contrary feelings side by side that lies the essential character of what we call emotional ambivalence.

What I have in mind is rivalry in love, with a clear emphasis on the subject's sex. While he is still a small child, a son will already begin to develop a special affection for his mother, whom he regards as belonging to him; he begins to feel his father as a rival who disputes his sole possession. And in the same way a little girl looks on her mother as a person who interferes with her affectionate relation to her father and who occupies a position which she herself could very well fill. Observation shows us to what early years these attitudes go back. We refer to them as the 'Oedipus complex', because the legend of Oedipus realizes, with only a slight softening, the two extreme wishes that arise from the son's situation - to kill his father and take his mother to wife. I do not wish to assert that the Oedipus complex exhausts the relation of children to their parents: it can easily be far more complicated. The Oedipus complex can, moreover, be developed to a greater or less strength, it can even be reversed; but it is a regular and very important factor in a child's mental life, and there is more danger of our under estimating rather than over-estimating its influence and that of the developments which proceed from it. Incidentally, children often react in their Oedipus attitude to a stimulus coming from their parents, who are frequently led in their preferences by difference of sex, so that the father will choose his daughter and the mother her son as a favourite, or, in case of a cooling-off in the marriage, as a substitute for a love-object that has lost its value.

And now you will be eager to hear what this terrible Oedipus complex contains. Its name tells you. You all know the Greek legend of King Oedipus, who was destined by fate to kill his father and take his mother to wife, who did everything possible to escape the oracle's decree and punished himself by blinding when he learned that he had none the less unwittingly committed both these crimes. I hope many of you may yourselves have felt the shattering effect of the tragedy in which Sophocles has treated the story. The work of the Athenian dramatist exhibits the way in which the long-past deed of Oedipus is gradually brought to light by an investigation ingeniously protracted and fanned into life by ever fresh relays of evidence. To this extent it has a certain resemblance to the progress of a psycho-analysis. In the course of the dialogue Jocasta, the deluded mother and wife, declares herself opposed to the continuance of the enquiry. She appeals to the fact that many people have dreamt of lying with their mothers, but that dreams should be despised. We do not despise dreams - least of all, typical dreams which occur to many people; and we do not doubt that the dream referred to by Jocasta has an intimate connection with the strange and terrifying content of the legend.
It is a surprising thing that the tragedy of Sophocles does not call up indignant repudiation in his audience - a reaction similar to that of our simple-minded army doctor but far better justified. For fundamentally it is an amoral work: it absolves men from moral responsibility, exhibits the gods as promoters of crime and shows the impotence of the moral impulses of men which struggle against crime. It might easily be supposed that the material of the legend had in view an indictment of the gods and of fate; and in the hands of Euripides, the critic and enemy of the gods, it would probably have become such an indictment. But with the devout Sophocles there is no question of an application of that kind. The difficulty is overcome by the pious sophistry that to bow to the will of the gods is the highest morality even when it promotes crime. I cannot think that this morality is a strong point of the play, but it has no influence on its effect. It is not to it that the auditor reacts but to the secret sense and content of the legend. He reacts as though by self-analysis he had recognized the Oedipus complex in himself and had unveiled the will of the gods and the oracle as exalted disguises of his own unconscious. It is as though he was obliged to remember the two wishes - to do away with his father and in place of him to take his mother to wife - and to be horrified at them. And he understands the dramatist's voice as though it were saying to him: 'You are struggling in vain against your responsibility and are protesting in vain of what you have done in opposition to these criminal intentions. You are guilty, for you have not been able to destroy them; they still persist in you unconsciously.' And there is psychological truth contained in this. Even if a man has repressed his evil impulses into the unconscious and would like to tell himself afterwards that he is not responsible for them, he is nevertheless bound to be aware of this responsibility as a sense of guilt whose basis is unknown to him.

Mother-incest was one of the crimes of Oedipus, parricide was the other. It may be remarked in passing that they are also the two great crimes proscribed by totemism, the first socio-religious institution of mankind.

We know from psycho-analytic experience, however, that the fear of damaging or losing one's eyes is a terrible one in children. Many adults retain their apprehensiveness in this respect, and no physical injury is so much dreaded by them as an injury to the eye. We are accustomed to say, too, that we will treasure a thing as the apple of our eye. A study of dreams, phantasies and myths has taught us that anxiety about one's eyes, the fear of going blind, is often enough a substitute for the dread of being castrated. The self-blinding of the mythical criminal, Oedipus, was simply a mitigated form of the punishment of castration - the only punishment that was adequate for him by the *lex talionis*. We may try on rationalistic grounds to deny that fears about the eye are derived from the fear of castration, and may argue that it is very natural that so precious an organ as the eye should be guarded by a proportionate dread. Indeed, we might go further and say that the fear of castration itself contains no other significance and no deeper secret than a justifiable dread of this rational kind. But this view does not account adequately for the substitutive relation between the eye and the male organ which is seen to exist in dreams and myths and phantasies; nor can it dispel the impression that the threat of being castrated in especial excites a peculiarly violent and obscure emotion, and that this emotion is what first gives the idea of losing other organs its intense colouring. All further doubts are removed when we learn the details of their 'castration complex' from the analysis of neurotic patients, and realize its immense importance in their mental life.
But our interest in the genesis of these manifestly immoral dreams is greatly reduced when we find from analysis that the majority of dreams - innocent dreams, dreams without affect and anxiety-dreams - are revealed, when the distortions of the censorship have been undone, as the fulfilments of immoral - egoistic, sadistic, perverse or incestuous - wishful impulses. As in the world of waking life, these masked criminals are far commoner than those with their visors raised. The straightforward dream of sexual relations with one’s mother, which Jocasta alludes to in the Oedipus Rex, is a rarity in comparison with all the multiplicity of dreams which psycho-analysis must interpret in the same sense.

[1925i, 4049]

I am surprised that you are still silent. That can scarcely mean consent. - In asserting that a child’s first choice of an object is, to use the technical term, an incestuous one, analysis no doubt once more hurt the most sacred feelings of humanity, and might well be prepared for a corresponding amount of disbelief, contradiction and attack. And these it has received in abundance. Nothing has damaged it more in the good opinion of its contemporaries than its hypothesis of the Oedipus complex as a structure universally bound to human destiny. The Greek myth, incidentally, must have had the same meaning; but the majority of men to-day, learned and unlearned alike, prefer to believe that Nature has laid down an innate abhorrence in us as a guard against the possibility of incest.

[1926e, 4355]

The most straightforward is certainly the representation in the drama derived from the Greek legend. In this it is still the hero himself who commits the crime. But poetic treatment is impossible without softening and disguise. The naked admission of an intention to commit parricide, as we arrive at it in analysis, seems intolerable without analytic preparation. The Greek drama, while retaining the crime, introduces the indispensable toning-down in a masterly fashion by projecting the hero’s unconscious motive into reality in the form of a compulsion by a destiny which is alien to him. The hero commits the deed unintentionally and apparently uninfluenced by the woman; this latter element is however taken into account in the circumstance that the hero can only obtain possession of the queen mother after he has repeated his deed upon the monster who symbolizes the father. After his guilt has been revealed and made conscious, the hero makes no attempt to exculpate himself by appealing to the artificial expedient of the compulsion of destiny. His crime is acknowledged and punished as though it were a full and conscious one - which is bound to appear unjust to our reason, but which psychologically is perfectly correct.

[1928b, 4564]

However instructive cases of this kind may be, a still higher degree of interest must attach to the influence of a situation which every child is destined to pass through and which follows inevitably from the factor of the prolonged period during which a child is cared for by other people and lives with his parents. I am thinking of the Oedipus complex, so named because its essential substance is to be found in the Greek legend of King Oedipus, which has fortunately been preserved for us in a version by a great dramatist. The Greek hero killed his father and took his mother to wife. That he did so unwittingly, since he did not know them as his parents, is a deviation from the analytic facts which we can easily understand and which, indeed, we shall recognize as inevitable.

[1940a [1938], 4995]
This preface is not superfluous, for it can heighten our realization of the intensity of the Oedipus complex. When a boy (from the age of two or three) has entered the phallic phrase of his libidinal development, is feeling pleasurable sensations in his sexual organ and has learnt to procure these at will by manual stimulation, he becomes his mother’s lover. He wishes to possess her physically in such ways as he has divined from his observations and intuitions about sexual life, and he tries to seduce her by showing her the male organ which he is proud to own. In a word, his early awakened masculinity seeks to take his father’s place with her; his father has hitherto in any case been an envied model to the boy, owing to the physical strength he perceives in him and the authority with which he finds him clothed. His father now becomes a rival who stands in his way and whom he would like to get rid of. If while his father is away he is allowed to share his mother’s bed and if when his father returns he is once more banished from it, his satisfaction when his father disappears and his disappointment when he emerges again are deeply felt experiences. This is the subject of the Oedipus complex, which the Greek legend has translated from the world of a child’s phantasy into pretended reality. Under the conditions of our civilization it is invariably doomed to a frightening end.

[1940a [1938], 4997]

¹ Castration has a place too in the Oedipus legend, for the blinding with which Oedipus punishes himself after the discovery of his crime is, by the evidence of dreams, a symbolic substitute for castration. The possibility cannot be excluded that a phylogenetic memory-trace may contribute to the extraordinarily terrifying effect of the threat - a memory-trace from the prehistory of the primal family, where the jealous father actually robbed his son of his genitals if the latter became troublesome to him as a rival with a woman. The primaeval custom of circumcision, another symbolic substitute for castration, can only be understood as an expression of submission to the father’s will. (Cf. the puberty rites of primitive peoples.) No investigation has yet been made of the form taken by the events described above among peoples and in civilizations which do not suppress masturbation in children.

[1940a [1938], 4997]

It is no doubt true that the impact of the threat of castration upon a boy’s budding sexual life does not always have these dreaded consequences. It will depend once again on quantitative relations how much damage is done and how much avoided. The whole occurrence, which may probably be regarded as the central experience of the years of childhood, the greatest problem of early life and the strongest source of later inadequacy, is so completely forgotten that its reconstruction during the work of analysis is met in adults by the most decided disbelief. Indeed, aversion to it is so great that people try to silence any mention of the proscribed subject and the most obvious reminders of it are overlooked by a strange intellectual blindness. One may hear it objected, for instance, that the legend of King Oedipus has in fact no connection with the construction made by analysis: the cases are quite different, since Oedipus did not know that it was his father that he killed and his mother that he married. What is overlooked in this is that a distortion of this kind is inevitable if an attempt is made at a poetic handling of the material, and that there is no introduction of extraneous material but only a skilful employment of the factors presented by the theme. The ignorance of Oedipus is a legitimate representation of the unconscious state into which, for adults, the whole experience has fallen; and the coercive power of the oracle, which makes or should make the hero innocent, is a recognition of the inevitability of the fate which has condemned every son to live through the Oedipus complex. Again it was pointed out from psycho-analytic quarters how easily the riddle of another dramatic hero, Shakespeare’s procrastinator, Hamlet, can be solved by reference to the Oedipus complex, since the prince came to grief over the task of punishing someone else for what coincided with the substance of his own Oedipus wish - whereupon the general lack of understanding on the part of the literary world showed how ready is the mass of mankind to hold fast to its infantile repressions.¹

[1940a [1938], 4999]
The picture of an ego which mediates between the id and the external world, which takes over the instinctual demands of the former in order to lead them to satisfaction, which derives perceptions from the latter and uses them as memories, which, intent on its self-preservation, puts itself in defence against excessively strong claims from both sides and which, at the same time, is guided in all its decisions by the injunctions of a modified pleasure principle - this picture in fact applies to the ego only up to the end of the first period of childhood, till about the age of five. At about that time an important change has taken place. A portion of the external world has, at least partially, been abandoned as an object and has instead, by identification, been taken into the ego and thus become an integral part of the internal world. This new psychical agency continues to carry on the functions which have hitherto been performed by the people in the external world: it observes the ego, gives it orders, judges it and threatens it with punishments, exactly like the parents whose place it has taken. We call this agency the super-ego and are aware of it in its judicial functions as our conscience. It is a remarkable thing that the super-ego often displays a severity for which no model has been provided by the real parents, and moreover that it calls the ego to account not only for its deeds but equally for its thoughts and unexecuted intentions, of which the super-ego seems to have knowledge. This reminds us that the hero of the Oedipus legend too felt guilty for his deeds and submitted himself to self-punishment, although the coercive power of the oracle should have acquitted him of guilt in our judgement and his own. The super-ego is in fact the heir to the Oedipus complex and is only established after that complex has been disposed of. For that reason its excessive severity does not follow a real model but corresponds to the strength of the defence used against the temptation of the Oedipus complex. Some suspicion of this state of things lies, no doubt, at the bottom of the assertion made by philosophers and believers that the moral sense is not instilled into men by education or acquired by them in their social life but is implanted in them from a higher source.

[1940a [1938], 5010]
Although the diphasic nature of object-choice comes down in essentials to no more than the operation of the latency period, it is of the highest importance in regard to disturbances of that final outcome. The resultants of infantile object-choice are carried over into the later period. They either persist as such or are revived at the actual time of puberty. But as a consequence of the repression which has developed between the two phases they prove unutilizable. Their sexual aims have become mitigated and they now represent what may be described as the 'affectionate current' of sexual life. Only psycho-analytic investigation can show that behind this affection, admiration and respect there lie concealed the old sexual longings of the infantile component instincts which have now become unserviceable. The object-choice of the pubertal period is obliged to dispense with the objects of childhood and to start afresh as a 'sensual current'. Should these two currents fail to converge, the result is often that one of the ideals of sexual life, the focusing of all desires upon a single object, will be unattainable.

THE BARRIER AGAINST INCEST  We see, therefore, that the parents' affection for their child may awaken his sexual instinct prematurely (i.e. before the somatic conditions of puberty are present) to such a degree that the mental excitation breaks through in an unmistakable fashion to the genital system. If, on the other hand, they are fortunate enough to avoid this, then their affection can perform its task of directing the child in his choice of a sexual object when he reaches maturity. No doubt the simplest course for the child would be to choose as his sexual objects the same persons whom, since his childhood, he has loved with what may be described as damped-down libido.¹ But, by the postponing of sexual maturation, time has been gained in which the child can erect, among other restraints on sexuality, the barrier against incest, and can thus take up into himself the moral precepts which expressly exclude from his object-choice, as being blood relations, the persons whom he has loved in his childhood. Respect for this barrier is essentially a cultural demand made by society. Society must defend itself against the danger that the interests which it needs for the establishment of higher social units may be swallowed up by the family; and for this reason, in the case of every individual, but in particular of adolescent boys, it seeks by all possible means to loosen their connection with their family - a connection which, in their childhood, is the only important one.²

It is in the world of ideas, however, that the choice of an object is accomplished at first; and the sexual life of maturing youth is almost entirely restricted to indulging in phantasies, that is, in ideas that are not destined to be carried into effect.¹ In these phantasies the infantile tendencies invariably emerge once more, but this time with intensified pressure from somatic sources. Among these tendencies the first place is taken with uniform frequency by the child's sexual impulses towards his parents, which are as a rule already differentiated owing to the attraction of the opposite sex - the son being drawn towards his mother and the daughter towards her father.² At the same time as these plainly incestuous phantasies are overcome and repudiated, one of the most significant, but also one of the most painful, psychical achievements of the pubertal period is completed: detachment from parental authority, a process that alone makes possible the opposition, which is so important for the progress of civilization, between the new generation and the old. At every stage in the course of development through which all human beings ought by rights to pass, a certain number are held back; so there are some who have never got over their parents' authority and have withdrawn their affection from them either very incompletely or not at all. They are mostly girls, who, to the delight of their parents, have persisted in all their childish love far beyond puberty. It is most instructive to find that it is precisely these girls who in their later marriage lack the capacity to give their husbands what is due to them; they make cold wives and remain sexually anaesthetic. We learn from this that sexual love and what appears to be non-sexual love for parents are fed from the same sources; the latter, that is to say, merely corresponds to an infantile fixation of the libido.
Let us return to the sexual development of children. We have some arrears to make up owing to our having paid more attention to the somatic than to the mental phenomena of sexual life. The child's first choice of an object, which derives from its need for help, claims our further interest. Its choice is directed in the first instance to all those who look after it, but these soon give place to its parents. Children's relations to their parents, as we learn alike from direct observations of children and from later analytic examination of adults, are by no means free from elements of accompanying sexual excitation. The child takes both of its parents, and more particularly one of them, as the object of its erotic wishes. In so doing, it usually follows some indication from its parents, whose affection bears the clearest characteristics of a sexual activity, even though of one that is inhibited in its aims. As a rule a father prefers his daughter and a mother her son; the child reacts to this by wishing, if he is a son, to take his father's place, and, if she is a daughter, her mother's. The feelings which are aroused in these relations between parents and children and in the resulting ones between brothers and sisters are not only of a positive or affectionate kind but also of a negative or hostile one. The complex which is thus formed is doomed to early repression; but it continues to exercise a great and lasting influence from the unconscious. It is to be suspected that, together with its extensions, it constitutes the nuclear complex of every neurosis, and we may expect to find it no less actively at work in other regions of mental life. The myth of King Oedipus, who killed his father and took his mother to wife, reveals, with little modification, the infantile wish, which is later opposed and repudiated by the barrier against incest. Shakespeare's Hamlet is equally rooted in the soil of the incest-complex, but under a better disguise.

[1910a, 2232]

After the stage of heterosexual object-choice has been reached, the homosexual tendencies are not, as might be supposed, done away with or brought to a stop; they are merely deflected from their sexual aim and applied to fresh uses. They now combine with portions of the ego-instincts and, as 'attached' components, help to constitute the social instincts, thus contributing an erotic factor to friendship and comradeship, to esprit de corps and to the love of mankind in general. How large a contribution is in fact derived from erotic sources (with the sexual aim inhibited) could scarcely be guessed from the normal social relations of mankind. But it is not irrelevant to note that it is precisely manifest homosexuals, and among them again precisely those that set themselves against an indulgence in sensual acts, who are distinguished by taking a particularly active share in the general interests of humanity - interests which have themselves sprung from a sublimation of erotic instincts.

[1911c, 2431]

The aim [Ziel] of an instinct is in every instance satisfaction, which can only be obtained by removing the state of stimulation at the source of the instinct. But although the ultimate aim of each instinct remains unchangeable, there may yet be different paths leading to the same ultimate aim; so that an instinct may be found to have various nearer or intermediate aims, which are combined or interchanged with one another. Experience permits us also to speak of instincts which are 'inhibited in their aim', in the case of processes which are allowed to make some advance towards instincual satisfaction but are then inhibited or deflected. We may suppose that even processes of this kind involve a partial satisfaction.

[1915c, 2960]
The processes of finding an object are fairly complex and no comprehensive account has hitherto been given of them. For our purposes it may be specially pointed out that when, in the years of childhood before puberty, the process has in some respects reached a conclusion, the object that has been found turns out to be almost identical with the first object of the oral pleasure-instinct, which was reached by attachment. Though it is not actually the mother's breast, at least it is the mother. We call the mother the first love-object. For we speak of love when we bring the mental side of the sexual trends into the foreground and want to force back the underlying physical or 'sensual' instinctual demands or to forget them for a moment. At the time at which the child's mother becomes his love-object the psychical work of repression has already begun in him, which is withdrawing from his knowledge awareness of a part of his sexual aims. To his choice of his mother as a love-object everything becomes attached which, under the name of the 'Oedipus complex', has attained so much importance in the psychoanalytic explanation of the neuroses and has played no less a part, perhaps, in the resistance to psycho-analysis.

[1916-1917, 3397]

This is the place for two remarks. First, how do we differentiate between the concepts of narcissism and egoism? Well, narcissism, I believe, is the libidinal complement to egoism. When we speak of egoism, we have in view only the individual's advantage; when we talk of narcissism we are also taking his libidinal satisfaction into account. As practical motives the two can be traced separately for quite a distance. It is possible to be absolutely egoistic and yet maintain powerful object-cathexes, in so far as libidinal satisfaction in relation to the object forms part of the ego's needs. In that case, egoism will see to it that striving for the object involves no damage to the ego. It is possible to be egoistic and at the same time to be excessively narcissistic - that is to say, to have very little need for an object, whether, once more, for the purpose of direct sexual satisfaction, or in connection with the higher aspirations, derived from sexual need, which we are occasionally in the habit of contrasting with 'sensuality' under the name of 'love'. In all these connections egoism is what is self-evident and constant, while narcissism is the variable element. The opposite to egoism, altruism, does not, as a concept, coincide with libidinal object-cathexis, but is distinguished from it by the absence of longings for sexual satisfaction. When someone is completely in love, however, altruism converges with libidinal object-cathexis. As a rule the sexual object attracts a portion of the ego's narcissism to itself, and this becomes noticeable as what is known as the 'sexual overvaluation' of the object. If in addition there is an altruistic transposition of egoism on to the sexual object, the object becomes supremely powerful; it has, as it were, absorbed the ego.

[1916-1917, 3462]

Libido is an expression taken from the theory of the emotions. We call by that name the energy, regarded as a quantitative magnitude (though not at present actually measurable), of those instincts which have to do with all that may be comprised under the word 'love'. The nucleus of what we mean by love naturally consists (and this is what is commonly called love, and what the poets sing of) in sexual love with sexual union as its aim. But we do not separate from this - what in any case has a share in the name 'love' - on the one hand, self-love, and on the other, love for parents and children, friendship and love for humanity in general, and also devotion to concrete objects and to abstract ideas. Our justification lies in the fact that psychoanalytic research has taught us that all these tendencies are an expression of the same instinctual impulses; in relations between the sexes these impulses force their way towards sexual union, but in other circumstances they are diverted from this aim or are prevented from reaching it, though always preserving enough of their original nature to keep their identity recognizable (as in such features as the longing for proximity, and self-sacrifice).

[1921c, 3784]
Psycho-analysis, then, gives these love instincts the name of sexual instincts, *a potiori* and by reason of their origin. The majority of 'educated' people have regarded this nomenclature as an insult, and have taken their revenge by retorting upon psycho-analysis with the reproach of 'pan-sexualism'. Anyone who considers sex as something mortifying and humiliating to human nature is at liberty to make use of the more genteel expressions 'Eros' and 'erotic'. I might have done so myself from the first and thus have spared myself much opposition. But I did not want to, for I like to avoid concessions to faintheartedness. One can never tell where that road may lead one; one gives way first in words, and then little by little in substance too. I cannot see any merit in being ashamed of sex; the Greek word 'Eros', which is to soften the affront, is in the end nothing more than a translation of our German word *Liebe*; and finally, he who knows how to wait need make no concessions.

[1921c, 3785]

Our interest now leads us on to the pressing question as to what may be the nature of these ties which exist in groups. In the psycho-analytic study of neuroses we have hitherto been occupied almost exclusively with ties with objects made by love instincts which still pursue directly sexual aims. In groups there can evidently be no question of sexual aims of that kind. We are concerned here with love instincts which have been diverted from their original aims, though they do not operate with less energy on that account. Now, within the range of the usual sexual object-cathexis, we have already observed phenomena which represent a diversion of the instinct from its sexual aim. We have described them as degrees of being in love, and have recognized that they involve a certain encroachment upon the ego. We shall now turn our attention more closely to these phenomena of being in love, in the firm expectation of finding in them conditions which can be transferred to the ties that exist in groups. But we should also like to know whether this kind of object-cathexis, as we know it in sexual life, represents the only manner of emotional tie with other people, or whether we must take other mechanisms of the sort into account. As a matter of fact we learn from psycho-analysis that there do exist other mechanisms for emotional ties, the so-called *identifications*, insufficiently-known processes and hard to describe, the investigation of which will for some time keep us away from the subject of group psychology.

[1921c, 3796]

To this must be added another factor derived from the very remarkable course of development which is pursued by the erotic life of man. In its first phase, which has usually come to an end by the time a child is five years old, he has found the first object for his love in one or other of his parents, and all of his sexual instincts with their demand for satisfaction have been united upon this object. The repression which then sets in compels him to renounce the greater number of these infantile sexual aims, and leaves behind a profound modification in his relation to his parents. The child still remains tied to his parents, but by instincts which must be described as being 'inhibited in their aim'. The emotions which he feels henceforward towards these objects of his love are characterized as 'affectionate'. It is well known that the earlier 'sensual' tendencies remain more of less strongly preserved in the unconscious, so that in a certain sense the whole of the original current continues to exist.¹

[1921c, 3803]
At puberty, as we know, there set in new and very strong impulsions towards directly sexual aims. In unfavourable cases they remain separate, in the form of a sensual current, from the 'affectionate' trends of feeling which persist. We then have before us a picture whose two aspects are typified with such delight by certain schools of literature. A man will show a sentimental enthusiasm for women whom he deeply respects but who do not excite him to sexual activities, and he will only be potent with other women whom he does not 'love' and thinks little of or even despises.¹ More often, however, the adolescent succeeds in bringing about a certain degree of synthesis between the unsensual, heavenly love and the sensual, earthly love, and his relation to his sexual object is characterized by the interaction of uninhibited instincts and of instincts inhibited in their aim. The depth to which anyone is in love, as contrasted with his purely sensual desire, may be measured by the size of the share taken by the aim-inhibited instincts of affection.

[1921c, 3804]

It is interesting to see that it is precisely those sexual impulsions that are inhibited in their aims which achieve such lasting ties between people. But this can easily be understood from the fact that they are not capable of complete satisfaction, while sexual impulsions which are uninhibited in their aims suffer an extraordinary reduction through the discharge of energy every time the sexual aim is attained. It is the fate of sensual love to become extinguished when it is satisfied; for it to be able to last, it must from the beginning be mixed with purely affectionate components - with such, that is, as are inhibited in their aims - or it must itself undergo a transformation of this kind.

[1921c, 3807]

C. A great deal has been said in this paper about directly sexual instincts and those that are inhibited in their aims, and it may be hoped that this distinction will not meet with too much resistance. But a detailed discussion of the question will not be out of place, even if it only repeats what has to a great extent already been said before.

[1921c, 3828]

The development of the libido in children has made us acquainted with the first but also the best example of sexual instincts which are inhibited in their aims. All the feelings which a child has towards its parents and those who look after it pass by an easy transition into the wishes which give expression to the child's sexual impulsions. The child claims from these objects of its love all the signs of affection which it knows of; it wants to kiss them, touch them, and look at them; it is curious to see their genitals, and to be with them when they perform their intimate excretory functions; it promises to marry its mother or nurse - whatever it may understand by marriage; it proposes to itself to bear its father a child, etc. Direct observation, as well as the subsequent analytic investigation of the residues of childhood, leave no doubt as to the complete fusion of tender and jealous feelings and of sexual intentions, and show us in what a fundamental way the child makes the person it loves into the object of all its still not properly centred sexual trends.¹

[1921c, 3828]
This first configuration of the child’s love, which in typical cases takes the shape of the Oedipus complex, succumbs, as we know, from the beginning of the period of latency onwards to a wave of repression. Such of it as is left over shows itself as a purely affectionate emotional tie, relating to the same people, but no longer to be described as ‘sexual’. Psycho-analysis, which illuminates the depths of mental life, has no difficulty in showing that the sexual ties of the earliest years of childhood also persist, though repressed and unconscious. It gives us courage to assert that wherever we come across an affectionate feeling it is successor to a completely ‘sensual’ object-tie with the person in question or rather with that person’s prototype (or *imago*). It cannot indeed disclose to us without a special investigation whether in a given case this former complete sexual current still exists under repression or whether it has already been exhausted. To speak still more precisely; it is quite certain that this current is still there as a form and possibility, and can always be cathected and put into activity again by means of regression; the only question is (and it cannot always be answered) what degree of cathectic and operative force it still has at the present moment. Equal care must be taken in this connection to avoid two sources of error - the Scylla of underestimating the importance of the repressed unconscious, and the Charybdis of judging the normal entirely by the standards of the pathological.

A psychology which will not or cannot penetrate the depths of what is repressed regards affectionate emotional ties as being invariably the expression of impulsions which have no sexual aim, even though they are derived from impulsions which have such an aim.¹

We are justified in saying that they have been diverted from these sexual aims, even though there is some difficulty in giving a description of such a diversion of aim which will conform to the requirements of metapsychology. Moreover, those instincts which are inhibited in their aims always preserve some few of their original sexual aims; even an affectionate devotee, even a friend or an admirer, desires the physical proximity and the sight of the person who is now loved only in the ‘Pauline’ sense. If we choose, we may recognize in this diversion of aim a beginning of the *sublimation* of the sexual instincts, or on the other hand we may fix the limits of sublimation at some more distant point. Those sexual instincts which are inhibited in their aims have a great functional advantage over those which are uninhibited. Since they are not capable of really complete satisfaction, they are especially adapted to create permanent ties; while those instincts which are directly sexual incur a loss of energy each time they are satisfied, and must wait to be renewed by a fresh accumulation of sexual libido, so that meanwhile the object may have changed. The inhibited instincts are capable of any degree of admixture with the uninhibited; they can be transformed back into them, just as they arose out of them. It is well known how easily erotic wishes develop out of emotional relations of a friendly character, based upon appreciation and admiration (compare Molière’s ‘Kiss me for the love of Greek’), between a master and a pupil, between a performer and a delighted listener, and especially in the case of women. In fact the growth of emotional ties of this kind, with their purposeless beginnings, provides a much frequented pathway to sexual object-choice. Pfister, in his *Frömmigkeit des Grafen von Zinzendorf* (1910), has given an extremely clear and certainly not an isolated example of how easily even an intense religious tie can revert to ardent sexual excitement. On the other hand it is also very usual for directly sexual impulsions, short-lived in themselves, to be transformed into a lasting and purely affectionate tie; and the consolidation of a passionate love marriage rests to a large extent upon this process.

¹ [1921c, 3830]
We shall naturally not be surprised to hear that the sexual impulsions that are inhibited in their aims arise out of the directly sexual ones when internal or external obstacles make the sexual aims unattainable. The repression during the period of latency is an internal obstacle of this kind - or rather one which has become internal. We have assumed that the father of the primal horde owing to his sexual intolerance compelled all his sons to be abstinent, and thus forced them into ties that were inhibited in their aims, while he reserved for himself freedom of sexual enjoyment and in this way remained without ties. All the ties upon which a group depends are of the character of instincts that are inhibited in their aims. But here we have approached the discussion of a new subject, which deals with the relation between directly sexual instincts and the formation of groups.

The psycho-analytic investigation of the psychoneuroses has taught us that their symptoms are to be traced back to directly sexual impulsions which are repressed but still remain active. We can complete this formula by adding - 'or, to aim-inhibited impulsions, whose inhibition has not been entirely successful or has made room for a return to the repressed sexual aim'. It is in accordance with this that a neurosis should make its victim asocial and should remove him from the usual group formations. It may be said that a neurosis has the same disintegrating effect upon a group as being in love. On the other hand it appears that where a powerful impetus has been given to group formation neuroses may diminish and, at all events temporarily, disappear. Justifiable attempts have also been made to turn this antagonism between neuroses and group formation to therapeutic account. Even those who do not regret the disappearance of religious illusions from the civilized world of to-day will admit that so long as they were in force they offered those who were bound by them the most powerful protection against the danger of neurosis. Nor is it hard to discern that all the ties that bind people to mystico-religious or philosophico-religious sects and communities are expressions of crooked cures of all kinds of neuroses. All of this is correlated with the contrast between directly sexual impulsions and those which are inhibited in their aims.

Both states, hypnosis and group formation, are an inherited deposit from the phylogenesis of the human libido - hypnosis in the form of a predisposition, and the group, besides this, as a direct survival. The replacement of the directly sexual impulsions by those that are inhibited in their aims promotes in both states a separation between the ego and the ego ideal, a separation with which a beginning has already been made in the state of being in love.

Neurosis stands outside this series. It also is based upon a peculiarity in the development of the human libido - the twice repeated start made by the directly sexual function, with an intervening period of latency.¹ To this extent it resembles hypnosis and group formation in having the character of a regression, which is absent from being in love. It makes its appearance wherever the advance from directly sexual instincts to those that are inhibited in their aims has not been wholly successful; and it represents a conflict between those portions of the instincts which have been received into the ego after having passed through this development and those portions of them which, springing from the repressed unconscious, strive - as do other, completely repressed, instinctual impulses - to attain direct satisfaction. Neuroses are extraordinarily rich in content, for they embrace all possible relations between the ego and the object - both those in which the object is retained and others in which it is abandoned or erected inside the ego itself - and also the conflicting relations between the ego and its ego ideal.
Aim-inhibited Sexual Impulses. - The social instincts belong to a class of instinctual impulses which need not be described as sublimated, though they are closely related to these. They have not abandoned their directly sexual aims, but they are held back by internal resistances from attaining them; they rest content with certain approximations to satisfaction and for that very reason lead to especially firm and permanent attachments between human beings. To this class belong in particular the affectionate relations between parents and children, which were originally fully sexual, feelings of friendship, and the emotional ties in marriage which had their origin in sexual attraction.

[1923a, 3934]

I have lately developed a view of the instincts¹ which I shall here hold to and take as the basis of my further discussions. According to this view we have to distinguish two classes of instincts, one of which, the sexual instincts or Eros, is by far the more conspicuous and accessible to study. It comprises not merely the uninhibited sexual instinct proper and the instinctual impulses of an aim-inhibited or sublimated nature derived from it, but also the self-preservative instinct, which must be assigned to the ego and which at the beginning of our analytic work we had good reason for contrasting with the sexual object-instincts. The second class of instincts was not so easy to point to; in the end we came to recognize sadism as its representative. On the basis of theoretical considerations, supported by biology, we put forward the hypothesis of a death instinct, the task of which is to lead organic life back into the inanimate state; on the other hand, we supposed that Eros, by bringing about a more and more far-reaching combination of the particles into which living substance is dispersed, aims at complicating life and at the same time, of course, at preserving it. Acting in this way, both the instincts would be conservative in the strictest sense of the word, since both would be endeavouring to re-establish a state of things that was disturbed by the emergence of life. The emergence of life would thus be the cause of the continuance of life and also at the same time of the striving towards death; and life itself would be a conflict and compromise between these two trends. The problem of the origin of life would remain a cosmological one; and the problem of the goal and purpose of life would be answered dualistically.

[1923b, 3974]

I have described elsewhere how this turning away takes place. The object-cathexes are given up and replaced by identifications. The authority of the father or the parents is introjected into the ego, and there it forms the nucleus of the super-ego, which takes over the severity of the father and perpetuates his prohibition against incest, and so secures the ego from the return of the libidinal object-cathexis. The libidinal trends belonging to the Oedipus complex are in part desexualized and sublimated (a thing which probably happens with every transformation into an identification) and in part inhibited in their aim and changed into impulses of affection. The whole process has, on the one hand, preserved the genital organ - has averted the danger of its loss - and, on the other, has paralysed it - has removed its function. This process ushers in the latency period, which now interrupts the child's sexual development.

[1924d, 4088]
The fear of castration being thus excluded in the little girl, a powerful motive also drops out for the setting-up of a super-ego and for the breaking-off of the infantile genital organization. In her, far more than in the boy, these changes seem to be the result of upbringing and of intimidation from outside which threatens her with a loss of love. The girl's Oedipus complex is much simpler than that of the small bearer of the penis; in my experience, it seldom goes beyond the taking of her mother's place and the adopting of a feminine attitude towards her father. Renunciation of the penis is not tolerated by the girl without some attempt at compensation. She slips - along the line of a symbolic equation, one might say - from the penis to a baby. Her Oedipus complex culminates in a desire, which is long retained, to receive a baby from her father as a gift - to bear him a child. One has an impression that the Oedipus complex is then gradually given up because this wish is never fulfilled. The two wishes - to possess a penis and a child - remain strongly cathexed in the unconscious and help to prepare the female creature for her later sexual role. The comparatively lesser strength of the sadistic contribution to her sexual instinct, which we may no doubt connect with the stunted growth of her penis, makes it easier in her case for the direct sexual trends to be transformed into aim-inhibited trends of an affectionate kind. It must be admitted, however, that in general our insight into these developmental processes in girls is unsatisfactory, incomplete and vague.

[1924d, 4090]

In order to make this condensed account of my discoveries upon the sexual life of man more intelligible, I have brought together conclusions which I reached at different dates and incorporated by way of supplement or correction in the successive editions of my *Three Essays on the Theory of Sexuality* (1905d). I hope it will have been easy to gather the nature of my extension (on which so much stress has been laid and which has excited so much opposition) of the concept of sexuality. That extension is of a twofold kind. In the first place sexuality is divorced from its too close connection with the genitals and is regarded as a more comprehensive bodily function, having pleasure as its goal and only secondarily coming to serve the ends of reproduction. In the second place the sexual impulses are regarded as including all of those merely affectionate and friendly impulses to which usage applies the exceedingly ambiguous word 'love'. I do not, however, consider that these extensions are innovations but rather restorations: they signify the removal of inexpedient limitations of the concept into which we had allowed ourselves to be led.

[1925d, 4213]

The second of my alleged extensions of the concept of sexuality finds its justification in the fact revealed by psycho-analytic investigation that all of these affectionate impulses were originally of a completely sexual nature but have become inhibited in their aim or sublimated. The manner in which the sexual instincts can thus be influenced and diverted enables them to be employed for cultural activities of every kind, to which indeed they bring the most important contributions.

[1925d, 4214]
We may go on from here to consider the interesting case in which happiness in life is predominantly sought in the enjoyment of beauty, wherever beauty presents itself to our senses and our judgement - the beauty of human forms and gestures, of natural objects and landscapes and of artistic and even scientific creations. This aesthetic attitude to the goal of life offers little protection against the threat of suffering, but it can compensate for a great deal. The enjoyment of beauty has a peculiar, mildly intoxicating quality of feeling. Beauty has no obvious use; nor is there any clear cultural necessity for it. Yet civilization could not do without it. The science of aesthetics investigates the conditions under which things are felt as beautiful, but it has been unable to give any explanation of the nature and origin of beauty, and, as usually happens, lack of success is concealed beneath a flood of resounding and empty words. Psycho-analysis, unfortunately, has scarcely anything to say about beauty either. All that seems certain is its derivation from the field of sexual feeling. The love of beauty seems a perfect example of an impulse inhibited in its aim. 'Beauty' and 'attraction' are originally attributes of the sexual object. It is worth remarking that the genitals themselves, the sight of which is always exciting, are nevertheless hardly ever judged to be beautiful; the quality of beauty seems, instead, to attach to certain secondary sexual characters.

[1930a, 4481]

A small minority are enabled by their constitution to find happiness, in spite of everything, along the path of love. But far-reaching mental changes in the function of love are necessary before this can happen. These people make themselves independent of their object's acquiescence by displacing what they mainly value from being loved on to loving; they protect themselves against the loss of the object by directing their love, not to single objects but to all men alike; and they avoid the uncertainties and disappointments of genital love by turning away from its sexual aims and transforming the instinct into an impulse with an inhibited aim. What they bring about in themselves in this way is a state of evenly suspended, steadfast, affectionate feeling, which has little external resemblance any more to the stormy agitations of genital love, from which it is nevertheless derived. Perhaps St. Francis of Assisi went furthest in thus exploiting love for the benefit of an inner feeling of happiness. Moreover, what we have recognized as one of the techniques for fulfilling the pleasure principle has often been brought into connection with religion; this connection may lie in the remote regions where the distinction between the ego and objects or between objects themselves is neglected. According to one ethical view, whose deeper motivation will become clear to us presently, this readiness for a universal love of mankind and the world represents the highest standpoint which man can reach. Even at this early stage of the discussion I should like to bring forward my two main objections to this view. A love that does not discriminate seems to me to forfeit a part of its own value, by doing an injustice to its object; and secondly, not all men are worthy of love.

[1930a, 4496]
The love which founded the family continues to operate in civilization both in its original form, in which it does not renounce direct sexual satisfaction, and in its modified form as aim-inhibited affection. In each, it continues to carry on its function of binding together considerable numbers of people, and it does so in a more intensive fashion than can be effected through the interest of work in common. The careless way in which language uses the word 'love' has its genetic justification. People give the name 'love' to the relation between a man and a woman whose genital needs have led them to found a family; but they also give the name 'love' to the positive feelings between parents and children, and between the brothers and sisters of a family, although we are obliged to describe this as 'aim-inhibited love' or 'affection'. Love with an inhibited aim was in fact originally fully sensual love, and it is so still in man's unconscious. Both - fully sensual love and aim-inhibited love - extend outside the family and create new bonds with people who before were strangers. Genital love leads to the formation of new families, and aim-inhibited love to 'friendships' which become valuable from a cultural standpoint because they escape some of the limitations of genital love, as, for instance, its exclusiveness. But in the course of development the relation of love to civilization loses its unambiguity. On the one hand love comes into opposition to the interests of civilization; on the other, civilization threatens love with substantial restrictions.

[1930a, 4497]

So far, we can quite well imagine a cultural community consisting of double individuals like this, who, libidinally satisfied in themselves, are connected with one another through the bonds of common work and common interests. If this were so, civilization would not have to withdraw any energy from sexuality. But this desirable state of things does not, and never did, exist. Reality shows us that civilization is not content with the ties we have so far allowed it. It aims at binding the members of the community together in a libidinal way as well and employs every means to that end. It favours every path by which strong identifications can be established between the members of the community, and it summons up aim-inhibited libido on the largest scale so as to strengthen the communal bond by relations of friendship. In order for these aims to be fulfilled, a restriction upon sexual life is unavoidable. But we are unable to understand what the necessity is which forces civilization along this path and which causes its antagonism to sexuality. There must be some disturbing factor which we have not yet discovered.

[1930a, 4500]

Among these factors are some which are determined by the circumstances of infantile sexuality in general, and so hold good equally for the erotic life of boys. First and foremost we may mention jealousy of other people - of brothers and sisters, rivals, among whom the father too has a place. Childhood love is boundless; it demands exclusive possession, it is not content with less than all. But it has a second characteristic: it has, in point of fact, no aim and is incapable of obtaining complete satisfaction; and principally for that reason it is doomed to end in disappointment and to give place to a hostile attitude. Later on in life the lack of an ultimate satisfaction may favour a different result. This very factor may ensure the uninterrupted continuance of the libidinal cathexis, as happens with love-relations that are inhibited in their aim. But in the stress of the processes of development it regularly happens that the libido abandons its unsatisfying position in order to find a new one.

[1931b, 4595]
An instinct, then, is distinguished from a stimulus by the fact that it arises from sources of stimulation within the body, that it operates as a constant force and that the subject cannot avoid it by flight, as is possible with an external stimulus. We can distinguish an instinct's source, object and aim. Its source is a state of excitation in the body, its aim is the removal of that excitation; on its path from its source to its aim the instinct becomes operative psychically. We picture it as a certain quota of energy which presses in a particular direction. It is from this pressing that it derives its name of 'Trieb'. People speak of 'active' and 'passive' instincts, but it would be more correct to speak of instincts with active and passive aims: for an expenditure of activity is needed to achieve a passive aim as well. The aim can be achieved in the subject's own body; as a rule an external object is brought in, in regard to which the instinct achieves its external aim; its internal aim invariably remains the bodily change which is felt as satisfaction. It has not become clear to us whether the relation of the instinct to its somatic source gives it a specific quality and if so what. The evidence of analytic experience shows that it is an undoubted fact that instinctual impulses from one source attach themselves to those from other sources and share their further vicissitudes and that in general one instinctual satisfaction can be replaced by another. But it must be admitted that we do not understand this very well. The relations of an instinct to its aim and object are also open to alterations; both can be exchanged for other ones, though its relation to its object is nevertheless the more easily loosened. A certain kind of modification of the aim and change of the object, in which our social valuation is taken into account, is described by us as 'sublimation'. Besides this, we have grounds for distinguishing instincts which are 'inhibited in their aim' - instinctual impulses from sources well known to us with an unambiguous aim, but which come to a stop on their way to satisfaction, so that a lasting object-cathexis comes about and a permanent trend. Such, for instance, is the relation of tenderness, which undoubtedly originates from the sources of sexual need and invariably renounces its satisfaction.

[1933a, 4702]

You see how many of the characteristics and vicissitudes of the instincts still escape our comprehension. A further distinction should be mentioned here which is exhibited between the sexual and self-preservative instincts and which would be of the greatest theoretical importance if it applied to the groups as a whole. The sexual instincts are noticeable to us for their plasticity, their capacity for altering their aims, their replaceability, which admits of one instinctual satisfaction being replaced by another, and their readiness for being deferred, of which we have just given a good example in the aim-inhibited instincts. We should be glad to deny these characteristics to the self-preservative instincts, and to say of them that they are inflexible, admit of no delay, are imperative in a very different sense and have a quite other relation to repression and to anxiety. But a little reflection tells us that this exceptional position applies, not to all the ego-instincts, but only to hunger and thirst, and is evidently based on a peculiar character of the sources of those instincts. A good part of the confusing impression made by all this is that we have not given separate consideration to the alterations which the influence of the organized ego makes in the instinctual impulses that belonged originally to the id.

[1933a, 4703]
Our mythological theory of instincts makes it easy for us to find a formula for *indirect* methods of combating war. If willingness to engage in war is an effect of the destructive instinct, the most obvious plan will be to bring Eros, its antagonist, into play against it. Anything that encourages the growth of emotional ties between men must operate against war. These ties may be of two kinds. In the first place they may be relations resembling those towards a loved object, though without having a sexual aim. There is no need for psycho-analysis to be ashamed to speak of love in this connection, for religion itself uses the same words: 'Thou shalt love thy neighbour as thyself.' This, however, is more easily said than done. The second kind of emotional tie is by means of identification. Whatever leads men to share important interests produces this community of feeling, these identifications. And the structure of human society is to a large extent based on them.

[1933b, 4801]
DIPHASIC CHOICE OF OBJECT It may be regarded as typical of the choice of an object that the process is diphasic, that is, that it occurs in two waves. The first of these begins between the ages of two and five, and is brought to a halt or to a retreat by the latency period; it is characterized by the infantile nature of the sexual aims. The second wave sets in with puberty and determines the final outcome of sexual life.

Although the diphasic nature of object-choice comes down in essentials to no more than the operation of the latency period, it is of the highest importance in regard to disturbances of that final outcome. The resultants of infantile object-choice are carried over into the later period. They either persist as such or are revived at the actual time of puberty. But as a consequence of the repression which has developed between the two phases they prove unutilizable. Their sexual aims have become mitigated and they now represent what may be described as the 'affectionate current' of sexual life. Only psycho-analytic investigation can show that behind this affection, admiration and respect there lie concealed the old sexual longings of the infantile component instincts which have now become unserviceable. The object-choice of the pubertal period is obliged to dispense with the objects of childhood and to start afresh as a 'sensual current'. Should these two currents fail to converge, the result is often that one of the ideals of sexual life, the focusing of all desires upon a single object, will be unattainable.

Let us return to the sexual development of children. We have some arrears to make up owing to our having paid more attention to the somatic than to the mental phenomena of sexual life. The child's first choice of an object, which derives from its need for help, claims our further interest. Its choice is directed in the first instance to all those who look after it, but these soon give place to its parents. Children's relations to their parents, as we learn alike from direct observations of children and from later analytic examination of adults, are by no means free from elements of accompanying sexual excitation. The child takes both of its parents, and more particularly one of them, as the object of its erotic wishes. In so doing, it usually follows some indication from its parents, whose affection bears the clearest characteristics of a sexual activity, even though of one that is inhibited in its aims. As a rule a father prefers his daughter and a mother her son; the child reacts to this by wishing, if he is a son, to take his father's place, and, if she is a daughter, her mother's. The feelings which are aroused in these relations between parents and children and in the resulting ones between brothers and sisters are not only of a positive or affectionate kind but also of a negative or hostile one. The complex which is thus formed is doomed to early repression; but it continues to exercise a great and lasting influence from the unconscious. It is to be suspected that, together with its extensions, it constitutes the nuclear complex of every neurosis, and we may expect to find it no less actively at work in other regions of mental life. The myth of King Oedipus, who killed his father and took his mother to wife, reveals, with little modification, the infantile wish, which is later opposed and repudiated by the barrier against incest. Shakespeare's Hamlet is equally rooted in the soil of the incest-complex, but under a better disguise.

[1905d, 1518]
[1910a, 2232]
However, this motive does not go deep enough either; besides, being bound up with civilized conditions, it fails to provide a satisfactory connection with the state of affairs among primitive people. All the more important, therefore, is the next factor, which is based on the evolution of the libido. We have learnt from analytic researches how universal and how powerful the earliest allocations of libido are. In these we are concerned with infantile sexual wishes which are clung to (in women usually a fixation of the libido on the father or a brother who takes his place) - wishes which frequently enough were directed towards other things than intercourse, or included it only as a dimly perceived goal. The husband is almost always so to speak only a substitute, never the right man; it is another man - in typical cases the father - who has first claim to a woman's love, the husband at most takes second place. It depends on how intense this fixation is and on how obstinately it is maintained whether the substitute is rejected as unsatisfying. Frigidity is thus among the genetic determinants of neuroses. The more powerful the psychical element in a woman's sexual life is, the greater will be the capacity for resistance shown by her distribution of libido to the upheaval of the first sexual act, and the less overpowering will be the effect which bodily possession of her can produce. Frigidity may then become established as a neurotic inhibition or provide the foundation for the development of other neuroses and even a moderate diminution of potency in the man will greatly contribute to help this process.

Among these forbidden wishes special emphasis deserves to be further laid on the incestuous ones - that is, on those aiming at sexual intercourse with parents and brothers and sisters. You know what horror is felt, or at least professed, in human society at such intercourse, and what stress is laid on the prohibitions directed against it. Tremendous efforts have been made to explain this horror of incest. Some people have supposed that breeding considerations on the part of Nature have found psychical representation in this prohibition, since inbreeding would impair racial characters. Others have maintained that, as a result of living together from early childhood onwards, sexual desire has been diverted from the people in question. In both these cases, it may be remarked, an avoidance of incest would be secured automatically, and it would not be clear why such severe prohibitions were called for, which would point rather to the presence of a strong desire for it. Psycho-analytic researches have shown unmistakably that the choice of an incestuous love-object is, on the contrary, the first and invariable one, and that it is not until later that resistance to it sets in; it is no doubt impossible to trace back this resistance to individual psychology.

The processes of finding an object are fairly complex and no comprehensive account has hitherto been given of them. For our purposes it may be specially pointed out that when, in the years of childhood before puberty, the process has in some respects reached a conclusion, the object that has been found turns out to be almost identical with the first object of the oral pleasure-instinct, which was reached by attachment. Though it is not actually the mother's breast, at least it is the mother. We call the mother the first love-object. For we speak of love when we bring the mental side of the sexual trends into the foreground and want to force back the underlying physical or 'sensual' instinctual demands or to forget them for a moment. At the time at which the child's mother becomes his love-object the psychical work of repression has already begun in him, which is withdrawing from his knowledge awareness of a part of his sexual aims. To his choice of his mother as a love-object everything becomes attached which, under the name of the 'Oedipus complex', has attained so much importance in the psycho-analytic explanation of the neuroses and has played no less a part, perhaps, in the resistance to psycho-analysis.
This and very much else of a similar nature will be shown to you by the direct observation of children and by the consideration of clearly retained memories from childhood uninfluenced by analysis. From this you will conclude among other things that the position of a child in the family order is a factor of extreme importance in determining the shape of his later life and should deserve consideration in every life-history. But, what is more important, in view of this information which can be so easily obtained, you will not be able to recall without a smile the pronouncements of science in explanation of the prohibition of incest. There is no end to what has been invented on the subject. It has been said that sexual inclination is diverted from members of the same family who are of the opposite sex by the fact of having lived together from childhood; or, again, that a biological purpose of avoiding inbreeding is represented psychically by an innate horror of incest. In all this the fact is entirely overlooked that such an inexorable prohibition of it in law and custom would not be needed if there were any reliable natural barriers against the temptation to incest. The truth is just the opposite. A human being's first choice of an object is regularly an incestuous one, aimed, in the case of the male, at his mother and sister; and it calls for the severest prohibitions to deter this persistent infantile tendency from realization. Among the primitive races still living to-day, among savages, the prohibitions against incest are even very much stricter than among ourselves, and Theodor Reik has only recently shown in a brilliant work that the puberty rites of savages, which represent a re-birth, have the sense of releasing the boy from his incestuous bond with his mother and of reconciling him with his father. [1916-1917, 3400]

To this must be added another factor derived from the very remarkable course of development which is pursued by the erotic life of man. In its first phase, which has usually come to an end by the time a child is five years old, he has found the first object for his love in one or other of his parents, and all of his sexual instincts with their demand for satisfaction have been united upon this object. The repression which then sets in compels him to renounce the greater number of these infantile sexual aims, and leaves behind a profound modification in his relation to his parents. The child still remains tied to his parents, but by instincts which must be described as being 'inhibited in their aim'. The emotions which he feels henceforward towards these objects of his love are characterized as 'affectionate'. It is well known that the earlier 'sensual' tendencies remain more of less strongly preserved in the unconscious, so that in a certain sense the whole of the original current continues to exist.¹

[1921c, 3803]

In that volume (p. 1400) I wrote that 'the choice of an object, such as we have shown to be characteristic of the pubertal phase of development, has already frequently or habitually been effected during the years of childhood: that is to say, the whole of the sexual currents have become directed towards a single person in relation to whom they seek to achieve their aims. This then is the closest approximation possible in childhood to the final form taken by sexual life after puberty. The only difference lies in the fact that in childhood the combination of the component instincts and their subordination under the primacy of the genitals have been effected only very incompletely or not at all. Thus the establishment of that primacy in the service of reproduction is the last phase through which the organization of sexuality passes.' [1923e, 4058]
To-day I should no longer be satisfied with the statement that in the early period of childhood the primacy of the genitals has been effected only very incompletely or not at all. The approximation of the child's sexual life to that of the adult goes much further and is not limited solely to the coming into being of the choice of an object. Even if a proper combination of the component instincts under the primacy of the genitals is not effected, nevertheless, at the height of the course of development of infantile sexuality, interest in the genitals and in their activity acquires a dominating significance which falls little short of that reached in maturity. At the same time, the main characteristic of this 'infantile genital organization' is its difference from the final genital organization of the adult. This consists in the fact that, for both sexes, only one genital, namely the male one, comes into account. What is present, therefore, is not a primacy of the genitals, but a primacy of the phallus.

[1923e, 4059]

In boys the situation of the Oedipus complex is the first stage that can be recognized with certainty. It is easy to understand, because at that stage a child retains the same object which he previously cathexed with his libido - not as yet a genital one - during the preceding period while he was being suckled and nursed. The fact, too, that in this situation he regards his father as a disturbing rival and would like to get rid of him and take his place is a straightforward consequence of the actual state of affairs. I have shown elsewhere¹ how the Oedipus attitude in little boys belongs to the phallic phase, and how its destruction is brought about by the fear of castration - that is, by narcissistic interest in their genitals. The matter is made more difficult to grasp by the complicating circumstance that even in boys the Oedipus complex has a double orientation, active and passive, in accordance with their bisexual constitution; a boy also wants to take his mother's place as the love-object of his father - a fact which we describe as the feminine attitude.

[1925j, 4147]
The process of arriving at an object, which plays such an important part in mental life, takes place alongside of the organization of the libido. After the stage of auto-erotism, the first love-object in the case of both sexes is the mother; and it seems probable that to begin with a child does not distinguish its mother's organ of nutrition from its own body. Later, but still in the first years of infancy, the relation known as the Oedipus complex becomes established: boys concentrate their sexual wishes upon their mother and develop hostile impulses against their father as being a rival, while girls adopt an analogous attitude.¹ All of the different variations and consequences of the Oedipus complex are important; and the innately bisexual constitution of human beings makes itself felt and increases the number of simultaneously active tendencies. Children do not become clear for quite a long time about the differences between the sexes; and during this period of sexual researches they produce typical sexual theories which, being circumscribed by the incompleteness of their authors' own physical development, are a mixture of truth and error and fail to solve the problems of sexual life (the riddle of the Sphinx - that is, the question of where babies come from). We see, then, that a child's first object-choice is an incestuous one. The whole course of development that I have described is run through rapidly. For the most remarkable feature of the sexual life of man is its diphasic onset, its onset in two waves, with an interval between them. It reaches a first climax in the fourth or fifth year of a child's life. But thereafter this early efflorescence of sexuality passes off; the sexual impulses which have shown such liveliness are overcome by repression, and a period of latency follows, which lasts until puberty and during which the reaction-formations of morality, shame, and disgust are built up.² Of all living creatures man alone seems to show this diphasic onset of sexual growth, and it may perhaps be the biological determinant of his predisposition to neuroses. At puberty the impulses and object-relations of a child's early years become re-animated, and amongst them the emotional ties of its Oedipus complex. In the sexual life of puberty there is a struggle between the urges of early years and the inhibitions of the latency period. Before this, and while the child is at the highest point of its infantile sexual development, a genital organization of a sort is established; but only the male genitals play a part in it, and the female ones remain undiscovered. (I have described this as the period of phallic primacy.) At this stage the contrast between the sexes is not stated in terms of 'male' or 'female' but of 'possessing a penis' or 'castrated'. The castration complex which arises in this connection is of the profoundest importance in the formation alike of character and of neuroses.

I am surprised that you are still silent. That can scarcely mean consent. - In asserting that a child's first choice of an object is, to use the technical term, an incestuous one, analysis no doubt once more hurt the most sacred feelings of humanity, and might well be prepared for a corresponding amount of disbelief, contradiction and attack. And these it has received in abundance. Nothing has damaged it more in the good opinion of its contemporaries than its hypothesis of the Oedipus complex as a structure universally bound to human destiny. The Greek myth, incidentally, must have had the same meaning; but the majority of men to-day, learned and unlearned alike, prefer to believe that Nature has laid down an innate abhorrence in us as a guard against the possibility of incest.
The core of a dream of exhibiting lies in the figure of the dreamer himself (not as he was as a child but as he appears at the present time) and his inadequate clothing (which emerges indistinctly, whether owing to superimposed layers of innumerable later memories of being in undress or as a result of the censorship). Added to these are the figures of the people in whose presence the dreamer feels ashamed. I know of no instance in which the actual spectators of the infantile scene of exhibiting have appeared in the dream; a dream is scarcely ever a simple memory. Curiously enough, the people upon whom our sexual interest was directed in childhood are omitted in all the reproductions which occur in dreams, in hysteria and in obsessional neurosis. It is only in paranoia that these spectators reappear and, though they remain invisible, their presence is inferred with fanatical conviction. What takes their place in dreams - 'a lot of strangers' who take no notice of the spectacle that is offered - is nothing more nor less than the wishful contrary of the single familiar individual before whom the dreamer exposed himself. Incidentally, 'a lot of strangers' frequently appear in dreams in many other connections, and they always stand as the wishful contrary of 'secrecy'. It is to be noticed that even in paranoia, where the original state of things is restored, this reversal into a contrary is observed. The subject feels that he is no longer alone, he has no doubt that he is being observed, but the observers are 'a lot of strangers' whose identity is left curiously vague.

If, then, a child's death-wishes against his brothers and sisters are explained by the childish egoism which makes him regard them as his rivals, how are we to explain his death-wishes against his parents, who surround him with love and fulfil his needs and whose preservation that same egoism should lead him to desire?

A solution of this difficulty is afforded by the observation that dreams of the death of parents apply with preponderant frequency to the parent who is of the same sex as the dreamer: that men, that is, dream mostly of their father's death and women of their mother's. I cannot pretend that this is universally so, but the preponderance in the direction I have indicated is so evident that it requires to be explained by a factor of general importance.¹ It is as though - to put it bluntly - a sexual preference were making itself felt at an early age: as though boys regarded their fathers and girls their mothers as their rivals in love, whose elimination could not fail to be to their advantage.

Before this idea is rejected as a monstrous one, it is as well in this case, too, to consider the real relations obtaining - this time between parents and children. We must distinguish between what the cultural standards of filial piety demand of this relation and what everyday observation shows it in fact to be. More than one occasion for hostility lies concealed in the relation between parents and children - a relation which affords the most ample opportunities for wishes to arise which cannot pass the censorship.
This supposition is confirmed with a certainty beyond all doubt in the case of psychoneurotics when they are subjected to analysis. We learn from them that a child's sexual wishes - if in their embryonic stage they deserve to be so described - awaken very early, and that a girl's first affection is for her father and a boy's first childish desires are for his mother. Accordingly, the father becomes a disturbing rival to the boy and the mother to the girl; and I have already shown in the case of brothers and sisters how easily such feelings can lead to a death-wish. The parents too give evidence as a rule of sexual partiality: a natural predilection usually sees to it that a man tends to spoil his little daughters, while his wife take her sons' part; though both of them, where their judgement is not disturbed by the magic of sex, keep a strict eye upon their children's education. The child is very well aware of this partiality and turns against that one of his parents who is opposed to showing it. Being loved by an adult does not merely bring a child the satisfaction of a special need; it also means that he will get what he wants in every other respect as well. Thus he will be following his own sexual instinct and at the same time giving fresh strength to the inclination shown by his parents if his choice between them falls in with theirs.

[1900a, 736]

The signs of these infantile preferences are for the most part overlooked; yet some of them are to be observed even after the first years of childhood. An eight-year-old girl of my acquaintance, if her mother is called away from the table, makes use of the occasion to proclaim herself her successor: 'I'm going to be Mummy now. Do you want some more greens, Karl? Well, help yourself, then!' and so on. A particularly gifted and lively girl of four, in whom this piece of child psychology is especially transparent, declared quite openly: 'Mummy can go away now. Then Daddy must marry me and I'll be his wife.' Such a wish occurring in a child is not in the least inconsistent with her being tenderly attached to her mother. If a little boy is allowed to sleep beside his mother when his father is away from home, but has to go back to the nursery and to someone of whom he is far less fond as soon as his father returns, he may easily begin to form a wish that his father should always be away, so that he himself could keep his place beside his dear, lovely Mummy. One obvious way of attaining this wish would be if his father were dead; for the child has learnt one thing by experience namely that 'dead' people, such as Grandaddy, are always away and never come back.

[1900a, 737]

In my experience, which is already extensive, the chief part in the mental lives of all children who later become psychoneurotics is played by their parents. Being in love with the one parent and hating the other are among the essential constituents of the stock of psychical impulses which is formed at that time and which is of such importance in determining the symptoms of the later neurosis. It is not my belief, however, that psychoneurotics differ sharply in this respect from other human beings who remain normal - that they are able, that is, to create something absolutely new and peculiar to themselves. It is far more probable - and this is confirmed by occasional observations on normal children - that they are only distinguished by exhibiting on a magnified scale feelings of love and hatred to their parents which occur less obviously and less intensely in the minds of most children.

[1900a, 740]
If *Oedipus Rex* moves a modern audience no less than it did the contemporary Greek one, the explanation can only be that its effect does not lie in the contrast between destiny and human will, but is to be looked for in the particular nature of the material on which that contrast is exemplified. There must be something which makes a voice within us ready to recognize the compelling force of destiny in the *Oedipus*, while we can dismiss as merely arbitrary such dispositions as are laid down in *Die Ahnfrau* or other modern tragedies of destiny. And a factor of this kind is in fact involved in the story of King Oedipus. His destiny moves us only because it might have been ours - because the oracle laid the same curse upon us before our birth as upon him. It is the fate of all of us, perhaps, to direct our first sexual impulse towards our mother and our first hatred and our first murderous wish against our father. Our dreams convince us that that is so. King Oedipus, who slew his father Laïus and married his mother Jocasta, merely shows us the fulfilment of our own childhood wishes. But, more fortunate than he, we have meanwhile succeeded, in so far as we have not become psychoneurotics, in detaching our sexual impulses from our mothers and in forgetting our jealousy of our fathers. Here is one in whom these primaeval wishes of our childhood have been fulfilled, and we shrink back from him with the whole force of the repression by which those wishes have since that time been held down within us. While the poet, as he unravels the past, brings to light the guilt of Oedipus, he is at the same time compelling us to recognize our own inner minds, in which those same impulses, though suppressed, are still to be found. The contrast with which the closing Chorus leaves us confronted -

[1900a, 741]

¹ [Footnote added 1914:] None of the findings of psycho-analytic research has provoked such embittered denials, such fierce opposition - or such amusing contortions - on the part of critics as this indication of the childhood impulses towards incest which persist in the unconscious. An attempt has even been made recently to make out, in the face of all experience, that the incest should only be taken as 'symbolic'. - Ferenczi (1912) has proposed an ingenious 'over-interpretation' of the Oedipus myth, based on a passage in one of Schopenhauer's letters. - [Added 1919:] Later studies have shown that the 'Oedipus complex', which was touched upon for the first time in the above paragraphs in the *Interpretation of Dreams*, throws a light of undreamt-of importance on the history of the human race and the evolution of religion and morality - (See my *Totem and Taboo*, 1912-13.)

[1900a, 741]

There is an unmistakable indication in the text of Sophocles' tragedy itself that the legend of Oedipus sprang from some primaeval dream-material which had as its content the distressing disturbance of a child's relation to his parents owing to the first stirrings of sexuality. At a point when Oedipus, though he is not yet enlightened, has begun to feel troubled by his recollection of the oracle, Jocasta consoles him by referring to a dream which many people dream, though, as she thinks, it has no meaning:

[1900a, 742]

It is, I may say, a matter of daily experience that sexual intercourse between adults strikes any children who may observe it as something uncanny and that it arouses anxiety in them. I have explained this anxiety by arguing that what we are dealing with is a sexual excitation with which their understanding is unable to cope and which they also, no doubt, repudiate because their parents are involved in it, and which is therefore transformed into anxiety. At a still earlier period of life sexual excitations directed towards a parent of the opposite sex have not yet met with repression and, as we have seen, are freely expressed. (See p. 735 ff.)

[1900a, 1013]
In attempting to analyse this small mistake I first thought of the phrase 'sich an der Alten
vergreifen',¹ which provided a short cut to the solution. I was under the influence of a dream
which had been told me by a young man the previous evening and the content of which could
only point to sexual intercourse with his own mother.² The strange fact that the legend finds
nothing objectionable in Queen Jocasta's age seemed to me to fit in well with the conclusion
that in being in love with one's own mother one is never concerned with her as she is in the
present but with her youthful mnemonic image carried over from one's childhood. Such
incongruities always appear when a phantasy that fluctuates between two periods is made
conscious and so becomes definitely attached to one of the two periods. While absorbed in
thoughts of this kind I came to my patient, who is over ninety, and I must have been on the way
to grasping the universal human application of the Oedipus myth as correlated with the Fate
which is revealed in the oracles; for at that point I did violence to or committed a blunder on 'the
old woman'. Here again the bungled action was a harmless one; of the two possible errors,
using the morphine solution for the eye or the eye lotion for the injection, I had chosen by far the
more harmless one. This still leaves the question open of whether we may admit the possibility
of an unconscious intention in mistakes that can cause serious harm, in the same way as in the
cases which I have discussed.
[1901b, 1258]

During the girl's earlier years, her only brother (her elder by a year and a half) had been the
model which her ambitions had striven to follow. But in the last few years the relations between
the brother and sister had grown more distant. The young man used to try so far as he could to
keep out of the family disputes; but when he was obliged to take sides he would support his
mother. So that the usual sexual attraction had drawn together the father and daughter on the
one side and the mother and son on the other.
[1905e, 1362]

I have learnt to look upon unconscious love relations like this (which are marked by their
abnormal consequences) - between a father and a daughter, or between a mother and a son -
as a revival of germs of feeling in infancy. I have shown at length elsewhere³ at what an early
age sexual attraction makes itself felt between parents and children, and I have explained that
the legend of Oedipus is probably to be regarded as a poetical rendering of what is typical in
these relations. Distinct traces are probably to be found in most people of an early partiality of
this kind - on the part of a daughter for her father, or on the part of a son for his mother; but it
must be assumed to be more intense from the very first in the case of those children whose
constitution marks them down for a neurosis, who develop prematurely and have a craving for
love. At this point certain other influences, which need not be discussed here, come into play,
and lead to a fixation of this rudimentary feeling of love or to a reinforcement of it; so that it turns
into something (either while the child is still young or not until it has reached the age of puberty)
which must be put on a par with a sexual inclination and which, like the latter, has the forces of
the libido at its command.² The nature of her disposition had always drawn her towards her
father, and his numerous illnesses were bound to have increased her affection for him. In some
of these illnesses he would allow no one but her to discharge the lighter duties of nursing. He
had been so proud of the early growth of her intelligence that he had made her his confidante
while she was still a child. It was really she and not her mother whom Frau K.'s appearance had
driven out of more than one position.
[1905e, 1393]

³ [Footnote added 1920:] As regards the origin of the perversions, I will add a word in anticipation of what
is to come. There is reason to suppose that, just as in the case of fetishism, abortive beginnings of normal
sexual development occur before the perversions become fixated. Analytic investigation has already been
able to show in a few cases that perversions are a residue of development towards the Oedipus complex
and that after the repression of that complex the components of the sexual instinct which are strongest in
the disposition of the individual concerned emerge once more.
[1905d, 1487]
It is in the world of ideas, however, that the choice of an object is accomplished at first; and the sexual life of maturing youth is almost entirely restricted to indulging in phantasies, that is, in ideas that are not destined to be carried into effect.¹ In these phantasies the infantile tendencies invariably emerge once more, but this time with intensified pressure from somatic sources. Among these tendencies the first place is taken with uniform frequency by the child's sexual impulses towards his parents, which are as a rule already differentiated owing to the attraction of the opposite sex - the son being drawn towards his mother and the daughter towards her father.² At the same time as these plainly incestuous phantasies are overcome and repudiated, one of the most significant, but also one of the most painful, psychical achievements of the pubertal period is completed: detachment from parental authority, a process that alone makes possible the opposition, which is so important for the progress of civilization, between the new generation and the old. At every stage in the course of development through which all human beings ought by rights to pass, a certain number are held back; so there are some who have never got over their parents' authority and have withdrawn their affection from them either very incompletely or not at all. They are mostly girls, who, to the delight of their parents, have persisted in all their childish love far beyond puberty. It is most instructive to find that it is precisely these girls who in their later marriage lack the capacity to give their husbands what is due to them; they make cold wives and remain sexually anaesthetic. We learn from this that sexual love and what appears to be non-sexual love for parents are fed from the same sources; the latter, that is to say, merely corresponds to an infantile fixation of the libido.

¹ [1905d, 1539]
² The second great problem which exercises a child's mind - only at a somewhat later age, no doubt - is the question of the origin of babies. This is usually started by the unwelcome arrival of a small brother or sister. It is the oldest and most burning question that confronts immature humanity. Those who understand how to interpret myths and legends can detect it in the riddle which the Theban Sphinx set to Oedipus. The customary answers given to the child in the nursery damage his genuine instinct of research and as a rule deal the first blow, too, at his confidence in his parents. From that time on he usually begins to mistrust grown-up people, and to keep his most intimate interests secret from them. The following little document shows how tormenting this curiosity can become in older children. It is a letter written by a motherless girl of eleven and a half who had been speculating on the problem with her younger sister.

² [1907c, 1916]
For a small child his parents are at first the only authority and the, source of all belief. The child's most intense and most momentous wish during these early years is to be like his parents (that is, the parent of his own sex) and to be big like his father and mother. But as intellectual growth increases, the child cannot help discovering by degrees the category to which his parents belong. He gets to know other parents and compares them with his own, and so acquires the right to doubt the incomparable and unique quality which he had attributed to them. Small events in the child's life which make him feel dissatisfied afford him provocation for beginning to criticize his parents, and for using, in order to support his critical attitude, the knowledge which he has acquired that other parents are in some respects preferable to them. The psychology of the neuroses teaches us that, among other factors, the most intense impulses of sexual rivalry contribute to this result. A feeling of being slighted is obviously what constitutes the subject-matter of such provocations. There are only too many occasions on which a child is slighted, or at least *feels* he has been slighted, on which he feels he is not receiving the whole of his parents' love, and, most of all, of which he feels regrets at having to share it with brothers and sisters. His sense that his own affection is not being fully reciprocated then finds a vent in the idea, often consciously recollected later from early childhood, of being a step-child or an adopted child. People who have not developed neuroses very frequently remember such occasions, on which - usually as a result of something they have read - they interpreted and responded to their parent's hostile behaviour in this fashion. But here the influence of sex is already in evidence, for a boy is far more inclined to feel hostile impulses towards his father than towards his mother and has a far more intense desire to get free from *him* than from *her*. In this respect the imagination of girls is apt to show itself much weaker. These consciously remembered mental impulses of childhood embody the factor which enables us to understand the nature of myths.

[1909c, 1987]

The later stage in the development of the neurotic's estrangement from his parents, begun in this manner, might be described as 'the neurotic's family romance'. It is seldom remembered consciously but can almost always be revealed by psycho-analysis. For a quite peculiarly marked imaginative activity is one of the essential characteristics of neurotics and also of all comparatively highly gifted people. This activity emerges first in children's play, and then, starting roughly from the period before puberty, takes over the topic of family relations. A characteristic example of this peculiar imaginative activity is to be seen in the familiar day-dreaming¹ which persists far beyond puberty. If these day-dreams are carefully examined, they are found to serve as the fulfilment of wishes and as a correction of actual life. They have two principal aims, an erotic and an ambitious one - though an erotic aim is usually concealed behind the latter too. At about the period I have mentioned, then, the child's imagination becomes engaged in the task of getting free from the parents of whom he now has a low opinion and of replacing them by others, who, as a rule, are of higher social standing. He will make use in this connection of any opportune coincidences from his actual experience, such as his becoming acquainted with the Lord of the Manor or some landed proprietor if he lives in the country or with some member of the aristocracy if he lives in town. Chance occurrences of this kind arouse the child's envy, which finds expression in a phantasy in which both his parents are replaced by others of better birth. The technique used in developing phantasies like this (which are, of course, conscious at this period) depends upon the ingenuity and the material which the child has at his disposal. There is also the question of whether the phantasies are worked out with greater or less effort to obtain verisimilitude. This state is reached at a time at which the child is still in ignorance of the sexual determinants of procreation.

[1909c, 1988]
Moreover the motive of revenge and retaliation, which was in the foreground at the earlier state, is also to be found at the later one. It is, as a rule, precisely these neurotic children who were punished by their parents for sexual naughtiness and who now revenge themselves on their parents by means of phantasies of this kind.

If anyone is inclined to turn away in horror from this depravity of the childish heart or feels tempted, indeed, to dispute the possibility of such things, he should observe that these works of fiction, which seem so full of hostility, are none of them really so badly intended, and that they still preserve, under a slight disguise, the child's original affection for his parents. The faithlessness and ingratitude are only apparent. If we examine in detail the commonest of these imaginative romances, the replacement of both parents or of the father alone by grander people, we find that these new and aristocratic parents are equipped with attributes that are derived entirely from real recollections of the actual and humble ones; so that in fact the child is not getting rid of his father but exalting him. Indeed the whole effort at replacing the real father by a superior one is only an expression of the child's longing for the happy, vanished days when his father seemed to him the noblest and strongest of men and his mother the dearest and loveliest of women. He is turning away from the father whom he knows to-day to the father in whom he believed in the earlier years of his childhood; and his phantasy is no more than the expression of a regret that those happy days have gone. Thus in these phantasies the overvaluation that characterizes a child's earliest years comes into its own again. An interesting contribution to this subject is afforded by the study of dreams. We learn from their interpretation that even in later years, if the Emperor and Empress appear in dreams, those exalted personages stand for the dreamer's father and mother. So that the child's overvaluation of his parents survives as well in the dreams of normal adults.

The content of the sexual life of infancy consists in auto-erotic activity on the part of the dominant sexual components, in traces of object-love, and in the formation of that complex which deserves to be called the nuclear complex of the neuroses. It is the complex which comprises the child's earliest impulses, alike tender and hostile, towards its parents and brothers and sisters, after its curiosity has been awakened - usually by the arrival of a new baby brother or sister. The uniformity of the content of the sexual life of children, together with the unvarying character of the modifying tendencies which are later brought to bear upon it, will easily account for the constant sameness which as a rule characterizes the phantasies that are constructed around the period of childhood, irrespective of how greatly or how little real experiences have contributed towards them. It is entirely characteristic of the nuclear complex of infancy that the child's father should be assigned the part of a sexual opponent and of an interferer with auto-erotic sexual activities; and real events are usually to a large extent responsible for bringing this about.
Let us return to the sexual development of children. We have some arrears to make up owing to our having paid more attention to the somatic than to the mental phenomena of sexual life. The child's first choice of an object, which derives from its need for help, claims our further interest. Its choice is directed in the first instance to all those who look after it, but these soon give place to its parents. Children's relations to their parents, as we learn alike from direct observations of children and from later analytic examination of adults, are by no means free from elements of accompanying sexual excitation. The child takes both of its parents, and more particularly one of them, as the object of its erotic wishes. In so doing, it usually follows some indication from its parents, whose affection bears the clearest characteristics of a sexual activity, even though of one that is inhibited in its aims. As a rule a father prefers his daughter and a mother her son; the child reacts to this by wishing, if he is a son, to take his father's place, and, if she is a daughter, her mother's. The feelings which are aroused in these relations between parents and children and in the resulting ones between brothers and sisters are not only of a positive or affectionate kind but also of a negative or hostile one. The complex which is thus formed is doomed to early repression; but it continues to exercise a great and lasting influence from the unconscious. It is to be suspected that, together with its extensions, it constitutes the nuclear complex of every neurosis, and we may expect to find it no less actively at work in other regions of mental life. The myth of King Oedipus, who killed his father and took his mother to wife, reveals, with little modification, the infantile wish, which is later opposed and repudiated by the barrier against incest. Shakespeare's Hamlet is equally rooted in the soil of the incest-complex, but under a better disguise.

[1910a, 2232]

If Leonardo was successful in reproducing on Mona Lisa's face the double meaning which this smile contained, the promise of unbounded tenderness and at the same time sinister menace (to quote Pater's phrase), then here too he had remained true to the content of his earliest memory. For his mother's tenderness was fateful for him; it determined his destiny and the privations that were in store for him. The violence of the caresses, to which his phantasy of the vulture points, was only too natural. In her love for her child the poor forsaken mother had to give vent to all her memories of the caresses she had enjoyed as well as her longing for new ones; and she was forced to do so not only to compensate herself for having no husband, but also to compensate her child for having no father to fondle him. So, like all unsatisfied mothers, she took her little son in place of her husband, and by the too early maturing of his erotism robbed him of a part of his masculinity. A mother's love for the infant she suckles and cares for is something far more profound than her later affection for the growing child. It is in the nature of a completely satisfying love-relation, which not only fulfils every mental wish but also every physical need; and if it represents one of the forms of attainable human happiness, that is in no little measure due to the possibility it offers of satisfying, without reproach, wishful impulses which have long been repressed and which must be called perverse.¹ In the happiest young marriage the father is aware that the baby, especially if he is a baby son, has become his rival, and this is the starting-point of an antagonism towards the favourite which is deeply rooted in the unconscious.

[1910c, 2288]
As an almost invariable corollary to this sexual enlightenment, the boy at the same time gains a knowledge of the existence of certain women who practise sexual intercourse as a means of livelihood, and who are for this reason held in general contempt. The boy himself is necessarily far from feeling this contempt: as soon as he learns that he too can be initiated by these unfortunates into sexual life, which till then he accepted as being reserved exclusively for 'grown-ups', he regards them only with a mixture of longing and horror. When after this he can no longer maintain the doubt which makes his parents an exception to the universal and odious norms of sexual activity, he tells himself with cynical logic that the difference between his mother and a whore is not after all so very great, since basically they do the same thing. The enlightening information he has received has in fact awakened the memory-traces of the impressions and wishes of his early infancy, and these have led to a reactivation in him of certain mental impulses. He begins to desire his mother herself in the sense with which he has recently become acquainted, and to hate his father anew as a rival who stands in the way of this wish; he comes, as we say, under the dominance of the Oedipus complex. He does not forgive his mother for having granted the favour of sexual intercourse not to himself but to his father, and he regards it as an act of unfaithfulness. If these impulses do not quickly pass, there is no outlet for them other than to run their course in phantasies which have as their subject his mother's sexual activities under the most diverse circumstances; and the consequent tension leads particularly readily to his finding relief in masturbation. As a result of the constant combined operation of the two driving forces, desire and thirst for revenge, phantasies of his mother's unfaithfulness are by far the most preferred; the lover with whom she commits her act of infidelity almost always exhibits the features of the boy's own ego, or more accurately, of his own idealized personality, grown up and so raised to a level with his father. What I have elsewhere¹ described as the 'family romance' comprises the manifold ramifications of this imaginative activity and the way in which they are interwoven with various egoistic interests of this period of life.

The affectionate current is the older of the two. It springs from the earliest years of childhood; it is formed on the basis of the interests of the self-preservative instinct and is directed to the members of the family and those who look after the child. From the very beginning it carries along with it contributions from the sexual instincts - components of erotic interest - which can already be seen more or less clearly even in childhood and in any event are uncovered in neurotics by psycho-analysis later on. It corresponds to the child's primary object-choice. We learn in this way that the sexual instincts find their first objects by attaching themselves to the valuations made by the ego-instincts, precisely in the way in which the first sexual satisfactions are experienced in attachment to the bodily functions necessary for the preservation of life. The 'affection' shown by the child's parents and those who look after him, which seldom fails to betray its erotic nature ('the child is an erotic plaything'), does a very great deal to raise the contributions made by erotism to the cathexes of his ego-instincts, and to increase them to an amount which is bound to play a part in his later development, especially when certain other circumstances lend their support.

¹ In the same way, Schreber's 'feminine wishful phantasy' is simply one of the typical forms taken by the infantile nuclear complex.

¹ The sense of guilt in the case of taboos is not in the least diminished if the violation occurs unwittingly. (Cf. the instances above.) An interesting parallel is found in Greek mythology: the guilt of Oedipus was not palliated by the fact that he incurred it without his knowledge and even against his intention.
If we may regard the existence among primitive races of the omnipotence of thoughts as
evidence in favour of narcissism, we are encouraged to attempt a comparison between the
phases in the development of men's view of the universe and the stages of an individual's
libidinal development. The animistic phase would correspond to narcissism both chronologically
and in its content; the religious phase would correspond to the stage of object-choice of which
the characteristic is a child's attachment to his parents; while the scientific phase would have an
exact counterpart in the stage at which an individual has reached maturity, has renounced the
pleasure principle, adjusted himself to reality and turned to the external world for the object of
his desires.¹

[1912-1913, 2733]

In order that these latter consequences may seem plausible, leaving their premises on one
side, we need only suppose that the tumultuous mob of brothers were filled with the same
contradictory feelings which we can see at work in the ambivalent father-complexes of our
children and of our neurotic patients. They hated their father, who presented such a formidable
obstacle to their craving for power and their sexual desires; but they loved and admired him too.
After they had got rid of him, had satisfied their hatred and had put into effect their wish to
identify themselves with him, the affection which had all this time been pushed under was
bound to make itself felt.¹ It did so in the form of remorse. A sense of guilt made its appearance,
which in this instance coincided with the remorse felt by the whole group. The dead father
became stronger than the living one had been - for events took the course we so often see
them follow in human affairs to this day. What had up to then been prevented by his actual
existence was thenceforward prohibited by the sons themselves, in accordance with the
psychological procedure so familiar to us in psycho-analyses under the name of 'deferred
obedience'. They revoked their deed by forbidding the killing of the totem, the substitute for their
father; and they renounced its fruits by resigning their claim to the women who had now been
set free. They thus created out of their filial sense of guilt the two fundamental taboos of
totemism, which for that very reason inevitably corresponded to the two repressed wishes of the
Oedipus complex. Whoever contravened those taboos became guilty of the only two crimes
with which primitive society concerned itself.²

[1912-1913, 2783]

Of all the imagos of a childhood which, as a rule, is no longer remembered, none is more
important for a youth or a man than that of his father. Organic necessity introduces into a man's
relation to his father an emotional ambivalence which we have found most strikingly expressed
in the Greek myth of King Oedipus. A little boy is bound to love and admire his father, who
seems to him the most powerful, the kindest and the wisest creature in the world. God himself is
after all only an exaltation of this picture of a father as he is represented in the mind of early
childhood. But soon the other side of this emotional relationship emerges. One’s father is
recognized as the paramount disturber of one's instinctual life; he becomes a model not only to
imitate but also to get rid of, in order to take his place. Thenceforward affectionate and hostile
impulses towards him persist side by side, often to the end of one's life, without either of them
being able to do away with the other. It is in this existence of contrary feelings side by side that
lies the essential character of what we call emotional ambivalence.

[1914f, 2873]
An examination of the first question held out the promise of bringing us information about the source of mankind's sense of guilt in general. The invariable outcome of analytic work was to show that this obscure sense of guilt derived from the Oedipus complex and was a reaction to the two great criminal intentions of killing the father and having sexual relations with the mother. In comparison with these two, the crimes committed in order to fix the sense of guilt to something came as a relief to the sufferers. We must remember in this connection that parricide and incest with the mother are the two great human crimes, the only ones which, as such, are pursued and abhorred in primitive communities. And we must remember, too, how close other investigations have brought us to the hypothesis that the conscience of mankind, which now appears as an inherited mental force, was acquired in connection with the Oedipus complex.

What I have in mind is rivalry in love, with a clear emphasis on the subject's sex. While he is still a small child, a son will already begin to develop a special affection for his mother, whom he regards as belonging to him; he begins to feel his father as a rival who disputes his sole possession. And in the same way a little girl looks on her mother as a person who interferes with her affectionate relation to her father and who occupies a position which she herself could very well fill. Observation shows us to what early years these attitudes go back. We refer to them as the 'Oedipus complex', because the legend of Oedipus realizes, with only a slight softening, the two extreme wishes that arise from the son's situation - to kill his father and take his mother to wife. I do not wish to assert that the Oedipus complex exhausts the relation of children to their parents: it can easily be far more complicated. The Oedipus complex can, moreover, be developed to a greater or less strength, it can even be reversed; but it is a regular and very important factor in a child's mental life, and there is more danger of our under estimating rather than over-estimating its influence and that of the developments which proceed from it. Incidentally, children often react in their Oedipus attitude to a stimulus coming from their parents, who are frequently led in their preferences by difference of sex, so that the father will choose his daughter and the mother her son as a favourite, or, in case of a cooling-off in the marriage, as a substitute for a love-object that has lost its value.

As you see, I have only described the relation of a boy to his father and mother. Things happen in just the same way with little girls, with the necessary changes: an affectionate attachment to her father, a need to get rid of her mother as superfluous and to take her place, a coquetry which already employs the methods of later womanhood - these offer a charming picture, especially in small girls, which makes us forget the possibly grave consequences lying behind this infantile situation. We must not omit to add that the parents themselves often exercise a determining influence on the awakening of a child's Oedipus attitude by themselves obeying the pull of sexual attraction, and that where there are several children the father will give the plainest evidence of his greater affection for his little daughter and the mother for her son. But the spontaneous nature of the Oedipus complex in children cannot be seriously shaken even by this factor.
This and very much else of a similar nature will be shown to you by the direct observation of children and by the consideration of clearly retained memories from childhood uninfluenced by analysis. From this you will conclude among other things that the position of a child in the family order is a factor of extreme importance in determining the shape of his later life and should deserve consideration in every life-history. But, what is more important, in view of this information which can be so easily obtained, you will not be able to recall without a smile the pronouncements of science in explanation of the prohibition of incest. There is no end to what has been invented on the subject. It has been said that sexual inclination is diverted from members of the same family who are of the opposite sex by the fact of having lived together from childhood; or, again, that a biological purpose of avoiding inbreeding is represented psychically by an innate horror of incest. In all this the fact is entirely overlooked that such an inexorable prohibition of it in law and custom would not be needed if there were any reliable natural barriers against the temptation to incest. The truth is just the opposite. A human being's first choice of an object is regularly an incestuous one, aimed, in the case of the male, at his mother and sister; and it calls for the severest prohibitions to deter this persistent infantile tendency from realization. Among the primitive races still living to-day, among savages, the prohibitions against incest are even very much stricter than among ourselves, and Theodor Reik has only recently shown in a brilliant work that the puberty rites of savages, which represent a re-birth, have the sense of releasing the boy from his incestuous bond with his mother and of reconciling him with his father.

The early efflorescence of infantile sexual life is doomed to extinction because its wishes are incompatible with reality and with the inadequate stage of development which the child has reached. That efflorescence comes to an end in the most distressing circumstances and to the accompaniment of the most painful feelings. Loss of love and failure leave behind them a permanent injury to self-regard in the form of a narcissistic scar, which in my opinion, as well as in Marcinowski's (1918), contributes more than anything to the 'sense of inferiority' which is so common in neurotics. The child's sexual researches, on which limits are imposed by his physical development, lead to no satisfactory conclusion; hence such later complaints as 'I can't accomplish anything; I can't succeed in anything'. The tie of affection, which binds the child as a rule to the parent of the opposite sex, succumbs to disappointment, to a vain expectation of satisfaction or to jealousy over the birth of a new baby - unmistakable proof of the infidelity of the object of the child's affections. His own attempt to make a baby himself, carried out with tragic seriousness, fails shamefully. The lessening amount of affection he receives, the increasing demands of education, hard words and an occasional punishment - these show him at last the full extent to which he has been scorned. These are a few typical and constantly recurring instances of the ways in which the love characteristic of the age of childhood is brought to a conclusion.

To this must be added another factor derived from the very remarkable course of development which is pursued by the erotic life of man. In its first phase, which has usually come to an end by the time a child is five years old, he has found the first object for his love in one or other of his parents, and all of his sexual instincts with their demand for satisfaction have been united upon this object. The repression which then sets in compels him to renounce the greater number of these infantile sexual aims, and leaves behind a profound modification in his relation to his parents. The child still remains tied to his parents, but by instincts which must be described as being 'inhibited in their aim'. The emotions which he feels henceforward towards these objects of his love are characterized as 'affectionate'. It is well known that the earlier 'sensual' tendencies remain more of less strongly preserved in the unconscious, so that in a certain sense the whole of the original current continues to exist.
By its theory of the instincts psycho-analysis offended the feelings of individuals in so far as they regarded themselves as members of the social community; another branch of its theory was calculated to hurt every single person at the tenderest point of his own psychical development. Psycho-analysis disposed once and for all of the fairy tale of an asexual childhood. It demonstrated the fact that sexual interests and activities occur in small children from the beginning of their lives. It showed what transformations those activities pass through, how at about the age of five they succumb to inhibition and how from puberty onwards they enter the service of the reproductive function. It recognized that early infantile sexual life reaches its peak in what is known as the Oedipus complex (an emotional attachment of the child to the parent of the opposite sex accompanied by an attitude of rivalry to the parent of the same sex) and that at that period of life this impulse extends uninhibited into a straightforward sexual desire. This can be confirmed so easily that only the greatest efforts could make it possible to overlook it. Every individual has in fact gone through this phase but has afterwards energetically repressed its purport and succeeded in forgetting it. A horror of incest and an enormous sense of guilt are left over from this prehistoric epoch of the individual's existence. It may be that something quite similar occurred in the prehistoric epoch of the human species as a whole and that the beginnings of morality, religion and social order were intimately connected with the surmounting of that primaeval era. To adults their prehistory seems so inglorious that they refuse to allow themselves to be reminded of it: they were infuriated when psycho-analysis tried to lift the veil of amnesia from their years of childhood. There was only one way out: what psycho-analysis asserted must be false and what posed as a new science must be a tissue of fancies and distortions.

[1925e, 4128]

The chief literary sources of my studies in this field were the well-known works of J. G. Frazer (*Totemism and Exogamy* and *The Golden Bough*), a mine of valuable facts and opinions. But Frazer effected little towards elucidating the problems of totemism; he had several times fundamentally altered his views on the subject, and the other ethnologists and prehistorians seemed in equal uncertainty and disagreement. My starting-point was the striking correspondence between the two taboo-ordinances of totemism (not to kill the totem and not to have sexual relations with any woman of the same totem-clan) and the two elements of the Oedipus complex (getting rid of the father and taking the mother to wife). I was therefore tempted to equate the totem-animal with the father; and in fact primitive peoples themselves do this explicitly, by honouring it as the forefather of the clan. There next came to my help two facts from psycho-analysis, a lucky observation of a child made by Ferenczi, which enabled me to speak of an 'infantile return of totemism', and the analysis of early animal-phobias in children, which so often showed that the animal was a substitute for the father, a substitute on to which the fear of the father derived from the Oedipus complex had been displaced. Not much was lacking to enable me to recognize the killing of the father as the nucleus of totemism and the starting-point in the formation of religion.

[1925d, 4240]
Nothing, however, deserves more notice than the fact that children regularly direct their sexual wishes towards their nearest relatives - in the first place, therefore, towards their father and mother, and afterwards towards their brothers and sisters. The first object of a boy's love is his mother, and of a girl's her father (except in so far as an innate bisexual disposition favours the simultaneous presence of the contrary attitude). The other parent is felt as a disturbing rival and not infrequently viewed with strong hostility. You must understand me aright. What I mean to say is not that the child wants to be treated by its favourite parent merely with the kind of affection which we adults like to regard as the essence of the parent-child relation. No, analysis leaves us in no doubt that the child's wishes extend beyond such affection to all that we understand by sensual satisfaction - so far, that is, as the child's powers of imagination allow. It is easy to see that the child never guesses the actual facts of sexual intercourse; he replaces them by other notions derived from his own experience and feelings. As a rule his wishes culminate in the intention to bear, or in some in definable way, to procreate a baby. Boys, too, in their ignorance, do not exclude themselves from the wish to bear a baby. We give the whole of this mental structure the name of 'Oedipus complex', after the familiar Greek legend. With the end of the early sexual period it should normally be given up, should radically disintegrate and become transformed; and the results of this transformation are destined for important functions in later mental life. But as a rule this is not effected radically enough, in which case puberty brings about a revival of the complex, which may have serious consequences. [1926e, 4355]

The contradiction between this statement and what we have previously said about the genesis of conscience is in point of fact not so very great, and we see a way of further reducing it. In order to make our exposition easier, let us take as our example the aggressive instinct, and let us assume that the renunciation in question is always a renunciation of aggression. (This, of course, is only to be taken as a temporary assumption.) The effect of instinctual renunciation on the conscience then is that every piece of aggression whose satisfaction the subject gives up is taken over by the super-ego and increases the latter's aggressiveness (against the ego). This does not harmonize well with the view that the original aggressiveness of conscience is a continuance of the severity of the external authority and therefore has nothing to do with renunciation. But the discrepancy is removed if we postulate a different derivation for this first instalment of the super-ego's aggressivity. A considerable amount of aggressiveness must be developed in the child against the authority which prevents him from having his first, but none the less his most important, satisfactions, whatever the kind of instinctual deprivation that is demanded of him may be; but he is obliged to renounce the satisfaction of this revengeful aggressiveness. He finds his way out of this economically difficult situation with the help of familiar mechanisms. By means of identification he takes the unattackable authority into himself. The authority now turns into his super-ego and enters into possession of all the aggressiveness which a child would have liked to exercise against it. The child's ego has to content itself with the unhappy role of the authority - the father - who has been thus degraded. Here, as so often, the situation is reversed: 'If I were the father and you were the child, I should treat you badly.' The relationship between the super-ego and the ego is a return, distorted by a wish, of the real relationships between the ego, as yet undivided, and an external object. That is typical, too. But the essential difference is that the original severity of the super-ego does not - or does not so much - represent the severity which one has experienced from it, or which one attributes to it; it represents rather one's own aggressiveness towards it. If this is correct, we may assert truly that in the beginning conscience arises through the suppression of an aggressive impulse, and that it is subsequently reinforced by fresh suppressions of the same kind. [1930a, 4519]
During the phase of the normal Oedipus complex we find the child tenderly attached to the parent of the opposite sex, while its relation to the parent of its own sex is predominantly hostile. In the case of a boy there is no difficulty in explaining this. His first love-object was his mother. She remains so; and, with the strengthening of his erotic desires and his deeper insight into the relations between his father and mother, the former is bound to become his rival. With the small girl it is different. Her first object, too, was her mother. How does she find her way to her father? How, when and why does she detach herself from her mother? We have long understood that the development of female sexuality is complicated by the fact that the girl has the task of giving up what was originally her leading genital zone the clitoris - in favour of a new zone - the vagina. But it now seems to us that there is a second change of the same sort which is no less characteristic and important for the development of the female: the exchange of her original object - her mother - for her father. The way in which the two tasks are connected with each other is not yet clear to us.

Abraham's (1921) description of the manifestations of the castration complex in the female is still unsurpassed; but one would be glad if it had included the factor of the girl's original exclusive attachment to her mother. I am in agreement with the principal points in Jeanne Lampl-de Groot's¹ (1927) important paper. In this the complete identity of the pre-Oedipus phase in boys and girls is recognized, and the girl's sexual (phallic) activity towards her mother is affirmed and substantiated by observations. The turning-away from the mother is traced to the influence of the girl's recognition of castration, which obliges her to give up her sexual object, and often masturbation along with it. The whole development is summed up in the formula that the girl goes through a phase of the 'negative' Oedipus complex before she can enter the positive one. A point on which I find the writer's account inadequate is that it represents the turning-away from the mother as being merely a change of object and does not discuss the fact that it is accompanied by the plainest manifestations of hostility. To this hostility full justice is done in Helene Deutsch's latest paper, on feminine masochism and its relation to frigidity (1930), in which she also recognizes the girl's phallic activity and the intensity of her attachment to her mother. Helene Deutsch states further that the girl's turning towards her father takes place via her passive trends (which have already been awakened in relation to her mother). In her earlier book (1925) the author had not yet set herself free from the endeavour to apply the Oedipus pattern to the pre-Oedipus phase, and she therefore interpreted the little girl's phallic activity as an identification with her father.

¹ Lampl-de Groot, Jeanne
Let us consider first the relation between father and son. The sanctity which we attribute to the rules laid down in the Decalogue has, I think, blunted our powers of perceiving the real facts. We seem scarcely to venture to observe that the majority of mankind disobey the Fifth Commandment. Alike in the lowest and in the highest strata of human society filial piety is wont to give way to other interests. The obscure information which is brought to us by mythology and legend from the primaeval ages of human society gives an unpleasing picture of the father's despotic power and of the ruthlessness with which he made use of it. Kronos devoured his children, just as the wild boar devours the sow's litter; while Zeus emasculated his father² and made himself ruler in his place. The more unrestricted was the rule of the father in the ancient family, the more must the son, as his destined successor, have found himself in the position of an enemy, and the more impatient must he have been to become ruler himself though his father's death. Even in our middle-class families fathers are as a rule inclined to refuse their sons independence and the means necessary to secure it and thus to foster the growth of the germ of hostility which is inherent in their relation. A physician will often be in a position to notice how a son's grief at the loss of his father cannot suppress his satisfaction at having at length won his freedom. In our society to-day fathers are apt to cling desperately to what is left of a now sadly antiquated *protestas patris familias*; and an author who, like Ibsen, brings the immemorial struggle between fathers and sons into prominence in his writings may be certain of producing his effect.

[1900a, 735]

The signs of these infantile preferences are for the most part overlooked; yet some of them are to be observed even after the first years of childhood. An eight-year-old girl of my acquaintance, if her mother is called away from the table, makes use of the occasion to proclaim herself her successor: 'I'm going to be Mummy now. Do you want some more greens, Karl? Well, help yourself, then!' and so on. A particularly gifted and lively girl of four, in whom this piece of child psychology is especially transparent, declared quite openly: 'Mummy can go away now. Then Daddy must marry me and I'll be his wife.' Such a wish occurring in a child is not in the least inconsistent with her being tenderly attached to her mother. If a little boy is allowed to sleep beside his mother when his father is away from home, but has to go back to the nursery and to someone of whom he is far less fond as soon as his father returns, he may easily begin to form a wish that his father should always be away, so that he himself could keep his place beside his dear, lovely Mummy. One obvious way of attaining this wish would be if his father were dead; for the child has learnt one thing by experience namely that 'dead' people, such as Grandaddy, are always away and never come back.

[1900a, 737]

There is an unmistakable indication in the text of Sophocles' tragedy itself that the legend of Oedipus sprang from some primaeval dream-material which had as its content the distressing disturbance of a child's relation to his parents owing to the first stirrings of sexuality. At a point when Oedipus, though he is not yet enlightened, has begun to feel troubled by his recollection of the oracle, Jocasta consoles him by referring to a dream which many people dream, though, as she thinks, it has no meaning:

[1900a, 742]
Another of the great creations of tragic poetry, Shakespeare's Hamlet, has its roots in the same soil as Oedipus Rex. But the changed treatment of the same material reveals the whole difference in the mental life of these two widely separated epochs of civilization: the secular advance of repression in the emotional life of mankind. In the Oedipus the child's wishful phantasy that underlies it is brought into the open and realized as it would be in a dream. In Hamlet it remains repressed; and - just as in the case of a neurosis - we only learn of its existence from its inhibiting consequences. Strangely enough, the overwhelming effect produced by the more modern tragedy has turned out to be compatible with the fact that people have remained completely in the dark as to the hero's character. The play is built up on Hamlet's hesitations over fulfilling the task of revenge that is assigned to him; but its text offers no reasons or motives for these hesitations and an immense variety of attempts at interpreting them have failed to produce a result. According to the view which was originated by Goethe and is still the prevailing one to-day, Hamlet represents the type of man whose power of direct action is paralysed by an excessive development of his intellect. (He is 'sicklied o'er with the pale cast of thought'.) According to another view, the dramatist has tried to portray a pathologically irresolute character which might be classed as neurasthenic. The plot of the drama shows us, however, that Hamlet is far from being represented as a person incapable of taking any action. We see him doing so on two occasions: first in a sudden outburst of temper, when he runs his sword through the eavesdropper behind the arras, and secondly in a premeditated and even crafty fashion, when, with all the callousness of a Renaissance prince, he sends the two courtiers to the death that had been planned for himself. What is it, then, that inhibits him in fulfilling the task set him by his father's ghost? The answer, once again, is that it is the peculiar nature of the task. Hamlet is able to do anything - except take vengeance on the man who did away with his father and took that father's place with his mother, the man who shows him the repressed wishes of his own childhood realized. Thus the loathing which should drive him on to revenge is replaced in him by self-reproaches, by scruples of conscience, which remind him that he himself is literally no better than the sinner whom he is to punish. Here I have translated into conscious terms what was bound to remain unconscious in Hamlet's mind; and if any one is inclined to call him a hysteric, I can only accept the fact as one that is implied by my interpretation. The distaste for sexuality expressed by Hamlet in his conversation with Ophelia fits in very well with this: the same distaste which was destined to take possession of the poet's mind more and more during the years that followed, and which reached its extreme expression in Timon of Athens. For it can of course only be the poet's own mind which confronts us in Hamlet. I observe in a book on Shakespeare by Georg Brandes (1896) a statement that Hamlet was written immediately after the death of Shakespeare's father (in 1601), that is, under the immediate impact of his bereavement and, as we may well assume, while his childhood feelings about his father had been freshly revived. It is known, too, that Shakespeare's own son who died at an early age bore the name of 'Hamnet', which is identical with 'Hamlet'. Just as Hamlet deals with the relation of a son to his parents, so Macbeth (written at approximately the same period) is concerned with the subject of childlessness. But just as all neurotic symptoms, and, for that matter, dreams, are capable of being "over-interpreted" and indeed need to be, if they are to be fully understood, so all genuinely creative writings are the product of more than a single motive and more than a single impulse in the poet's mind, and are open to more than a single interpretation. In what I have written I have only attempted to interpret the deepest layer of impulses in the mind of the creative writer.¹

¹ [1900a, 743]

(a) A boy aged three years and five months, who obviously disliked the idea of his father's returning from the front, woke up one morning in a disturbed and excited state. He kept on repeating: 'Why was Daddy carrying his head on a plate? Last night Daddy was carrying his head on a plate.'

[1900a, 828]
¹ [Footnote added 1911:] I have published elsewhere a typical example of a disguised Oedipus dream of this kind. [Reprinted below.] Another example, with a detailed analysis, has been published by Otto Rank (1911a). - [Added 1914:] For some other disguised Oedipus dreams, in which eye-symbolism is prominent, see Rank (1913). Other papers on eye-dreams and eye-symbolism, by Eder, Ferenczi and Reitler will be found in the same place. The blinding in the legend of Oedipus, as well as elsewhere, stands for castration. - [Added 1911:] Incidentally, the symbolic interpretation of undisguised Oedipus dreams was not unknown to the ancients. Rank (1910, 534) writes: 'Thus Julius Caesar is reported to have had a dream of sexual intercourse with his mother which was explained by the dream-interpreters as a favourable augury for his taking possession of the earth (Mother Earth). The oracle given to the Tarquins is equally well known, which prophesied that the conquest of Rome would fall to that one of them who should first kiss his mother ("osculum matri tulerit"). This was interpreted by Brutus as referring to Mother Earth. ("Terram osculo contigit, scilicet quod ea communis mater omnium mortalium esset" Livy, I, 56.)' - [Added 1914:] Compare in this connection the dream of Hippias reported by Herodotus (VI, 107): 'As for the Persians, they were guided to Marathon by Hippias son of Pisistratus. Hippias in the past night had seen a vision in his sleep wherein he thought that he lay with his own mother; he interpreted this dream to signify that he should return to Athens and recover his power, and so die an old man in his own mother-country.' - [Added 1911:] These myths and interpretations reveal a true psychological insight. I have found that people who know that they are preferred or favoured by the mother give evidence in their lives of a peculiar self-reliance and an unshakeable optimism which often seem like heroic attributes and bring actual success to their possessors.

[1900a, 855]

In attempting to analyse this small mistake I first thought of the phrase 'sich an der Alten vergreifen',¹ which provided a short cut to the solution. I was under the influence of a dream which had been told me by a young man the previous evening and the content of which could only point to sexual intercourse with his own mother.² The strange fact that the legend finds nothing objectionable in Queen Jocasta's age seemed to me to fit in well with the conclusion that in being in love with one's own mother one is never concerned with her as she is in the present but with her youthful mnemic image carried over from one's childhood. Such incongruities always appear when a phantasy that fluctuates between two periods is made conscious and so becomes definitely attached to one of the two periods. While absorbed in thoughts of this kind I came to my patient, who is over ninety, and I must have been on the way to grasping the universal human application of the Oedipus myth as correlated with the Fate which is revealed in the oracles; for at that point I did violence to or committed a blunder on 'the old woman'. Here again the bungled action was a harmless one; of the two possible errors, using the morphine solution for the eye or the eye lotion for the injection, I had chosen by far the more harmless one. This still leaves the question open of whether we may admit the possibility of an unconscious intention in mistakes that can cause serious harm, in the same way as in the cases which I have discussed.

[1901b, 1258]
I have learnt to look upon unconscious love relations like this (which are marked by their abnormal consequences) - between a father and a daughter, or between a mother and a son - as a revival of germs of feeling in infancy. I have shown at length elsewhere¹ at what an early age sexual attraction makes itself felt between parents and children, and I have explained that the legend of Oedipus is probably to be regarded as a poetical rendering of what is typical in these relations. Distinct traces are probably to be found in most people of an early partiality of this kind - on the part of a daughter for her father, or on the part of a son for his mother; but it must be assumed to be more intense from the very first in the case of those children whose constitution marks them down for a neurosis, who develop prematurely and have a craving for love. At this point certain other influences, which need not be discussed here, come into play, and lead to a fixation of this rudimentary feeling of love or to a reinforcement of it; so that it turns into something (either while the child is still young or not until it has reached the age of puberty) which must be put on a par with a sexual inclination and which, like the latter, has the forces of the libido at its command.² The nature of her disposition had always drawn her towards her father, and his numerous illnesses were bound to have increased her affection for him. In some of these illnesses he would allow no one but her to discharge the lighter duties of nursing. He had been so proud of the early growth of her intelligence that he had made her his confidante while she was still a child. It was really she and not her mother whom Frau K.’s appearance had driven out of more than one position. [1905e, 1393]

It is in the world of ideas, however, that the choice of an object is accomplished at first; and the sexual life of maturing youth is almost entirely restricted to indulging in phantasies, that is, in ideas that are not destined to be carried into effect.¹ In these phantasies the infantile tendencies invariably emerge once more, but this time with intensified pressure from somatic sources. Among these tendencies the first place is taken with uniform frequency by the child's sexual impulses towards his parents, which are as a rule already differentiated owing to the attraction of the opposite sex - the son being drawn towards his mother and the daughter towards her father.² At the same time as these plainly incestuous phantasies are overcome and repudiated, one of the most significant, but also one of the most painful, psychical achievements of the pubertal period is completed: detachment from parental authority, a process that alone makes possible the opposition, which is so important for the progress of civilization, between the new generation and the old. At every stage in the course of development through which all human beings ought by rights to pass, a certain number are held back; so there are some who have never got over their parents' authority and have withdrawn their affection from them either very incompletely or not at all. They are mostly girls, who, to the delight of their parents, have persisted in all their childish love far beyond puberty. It is most instructive to find that it is precisely these girls who in their later marriage lack the capacity to give their husbands what is due to them; they make cold wives and remain sexually anaesthetic. We learn from this that sexual love and what appears to be non-sexual love for parents are fed from the same sources; the latter, that is to say, merely corresponds to an infantile fixation of the libido. [1905d, 1539]
For a small child his parents are at first the only authority and the, source of all belief. The child's most intense and most momentous wish during these early years is to be like his parents (that is, the parent of his own sex) and to be big like his father and mother. But as intellectual growth increases, the child cannot help discovering by degrees the category to which his parents belong. He gets to know other parents and compares them with his own, and so acquires the right to doubt the incomparable and unique quality which he had attributed to them. Small events in the child's life which make him feel dissatisfied afford him provocation for beginning to criticize his parents, and for using, in order to support his critical attitude, the knowledge which he has acquired that other parents are in some respects preferable to them. The psychology of the neuroses teaches us that, among other factors, the most intense impulses of sexual rivalry contribute to this result. A feeling of being slighted is obviously what constitutes the subject-matter of such provocations. There are only too many occasions on which a child is slighted, or at least feels he has been slighted, on which he feels he is not receiving the whole of his parents' love, and, most of all, of which he feels regrets at having to share it with brothers and sisters. His sense that his own affection is not being fully reciprocated then finds a vent in the idea, often consciously recollected later from early childhood, of being a step-child or an adopted child. People who have not developed neuroses very frequently remember such occasions, on which - usually as a result of something they have read - they interpreted and responded to their parent's hostile behaviour in this fashion. But here the influence of sex is already in evidence, for a boy is far more inclined to feel hostile impulses towards his father than towards his mother and has a far more intense desire to get free from him than from her. In this respect the imagination of girls is apt to show itself much weaker. These consciously remembered mental impulses of childhood embody the factor which enables us to understand the nature of myths.
[1909c, 1987]

When presently the child comes to know the difference in the parts played by fathers and mothers in their sexual relations, and realizes that 'pater semper incertus est', while the mother is 'certissima',¹ the family romance undergoes a curious curtailment: it contents itself with exalting the child's father, but no longer casts any doubts on his maternal origin, which is regarded as something unalterable. This second (sexual) stage of the family romance is actuated by another motive as well, which is absent in the first (asexual) stage. The child, having learnt about sexual processes, tends to picture to himself erotic situations and relations, the motive force behind this being his desire to bring his mother (who is the subject of the most intense sexual curiosity) into situations of secret infidelity and into secret love-affairs. In this way the child's phantasies, which started by being, as it were, asexual, are brought up to the level of his later knowledge.
[1909c, 1989]

A younger child is very specially inclined to use imaginative stories such as these in order to rob those born before him of their prerogatives - in a way which reminds one of historical intrigues; and he often has no hesitation in attributing to his mother as many fictitious love-affairs as he himself has competitors. An interesting variant of the family romance may then appear, in which the hero and author returns to legitimacy himself while his brothers and sisters are eliminated by being bastardized. So too if there are any other particular interests at work they can direct the course to be taken by the family romance; for its many-sidedness and its great range of applicability enable it to meet every sort of requirement. In this way, for instance, the young phantasy-builder can get rid of his forbidden degree of kinship with one of his sisters if he finds himself sexually attracted by her.
[1909c, 1990]

¹ 'certissima' is a play on words in Latin, where 'certis' means 'sure' and 'issima' is a diminutive suffix, so 'certissima' could mean 'very sure' or 'very certain'.
That afternoon the father and son visited me during my consulting hours. I already knew the funny little fellow, and with all his self-assurance he was yet so amiable that I had always been glad to see him. I do not know whether he remembered me, but he behaved irreproachably and like a perfectly reasonable member of human society. The consultation was a short one. His father opened it by remarking that, in spite of all the pieces of enlightenment we had given Hans, his fear of horses had not yet diminished. We were also forced to confess that the connections between the horses he was afraid of and the affectionate feelings towards his mother which had been revealed were by no means abundant. Certain details which I now learnt - to the effect that he was particularly bothered by what horses wear in front of their eyes and by the black round their mouths - were certainly not to be explained from what we knew. But as I saw the two of them sitting in front of me and at the same time heard Hans's description of his anxiety-horses, a further piece of the solution shot through my mind, and a piece which I could well understand might escape his father. I asked Hans jokingly whether his horses wore eyeglasses, to which he replied that they did not. I then asked him whether his father wore eyeglasses, to which, against all the evidence, he once more said no. Finally I asked him whether by 'the black round the mouth' he meant a moustache; and I then disclosed to him that he was afraid of his father, precisely because he was so fond of his mother. It must be, I told him, that he thought his father was angry with him on that account; but this was not so, his father was fond of him in spite of it, and he might admit everything to him without any fear. Long before he was in the world, I went on, I had known that a little Hans would come who would be so fond of his mother that he would be bound to feel afraid of his father because of it; and I had told his father this. 'But why do you think I'm angry with you?' his father interrupted me at this point; 'have I ever scolded you or hit you?' Hans corrected him: 'Oh yes! You have hit me.' 'That's not true. When was it, anyhow?' 'This morning,' answered the little boy; and his father recollected that Hans had quite unexpectedly butted his head into his stomach, so that he had given him as it were a reflex blow with his hand. It was remarkable that he had not brought this detail into connection with the neurosis; but he now recognized it as an expression of the little boy's hostile disposition towards him, and perhaps also as a manifestation of a need for getting punished for it.¹

¹ Later on the boy repeated his reaction towards his father in a clearer and more complete manner, by first hitting his father on the hand and then affectionately kissing the same hand.

Here the little boy was displaying a really unusual degree of clarity. He was bringing to notice the fact that his love for his father was wrestling with his hostility towards him in his capacity of rival with his mother; and he was reproaching his father with not having yet drawn his attention to this interplay of forces, which was bound to end in anxiety. His father did not entirely understand him as yet, for during this conversation he only succeeded in convincing himself of the little boy's hostility towards him, the existence of which I had asserted during our consultation. The following dialogue, which I nevertheless give without alteration, is really of more importance in connection with the progress of the father's enlightenment than with the little patient.

We know that this portion of Hans's anxiety had two constituents: there was fear of his father and fear for his father. The former was derived from his hostility towards his father, and the latter from the conflict between his affection, which was exaggerated at this point by way of compensation, and his hostility.
Speaking with the air of superiority which is so easily acquired after the event, we may correct Hans's father, and explain that the boy's wish to 'tease' the horse had two constituents; it was compounded of an obscure sadistic desire for his mother and of a clear impulse for revenge against his father. The latter could not be reproduced until the former's turn had come to emerge in connection with the pregnancy complex. In the process of the formation of a phobia from the unconscious thoughts underlying it, condensation takes place; and for that reason the course of the analysis can never follow that of the development of the neurosis.

[1909b, 2069]

'Hans: "I know. I was their Mummy before, now I'm their Daddy."'  
[1909b, 2082]

Things were moving towards a satisfactory conclusion. The little Oedipus had found a happier solution than that prescribed by destiny. Instead of putting his father out of the way, he had granted him the same happiness that he desired himself: he made him a grandfather and married him to his own mother too.

[1909b, 2082]

In his attitude towards his father and mother Hans confirms in the most concrete and uncompromising manner what I have said in my *Interpretation of Dreams* and in my *Three Essays* with regard to the sexual relations of a child to his parents. Hans really was a little Oedipus who wanted to have his father 'out of the way', to get rid of him, so that he might be alone with his beautiful mother and sleep with her. This wish had originated during his summer holidays, when the alternating presence and absence of his father had drawn Hans's attention to the condition upon which depended the intimacy with his mother which he longed for. At that time the form taken by the wish had been merely that his father should 'go away'; and at a later stage it became possible for his fear of being bitten by a white horse to attach itself directly onto this form of the wish, owing to a chance impression which he received at the moment of some one else's departure. But subsequently (probably not until they had moved back to Vienna, where his father's absences were no longer to be reckoned on) the wish had taken the form that his father should be *permanently* away - that he should be 'dead'. The fear which sprang from this death-wish against his father, and which may thus be said to have had a normal motive, formed the chief obstacle to the analysis until it was removed during the conversation in my consulting-room.¹

[1909b, 2096]

There are not many more mysteries ahead of us now. An obscure phantasy of missing a train seems to have been a forerunner of the later notion of handing over Hans's father to his grandmother at Lainz, for the phantasy dealt with a visit to Lainz, and his grandmother appeared in it. Another phantasy, in which a boy gave the guard 50,000 florins to let him ride on the truck, almost sounds like a plan of buying his mother from his father, part of whose power, of course, lay in his wealth. At about this time, too, he confessed, with a degree of openness which he had never before reached, that he wished to get rid of his father, and that the reason he wished it was that his father interfered with his own intimacy with his mother. We must not be surprised to find the same wishes constantly reappearing in the course of an analysis. The monotony only attaches to the analyst's interpretations of these wishes. For Hans they were not mere repetitions, but steps in a progressive development from timid hinting to fully conscious, undistorted perspicuity.

[1909b, 2111]
But there was something else, which could not fail to make him uneasy. His father must have had something to do with little Hanna's birth, for he had declared that Hanna and Hans himself were his children. Yet it was certainly not his father who had brought them into the world, but his mother. This father of his came between him and his mother. When he was there Hans could not sleep with his mother, and when his mother wanted to take Hans into bed with her, his father used to call out. Hans had learnt from experience how well-off he could be in his father's absence, and it was only justifiable that he should wish to get rid of him. And then Hans's hostility had received a fresh reinforcement. His father had told him the lie about the stork and so made it impossible for him to ask for enlightenment upon these things. He not only prevented his being in bed with his mother, but also kept from him the knowledge he was thirsting for. He was putting Hans at a disadvantage in both directions, and was obviously doing so for his own benefit.

But this father, whom he could not help hating as a rival, was the same father whom he had always loved and was bound to go on loving, who had been his model, had been his first playmate, and had looked after him from his earliest infancy: and this it was that gave rise to the first conflict. Nor could this conflict find an immediate solution. For Hans's nature had so developed that for the moment his love could not but keep the upper hand and suppress his hate - though it could not kill it, for his hate was perpetually kept alive by his love for his mother. But his father not only knew where children came from, he actually performed it - the thing that Hans could only obscurely divine. The widdler must have something to do with it, for his own grew excited whenever he thought of these things - and it must be a big widdler too, bigger than Hans's own. If he listened to these premonitory sensations he could only suppose that it was a question of some act of violence performed upon his mother, of smashing something, of making an opening into something, of forcing a way into an enclosed space - such were the impulses that he felt stirring within him. But although the sensations of his penis had put him on the road to postulating a vagina, yet he could not solve the problem, for within his experience no such thing existed as his widdler required. On the contrary, his conviction that his mother possessed a penis just as he did stood in the way of any solution. His attempt at discovering what it was that had to be done with his mother in order that she might have children sank down into his unconscious; and his two active impulses - the hostile one towards his father and the sadistic-tender one towards his mother - could be put to no use, the first because of the love that existed side by side with the hatred, and the second because of the perplexity in which his infantile sexual theories left him.

It deserves to be noticed that the ideational content of Hans's phobia as it then stood had to be submitted to one further process of distortion and substitution before his consciousness took cognizance of it. Hans's first formulation of his anxiety was: 'the horse will bite me'; and this was derived from another episode at Gmunden, which was on the one hand related to his hostile wishes towards his father and on the other hand was reminiscent of the warning he had been given against masturbation. Some interfering influence, emanating from his parents perhaps, had made itself felt. I am not certain whether the reports upon Hans were at that time drawn up with sufficient care to enable us to decide whether he expressed his anxiety in this form before or not until after his mother had taken him to task on the subject of masturbating. I should be inclined to suspect that it was not until afterwards, though this would contradict the account given in the case history. At any rate, it is evident that at every point Hans's hostile complex against his father screened his lustful one about his mother, just as it was the first to be disclosed and dealt with in the analysis.
This allows us, therefore, to make a radical distinction. We shall probably come to understand the case more deeply if we turn to those other components which do fulfil the two conditions that have just been mentioned. These other components were tendencies in Hans which had already been suppressed and which, so far as we can tell, had never been able to find uninhibited expression: hostile and jealous feelings towards his father, and sadistic impulses (premonitions, as it were, of copulation) towards his mother. These early suppressions may perhaps have gone to form the predisposition for his subsequent illness. These aggressive propensities of Hans's found no outlet, and as soon as there came a time of privation and of intensified sexual excitement, they tried to break their way out with reinforced strength. It was then that the battle which we call his 'phobia' burst out. During the course of it a part of the repressed ideas, in a distorted form and transposed on to another complex, forced their way into consciousness as the content of the phobia. But it was a decidedly paltry success. Victory lay with the forces of repression; and they made use of the opportunity to extend their domain over components other than those that had rebelled. This last circumstance, however, does not in the least alter the fact that the essence of Hans's illness was entirely dependent upon the nature of the instinctual components that had to be repulsed. The content of his phobia was such as to impose a very great measure of restriction upon his freedom of movement, and that was its purpose. It was therefore a powerful reaction against the obscure impulses to movement which were especially directed against his mother. For Hans horses had always typified pleasure in movement ('I'm a young horse', he had said as he jumped about); but since this pleasure in movement included the impulse to copulate, the neurosis imposed a restriction on it and exalted the horse into an emblem of terror. Thus it would seem as though all that the repressed instincts got from the neurosis was the honour of providing pretexts for the appearance of the anxiety in consciousness. But however clear may have been the victory in Hans's phobia of the forces that were opposed to sexuality, nevertheless, since such an illness is in its very nature a compromise, this cannot have been all that the repressed instincts obtained. After all, Hans's phobia of horses was an obstacle to his going into the street, and could serve as a means of allowing him to stay at home with his beloved mother. In this way, therefore, his affection for his mother triumphantly achieved its aim. In consequence of his phobia, the lover clung to the object of his love - though, to be sure, steps had been taken to make him innocuous. The true character of a neurotic disorder is exhibited in this twofold result. [1909b, 2117]
He admitted that all of this sounded quite plausible, but he was naturally not in the very least convinced by it. He would venture to ask, he said, how it was that an idea of this kind could have remissions, how it could appear for a moment when he was twelve years old, and again when he was twenty, and then once more two years later, this time for good. He could not believe that his hostility had been extinguished in the intervals, and yet during them there had been no sign of self-reproaches. - To this I replied that whenever any one asked a question like that, he was already prepared with an answer; he needed only to be encouraged to go on talking. - He then proceeded, somewhat disconnectedly as it seemed, to say that he had been his father's best friend, and that his father had been his. Except on a few subjects, upon which fathers and sons usually hold aloof from one another - (What could he mean by that?) -, there had been a greater intimacy between them than there now was between him and his best friend. As regards the lady for whose sake he had sacrificed his father in that idea of his, it was true that he had loved her very much, but he had never felt really sensual wishes towards her, such as he had constantly had in his childhood. Altogether, in his childhood his sensual impulses had been much stronger than during his puberty. - At this I told him I thought he had now produced the answer we were waiting for, and had at the same time discovered the third great characteristic of the unconscious. The source from which his hostility to his father derived its indestructibility was evidently something in the nature of sensual desires, and in that connection he must have felt his father as in some way or other an interference. A conflict of this kind, I added, between sensuality and childish love was entirely typical. The remissions he had spoken of had occurred because the premature explosion of his sensual feelings had had as its immediate consequence a considerable diminution of their violence. It was not until he was once more seized with intense erotic desires that his hostility reappeared again owing to the revival of the old situation. I then got him to agree that I had not led him on to the subject either of childhood or of sex, but that he had raised them both of his own free will. - He then went on to ask why he had not simply come to a decision, at the time he was in love with the lady, that his father's interference with that love could not for a moment weigh against his love of his father. - I replied that it was scarcely possible to destroy a person in absentia. Such a decision would only have been possible if the wish that he took objection to had made its first appearance on that occasion; whereas, as a matter of fact, it was a long-repressed wish, towards which he could not behave otherwise than he had formerly done, and which was consequently immune from destruction. This wish (to get rid of his father as being an interference) must have originated at a time when circumstances had been very different - at a time, perhaps, when he had not loved his father more than the person whom he desired sensually, or when he was incapable of making a clear decision. It must have been in his very early childhood, therefore, before he had reached the age of six, and before the date at which his memory became continuous; and things must have remained in the same state ever since. - With this piece of construction our discussion was broken off for the time being.

[1909d, 2145]

There can be no question that there was something in the sphere of sexuality that stood between the father and son, and that the father had come into some sort of opposition to the son's prematurely developed erotic life. Several years after his father's death, the first time he experienced the pleasurable sensations of copulation, an idea sprang into his mind: ‘This is glorious! One might murder one's father for this!’ This was at once an echo and an elucidation of the obsessional ideas of his childhood. Moreover, his father, shortly before his death, had directly opposed what later became our patient's dominating passion. He had noticed that his son was always in the lady's company, and had advised him to keep away from her, saying that it was imprudent of him and that he would only make a fool of himself.

[1909d, 2158]
It is seldom that we are in the fortunate position of being able, as in the present instance, to establish the facts upon which these tales of the individual's prehistoric past are based, by recourse to the unimpeachable testimony of a grown-up person. Even so, the statement made by our patient's mother leaves the way open to various possibilities. That she did not proclaim the sexual character of the offence for which the child was punished may have been due to the activity of her own censorship; for with all parents it is precisely this sexual element in their children's past that their own censorship is most anxious to eliminate. But it is just as possible that the child was reproved by his nurse or by his mother herself for some commonplace piece of naughtiness of a non-sexual nature, and that his reaction was so violent that he was castigated by his father. In phantasies of this kind nurses and servants are regularly replaced by the superior figure of the mother. A deeper interpretation of the patient's dreams in relation to this episode revealed the clearest traces of the presence in his mind of an imaginative production of a positively epic character. In this his sexual desires for his mother and sister and his sister's premature death were linked up with the young hero's chastisement at his father's hand. It was impossible to unravel this tissue of phantasy thread by thread; the therapeutic success of the treatment was precisely what stood in the way of this. The patient recovered, and his ordinary life began to assert its claims: there were many tasks before him, which he had already neglected far too long, and which were incompatible with a continuation of the treatment. I am not to be blamed, therefore, for this gap in the analysis. The scientific results of psycho-analysis are at present only a by-product of its therapeutic aims, and for that reason it is often just in those cases where treatment fails that most discoveries are made.

The content of the sexual life of infancy consists in auto-erotic activity on the part of the dominant sexual components, in traces of object-love, and in the formation of that complex which deserves to be called the nuclear complex of the neuroses. It is the complex which comprises the child's earliest impulses, alike tender and hostile, towards its parents and brothers and sisters, after its curiosity has been awakened - usually by the arrival of a new baby brother or sister. The uniformity of the content of the sexual life of children, together with the unvarying character of the modifying tendencies which are later brought to bear upon it, will easily account for the constant sameness which as a rule characterizes the phantasies that are constructed around the period of childhood, irrespective of how greatly or how little real experiences have contributed towards them. It is entirely characteristic of the nuclear complex of infancy that the child's father should be assigned the part of a sexual opponent and of an interferer with auto-erotic sexual activities; and real events are usually to a large extent responsible for bringing this about.

If Leonardo was successful in reproducing on Mona Lisa's face the double meaning which this smile contained, the promise of unbounded tenderness and at the same time sinister menace (to quote Pater's phrase), then here too he had remained true to the content of his earliest memory. For his mother's tenderness was fateful for him; it determined his destiny and the privations that were in store for him. The violence of the caresses, to which his phantasy of the vulture points, was only too natural. In her love for her child the poor forsaken mother had to give vent to all her memories of the caresses she had enjoyed as well as her longing for new ones; and she was forced to do so not only to compensate herself for having no husband, but also to compensate her child for having no father to fondle him. So, like all unsatisfied mothers, she took her little son in place of her husband, and by the too early maturing of his erotism robbed him of a part of his masculinity. A mother's love for the infant she suckles and cares for is something far more profound than her later affection for the growing child. It is in the nature of a completely satisfying love-relation, which not only fulfils every mental wish but also every physical need; and if it represents one of the forms of attainable human happiness, that is in no little measure due to the possibility it offers of satisfying, without reproach, wishful impulses which have long been repressed and which must be called perverse.¹ In the happiest young marriage the father is aware that the baby, especially if he is a baby son, has become his rival, and this is the starting-point of an antagonism towards the favourite which is deeply rooted in the unconscious.

[1909d, 2162]

[1910c, 2288]
It cannot be doubted that his father too came to play an important part in Leonardo's psychosexual development, and not only negatively by his absence during the boy's first childhood years, but also directly by his presence in the later part of Leonardo's childhood. No one who as a child desires his mother can escape wanting to put himself in his father's place, can fail to identify himself with him in his imagination, and later to make it his task in life to gain ascendancy over him. When Leonardo was received into his grandfather's house before he had reached the age of five, his young step-mother Albiera must certainly have taken his mother's place where his feelings were concerned, and he must have found himself in what may be called the normal relationship of rivalry with his father. As we know, a decision in favour of homosexuality only takes place round about the years of puberty. When this decision had been arrived at in Leonardo's case, his identification with his father lost all significance for his sexual life, but it nevertheless continued in other spheres of non-erotic activity. We hear that he was fond of magnificence and fine clothes, and kept servants and horses, although, in Vasari's words, 'he possessed almost nothing and did little work'. The responsibility for these tastes is not to be attributed solely to his feeling for beauty: we recognize in them at the same time a compulsion to copy and to outdo his father. His father had been a great gentleman to the poor peasant girl, and the son, therefore, never ceased to feel the spur to play the great gentleman as well, the urge 'to out-herod Herod',³ to show his father what a great gentleman really looks like.

As an almost invariable corollary to this sexual enlightenment, the boy at the same time gains a knowledge of the existence of certain women who practise sexual intercourse as a means of livelihood, and who are for this reason held in general contempt. The boy himself is necessarily far from feeling this contempt: as soon as he learns that he too can be initiated by these unfortunates into sexual life, which till then he accepted as being reserved exclusively for 'grown-ups', he regards them only with a mixture of longing and horror. When after this he can no longer maintain the doubt which makes his parents an exception to the universal and odious norms of sexual activity, he tells himself with cynical logic that the difference between his mother and a whore is not after all so very great, since basically they do the same thing. The enlightening information he has received has in fact awakened the memory-traces of the impressions and wishes of his early infancy, and these have led to a reactivation in him of certain mental impulses. He begins to desire his mother herself in the sense with which he has recently become acquainted, and to hate his father anew as a rival who stands in the way of this wish; he comes, as we say, under the dominance of the Oedipus complex. He does not forgive his mother for having granted the favour of sexual intercourse not to himself but to his father, and he regards it as an act of unfaithfulness. If these impulses do not quickly pass, there is no outlet for them other than to run their course in phantasies which have as their subject his mother's sexual activities under the most diverse circumstances; and the consequent tension leads particularly readily to his finding relief in masturbation. As a result of the constant combined operation of the two driving forces, desire and thirst for revenge, phantasies of his mother's unfaithfulness are by far the most preferred; the lover with whom she commits her act of infidelity almost always exhibits the features of the boy's own ego, or more accurately, of his own idealized personality, grown up and so raised to a level with his father. What I have elsewhere' described as the 'family romance' comprises the manifold ramifications of this imaginative activity and the way in which they are interwoven with various egoistic interests of this period of life.

[1910c, 2291]

[1910h, 2332]
Thus in the case of Schreber we find ourselves once again on the familiar ground of the father-complex.¹ The patient's struggle with Flechsig became revealed to him as a conflict with God, and we must therefore construe it as an infantile conflict with the father whom he loved; the details of that conflict (of which we know nothing) are what determined the content of his delusions. None of the material which in other cases of the sort is brought to light by analysis is absent in the present one: every element is hinted at in one way or another. In infantile experiences such as this the father appears as an interferer with the satisfaction which the child is trying to obtain; this is usually of an auto-erotic character, though at a later date it is often replaced in phantasy by some other satisfaction of a less inglorious kind.² In the final stage of Schreber's delusion a magnificent victory was scored by the infantile sexual urge; for voluptuousness became God-fearing, and God Himself (his father) never tired of demanding it from him. His father's most dreaded threat, castration, actually provided the material for his wishful phantasy (at first resisted but later accepted) of being transformed into a woman. His allusion to an offence covered by the surrogate idea 'soul-murder' could not be more transparent. The chief attendant was discovered to be identical with his neighbour von W., who, according to the voices, had falsely accused him of masturbation (108). The voices said, as though giving grounds for the threat of castration: 'For you are to be represented as being given over to voluptuous excesses.'³ (127-8.) Finally, we come to the enforced thinking (47) to which the patient submitted himself because he supposed that God would believe he had become an idiot and would withdraw from him if he ceased thinking for a moment. This is a reaction (with which we are also familiar in other connections) to the threat or fear of losing one's reason⁴ as a result of indulging in sexual practices and especially in masturbation. Considering the enormous number of delusional ideas of a hypochondriacal nature which the patient developed, no great importance should perhaps be attached to the fact that some of them coincide word for word with the hypochondriacal fears of masturbators.⁵

¹ In the same way, Schreber's 'feminine wishful phantasy' is simply one of the typical forms taken by the infantile nuclear complex.

² I recently published (1909 b) an 'Analysis of a Phobia in a Five-Year-Old Boy', the material of which was supplied to me by the little patient's father. The boy had a phobia of horses, and as a result he refused to go out in the street. He expressed a fear that the horse would come into the room and bite him; and it turned out that this must be the punishment for a wish that the horse might fall down (that is, die). After the boy's fear of his father had been removed by reassurances, it became evident that he was struggling against wishes which had as their subject the idea of his father being absent (going away on a journey, dying). He regarded his father (as he made all too clear) as a competitor for the favours of his mother, towards whom the obscure foreshadowings of his budding sexual wishes were aimed. Thus he was situated in the typical attitude of a male child towards his parents to which we have given the name of the 'Oedipus complex' and which we regard in general as the nuclear complex of the neuroses. The new fact that we have learnt from the analysis of 'little Hans' - a fact with an important bearing upon totemism - is that in such circumstances children displace some of their feelings from their father on to an animal.

³ [1911c, 2427]

⁴ [1909b]

⁵ [1911c, 2427]
Analysis is able to trace the associative paths along which this displacement passes - both the fortuitous paths and those with a significant content. Analysis also enables us to discover the motives for the displacement. The hatred of his father that arises in a boy from rivalry for his mother is not able to achieve uninhibited sway over his mind; it has to contend against his old-established affection and admiration for the very same person. The child finds relief from the conflict arising out of this double-sided, this ambivalent emotional attitude towards his father by displacing his hostile and fearful feelings on to a substitute for his father. The displacement cannot, however, bring the conflict to an end, it cannot effect a clear-cut severance between the affectionate and the hostile feelings. On the contrary, the conflict is resumed in relation to the object on to which the displacement has been made: the ambivalence is extended to it. There could be no doubt that little Hans was not only frightened of horses; he also approached them with admiration and interest. As soon as his anxiety began to diminish, he identified himself with the dreaded creature: he began to jump about like a horse and in his turn bit his father.¹ At another stage in the resolution of his phobia he did not hesitate to identify his parents with some other large animals.²

The son's efforts to put himself in the place of the father-god became ever more obvious. The introduction of agriculture increased the son's importance in the patriarchal family. He ventured upon new demonstrations of his incestuous libido, which found symbolic satisfaction in his cultivation of Mother Earth. Divine figures such as Attis, Adonis and Tammuz emerged, spirits of vegetation and at the same time youthful divinities enjoying the favours of mother goddesses and committing incest with their mother in defiance of their father. But the sense of guilt, which was not allayed by these creations, found expression in myths which granted only short lives to these youthful favourites of the mother-goddesses and decreed their punishment by emasculation or by the wrath of the father in the form of an animal. Adonis was killed by a wild boar, the sacred animal of Aphrodite; Attis, beloved of Cybele, perished by castration.¹ The mourning for these gods and the rejoicings over their resurrection passed over into the ritual of another son-deity who was destined to lasting success.

Of all the imagos of a childhood which, as a rule, is no longer remembered, none is more important for a youth or a man than that of his father. Organic necessity introduces into a man's relation to his father an emotional ambivalence which we have found most strikingly expressed in the Greek myth of King Oedipus. A little boy is bound to love and admire his father, who seems to him the most powerful, the kindest and the wisest creature in the world. God himself is after all only an exaltation of this picture of a father as he is represented in the mind of early childhood. But soon the other side of this emotional relationship emerges. One's father is recognized as the paramount disturber of one's instinctual life; he becomes a model not only to imitate but also to get rid of, in order to take his place. Thenceforward affectionate and hostile impulses towards him persist side by side, often to the end of one's life, without either of them being able to do away with the other. It is in this existence of contrary feelings side by side that lies the essential character of what we call emotional ambivalence.
In the second half of childhood a change sets in in the boy's relation to his father - a change whose importance cannot be exaggerated. From his nursery the boy begins to cast his eyes upon the world outside. And he cannot fail now to make discoveries which undermine his original high opinion of his father and which expedite his detachment from his first ideal. He finds that his father is no longer the mightiest, wisest and richest of beings; he grows dissatisfied with him, he learns to criticize him and to estimate his place in society; and then, as a rule, he makes him pay heavily for the disappointment that has been caused by him. Everything that is hopeful, as well as everything that is unwelcome, in the new generation is determined by this detachment from the father.

[1914f, 2874]

An examination of the first question held out the promise of bringing us information about the source of mankind's sense of guilt in general. The invariable outcome of analytic work was to show that this obscure sense of guilt derived from the Oedipus complex and was a reaction to the two great criminal intentions of killing the father and having sexual relations with the mother. In comparison with these two, the crimes committed in order to fix the sense of guilt to something came as a relief to the sufferers. We must remember in this connection that parricide and incest with the mother are the two great human crimes, the only ones which, as such, are pursued and abhorred in primitive communities. And we must remember, too, how close other investigations have brought us to the hypothesis that the conscience of mankind, which now appears as an inherited mental force, was acquired in connection with the Oedipus complex.

[1916d, 3118]

What I have in mind is rivalry in love, with a clear emphasis on the subject's sex. While he is still a small child, a son will already begin to develop a special affection for his mother, whom he regards as belonging to him; he begins to feel his father as a rival who disputes his sole possession. And in the same way a little girl looks on her mother as a person who interferes with her affectionate relation to her father and who occupies a position which she herself could very well fill. Observation shows us to what early years these attitudes go back. We refer to them as the 'Oedipus complex', because the legend of Oedipus realizes, with only a slight softening, the two extreme wishes that arise from the son's situation - to kill his father and take his mother to wife. I do not wish to assert that the Oedipus complex exhausts the relation of children to their parents: it can easily be far more complicated. The Oedipus complex can, moreover, be developed to a greater or less strength, it can even be reversed; but it is a regular and very important factor in a child's mental life, and there is more danger of our under estimating rather than over-estimating its influence and that of the developments which proceed from it. Incidentally, children often react in their Oedipus attitude to a stimulus coming from their parents, who are frequently led in their preferences by difference of sex, so that the father will choose his daughter and the mother her son as a favourite, or, in case of a cooling-off in the marriage, as a substitute for a love-object that has lost its value.

[1916-1917, 3295]
It is a surprising thing that the tragedy of Sophocles does not call up indignant repudiation in his audience - a reaction similar to that of our simple-minded army doctor but far better justified. For fundamentally it is an amoral work: it absolves men from moral responsibility, exhibits the gods as promoters of crime and shows the impotence of the moral impulses of men which struggle against crime. It might easily be supposed that the material of the legend had in view an indictment of the gods and of fate; and in the hands of Euripides, the critic and enemy of the gods, it would probably have become such an indictment. But with the devout Sophocles there is no question of an application of that kind. The difficulty is overcome by the pious sophistry that to bow to the will of the gods is the highest morality even when it promotes crime. I cannot think that this morality is a strong point of the play, but it has no influence on its effect. It is not to it that the auditor reacts but to the secret sense and content of the legend. He reacts as though by self-analysis he had recognized the Oedipus complex in himself and had unveiled the will of the gods and the oracle as exalted disguises of his own unconscious. It is as though he was obliged to remember the two wishes - to do away with his father and in place of him to take his mother to wife - and to be horrified at them. And he understands the dramatist's voice as though it were saying to him: 'You are struggling in vain against your responsibility and are protesting in vain of what you have done in opposition to these criminal intentions. You are guilty, for you have not been able to destroy them; they still persist in you unconsciously.' And there is psychological truth contained in this. Even if a man has repressed his evil impulses into the unconscious and would like to tell himself afterwards that he is not responsible for them, he is nevertheless bound to be aware of this responsibility as a sense of guilt whose basis is unknown to him.

[1916-1917, 3398]

What, then, can be gathered about the Oedipus complex from the direct observation of children at the time of their making their choice of an object before the latency period? Well, it is easy to see that the little man wants to have his mother all to himself, that he feels the presence of his father as a nuisance, that he is resentful if his father indulges in any signs of affection towards his mother and that he shows satisfaction when his father has gone on a journey or is absent. He will often express his feelings directly in words and promise his mother to marry her. It will be thought that this amounts to little compared to the deeds of Oedipus; but in fact it is enough, it is the same thing at root. Observation is often obscured by the circumstance that on other occasions the same child will simultaneously give evidence of great affection for his father. But contrary - or, as it is better to say, 'ambivalent' - emotional attitudes, which in adults would lead to a conflict, remain compatible with each other for a long time in children, just as later they find a permanent place beside each other in the unconscious. It will also be objected that the little boy's conduct arises from egoistic motives and gives no grounds for postulating an erotic complex: the child's mother attends to all his needs, so that he has an interest in preventing her from looking after anyone else. This also is true; but it will soon become clear that in this situation as in similar ones the egoistic interest is merely affording a point of support to which the erotic trend is attached. The little boy may show the most undisguised sexual curiosity about his mother, he may insist upon sleeping beside her at night, he may force his presence on her while she is dressing or may even make actual attempts at seducing her, as his mother will often notice and report with amusement - all of which puts beyond doubt the erotic nature of his tie with his mother. Nor must it be forgotten that the mother devotes the same attention to a little daughter without producing the same result and that the father often competes with her in looking after the boy and yet fails to gain the same significance as she does. In short, the factor of sexual preference cannot be eliminated from the situation by any criticism. From the standpoint of egoistic interest it would be simply foolish of the little man not to prefer to put up with having two people in his service rather than only one of them.

[1916-1917, 3399]
As you see, I have only described the relation of a boy to his father and mother. Things happen in just the same way with little girls, with the necessary changes: an affectionate attachment to her father, a need to get rid of her mother as superfluous and to take her place, a coquetry which already employs the methods of later womanhood - these offer a charming picture, especially in small girls, which makes us forget the possibly grave consequences lying behind this infantile situation. We must not omit to add that the parents themselves often exercise a determining influence on the awakening of a child's Oedipus attitude by themselves obeying the pull of sexual attraction, and that where there are several children the father will give the plainest evidence of his greater affection for his little daughter and the mother for her son. But the spontaneous nature of the Oedipus complex in children cannot be seriously shaken even by this factor.
[1916-1917, 3400]

When other children appear on the scene the Oedipus complex is enlarged into a family complex. This, with fresh support from the egoistic sense of injury, gives grounds for receiving the new brothers or sisters with repugnance and for unhesitatingly getting rid of them by a wish. It is even true that as a rule children are far readier to give verbal expression to these feelings of hate than to those arising from the parental complex. If a wish of this kind is fulfilled and the undesired addition to the family is removed again shortly afterwards by death, we can discover from a later analysis what an important experience this death has been to the child, even though it need not have remained fixed in his memory. A child who has been put into second place by the birth of a brother or sister, and who is now for the first time almost isolated from his mother, does not easily forgive her this loss of place; feelings which in an adult would be described as greatly embittered arise in him and are often the basis of a permanent estrangement. We have already mentioned that the child's sexual researches, with all their consequences, usually follow from this vital experience of his. As these brothers and sisters grow up, the boy's attitude to them undergoes very significant transformations. He may take his sister as a love-object by way of substitute for his faithless mother. Where there are several brothers, all of them courting a younger sister, situations of hostile rivalry, which are so important for later life, arise already in the nursery. A little girl may find in her elder brother a substitute for her father who no longer takes an affectionate interest in her as he did in her earliest years. Or she may take a younger sister as a substitute for the baby she has vainly wished for from her father.
[1916-1917, 3400]
This and very much else of a similar nature will be shown to you by the direct observation of children and by the consideration of clearly retained memories from childhood uninfluenced by analysis. From this you will conclude among other things that the position of a child in the family order is a factor of extreme importance in determining the shape of his later life and should deserve consideration in every life-history. But, what is more important, in view of this information which can be so easily obtained, you will not be able to recall without a smile the pronouncements of science in explanation of the prohibition of incest. There is no end to what has been invented on the subject. It has been said that sexual inclination is diverted from members of the same family who are of the opposite sex by the fact of having lived together from childhood; or, again, that a biological purpose of avoiding inbreeding is represented psychically by an innate horror of incest. In all this the fact is entirely overlooked that such an inexorable prohibition of it in law and custom would not be needed if there were any reliable natural barriers against the temptation to incest. The truth is just the opposite. A human being's first choice of an object is regularly an incestuous one, aimed, in the case of the male, at his mother and sister; and it calls for the severest prohibitions to deter this persistent infantile tendency from realization. Among the primitive races still living to-day, among savages, the prohibitions against incest are even very much stricter than among ourselves, and Theodor Reik has only recently shown in a brilliant work that the puberty rites of savages, which represent a re-birth, have the sense of releasing the boy from his incestuous bond with his mother and of reconciling him with his father.

[1916-1917, 3400]

But let us now turn from the direct observation of children to the analytic examination of adults who have become neurotic. What help does analysis give towards a further knowledge of the Oedipus complex? That can be answered in a word. Analysis confirms all that the legend describes. It shows that each of these neurotics has himself been an Oedipus or, what comes to the same thing, has, as a reaction to the complex, become a Hamlet. The analytic account of the Oedipus complex is, of course, a magnification and coarsening of the infantile sketch. The hatred of the father, the death-wishes against him, are no longer hinted at timidly, the affection for the mother admits that its aim is to possess her as a woman. Should we really attribute such blatant and extreme emotional impulses to the tender years of childhood, or is analysis deceiving us by an admixture of some new factor? It is not hard to find one. Whenever someone gives an account of a past event, even if he is a historian, we must take into account what he unintentionally puts back into the past from the present or from some intermediate time, thus falsifying his picture of it. In the case of a neurotic it is even a question whether this putting back is an entirely unintentional one; later on we shall have to discover reasons for this and have to do justice in general to the fact of 'retrospective phantasying'. We can easily see, too, that hatred of the father is reinforced by a number of factors arising from later times and circumstances and that the sexual desires towards the mother are cast into forms which must have been alien as yet to a child. But it would be a vain effort to seek to explain the whole Oedipus complex by retrospective phantasying and to attach it to later times. Its infantile core and more or less of its accessories remain as they were confirmed by the direct observation of children.

[1916-1917, 3401]
The boy's masochistic trends lead on to another point, which I have so far avoided mentioning, because it can only be confirmed by means of the analysis of the subsequent phase of his development. I have already mentioned that after his refusal by his Nanya his libidinal expectation detached itself from her and began to contemplate another person as a sexual object. This person was his father, at that time away from home. He was no doubt led to this choice by a number of convergent factors, including such fortuitous ones as the recollection of the snake being cut to pieces; but above all he was in this way able to renew his first and most primitive object-choice, which, in conformity with a small child's narcissism, had taken place along the path of identification. We have heard already that his father had been his admired model, and that when he was asked what he wanted to be he used to reply: a gentleman like his father. This object of identification of his active current became the sexual object of a passive current in his present anal-sadistic phase. It looks as though his seduction by his sister had forced him into a passive role, and had given him a passive sexual aim. Under the persisting influence of this experience he pursued a path from his sister via his Nanya to his father - from a passive attitude towards women to the same attitude towards men - and had, nevertheless, by this means found a link with his earlier and spontaneous phase of development. His father was now his object once more; in conformity with his higher stage of development, identification was replaced by object-choice; while the transformation of his active attitude into a passive one was the consequence and the record of the seduction which had occurred meanwhile. It would naturally not have been so easy to achieve an active attitude in the sadistic phase towards his all-powerful father. When his father came home in the late summer or autumn the patient's fits of rage and scenes of fury were put to a new use. They had served for active sadistic ends in relation to his Nanya; in relation to his father their purpose was masochistic. By bringing his naughtiness forward he was trying to force punishments and beatings out of his father, and in that way to obtain from him the masochistic sexual satisfaction that he desired. His screaming fits were therefore simply attempts at seduction. In accordance, moreover, with the motives which underlie masochism, this beating would also have satisfied his sense of guilt. He had preserved a memory of how, during one of these scenes of naughtiness, he had redoubled his screams as soon as his father came towards him. His father did not beat him, however, but tried to pacify him by playing ball in front of him with the pillows of his cot.

[1918b, 3518]

It is clear that the child's sexual life has reached the stage of genital organization, now that its incestuous love has achieved this premature choice of an object. This can be demonstrated more easily in the case of boys, but is also indisputable in the case of girls. Something like a premonition of what are later to be the final and normal sexual aims governs the child's libidinal trends. We may justly wonder why this should be so, but we may regard it as a proof of the fact that the genitals have already begun playing their part in the process of excitation. With boys the wish to beget a child from their mother is never absent, with girls the wish to have a child by their father is equally constant; and this in spite of their being completely incapable of forming any clear idea of the means for fulfilling these wishes. The child seems to be convinced that the genitals have something to do with the matter, even though in its constant brooding it may look for the essence of the presumed intimacy between its parents in relations of another sort, such as in their sleeping together, micturating in each other's presence, etc.; and material of the latter kind can be more easily apprehended in verbal images than the mystery that is connected with the genitals.

[1919e, 3650]
Before we are led by this difficulty to a suspicion that the whole conception of the masculine protest is inadequate to meet the problem of neuroses and perversions, and that its application to them is unfruitful, we will for a moment leave the passive beating-phantasies and turn our attention to other instinctual manifestations of infantile sexual life - manifestations which have equally undergone repression. No one can doubt that there are also wishes and phantasies which keep to the masculine line from their very nature, and which are the expression of masculine instinctual impulses - sadistic tendencies, for instance, or a boy's lustful feelings towards his mother arising out of the normal Oedipus complex. It is no less certain that these impulses, too, are overtaken by repression. If the masculine protest is to be taken as having satisfactorily explained the repression of passive phantasies (which later become masochistic), then it becomes for that very reason totally inapplicable to the opposite case of active phantasies. That is to say, the doctrine of the masculine protest is altogether incompatible with the fact of repression. Unless we are prepared to throw away all that has been acquired in psychology since Breuer's first cathartic treatment and through its agency, we cannot expect that the principle of the masculine protest will acquire any significance in the elucidation of the neuroses and perversions.

[1919e, 3661]

No certain decision can be reached from the analysis of a single case like this. On an unprejudiced view one gets an impression that the child turned his experience into a game from another motive. At the outset he was in a passive situation - he was overpowered by the experience; but, by repeating it, unpleasurable though it was, as a game, he took on an active part. These efforts might be put down to an instinct for mastery that was acting independently of whether the memory was in itself pleasurable or not. But still another interpretation may be attempted. Throwing away the object so that it was 'gone' might satisfy an impulse of the child's, which was suppressed in his actual life, to revenge himself on his mother for going away from him. In that case it would have a defiant meaning: 'All right, then, go away! I don't need you. I'm sending you away myself.' A year later, the same boy whom I had observed at his first game used to take a toy, if he was angry with it, and throw it on the floor, exclaiming: 'Go to the fwort!' He had heard at that time that his absent father was 'at the front', and was far from regretting his absence; on the contrary he made it quite clear that he had no desire to be disturbed in his sole possession of his mother.¹ We know of other children who liked to express similar hostile impulses by throwing away objects instead of persons.² We are therefore left in doubt as to whether the impulse to work over in the mind some overpowering experience so as to make oneself master of it can find expression as a primary event, and independently of the pleasure principle. For, in the case we have been discussing, the child may, after all, only have been able to repeat his unpleasant experience in play because the repetition carried along with it a yield of pleasure of another sort but none the less a direct one.

[1920g, 3721]
At the same time as this identification with his father, or a little later, the boy has begun to develop a true object-cathexis towards his mother according to the attachment type. He then exhibits, therefore, two psychologically distinct ties: a straightforward sexual object-cathexis towards his mother and an identification with his father which takes him as his model. The two subsist side by side for a time without any mutual influence or interference. In consequence of the irresistible advance towards a unification of mental life, they come together at last; and the normal Oedipus complex originates from their confluence. The little boy notices that his father stands in his way with his mother. His identification with his father then takes on a hostile colouring and becomes identical with the wish to replace his father in regard to his mother as well. Identification, in fact, is ambivalent from the very first; it can turn into an expression of tenderness as easily as into a wish for someone's removal. It behaves like a derivative of the first, oral phase of the organization of the libido, in which the object that we long for and prize is assimilated by eating and is in that way annihilated as such. The cannibal, as we know, has remained at this standpoint; he has a devouring affection for his enemies and only devours people of whom he is fond.

[1921c, 3797]

In the very earliest years of childhood (approximately between the ages of two and five) a convergence of the sexual impulses occurs of which, in the case of boys, the object is the mother. This choice of an object, in conjunction with a corresponding attitude of rivalry and hostility towards the father, provides the content of what is known as the Oedipus complex, which in every human being is of the greatest importance in determining the final shape of his erotic life. It has been found to be characteristic of a normal individual that he learns to master his Oedipus complex, whereas the neurotic subject remains involved in it.

[1923a, 3922]

In its simplified form the case of a male child may be described as follows. At a very early age the little boy develops an object-cathexis for his mother, which originally related to the mother's breast and is the prototype of an object-choice on the anaclitic model; the boy deals with his father by identifying himself with him. For a time these two relationships proceed side by side, until the boy's sexual wishes in regard to his mother become more intense and his father is perceived as an obstacle to them; from this the Oedipus complex originates.² His identification with his father then takes on a hostile colouring and changes into a wish to get rid of his father in order to take his place with his mother. Henceforward his relation to his father is ambivalent; it seems as if the ambivalence inherent in the identification from the beginning had become manifest. An ambivalent attitude to his father and an object-relation of a solely affectionate kind to his mother make up the content of the simple positive Oedipus complex in a boy.

[1923b, 3965]
It would appear, therefore, that in both sexes the relative strength of the masculine and feminine sexual dispositions is what determines whether the outcome of the Oedipus situation shall be an identification with the father or with the mother. This is one of the ways in which bisexuality takes a hand in the subsequent vicissitudes of the Oedipus complex. The other way is even more important. For one gets an impression that the simple Oedipus complex is by no means its commonest form, but rather represents a simplification or schematization which, to be sure, is often enough justified for practical purposes. Closer study usually discloses the more complete Oedipus complex, which is twofold, positive and negative, and is due to the bisexuality originally present in children: that is to say, a boy has not merely an ambivalent attitude towards his father and an affectionate object-choice towards his mother, but at the same time he also behaves like a girl and displays an affectionate feminine attitude to his father and a corresponding jealousy and hostility towards his mother. It is this complicating element introduced by bisexuality that makes it so difficult to obtain a clear view of the facts in connection with the earliest object-choices and identifications, and still more difficult to describe them intelligibly. It may even be that the ambivalence displayed in the relations to the parents should be attributed entirely to bisexuality and that it is not, as I have represented above, developed out of identification in consequence of rivalry.

The super-ego is, however, not simply a residue of the earliest object-choices of the id; it also represents an energetic reaction-formation against those choices. Its relation to the ego is not exhausted by the precept: 'You ought to be like this (like your father).'</span> It also comprises the prohibition: 'You may not be like this (like your father) - that is, you may not do all that he does; some things are his prerogative.' This double aspect of the ego ideal derives from the fact that the ego ideal had the task of repressing the Oedipus complex; indeed, it is to that revolutionary event that it owes its existence. Clearly the repression of the Oedipus complex was no easy task. The child's parents, and especially his father, were perceived as the obstacle to a realization of his Oedipus wishes; so his infantile ego fortified itself for the carrying out of the repression by erecting this same obstacle within itself. It borrowed strength to do this, so to speak, from the father, and this loan was an extraordinarily momentous act. The super-ego retains the character of the father, while the more powerful the Oedipus complex was and the more rapidly it succumbed to repression (under the influence of authority, religious teaching, schooling and reading), the stricter will be the domination of the super-ego over the ego later on - in the form of conscience or perhaps of an unconscious sense of guilt. I shall presently bring forward a suggestion about the source of its power to dominate in this way - the source, that is, of its compulsive character which manifests itself in the form of a categorical imperative.

But why should his father, after being reduced to the status of a Devil, bear this physical mark of a woman? The feature seems at first hard to interpret; but soon we find two explanations which compete with each other without being mutually exclusive. A boy's feminine attitude to his father undergoes repression as soon as he understands that his rivalry with a woman for his father's love has as a precondition the loss of his own male genitals - in other words, castration. Repudiation of the feminine attitude is thus the result of a revolt against castration. It regularly finds its strongest expression in the converse phantasy of castrating the father, of turning him into a woman. Thus the Devil's breasts would correspond to a projection of the subject's own femininity on to the father-substitute. The second explanation of these female additions to the Devil's body no longer has a hostile meaning but an affectionate one. It sees in the adoption of this shape an indication that the child's tender feelings towards his mother have been displaced on to his father; and this suggests that there has previously been a strong fixation on the mother, which, in its turn, is responsible for part of the child's hostility towards his father. Large breasts are the positive sexual characteristics of the mother even at a time when the negative characteristic of the female - her lack of a penis - is as yet unknown to the child.¹

[1923b, 3967]

[1923b, 3968]

[1923d, 4014]
We should not be as short-sighted as the person in charge of the child who threatens him with castration, and we must not overlook the fact that at this time masturbation by no means represents the whole of his sexual life. As can be clearly shown, he stands in the Oedipus attitude to his parents; his masturbation is only a genital discharge of the sexual excitation belonging to the complex, and throughout his later years will owe its importance to that relationship. The Oedipus complex offered the child two possibilities of satisfaction, an active and a passive one. He could put himself in his father's place in a masculine fashion and have intercourse with his mother as his father did, in which case he would soon have felt the latter as a hindrance; or he might want to take the place of his mother and be loved by his father, in which case his mother would become superfluous. The child may have had only very vague notions as to what constitutes a satisfying erotic intercourse; but certainly the penis must play a part in it, for the sensations in his own organ were evidence of that. So far he had had no occasion to doubt that women possessed a penis. But now his acceptance of the possibility of castration, his recognition that women were castrated, made an end of both possible ways of obtaining satisfaction from the Oedipus complex. For both of them entailed the loss of his penis - the masculine one as a resulting punishment and the feminine one as a precondition. If the satisfaction of love in the field of the Oedipus complex is to cost the child his penis, a conflict is bound to arise between his narcissistic interest in that part of his body and the libidinal cathexis of his parental objects. In this conflict the first of these forces normally triumphs: the child's ego turns away from the Oedipus complex.

[1924d, 4088]

In boys the situation of the Oedipus complex is the first stage that can be recognized with certainty. It is easy to understand, because at that stage a child retains the same object which he previously cathexed with his libido - not as yet a genital one - during the preceding period while he was being suckled and nursed. The fact, too, that in this situation he regards his father as a disturbing rival and would like to get rid of him and take his place is a straightforward consequence of the actual state of affairs. I have shown elsewhere⁴ how the Oedipus attitude in little boys belongs to the phallic phase, and how its destruction is brought about by the fear of castration - that is, by narcissistic interest in their genitals. The matter is made more difficult to grasp by the complicating circumstance that even in boys the Oedipus complex has a double orientation, active and passive, in accordance with their bisexual constitution; a boy also wants to take his mother's place as the love-object of his father - a fact which we describe as the feminine attitude.

[1925j, 4147]
As regards the prehistory of the Oedipus complex in boys we are far from complete clarity. We know that that period includes an identification of an affectionate sort with the boy's father, an identification which is still free from any sense of rivalry in regard to his mother. Another element of that stage is invariably, I believe, a masturbatory activity in connection with the genitals, the masturbation of early childhood, the more or less violent suppression of which by those in charge of the child sets the castration complex in action. It is to be assumed that this masturbation is attached to the Oedipus complex and serves as a discharge for the sexual excitation belonging to it. It is, however, uncertain whether the masturbation has this character from the first, or whether on the contrary it makes its first appearance spontaneously as an activity of a bodily organ and is only brought into relation with the Oedipus complex at some later date; this second possibility is by far the more probable. Another doubtful question is the part played by bed-wetting and by the breaking of that habit through the intervention of training measures. We are inclined to make the simple connection that continued bed-wetting is a result of masturbation and that its suppression is regarded by boys as an inhibition of their genital activity - that is, as having the meaning of a threat of castration; but whether we are always right in supposing this remains to be seen. Finally, analysis shows us in a shadowy way how the fact of a child at a very early age listening to his parents copulating may set up his first sexual excitation, and how that event may, owing to its after-effects, act as a starting-point for the child's whole sexual development. Masturbation, as well as the two attitudes in the Oedipus complex, later on become attached to this early experience, the child having subsequently interpreted its meaning. It is impossible, however, to suppose that these observations of coitus are of universal occurrence, so that at this point we are faced with the problem of 'primal phantasies'. Thus the prehistory of the Oedipus complex, even in boys, raises all of these questions for sifting and explanation; and there is the further problem of whether we are to suppose that the process invariably follows the same course, or whether a great variety of different preliminary stages may not converge upon the same terminal situation.

[1925j, 4148]

In little girls the Oedipus complex raises one problem more than in boys. In both cases the mother is the original object; and there is no cause for surprise that boys retain that object in the Oedipus complex. But how does it happen that girls abandon it and instead take their father as an object? In pursuing this question I have been able to reach some conclusions which may throw light precisely on the prehistory of the Oedipus relation in girls.

[1925j, 4149]
The process of arriving at an *object*, which plays such an important part in mental life, takes place alongside of the organization of the libido. After the stage of *auto-erotism*, the first love-object in the case of both sexes is the mother; and it seems probable that to begin with a child does not distinguish its mother's organ of nutrition from its own body. Later, but still in the first years of infancy, the relation known as the *Oedipus complex* becomes established: boys concentrate their sexual wishes upon their mother and develop hostile impulses against their father as being a rival, while girls adopt an analogous attitude.¹ All of the different variations and consequences of the Oedipus complex are important; and the innately bisexual constitution of human beings makes itself felt and increases the number of simultaneously active tendencies. Children do not become clear for quite a long time about the differences between the sexes; and during this period of *sexual researches* they produce typical *sexual theories* which, being circumscribed by the incompleteness of their authors' own physical development, are a mixture of truth and error and fail to solve the problems of sexual life (the riddle of the Sphinx - that is, the question of where babies come from). We see, then, that a child's first object-choice is an *incestuous* one. The whole course of development that I have described is run through rapidly. For the most remarkable feature of the sexual life of man is its *diphasic* onset, its onset in two waves, with an interval between them. It reaches a first climax in the fourth or fifth year of a child's life. But thereafter this early efflorescence of sexuality passes off; the sexual impulses which have shown such liveliness are overcome by repression, and a *period of latency* follows, which lasts until puberty and during which the *reaction-formations* of morality, shame, and disgust are built up.² Of all living creatures man alone seems to show this diphasic onset of sexual growth, and it may perhaps be the biological determinant of his predisposition to neuroses. At puberty the impulses and object-relations of a child's early years become reanimated, and amongst them the emotional ties of its Oedipus complex. In the sexual life of puberty there is a struggle between the urges of early years and the inhibitions of the latency period. Before this, and while the child is at the highest point of its infantile sexual development, a genital organization of a sort is established; but only the male genitals play a part in it, and the female ones remain undiscovered. (I have described this as the period of *phallic* primacy.) At this stage the contrast between the sexes is not stated in terms of 'male' or 'female' but of 'possessing a penis' or 'castrated'. The *castration complex* which arises in this connection is of the profoundest importance in the formation alike of character and of neuroses.

[1925d, 4212]

The chief literary sources of my studies in this field were the well-known works of J. G. Frazer (*Totemism and Exogamy* and *The Golden Bough*), a mine of valuable facts and opinions. But Frazer effected little towards elucidating the problems of totemism; he had several times fundamentally altered his views on the subject, and the other ethnologists and prehistorians seemed in equal uncertainty and disagreement. My starting-point was the striking correspondence between the two taboo-ordinances of totemism (not to kill the totem and not to have sexual relations with any woman of the same totem-clan) and the two elements of the Oedipus complex (getting rid of the father and taking the mother to wife). I was therefore tempted to equate the totem-animal with the father; and in fact primitive peoples themselves do this explicitly, by honouring it as the forefather of the clan. There next came to my help two facts from psycho-analysis, a lucky observation of a child made by Ferenczi, which enabled me to speak of an *infantile return of totemism*, and the analysis of early animal-phobias in children, which so often showed that the animal was a substitute for the father, a substitute on to which the fear of the father derived from the Oedipus complex had been displaced. Not much was lacking to enable me to recognize the killing of the father as the nucleus of totemism and the starting-point in the formation of religion.

[1925d, 4240]
We shall not make any headway until we have reviewed the little boy's psychical situation as a whole as it came to light in the course of the analytic treatment. He was at the time in the jealous and hostile Oedipus attitude towards his father, whom nevertheless - except in so far as his mother was the cause of estrangement - he dearly loved. Here, then, we have a conflict due to ambivalence: a well-grounded love and a no less justifiable hatred directed towards one and the same person. 'Little Hans's' phobia must have been an attempt to solve this conflict. Conflicts of this kind due to ambivalence are very frequent and they can have another typical outcome, in which one of the two conflicting feelings (usually that of affection) becomes enormously intensified and the other vanishes. The exaggerated degree and compulsive character of the affection alone betray the fact that it is not the only one present but is continually on the alert to keep the opposite feeling under suppression, and enable us to postulate the operation of a process which we call repression by means of reaction-formation (in the ego). Cases like 'Little Hans's' show no traces of a reaction-formation of this kind. There are clearly different ways of egress from a conflict due to ambivalence.

Meanwhile we have been able to establish another point with certainty. The instinctual impulse which underwent repression in 'Little Hans' was a hostile one against his father. Proof of this was obtained in his analysis while the idea of the biting horse was being followed up. He had seen a horse fall down and he had also seen a playmate, with whom he was playing at horses, fall down and hurt himself. Analysis justified the inference that he had a wishful impulse that his father should fall down and hurt himself as his playmate and the horse had done. Moreover, his attitude towards someone's departure on a certain occasion makes it probable that his wish that his father should be out of the way also found less hesitating expression. But a wish of this sort is tantamount to an intention of putting one's father out of the way oneself - is tantamount, that is, to the murderous impulse of the Oedipus complex.

So far there seem to be no connecting links between 'Little Hans's' repressed instinctual impulse and the substitute for it which we suspect is to be seen in his phobia of horses. Let us simplify his psychical situation by setting on one side the infantile factor and the ambivalence. Let us imagine that he is a young servant who is in love with the mistress of the house and has received some tokens of her favour. He hates his master, who is more powerful than he is, and he would like to have him out of the way. It would then be eminently natural for him to dread his master's vengeance and to develop a fear of him - just as 'Little Hans' developed a phobia of horses. We cannot, therefore, describe the fear belonging to this phobia as a symptom. If 'Little Hans', being in love with his mother, had shown fear of his father, we should have no right to say that he had a neurosis or a phobia. His emotional reaction would have been entirely comprehensible. What made it a neurosis was one thing alone: the replacement of his father by a horse. It is this displacement, then, which has a claim to be called a symptom, and which, incidentally, constitutes the alternative mechanism which enables a conflict due to ambivalence to be resolved without the aid of a reaction-formation. Such a displacement is made possible or facilitated at 'Little Hans's' early age because the inborn traces of totemic thought can still be easily revived. Children do not as yet recognize or, at any rate, lay such exaggerated stress upon the gulf that separates human beings from the animal world. In their eyes the grown man, the object of their fear and admiration, still belongs to the same category as the big animal who has so many enviable attributes but against whom they have been warned because he may become dangerous. As we see, the conflict due to ambivalence is not dealt with in relation to one and the same person: it is circumvented, as it were, by one of the pair of conflicting impulses being directed to another person as a substitutive object.
The idea of being devoured by the father is typical age-old childhood material. It has familiar parallels in mythology (e.g. the myth of Kronos) and in the animal kingdom. Yet in spite of this confirmation the idea is so strange to us that we can hardly credit its existence in a child. Nor do we know whether it really means what it seems to say, and we cannot understand how it can have become the subject of a phobia. Analytic observation supplies the requisite information. It shows that the idea of being devoured by the father gives expression, in a form that has undergone regressive degradation, to a passive, tender impulse to be loved by him in a genital-erotic sense. Further investigation of the case history leaves no doubt of the correctness of this explanation. The genital impulse, it is true, betrays no sign of its tender purpose when it is expressed in the language belonging to the superseded transitional phase between the oral and sadistic organizations of the libido. Is it, moreover, a question merely of the replacement of the representative by a regressive form of expression or is it a question of a genuine regressive degradation of the genitally-directed impulse in the id? It is not at all easy to make certain. The case history of the Russian ‘Wolf Man’ gives very definite support to the second, more serious, view; for, from the time of the decisive dream onward, the boy became naughty, tormenting and sadistic, and soon afterwards developed a regular obsessional neurosis. At any rate, we can see that repression is not the only means which the ego can employ for the purpose of defence against an unwelcome instinctual impulse. If it succeeds in making an instinct regress, it will actually have done it more injury than it could have by repressing it. Sometimes, indeed, after forcing an instinct to regress in this way, it goes on to repress it.

[1926d, 4265]
These are unwelcome complications, considering that we only set out to study simple cases of symptom-formation due to repression, and with that intention selected the earliest and to all appearances, most transparent neuroses of childhood. Instead of a single repression we have found a collection of them and have become involved with regression into the bargain. Perhaps we have added to the confusion by treating the two cases of animal phobia at our disposal - 'Little Hans' and the 'Wolf Man' - as though they were cast in the same mould. As a matter of fact, certain differences between them stand out. It is only with regard to 'Little Hans' that we can say with certainty that what his phobia disposed of were the two main impulses of the Oedipus complex - his aggressiveness towards his father and his over-fondness for his mother. A tender feeling for his father was undoubtedly there too and played a part in repressing the opposite feeling; but we can prove neither that it was strong enough to draw repression upon itself nor that it disappeared afterwards. 'Hans' seems, in fact, to have been a normal boy with what is called a 'positive' Oedipus complex. It is possible that the factors which we do not find were actually at work in him, but we cannot demonstrate their existence. Even the most exhaustive analysis has gaps in its data and is insufficiently documented. In the case of the Russian the deficiency lies elsewhere. His attitude to female objects had been disturbed by an early seduction and his passive, feminine side was strongly developed. The analysis of his wolf-dream revealed very little intentional aggressiveness towards his father, but it brought forward unmistakable proof that what repression overtook was his passive tender attitude to his father. In his case, too, the other factors may have been operative as well; but they were not in evidence. How is it that, in spite of these differences in the two cases, almost amounting to an antithesis, the final outcome - a phobia - was approximately the same? The answer must be sought in another quarter. I think it will be found in the second fact which emerges from our brief comparative examination. It seems to me that in both cases we can detect what the motive force of the repression was and can substantiate our view of its nature from the line of development which the two children subsequently pursued. This motive force was the same in both of them. It was the fear of impending castration. 'Little Hans' gave up his aggressiveness towards his father from fear of being castrated. His fear that a horse would bite him can, without any forcing, be given the full sense of a fear that a horse would bite off his genitals, would castrate him. But it was from fear of being castrated, too, that the little Russian relinquished his wish to be loved by his father, for he thought that a relation of that sort presupposed a sacrifice of his genitals - of the organ which distinguished him from a female. As we see, both forms of the Oedipus complex, the normal, active form and the inverted one, came to grief through the castration complex. The Russian boy's anxiety-idea of being devoured by a wolf contained, it is true, no suggestion of castration, for the oral regression it had undergone had removed it too far from the phallic stage. But the analysis of his dream rendered further proof superfluous. It was a triumph of repression that the form in which his phobia was expressed should no longer have contained any allusion to castration.

[1926d, 4267]
Let us go back again to infantile phobias of animals; for, when all is said and done, we understand them better than any other cases. In animal phobias, then, the ego has to oppose a libidinal object-cathexis coming from the id - a cathexis that belongs either to the positive or the negative Oedipus complex - because it believes that to give way to it would entail the danger of castration. This question has already been discussed, but there still remains a doubtful point to clear up. In 'Little Hans's' case - that is, in the case of a positive Oedipus complex - was it his fondness for his mother or was it his aggressiveness towards his father which called out the defence by the ego? In practice it seems to make no difference, especially as each set of feelings implies the other; but the question has a theoretical interest, since it is only the feeling of affection for the mother which can count as a purely erotic one. The aggressive impulse flows mainly from the destructive instinct; and we have always believed that in a neurosis it is against the demands of the libido and not against those of any other instinct that the ego is defending itself. In point of fact we know that after 'Hans's' phobia had been formed, his tender attachment to his mother seemed to disappear, having been completely disposed of by repression, while the formation of the symptom (the substitutive formation) took place in relation to his aggressive impulses. In the 'Wolf Man' the situation was simpler. The impulse that was repressed - his feminine attitude towards his father - was a genuinely erotic one; and it was in relation to that impulse that the formation of his symptoms took place.

[1926d, 4282]

This study of the determinants of anxiety has, as it were, shown the defensive behaviour of the ego transfigured in a rational light. Each situation of danger corresponds to a particular period of life or a particular developmental phase of the mental apparatus and appears to be justifiable for it. In early infancy the individual is really not equipped to master psychically the large sums of excitation that reach him whether from without or from within. Again, at a certain period of life his most important interest really is that the people he is dependent on should not withdraw their loving care of him. Later on in his boyhood, when he feels that his father is a powerful rival in regard to his mother and becomes aware of his own aggressive inclinations towards him and of his sexual intentions towards his mother, he really is justified in being afraid of his father; and his fear of being punished by him can find expression through phylogenetic reinforcement in the fear of being castrated. Finally, as he enters into social relationships, it really is necessary for him to be afraid of his super-ego, to have a conscience; and the absence of that factor would give rise to severe conflicts, dangers and so on.

[1926d, 4301]
Nothing, however, deserves more notice than the fact that children regularly direct their sexual wishes towards their nearest relatives - in the first place, therefore, towards their father and mother, and afterwards towards their brothers and sisters. The first object of a boy's love is his mother, and of a girl's her father (except in so far as an innate bisexual disposition favours the simultaneous presence of the contrary attitude). The other parent is felt as a disturbing rival and not infrequently viewed with strong hostility. You must understand me aright. What I mean to say is not that the child wants to be treated by its favourite parent merely with the kind of affection which we adults like to regard as the essence of the parent-child relation. No, analysis leaves us in no doubt that the child's wishes extend beyond such affection to all that we understand by sensual satisfaction - so far, that is, as the child's powers of imagination allow. It is easy to see that the child never guesses the actual facts of sexual intercourse; he replaces them by other notions derived from his own experience and feelings. As a rule his wishes culminate in the intention to bear, or in some in definable way, to procreate a baby. Boys, too, in their ignorance, do not exclude themselves from the wish to bear a baby. We give the whole of this mental structure the name of 'Oedipus complex', after the familiar Greek legend. With the end of the early sexual period it should normally be given up, should radically disintegrate and become transformed; and the results of this transformation are destined for important functions in later mental life. But as a rule this is not effected radically enough, in which case puberty brings about a revival of the complex, which may have serious consequences.

During the phase of the normal Oedipus complex we find the child tenderly attached to the parent of the opposite sex, while its relation to the parent of its own sex is predominantly hostile. In the case of a boy there is no difficulty in explaining this. His first love-object was his mother. She remains so; and, with the strengthening of his erotic desires and his deeper insight into the relations between his father and mother, the former is bound to become his rival. With the small girl it is different. Her first object, too, was her mother. How does she find her way to her father? How, when and why does she detach herself from the wish to bear a baby? We have long understood that the development of female sexuality is complicated by the fact that the girl has the task of giving up what was originally her leading genital zone the clitoris - in favour of a new zone - the vagina. But it now seems to us that there is a second change of the same sort which is no less characteristic and important for the development of the female: the exchange of her original object - her mother - for her father. The way in which the two tasks are connected with each other is not yet clear to us.

Since this phase allows room for all the fixations and repressions from which we trace the origin of the neuroses, it would seem as though we must retract the universality of the thesis that the Oedipus complex is the nucleus of the neuroses. But if anyone feels reluctant about making this correction, there is no need for him to do so. On the one hand, we can extend the content of the Oedipus complex to include all the child's relations to both parents; or, on the other, we can take due account of our new findings by saying that the female only reaches the normal positive Oedipus situation after she has surmounted a period before it that is governed by the negative complex. And indeed during that phase a little girl's father is not much else for her than a troublesome rival, although her hostility towards him never reaches the pitch which is characteristic of boys. We have, after all, long given up any expectation of a neat parallelism between male and female sexual development.
Parallel with this first great difference there is the other, concerned with the finding of the object. In the case of a male, his mother becomes his first love-object as a result of her feeding him and looking after him, and she remains so until she is replaced by someone who resembles her or is derived from her. A female's first object, too, must be her mother: the primary conditions for a choice of object are, of course, the same for all children. But at the end of her development, her father - a man - should have become her new love-object. In other words, to the change in her own sex there must correspond a change in the sex of her object. The new problems that now require investigating are in what way this change takes place, how radically or how incompletely it is carried out, and what the different possibilities are which present themselves in the course of this development.

We have already learned, too, that there is yet another difference between the sexes, which relates to the Oedipus complex. We have an impression here that what we have said about the Oedipus complex applies with complete strictness to the male child only and that we are right in rejecting the term 'Electra complex' which seeks to emphasize the analogy between the attitude of the two sexes. It is only in the male child that we find the fateful combination of love for the one parent and simultaneous hatred for the other as a rival. In his case it is the discovery of the possibility of castration, as proved by the sight of the female genitals, which forces on him the transformation of his Oedipus complex, and which leads to the creation of his super-ego and thus initiates all the processes that are designed to make the individual find a place in the cultural community. After the paternal agency has been internalized and become a super-ego, the next task is to detach the latter from the figures of whom it was originally the psychical representative. In this remarkable course of development it is precisely the boy's narcissistic interest in his genitals - his interest in preserving his penis - which is turned round into a curtailing of his infantile sexuality.

The explanation I have attempted to give is at once met by a question: 'How is it, then, that boys are able to keep intact their attachment to their mother, which is certainly no less strong than that of girls? The answer comes equally promptly: 'Because boys are able to deal with their ambivalent feelings towards their mother by directing all their hostility on to their father.' But, in the first place, we ought not to make this reply until we have made a close study of the pre-Oedipus phase in boys, and, in the second place, it is probably more prudent in general to admit that we have as yet no clear understanding of these processes, with which we have only just become acquainted.
For we have recently been examining the way in which anxiety is generated in certain phobias which we class as anxiety hysteria, and have chosen cases in which we were dealing with the typical repression of wishful impulses arising from the Oedipus complex. We should have expected to find that it was a libidinal cathexis of the boy's mother as object which, as a result of repression, had been changed into anxiety and which now emerged, expressed in symptomatic terms, attached to a substitute for his father. I cannot present you with the detailed steps of an investigation such as this; it will be enough to say that the surprising result was the opposite of what we expected. It was not the repression that created the anxiety; the anxiety was there earlier; it was the anxiety that made the repression. But what sort of anxiety can it have been? Only anxiety in the face of a threatening external danger - that is to say, a realistic anxiety. It is true that the boy felt anxiety in the face of a demand by his libido - in this instance, anxiety at being in love with his mother; so the case was in fact one of neurotic anxiety. But this being in love only appeared to him as an internal danger, which he must avoid by renouncing that object, because it conjured up an external situation of danger. And in every case we examine we obtain the same result. It must be confessed that we were not prepared to find that internal instinctual danger would turn out to be a determinant and preparation for an external, real, situation of danger.

[1933a, 4692]

But we have not made any mention at all so far of what the real danger is that the child is afraid of as a result of being in love with his mother. The danger is the punishment of being castrated, of losing his genital organ. You will of course object that after all that is not a real danger. Our boys are not castrated because they are in love with their mothers during the phase of the Oedipus complex. But the matter cannot be dismissed so simply. Above all, it is not a question of whether castration is really carried out; what is decisive is that the danger is one that threatens from outside and that the child believes in it. He has some ground for this, for people threaten him often enough with cutting off his penis during the phallic phase, at the time of his early masturbation, and hints at that punishment must regularly find a phylogenetic reinforcement in him. It is our suspicion that during the human family's primaeval period castration used actually to be carried out by a jealous and cruel father upon growing boys, and that circumcision, which so frequently plays a part in puberty rites among primitive peoples, is a clearly recognizable relic of it. We are aware that here we are diverging widely from the general opinion; but we must hold fast to the view that fear of castration is one of the commonest and strongest motives for repression and thus for the formation of neuroses. The analysis of cases in which circumcision, though not, it is true, castration, has been carried out on boys as a cure or punishment for masturbation (a far from rare occurrence in Anglo-American society) has given our conviction a last degree of certainty. It is very tempting at this point to go more deeply into the castration complex, but I will stick to our subject.

[1933a, 4693]

We shall return to the part played by the clitoris; let us now turn to the second task with which a girl's development is burdened. A boy's mother is the first object of his love, and she remains so too during the formation of his Oedipus complex and, in essence, all through his life. For a girl too her first object must be her mother (and the figures of wet-nurses and foster-mothers that merge into her). The first object-cathexes occur in attachment to the satisfaction of the major and simple vital needs, and the circumstances of the care of children are the same for both sexes. But in the Oedipus situation the girl's father has become her love-object, and we expect that in the normal course of development she will find her way from this paternal object to her final choice of an object. In the course of time, therefore, a girl has to change her erotogenic zone and her object - both of which a boy retains. The question then arises of how this happens: in particular, how does a girl pass from her mother to an attachment to her father? or, in other words, how does she pass from her masculine phase to the feminine one to which she is biologically destined?

[1933a, 4720]
With the transference of the wish for a penis-baby on to her father, the girl has entered the situation of the Oedipus complex. Her hostility to her mother, which did not need to be freshly created, is now greatly intensified, for she becomes the girl's rival, who receives from her father everything that she desires from him. For a long time the girl's Oedipus complex concealed her pre-Oedipus attachment to her mother from our view, though it is nevertheless so important and leaves such lasting fixations behind it. For girls the Oedipus situation is the outcome of a long and difficult development; it is a kind of preliminary solution, a position of rest which is not soon abandoned, especially as the beginning of the latency period is not far distant. And we are now struck by a difference between the two sexes, which is probably momentous, in regard to the relation of the Oedipus complex to the castration complex. In a boy the Oedipus complex, in which he desires his mother and would like to get rid of his father as being a rival, develops naturally from the phase of his phallic sexuality. The threat of castration compels him, however, to give up that attitude. Under the impression of the danger of losing his penis, the Oedipus complex is abandoned, repressed and, in the most normal cases, entirely destroyed, and a severe super-ego is set up as its heir. What happens with a girl is almost the opposite. The castration complex prepares for the Oedipus complex instead of destroying it; the girl is driven out of her attachment to her mother through the influence of her envy for the penis and she enters the Oedipus situation as though into a haven of refuge. In the absence of fear of castration the chief motive is lacking which leads boys to surmount the Oedipus complex. Girls remain in it for an indeterminate length of time; they demolish it late and, even so, incompletely. In these circumstances the formation of the super-ego must suffer; it cannot attain the strength and independence which give it its cultural significance, and feminists are not pleased when we point out to them the effects of this factor upon the average feminine character.

[1933a, 4731]

With the phallic phase and in the course of it the sexuality of early childhood reaches its height and approaches its dissolution. Thereafter boys and girls have different histories. Both have begun to put their intellectual activity at the service of sexual researches; both start off from the premiss of the universal presence of the penis. But now the paths of the sexes diverge. The boy enters the Oedipus phase; he begins to manipulate his penis and simultaneously has phantasies of carrying out some sort of activity with it in relation to his mother, till, owing to the combined effect of a threat of castration and the sight of the absence of a penis in females, he experiences the greatest trauma of his life and this introduces the period of latency with all its consequences. The girl, after vainly attempting to do the same as the boy, comes to recognize her lack of a penis or rather the inferiority of her clitoris, with permanent effects on the development of her character; as a result of this first disappointment in rivalry, she often begins by turning away altogether from sexual life.

[1940a [1938], 4965]
This preface is not superfluous, for it can heighten our realization of the intensity of the Oedipus complex. When a boy (from the age of two or three) has entered the phallic phase of his libidinal development, is feeling pleasurable sensations in his sexual organ and has learnt to procure these at will by manual stimulation, he becomes his mother's lover. He wishes to possess her physically in such ways as he has divined from his observations and intuitions about sexual life, and he tries to seduce her by showing her the male organ which he is proud to own. In a word, his early awakened masculinity seeks to take his father's place with her; his father has hitherto in any case been an envied model to the boy, owing to the physical strength he perceives in him and the authority with which he finds him clothed. His father now becomes a rival who stands in his way and whom he would like to get rid of. If while his father is away he is allowed to share his mother's bed and if when his father returns he is once more banished from it, his satisfaction when his father disappears and his disappointment when he emerges again are deeply felt experiences. This is the subject of the Oedipus complex, which the Greek legend has translated from the world of a child's phantasy into pretended reality. Under the conditions of our civilization it is invariably doomed to a frightening end.

[1940a [1938], 4997]

The boy's mother has understood quite well that his sexual excitation relates to herself. Sooner or later she reflects that it is not right to allow it to continue. She thinks she is doing the correct thing in forbidding him to handle his genital organ. Her prohibition has little effect; at the most it brings about some modification in his method of obtaining satisfaction. At last his mother adopts the severest measures; she threatens to take away from him the thing he is defying her with. Usually, in order to make the threat more frightening and more credible, she delegates its execution to the boy's father, saying that she will tell him and that he will cut the penis off. Strange to say, this threat operates only if another condition is fulfilled before or afterwards. In itself it seems too inconceivable to the boy that such a thing could happen. But if at the time of the threat he can recall the appearance of female genitals or if shortly afterwards he has a sight of them - of genitals, that is to say, which really lack this supremely valued part, then he takes what he has heard seriously and, coming under the influence of the castration complex, experiences the severest trauma of his young life.¹

[1940a [1938], 4997]
We have heard how the weak and immature ego of the first period of childhood is permanently damaged by the stresses put upon it in its efforts to fend off the dangers that are peculiar to that period of life. Children are protected against the dangers that threaten them from the external world by the solicitude of their parents; they pay for this security by a fear of loss of love which would deliver them over helpless to the dangers of the external world. This factor exerts a decisive influence on the outcome of the conflict when a boy finds himself in the situation of the Oedipus complex, in which the threat to his narcissism by the danger of castration, reinforced from primaeval sources, takes possession of him. Driven by the combined operation of these two influences, the contemporary real danger and the remembered one with its phylogenetic basis, the child embarks on his attempts at defence - repressions - which are effective for the moment but nevertheless turn out to be psychologically inadequate when the later re-animation of sexual life brings a reinforcement to the instinctual demands which have been repudiated in the past. If this is so, it would have to be said from a biological standpoint that the ego comes to grief over the task of mastering the excitations of the early sexual period, at a time when its immaturity makes it incompetent to do so. It is in this lagging of ego development behind libidinal development that we see the essential precondition of neurosis; and we cannot escape the conclusion that neuroses could be avoided if the childish ego were spared this task - if, that is to say, the child's sexual life were allowed free play, as happens among many primitive peoples. It may be that the aetiology of neurotic illnesses is more complicated than we have here described it; if so, we have at least brought out one essential part of the aetiological complex. Nor should we forget the phylogenetic influences, which are represented in some way in the id in forms that we are not yet able to grasp, and which must certainly act upon the ego more powerfully in that early period than later. On the other hand, the realization dawns on us that such an early attempt at damming up the sexual instinct, so decided a partisanship by the young ego in favour of the external as opposed to the internal world, brought about by the prohibition of infantile sexuality, cannot be without its effect on the individual's later readiness for culture. The instinctual demands forced away from direct satisfaction are compelled to enter on new paths leading to substitutive satisfaction, and in the course of these détours they may become desexualized and their connection with their original instinctual aims may become looser. And at this point we may anticipate the thesis that many of the highly valued assets of our civilization were acquired at the cost of sexuality and by the restriction of sexual motive forces.

[1940a [1938], 5006]
I have learnt to look upon unconscious love relations like this (which are marked by their abnormal consequences) - between a father and a daughter, or between a mother and a son - as a revival of germs of feeling in infancy. I have shown at length elsewhere¹ at what an early age sexual attraction makes itself felt between parents and children, and I have explained that the legend of Oedipus is probably to be regarded as a poetical rendering of what is typical in these relations. Distinct traces are probably to be found in most people of an early partiality of this kind - on the part of a daughter for her father, or on the part of a son for his mother; but it must be assumed to be more intense from the very first in the case of those children whose constitution marks them down for a neurosis, who develop prematurely and have a craving for love. At this point certain other influences, which need not be discussed here, come into play, and lead to a fixation of this rudimentary feeling of love or to a reinforcement of it; so that it turns into something (either while the child is still young or not until it has reached the age of puberty) which must be put on a par with a sexual inclination and which, like the latter, has the forces of the libido at its command.² The nature of her disposition had always drawn her towards her father, and his numerous illnesses were bound to have increased her affection for him. In some of these illnesses he would allow no one but her to discharge the lighter duties of nursing. He had been so proud of the early growth of her intelligence that he had made her his confidante while she was still a child. It was really she and not her mother whom Frau K.'s appearance had driven out of more than one position. [1905e, 1393]

It is in the world of ideas, however, that the choice of an object is accomplished at first; and the sexual life of maturing youth is almost entirely restricted to indulging in phantasies, that is, in ideas that are not destined to be carried into effect.¹ In these phantasies the infantile tendencies invariably emerge once more, but this time with intensified pressure from somatic sources. Among these tendencies the first place is taken with uniform frequency by the child's sexual impulses towards his parents, which are as a rule already differentiated owing to the attraction of the opposite sex - the son being drawn towards his mother and the daughter towards her father.² At the same time as these plainly incestuous phantasies are overcome and repudiated, one of the most significant, but also one of the most painful, psychical achievements of the pubertal period is completed: detachment from parental authority, a process that alone makes possible the opposition, which is so important for the progress of civilization, between the new generation and the old. At every stage in the course of development through which all human beings ought by rights to pass, a certain number are held back; so there are some who have never got over their parents' authority and have withdrawn their affection from them either very incompletely or not at all. They are mostly girls, who, to the delight of their parents, have persisted in all their childish love far beyond puberty. It is most instructive to find that it is precisely these girls who in their later marriage lack the capacity to give their husbands what is due to them; they make cold wives and remain sexually anaesthetic. We learn from this that sexual love and what appears to be non-sexual love for parents are fed from the same sources; the latter, that is to say, merely corresponds to an infantile fixation of the libido. [1905d, 1539]
When presently the child comes to know the difference in the parts played by fathers and mothers in their sexual relations, and realizes that 'pater semper incertus est', while the mother is 'certissima',¹ the family romance undergoes a curious curtailment: it contents itself with exalting the child's father, but no longer casts any doubts on his maternal origin, which is regarded as something unalterable. This second (sexual) stage of the family romance is actuated by another motive as well, which is absent in the first (asexual) stage. The child, having learnt about sexual processes, tends to picture to himself erotic situations and relations, the motive force behind this being his desire to bring his mother (who is the subject of the most intense sexual curiosity) into situations of secret infidelity and into secret love-affairs. In this way the child's phantasies, which started by being, as it were, asexual, are brought up to the level of his later knowledge.

[1909c, 1989]

Then again, there were the states into which he fell on two consecutive evenings before going to sleep, and which were characterized by anxiety mingled with clear traces of tenderness. These states show that at the beginning of his illness there was as yet no phobia whatever present, whether of streets or of walking or even of horses. If there had been, his evening states would be inexplicable; for who bothers at bed time about streets and walking? On the other hand it becomes quite clear why he was so fearful in the evening, if we suppose that at bedtime he was overwhelmed by an intensification of his libido - for its object was his mother, and its aim may perhaps have been to sleep with her. He had besides learnt from his experience that at Gmunden his mother could be prevailed upon, when he got into such moods, to take him into her bed, and he wanted to gain the same ends here in Vienna. Nor must we forget that for part of the time at Gmunden he had been alone with his mother, as his father had not been able to spend the whole of the holidays there, and further, that in the country his affections had been divided among a number of playmates and friends of both sexes, while in Vienna he had none, so that his libido was in a position to return undivided to his mother.

[1909b, 2018]
That afternoon the father and son visited me during my consulting hours. I already knew the funny little fellow, and with all his self-assurance he was yet so amiable that I had always been glad to see him. I do not know whether he remembered me, but he behaved irreproachably and like a perfectly reasonable member of human society. The consultation was a short one. His father opened it by remarking that, in spite of all the pieces of enlightenment we had given Hans, his fear of horses had not yet diminished. We were also forced to confess that the connections between the horses he was afraid of and the affectionate feelings towards his mother which had been revealed were by no means abundant. Certain details which I now learnt - to the effect that he was particularly bothered by what horses wear in front of their eyes and by the black round their mouths - were certainly not to be explained from what we knew. But as I saw the two of them sitting in front of me and at the same time heard Hans's description of his anxiety-horses, a further piece of the solution shot through my mind, and a piece which I could well understand might escape his father. I asked Hans jokingly whether his horses wore eyeglasses, to which he replied that they did not. I then asked him whether his father wore eyeglasses, to which, against all the evidence, he once more said no. Finally I asked him whether by 'the black round the mouth' he meant a moustache; and I then disclosed to him that he was afraid of his father, precisely because he was so fond of his mother. It must be, I told him, that he thought his father was angry with him on that account; but this was not so, his father was fond of him in spite of it, and he might admit everything to him without any fear. Long before he was in the world, I went on, I had known that a little Hans would come who would be so fond of his mother that he would be bound to feel afraid of his father because of it; and I had told his father this. 'But why do you think I'm angry with you?' his father interrupted me at this point; 'have I ever scolded you or hit you?' Hans corrected him: 'Oh yes! You have hit me.' 'That's not true. When was it, anyhow?' 'This morning,' answered the little boy; and his father recollected that Hans had quite unexpectedly butted his head into his stomach, so that he had given him as it were a reflex blow with his hand. It was remarkable that he had not brought this detail into connection with the neurosis; but he now recognized it as an expression of the little boy's hostile disposition towards him, and perhaps also as a manifestation of a need for getting punished for it.¹

[1909b, 2031]

Here the little boy was displaying a really unusual degree of clarity. He was bringing to notice the fact that his love for his father was wrestling with his hostility towards him in his capacity of rival with his mother; and he was reproaching his father with not having yet drawn his attention to this interplay of forces, which was bound to end in anxiety. His father did not entirely understand him as yet, for during this conversation he only succeeded in convincing himself of the little boy's hostility towards him, the existence of which I had asserted during our consultation. The following dialogue, which I nevertheless give without alteration, is really of more importance in connection with the progress of the father's enlightenment than with the little patient.

[1909b, 2033]

We know that this portion of Hans's anxiety had two constituents: there was fear of his father and fear for his father. The former was derived from his hostility towards his father, and the latter from the conflict between his affection, which was exaggerated at this point by way of compensation, and his hostility.

[1909b, 2034]
Speaking with the air of superiority which is so easily acquired after the event, we may correct
Hans's father, and explain that the boy's wish to 'tease' the horse had two constituents; it was
compounded of an obscure sadistic desire for his mother and of a clear impulse for revenge
against his father. The latter could not be reproduced until the former's turn had come to
emerge in connection with the pregnancy complex. In the process of the formation of a phobia
from the unconscious thoughts underlying it, condensation takes place; and for that reason the
course of the analysis can never follow that of the development of the neurosis.
[1909b, 2069]

In his subsequent development, however, it was not to homosexuality that our young libertine
proceeded, but to an energetic masculinity with traits of polygamy; he knew how to vary his
behaviour, too, with his varying feminine objects - audaciously aggressive in one case,
languishing and bashful in another. His affection had moved from his mother on to other objects
of love, but at a time when there was a scarcity of these it returned to her, only to break down in
a neurosis. It was not until this happened that it became evident to what a pitch of intensity his
love for his mother had developed and through what vicissitudes it had passed. The sexual aim
which he pursued with his girl playmates, of sleeping with them, had originated in relation to his
mother. It was expressed in words which might be retained in maturity, though they would then
bear a richer connotation.¹ The boy had found his way to object-love in the usual manner from
the care he had received when he was an infant; and a new pleasure had now become the
most important for him - that of sleeping beside his mother. I should like to emphasize the
importance of pleasure derived from cutaneous contact as a component in this new aim of
Hans's, which, according to the nomenclature (artificial to my mind) of Moll, would have to be
described as satisfaction of the instinct of contrectation.
[1909b, 2095]

In his attitude towards his father and mother Hans confirms in the most concrete and
uncompromising manner what I have said in my Interpretation of Dreams and in my Three
Essays with regard to the sexual relations of a child to his parents. Hans really was a little
Oedipus who wanted to have his father 'out of the way', to get rid of him, so that he might be
alone with his beautiful mother and sleep with her. This wish had originated during his summer
holidays, when the alternating presence and absence of his father had drawn Hans's attention
to the condition upon which depended the intimacy with his mother which he longed for. At that
time the form taken by the wish had been merely that his father should 'go away'; and at a later
stage it became possible for his fear of being bitten by a white horse to attach itself directly on
to this form of the wish, owing to a chance impression which he received at the moment of
some one else's departure. But subsequently (probably not until they had moved back to
Vienna, where his father's absences were no longer to be reckoned on) the wish had taken the
form that his father should be permanently away - that he should be 'dead'. The fear which
sprang from this death-wish against his father, and which may thus be said to have had a
normal motive, formed the chief obstacle to the analysis until it was removed during the
conversation in my consulting-room.¹
[1909b, 2096]
The most important influence upon the course of Hans's psychosexual development was the birth of a baby sister when he was three and a half years old. That event accentuated his relations to his parents and gave him some insoluble problems to think about; and later, as he watched the way in which the infant was looked after, the memory-traces of his own earliest experiences of pleasure were revived in him. This influence, too, is a typical one: in an unexpectedly large number of life-histories, normal as well as pathological, we find ourselves obliged to take as our starting-point an outburst of sexual pleasure and sexual curiosity connected, like this one, with the birth of the next child. Hans's behaviour towards the new arrival was just what I have described in The Interpretation of Dreams. In his fever a few days later he betrayed how little he liked the addition to the family. Affection for his sister might come later,¹ but his first attitude was hostility. From that time forward fear that yet another baby might arrive found a place among his conscious thoughts. In the neurosis, his hostility, already suppressed, was represented by a special fear - a fear of the bath. In the analysis he gave undisguised expression to his death-wish against his sister, and was not content with allusions which required supplementing by his father. His inner conscience did not consider this wish so wicked as the analogous one against his father; but it is clear that in his unconscious he treated both persons in the same way, because they both took his mummy away from him, and interfered with his being alone with her.

[1909b, 2098]

Moreover, this event and the feelings that were revived by it gave a new direction to his wishes. In his triumphant final phantasy he summed up all of his erotic wishes, both those derived from his auto-erotic phase and those connected with his object-love. In that phantasy he was married to his beautiful mother and had innumerable children whom he could look after in his own way.

[1909b, 2098]

The first thing we learn is that the outbreak of the anxiety state was by no means so sudden as appeared at first sight. A few days earlier the child had woken from an anxiety-dream to the effect that his mother had gone away, and that now he had no mother to coax with. This dream alone points to the presence of a repressive process of ominous intensity. We cannot explain it, as we can so many other anxiety-dreams, by supposing that the child had in his dream felt anxiety arising from some somatic cause and had made use of the anxiety for the purpose of fulfilling an unconscious wish which would otherwise have been deeply repressed.¹ We must regard it rather as a genuine punishment and repression dream, and, moreover, as a dream which failed in its function, since the child woke from his sleep in a state of anxiety. We can easily reconstruct what actually occurred in the unconscious. The child dreamt of exchanging endearments with his mother and of sleeping with her; but all the pleasure was transformed into anxiety, and all the ideal content into its opposite. Repression had defeated the purpose of the mechanism of dreaming.

[1909b, 2101]
But the beginnings of this psychological situation go back further still. During the preceding
summer Hans had had similar moods of mingled longing and apprehension, in which he had
said similar things; and at that time they had secured him the advantage of being taken by his
mother into her bed. We may assume that since then Hans had been in a state of intensified
sexual excitement, the object of which was his mother. The intensity of this excitement was
shown by his two attempts at seducing his mother (the second of which occurred just before the
outbreak of his anxiety); and he found an incidental channel of discharge for it by masturbating
every evening and in that way obtaining gratification. Whether the sudden change-over of this
excitement into anxiety took place spontaneously, or as a result of his mother's rejection of his
advances, or owing to the accidental revival of earlier impressions by the 'precipitating cause' of
his illness (about which we shall hear presently) - this we cannot decide; and, indeed, it is a
matter of indifference, for these three alternative possibilities cannot be regarded as mutually
incompatible. The fact remains that his sexual excitement suddenly changed into anxiety.

We have already described the child's behaviour at the beginning of his anxiety, as well as the
first content which he assigned to it, namely, that a horse would bite him. It was at this point that
the first piece of therapy was interposed. His parents represented to him that his anxiety was
the result of masturbation, and encouraged him to break himself of the habit. I took care that
when they spoke to him great stress was laid upon his affection for his mother, for that was
what he was trying to replace by his fear of horses. This first intervention brought a slight
improvement, but the ground was soon lost again during a period of physical illness. Hans's
condition remained unchanged. Soon afterwards he traced back his fear of being bitten by a
horse to an impression he had received at Gmunden. A father had addressed his child on her
departure with these words of warning: 'Don't put your finger to the horse; if you do, it'll bite you.'
The words, 'don't put your finger to', which Hans used in reporting this warning, resembled the
form of words in which the warning against masturbation had been framed. It seemed at first,
therefore, as though Hans's parents were right in supposing that what he was frightened of was
his own masturbatory indulgence. But the whole nexus remained loose, and it seemed to be
merely by chance that horses had become his bugbear.

There are no difficulties in the way of our understanding these two criminal phantasies. They
belonged to Hans's complex of taking possession of his mother. Some kind of vague notion was
struggling in the child's mind of something that he might do with his mother by means of which
his taking possession of her would be consummated; for this elusive thought he found certain
pictorial representations, which had in common the qualities of being violent and forbidden, and
the content of which strikes us as fitting in most remarkably well with the hidden truth. We can
only say that they were symbolic phantasies of intercourse, and it was no irrelevant detail that
his father was represented as sharing in his actions: 'I should like', he seems to have been
saying, 'to be doing something with my mother, something forbidden; I do not know what it is,
but I do know that you are doing it too.'
There are not many more mysteries ahead of us now. An obscure phantasy of missing a train seems to have been a forerunner of the later notion of handing over Hans's father to his grandmother at Lainz, for the phantasy dealt with a visit to Lainz, and his grandmother appeared in it. Another phantasy, in which a boy gave the guard 50,000 florins to let him ride on the truck, almost sounds like a plan of buying his mother from his father, part of whose power, of course, lay in his wealth. At about this time, too, he confessed, with a degree of openness which he had never before reached, that he wished to get rid of his father, and that the reason he wished it was that his father interfered with his own intimacy with his mother. We must not be surprised to find the same wishes constantly reappearing in the course of an analysis. The monotony only attaches to the analyst's interpretations of these wishes. For Hans they were not mere repetitions, but steps in a progressive development from timid hinting to fully conscious, undistorted perspicuity.

But there was something else, which could not fail to make him uneasy. His father must have had something to do with little Hanna's birth, for he had declared that Hanna and Hans himself were his children. Yet it was certainly not his father who had brought them into the world, but his mother. This father of his came between him and his mother. When he was there Hans could not sleep with his mother, and when his mother wanted to take Hans into bed with her, his father used to call out. Hans had learnt from experience how well-off he could be in his father's absence, and it was only justifiable that he should wish to get rid of him. And then Hans's hostility had received a fresh reinforcement. His father had told him the lie about the stork and so made it impossible for him to ask for enlightenment upon these things. He not only prevented his being in bed with his mother, but also kept from him the knowledge he was thirsting for. He was putting Hans at a disadvantage in both directions, and was obviously doing so for his own benefit.

But this father, whom he could not help hating as a rival, was the same father whom he had always loved and was bound to go on loving, who had been his model, had been his first playmate, and had looked after him from his earliest infancy: and this it was that gave rise to the first conflict. Nor could this conflict find an immediate solution. For Hans's nature had so developed that for the moment his love could not but keep the upper hand and suppress his hate - though it could not kill it, for his hate was perpetually kept alive by his love for his mother.

But his father not only knew where children came from, he actually performed it - the thing that Hans could only obscurely divine. The widdler must have something to do with it, for his own grew excited whenever he thought of these things - and it must be a big widdler too, bigger than Hans's own. If he listened to these premonitory sensations he could only suppose that it was a question of some act of violence performed upon his mother, of smashing something, of making an opening into something, of forcing a way into an enclosed space - such were the impulses that he felt stirring within him. But although the sensations of his penis had put him on the road to postulating a vagina, yet he could not solve the problem, for within his experience no such thing existed as his widdler required. On the contrary, his conviction that his mother possessed a penis just as he did stood in the way of any solution. His attempt at discovering what it was that had to be done with his mother in order that she might have children sank down into his unconscious; and his two active impulses - the hostile one towards his father and the sadistic-tender one towards his mother - could be put to no use, the first because of the love that existed side by side with the hatred, and the second because of the perplexity in which his infantile sexual theories left him.
It deserves to be noticed that the ideational content of Hans's phobia as it then stood had to be submitted to one further process of distortion and substitution before his consciousness took cognizance of it. Hans's first formulation of his anxiety was: 'the horse will bite me'; and this was derived from another episode at Gmunden, which was on the one hand related to his hostile wishes towards his father and on the other hand was reminiscent of the warning he had been given against masturbation. Some interfering influence, emanating from his parents perhaps, had made itself felt. I am not certain whether the reports upon Hans were at that time drawn up with sufficient care to enable us to decide whether he expressed his anxiety in this form before or not until after his mother had taken him to task on the subject of masturbating. I should be inclined to suspect that it was not until afterwards, though this would contradict the account given in the case history. At any rate, it is evident that at every point Hans's hostile complex against his father screened his lustful one about his mother, just as it was the first to be disclosed and dealt with in the analysis.

This allows us, therefore, to make a radical distinction. We shall probably come to understand the case more deeply if we turn to those other components which do fulfil the two conditions that have just been mentioned. These other components were tendencies in Hans which had already been suppressed and which, so far as we can tell, had never been able to find uninhibited expression: hostile and jealous feelings towards his father, and sadistic impulses (premonitions, as it were, of copulation) towards his mother. These early suppressions may perhaps have gone to form the predisposition for his subsequent illness. These aggressive propensities of Hans's found no outlet, and as soon as there came a time of privation and of intensified sexual excitement, they tried to break their way out with reinforced strength. It was then that the battle which we call his 'phobia' burst out. During the course of it a part of the repressed ideas, in a distorted form and transposed on to another complex, forced their way into consciousness as the content of the phobia. But it was a decidedly paltry success. Victory lay with the forces of repression; and they made use of the opportunity to extend their domain over components other than those that had rebelled. This last circumstance, however, does not in the least alter the fact that the essence of Hans's illness was entirely dependent upon the nature of the instinctual components that had to be repulsed. The content of his phobia was such as to impose a very great measure of restriction upon his freedom of movement, and that was its purpose. It was therefore a powerful reaction against the obscure impulses to movement which were especially directed against his mother. For Hans horses had always typified pleasure in movement ('I'm a young horse', he had said as he jumped about); but since this pleasure in movement included the impulse to copulate, the neurosis imposed a restriction on it and exalted the horse into an emblem of terror. Thus it would seem as though all that the repressed instincts got from the neurosis was the honour of providing pretexts for the appearance of the anxiety in consciousness. But however clear may have been the victory in Hans's phobia of the forces that were opposed to sexuality, nevertheless, since such an illness is in its very nature a compromise, this cannot have been all that the repressed instincts obtained. After all, Hans's phobia of horses was an obstacle to his going into the street, and could serve as a means of allowing him to stay at home with his beloved mother. In this way, therefore, his affection for his mother triumphantly achieved its aim. In consequence of his phobia, the lover clung to the object of his love - though, to be sure, steps had been taken to make him innocuous. The true character of a neurotic disorder is exhibited in this twofold result.

[1909b, 2117]
Alfred Adler, in a suggestive paper,¹ has recently developed the view that anxiety arises from the suppression of what he calls the 'aggressive instinct', and by a very sweeping synthetic process he ascribes to that instinct the chief part in human events, 'in real life and in the neuroses'. As we have come to the conclusion that in our present case of phobia the anxiety is to be explained as being due to the repression of Hans's aggressive propensities (the hostile ones against his father and the sadistic ones against his mother), we seem to have produced a most striking piece of confirmation of Adler's view. I am nevertheless unable to assent to it, and indeed I regard it as a misleading generalization. I cannot bring myself to assume the existence of a special aggressive instinct alongside of the familiar instincts of self-preservation and of sex, and on an equal footing with them.² It appears to me that Adler has mistakenly promoted into a special and self-subsisting instinct what is in reality a universal and indispensable attribute of all instincts - their instinctual [triebhaft] and 'pressing' character, what might be described as their capacity for initiating movement. Nothing would then remain of the other instincts but their relation to an aim, for their relation to the means of reaching that aim would have been taken over from them by the 'aggressive instinct'. In spite of all the uncertainty and obscurity of our theory of instincts I should prefer for the present to adhere to the usual view, which leaves each instinct its own power of becoming aggressive; and I should be inclined to recognize the two instincts which became repressed in Hans as familiar components of the sexual libido.

[1909b, 2118]
He admitted that all of this sounded quite plausible, but he was naturally not in the very least convinced by it. He would venture to ask, he said, how it was that an idea of this kind could have remissions, how it could appear for a moment when he was twelve years old, and again when he was twenty, and then once more two years later, this time for good. He could not believe that his hostility had been extinguished in the intervals, and yet during them there had been no sign of self-reproaches. - To this I replied that whenever any one asked a question like that, he was already prepared with an answer; he needed only to be encouraged to go on talking. - He then proceeded, somewhat disconnectedly as it seemed, to say that he had been his father's best friend, and that his father had been his. Except on a few subjects, upon which fathers and sons usually hold aloof from one another - (What could he mean by that?) - there had been a greater intimacy between them than there now was between him and his best friend. As regards the lady for whose sake he had sacrificed his father in that idea of his, it was true that he had loved her very much, but he had never felt really sensual wishes towards her, such as he had constantly had in his childhood. Altogether, in his childhood his sensual impulses had been much stronger than during his puberty. - At this I told him I thought he had now produced the answer we were waiting for, and had at the same time discovered the third great characteristic of the unconscious. The source from which his hostility to his father derived its indestructibility was evidently something in the nature of sensual desires, and in that connection he must have felt his father as in some way or other an interference. A conflict of this kind, I added, between sensuality and childish love was entirely typical. The remissions he had spoken of had occurred because the premature explosion of his sensual feelings had had as its immediate consequence a considerable diminution of their violence. It was not until he was once more seized with intense erotic desires that his hostility reappeared again owing to the revival of the old situation. I then got him to agree that I had not led him on to the subject either of childhood or of sex, but that he had raised them both of his own free will. - He then went on to ask why he had not simply come to a decision, at the time he was in love with the lady, that his father's interference with that love could not for a moment weigh against his love of his father. - I replied that it was scarcely possible to destroy a person in absentia. Such a decision would only have been possible if the wish that he took objection to had made its first appearance on that occasion; whereas, as a matter of fact, it was a long-repressed wish, towards which he could not behave otherwise than he had formerly done, and which was consequently immune from destruction. This wish (to get rid of his father as being an interference) must have originated at a time when circumstances had been very different - at a time, perhaps, when he had not loved his father more than the person whom he desired sensually, or when he was incapable of making a clear decision. It must have been in his very early childhood, therefore, before he had reached the age of six, and before the date at which his memory became continuous; and things must have remained in the same state ever since. - With this piece of construction our discussion was broken off for the time being.

[1909d, 2145]
It is seldom that we are in the fortunate position of being able, as in the present instance, to establish the facts upon which these tales of the individual's prehistoric past are based, by recourse to the unimpeachable testimony of a grown-up person. Even so, the statement made by our patient's mother leaves the way open to various possibilities. That she did not proclaim the sexual character of the offence for which the child was punished may have been due to the activity of her own censorship; for with all parents it is precisely this sexual element in their children's past that their own censorship is most anxious to eliminate. But it is just as possible that the child was reproved by his nurse or by his mother herself for some commonplace piece of naughtiness of a non-sexual nature, and that his reaction was so violent that he was castigated by his father. In phantasies of this kind nurses and servants are regularly replaced by the superior figure of the mother. A deeper interpretation of the patient's dreams in relation to this episode revealed the clearest traces of the presence in his mind of an imaginative production of a positively epic character. In this his sexual desires for his mother and sister and his sister's premature death were linked up with the young hero's chastisement at his father's hand. It was impossible to unravel this tissue of phantasy thread by thread; the therapeutic success of the treatment was precisely what stood in the way of this. The patient recovered, and his ordinary life began to assert its claims: there were many tasks before him, which he had already neglected far too long, and which were incompatible with a continuation of the treatment. I am not to be blamed, therefore, for this gap in the analysis. The scientific results of psycho-analysis are at present only a by-product of its therapeutic aims, and for that reason it is often just in those cases where treatment fails that most discoveries are made.

If Leonardo was successful in reproducing on Mona Lisa's face the double meaning which this smile contained, the promise of unbounded tenderness and at the same time sinister menace (to quote Pater's phrase), then here too he had remained true to the content of his earliest memory. For his mother's tenderness was fateful for him; it determined his destiny and the privations that were in store for him. The violence of the caresses, to which his phantasy of the vulture points, was only too natural. In her love for her child the poor forsaken mother had to give vent to all her memories of the caresses she had enjoyed as well as her longing for new ones; and she was forced to do so not only to compensate herself for having no husband, but also to compensate her child for having no father to fondle him. So, like all unsatisfied mothers, she took her little son in place of her husband, and by the too early maturing of his erotism robbed him of a part of his masculinity. A mother's love for the infant she suckles and cares for is something far more profound than her later affection for the growing child. It is in the nature of a completely satisfying love-relation, which not only fulfils every mental wish but also every physical need; and if it represents one of the forms of attainable human happiness, that is in no little measure due to the possibility it offers of satisfying, without reproach, wishful impulses which have long been repressed and which must be called perverse.¹ In the happiest young marriage the father is aware that the baby, especially if he is a baby son, has become his rival, and this is the starting-point of an antagonism towards the favourite which is deeply rooted in the unconscious.

¹
It cannot be doubted that his father too came to play an important part in Leonardo's psychosexual development, and not only negatively by his absence during the boy's first childhood years, but also directly by his presence in the later part of Leonardo's childhood. No one who as a child desires his mother can escape wanting to put himself in his father's place, can fail to identify himself with him in his imagination, and later to make it his task in life to gain ascendancy over him. When Leonardo was received into his grandfather's house before he had reached the age of five, his young step-mother Albiera must certainly have taken his mother's place where his feelings were concerned, and he must have found himself in what may be called the normal relationship of rivalry with his father. As we know, a decision in favour of homosexuality only takes place round about the years of puberty. When this decision had been arrived at in Leonardo's case, his identification with his father lost all significance for his sexual life, but it nevertheless continued in other spheres of non-erotic activity. We hear that he was fond of magnificence and fine clothes, and kept servants and horses, although, in Vasari's words, 'he possessed almost nothing and did little work'. The responsibility for these tastes is not to be attributed solely to his feeling for beauty: we recognize in them at the same time a compulsion to copy and to outdo his father. His father had been a great gentleman to the poor peasant girl, and the son, therefore, never ceased to feel the spur to play the great gentleman as well, the urge 'to out-herod Herod', to show his father what a great gentleman really looks like.

If we survey the different features of the picture presented here - the conditions imposed on the man that his loved one should not be unattached and should be like a prostitute, the high value he sets on her, his need for feeling jealousy, his fidelity, which is nevertheless compatible with being broken down into a long series of instances, and the urge to rescue the woman - it will seem scarcely probable that they should all be derived from a single source. Yet psychoanalytic exploration into the life-histories of men of this type has no difficulty in showing that there is such a single source. The object-choice which is so strangely conditioned, and this very singular way of behaving in love, have the same psychical origin as we find in the loves of normal people. They are derived from the infantile fixation of tender feelings on the mother, and represent one of the consequences of that fixation. In normal love only a few characteristics survive which reveal unmistakably the maternal prototype of the object-choice, as, for instance, the preference shown by young men for maturer women; the detachment of libido from the mother has been effected relatively swiftly. In our type, on the other hand, the libido has remained attached to the mother for so long, even after the onset of puberty, that the maternal characteristics remain stamped on the love-objects that are chosen later, and all these turn into easily recognizable mother-surrogates. The comparison with the way in which the skull of a newly born child is shaped springs to mind at this point: after a protracted labour it always takes the form of a cast of the narrow part of the mother's pelvis.

We have now to show the plausibility of our assertion that the characteristic features of our type - its conditions for loving and its behaviour in love - do in fact arise from the psychical constellation connected with the mother. This would seem to be easiest where the first precondition is concerned - the condition that the woman should not be unattached, or that there should be an injured third party. It is at once clear that for the child who is growing up in the family circle the fact of the mother belonging to the father becomes an inseparable part of the mother's essence, and that the injured third party is none other than the father himself. The trait of overvaluing the loved one, and regarding her as unique and irreplaceable, can be seen to fall just as naturally into the context of the child's experience, for no one possesses more than one mother, and the relation to her is based on an event that is not open to any doubt and cannot be repeated.
If we are to understand the love-objects chosen by our type as being above all mother-surrrogates, then the formation of a series of them, which seems so flatly to contradict the condition of being faithful to one, can now also be understood. We have learnt from psycho-analysis in other examples that the notion of something irreplaceable, when it is active in the unconscious, frequently appears as broken up into an endless series: endless for the reason that every surrogate nevertheless fails to provide the desired satisfaction. This is the explanation of the insatiable urge to ask questions shown by children at a certain age: they have one single question to ask, but it never crosses their lips. It explains, too, the garrulity of some people affected by neurosis; they are under the pressure of a secret which is burning to be disclosed but which, despite all temptation, they never reveal.

[1910h, 2330]

On the other hand the second precondition for loving - the condition that the object chosen should be like a prostitute - seems energetically to oppose a derivation from the mother complex. The adult's conscious thought likes to regard his mother as a person of unimpeachable moral purity; and there are few ideas which he finds so offensive when they come from others, or feels as so tormenting when they spring from his own mind, as one which calls this aspect of his mother in question. This very relation of the sharpest contrast between 'mother' and 'prostitute' will however encourage us to enquire into the history of the development of these two complexes and the unconscious relation between them, since we long ago discovered that what, in the conscious, is found split into a pair of opposites often occurs in the unconscious as a unity. Investigation then leads us back to the time in a boy's life at which he first gains a more or less complete knowledge of the sexual relations between adults, somewhere about the years of pre-puberty. Brutal pieces of information, which are undisguisedly intended to arouse contempt and rebelliousness, now acquaint him with the secret of sexual life and destroy the authority of adults, which appears incompatible with the revelation of their sexual activities. The aspect of these disclosures which affects the newly initiated child most strongly is the way in which they apply to his own parents. This application is often flatly rejected by him, in some such words as these: 'Your parents and other people may do something like that with one another, but my parents can't possibly do it.

[1910h, 2331]
As an almost invariable corollary to this sexual enlightenment, the boy at the same time gains a knowledge of the existence of certain women who practise sexual intercourse as a means of livelihood, and who are for this reason held in general contempt. The boy himself is necessarily far from feeling this contempt: as soon as he learns that he too can be initiated by these unfortunates into sexual life, which till then he accepted as being reserved exclusively for 'grown-ups', he regards them only with a mixture of longing and horror. When after this he can no longer maintain the doubt which makes his parents an exception to the universal and odious norms of sexual activity, he tells himself with cynical logic that the difference between his mother and a whore is not after all so very great, since basically they do the same thing. The enlightening information he has received has in fact awakened the memory-traces of the impressions and wishes of his early infancy, and these have led to a reactivation in him of certain mental impulses. He begins to desire his mother herself in the sense with which he has recently become acquainted, and to hate his father anew as a rival who stands in the way of this wish; he comes, as we say, under the dominance of the Oedipus complex. He does not forgive his mother for having granted the favour of sexual intercourse not to himself but to his father, and he regards it as an act of unfaithfulness. If these impulses do not quickly pass, there is no outlet for them other than to run their course in phantasies which have as their subject his mother's sexual activities under the most diverse circumstances; and the consequent tension leads particularly readily to his finding relief in masturbation. As a result of the constant combined operation of the two driving forces, desire and thirst for revenge, phantasies of his mother's unfaithfulness are by far the most preferred; the lover with whom she commits her act of infidelity almost always exhibits the features of the boy's own ego, or more accurately, of his own idealized personality, grown up and so raised to a level with his father. What I have elsewhere described as the 'family romance' comprises the manifold ramifications of this imaginative activity and the way in which they are interwoven with various egoistic interests of this period of life.
[1910h, 2332]
To these phantasies which have succeeded in dominating the man's love in real life, the urge to rescue the loved one seems to bear merely a loose and superficial relation, and one that is fully accounted for by conscious reasons. By her propensity to be fickle and unfaithful the loved one brings herself into dangerous situations, and thus it is understandable that the lover should be at pains to protect her from these dangers by watching over her virtue and counteracting her bad inclinations. However, the study of people's screen-memories, phantasies and nocturnal dreams shows that we have here a particularly felicitous 'rationalization' of an unconscious motive, a process which may be compared to a successful secondary revision of a dream. In actual fact the 'rescue-motif' has a meaning and history of its own, and is an independent derivative of the mother-complex, or more accurately, of the parental complex. When a child hears that he owes his life to his parents, or that his mother gave him life, his feelings of tenderness unite with impulses which strive at power and independence, and they generate the wish to return this gift to the parent and to repay them with one of equal value. It is as though the boy's defiance were to make him say: 'I want nothing from my father; I will give him back all I have cost him.' He then forms the phantasy of rescuing his father from danger and saving his life; in this way he puts his account square with him. This phantasy is commonly enough displaced on to the emperor, king or some other great man; after being thus distorted it becomes admissible to consciousness, and may even be made use of by creative writers. In its application to a boy's father it is the defiant meaning in the idea of rescuing which is by far the most important; where his mother is concerned it is usually its tender meaning. The mother gave the child life, and it is not easy to find a substitute, of equal value for this unique gift. With a slight change of meaning, such as is easily effected in the unconscious and is comparable to the way in which in consciousness concepts shade into one another, rescuing his mother takes on the significance of giving her a child or making a child for her - needless to say, one like himself. This is not too remote from the original sense of rescuing, and the change in meaning is not an arbitrary one. His mother gave him a life - his own life - and in exchange he gives her another life, that of a child which has the greatest resemblance to himself. The son shows his gratitude by wishing to have by his mother a son who is like himself: in other words, in the rescue-phantasy he is completely identifying himself with his father. All his instincts, those of tenderness, gratitude, lustfulness, defiance and independence, find satisfaction in the single wish to be his own father. Even the element of danger has not been lost in the change of meaning; for the act of birth itself is the danger from which he was saved by his mother's efforts. Birth is both the first of all dangers to life and the prototype of all the later ones that cause us to feel anxiety, and the experience of birth has probably left behind in us the expression of affect which we call anxiety. Macduff of the Scottish legend, who was not born of his mother but ripped from her womb, was for that reason unacquainted with anxiety.

Psycho-analytic studies of psychical impotence have already been carried out and published by several writers.¹ Every analyst can confirm the explanations provided by them from his own clinical experience. It is in fact a question of the inhibitory influence of certain psychical complexes which are withdrawn from the subject's knowledge. An incestuous fixation on mother or sister, which has never been surmounted, plays a prominent part in this pathogenic material and is its most universal content. In addition there is the influence to be considered of accidental distressing impressions connected with infantile sexual activity, and also those factors which in a general way reduce the libido that is to be directed on to the female sexual object.²

We can now understand the motives behind the boy's phantasies mentioned in the first of these 'Contributions' (above, p. 2331), which degrade the mother to the level of a prostitute. They are efforts to bridge the gulf between the two currents in love, at any rate in phantasy, and by debasing the mother to acquire her as an object of sensuality.
A man's relation to his mother-in-law is complicated by similar impulses, though they have another source. It is regularly found that he chose his mother as the object of his love, and perhaps his sister as well, before passing on to his final choice. Because of the barrier that exists against incest, his love is deflected from the two figures on whom his affection was centred in his childhood on to an outside object that is modelled upon them. The place of his own and his sister's mother is taken by his mother-in-law. He has an impulse to fall back upon his original choice, though everything in him fights against it. His horror of incest insists that the genealogical history of his choice of an object for his love shall not be recalled. His repudiation of this impulse is also facilitated by the fact that his mother-in-law is only a contemporary figure; he has not known her all his life, so that there is no unchangeable picture of her preserved in his unconscious. A streak of irritability and malevolence that is apt to be present in the medley of his feelings leads us to suspect that she does in fact offer him a temptation to incest; and this is confirmed by the not uncommon event of a man openly falling in love with the woman who is later to be his mother-in-law before transferring his love to her daughter.

[1912-1913, 2664]

There has been little opportunity in the preceding pages for showing how new light can be thrown upon the facts of social psychology by the adoption of a psycho-analytic method of approach: for the horror of incest displayed by savages has long been recognized as such and stands in need of no further interpretation. All that I have been able to add to our understanding of it is to emphasize the fact that it is essentially an infantile feature and that it reveals a striking agreement with the mental life of neurotic patients. Psycho-analysis has taught us that a boy's earliest choice of objects for his love is incestuous and that those objects are forbidden ones - his mother and his sister. We have learnt, too, the manner in which, as he grows up, he liberates himself from this incestuous attraction. A neurotic, on the other hand, invariably exhibits some degree of psychical infantilism. He has either failed to get free from the psychosexual conditions that prevailed in his childhood or he has returned to them - two possibilities which may be summed up as developmental inhibition and regression. Thus incestuous fixations of libido continue to play (or begin once more to play) the principal part in his unconscious mental life. We have arrived at the point of regarding a child's relation to his parents, dominated as it is by incestuous longings, as the nuclear complex of neurosis. This revelation of the importance of incest in neurosis is naturally received with universal scepticism by adults and normal people. Similar expressions of disbelief, for instance, inevitably greet the writings of Otto Rank, which have brought more and more evidence to show the extent to which the interest of creative writers centres round the theme of incest and how the same theme, in countless variations and distortions, provides the subject-matter of poetry. We are driven to believe that this rejection is principally a product of the distaste which human beings feel for their early incestuous wishes, now over taken by repression. It is therefore of no small importance that we are able to show that these same incestuous wishes, which are later destined to become unconscious, are still regarded by savage peoples as immediate perils against which the most severe measures of defence must be enforced.

[1912-1913, 2665]
The son's efforts to put himself in the place of the father-god became ever more obvious. The introduction of agriculture increased the son's importance in the patriarchal family. He ventured upon new demonstrations of his incestuous libido, which found symbolic satisfaction in his cultivation of Mother Earth. Divine figures such as Attis, Adonis and Tammuz emerged, spirits of vegetation and at the same time youthful divinities enjoying the favours of mother goddesses and committing incest with their mother in defiance of their father. But the sense of guilt, which was not allayed by these creations, found expression in myths which granted only short lives to these youthful favourites of the mother-goddesses and decreed their punishment by emasculation or by the wrath of the father in the form of an animal. Adonis was killed by a wild boar, the sacred animal of Aphrodite; Attis, beloved of Cybele, perished by castration.¹ The mourning for these gods and the rejoicings over their resurrection passed over into the ritual of another son-deity who was destined to lasting success.

¹ [1912-1913, 2792]

This relation is undoubtedly a more favourable one, from the children's point of view as well. That is what our expectations demand; we find an absence of love far more repellent between parents and children than between brothers and sisters. In the former case we have, as it were, made something sacred which in the latter we have left profane. Yet daily observation can show us how frequently the emotional relations between parents and their grown-up children fall behind the ideal set up by society, how much hostility is ready to hand and would be expressed if it were not held back by admixtures of filial piety and affectionate impulses. The motives for this hostility are generally known and their tendency is to divide those of the same sex - the daughter from the mother and the father from the son. The daughter finds in her mother the authority which restricts her will and which is entrusted with the task of imposing on her the renunciation of sexual freedom which society demands; in a few instances she even finds in her a competitor who struggles against being supplanted. The same thing is repeated between the son and his father still more glaringly. In the son's eyes his father embodies every unwillingly tolerated social restraint; his father prevents him from exercising his will, from early sexual pleasure and, where there is common property in the family, from enjoying it. In the case of an heir to the throne this waiting for a father's death reaches an almost tragic height. There seems less danger to the relation between father and daughter or mother and son. This last provides the purest examples of an unchangeable affection, unimpaired by any egoistic considerations.

¹ [1916-1917, 3294]

What I have in mind is rivalry in love, with a clear emphasis on the subject's sex. While he is still a small child, a son will already begin to develop a special affection for his mother, whom he regards as belonging to him; he begins to feel his father as a rival who disputes his sole possession. And in the same way a little girl looks on her mother as a person who interferes with her affectionate relation to her father and who occupies a position which she herself could very well fill. Observation shows us to what early years these attitudes go back. We refer to them as the 'Oedipus complex', because the legend of Oedipus realizes, with only a slight softening, the two extreme wishes that arise from the son's situation - to kill his father and take his mother to wife. I do not wish to assert that the Oedipus complex exhausts the relation of children to their parents: it can easily be far more complicated. The Oedipus complex can, moreover, be developed to a greater or less strength, it can even be reversed; but it is a regular and very important factor in a child's mental life, and there is more danger of our underestimating rather than over-estimating its influence and that of the developments which proceed from it. Incidentally, children often react in their Oedipus attitude to a stimulus coming from their parents, who are frequently led in their preferences by difference of sex, so that the father will choose his daughter and the mother her son as a favourite, or, in case of a cooling-off in the marriage, as a substitute for a love-object that has lost its value.

¹ [1916-1917, 3295]
What, then, can be gathered about the Oedipus complex from the direct observation of children at the time of their making their choice of an object before the latency period? Well, it is easy to see that the little man wants to have his mother all to himself, that he feels the presence of his father as a nuisance, that he is resentful if his father indulges in any signs of affection towards his mother and that he shows satisfaction when his father has gone on a journey or is absent. He will often express his feelings directly in words and promise his mother to marry her. It will be thought that this amounts to little compared to the deeds of Oedipus; but in fact it is enough, it is the same thing at root. Observation is often obscured by the circumstance that on other occasions the same child will simultaneously give evidence of great affection for his father. But contrary - or, as it is better to say, 'ambivalent' - emotional attitudes, which in adults would lead to a conflict, remain compatible with each other for a long time in children, just as later they find a permanent place beside each other in the unconscious. It will also be objected that the little boy's conduct arises from egoistic motives and gives no grounds for postulating an erotic complex: the child's mother attends to all his needs, so that he has an interest in preventing her from looking after anyone else. This also is true; but it will soon become clear that in this situation as in similar ones the egoistic interest is merely affording a point of support to which the erotic trend is attached. The little boy may show the most undisguised sexual curiosity about his mother, he may insist upon sleeping beside her at night, he may force his presence on her while she is dressing or may even make actual attempts at seducing her, as his mother will often notice and report with amusement - all of which puts beyond doubt the erotic nature of his tie with his mother. Nor must it be forgotten that the mother devotes the same attention to a little daughter without producing the same result and that the father often competes with her in looking after the boy and yet fails to gain the same significance as she does. In short, the factor of sexual preference cannot be eliminated from the situation by any criticism. From the standpoint of egoistic interest it would be simply foolish of the little man not to prefer to put up with having two people in his service rather than only one of them.

When other children appear on the scene the Oedipus complex is enlarged into a family complex. This, with fresh support from the egoistic sense of injury, gives grounds for receiving the new brothers or sisters with repugnance and for unhesitatingly getting rid of them by a wish. It is even true that as a rule children are far readier to give verbal expression to these feelings of hate than to those arising from the parental complex. If a wish of this kind is fulfilled and the undesired addition to the family is removed again shortly afterwards by death, we can discover from a later analysis what an important experience this death has been to the child, even though it need not have remained fixed in his memory. A child who has been put into second place by the birth of a brother or sister, and who is now for the first time almost isolated from his mother, does not easily forgive her this loss of place; feelings which in an adult would be described as greatly embittered arise in him and are often the basis of a permanent estrangement. We have already mentioned that the child's sexual researches, with all their consequences, usually follow from this vital experience of his. As these brothers and sisters grow up, the boy's attitude to them undergoes very significant transformations. He may take his sister as a love-object by way of substitute for his faithless mother. Where there are several brothers, all of them courting a younger sister, situations of hostile rivalry, which are so important for later life, arise already in the nursery. A little girl may find in her elder brother a substitute for her father who no longer takes an affectionate interest in her as he did in her earliest years. Or she may take a younger sister as a substitute for the baby she has vainly wished for from her father.
But let us now turn from the direct observation of children to the analytic examination of adults who have become neurotic. What help does analysis give towards a further knowledge of the Oedipus complex? That can be answered in a word. Analysis confirms all that the legend describes. It shows that each of these neurotics has himself been an Oedipus or, what comes to the same thing, has, as a reaction to the complex, become a Hamlet. The analytic account of the Oedipus complex is, of course, a magnification and coarsening of the infantile sketch. The hatred of the father, the death-wishes against him, are no longer hinted at timidly, the affection for the mother admits that its aim is to possess her as a woman. Should we really attribute such blatant and extreme emotional impulses to the tender years of childhood, or is analysis deceiving us by an admixture of some new factor? It is not hard to find one. Whenever someone gives an account of a past event, even if he is a historian, we must take into account what he unintentionally puts back into the past from the present or from some intermediate time, thus falsifying his picture of it. In the case of a neurotic it is even a question whether this putting back is an entirely unintentional one; later on we shall have to discover reasons for this and have to do justice in general to the fact of 'retrospective phantasying'. We can easily see, too, that hatred of the father is reinforced by a number of factors arising from later times and circumstances and that the sexual desires towards the mother are cast into forms which must have been alien as yet to a child. But it would be a vain effort to seek to explain the whole Oedipus complex by retrospective phantasying and to attach it to later times. Its infantile core and more or less of its accessories remain as they were confirmed by the direct observation of children.

[1916-1917, 3401]

The clinical fact which meets us behind the form of the Oedipus complex as it is established by analysis is of the highest practical significance. We learn that at puberty, when the sexual instinct first makes its demands in full strength, the old familiar incestuous objects are taken up again and freshly cathedected with libido. The infantile object-choice was only a feeble one, but it was a prelude, pointing the direction for the object-choice at puberty. At this point, then, very intense emotional processes come into play, following the direction of the Oedipus complex or reacting against it, processes which, however, since their premisses have become intolerable, must to a large extent remain apart from consciousness. From this time onwards, the human individual has to devote himself to the great task of detaching himself from his parents, and not until that task is achieved can he cease to be a child and become a member of the social community. For the son this task consists in detaching his libidinal wishes from his mother and employing them for the choice of a real outside love-object, and in reconciling himself with his father if he has remained in opposition to him, or in freeing himself from his pressure if, as a reaction to his infantile rebelliousness, he has become subservient to him. These tasks are set to everyone; and it is remarkable how seldom they are dealt with in an ideal manner - that is, in one which is correct both psychologically and socially. By neurotics, however, no solution at all is arrived at: the son remains all his life bowed beneath his father's authority and he is unable to transfer his libido to an outside sexual object. With the relationship changed round, the same fate can await the daughter. In this sense the Oedipus complex may justly be regarded as the nucleus of the neuroses.

[1916-1917, 3402]
Before we are led by this difficulty to a suspicion that the whole conception of the masculine protest is inadequate to meet the problem of neuroses and perversions, and that its application to them is unfruitful, we will for a moment leave the passive beating-phantasies and turn our attention to other instinctual manifestations of infantile sexual life - manifestations which have equally undergone repression. No one can doubt that there are also wishes and phantasies which keep to the masculine line from their very nature, and which are the expression of masculine instinctual impulses - sadistic tendencies, for instance, or a boy's lustful feelings towards his mother arising out of the normal Oedipus complex. It is no less certain that these impulses, too, are overtaken by repression. If the masculine protest is to be taken as having satisfactorily explained the repression of passive phantasies (which later become masochistic), then it becomes for that very reason totally inapplicable to the opposite case of active phantasies. That is to say, the doctrine of the masculine protest is altogether incompatible with the fact of repression. Unless we are prepared to throw away all that has been acquired in psychology since Breuer's first cathartic treatment and through its agency, we cannot expect that the principle of the masculine protest will acquire any significance in the elucidation of the neuroses and perversions.

2 Perhaps with the solitary exception of the relation of a mother to her son, which is based on narcissism, is not disturbed by subsequent rivalry, and is reinforced by a rudimentary attempt at sexual object-choice.

At the same time as this identification with his father, or a little later, the boy has begun to develop a true object-cathexis towards his mother according to the attachment type. He then exhibits, therefore, two psychologically distinct ties: a straightforward sexual object-cathexis towards his mother and an identification with his father which takes him as his model. The two subsist side by side for a time without any mutual influence or interference. In consequence of the irresistible advance towards a unification of mental life, they come together at last; and the normal Oedipus complex originates from their confluence. The little boy notices that his father stands in his way with his mother. His identification with his father then takes on a hostile colouring and becomes identical with the wish to replace his father in regard to his mother as well. Identification, in fact, is ambivalent from the very first; it can turn into an expression of tenderness as easily as into a wish for someone's removal. It behaves like a derivative of the first, oral phase of the organization of the libido, in which the object that we long for and prize is assimilated by eating and is in that way annihilated as such. The cannibal, as we know, has remained at this standpoint; he has a devouring affection for his enemies and only devours people of whom he is fond.

In the very earliest years of childhood (approximately between the ages of two and five) a convergence of the sexual impulses occurs of which, in the case of boys, the object is the mother. This choice of an object, in conjunction with a corresponding attitude of rivalry and hostility towards the father, provides the content of what is known as the Oedipus complex, which in every human being is of the greatest importance in determining the final shape of his erotic life. It has been found to be characteristic of a normal individual that he learns to master his Oedipus complex, whereas the neurotic subject remains involved in it.
In its simplified form the case of a male child may be described as follows. At a very early age the little boy develops an object-cathexis for his mother, which originally related to the mother's breast and is the prototype of an object-choice on the anaclitic model; the boy deals with his father by identifying himself with him. For a time these two relationships proceed side by side, until the boy's sexual wishes in regard to his mother become more intense and his father is perceived as an obstacle to them; from this the Oedipus complex originates.² His identification with his father then takes on a hostile colouring and changes into a wish to get rid of his father in order to take his place with his mother. Henceforward his relation to his father is ambivalent; it seems as if the ambivalence inherent in the identification from the beginning had become manifest. An ambivalent attitude to his father and an object-relation of a solely affectionate kind to his mother make up the content of the simple positive Oedipus complex in a boy.

[1923b, 3965]

It would appear, therefore, that in both sexes the relative strength of the masculine and feminine sexual dispositions is what determines whether the outcome of the Oedipus situation shall be an identification with the father or with the mother. This is one of the ways in which bisexuality takes a hand in the subsequent vicissitudes of the Oedipus complex. The other way is even more important. For one gets an impression that the simple Oedipus complex is by no means its commonest form, but rather represents a simplification or schematization which, to be sure, is often enough justified for practical purposes. Closer study usually discloses the more complete Oedipus complex, which is twofold, positive and negative, and is due to the bisexuality originally present in children: that is to say, a boy has not merely an ambivalent attitude towards his father and an affectionate object-choice towards his mother, but at the same time he also behaves like a girl and displays an affectionate feminine attitude to his father and a corresponding jealousy and hostility towards his mother. It is this complicating element introduced by bisexuality that makes it so difficult to obtain a clear view of the facts in connection with the earliest object-choices and identifications, and still more difficult to describe them intelligibly. It may even be that the ambivalence displayed in the relations to the parents should be attributed entirely to bisexuality and that it is not, as I have represented above, developed out of identification in consequence of rivalry.

[1923b, 3967]

To an ever-increasing extent the Oedipus complex reveals its importance as the central phenomenon of the sexual period of early childhood. After that, its dissolution takes place; it succumbs to repression, as we say, and is followed by the latency period. It has not yet become clear, however, what it is that brings about its destruction. Analyses seem to show that it is the experience of painful disappointments. The little girl likes to regard herself as what her father loves above all else; but the time comes when she has to endure a harsh punishment from him and she is cast out of her fool's paradise. The boy regards his mother as his own property; but he finds one day that she has transferred her love and solicitude to a new arrival. Reflection must deepen our sense of the importance of those influences, for it will emphasize the fact that distressing experiences of this sort, which act in opposition to the content of the complex, are inevitable. Even when no special events occur, like those we have mentioned as examples, the absence of the satisfaction hoped for, the continued denial of the desired baby, must in the end lead the small lover to turn away from his hopeless longing. In this way the Oedipus complex would go to its destruction from its lack of success, from the effects of its internal impossibility.

[1924d, 4085]
In boys the situation of the Oedipus complex is the first stage that can be recognized with certainty. It is easy to understand, because at that stage a child retains the same object which he previously catheted with his libido - not as yet a genital one - during the preceding period while he was being suckled and nursed. The fact, too, that in this situation he regards his father as a disturbing rival and would like to get rid of him and take his place is a straightforward consequence of the actual state of affairs. I have shown elsewhere¹ how the Oedipus attitude in little boys belongs to the phallic phase, and how its destruction is brought about by the fear of castration - that is, by narcissistic interest in their genitals. The matter is made more difficult to grasp by the complicating circumstance that even in boys the Oedipus complex has a double orientation, active and passive, in accordance with their bisexual constitution; a boy also wants to take his mother's place as the love-object of his father - a fact which we describe as the feminine attitude.

The process of arriving at an object, which plays such an important part in mental life, takes place alongside of the organization of the libido. After the stage of auto-erotism, the first love-object in the case of both sexes is the mother; and it seems probable that to begin with a child does not distinguish its mother's organ of nutrition from its own body. Later, but still in the first years of infancy, the relation known as the Oedipus complex becomes established: boys concentrate their sexual wishes upon their mother and develop hostile impulses against their father as being a rival, while girls adopt an analogous attitude.¹ All of the different variations and consequences of the Oedipus complex are important; and the innately bisexual constitution of human beings makes itself felt and increases the number of simultaneously active tendencies. Children do not become clear for quite a long time about the differences between the sexes; and during this period of sexual researches they produce typical sexual theories which, being circumscribed by the incompleteness of their authors' own physical development, are a mixture of truth and error and fail to solve the problems of sexual life (the riddle of the Sphinx - that is, the question of where babies come from). We see, then, that a child's first object-choice is an incestuous one. The whole course of development that I have described is run through rapidly. For the most remarkable feature of the sexual life of man is its diphasic onset, its onset in two waves, with an interval between them. It reaches a first climax in the fourth or fifth year of a child's life. But thereafter this early efflorescence of sexuality passes off; the sexual impulses which have shown such liveliness are overcome by repression, and a period of latency follows, which lasts until puberty and during which the reaction-formations of morality, shame, and disgust are built up.² Of all living creatures man alone seems to show this diphasic onset of sexual growth, and it may perhaps be the biological determinant of his predisposition to neuroses. At puberty the impulses and object-relations of a child's early years become reanimated, and amongst them the emotional ties of its Oedipus complex. In the sexual life of puberty there is a struggle between the urges of early years and the inhibitions of the latency period. Before this, and while the child is at the highest point of its infantile sexual development, a genital organization of a sort is established; but only the male genitals play a part in it, and the female ones remain undiscovered. (I have described this as the period of phallic primacy.) At this stage the contrast between the sexes is not stated in terms of 'male' or 'female' but of 'possessing a penis' or 'castrated'. The castration complex which arises in this connection is of the profoundest importance in the formation alike of character and of neuroses.

¹ [1925], 4147

² [1925d, 4212]
The information about infantile sexuality was obtained from the study of men and the theory deduced from it was concerned with male children. It was natural enough to expect to find a complete parallel between the two sexes; but this turned out not to hold. Further investigations and reflections revealed profound differences between the sexual development of men and women. The first sexual object of a baby girl (just as of a baby boy) is her mother; and before a woman can reach the end of her normal development she has to change not only her sexual object but also her leading genital zone. From this circumstance difficulties arise and possibilities of inhibition which are not present in the case of men.
[1925d, 4212]

The chief literary sources of my studies in this field were the well-known works of J. G. Frazer (Totemism and Exogamy and The Golden Bough), a mine of valuable facts and opinions. But Frazer effected little towards elucidating the problems of totemism; he had several times fundamentally altered his views on the subject, and the other ethnologists and prehistorians seemed in equal uncertainty and disagreement. My starting-point was the striking correspondence between the two taboo-ordinances of totemism (not to kill the totem and not to have sexual relations with any woman of the same totem-clan) and the two elements of the Oedipus complex (getting rid of the father and taking the mother to wife). I was therefore tempted to equate the totem-animal with the father; and in fact primitive peoples themselves do this explicitly, by honouring it as the forefather of the clan. There next came to my help two facts from psycho-analysis, a lucky observation of a child made by Ferenczi, which enabled me to speak of an 'infantile return of totemism', and the analysis of early animal-phobias in children, which so often showed that the animal was a substitute for the father, a substitute on to which the fear of the father derived from the Oedipus complex had been displaced. Not much was lacking to enable me to recognize the killing of the father as the nucleus of totemism and the starting-point in the formation of religion.
[1925d, 4240]

We may suppose, therefore, that this was the way in which things happened. The sight of a woman's dead body, naked or on the point of being stripped, reminded the young man of his mother. It roused in him a longing for his mother which sprang from his Oedipus complex, and this was immediately completed by a feeling of indignation against his father. His ideas of 'father' and 'God' had not yet become widely separated; so that his desire to destroy his father could become conscious as doubt in the existence of God and could seek to justify itself in the eyes of reason as indignation about the ill-treatment of a mother object. It is of course typical for a child to regard what his father does to his mother in sexual intercourse as ill-treatment. The new impulse, which was displaced into the sphere of religion, was only a repetition of the Oedipus situation and consequently soon met with a similar fate. It succumbed to a powerful opposing current. During the actual conflict the level of displacement was not maintained: there is no mention of arguments in justification of God, nor are we told what the infallible signs were by which God proved his existence to the doubter. The conflict seems to have been unfolded in the form of a hallucinatory psychosis: inner voices were heard which uttered warnings against resistance to God. But the outcome of the struggle was displayed once again in the sphere of religion and it was of a kind predetermined by the fate of the Oedipus complex: complete submission to the will of God the Father. The young man became a believer and accepted everything he had been taught since his childhood about God and Jesus Christ. He had had a religious experience and had undergone a conversion.
[1928a, 4550]
Parallel with this first great difference there is the other, concerned with the finding of the object. In the case of a male, his mother becomes his first love-object as a result of her feeding him and looking after him, and she remains so until she is replaced by someone who resembles her or is derived from her. A female’s first object, too, must be her mother: the primary conditions for a choice of object are, of course, the same for all children. But at the end of her development, her father - a man - should have become her new love-object. In other words, to the change in her own sex there must correspond a change in the sex of her object. The new problems that now require investigating are in what way this change takes place, how radically or how incompletely it is carried out, and what the different possibilities are which present themselves in the course of this development.

[1931b, 4592]

A prohibition of masturbation, as we have seen, becomes an incentive for giving it up; but it also becomes a motive for rebelling against the person who prohibits it - that is to say, the mother, or the mother-substitute who later regularly merges with her. A defiant persistence in masturbation appears to open the way to masculinity. Even where the girl has not succeeded in suppressing her masturbation, the effect of the apparently vain prohibition is seen in her later efforts to free herself at all costs from a satisfaction which has been spoilt for her. When she reaches maturity her object-choice may still be influenced by this persisting purpose. Her resentment at being prevented from free sexual activity plays a big part in her detachment from her mother. The same motive comes into operation again after puberty, when her mother takes up her duty of guarding her daughter's chastity. We shall, of course, not forget that the mother is similarly opposed to a boy’s masturbating and thus provides him, too, with a strong motive for rebellion.

[1931b, 4596]

The first sexual and sexually coloured experiences which a child has in relation to its mother are naturally of a passive character. It is suckled, fed, cleaned, and dressed by her, and taught to perform all its functions. A part of its libido goes on clinging to those experiences and enjoys the satisfactions bound up with them; but another part strives to turn them into activity. In the first place, being suckled at the breast gives place to active sucking. As regards the other experiences the child contents itself either with becoming self-sufficient - that is, with itself successfully carrying out what had hitherto been done for it - or with repeating its passive experiences in an active form in play; or else it actually makes its mother into the object and behaves as the active subject towards her. For a long time I was unable to credit this last behaviour, which takes place in the field of real action, until my observations removed all doubts on the matter.

[1931b, 4600]

Lastly, intense active wishful impulses directed towards the mother also arise during the phallic phase. The sexual activity of this period culminates in clitoridal masturbation. This is probably accompanied by ideas of the mother, but whether the child attaches a sexual aim to the idea, and what that aim is, I have not been able to discover from my observations. It is only when all her interests have received a fresh impetus through the arrival of a baby brother or sister that we can clearly recognize such an aim. The little girl wants to believe that she has given her mother the new baby, just as the boy wants to; and her reaction to this event and her behaviour to the baby is exactly the same as his. No doubt this sounds quite absurd, but perhaps that is only because it sounds so unfamiliar.

[1931b, 4603]
We shall return to the part played by the clitoris; let us now turn to the second task with which a girl's development is burdened. A boy's mother is the first object of his love, and she remains so too during the formation of his Oedipus complex and, in essence, all through his life. For a girl too her first object must be her mother (and the figures of wet-nurses and foster-mothers that merge into her). The first object-cathexes occur in attachment to the satisfaction of the major and simple vital needs, and the circumstances of the care of children are the same for both sexes. But in the Oedipus situation the girl's father has become her love-object, and we expect that in the normal course of development she will find her way from this paternal object to her final choice of an object. In the course of time, therefore, a girl has to change her erotogenic zone and her object - both of which a boy retains. The question then arises of how this happens: in particular, how does a girl pass from her mother to an attachment to her father? or, in other words, how does she pass from her masculine phase to the feminine one to which she is biologically destined?

[1933a, 4720]

An abundant source of a child's hostility to its mother is provided by its multifarious sexual wishes, which alter according to the phase of the libido and which cannot for the most part be satisfied. The strongest of these frustrations occur at the phallic period, if the mother forbids pleasurable activity with the genitals - often with severe threats and every sign of displeasure - activity to which, after all, she herself had introduced the child. One would think these were reasons enough to account for a girl's turning away from her mother. One would judge, if so, that the estrangement follows inevitably from the nature of children's sexuality, from the immoderate character of their demand for love and the impossibility of fulfilling their sexual wishes. It might be thought indeed that this first love-relation of the child's is doomed to dissolution for the very reason that it is the first, for these early object-cathexes are regularly ambivalent to a high degree. A powerful tendency to aggressiveness is always present beside a powerful love, and the more passionately a child loves its object the more sensitive does it become to disappointments and frustrations from that object; and in the end the love must succumb to the accumulated hostility. Or the idea that there is an original ambivalence such as this in erotic cathexes may be rejected, and it may be pointed out that it is the special nature of the mother-child relation that leads, with equal inevitability, to the destruction of the child's love; for even the mildest upbringing cannot avoid using compulsion and introducing restrictions, and any such intervention in the child's liberty must provoke as a reaction an inclination to rebelliousness and aggressiveness. A discussion of these possibilities might, I think, be most interesting; but an objection suddenly emerges which forces our interest in another direction. All these factors - the slights, the disappointments in love, the jealousy, the seduction followed by prohibition - are, after all, also in operation in the relation of a boy to his mother and are yet unable to alienate him from the maternal object. Unless we can find something that is specific for girls and is not present or not in the same way present in boys, we shall not have explained the termination of the attachment of girls to their mother.

[1933a, 4726]
A woman's identification with her mother allows us to distinguish two strata: the pre-Oedipus one which rests on her affectionate attachment to her mother and takes her as a model, and the later one from the Oedipus complex which seeks to get rid of her mother and take her place with her father. We are no doubt justified in saying that much of both of them is left over for the future and that neither of them is adequately surmounted in the course of development. But the phase of the affectionate pre-Oedipus attachment is the decisive one for a woman's future: during it preparations are made for the acquisition of the characteristics with which she will later fulfil her role in the sexual function and perform her invaluable social tasks. It is in this identification too that she acquires her attractiveness to a man, whose Oedipus attachment to his mother it kindles into passion. How often it happens, however, that it is only his son who obtains what he himself aspired to! One gets an impression that a man's love and a woman's are a phase apart psychologically.

[1933a, 4736]

With the phallic phase and in the course of it the sexuality of early childhood reaches its height and approaches its dissolution. Thereafter boys and girls have different histories. Both have begun to put their intellectual activity at the service of sexual researches; both start off from the premiss of the universal presence of the penis. But now the paths of the sexes diverge. The boy enters the Oedipus phase; he begins to manipulate his penis and simultaneously has phantasies of carrying out some sort of activity with it in relation to his mother, till, owing to the combined effect of a threat of castration and the sight of the absence of a penis in females, he experiences the greatest trauma of his life and this introduces the period of latency with all its consequences. The girl, after vainly attempting to do the same as the boy, comes to recognize her lack of a penis or rather the inferiority of her clitoris, with permanent effects on the development of her character; as a result of this first disappointment in rivalry, she often begins by turning away altogether from sexual life.

[1940a [1938], 4965]

A child's first erotic object is the mother's breast that nourishes it; love has its origin in attachment to the satisfied need for nourishment. There is no doubt that, to begin with, the child does not distinguish between the breast and its own body; when the breast has to be separated from the body and shifted to the 'outside' because the child so often finds it absent, it carries with it as an 'object' a part of the original narcissistic libidinal cathexis. This first object is later completed into the person of the child's mother, who not only nourishes it but also looks after it and thus arouses in it a number of other physical sensations, pleasurable and unpleasurable. By her care of the child's body she becomes its first seducer. In these two relations lies the root of a mother's importance, unique, without parallel, established unalterably for a whole lifetime as the first and strongest love-object and as the prototype of all later love-relations - for both sexes. In all this the phylogenetic foundation has so much the upper hand over personal accidental experience that it makes no difference whether a child has really sucked at the breast or has been brought up on the bottle and never enjoyed the tenderness of a mother's care. In both cases the child's development takes the same path; it may be that in the second case its later longing grows all the greater. And for however long it is fed at its mother's breast, it will always be left with a conviction after it has been weaned that its feeding was too short and too little.

[1940a [1938], 4996]
This preface is not superfluous, for it can heighten our realization of the intensity of the Oedipus complex. When a boy (from the age of two or three) has entered the phallic phase of his libidinal development, he is feeling pleasurable sensations in his sexual organ and has learnt to procure these at will by manual stimulation, he becomes his mother’s lover. He wishes to possess her physically in such ways as he has divined from his observations and intuitions about sexual life, and he tries to seduce her by showing her the male organ which he is proud to own. In a word, his early awakened masculinity seeks to take his father’s place with her; his father has hitherto in any case been an envied model to the boy, owing to the physical strength he perceives in him and the authority with which he finds him clothed. His father now becomes a rival who stands in his way and whom he would like to get rid of. If while his father is away he is allowed to share his mother’s bed and if when his father returns he is once more banished from it, his satisfaction when his father disappears and his disappointment when he emerges again are deeply felt experiences. This is the subject of the Oedipus complex, which the Greek legend has translated from the world of a child’s phantasy into pretended reality. Under the conditions of our civilization it is invariably doomed to a frightening end.

[1940a [1938], 4997]

The boy’s mother has understood quite well that his sexual excitation relates to herself. Sooner or later she reflects that it is not right to allow it to continue. She thinks she is doing the correct thing in forbidding him to handle his genital organ. Her prohibition has little effect; at the most it brings about some modification in his method of obtaining satisfaction. At last his mother adopts the severest measures; she threatens to take away from him the thing he is defying her with. Usually, in order to make the threat more frightening and more credible, she delegates its execution to the boy’s father, saying that she will tell him and that he will cut the penis off. Strange to say, this threat operates only if another condition is fulfilled before or afterwards. In itself it seems too inconceivable to the boy that such a thing could happen. But if at the time of the threat he can recall the appearance of female genitals or if shortly afterwards he has a sight of them - of genitals, that is to say, which really lack this supremely valued part, then he takes what he has heard seriously and, coming under the influence of the castration complex, experiences the severest trauma of his young life.¹

[1940a [1938], 4997]
Let us consider first the relation between father and son. The sanctity which we attribute to the rules laid down in the Decalogue has, I think, blunted our powers of perceiving the real facts. We seem scarcely to venture to observe that the majority of mankind disobey the Fifth Commandment. Alike in the lowest and in the highest strata of human society filial piety is wont to give way to other interests. The obscure information which is brought to us by mythology and legend from the primeval ages of human society gives an unpleasing picture of the father's despotic power and of the ruthlessness with which he made use of it. Kronos devoured his children, just as the wild boar devours the sow's litter; while Zeus emasculated his father² and made himself ruler in his place. The more unrestricted was the rule of the father in the ancient family, the more must the son, as his destined successor, have found himself in the position of an enemy, and the more impatient must he have been to become ruler himself though his father's death. Even in our middle-class families fathers are as a rule inclined to refuse their sons independence and the means necessary to secure it and thus to foster the growth of the germ of hostility which is inherent in their relation. A physician will often be in a position to notice how a son's grief at the loss of his father cannot suppress his satisfaction at having at length won his freedom. In our society to-day fathers are apt to cling desperately to what is left of a now sadly antiquated protestas patris familias; and an author who, like Ibsen, brings the immemorial struggle between fathers and sons into prominence in his writings may be certain of producing his effect.

There is another kind of absurdity, which occurs in dreams of dead relatives but which does not express ridicule and derision. It indicates an extreme degree of repudiation, and so makes it possible to represent a repressed thought which the dreamer would prefer to regard as utterly unthinkable. It seems impossible to elucidate dreams of this kind unless one bears in mind the fact that dreams do not differentiate between what is wished and what is real. For instance, a man who had nursed his father during his last illness and had been deeply grieved by his death, had the following senseless dream some time afterwards. His father was alive once more and talking to him in his usual way, but (the remarkable thing was that) he had really died, only he did not know it. This dream only becomes intelligible if, after the words 'but he had really died' we insert 'in consequence of the dreamer's wish', and if we explain that what 'he did not know' was that the dreamer had had this wish. While he was nursing his father he had repeatedly wished his father were dead; that is to say, he had had what was actually a merciful thought that death might put an end to his sufferings. During his mourning, after his father's death, even this sympathetic wish became a subject of unconscious self-reproach, as though by means of it he had really helped to shorten the sick man's life. A stirring up of the dreamer's earliest infantile impulses against his father made it possible for this self-reproach to find expression as a dream; but the fact that the instigator of the dream and the daytime thoughts were such worlds apart was precisely what necessitated the dream's absurdity.¹
Goethe said of Lichtenberg: 'Where he makes a jest a problem lies concealed.' Similarly it can be said of the passages in my book that I have quoted here: where an error makes its appearance a repression lies behind it - or more correctly, an insincerity, a distortion, which is ultimately rooted in repressed material. In analysing the dreams reported there I was compelled, by the very nature of the themes to which the dream-thoughts related, on the one hand to break off the analysis at some point before it had been rounded off, and on the other hand to take the edge off some indiscreet detail by mild distortion. I could not do otherwise, and I had in fact no other choice if I wished to bring forward examples and evidence at all. My awkward position was a necessary result of the peculiar character of dreams, which consists in giving expression to repressed material - in other words, to material that is inadmissible to consciousness. (In spite of this it would seem that enough was still left to give offence to some sensitive souls.) I did not succeed, however, in carrying through the distortion or concealment of the thoughts, whose continuation was known to me, without leaving some trace of them behind. What I wanted to suppress often succeeded against my will in gaining access to what I had chosen to relate and appeared in it in the form of an error that I failed to notice. Moreover, the same theme is at the bottom of all the three examples I have given: the errors are derivatives of repressed thoughts connected with my dead father.

[1901b, 1293]

For a small child his parents are at first the only authority and the, source of all belief. The child's most intense and most momentous wish during these early years is to be like his parents (that is, the parent of his own sex) and to be big like his father and mother. But as intellectual growth increases, the child cannot help discovering by degrees the category to which his parents belong. He gets to know other parents and compares them with his own, and so acquires the right to doubt the incomparable and unique quality which he had attributed to them. Small events in the child's life which make him feel dissatisfied afford him provocation for beginning to criticize his parents, and for using, in order to support his critical attitude, the knowledge which he has acquired that other parents are in some respects preferable to them. The psychology of the neuroses teaches us that, among other factors, the most intense impulses of sexual rivalry contribute to this result. A feeling of being slighted is obviously what constitutes the subject-matter of such provocations. There are only too many occasions on which a child is slighted, or at least feels he has been slighted, on which he feels he is not receiving the whole of his parents' love, and, most of all, of which he feels regrets at having to share it with brothers and sisters. His sense that his own affection is not being fully reciprocated then finds a vent in the idea, often consciously recollected later from early childhood, of being a step-child or an adopted child. People who have not developed neuroses very frequently remember such occasions, on which - usually as a result of something they have read - they interpreted and responded to their parent's hostile behaviour in this fashion. But here the influence of sex is already in evidence, for a boy is far more inclined to feel hostile impulses towards his father than towards his mother and has a far more intense desire to get free from him than from her. In this respect the imagination of girls is apt to show itself much weaker. These consciously remembered mental impulses of childhood embody the factor which enables us to understand the nature of myths.

[1909c, 1987]
That afternoon the father and son visited me during my consulting hours. I already knew the funny little fellow, and with all his self-assurance he was yet so amiable that I had always been glad to see him. I do not know whether he remembered me, but he behaved irreproachably and like a perfectly reasonable member of human society. The consultation was a short one. His father opened it by remarking that, in spite of all the pieces of enlightenment we had given Hans, his fear of horses had not yet diminished. We were also forced to confess that the connections between the horses he was afraid of and the affectionate feelings towards his mother which had been revealed were by no means abundant. Certain details which I now learnt - to the effect that he was particularly bothered by what horses wear in front of their eyes and by the black round their mouths - were certainly not to be explained from what we knew. But as I saw the two of them sitting in front of me and at the same time heard Hans's description of his anxiety-horses, a further piece of the solution shot through my mind, and a piece which I could well understand might escape his father. I asked Hans jokingly whether his horses wore eyeglasses, to which they replied that they did not. I then asked him whether his father wore eyeglasses, to which, against all the evidence, he once more said no. Finally I asked him whether by 'the black round the mouth' he meant a moustache; and I then disclosed to him that he was afraid of his father, precisely because he was so fond of his mother. It must be, I told him, that he thought his father was angry with him on that account; but this was not so, his father was fond of him in spite of it, and he might admit everything to him without any fear. Long before he was in the world, I went on, I had known that a little Hans would come who would be so fond of his mother that he would be bound to feel afraid of his father because of it; and I had told his father this. 'But why do you think I'm angry with you?' his father interrupted me at this point; 'have I ever scolded you or hit you?' Hans corrected him: 'Oh yes! You have hit me.' 'That's not true. When was it, anyhow?' 'This morning,' answered the little boy; and his father recollected that Hans had quite unexpectedly butted his head into his stomach, so that he had given him as it were a reflex blow with his hand. It was remarkable that he had not brought this detail into connection with the neurosis; but he now recognized it as an expression of the little boy's hostile disposition towards him, and perhaps also as a manifestation of a need for getting punished for it.¹

¹ Later on the boy repeated his reaction towards his father in a clearer and more complete manner, by first hitting his father on the hand and then affectionately kissing the same hand.

Here the little boy was displaying a really unusual degree of clarity. He was bringing to notice the fact that his love for his father was wrestling with his hostility towards him in his capacity of rival with his mother; and he was reproaching his father with not having yet drawn his attention to this interplay of forces, which was bound to end in anxiety. His father did not entirely understand him as yet, for during this conversation he only succeeded in convincing himself of the little boy's hostility towards him, the existence of which I had asserted during our consultation. The following dialogue, which I nevertheless give without alteration, is really of more importance in connection with the progress of the father's enlightenment than with the little patient.

We know that this portion of Hans's anxiety had two constituenets: there was fear of his father and fear for his father. The former was derived from his hostility towards his father, and the latter from the conflict between his affection, which was exaggerated at this point by way of compensation, and his hostility.
His father's investigations may have been without success at some points; but it does no harm to make acquaintance at close quarters with a phobia of this sort - which we may feel inclined to name after its new objects. For in this way we get to see how diffuse it really is. It extends on to horses and on to carts, on to the fact that horses fall down and that they bite, on to horses of a particular character, on to carts that are heavily loaded. I will reveal at once that all these characteristics were derived from the circumstance that the anxiety originally had no reference at all to horses but was transposed on to them secondarily and had now become fixed upon those elements of the horse-complex which showed themselves well adapted for certain transferences. We must specially acknowledge one most important result of the boy's examination by his father. We have learned the immediate precipitating cause after which the phobia broke out. This was when the boy saw a big heavy horse fall down; and one at least of the interpretations of this impression seems to be that emphasized by his father, namely, that Hans at that moment perceived a wish that his father might fall down in the same way - and be dead. His serious expression as he was telling the story no doubt referred to this unconscious meaning. May there not have been yet another meaning concealed behind all this? And what can have been the significance of the making a row with its legs?

In this way he was accepting the last interpretations more decidedly than he could in words, but naturally with a change of parts, for the game was played in obedience to a wishful phantasy. Thus he was the horse, and bit his father, and in this way was identifying himself with his father.

Speaking with the air of superiority which is so easily acquired after the event, we may correct Hans's father, and explain that the boy's wish to 'tease' the horse had two constituents; it was compounded of an obscure sadistic desire for his mother and of a clear impulse for revenge against his father. The latter could not be reproduced until the former's turn had come to emerge in connection with the pregnancy complex. In the process of the formation of a phobia from the unconscious thoughts underlying it, condensation takes place; and for that reason the course of the analysis can never follow that of the development of the neurosis.

In his attitude towards his father and mother Hans confirms in the most concrete and uncompromising manner what I have said in my Interpretation of Dreams and in my Three Essays with regard to the sexual relations of a child to his parents. Hans really was a little Oedipus who wanted to have his father 'out of the way', to get rid of him, so that he might be alone with his beautiful mother and sleep with her. This wish had originated during his summer holidays, when the alternating presence and absence of his father had drawn Hans's attention to the condition upon which depended the intimacy with his mother which he longed for. At that time the form taken by the wish had been merely that his father should 'go away'; and at a later stage it became possible for his fear of being bitten by a white horse to attach itself directly on to this form of the wish, owing to a chance impression which he received at the moment of some one else's departure. But subsequently (probably not until they had moved back to Vienna, where his father's absences were no longer to be reckoned on) the wish had taken the form that his father should be permanently away - that he should be 'dead'. The fear which sprang from this death-wish against his father, and which may thus be said to have had a normal motive, formed the chief obstacle to the analysis until it was removed during the conversation in my consulting-room.¹
It is quite certain that Hans's two associations, 'raspberry syrup' and 'a gun for shooting people dead with' must have had more than one set of determinants. They probably had just as much to do with his hatred of his father as with his constipation complex. His father, who himself guessed the latter connection, also suggested that 'raspberry syrup' might be related to 'blood'.

But Hans was not by any means a bad character; he was not even one of those children who at his age still give free play to the propensity towards cruelty and violence which is a constituent of human nature. On the contrary, he had an unusually kind-hearted and affectionate disposition; his father reported that the transformation of aggressive tendencies into feelings of pity took place in him at a very early age. Long before the phobia he had become uneasy when he saw the horses in a merry-go-round being beaten; and he was never unmoved if any one wept in his presence. At one stage in the analysis a piece of suppressed sadism made its appearance in a particular context:¹ but it was *suppressed* sadism, and we shall presently have to discover from the content what it stood for and what it was meant to replace. And Hans deeply loved the father against whom he cherished these death-wishes; and while his intellect demurred to such a contradiction,² he could not help demonstrating the fact of its existence, by hitting his father and immediately afterwards kissing the place he had hit. We ourselves, too, must guard against making a difficulty of such a contradiction. The emotional life of man is in general made up of pairs of contraries such as these.³ Indeed, if it were not so, repressions and neuroses would perhaps never come about. In the adult these pairs of contrary emotions do not as a rule become simultaneously conscious except at the climaxes of passionate love; at other times they usually go on suppressing each other until one of them succeeds in keeping the other altogether out of sight. But in children they can exist peaceably side by side for quite a considerable time.

The most important influence upon the course of Hans's psychosexual development was the birth of a baby sister when he was three and a half years old. That event accentuated his relations to his parents and gave him some insoluble problems to think about; and later, as he watched the way in which the infant was looked after, the memory-traces of his own earliest experiences of pleasure were revived in him. This influence, too, is a typical one: in an unexpectedly large number of life-histories, normal as well as pathological, we find ourselves obliged to take as our starting-point an outburst of sexual pleasure and sexual curiosity connected, like this one, with the birth of the next child. Hans's behaviour towards the new arrival was just what I have described in *The Interpretation of Dreams*. In his fever a few days later he betrayed how little he liked the addition to the family. Affection for his sister might come later,¹ but his first attitude was hostility. From that time forward fear that yet another baby might arrive found a place among his conscious thoughts. In the neurosis, his hostility, already suppressed, was represented by a special fear - a fear of the bath. In the analysis he gave undisguised expression to his death-wish against his sister, and was not content with allusions which required supplementing by his father. His inner conscience did not consider this wish so wicked as the analogous one against his father; but it is clear that in his unconscious he treated both persons in the same way, because they both took his mummy away from him, and interfered with his being alone with her.

Moreover, this event and the feelings that were revived by it gave a new direction to his wishes. In his triumphant final phantasy he summed up all of his erotic wishes, both those derived from his auto-erotic phase and those connected with his object-love. In that phantasy he was married to his beautiful mother and had innumerable children whom he could look after in his own way.
The giraffe phantasy strengthened a conviction which had already begun to form in my mind when Hans expressed his fear that 'the horse'll come into the room'; and I thought the right moment had now arrived for informing him that he was afraid of his father because he himself nourished jealous and hostile wishes against him - for it was essential to postulate this much with regard to his unconscious impulses. In telling him this, I had partly interpreted his fear of horses for him: the horse must be his father - whom he had good internal reasons for fearing. Certain details of which Hans had shown he was afraid, the black on horses' mouths and the things in front of their eyes (the moustaches and eyeglasses which are the privilege of a grown-up man), seemed to me to have been directly transposed from his father on to the horses.

[1909b, 2105]

There are not many more mysteries ahead of us now. An obscure phantasy of missing a train seems to have been a forerunner of the later notion of handing over Hans's father to his grandmother at Lainz, for the phantasy dealt with a visit to Lainz, and his grandmother appeared in it. Another phantasy, in which a boy gave the guard 50,000 florins to let him ride on the truck, almost sounds like a plan of buying his mother from his father, part of whose power, of course, lay in his wealth. At about this time, too, he confessed, with a degree of openness which he had never before reached, that he wished to get rid of his father, and that the reason he wished it was that his father interfered with his own intimacy with his mother. We must not be surprised to find the same wishes constantly reappearing in the course of an analysis. The monotony only attaches to the analyst's interpretations of these wishes. For Hans they were not mere repetitions, but steps in a progressive development from timid hinting to fully conscious, undistorted perspicuity.

[1909b, 2111]

What remains are just such confirmations on Hans's part of analytical conclusions which our interpretations had already established. In an entirely unequivocal symptomatic act, which he disguised slightly from the maid but not at all from his father, he showed how he imagined a birth took place; but if we look into it more closely we can see that he showed something else, that he was hinting at something which was not alluded to again in the analysis. He pushed a small penknife which belonged to his mother in through a round hole in the body of an india-rubber doll, and then let it drop out again by tearing apart the doll's legs. The enlightenment which he received from his parents soon afterwards, to the effect that children do in fact grow inside their mother's body and are pushed out of it like a lumf, came too late; it could tell him nothing new. Another symptomatic act, happening as though by accident, involved a confession that he had wished his father dead; for, just at the moment his father was talking of this death-wish, Hans let a horse that he was playing with fall down - knocked it over in fact. Further, he confirmed in so many words the hypothesis that heavily loaded carts represented his mother's pregnancy to him, and the horse's falling down was like having a baby. The most delightful piece of confirmation in this connection - a proof that, in his view, children were 'lumfs' - was his inventing the name of 'Lodi' for his favourite child. There was some delay in reporting this fact, for it then appeared that he had been playing with this sausage child of his for a long time past.¹

[1909b, 2111]
But there was something else, which could not fail to make him uneasy. His father must have had something to do with little Hanna's birth, for he had declared that Hanna and Hans himself were his children. Yet it was certainly not his father who had brought them into the world, but his mother. This father of his came between him and his mother. When he was there Hans could not sleep with his mother, and when his mother wanted to take Hans into bed with her, his father used to call out. Hans had learnt from experience how well-off he could be in his father's absence, and it was only justifiable that he should wish to get rid of him. And then Hans's hostility had received a fresh reinforcement. His father had told him the lie about the stork and so made it impossible for him to ask for enlightenment upon these things. He not only prevented his being in bed with his mother, but also kept from him the knowledge he was thirsting for. He was putting Hans at a disadvantage in both directions, and was obviously doing so for his own benefit.

But this father, whom he could not help hating as a rival, was the same father whom he had always loved and was bound to go on loving, who had been his model, had been his first playmate, and had looked after him from his earliest infancy: and this it was that gave rise to the first conflict. Nor could this conflict find an immediate solution. For Hans's nature had so developed that for the moment his love could not but keep the upper hand and suppress his hate - though it could not kill it, for his hate was perpetually kept alive by his love for his mother.

But his father not only knew where children came from, he actually performed it - the thing that Hans could only obscurely divine. The widdler must have something to do with it, for his own grew excited whenever he thought of these things - and it must be a big widdler too, bigger than Hans's own. If he listened to these premonitory sensations he could only suppose that it was a question of some act of violence performed upon his mother, of smashing something, of making an opening into something, of forcing a way into an enclosed space - such were the impulses that he felt stirring within him. But although the sensations of his penis had put him on the road to postulating a vagina, yet he could not solve the problem, for within his experience no such thing existed as his widdler required. On the contrary, his conviction that his mother possessed a penis just as he did stood in the way of any solution. His attempt at discovering what it was that had to be done with his mother in order that she might have children sank down into his unconscious; and his two active impulses - the hostile one towards his father and the sadistic-tender one towards his mother - could be put to no use, the first because of the love that existed side by side with the hatred, and the second because of the perplexity in which his infantile sexual theories left him.

It deserves to be noticed that the ideational content of Hans's phobia as it then stood had to be submitted to one further process of distortion and substitution before his consciousness took cognizance of it. Hans's first formulation of his anxiety was: 'the horse will bite me'; and this was derived from another episode at Gmunden, which was on the one hand related to his hostile wishes towards his father and on the other hand was reminiscent of the warning he had been given against masturbation. Some interfering influence, emanating from his parents perhaps, had made itself felt. I am not certain whether the reports upon Hans were at that time drawn up with sufficient care to enable us to decide whether he expressed his anxiety in this form before or not until after his mother had taken him to task on the subject of masturbating. I should be inclined to suspect that it was not until afterwards, though this would contradict the account given in the case history. At any rate, it is evident that at every point Hans's hostile complex against his father screened his lustful one about his mother, just as it was the first to be disclosed and dealt with in the analysis.
This allows us, therefore, to make a radical distinction. We shall probably come to understand the case more deeply if we turn to those other components which do fulfil the two conditions that have just been mentioned. These other components were tendencies in Hans which had already been suppressed and which, so far as we can tell, had never been able to find uninhibited expression: hostile and jealous feelings towards his father, and sadistic impulses (premonitions, as it were, of copulation) towards his mother. These early suppressions may perhaps have gone to form the predisposition for his subsequent illness. These aggressive propensities of Hans's found no outlet, and as soon as there came a time of privation and of intensified sexual excitement, they tried to break their way out with reinforced strength. It was then that the battle which we call his 'phobia' burst out. During the course of it a part of the repressed ideas, in a distorted form and transposed on to another complex, forced their way into consciousness as the content of the phobia. But it was a decidedly paltry success. Victory lay with the forces of repression; and they made use of the opportunity to extend their domain over components other than those that had rebelled. This last circumstance, however, does not in the least alter the fact that the essence of Hans's illness was entirely dependent upon the nature of the instinctual components that had to be repulsed. The content of his phobia was such as to impose a very great measure of restriction upon his freedom of movement, and that was its purpose. It was therefore a powerful reaction against the obscure impulses to movement which were especially directed against his mother. For Hans horses had always typified pleasure in movement ('I'm a young horse', he had said as he jumped about); but since this pleasure in movement included the impulse to copulate, the neurosis imposed a restriction on it and exalted the horse into an emblem of terror. Thus it would seem as though all that the repressed instincts got from the neurosis was the honour of providing pretexts for the appearance of the anxiety in consciousness. But however clear may have been the victory in Hans's phobia of the forces that were opposed to sexuality, nevertheless, since such an illness is in its very nature a compromise, this cannot have been all that the repressed instincts obtained. After all, Hans's phobia of horses was an obstacle to his going into the street, and could serve as a means of allowing him to stay at home with his beloved mother. In this way, therefore, his affection for his mother triumphantly achieved its aim. In consequence of his phobia, the lover clung to the object of his love - though, to be sure, steps had been taken to make him innocuous. The true character of a neurotic disorder is exhibited in this twofold result.

Alfred Adler, in a suggestive paper,¹ has recently developed the view that anxiety arises from the suppression of what he calls the 'aggressive instinct', and by a very sweeping synthetic process he ascribes to that instinct the chief part in human events, 'in real life and in the neurones'. As we have come to the conclusion that in our present case of phobia the anxiety is to be explained as being due to the repression of Hans's aggressive propensities (the hostile ones against his father and the sadistic ones against his mother), we seem to have produced a most striking piece of confirmation of Adler's view. I am nevertheless unable to assent to it, and indeed I regard it as a misleading generalization. I cannot bring myself to assume the existence of a special aggressive instinct alongside of the familiar instincts of self-preservation and of sex, and on an equal footing with them.² It appears to me that Adler has mistakenly promoted into a special and self-subsisting instinct what is in reality a universal and indispensable attribute of all instincts - their instinctual [triebhaft] and 'pressing' character, what might be described as their capacity for initiating movement. Nothing would then remain of the other instincts but their relation to an aim, for their relation to the means of reaching that aim would have been taken over from them by the 'aggressive instinct'. In spite of all the uncertainty and obscurity of our theory of instincts I should prefer for the present to adhere to the usual view, which leaves each instinct its own power of becoming aggressive; and I should be inclined to recognize the two instincts which became repressed in Hans as familiar components of the sexual libido.

¹ [1909b, 2117]
² [1909b, 2118]
At the next session he began by saying that he must tell me an event in his childhood. From the age of seven, as he had already told me, he had had a fear that his parents guessed his thoughts, and this fear had in fact persisted all through his life. When he was twelve years old he had been in love with a little girl, the sister of a friend of his. (In answer to a question he said that his love had not been sensual; he had not wanted to see her naked for she was too small.) But she had not shown him as much affection as he had desired. And thereupon the idea had come to him that she would be kind to him if some misfortune were to befall him; and as an instance of such a misfortune his father's death had forced itself upon his mind. He had at once rejected the idea with energy. And even now he could not admit the possibility that what had arisen in this way could have been a 'wish'; it had clearly been no more than a 'train of thought'

By way of objection I asked him why, if it had not been a wish, he had repudiated it. - Merely, he replied, on account of the content of the idea, the notion that his father might die. - I remarked that he was treating the phrase as though it were one that involved lèse-majesté; it was well known, of course, that it was equally punishable to say 'The Emperor is an ass' or to disguise the forbidden words by saying 'If any one says, etc., . . . then he will have me to reckon with.' I added that I could easily insert the idea which he had so energetically repudiated into a context which would exclude the possibility of any such repudiation: for instance, 'If my father dies, I shall kill myself upon his grave.' - He was shaken, but did not abandon his objection. I therefore broke off the argument with the remark that I felt sure this had not been the first occurrence of his idea of his father's dying; it had evidently originated at an earlier date, and some day we should have to trace back its history. - He then proceeded to tell me that a precisely similar thought had flashed through his mind a second time, six months before his father's death. At that time² he had already been in love with his lady, but financial obstacles made it impossible to think of an alliance with her. The idea had then occurred to him that his father's death might make him rich enough to marry her. In defending himself against this idea he had gone to the length of wishing that his father might leave him nothing at all, so that he might have no compensation for his terrible loss. The same idea, though in a much milder form, had come to him for a third time, on the day before his father's death. He had then thought: 'Now I may be going to lose what I love most'; and then had come the contradiction: 'No, there is some one else whose loss would be even more painful to you.' These thoughts surprised him very much, for he was quite certain that his father's death could never have been an object of his desire but only of his fear. - After his forcible enunciation of these words I thought it advisable to bring a fresh piece of theory to his notice. According to psycho-analytic theory, I told him, every fear corresponded to a former wish which was now repressed; we were therefore obliged to believe the exact contrary of what he had asserted. This would also fit in with another theoretical requirement, namely, that the unconscious must be the precise contrary of the conscious. - He was much agitated at this and very incredulous. He wondered how he could possibly have had such a wish, considering that he loved his father more than any one else in the world; there could be no doubt that he would have renounced all his own prospects of happiness if by so doing he could have saved his father's life.

[1909d, 2144]
- I answered that it was precisely such intense love as his that was the necessary precondition of the repressed hatred. In the case of people to whom he felt indifferent he would certainly have no difficulty in maintaining side by side inclinations to a moderate liking and to an equally moderate dislike: supposing, for instance, that he were an official, he might think that his chief was agreeable as a superior, but at the same time pettifogging as a lawyer and inhuman as a judge. (Shakespeare makes Brutus speak in a similar way of Julius Caesar: 'As Caesar loved me, I weep for him; as he was fortunate, I rejoice at it; as he was valiant, I honour him; but, as he was ambitious, I slew him.' But these words already strike us as rather strange, and for the very reason that we had imagined Brutus's feeling for Caesar as something deeper.) In the case of some one who was closer to him, of his wife for instance, he would wish his feelings to be unmixed, and consequently, as was only human, he would overlook her faults, since they might make him dislike her - he would ignore them as though he were blind to them. So it was precisely the intensity of his love that would not allow his hatred - though to give it such a name was to caricature the feeling - to remain conscious. To be sure, the hatred must have a source, and to discover that source was certainly a problem; his own statements pointed to the time when he was afraid that his parents guessed his thoughts. On the other hand, too, it might be asked why this intense love of his had not succeeded in extinguishing his hatred, as usually happened where there were two opposing impulses. We could only presume that the hatred must flow from some source, must be connected with some particular cause, which made it indestructible. On the one hand, then, some connection of this sort must be keeping his hatred for his father alive, while on the other hand, his intense love prevented it from becoming conscious. Therefore nothing remained for it but to exist in the unconscious, though it was able from time to time to flash out for a moment into consciousness.

[1909d, 2144]
He admitted that all of this sounded quite plausible, but he was naturally not in the very least convinced by it.¹ He would venture to ask, he said, how it could have remissions, how it could appear for a moment when he was twelve years old, and again when he was twenty, and then once more two years later, this time for good. He could not believe that his hostility had been extinguished in the intervals, and yet during them there had been no sign of self-reproaches. - To this I replied that whenever any one asked a question like that, he was already prepared with an answer; he needed only to be encouraged to go on talking. - He then proceeded, somewhat disconnectedly as it seemed, to say that he had been his father's best friend, and that his father had been his. Except on a few subjects, upon which fathers and sons usually hold aloof from one another - (What could he mean by that?) -, there had been a greater intimacy between them than there now was between him and his best friend. As regards the lady for whose sake he had sacrificed his father in that idea of his, it was true that he had loved her very much, but he had never felt really sensual wishes towards her, such as he had constantly had in his childhood. Altogether, in his childhood his sensual impulses had been much stronger than during his puberty. - At this I told him I thought he had now produced the answer we were waiting for, and had at the same time discovered the third great characteristic of the unconscious. The source from which his hostility to his father derived its indestructibility was evidently something in the nature of sensual desires, and in that connection he must have felt his father as in some way or other an interference. A conflict of this kind, I added, between sensuality and childish love was entirely typical. The remissions he had spoken of had occurred because the premature explosion of his sensual feelings had had as its immediate consequence a considerable diminution of their violence. It was not until he was once more seized with intense erotic desires that his hostility reappeared again owing to the revival of the old situation. I then got him to agree that I had not led him on to the subject either of childhood or of sex, but that he had raised them both of his own free will. - He then went on to ask why he had not simply come to a decision, at the time he was in love with the lady, that his father's interference with that love could not for a moment weigh against his love of his father. - I replied that it was scarcely possible to destroy a person in absentia. Such a decision would only have been possible if the wish that he took objection to had made its first appearance on that occasion; whereas, as a matter of fact, it was a long-repressed wish, towards which he could not behave otherwise than he had formerly done, and which was consequently immune from destruction. This wish (to get rid of his father as being an interference) must have originated at a time when circumstances had been very different - at a time, perhaps, when he had not loved his father more than the person whom he desired sensually, or when he was incapable of making a clear decision. It must have been in his very early childhood, therefore, before he had reached the age of six, and before the date at which his memory became continuous; and things must have remained in the same state ever since. - With this piece of construction our discussion was broken off for the time being.

At the next session, which was the seventh, he took up the same subject once more. He could not believe, he said, that he had ever entertained such a wish against his father. He remembered a story of Sudermann's, he went on, that had made a deep impression upon him. In this story there was a woman who, as she sat by her sister's sick-bed, felt a wish that her sister should die so that she herself might marry her husband. The woman thereupon committed suicide, thinking she was not fit to live after being guilty of such baseness. He could understand this, he said, and it would be only right if his thoughts were the death of him, for he deserved nothing less.¹ - I remarked that it was well known to us that patients derived a certain satisfaction from their sufferings, so that in reality they all resisted their own recovery to some extent. He must never lose sight of the fact that a treatment like ours proceeded to the accompaniment of a constant resistance; I should be repeatedly reminding him of this fact.

[1909d, 2145]

[1909d, 2146]
He then went on to say that he would like to speak of a criminal act, whose author he did not recognize as himself, though he quite clearly recollected committing it. He quoted a saying of Nietzsche's:² "I did this," says my Memory. "I cannot have done this," says my Pride and remains inexorable. In the end - Memory yields.' 'Well,' he continued, 'my memory has not yielded on this point.' - 'That is because you derive pleasure from your self-reproaches as a means of self-punishment.' - 'My younger brother - I am really very fond of him now, and he is causing me a great deal of worry just at present, for he wants to make what I consider a preposterous match; I have thought before now of going and killing the person concerned so as to prevent his marrying her - well, my younger brother and I used to fight a lot when we were children. We were very fond of each other at the same time, and were inseparable; but I was plainly filled with jealousy, as he was the stronger and better-looking of the two and consequently the favourite.' - 'Yes. You have already given me a description of a scene of jealousy in connection with Fräulein Lina.' - 'Very well then, on some such occasion (it was certainly before I was eight years old, for I was not going to school yet, which I began to do when I was eight) - on some such occasion, this is what I did. We both had toy guns of the usual make. I loaded mine with the ram rod and told him that if he looked up the barrel he would see something. Then, while he was looking in, I pulled the trigger. He was hit on the forehead and not hurt; but I had meant to hurt him very much indeed. Afterwards I was quite beside myself, and threw myself on the ground and asked myself however I could have done such a thing. But I did do it.' - I took the opportunity of urging my case. If he had preserved the recollection of an action so foreign to him as this, he could not, I maintained, deny the possibility of something similar, which he had now forgotten entirely, having happened at a still earlier age in relation to his father. - He then told me he was aware of having felt other vindictive impulses, this time towards the lady he admired so much, of whose character he painted a glowing picture. It might be true, he said, that she could not love easily; but she was reserving her whole self for the one man to whom she would some day belong. She did not love him. When he had become certain of that, a conscious phantasy had taken shape in his mind of how he should grow very rich and marry some one else, and should then take her to call on the lady in order to hurt her feelings. But at that point the phantasy had broken down, for he had been obliged to own to himself that the other woman, his wife, was completely indifferent to him; then his thoughts had become confused, till finally it had been clearly borne in upon him that this other woman would have to die. In this phantasy, just as in his attempt upon his brother, he recognized the quality of cowardice which was so particularly horrible to him.³ - In the further course of our conversation I pointed out to him that he ought logically to consider himself as in no way responsible for any of these traits in his character; for all of these reprehensible impulses originated from his infancy, and were only derivatives of his infantile character surviving in his unconscious; and he must know that moral responsibility could not be applied to children. It was only by a process of development, I added, that a man, with his moral responsibility, grew up out of the sum of his infantile predispositions.⁴ He expressed a doubt, however, whether all his evil impulses had originated from that source. But I promised to prove it to him in the course of the treatment.

[1909d, 2146]

¹ This sense of guilt involves the most glaring contradiction of his opening denial that he had ever entertained such an evil wish against his father. This is a common type of reaction to repressed material which has become conscious: the 'No' with which the fact is first denied is immediately followed by a confirmation of it, though, to begin with, only an indirect one.

[1909d, 2146]
By all accounts our patient's father was a most excellent man. Before his marriage he had been a non-commissioned officer, and, as relics of that period of his life, he had retained a straightforward soldierly manner and a *penchant* for using downright language. Apart from those virtues which are celebrated upon every tombstone, he was distinguished by a hearty sense of humour and a kindly tolerance towards his fellow-men. That he could be hasty and violent was certainly not inconsistent with his other qualities, but was rather a necessary complement to them; but it occasionally brought down the most severe castigations upon the children, while they were young and naughty. When they grew up, however, he differed from other fathers in not attempting to exalt himself into a sacrosanct authority, but in sharing with them a knowledge of the little failures and misfortunes of his life with good-natured candour. His son was certainly not exaggerating when he declared that they had lived together like the best of friends, except upon a single point (p. 2145). And it must no doubt have been in connection with that very point that thoughts about his father's death had occupied his mind when he was a small boy with unusual and undue intensity (p. 2133), and that those thoughts made their appearance in the wording of the obsessional ideas of his childhood; and it can only have been in that same connection that he was able to wish for his father's death, in order that a certain little girl's sympathy might be aroused and that she might behave more kindly towards him (p. 2144).

[1909d, 2158]

There can be no question that there was something in the sphere of sexuality that stood between the father and son, and that the father had come into some sort of opposition to the son's prematurely developed erotic life. Several years after his father's death, the first time he experienced the pleasurable sensations of copulation, an idea sprang into his mind: 'This is glorious! One might murder one's father for this!' This was at once an echo and an elucidation of the obsessional ideas of his childhood. Moreover, his father, shortly before his death, had directly opposed what later became our patient's dominating passion. He had noticed that his son was always in the lady's company, and had advised him to keep away from her, saying that it was imprudent of him and that he would only make a fool of himself.

[1909d, 2158]

It seemed to the patient not a little strange that he should be impelled to masturbate precisely upon such beautiful and uplifting occasions as these. But I could not help pointing out that these two occasions had something in common - a prohibition, and the defiance of a command.

[1909d, 2160]
Starting from these indications and from other data of a similar kind, I ventured to put forward a construction to the effect that when he was a child of under six he had been guilty of some sexual misdemeanour connected with masturbation and had been soundly castigated for it by his father. This punishment, according to my hypothesis, had, it was true, put an end to his masturbating, but on the other hand it had left behind it an ineradicable grudge against his father and had established him for all time in his role of an interferer with the patient's sexual enjoyment.¹ To my great astonishment the patient then informed me that his mother had repeatedly described to him an occurrence of this kind which dated from his earliest childhood and had evidently escaped being forgotten by her on account of its remarkable consequences. He himself, however, had no recollection of it whatever. The tale was as follows. When he was very small - it became possible to establish the date more exactly owing to its having coincided with the fatal illness of an elder sister - he had done something naughty, for which his father had given him a beating. The little boy had flown into a terrible rage and had hurled abuse at his father even while he was under his blows. But as he knew no bad language, he had called him all the names of common objects that he could think of, and had screamed: 'You lamp! You towel! You plate!' and so on. His father, shaken by such an outburst of elemental fury, had stopped beating him, and had declared: 'The child will be either a great man or a great criminal!'² The patient believed that the scene made a permanent impression upon himself as well as upon his father. His father, he said, never beat him again; and he also attributed to this experience a part of the change which came over his own character. From that time forward he was a coward - out of fear of the violence of his own rage. His whole life long, moreover, he was terribly afraid of blows, and used to creep away and hide, filled with terror and indignation, when one of his brothers or sisters was beaten.

¹ [1909d, 2161]
² [1909d, 2161]

It is seldom that we are in the fortunate position of being able, as in the present instance, to establish the facts upon which these tales of the individual's prehistoric past are based, by recourse to the unimpeachable testimony of a grown-up person. Even so, the statement made by our patient's mother leaves the way open to various possibilities. That she did not proclaim the sexual character of the offence for which the child was punished may have been due to the activity of her own censorship; for with all parents it is precisely this sexual element in their children's past that their own censorship is most anxious to eliminate. But it is just as possible that the child was reproved by his nurse or by his mother herself for some commonplace piece of naughtiness of a non-sexual nature, and that his reaction was so violent that he was castigated by his father. In phantasies of this kind nurses and servants are regularly replaced by the superior figure of the mother. A deeper interpretation of the patient's dreams in relation to this episode revealed the clearest traces of the presence in his mind of an imaginative production of a positively epic character. In this his sexual desires for his mother and sister and his sister's premature death were linked up with the young hero's chastisement at his father's hand. It was impossible to unravel this tissue of phantasy thread by thread; the therapeutic success of the treatment was precisely what stood in the way of this. The patient recovered, and his ordinary life began to assert its claims: there were many tasks before him, which he had already neglected far too long, and which were incompatible with a continuation of the treatment. I am not to be blamed, therefore, for this gap in the analysis. The scientific results of psycho-analysis are at present only a by-product of its therapeutic aims, and for that reason it is often just in those cases where treatment fails that most discoveries are made.

[1909d, 2162]
The content of the sexual life of infancy consists in auto-erotic activity on the part of the dominant sexual components, in traces of object-love, and in the formation of that complex which deserves to be called the nuclear complex of the neuroses. It is the complex which comprises the child's earliest impulses, alike tender and hostile, towards its parents and brothers and sisters, after its curiosity has been awakened - usually by the arrival of a new baby brother or sister. The uniformity of the content of the sexual life of children, together with the unvarying character of the modifying tendencies which are later brought to bear upon it, will easily account for the constant sameness which as a rule characterizes the phantasies that are constructed around the period of childhood, irrespective of how greatly or how little real experiences have contributed towards them. It is entirely characteristic of the nuclear complex of infancy that the child's father should be assigned the part of a sexual opponent and of an interferer with auto-erotic sexual activities; and real events are usually to a large extent responsible for bringing this about.

[1909d, 2162]

A discussion of this childhood scene will be found in the footnote, and here I will only remark that its emergence shook the patient for the first time in his refusal to believe that at some prehistoric period in his childhood he had been seized with fury (which had subsequently become latent) against the father whom he loved so much. I must confess that I had expected it to have a greater effect, for the incident had been described to him so often - even by his father himself - that there could be no doubt of its objective reality. But, with that capacity for being illogical which never fails to bewilder one in such highly intelligent people as obsessional neurotics, he kept urging against the evidential value of the story the fact that he himself could not remember the scene. And so it was only along the painful road of transference that he was able to reach a conviction that his relation to his father really necessitated the postulation of this unconscious complement. Things soon reached a point at which, in his dreams, his waking phantasies, and his associations, he began heaping the grossest and filthiest abuse upon me and my family, though in his deliberate actions he never treated me with anything but the greatest respect. His demeanour as he repeated these insults to me was that of a man in despair. 'How can a gentleman like you, sir,' he used to ask, 'let yourself be abused in this way by a low, good-for-nothing fellow like me? You ought to turn me out: that's all I deserve.' While he talked like this, he would get up from the sofa and roam about the room, - a habit which he explained at first as being due to delicacy of feeling: he could not bring himself, he said, to utter such horrible things while he was lying there so comfortably. But soon he himself found a more cogent explanation, namely, that he was avoiding my proximity for fear of my giving him a beating. If he stayed on the sofa he behaved like some one in desperate terror trying to save himself from castigations of terrific violence; he would bury his head in his hands, cover his face with his arm, jump up suddenly and rush away, his features distorted with pain, and so on. He recalled that his father had had a passionate temper, and sometimes in his violence had not known where to stop. Thus, little by little, in this school of suffering, the patient won the sense of conviction which he had lacked - though to any disinterested mind the truth would have been almost self-evident.

[1909d, 2163]
In my description I shall, as I have already said, content myself with the briefest possible summary of the circumstances. Obviously the first problem to be solved was why the two speeches of the Czech captain - his rat story, and his request to the patient that he should pay back the money to Lieutenant A. - should have had such an agitating effect on him and should have provoked such violently pathological reactions. The presumption was that it was a question of 'complexive sensitiveness', and that the speeches had jarred upon certain hyperaesthetic spots in his unconscious. And so it proved to be. As always happened with the patient in connection with military matters, he had been in a state of unconscious identification with his father, who had seen many years' service and had been full of stories of his soldiering days. Now it happened by chance - for chance may play a part in the formation of a symptom, just as the wording may help in the making of a joke - that one of his father's little adventures had an important element in common with the captain's request. His father, in his capacity as non-commissioned officer, had control over a small sum of money and had on one occasion lost it at cards. (Thus he had been a 'Spielratte'.¹) He would have found himself in a serious position if one of his comrades had not advanced him the amount. After he had left the army and become well-off, he had tried to find this friend in need so as to pay him back the money, but had not managed to trace him. The patient was uncertain whether he had ever succeeded in returning the money. The recollection of this sin of his father's youth was painful to him, for, in spite of appearances, his unconscious was filled with hostile strictures upon his father's character. The captain's words, 'You must pay back the 3.80 kronen to Lieutenant A.', had sounded to his ears like an allusion to this unpaid debt of his father's.

But the information that the young lady at the post office at Z-- had herself paid the charges due upon the packet, with a complimentary remark about himself,¹ had intensified his identification with his father in quite another direction. At this stage in the analysis he brought out some new information, to the effect that the landlord of the inn at the little place where the post office was had had a pretty daughter. She had been decidedly encouraging to the smart young officer, so that he had thought of returning there after the manoeuvres were over and of trying his luck with her. Now, however, she had a rival in the shape of the young lady at the post office. Like his father in the tale of his marriage, he could afford now to hesitate upon which of the two he should bestow his favours when he had finished his military service. We can see at once that his singular indecision whether he should travel to Vienna or go back to the place where the post office was, and the constant temptation he felt to turn back while he was on the journey (p. 2140), were not so senseless as they seemed to us at first. To his conscious mind, the attraction exercised upon him by Z--, the place where the post office was, was explained by the necessity of seeing Lieutenant A. and fulfilling the vow with his assistance. But in reality what was attracting him was the young lady at the post office, and the lieutenant was merely a good substitute for her, since he had lived at the same place and had himself been in charge of the military postal service. And when subsequently he heard that it was not Lieutenant A. but another officer B., who had been on duty at the post office that day, he drew him into his combination as well; and he was then able to reproduce in his deliria in connection with the two officers the hesitation he felt between the two girls who were so kindly disposed towards him.² [1909d, 2165]
If we wish to obtain a grasp of the psychical forces whose interplay built up this neurosis, we must turn back to what we have learnt from the patient on the subject of the precipitating causes of his falling ill as a grown-up man and as a child. He fell ill when he was in his twenties on being faced with a temptation to marry another woman instead of the one whom he had loved so long; and he avoided a decision of this conflict by postponing all the necessary preliminary actions. The means for doing this was given him by his neurosis. His hesitation between the lady he loved and the other girl can be reduced to a conflict between his father's influence and his love for his lady, or, in other words, to a conflicting choice between his father and his sexual object, such as had already subsisted (judging from his recollections and obsessional ideas) in his remote childhood. All through his life, moreover, he was unmistakably victim to a conflict between love and hatred, in regard both to his lady and to his father. His phantasies of revenge and such obsessional phenomena as his obsession for understanding and his exploit with the stone in the road bore witness to his divided feelings; and they were to a certain degree comprehensible and normal, for the lady by her original refusal and subsequently by her coolness had given him some excuse for hostility. But his relations with his father were dominated by a similar division of feeling, as we have seen from our translation of his obsessional thoughts; and his father, too, must have given him an excuse for hostility in his childhood, as indeed we have been able to establish almost beyond question. His attitude towards the lady - a compound of tenderness and hostility - came to a great extent within the scope of his conscious knowledge; at most he deceived himself over the degree and violence of his negative feelings. But his hostility towards his father, on the contrary, though he had once been acutely conscious of it, had long since vanished from his ken, and it was only in the teeth of the most violent resistance that it could be brought back into his consciousness. We may regard the repression of his infantile hatred of his father as the event which brought his whole subsequent career under the dominion of the neurosis.

Let us return to the sexual development of children. We have some arrears to make up owing to our having paid more attention to the somatic than to the mental phenomena of sexual life. The child's first choice of an object, which derives from its need for help, claims our further interest. Its choice is directed in the first instance to all those who look after it, but these soon give place to its parents. Children's relations to their parents, as we learn alike from direct observations of children and from later analytic examination of adults, are by no means free from elements of accompanying sexual excitation. The child takes both of its parents, and more particularly one of them, as the object of its erotic wishes. In so doing, it usually follows some indication from its parents, whose affection bears the clearest characteristics of a sexual activity, even though of one that is inhibited in its aims. As a rule a father prefers his daughter and a mother her son; the child reacts to this by wishing, if he is a son, to take his father's place, and, if she is a daughter, her mother's. The feelings which are aroused in these relations between parents and children and in the resulting ones between brothers and sisters are not only of a positive or affectionate kind but also of a negative or hostile one. The complex which is thus formed is doomed to early repression; but it continues to exercise a great and lasting influence from the unconscious. It is to be suspected that, together with its extensions, it constitutes the nuclear complex of every neurosis, and we may expect to find it no less actively at work in other regions of mental life. The myth of King Oedipus, who killed his father and took his mother to wife, reveals, with little modification, the infantile wish, which is later opposed and repudiated by the barrier against incest. Shakespeare's Hamlet is equally rooted in the soil of the incest-complex, but under a better disguise.
If Leonardo was successful in reproducing on Mona Lisa's face the double meaning which this smile contained, the promise of unbounded tenderness and at the same time sinister menace (to quote Pater's phrase), then here too he had remained true to the content of his earliest memory. For his mother's tenderness was fateful for him; it determined his destiny and the privations that were in store for him. The violence of the caresses, to which his phantasy of the vulture points, was only too natural. In her love for her child the poor forsaken mother had to give vent to all her memories of the caresses she had enjoyed as well as her longing for new ones; and she was forced to do so not only to compensate herself for having no husband, but also to compensate her child for having no father to fondle him. So, like all unsatisfied mothers, she took her little son in place of her husband, and by the too early maturing of his erotism robbed him of a part of his masculinity. A mother's love for the infant she suckles and cares for is something far more profound than her later affection for the growing child. It is in the nature of a completely satisfying love-relation, which not only fulfils every mental wish but also every physical need; and if it represents one of the forms of attainable human happiness, that is in no little measure due to the possibility it offers of satisfying, without reproach, wishful impulses which have long been repressed and which must be called perverse.¹ In the happiest young marriage the father is aware that the baby, especially if he is a baby son, has become his rival, and this is the starting-point of an antagonism towards the favourite which is deeply rooted in the unconscious.

[1910c, 2288]

It cannot be doubted that his father too came to play an important part in Leonardo's psychosexual development, and not only negatively by his absence during the boy's first childhood years, but also directly by his presence in the later part of Leonardo's childhood. No one who as a child desires his mother can escape wanting to put himself in his father's place, can fail to identify himself with him in his imagination, and later to make it his task in life to gain ascendancy over him. When Leonardo was received into his grandfather's house before he had reached the age of five, his young step-mother Albiera must certainly have taken his mother's place where his feelings were concerned, and he must have found himself in what may be called the normal relationship of rivalry with his father. As we know, a decision in favour of homosexuality only takes place round about the years of puberty. When this decision had been arrived at in Leonardo's case, his identification with his father lost all significance for his sexual life, but it nevertheless continued in other spheres of non-erotic activity. We hear that he was fond of magnificence and fine clothes, and kept servants and horses, although, in Vasari's words, 'he possessed almost nothing and did little work'. The responsibility for these tastes is not to be attributed solely to his feeling for beauty: we recognize in them at the same time a compulsion to copy and to outdo his father. His father had been a great gentleman to the poor peasant girl, and the son, therefore, never ceased to feel the spur to play the great gentleman as well, the urge 'to out-herod Herod',³ to show his father what a great gentleman really looks like.

[1910c, 2291]

There is no doubt that the creative artist feels towards his works like a father. The effect which Leonardo's identification with his father had on his paintings was a fateful one. He created them and then cared no more about them, just as his father had not cared about him. His father's later concern could change nothing in this compulsion; for the compulsion derived from the impressions of the first years of childhood, and what has been repressed and has remained unconscious cannot be corrected by later experiences.

[1910c, 2292]
As an almost invariable corollary to this sexual enlightenment, the boy at the same time gains a knowledge of the existence of certain women who practise sexual intercourse as a means of livelihood, and who are for this reason held in general contempt. The boy himself is necessarily far from feeling this contempt: as soon as he learns that he too can be initiated by these unfortunates into sexual life, which till then he accepted as being reserved exclusively for 'grown-ups', he regards them only with a mixture of longing and horror. When after this he can no longer maintain the doubt which makes his parents an exception to the universal and odious norms of sexual activity, he tells himself with cynical logic that the difference between his mother and a whore is not after all so very great, since basically they do the same thing. The enlightening information he has received has in fact awakened the memory-traces of the impressions and wishes of his early infancy, and these have led to a reactivation in him of certain mental impulses. He begins to desire his mother herself in the sense with which he has recently become acquainted, and to hate his father anew as a rival who stands in the way of this wish; he comes, as we say, under the dominance of the Oedipus complex. He does not forgive his mother for having granted the favour of sexual intercourse not to himself but to his father, and he regards it as an act of unfaithfulness. If these impulses do not quickly pass, there is no outlet for them other than to run their course in phantasies which have as their subject his mother's sexual activities under the most diverse circumstances; and the consequent tension leads particularly readily to his finding relief in masturbation. As a result of the constant combined operation of the two driving forces, desire and thirst for revenge, phantasies of his mother's unfaithfulness are by far the most preferred; the lover with whom she commits her act of infidelity almost always exhibits the features of the boy's own ego, or more accurately, of his own idealized personality, grown up and so raised to a level with his father. What I have elsewhere described as the 'family romance' comprises the manifold ramifications of this imaginative activity and the way in which they are interwoven with various egoistic interests of this period of life.

[1910h, 2332]
To these phantasies which have succeeded in dominating the man's love in real life, the urge to rescue the loved one seems to bear merely a loose and superficial relation, and one that is fully accounted for by conscious reasons. By her propensity to be fickle and unfaithful the loved one brings herself into dangerous situations, and thus it is understandable that the lover should be at pains to protect her from these dangers by watching over her virtue and counteracting her bad inclinations. However, the study of people's screen-memories, phantasies and nocturnal dreams shows that we have here a particularly felicitous 'rationalization' of an unconscious motive, a process which may be compared to a successful secondary revision of a dream. In actual fact the 'rescue-motif' has a meaning and history of its own, and is an independent derivative of the mother-complex, or more accurately, of the parental complex. When a child hears that he owes his life to his parents, or that his mother gave him life, his feelings of tenderness unite with impulses which strive at power and independence, and they generate the wish to return this gift to the parents and to repay them with one of equal value. It is as though the boy's defiance were to make him say: 'I want nothing from my father; I will give him back all I have cost him.' He then forms the phantasy of rescuing his father from danger and saving his life; in this way he puts his account square with him. This phantasy is commonly enough displaced on to the emperor, king or some other great man; after being thus distorted it becomes admissible to consciousness, and may even be made use of by creative writers. In its application to a boy's father it is the defiant meaning in the idea of rescuing which is by far the most important; where his mother is concerned it is usually its tender meaning. The mother gave the child life, and it is not easy to find a substitute, of equal value for this unique gift. With a slight change of meaning, such as is easily effected in the unconscious and is comparable to the way in which in consciousness concepts shade into one another, rescuing his mother takes on the significance of giving her a child or making a child for her - needless to say, one like himself. This is not too remote from the original sense of rescuing, and the change in meaning is not an arbitrary one. His mother gave him a life - his own life - and in exchange he gives her another life, that of a child which has the greatest resemblance to himself. The son shows his gratitude by wishing to have by his mother a son who is like himself: in other words, in the rescue-phantasy he is completely identifying himself with his father. All his instincts, those of tenderness, gratitude, lustfulness, defiance and independence, find satisfaction in the single wish to be his own father. Even the element of danger has not been lost in the change of meaning; for the act of birth itself is the danger from which he was saved by his mother's efforts. Birth is both the first of all dangers to life and the prototype of all the later ones that cause us to feel anxiety, and the experience of birth has probably left behind in us the expression of affect which we call anxiety. Macduff of the Scottish legend, who was not born of his mother but ripped from her womb, was for that reason unacquainted with anxiety.

[1910h, 2333]
We are perfectly familiar with the infantile attitude of boys towards their father; it is composed of the same mixture of reverent submission and mutinous insubordination that we have found in Schreber's relation to his God, and is the unmistakable prototype of that relation, which is faithfully copied from it. But the circumstance that Schreber's father was a physician, and a most eminent physician, and one who was no doubt highly respected by his patients, is what explains the most striking characteristics of his God and those upon which he dwells in such a critical fashion. Could more bitter scorn be shown for such a physician than by declaring that he understands nothing about living men and only knows how to deal with corpses? No doubt it is an essential attribute of God to perform miracles; but a physician performs miracles too; he effects miraculous cures, as his enthusiastic clients proclaim. So that when we see that these very miracles (the material for which was provided by the patient's hypochondria) turn out to be incredible, absurd, and to some extent positively silly, we are reminded of the assertion in my *Interpretation of Dreams* that absurdity in dreams expresses ridicule and derision.¹ Evidently, therefore, it is used for the same purposes in paranoia. As regards some of the other reproaches which he levelled against God, such, for instance, as that He learned nothing by experience, it is natural to suppose that they are examples of the *tu quoque* mechanism used by children,² which, when they receive a reproof, flings it back unchanged upon the person who originated it. Similarly, the voices give us grounds for suspecting that the accusation of soul-murder brought against Flechsig was in the first instance a self-accusation.³

Thus in the case of Schreber we find ourselves once again on the familiar ground of the father-complex.¹ The patient's struggle with Flechsig became revealed to him as a conflict with God, and we must therefore construe it as an infantile conflict with the father whom he loved; the details of that conflict (of which we know nothing) are what determined the content of his delusions. None of the material which in other cases of the sort is brought to light by analysis is absent in the present one: every element is hinted at in one way or another. In infantile experiences such as this the father appears as an interferer with the satisfaction which the child is trying to obtain; this is usually of an auto-erotic character, though at a later date it is often replaced in phantasy by some other satisfaction of a less inglorious kind.² In the final stage of Schreber's delusion a magnificent victory was scored by the infantile sexual urge; for voluptuousness became God-fearing, and God Himself (his father) never tired of demanding it from him. His father's most dreaded threat, castration, actually provided the material for his wishful phantasy (at first resisted but later accepted) of being transformed into a woman. His allusion to an offence covered by the surrogate idea 'soul-murder' could not be more transparent. The chief attendant was discovered to be identical with his neighbour von W., who, according to the voices, had falsely accused him of masturbation (108). The voices said, as though giving grounds for the threat of castration: 'For you are to be *represented* as being given over to voluptuous excesses.'³ (127-8.) Finally, we come to the enforced thinking (47) to which the patient submitted himself because he supposed that God would believe he had become an idiot and would withdraw from him if he ceased thinking for a moment. This is a reaction (with which we are also familiar in other connections) to the threat or fear of losing one's reason⁴ as a result of indulging in sexual practices and especially in masturbation. Considering the enormous number of delusional ideas of a hypochondriacal nature which the patient developed, no great importance should perhaps be attached to the fact that some of them coincide word for word with the hypochondriacal fears of masturbators.⁶

[1911c, 2424]
Analysis is able to trace the associative paths along which this displacement passes - both the fortuitous paths and those with a significant content. Analysis also enables us to discover the motives for the displacement. The hatred of his father that arises in a boy from rivalry for his mother is not able to achieve uninhibited sway over his mind; it has to contend against his old-established affection and admiration for the very same person. The child finds relief from the conflict arising out of this double-sided, this ambivalent emotional attitude towards his father by displacing his hostile and fearful feelings on to a substitute for his father. The displacement cannot, however, bring the conflict to an end, it cannot effect a clear-cut severance between the affectionate and the hostile feelings. On the contrary, the conflict is resumed in relation to the object on to which the displacement has been made: the ambivalence is extended to it. There could be no doubt that little Hans was not only frightened of horses; he also approached them with admiration and interest. As soon as his anxiety began to diminish, he identified himself with the dreaded creature: he began to jump about like a horse and in his turn bit his father.¹ At another stage in the resolution of his phobia he did not hesitate to identify his parents with some other large animals.²

Of all the imagos of a childhood which, as a rule, is no longer remembered, none is more important for a youth or a man than that of his father. Organic necessity introduces into a man's relation to his father an emotional ambivalence which we have found most strikingly expressed in the Greek myth of King Oedipus. A little boy is bound to love and admire his father, who seems to him the most powerful, the kindest and the wisest creature in the world. God himself is after all only an exaltation of this picture of a father as he is represented in the mind of early childhood. But soon the other side of this emotional relationship emerges. One's father is recognized as the paramount disturber of one's instinctual life; he becomes a model not only to imitate but also to get rid of, in order to take his place. Thenceforward affectionate and hostile impulses towards him persist side by side, often to the end of one's life, without either of them being able to do away with the other. It is in this existence of contrary feelings side by side that lies the essential character of what we call emotional ambivalence.

In the second half of childhood a change sets in in the boy's relation to his father - a change whose importance cannot be exaggerated. From his nursery the boy begins to cast his eyes upon the world outside. And he cannot fail now to make discoveries which undermine his original high opinion of his father and which expedite his detachment from his first ideal. He finds that his father is no longer the mightiest, wisest and richest of beings; he grows dissatisfied with him, he learns to criticize him and to estimate his place in society; and then, as a rule, he makes him pay heavily for the disappointment that has been caused by him. Everything that is hopeful, as well as everything that is unwelcome, in the new generation is determined by this detachment from the father.
I do not doubt that this was really his attitude towards his father during the tedious illness and that his boastful assurances of his filial piety were meant to distract him from these memories. Under such conditions the death-wish against a father is apt to become active and to hide itself under the mask of such sympathetic reflections as that 'it would be a happy release for him'. But please observe that here we have passed a barrier in the latent dream-thoughts themselves. No doubt the first portion of them was unconscious only temporarily - that is, during the construction of the dream; but his hostile impulses against his father must have been permanently unconscious. They may have originated from scenes in his childhood and have occasionally slipped into consciousness, timidly and disguised, during his father's illness. We can assert this with greater certainty of other latent thoughts which have made unmistakable contributions to the content of the dream. Nothing, indeed, is to be discovered in the dream of his hostile impulses towards his father. But if we look for the roots of such hostility to a father in childhood, we shall recall that fear of a father is set up because, in the very earliest years, he opposes a boy's sexual activities, just as he is bound to do once more from social motives after the age of puberty. This relation to his father applies to our dreamer as well: his love for him included a fair admixture of awe and anxiety, which had their source in his having been early deterred by threats from sexual activity.

[1916-1917, 3280]

This relation is undoubtedly a more favourable one, from the children's point of view as well. That is what our expectations demand; we find an absence of love far more repellant between parents and children than between brothers and sisters. In the former case we have, as it were, made something sacred which in the latter we have left profane. Yet daily observation can show us how frequently the emotional relations between parents and their grown-up children fall behind the ideal set up by society, how much hostility is ready to hand and would be expressed if it were not held back by admixtures of filial piety and affectionate impulses. The motives for this hostility are generally known and their tendency is to divide those of the same sex - the daughter from the mother and the father from the son. The daughter finds in her mother the authority which restricts her will and which is entrusted with the task of imposing on her the renunciation of sexual freedom which society demands; in a few instances she even finds in her a competitor who struggles against being supplanted. The same thing is repeated between the son and his father still more glaringly. In the son's eyes his father embodies every unwillingly tolerated social restraint; his father prevents him from exercising his will, from early sexual pleasure and, where there is common property in the family, from enjoying it. In the case of an heir to the throne this waiting for a father's death reaches an almost tragic height. There seems less danger to the relation between father and daughter or mother and son. This last provides the purest examples of an unchangeable affection, unimpaired by any egoistic considerations.

[1916-1917, 3294]
What I have in mind is rivalry in love, with a clear emphasis on the subject's sex. While he is still a small child, a son will already begin to develop a special affection for his mother, whom he regards as belonging to him; he begins to feel his father as a rival who disputes his sole possession. And in the same way a little girl looks on her mother as a person who interferes with her affectionate relation to her father and who occupies a position which she herself could very well fill. Observation shows us to what early years these attitudes go back. We refer to them as the 'Oedipus complex', because the legend of Oedipus realizes, with only a slight softening, the two extreme wishes that arise from the son's situation - to kill his father and take his mother to wife. I do not wish to assert that the Oedipus complex exhausts the relation of children to their parents: it can easily be far more complicated. The Oedipus complex can, moreover, be developed to a greater or less strength, it can even be reversed; but it is a regular and very important factor in a child's mental life, and there is more danger of our under estimating rather than over-estimating its influence and that of the developments which proceed from it. Incidentally, children often react in their Oedipus attitude to a stimulus coming from their parents, who are frequently led in their preferences by difference of sex, so that the father will choose his daughter and the mother her son as a favourite, or, in case of a cooling-off in the marriage, as a substitute for a love-object that has lost its value.

[1916-1917, 3295]

What, then, can be gathered about the Oedipus complex from the direct observation of children at the time of their making their choice of an object before the latency period? Well, it is easy to see that the little man wants to have his mother all to himself, that he feels the presence of his father as a nuisance, that he is resentful if his father indulges in any signs of affection towards his mother and that he shows satisfaction when his father has gone on a journey or is absent. He will often express his feelings directly in words and promise his mother to marry her. It will be thought that this amounts to little compared to the deeds of Oedipus; but in fact it is enough, it is the same thing at root. Observation is often obscured by the circumstance that on other occasions the same child will simultaneously give evidence of great affection for his father. But contrary - or, as it is better to say, 'ambivalent' - emotional attitudes, which in adults would lead to a conflict, remain compatible with each other for a long time in children, just as later they find a permanent place beside each other in the unconscious. It will also be objected that the little boy's conduct arises from egoistic motives and gives no grounds for postulating an erotic complex: the child's mother attends to all his needs, so that he has an interest in preventing her from looking after anyone else. This also is true; but it will soon become clear that in this situation as in similar ones the egoistic interest is merely affording a point of support to which the erotic trend is attached. The little boy may show the most undisguised sexual curiosity about his mother, he may insist upon sleeping beside her at night, he may force his presence on her while she is dressing or may even make actual attempts at seducing her, as his mother will often notice and report with amusement - all of which puts beyond doubt the erotic nature of his tie with his mother. Nor must it be forgotten that the mother devotes the same attention to a little daughter without producing the same result and that the father often competes with her in looking after the boy and yet fails to gain the same significance as she does. In short, the factor of sexual preference cannot be eliminated from the situation by any criticism. From the standpoint of egoistic interest it would be simply foolish of the little man not to prefer to put up with having two people in his service rather than only one of them.

[1916-1917, 3399]
But let us now turn from the direct observation of children to the analytic examination of adults who have become neurotic. What help does analysis give towards a further knowledge of the Oedipus complex? That can be answered in a word. Analysis confirms all that the legend describes. It shows that each of these neurotics has himself been an Oedipus or, what comes to the same thing, has, as a reaction to the complex, become a Hamlet. The analytic account of the Oedipus complex is, of course, a magnification and coarsening of the infantile sketch. The hatred of the father, the death-wishes against him, are no longer hinted at timidly, the affection for the mother admits that its aim is to possess her as a woman. Should we really attribute such blatant and extreme emotional impulses to the tender years of childhood, or is analysis deceiving us by an admixture of some new factor? It is not hard to find one. Whenever someone gives an account of a past event, even if he is a historian, we must take into account what he unintentionally puts back into the past from the present or from some intermediate time, thus falsifying his picture of it. In the case of a neurotic it is even a question whether this putting back is an entirely unintentional one; later on we shall have to discover reasons for this and have to do justice in general to the fact of 'retrospective phantasying'. We can easily see, too, that hatred of the father is reinforced by a number of factors arising from later times and circumstances and that the sexual desires towards the mother are cast into forms which must have been alien as yet to a child. But it would be a vain effort to seek to explain the whole Oedipus complex by retrospective phantasying and to attach it to later times. Its infantile core and more or less of its accessories remain as they were confirmed by the direct observation of children.

[1916-1917, 3401]

The clinical fact which meets us behind the form of the Oedipus complex as it is established by analysis is of the highest practical significance. We learn that at puberty, when the sexual instinct first makes its demands in full strength, the old familiar incestuous objects are taken up again and freshly cathected with libido. The infantile object-choice was only a feeble one, but it was a prelude, pointing the direction for the object-choice at puberty. At this point, then, very intense emotional processes come into play, following the direction of the Oedipus complex or reacting against it, processes which, however, since their premisses have become intolerable, must to a large extent remain apart from consciousness. From this time onwards, the human individual has to devote himself to the great task of detaching himself from his parents, and not until that task is achieved can he cease to be a child and become a member of the social community. For the son this task consists in detaching his libidinal wishes from his mother and employing them for the choice of a real outside love-object, and in reconciling himself with his father if he has remained in opposition to him, or in freeing himself from his pressure if, as a reaction to his infantile rebelliousness, he has become subservient to him. These tasks are set to everyone; and it is remarkable how seldom they are dealt with in an ideal manner - that is, in one which is correct both psychologically and socially. By neurotics, however, no solution at all is arrived at: the son remains all his life bowed beneath his father's authority and he is unable to transfer his libido to an outside sexual object. With the relationship changed round, the same fate can await the daughter. In this sense the Oedipus complex may justly be regarded as the nucleus of the neuroses.

[1916-1917, 3402]

We also concluded from the first incomplete analysis of the dream that the wolf may have been a father-surrogate; so that, in that case, this first anxiety-dream would have brought to light the fear of his father which from that time forward was to dominate his life. This conclusion, indeed, was in itself not yet binding. But if we put together as the result of the provisional analysis what can be derived from the material produced by the dreamer, we then find before us for reconstruction some such fragments as these:

[1918b, 3525]
In the scene with Grusha (at the age of two and a half) we see the little boy at the beginning of a development which, except perhaps for its prematurity, deserves to be considered normal; thus we find in it identification with his father, and urethral erotism representing masculinity. It was also completely under the sway of the primal scene. We have hitherto regarded his identification with his father as being narcissistic; but if we take the content of the primal scene into account we cannot deny that it had already reached the stage of genital organization. His male genital organ had begun to play its part and it continued to do so under the influence of his seduction by his sister.

[1918b, 3583]

No certain decision can be reached from the analysis of a single case like this. On an unprejudiced view one gets an impression that the child turned his experience into a game from another motive. At the outset he was in a passive situation - he was overpowered by the experience; but, by repeating it, unpleasurable though it was, as a game, he took on an active part. These efforts might be put down to an instinct for mastery that was acting independently of whether the memory was in itself pleasurable or not. But still another interpretation may be attempted. Throwing away the object so that it was 'gone' might satisfy an impulse of the child's, which was suppressed in his actual life, to revenge himself on his mother for going away from him. In that case it would have a defiant meaning: 'All right, then, go away! I don't need you. I'm sending you away myself.' A year later, the same boy whom I had observed at his first game used to take a toy, if he was angry with it, and throw it on the floor, exclaiming: 'Go to the front!' He had heard at that time that his absent father was 'at the front', and was far from regretting his absence; on the contrary he made it quite clear that he had no desire to be disturbed in his sole possession of his mother.¹ We know of other children who liked to express similar hostile impulses by throwing away objects instead of persons.² We are therefore left in doubt as to whether the impulse to work over in the mind some overpowering experience so as to make oneself master of it can find expression as a primary event, and independently of the pleasure principle. For, in the case we have been discussing, the child may, after all, only have been able to repeat his unpleasant experience in play because the repetition carried along with it a yield of pleasure of another sort but none the less a direct one.

[1920g, 3721]

Identification is known to psycho-analysis as the earliest expression of an emotional tie with another person. It plays a part in the early history of the Oedipus complex. A little boy will exhibit a special interest in his father; he would like to grow like him and be like him, and take his place everywhere. We may say simply that he takes his father as his ideal. This behaviour has nothing to do with a passive or feminine attitude towards his father (and towards males in general); it is on the contrary typically masculine. It fits in very well with the Oedipus complex, for which it helps to prepare the way.

[1921c, 3797]
At the same time as this identification with his father, or a little later, the boy has begun to develop a true object-cathexis towards his mother according to the attachment type. He then exhibits, therefore, two psychologically distinct ties: a straightforward sexual object-cathexis towards his mother and an identification with his father which takes him as his model. The two subsist side by side for a time without any mutual influence or interference. In consequence of the irresistible advance towards a unification of mental life, they come together at last; and the normal Oedipus complex originates from their confluence. The little boy notices that his father stands in his way with his mother. His identification with his father then takes on a hostile colouring and becomes identical with the wish to replace his father in regard to his mother as well. Identification, in fact, is ambivalent from the very first; it can turn into an expression of tenderness as easily as into a wish for someone's removal. It behaves like a derivative of the first, oral phase of the organization of the libido, in which the object that we long for and prize is assimilated by eating and is in that way annihilated as such. The cannibal, as we know, has remained at this standpoint; he has a devouring affection for his enemies and only devours people of whom he is fond.

The subsequent history of this identification with the father may easily be lost sight of. It may happen that the Oedipus complex becomes inverted, and that the father is taken as the object of a feminine attitude, an object from which the directly sexual instincts look for satisfaction; in that event the identification with the father has become the precursor of an object-tie with the father. The same holds good, with the necessary substitutions, of the baby daughter as well.

It is easy to state in a formula the distinction between an identification with the father and the choice of the father as an object. In the first case one's father is what one would like to be and in the second he is what one would like to have. The distinction, that is, depends upon whether the tie attaches to the subject or to the object of the ego. The former kind of tie is therefore already possible before any sexual object-choice has been made. It is much more difficult to give a clear metapsychological representation of the distinction. We can only see that identification endeavours to mould a person's own ego after the fashion of the one that has been taken as a model.

In the very earliest years of childhood (approximately between the ages of two and five) a convergence of the sexual impulses occurs of which, in the case of boys, the object is the mother. This choice of an object, in conjunction with a corresponding attitude of rivalry and hostility towards the father, provides the content of what is known as the Oedipus complex, which in every human being is of the greatest importance in determining the final shape of his erotic life. It has been found to be characteristic of a normal individual that he learns to master his Oedipus complex, whereas the neurotic subject remains involved in it.
In its simplified form the case of a male child may be described as follows. At a very early age the little boy develops an object-cathexis for his mother, which originally related to the mother's breast and is the prototype of an object-choice on the anaclitic model; the boy deals with his father by identifying himself with him. For a time these two relationships proceed side by side, until the boy's sexual wishes in regard to his mother become more intense and his father is perceived as an obstacle to them; from this the Oedipus complex originates.² His identification with his father then takes on a hostile colouring and changes into a wish to get rid of his father in order to take his place with his mother. Henceforward his relation to his father is ambivalent; it seems as if the ambivalence inherent in the identification from the beginning had become manifest. An ambivalent attitude to his father and an object-relation of a solely affectionate kind to his mother make up the content of the simple positive Oedipus complex in a boy. [1923b, 3965]

It would appear, therefore, that in both sexes the relative strength of the masculine and feminine sexual dispositions is what determines whether the outcome of the Oedipus situation shall be an identification with the father or with the mother. This is one of the ways in which bisexuality takes a hand in the subsequent vicissitudes of the Oedipus complex. The other way is even more important. For one gets an impression that the simple Oedipus complex is by no means its commonest form, but rather represents a simplification or schematization which, to be sure, is often enough justified for practical purposes. Closer study usually discloses the more complete Oedipus complex, which is twofold, positive and negative, and is due to the bisexuality originally present in children: that is to say, a boy has not merely an ambivalent attitude towards his father and an affectionate object-choice towards his mother, but at the same time he also behaves like a girl and displays an affectionate feminine attitude to his father and a corresponding jealousy and hostility towards his mother. It is this complicating element introduced by bisexuality that makes it so difficult to obtain a clear view of the facts in connection with the earliest object-choices and identifications, and still more difficult to describe them intelligibly. It may even be that the ambivalence displayed in the relations to the parents should be attributed entirely to bisexuality and that it is not, as I have represented above, developed out of identification in consequence of rivalry. [1923b, 3967]

The super-ego is, however, not simply a residue of the earliest object-choices of the id; it also represents an energetic reaction-formation against those choices. Its relation to the ego is not exhausted by the precept: 'You ought to be like this (like your father).' It also comprises the prohibition: 'You may not be like this (like your father) - that is, you may not do all that he does; some things are his prerogative.' This double aspect of the ego ideal derives from the fact that the ego ideal had the task of repressing the Oedipus complex; indeed, it is to that revolutionary event that it owes its existence. Clearly the repression of the Oedipus complex was no easy task. The child's parents, and especially his father, were perceived as the obstacle to a realization of his Oedipus wishes; so his infantile ego fortified itself for the carrying out of the repression by erecting this same obstacle within itself. It borrowed strength to do this, so to speak, from the father, and this loan was an extraordinarily momentous act. The super-ego retains the character of the father, while the more powerful the Oedipus complex was and the more rapidly it succumbed to repression (under the influence of authority, religious teaching, schooling and reading), the stricter will be the domination of the super-ego over the ego later on - in the form of conscience or perhaps of an unconscious sense of guilt. I shall presently bring forward a suggestion about the source of its power to dominate in this way - the source, that is, of its compulsive character which manifests itself in the form of a categorical imperative. [1923b, 3968]
In this we are undoubtedly right. But we are not right if we conclude further that this relation has been merely one of love. On the contrary, his mourning over the loss of his father is the more likely to turn into melancholia, the more his attitude to him bore the stamp of ambivalence. This emphasis on ambivalence, however, prepares us for the possibility of the father being subjected to a debasement, as we see happening in the painter's demonological neurosis. If we were able to learn as much about Christoph Haizmann as about a patient undergoing an analysis with us, it would be an easy matter to elicit this ambivalence, to get him to remember when and under what provocations he was given cause to fear and hate his father; and, above all, to discover what were the accidental factors that were added to the typical motives for a hatred of the father which are necessarily inherent in the natural relationship of son to father. Perhaps we might then find a special explanation for the painter's inhibition in work. It is possible that his father had opposed his wish to become a painter. If that was so, his inability to practise his art after his father's death would on the one hand be an expression of the familiar phenomenon of 'deferred obedience'; and, on the other hand, by making him incapable of earning a livelihood, it would be bound to increase his longing for his father as a protector from the cares of life. In its aspect as deferred obedience it would also be an expression of remorse and a successful self-punishment.

These two slight indications give us an idea of what the typical factor is which determines the negative side of the painter's relation to his father. What he is rebelling against is his feminine attitude to him which culminates in a phantasy of bearing him a child (the nine years). We have an accurate knowledge of this resistance from our analyses, where it takes on very strange forms in the transference and gives us a great deal of trouble. With the painter's mourning for his lost father, and the heightening of his longing for him, there also comes about in him a re-activation of his long-since repressed phantasy of pregnancy, and he is obliged to defend himself against it by a neurosis and by debasing his father.

But why should his father, after being reduced to the status of a Devil, bear this physical mark of a woman? The feature seems at first hard to interpret; but soon we find two explanations which compete with each other without being mutually exclusive. A boy's feminine attitude to his father undergoes repression as soon as he understands that his rivalry with a woman for his father's love has as a precondition the loss of his own male genitals - in other words, castration. Repudiation of the feminine attitude is thus the result of a revolt against castration. It regularly finds its strongest expression in the converse phantasy of castrating the father, of turning him into a woman. Thus the Devil's breasts would correspond to a projection of the subject's own femininity on to the father-substitute. The second explanation of these female additions to the Devil's body no longer has a hostile meaning but an affectionate one. It sees in the adoption of this shape an indication that the child's tender feelings towards his mother have been displaced on to his father; and this suggests that there has previously been a strong fixation on the mother, which, in its turn, is responsible for part of the child's hostility towards his father. Large breasts are the positive sexual characteristics of the mother even at a time when the negative characteristic of the female - her lack of a penis - is as yet unknown to the child.¹

¹ [1923d, 4014]
Among the observations made by psycho-analysis of the mental life of children there is scarcely one which sounds so repugnant and unbelievable to a normal adult as that of a boy's feminine attitude to his father and the phantasy of pregnancy that arises from it. It is only since Senatspräsident Daniel Paul Schreber, a judge presiding over a division of the Appeal Court of Saxony, published the history of his psychotic illness and his extensive recovery from it,¹ that we can discuss the subject without trepidation or apology. We learn from this invaluable book that, somewhere about the age of fifty, the Senatspräsident became firmly convinced that God - who, incidentally, exhibited distinct traits of his father, the worthy physician, Dr. Schreber - had decided to emasculate him, to use him as a woman, and to beget from him 'a new race of men born from the spirit of Schreber'. (His own marriage was childless.) In his revolt against this intention of God's, which seemed to him highly unjust and 'contrary to the Order of Things', he fell ill with symptoms of paranoia, which, however, underwent a process of involution in the course of years, leaving only a small residue behind. The gifted author of his own case history could not have guessed that in it he had uncovered a typical pathogenic factor.

The fact that moral masochism is unconscious leads us to an obvious clue. We were able to translate the expression 'unconscious sense of guilt' as meaning a need for punishment at the hands of a parental power. We now know that the wish, which so frequently appears in phantasies, to be beaten by the father stands very close to the other wish, to have a passive (feminine) sexual relation to him and is only a regressive distortion of it. If we insert this explanation into the content of moral masochism, its hidden meaning becomes clear to us. Conscience and morality have arisen through the overcoming, the desexualization, of the Oedipus complex; but through moral masochism morality becomes sexualized once more, the Oedipus complex is revived and the way is opened for a regression from morality to the Oedipus complex. This is to the advantage neither of morality nor of the person concerned. An individual may, it is true, have preserved the whole or some measure of ethical sense alongside of his masochism; but, alternatively, a large part of his conscience may have vanished into his masochism. Again, masochism creates a temptation to perform 'sinful' actions, which must then be expiated by the reproaches of the sadistic conscience (as is exemplified in so many Russian character-types) or by chastisement from the great parental power of Destiny. In order to provoke punishment from this last representative of the parents, the masochist must do what is inexpedient, must act against his own interests, must ruin the prospects which open out to him in the real world and must, perhaps, destroy his own real existence.

In boys the situation of the Oedipus complex is the first stage that can be recognized with certainty. It is easy to understand, because at that stage a child retains the same object which he previously cathected with his libido - not as yet a genital one - during the preceding period while he was being suckled and nursed. The fact, too, that in this situation he regards his father as a disturbing rival and would like to get rid of him and take his place is a straightforward consequence of the actual state of affairs. I have shown elsewhere¹ how the Oedipus attitude in little boys belongs to the phallic phase, and how its destruction is brought about by the fear of castration - that is, by narcissistic interest in their genitals. The matter is made more difficult to grasp by the complicating circumstance that even in boys the Oedipus complex has a double orientation, active and passive, in accordance with their bisexual constitution; a boy also wants to take his mother's place as the love-object of his father - a fact which we describe as the feminine attitude.

[1923d, 4015]

[1924c, 4081]

[1925j, 4147]
The process of arriving at an object, which plays such an important part in mental life, takes place alongside of the organization of the libido. After the stage of auto-eroticism, the first love-object in the case of both sexes is the mother; and it seems probable that to begin with a child does not distinguish its mother's organ of nutrition from its own body. Later, but still in the first years of infancy, the relation known as the Oedipus complex becomes established: boys concentrate their sexual wishes upon their mother and develop hostile impulses against their father as being a rival, while girls adopt an analogous attitude.¹ All of the different variations and consequences of the Oedipus complex are important; and the innately bisexual constitution of human beings makes itself felt and increases the number of simultaneously active tendencies. Children do not become clear for quite a long time about the differences between the sexes; and during this period of sexual researches they produce typical sexual theories which, being circumscribed by the incompleteness of their authors' own physical development, are a mixture of truth and error and fail to solve the problems of sexual life (the riddle of the Sphinx - that is, the question of where babies come from). We see, then, that a child's first object-choice is an incestuous one. The whole course of development that I have described is run through rapidly. For the most remarkable feature of the sexual life of man is its diphasic onset, its onset in two waves, with an interval between them. It reaches a first climax in the fourth or fifth year of a child's life. But thereafter this early efflorescence of sexuality passes off; the sexual impulses which have shown such liveliness are overcome by repression, and a period of latency follows, which lasts until puberty and during which the reaction-formations of morality, shame, and disgust are built up.² Of all living creatures man alone seems to show this diphasic onset of sexual growth, and it may perhaps be the biological determinant of his predisposition to neuroses. At puberty the impulses and object-relations of a child's early years become re-animated, and amongst them the emotional ties of its Oedipus complex. In the sexual life of puberty there is a struggle between the urges of early years and the inhibitions of the latency period. Before this, and while the child is at the highest point of its infantile sexual development, a genital organization of a sort is established; but only the male genitals play a part in it, and the female ones remain undiscovered. (I have described this as the period of phallic primacy.) At this stage the contrast between the sexes is not stated in terms of 'male' or 'female' but of 'possessing a penis' or 'castrated'. The castration complex which arises in this connection is of the profoundest importance in the formation alike of character and of neuroses.

[1925d, 4212]

The chief literary sources of my studies in this field were the well-known works of J. G. Frazer (Totemism and Exogamy and The Golden Bough), a mine of valuable facts and opinions. But Frazer effected little towards elucidating the problems of totemism; he had several times fundamentally altered his views on the subject, and the other ethnologists and prehistorians seemed in equal uncertainty and disagreement. My starting-point was the striking correspondence between the two taboo-ordinances of totemism (not to kill the totem and not to have sexual relations with any woman of the same totem-clan) and the two elements of the Oedipus complex (getting rid of the father and taking the mother to wife). I was therefore tempted to equate the totem-animal with the father; and in fact primitive peoples themselves do this explicitly, by honouring it as the forefather of the clan. There next came to my help two facts from psycho-analysis, a lucky observation of a child made by Ferenczi, which enabled me to speak of an 'infantile return of totemism', and the analysis of early animal-phobias in children, which so often showed that the animal was a substitute for the father, a substitute on to which the fear of the father derived from the Oedipus complex had been displaced. Not much was lacking to enable me to recognize the killing of the father as the nucleus of totemism and the starting-point in the formation of religion.

[1925d, 4240]
The case of the 'Wolf Man' and the somewhat less complicated one of 'Little Hans' raise a number of further considerations. But we have already made two unexpected discoveries. There can be no doubt that the instinctual impulse which was repressed in both phobias was a hostile one against the father. One might say that that impulse had been repressed by the process of being transformed into its opposite. Instead of aggressiveness on the part of the subject towards his father, there appeared aggressiveness (in the shape of revenge) on the part of his father towards the subject. Since this aggressiveness is in any case rooted in the sadistic phase of the libido, only a certain amount of degradation is needed to reduce it to the oral stage. This stage, while only hinted at in 'Little Hans's' fear of being bitten, was blatantly exhibited in the 'Wolf Man's' terror of being devoured. But, besides this, the analysis has demonstrated, beyond a shadow of doubt, the presence of another instinctual impulse of an opposite nature which had succumbed to repression. This was a tender, passive impulse directed towards the father, which had already reached the genital (phallic) level of libidinal organization. As regards the final outcome of the process of repression, this impulse seems, indeed, to have been the more important of the two; it underwent a more far-reaching regression and had a decisive influence upon the content of the phobia. In following up a single instinctual repression we have thus had to recognize a convergence of two such processes. The two instinctual impulses that have been overtaken by repression - sadistic aggressiveness towards the father and a tender passive attitude to him - form a pair of opposites. Furthermore, a full appreciation of 'Little Hans's' case shows that the formation of his phobia had had the effect of abolishing his affectionate object-cathexis of his mother as well, though the actual content of his phobia betrayed no sign of this. The process of repression had attacked almost all the components of his Oedipus complex - both his hostile and his tender impulses towards his father and his tender impulses towards his mother. In my Russian patient this state of affairs was much less obvious. [1926d, 4266]

We may suppose, therefore, that this was the way in which things happened. The sight of a woman's dead body, naked or on the point of being stripped, reminded the young man of his mother. It roused in him a longing for his mother which sprang from his Oedipus complex, and this was immediately completed by a feeling of indignation against his father. His ideas of 'father' and 'God' had not yet become widely separated; so that his desire to destroy his father could become conscious as doubt in the existence of God and could seek to justify itself in the eyes of reason as indignation about the ill-treatment of a mother object. It is of course typical for a child to regard what his father does to his mother in sexual intercourse as ill-treatment. The new impulse, which was displaced into the sphere of religion, was only a repetition of the Oedipus situation and consequently soon met with a similar fate. It succumbed to a powerful opposing current. During the actual conflict the level of displacement was not maintained: there is no mention of arguments in justification of God, nor are we told what the infallible signs were by which God proved his existence to the doubter. The conflict seems to have been unfolded in the form of a hallucinatory psychosis: inner voices were heard which uttered warnings against resistance to God. But the outcome of the struggle was displayed once again in the sphere of religion and it was of a kind predetermined by the fate of the Oedipus complex: complete submission to the will of God the Father. The young man became a believer and accepted everything he had been taught since his childhood about God and Jesus Christ. He had had a religious experience and had undergone a conversion. [1928a, 4550]
Parricide, according to a well-known view, is the principal and primal crime of humanity as well as of the individual. (See my *Totem and Taboo* 1912-13.) It is in any case the main source of the sense of guilt, though we do not know if it is the only one: researches have not yet been able to establish with certainty the mental origin of guilt and the need for expiation. But it is not necessary for it to be the only one. The psychological situation is complicated and requires elucidation. The relation of a boy to his father is, as we say, an ‘ambivalent’ one. In addition to the hate which seeks to get rid of the father as a rival, a measure of tenderness for him is also habitually present. The two attitudes of mind combine to produce identification with the father; the boy wants to be in his father's place because he admires him and wants to be like him, and also because he wants to put him out of the way. This whole development now comes up against a powerful obstacle. At a certain moment the child comes to understand that an attempt to remove his father as a rival would be punished by him with castration. So from fear of castration - that is, in the interests of preserving his masculinity - he gives up his wish to possess his mother and get rid of his father. In so far as this wish remains in the unconscious it forms the basis of the sense of guilt. We believe that what we have here been describing are normal processes, the normal fate of the so-called 'Oedipus complex'; nevertheless it requires an important amplification.

What makes hatred of the father unacceptable is fear of the father; castration is terrible, whether as a punishment or as the price of love. Of the two factors which repress hatred of the father, the first, the direct fear of punishment and castration, may be called the normal one; its pathogenic intensification seems to come only with the addition of the second factor, the fear of the feminine attitude. Thus a strong innate bisexual disposition becomes one of the preconditions or reinforcements of neurosis. Such a disposition must certainly be assumed in Dostoevsky, and it shows itself in a viable form (as latent homosexuality) in the important part played by male friendships in his life, in his strangely tender attitude towards rivals in love and in his remarkable understanding of situations which are explicable only by repressed homosexuality, as many examples from his novels show.

I am sorry, though I cannot alter the facts, if this exposition of the attitudes of hatred and love towards the father and their transformations under the influence of the threat of castration seems to readers unfamiliar with psycho-analysis unsavoury and incredible. I should myself expect that it is precisely the castration complex that would be bound to arouse the most general repudiation. But I can only insist that psycho-analytic experience has put these matters in particular beyond the reach of doubt and has taught us to recognize in them the key to every neurosis. This key, then, we must apply to our author's so-called epilepsy. So alien to our consciousness are the things by which our unconscious mental life is governed!
But what has been said so far does not exhaust the consequences of the repression of the hatred of the father in the Oedipus complex. There is something fresh to be added: namely that in spite of everything the identification with the father finally makes a permanent place for itself in the ego. It is received into the ego, but establishes itself there as a separate agency in contrast to the rest of the content of the ego. We then give it the name of super-ego and ascribe to it, the inheritor of the parental influence, the most important functions. If the father was hard, violent and cruel, the super-ego takes over those attributes from him and, in the relations between the ego and it, the passivity which was supposed to have been repressed is re-established. The super-ego has become sadistic, and the ego becomes masochistic - that is to say, at bottom passive in a feminine way. A great need for punishment develops in the ego, which in part offers itself as a victim to Fate, and in part finds satisfaction in ill-treatment by the super-ego (that is, in the sense of guilt). For every punishment is ultimately castration and, as such, a fulfilment of the old passive attitude towards the father. Even Fate is, in the last resort, only a later projection of the father.

The very surprising sexual activity of little girls in relation to their mother is manifested chronologically in oral, sadistic, and finally even in phallic trends directed towards her. It is difficult to give a detailed account of these because they are often obscure instinctual impulses which it was impossible for the child to grasp psychically at the time of their occurrence, which were therefore only interpreted by her later, and which then appear in the analysis in forms of expression that were certainly not the original ones. Sometimes we come across them as transferences on to the later, father-object, where they do not belong and where they seriously interfere with our understanding of the situation. We find the little girl's aggressive oral and sadistic wishes in a form forced on them by early repression, as a fear of being killed by her mother - a fear which, in turn, justifies her death-wish against her mother, if that becomes conscious. It is impossible to say how often this fear of the mother is supported by an unconscious hostility on the mother's part which is sensed by the girl. (Hitherto, it is only in men that I have found the fear of being eaten up. This fear is referred to the father, but it is probably the product of a transformation of oral aggressivity directed to the mother. The child wants to eat up its mother from whom it has had its nourishment; in the case of the father there is no such obvious determinant for the wish.)

It must be admitted that this historical survey has gaps in it and is uncertain at some points. But anyone who is inclined to pronounce our construction of primaeval history purely imaginary would be gravely under-estimating the wealth and evidential value of the material contained in it. Large portions of the past, which have been linked together here into a whole, are historically attested: totemism and the male confederacies, for instance. Other portions have survived in excellent replicas. Thus authorities have often been struck by the faithful way in which the sense and content of the old totem meal is repeated in the rite of the Christian Communion, in which the believer incorporates the blood and flesh of his god in symbolic form. Numerous relics of the forgotten primaeval age have survived in popular legends and fairy tales, and the analytic study of the mental life of children has provided an unexpected wealth of material for filling the gaps in our knowledge of the earliest times. As contributions to our understanding of the son's relation to the father which is of such great importance, I need only bring forward animal phobias, the fear, which strikes us as so strange, of being eaten by the father, and the enormous intensity of the dread of being castrated. There is nothing wholly fabricated in our construction, nothing which could not be supported on solid foundations.
From the mass of material I shall first bring forward some cases which relate to the development of character. Take, for instance, the girl who has reached a state of the most decided opposition to her mother. She has cultivated all those characteristics which she has seen that her mother lacked, and has avoided everything that reminded her of her mother. We may supplement this by saying that in her early years, like every female child, she adopted an identification with her mother and that she is now rebelling against this energetically. But when this girl marries and herself becomes a wife and a mother, we need not be surprised to find that she begins to grow more and more like the mother to whom she was so antagonistic, till finally the identification with her which she surmounted is unmistakably re-established. The same thing happens too with boys; and even the great Goethe, who in the period of his genius certainly looked down upon his unbending and pedantic father, in his old age developed traits which formed a part of his father's character. The outcome can become even more striking when the contrast between the two personalities is sharper. A young man whose fate it was to grow up beside a worthless father, began by developing, in defiance of him, into a capable, trustworthy and honourable person. In the prime of life his character was reversed, and thenceforward he behaved as though he had taken this same father as a model. In order not to miss the connection with our theme, we must keep in mind the fact that at the beginning of such a course of events there is always an identification with the father in early childhood. This is afterwards repudiated, and even overcompensated, but in the end establishes itself once more. [1939a, 4943]

And now for the other side of the situation. Since the transference reproduces the patient's relation with his parents, it takes over the ambivalence of that relation as well. It almost inevitably happens that one day his positive attitude towards the analyst changes over into the negative, hostile one. This too is as a rule a repetition of the past. His obedience to his father (if it is his father that is in question), his courting of his father's favour, had its roots in an erotic wish directed towards him. Some time or other that demand will press its way forward in the transference as well and insist on being satisfied. In the analytic situation it can only meet with frustration. Real sexual relations between patients and analysts are out of the question, and even the subtler methods of satisfaction, such as the giving of preference, intimacy and so on, are only sparingly granted by the analyst. A rejection of this kind is taken as the occasion for the change-over; probably things happened in the same way in the patient's childhood. [1940a [1938], 4986]

This preface is not superfluous, for it can heighten our realization of the intensity of the Oedipus complex. When a boy (from the age of two or three) has entered the phallic phrase of his libidinal development, is feeling pleasurable sensations in his sexual organ and has learnt to procure these at will by manual stimulation, he becomes his mother's lover. He wishes to possess her physically in such ways as he has divined from his observations and intuitions about sexual life, and he tries to seduce her by showing her the male organ which he is proud to own. In a word, his early awakened masculinity seeks to take his father's place with her; his father has hitherto in any case been an envied model to the boy, owing to the physical strength he perceives in him and the authority with which he finds him clothed. His father now becomes a rival who stands in his way and whom he would like to get rid of. If while his father is away he is allowed to share his mother's bed and if when his father returns he is once more banished from it, his satisfaction when his father disappears and his disappointment when he emerges again are deeply felt experiences. This is the subject of the Oedipus complex, which the Greek legend has translated from the world of a child's phantasy into pretended reality. Under the conditions of our civilization it is invariably doomed to a frightening end. [1940a [1938], 4997]
The boy's mother has understood quite well that his sexual excitation relates to herself. Sooner or later she reflects that it is not right to allow it to continue. She thinks she is doing the correct thing in forbidding him to handle his genital organ. Her prohibition has little effect; at the most it brings about some modification in his method of obtaining satisfaction. At last his mother adopts the severest measures; she threatens to take away from him the thing he is defying her with. Usually, in order to make the threat more frightening and more credible, she delegates its execution to the boy's father, saying that she will tell him and that he will cut the penis off. Strange to say, this threat operates only if another condition is fulfilled before or afterwards. In itself it seems too inconceivable to the boy that such a thing could happen. But if at the time of the threat he can recall the appearance of female genitals or if shortly afterwards he has a sight of them - of genitals, that is to say, which really lack this supremely valued part, then he takes what he has heard seriously and, coming under the influence of the castration complex, experiences the severest trauma of his young life.¹ [1940a [1938], 4997]
The signs of these infantile preferences are for the most part overlooked; yet some of them are to be observed even after the first years of childhood. An eight-year-old girl of my acquaintance, if her mother is called away from the table, makes use of the occasion to proclaim herself her successor: 'I'm going to be Mummy now. Do you want some more greens, Karl? Well, help yourself, then!' and so on. A particularly gifted and lively girl of four, in whom this piece of child psychology is especially transparent, declared quite openly: 'Mummy can go away now. Then Daddy must marry me and I'll be his wife.' Such a wish occurring in a child is not in the least inconsistent with her being tenderly attached to her mother. If a little boy is allowed to sleep beside his mother when his father is away from home, but has to go back to the nursery and to someone of whom he is far less fond as soon as his father returns, he may easily begin to form a wish that his father should always be away, so that he himself could keep his place beside his dear, lovely Mummy. One obvious way of attaining this wish would be if his father were dead; for the child has learnt one thing by experience namely that 'dead' people, such as Grandaddy, are always away and never come back.

[1900a, 737]

ANALYSIS. - It is no easy matter to give a complete interpretation of the dream. It formed part of a cycle of dreams and can only be fully understood if it is taken in connection with the others. There is difficulty in obtaining in sufficient isolation the material necessary for establishing the symbolism. - In the first place, the patient declared that the train journey was to be interpreted historically, as an allusion to a journey she had taken when she was leaving a sanatorium for nervous diseases, with whose director, needless to say, she had been in love. Her mother had fetched her away, and the doctor had appeared at the station and handed her a bouquet of flowers as a parting present. It had been very awkward that her mother should have witnessed this tribute. At this point, then, her mother figured as interfering with her attempts at a love affair; and this had in fact been the part played by that severe lady during the patient's girlhood. - Her next association related to the sentence: 'she looked round to see whether the parts could not be seen from behind.' The façade of the dream would of course lead one to think of the parts of her little daughter who had been run over and mangled. But her association led in quite another direction. She recollected having once seen her father naked in the bath room from behind; she went on to talk of the distinctions between the sexes, and laid stress on the fact that a man's genitals can be seen even from behind but a woman's cannot. In this connection she herself interpreted 'the little one' as meaning the genitals and 'her little one' - she had a four-year-old daughter - as her own genitals. She reproached her mother with having expected her to live as though she had no genitals, and pointed out that the same reproach was expressed in the opening sentence of the dream: 'her mother sent her little one away, so that she had to go by herself.' In her imagination 'going by herself in the streets' meant not having a man, not having any sexual relations ('coire' in Latin means literally 'to go with') - and she disliked that. Her accounts all went to show that when she was a girl she had in fact suffered from her mother's jealousy owing to the preference shown her by her father.

[1900a, 825]
This same dream in its opening passage contained some sentences which could hardly be refused the name of an argument. This argument was not even absurd; it might just as well have occurred in waking thought: *I was amused in the dream at the communication from the town council since, in the first place, I was not yet in the world in 1851 and, in the second place, my father, to whom it might have related, was already dead.* Both of these statements were not only correct in themselves but agreed precisely with the real arguments that I should bring up if I were actually to receive a communication of that kind. My earlier analysis of the dream showed that it grew out of deeply embittered and derisive dream-thoughts. If we may also assume that there were strong reasons present for the activity of the censorship, we shall understand that the dream-work had every motive for producing a perfectly valid refutation of an absurd suggestion on the model contained in the dream-thoughts. The analysis showed, however, that the dream-work did not have a free hand in framing this parallel but was obliged, for that purpose, to use material from the dream-thoughts. It was just as though there were an algebraic equation containing (in addition to numerals) plus and minus signs, indices and radical signs, and as though someone were to copy out the equation without understanding it, taking over both the operational symbols and the numerals into his copy but mixing them all up together. The two arguments could be traced back to the following material. It was distressing to me to think that some of the premises which underlay my psychological explanations of the psychoneuroses were bound to excite scepticism and laughter when they were first met with. For instance, I had been driven to assume that impressions from the second year of life, and sometimes even from the first, left a lasting trace on the emotional life of those who were later to fall ill, and that these impressions - though distorted and exaggerated in many ways by the memory - might constitute the first and deepest foundation for hysterical symptoms. Patients, to whom I explained this at some appropriate moment, used to parody this newly gained knowledge by declaring that they were ready to look for recollections dating from a time *at which they were not yet alive.* My discovery of the unexpected part played by their father in the earliest sexual impulses of female patients might well be expected to meet with a similar reception (see the discussion on p. 736 f.). Nevertheless, it was my well-grounded conviction that both of these hypotheses were true. By way of confirmation I called to mind some instances in which the death of the father occurred while the child was at a very early age and in which later events, otherwise inexplicable, proved that the child had nevertheless retained unconsciously recollections of the figure which had disappeared so early in his life. I was aware that these two assertions of mine rested on the drawing of conclusions whose validity would be disputed. It was therefore an achievement of wish-fulfilment when the material of precisely those conclusions which I was afraid would be contested was employed by the dream-work for drawing conclusions which it was impossible to contest. [1900a, 897]
I have learnt to look upon unconscious love relations like this (which are marked by their abnormal consequences) - between a father and a daughter, or between a mother and a son - as a revival of germs of feeling in infancy. I have shown at length elsewhere¹ at what an early age sexual attraction makes itself felt between parents and children, and I have explained that the legend of Oedipus is probably to be regarded as a poetical rendering of what is typical in these relations. Distinct traces are probably to be found in most people of an early partiality of this kind - on the part of a daughter for her father, or on the part of a son for his mother; but it must be assumed to be more intense from the very first in the case of those children whose constitution marks them down for a neurosis, who develop prematurely and have a craving for love. At this point certain other influences, which need not be discussed here, come into play, and lead to a fixation of this rudimentary feeling of love or to a reinforcement of it; so that it turns into something (either while the child is still young or not until it has reached the age of puberty) which must be put on a par with a sexual inclination and which, like the latter, has the forces of the libido at its command.² The nature of her disposition had always drawn her towards her father, and his numerous illnesses were bound to have increased her affection for him. In some of these illnesses he would allow no one but her to discharge the lighter duties of nursing. He had been so proud of the early growth of her intelligence that he had made her his confidante while she was still a child. It was really she and not her mother whom Frau K.'s appearance had driven out of more than one position.

[1905e, 1393]

When I told Dora that I could not avoid supposing that her affection for her father must at a very early moment have amounted to her being completely in love with him, she of course gave me her usual reply: 'I don't remember that.' But she immediately went on to tell me something analogous about a seven-year-old girl who was her cousin (on her mother's side) and in whom she often thought she saw a kind of reflection of her own childhood. This little girl had (not for the first time) been the witness of a heated dispute between her parents, and, when Dora happened to come in on a visit soon afterwards, whispered in her ear: 'You can't think how I hate that person!' (pointing to her mother), 'and when she's dead I shall marry Daddy.' I am in the habit of regarding associations such as this, which bring forward something that agrees with the content of an assertion of mine, as a confirmation from the unconscious of what I have said. No other kind of 'Yes' can be extracted from the unconscious; there is no such thing at all as an unconscious 'No'.¹

[1905e, 1394]
It is in the world of ideas, however, that the choice of an object is accomplished at first; and
the sexual life of maturing youth is almost entirely restricted to indulging in phantasies, that is, in
ideas that are not destined to be carried into effect.¹ In these phantasies the infantile tendencies
invariably emerge once more, but this time with intensified pressure from somatic sources.
Among these tendencies the first place is taken with uniform frequency by the child's sexual
impulses towards his parents, which are as a rule already differentiated owing to the attraction
of the opposite sex - the son being drawn towards his mother and the daughter towards her
father.² At the same time as these plainly incestuous phantasies are overcome and repudiated,
one of the most significant, but also one of the most painful, psychical achievements of the
pubertal period is completed: detachment from parental authority, a process that alone makes
possible the opposition, which is so important for the progress of civilization, between the new
generation and the old. At every stage in the course of development through which all human
beings ought by rights to pass, a certain number are held back; so there are some who have
never got over their parents' authority and have withdrawn their affection from them either very
incompletely or not at all. They are mostly girls, who, to the delight of their parents, have
persisted in all their childish love far beyond puberty. It is most instructive to find that it is
precisely these girls who in their later marriage lack the capacity to give their husbands what is
due to them; they make cold wives and remain sexually anaesthetic. We learn from this that
sexual love and what appears to be non-sexual love for parents are fed from the same sources;
the latter, that is to say, merely corresponds to an infantile fixation of the libido.
[1905d, 1539]

The closer one comes to the deeper disturbances of psychosexual development, the more
unmistakably the importance of incestuous object-choice emerges. In psychoneurotics a large
portion or the whole of their psychosexual activity in finding an object remains in the
unconscious as a result of their repudiation of sexuality. Girls with an exaggerated need for
affection and an equally exaggerated horror of the real demands made by sexual life have an
irresistible temptation on the one hand to realize the ideal of asexual love in their lives and on
the other hand to conceal their libido behind an affection which they can express without self-
reproaches, by holding fast throughout their lives to their infantile fondness, revived at puberty,
for their parents or brothers and sisters. Psycho-analysis has no difficulty in showing persons of
this kind that they are in love, in the everyday sense of the word, with these blood-relations of
theirs; for, with the help of their symptoms and other manifestations of their illness, it traces their
unconscious thoughts and translates them into conscious ones. In cases in which someone who
has previously been healthy falls ill after an unhappy experience in love it is also possible to
show with certainty that the mechanism of his illness consists in a turning-back of his libido on
to those whom he preferred in his infancy.
[1905d, 1539]
The fact that the sexual instinct behaves in general in a self-willed and inflexible fashion is also seen in the results produced by efforts at abstinence. Civilized education may only attempt to suppress the instinct temporarily, till marriage, intending to give it free rein afterwards with the idea of then making use of it. But extreme measures are more successful against it than attempts at moderating it; thus the suppression often goes too far, with the unwished-for result that when the instinct is set free it turns out to be permanently impaired. For this reason complete abstinence in youth is often not the best preparation for marriage for a young man. Women sense this, and prefer among their suitors those who have already proved their masculinity with other women. The harmful results which the strict demand for abstinence before marriage produces in women's natures are quite especially apparent. It is clear that education is far from underestimating the task of suppressing a girl's sensuality till her marriage, for it makes use of the most drastic measures. Not only does it forbid sexual intercourse and set a high premium on the preservation of female chastity, but it also protects the young woman from temptation as she grows up, by keeping her ignorant of all the facts of the part she is to play and by not tolerating any impulse of love in her which cannot lead to marriage. The result is that when the girl's parental authorities suddenly allow her to fall in love, she is unequal to this psychical achievement and enters marriage uncertain of her own feelings. In consequence of this artificial retardation in her function of love, she has nothing but disappointments to offer the man who has saved up all his desire for her. In her mental feelings she is still attached to her parents, whose authority has brought about the suppression of her sexuality; and in her physical behaviour she shows herself frigid, which deprives the man of any high degree of sexual enjoyment. I do not know whether the anaesthetic type of woman exists apart from civilized education, though I consider it probable. But in any case such education actually breeds it, and these women who conceive without pleasure show little willingness afterwards to face the pains of frequent childbirth. In this way, the preparation for marriage frustrates the aims of marriage itself. When later on the retardation in the wife's development has been overcome and her capacity to love is awakened at the climax of her life as a woman, her relations to her husband have long since been ruined; and, as a reward for her previous docility, she is left with the choice between unappeased desire, unfaithfulness or a neurosis.

[1908d, 1959]
For a small child his parents are at first the only authority and the, source of all belief. The child's most intense and most momentous wish during these early years is to be like his parents (that is, the parent of his own sex) and to be big like his father and mother. But as intellectual growth increases, the child cannot help discovering by degrees the category to which his parents belong. He gets to know other parents and compares them with his own, and so acquires the right to doubt the incomparable and unique quality which he had attributed to them. Small events in the child's life which make him feel dissatisfied afford him provocation for beginning to criticize his parents, and for using, in order to support his critical attitude, the knowledge which he has acquired that other parents are in some respects preferable to them. The psychology of the neuroses teaches us that, among other factors, the most intense impulses of sexual rivalry contribute to this result. A feeling of being slighted is obviously what constitutes the subject-matter of such provocations. There are only too many occasions on which a child is slighted, or at least feels he has been slighted, on which he feels he is not receiving the whole of his parents' love, and, most of all, of which he feels regrets at having to share it with brothers and sisters. His sense that his own affection is not being fully reciprocated then finds a vent in the idea, often consciously recollected later from early childhood, of being a step-child or an adopted child. People who have not developed neuroses very frequently remember such occasions, on which - usually as a result of something they have read - they interpreted and responded to their parent's hostile behaviour in this fashion. But here the influence of sex is already in evidence, for a boy is far more inclined to feel hostile impulses towards his father than towards his mother and has a far more intense desire to get free from him than from her. In this respect the imagination of girls is apt to show itself much weaker. These consciously remembered mental impulses of childhood embody the factor which enables us to understand the nature of myths.

[1909c, 1987]

However, this motive does not go deep enough either; besides, being bound up with civilized conditions, it fails to provide a satisfactory connection with the state of affairs among primitive people. All the more important, therefore, is the next factor, which is based on the evolution of the libido. We have learnt from analytic researches how universal and how powerful the earliest allocations of libido are. In these we are concerned with infantile sexual wishes which are clung to (in women usually a fixation of the libido on the father or a brother who takes his place) - wishes which frequently enough were directed towards other things than intercourse, or included it only as a dimly perceived goal. The husband is almost always so to speak only a substitute, never the right man; it is another man - in typical cases the father - who has first claim to a woman's love, the husband at most takes second place. It depends on how intense this fixation is and on how obstinately it is maintained whether the substitute is rejected as unsatisfying. Frigidity is thus among the genetic determinants of neuroses. The more powerful the psychical element in a woman's sexual life is, the greater will be the capacity for resistance shown by her distribution of libido to the upheaval of the first sexual act, and the less overpowering will be the effect which bodily possession of her can produce. Frigidity may then become established as a neurotic inhibition or provide the foundation for the development of other neuroses and even a moderate diminution of potency in the man will greatly contribute to help this process.

[1918a, 2358]
To take money from anyone had thus early come to mean to her a physical surrender, an erotic relation. To take money from her father was equivalent to a declaration of love. The phantasy that her father was her lover was so seductive that with its help her childish wish for paints for the Easter eggs easily put itself into effect in spite of the prohibition. She could not admit, however, that she had appropriated the money; she was obliged to disavow it, because her motive for the deed, which was unconscious to herself, could not be admitted. Her father's punishment was thus a rejection of the tenderness she was offering him - a humiliation - and so it broke her spirit. During the treatment a period of severe depression occurred (whose explanation led to her remembering the events described here) when on one occasion I was obliged to reproduce this humiliation by asking her not to bring me any more flowers.

[1913g, 2618]

What I have in mind is rivalry in love, with a clear emphasis on the subject's sex. While he is still a small child, a son will already begin to develop a special affection for his mother, whom he regards as belonging to him; he begins to feel his father as a rival who disputes his sole possession. And in the same way a little girl looks on her mother as a person who interferes with her affectionate relation to her father and who occupies a position which she herself could very well fill. Observation shows us to what early years these attitudes go back. We refer to them as the 'Oedipus complex', because the legend of Oedipus realizes, with only a slight softening, the two extreme wishes that arise from the son's situation - to kill his father and take his mother to wife. I do not wish to assert that the Oedipus complex exhausts the relation of children to their parents: it can easily be far more complicated. The Oedipus complex can, moreover, be developed to a greater or less strength, it can even be reversed; but it is a regular and very important factor in a child's mental life, and there is more danger of our under estimating rather than over-estimating its influence and that of the developments which proceed from it. Incidentally, children often react in their Oedipus attitude to a stimulus coming from their parents, who are frequently led in their preferences by difference of sex, so that the father will choose his daughter and the mother her son as a favourite, or, in case of a cooling-off in the marriage, as a substitute for a love-object that has lost its value.

[1916-1917, 3295]

More could be made, too, of the analysis of this ceremonial if it could be properly linked up with the patient's other symptoms. But our path does not lead in that direction. You must be content with a hint that the girl was in the grip of an erotic attachment to her father whose beginnings went back to her childhood. Perhaps that was why she behaved in such an unfriendly way to her mother. Nor can we overlook the fact that the analysis of this symptom has once again taken us back to a patient's sexual life. We shall perhaps be less surprised at this the more often we gain an insight into the sense and intention of neurotic symptoms.

[1916-1917, 3348]

The same effect was produced on the life of our second patient, the young girl, by an erotic attachment to her father which had started during the years before her puberty. The conclusion she herself drew was that she could not marry as long as she was so ill. We, however, may suspect that she had become so ill in order not to have to marry and in order to remain with her father.

[1916-1917, 3351]
What, then, can be gathered about the Oedipus complex from the direct observation of children at the time of their making their choice of an object before the latency period? Well, it is easy to see that the little man wants to have his mother all to himself, that he feels the presence of his father as a nuisance, that he is resentful if his father indulges in any signs of affection towards his mother and that he shows satisfaction when his father has gone on a journey or is absent. He will often express his feelings directly in words and promise his mother to marry her. It will be thought that this amounts to little compared to the deeds of Oedipus; but in fact it is enough, it is the same thing at root. Observation is often obscured by the circumstance that on other occasions the same child will simultaneously give evidence of great affection for his father. But contrary - or, as it is better to say, 'ambivalent' - emotional attitudes, which in adults would lead to a conflict, remain compatible with each other for a long time in children, just as later they find a permanent place beside each other in the unconscious. It will also be objected that the little boy's conduct arises from egoistic motives and gives no grounds for postulating an erotic complex: the child's mother attends to all his needs, so that he has an interest in preventing her from looking after anyone else. This also is true; but it will soon become clear that in this situation as in similar ones the egoistic interest is merely affording a point of support to which the erotic trend is attached. The little boy may show the most undisguised sexual curiosity about his mother, he may insist upon sleeping beside her at night, he may force his presence on her while she is dressing or may even make actual attempts at seducing her, as his mother will often notice and report with amusement - all of which puts beyond doubt the erotic nature of his tie with his mother. Nor must it be forgotten that the mother devotes the same attention to a little daughter without producing the same result and that the father often competes with her in looking after the boy and yet fails to gain the same significance as she does. In short, the factor of sexual preference cannot be eliminated from the situation by any criticism. From the standpoint of egoistic interest it would be simply foolish of the little man not to prefer to put up with having two people in his service rather than only one of them.

As you see, I have only described the relation of a boy to his father and mother. Things happen in just the same way with little girls, with the necessary changes: an affectionate attachment to her father, a need to get rid of her mother as superfluous and to take her place, a coquetry which already employs the methods of later womanhood - these offer a charming picture, especially in small girls, which makes us forget the possibly grave consequences lying behind this infantile situation. We must not omit to add that the parents themselves often exercise a determining influence on the awakening of a child's Oedipus attitude by themselves obeying the pull of sexual attraction, and that where there are several children the father will give the plainest evidence of his greater affection for his little daughter and the mother for her son. But the spontaneous nature of the Oedipus complex in children cannot be seriously shaken even by this factor.
When other children appear on the scene the Oedipus complex is enlarged into a family complex. This, with fresh support from the egoistic sense of injury, gives grounds for receiving the new brothers or sisters with repugnance and for unhesitatingly getting rid of them by a wish. It is even true that as a rule children are far readier to give verbal expression to these feelings of hate than to those arising from the parental complex. If a wish of this kind is fulfilled and the undesired addition to the family is removed again shortly afterwards by death, we can discover from a later analysis what an important experience this death has been to the child, even though it need not have remained fixed in his memory. A child who has been put into second place by the birth of a brother or sister, and who is now for the first time almost isolated from his mother, does not easily forgive her this loss of place; feelings which in an adult would be described as greatly embittered arise in him and are often the basis of a permanent estrangement. We have already mentioned that the child's sexual researches, with all their consequences, usually follow from this vital experience of his. As these brothers and sisters grow up, the boy's attitude to them undergoes very significant transformations. He may take his sister as a love-object by way of substitute for his faithless mother. Where there are several brothers, all of them courting a younger sister, situations of hostile rivalry, which are so important for later life, arise already in the nursery. A little girl may find in her elder brother a substitute for her father who no longer takes an affectionate interest in her as he did in her earliest years. Or she may take a younger sister as a substitute for the baby she has vainly wished for from her father.

[1916-1917, 3400]

The affections of the little girl are fixed on her father, who has probably done all he could to win her love, and in this way has sown the seeds of an attitude of hatred and rivalry towards her mother. This attitude exists side by side with a current of affectionate dependence on her, and as years go on it may be destined to come into consciousness more and more clearly and forcibly, or else to give an impetus to an excessive reaction of devotion to her. But it is not with the girl's relation to her mother that the beating-phantasy is connected. There are other children in the nursery, only a few years older or younger, who are disliked on all sorts of other grounds, but chiefly because the parents' love has to be shared with them, and for this reason they are repelled with all the wild energy characteristic of the emotional life of those years. If the child in question is a younger brother or sister (as in three of my four cases) it is despised as well as hated; yet it attracts to itself the share of affection which the blinded parents are always ready to give the youngest child, and this is a spectacle the sight of which cannot be avoided. One soon learns that being beaten, even if it does not hurt very much, signifies a deprivation of love and a humiliation. And many children who believed themselves securely enthroned in the unshakable affection of their parents have by a single blow been cast down from all the heavens of their imaginary omnipotence. The idea of the father beating this hateful child is therefore an agreeable one, quite apart from whether he has actually been seen doing so. It means: 'My father does not love this other child, he loves only me.'

[1919e, 3649]
It is clear that the child's sexual life has reached the stage of genital organization, now that its incestuous love has achieved this premature choice of an object. This can be demonstrated more easily in the case of boys, but is also indisputable in the case of girls. Something like a premonition of what are later to be the final and normal sexual aims governs the child's libidinal trends. We may justly wonder why this should be so, but we may regard it as a proof of the fact that the genitals have already begun playing their part in the process of excitation. With boys the wish to beget a child from their mother is never absent, with girls the wish to have a child by their father is equally constant; and this in spite of their being completely incapable of forming any clear idea of the means for fulfilling these wishes. The child seems to be convinced that the genitals have something to do with the matter, even though in its constant brooding it may look for the essence of the presumed intimacy between its parents in relations of another sort, such as in their sleeping together, micturating in each other's presence, etc.; and material of the latter kind can be more easily apprehended in verbal images than the mystery that is connected with the genitals.

[1919e, 3650]

We find here for the first time, too, something like a constancy of sex in the persons who play a part in the phantasy. The children who are being beaten are almost invariably boys, in the phantasies of boys just as much as in those of girls. This characteristic is naturally not to be explained by any rivalry between the sexes, as otherwise of course in the phantasies of boys it would be girls who would be being beaten; and it has nothing to do with the sex of the child who was hated in the first phase. But it points to a complication in the case of girls. When they turn away from their incestuous love for their father, with its genital significance, they easily abandon their feminine role. They spur their 'masculinity complex' (Van Ophuijsen, 1917) into activity, and from that time forward only want to be boys. For that reason the whipping-boys who represent them are boys too. In both the cases of day-dreaming - one of which almost rose to the level of a work of art - the heroes were always young men; indeed women used not to come into these creations at all, and only made their first appearance after many years, and then in minor parts.

[1919e, 3652]

Let us disentangle identification as it occurs in the structure of a neurotic symptom from its rather complicated connections. Supposing that a little girl (and we will keep to her for the present) develops the same painful symptom as her mother - for instance, the same tormenting cough. This may come about in various ways. The identification may come from the Oedipus complex; in that case it signifies a hostile desire on the girl's part to take her mother's place, and the symptom expresses her object-love towards her father, and brings about a realization, under the influence of a sense of guilt, of her desire to take her mother's place: 'You wanted to be your mother, and now you are - anyhow so far as your sufferings are concerned.' This is the complete mechanism of the structure of a hysterical symptom. Or, on the other hand, the symptom may be the same as that of the person who is loved; so, for instance, Dora imitated her father's cough. In that case we can only describe the state of things by saying that identification has appeared instead of object-choice, and that object-choice has regressed to identification. We have heard that identification is the earliest and original form of emotional tie; it often happens that under the conditions in which symptoms are constructed, that is, where there is repression and where the mechanisms of the unconscious are dominant, object-choice is turned back into identification - the ego assumes the characteristics of the object. It is noticeable that in these identifications the ego sometimes copies the person who is not loved and sometimes the one who is loved. It must also strike us that in both cases the identification is a partial and extremely limited one and only borrows a single trait from the person who is its object.

[1921c, 3798]
After this highly discursive introduction I am only able to present a very concise summary of the sexual history of the case under consideration. In childhood the girl had passed through the normal attitude characteristic of the feminine Oedipus complex¹ in a way that was not at all remarkable, and had later also begun to substitute for her father a brother slightly older than herself. She did not remember any sexual traumas in early life, nor were any discovered by the analysis. Comparison of her brother's genital organs and her own, which took place about the beginning of the latency period (at five years old or perhaps a little earlier), left a strong impression on her and had far-reaching after-effects. There were very few signs pointing to infantile masturbation, or else the analysis did not go far enough to throw light on this point. The birth of a second brother when she was between five and six years old exercised no special influence upon her development. During the pre-pubertal years at school she gradually became acquainted with the facts of sex, and she received this knowledge with mixed feelings of lasciviousness and frightened aversion, in a way which may be called normal and was not exaggerated in degree. This amount of information about her seems meagre enough, nor can I guarantee that it is complete. It may be that the history of her youth was much richer in experiences; I do not know. As I have already said, the analysis was broken off after a short time, and therefore yielded an anamnesis not much more reliable than the other anamneses of homosexuals, which there is good cause to question. Further, the girl had never been neurotic, and came to the analysis without even one hysterical symptom, so that opportunities for investigating the history of her childhood did not present themselves so readily as usual. [1920a, 3845]

With these indications of tenderness for her father, of contact with his genitals, and of death-wishes against her mother, the outline of the female Oedipus complex is sketched in. Her long retention of her ignorance of sexual matters, and her frigidity at a later period bear out these suppositions. The writer of the letter became potentially - and at times no doubt actually - a hysterical neurotic. The forces of life have, for her own happiness, carried her along with them. They have awakened in her the sexual feelings of a woman and brought her the joys of motherhood, and the capacity to work. But a portion of her libido still clings to its points of fixation in childhood; she still dreams the dream that throws her out of bed and punishes her for her incestuous object-choice by 'not inconsiderable injuries'. [1922a, 3893]
The little series of reminiscences must engage our attention for a while longer. I have stated elsewhere that such scenes of childhood are ‘screen memories’ selected at a later period, put together, and not infrequently falsified in the process. This subsequent remodelling serves a purpose that is sometimes easy to guess. In our case one can almost hear the writer’s ego glorifying or soothing itself by means of this series of recollections. ‘I was from infancy a particularly noble and compassionate creature. I learnt quite early that animals have souls as we have, and could not endure cruelty to animals. The sins of the flesh were far from me and I preserved my chastity till late in life.’ With declarations such as these she was loudly contradicting the inferences that we have to make about her early childhood on the basis of our analytical experience, namely, that she had an abundance of premature sexual impulses and violent feelings of hatred for her mother and her younger brothers and sisters. (Besides the genital significance I have just assigned to it, the little bird may also be a symbol of a child, like all small animals; her recollection thus accentuated very insistently the fact that this small creature had the same right to exist as she herself.) Hence the short series of recollections furnishes a very nice example of a mental structure with a twofold aspect. Viewed superficially, we may find in it the expression of an abstract idea, here, as usually, with an ethical reference. In Silberer’s nomenclature the structure has an *anagogic* content. On deeper investigation it reveals itself as a chain of phenomena belonging to the region of the repressed life of the instincts - it displays its *psycho-analytic* content. As you know, Silberer, who was among the first to issue a warning to us not to lose sight of the nobler side of the human soul, has put forward the view that all or nearly all dreams permit such a twofold interpretation, a purer, anagogic one beside the ignoble, psycho-analytic one. This is, however, unfortunately not so. On the contrary, an over-interpretation of this kind is rarely possible. To my knowledge no valid example of such a dream-analysis with a double meaning has been published up to the present time. But observations of this kind can often be made upon the series of associations that our patients produce during analytic treatment. On the one hand the successive ideas are linked by a line of association which is plain to the eye, while on the other hand you become aware of an underlying theme which is kept secret but which at the same time plays a part in all these ideas. The contrast between the two themes that dominate the same series of ideas is not always one between the lofty anagogic and the low psycho-analytic, but one rather between offensive and respectable or indifferent ideas - a fact that easily explains why such a chain of associations with a twofold determination arises. In our present example it is of course not accidental that the anagogic and the psycho-analytic interpretations stood in such a sharp contrast to each other; both related to the same material, and the later trend was no other than that of the reaction-formations which had been erected against the disowned instinctual impulses. [1922a, 3894]
The fear of castration being thus excluded in the little girl, a powerful motive also drops out for the setting-up of a super-ego and for the breaking-off of the infantile genital organization. In her, far more than in the boy, these changes seem to be the result of upbringing and of intimidation from outside which threatens her with a loss of love. The girl's Oedipus complex is much simpler than that of the small bearer of the penis; in my experience, it seldom goes beyond the taking of her mother's place and the adopting of a feminine attitude towards her father. Renunciation of the penis is not tolerated by the girl without some attempt at compensation. She slips - along the line of a symbolic equation, one might say - from the penis to a baby. Her Oedipus complex culminates in a desire, which is long retained, to receive a baby from her father as a gift - to bear him a child. One has an impression that the Oedipus complex is then gradually given up because this wish is never fulfilled. The two wishes - to possess a penis and a child - remain strongly cathected in the unconscious and help to prepare the female creature for her later sexual role. The comparatively lesser strength of the sadistic contribution to her sexual instinct, which we may no doubt connect with the stunted growth of her penis, makes it easier in her case for the direct sexual trends to be transformed into aim-inhibited trends of an affectionate kind. It must be admitted, however, that in general our insight into these developmental processes in girls is unsatisfactory, incomplete and vague.

[1924d, 4090]

In little girls the Oedipus complex raises one problem more than in boys. In both cases the mother is the original object; and there is no cause for surprise that boys retain that object in the Oedipus complex. But how does it happen that girls abandon it and instead take their father as an object? In pursuing this question I have been able to reach some conclusions which may throw light precisely on the prehistory of the Oedipus relation in girls.

[1925j, 4149]

Every analyst has come across certain women who cling with especial intensity and tenacity to the bond with their father and to the wish in which it culminates of having a child by him. We have good reason to suppose that the same wishful phantasy was also the motive force of their infantile masturbation, and it is easy to form an impression that at this point we have been brought up against an elementary and unanalysable fact of infantile sexual life. But a thorough analysis of these very cases brings something different to light - namely, that here the Oedipus complex has a long prehistory and is in some respects a secondary formation.

[1925j, 4149]

So far there has been no question of the Oedipus complex, nor has it up to this point played any part. But now the girl's libido slips into a new position along the line - there is no other way of putting it - of the equation 'penis-child'. She gives up her wish for a penis and puts in place of it a wish for a child: and with that purpose in view she takes her father as a love object. Her mother becomes the object of her jealousy. The girl has turned into a little woman. If I am to credit a single analytic instance, this new situation can give rise to physical sensations which would have to be regarded as a premature awakening of the female genital apparatus. When the girl's attachment to her father comes to grief later on and has to be abandoned, it may give place to an identification with him and the girl may thus return to her masculinity complex and perhaps remain fixated in it.

[1925j, 4154]
The process of arriving at an object, which plays such an important part in mental life, takes place alongside of the organization of the libido. After the stage of auto-erotism, the first love-object in the case of both sexes is the mother; and it seems probable that to begin with a child does not distinguish its mother’s organ of nutrition from its own body. Later, but still in the first years of infancy, the relation known as the Oedipus complex becomes established: boys concentrate their sexual wishes upon their mother and develop hostile impulses against their father as being a rival, while girls adopt an analogous attitude.¹ All of the different variations and consequences of the Oedipus complex are important; and the innately bisexual constitution of human beings makes itself felt and increases the number of simultaneously active tendencies. Children do not become clear for quite a long time about the differences between the sexes; and during this period of sexual researches they produce typical sexual theories which, being circumscribed by the incompleteness of their authors’ own physical development, are a mixture of truth and error and fail to solve the problems of sexual life (the riddle of the Sphinx - that is, the question of where babies come from). We see, then, that a child’s first object-choice is an incestuous one. The whole course of development that I have described is run through rapidly. For the most remarkable feature of the sexual life of man is its diphasic onset, its onset in two waves, with an interval between them. It reaches a first climax in the fourth or fifth year of a child’s life. But thereafter this early efflorescence of sexuality passes off; the sexual impulses which have shown such liveliness are overcome by repression, and a period of latency follows, which lasts until puberty and during which the reaction-formations of morality, shame, and disgust are built up.² Of all living creatures man alone seems to show this diphasic onset of sexual growth, and it may perhaps be the biological determinant of his predisposition to neuroses. At puberty the impulses and object-relations of a child’s early years become re-animated, and amongst them the emotional ties of its Oedipus complex. In the sexual life of puberty there is a struggle between the urges of early years and the inhibitions of the latency period. Before this, and while the child is at the highest point of its infantile sexual development, a genital organization of a sort is established; but only the male genitals play a part in it, and the female ones remain undiscovered. (I have described this as the period of phallic primacy.) At this stage the contrast between the sexes is not stated in terms of ‘male’ or ‘female’ but of ‘possessing a penis’ or ‘castrated’. The castration complex which arises in this connection is of the profoundest importance in the formation alike of character and of neuroses.

¹ (Footnote added 1935:) The information about infantile sexuality was obtained from the study of men and the theory deduced from it was concerned with male children. It was natural enough to expect to find a complete parallel between the two sexes; but this turned out not to hold. Further investigations and reflections revealed profound differences between the sexual development of men and women. The first sexual object of a baby girl (just as of a baby boy) is her mother; and before a woman can reach the end of her normal development she has to change not only her sexual object but also her leading genital zone. From this circumstance difficulties arise and possibilities of inhibition which are not present in the case of men.

² [1925d, 4212]

¹ [1925d, 4212]
Nothing, however, deserves more notice than the fact that children regularly direct their sexual wishes towards their nearest relatives - in the first place, therefore, towards their father and mother, and afterwards towards their brothers and sisters. The first object of a boy's love is his mother, and of a girl's her father (except in so far as an innate bisexual disposition favours the simultaneous presence of the contrary attitude). The other parent is felt as a disturbing rival and not infrequently viewed with strong hostility. You must understand me aright. What I mean to say is not that the child wants to be treated by its favourite parent merely with the kind of affection which we adults like to regard as the essence of the parent-child relation. No, analysis leaves us in no doubt that the child's wishes extend beyond such affection to all that we understand by sensual satisfaction - so far, that is, as the child's powers of imagination allow. It is easy to see that the child never guesses the actual facts of sexual intercourse; he replaces them by other notions derived from his own experience and feelings. As a rule his wishes culminate in the intention to bear, or in some in definable way, to procreate a baby. Boys, too, in their ignorance, do not exclude themselves from the wish to bear a baby. We give the whole of this mental structure the name of 'Oedipus complex', after the familiar Greek legend. With the end of the early sexual period it should normally be given up, should radically disintegrate and become transformed; and the results of this transformation are destined for important functions in later mental life. But as a rule this is not effected radically enough, in which case puberty brings about a revival of the complex, which may have serious consequences.

During the phase of the normal Oedipus complex we find the child tenderly attached to the parent of the opposite sex, while its relation to the parent of its own sex is predominantly hostile. In the case of a boy there is no difficulty in explaining this. His first love-object was his mother. She remains so; and, with the strengthening of his erotic desires and his deeper insight into the relations between his father and mother, the former is bound to become his rival. With the small girl it is different. Her first object, too, was her mother. How does she find her way to her father? How, when and why does she detach herself from her mother? We have long understood that the development of female sexuality is complicated by the fact that the girl has the task of giving up what was originally her leading genital zone the clitoris - in favour of a new zone - the vagina. But it now seems to us that there is a second change of the same sort which is no less characteristic and important for the development of the female: the exchange of her original object - her mother - for her father. The way in which the two tasks are connected with each other is not yet clear to us.

It is well known that there are many women who have a strong attachment to their father; nor need they be in any way neurotic. It is upon such women that I have made the observations which I propose to report here and which have led me to adopt a particular view of female sexuality. I was struck, above all, by two facts. The first was that where the woman's attachment to her father was particularly intense, analysis showed that it had been preceded by a phase of exclusive attachment to her mother which had been equally intense and passionate. Except for the change of her love-object, the second phase had scarcely added any new feature to her erotic life. Her primary relation to her mother had been built up in a very rich and many-sided manner. The second fact taught me that the duration of this attachment had also been greatly underestimated. In several cases it lasted until well into the fourth year - in one case into the fifth year - so that it covered by far the longer part of the period of early sexual efflorescence. Indeed, we had to reckon with the possibility that a number of women remain arrested in their original attachment to their mother and never achieve a true change-over towards men. This being so, the pre-Oedipus phase in women gains an importance which we have not attributed to it hitherto.
Since this phase allows room for all the fixations and repressions from which we trace the origin of the neuroses, it would seem as though we must retract the universality of the thesis that the Oedipus complex is the nucleus of the neuroses. But if anyone feels reluctant about making this correction, there is no need for him to do so. On the one hand, we can extend the content of the Oedipus complex to include all the child's relations to both parents; or, on the other, we can take due account of our new findings by saying that the female only reaches the normal positive Oedipus situation after she has surmounted a period before it that is governed by the negative complex. And indeed during that phase a little girl's father is not much else for her than a troublesome rival, although her hostility towards him never reaches the pitch which is characteristic of boys. We have, after all, long given up any expectation of a neat parallelism between male and female sexual development.

Our insight into this early, pre-Oedipus, phase in girls comes to us as a surprise, like the discovery, in another field, of the Minoan-Mycenean civilization behind the civilization of Greece.

Everything in the sphere of this first attachment to the mother seemed to me so difficult to grasp in analysis - so grey with age and shadowy and almost impossible to revivify - that it was as if it had succumbed to an especially inexorable repression. But perhaps I gained this impression because the women who were in analysis with me were able to cling to the very attachment to the father in which they had taken refuge from the early phase that was in question. It does indeed appear that women analysts - as, for instance, Jeanne Lampl-de Groot and Helene Deutsch - have been able to perceive these facts more easily and clearly because they were helped in dealing with those under their treatment by the transference to a suitable mother-substitute. Nor have I succeeded in seeing my way though any case completely, and I shall therefore confine myself to reporting the most general findings and shall give only a few examples of the new ideas which I have arrived at. Among these is a suspicion that this phase of attachment to the mother is especially intimately related to the aetiology of hysteria, which is not surprising when we reflect that both the phase and the neurosis are characteristically feminine, and further, that in this dependence on the mother we have the germ of later paranoia in women.¹ For this germ appears to be the surprising, yet regular, fear of being killed (?) devoured) by the mother. It is plausible to assume that this fear corresponds to a hostility which develops in the child towards her mother in consequence of the manifold restrictions imposed by the latter in the course of training and bodily care and that the mechanism of projection isfavoured by the early age of the child's psychical organization.

I began by stating the two facts which have struck me as new: that a woman's strong dependence on her father merely takes over the heritage of an equally strong attachment to her mother, and that this earlier phase has lasted for an unexpectedly long period of time. I shall now go back a little in order to insert these new findings into the picture of female sexual development with which we are familiar. In doing this, a certain amount of repetition will be inevitable. It will help our exposition if, as we go along, we compare the state of things in women with that in men.
Parallel with this first great difference there is the other, concerned with the finding of the object. In the case of a male, his mother becomes his first love-object as a result of her feeding him and looking after him, and she remains so until she is replaced by someone who resembles her or is derived from her. A female's first object, too, must be her mother: the primary conditions for a choice of object are, of course, the same for all children. But at the end of her development, her father - a man - should have become her new love-object. In other words, to the change in her own sex there must correspond a change in the sex of her object. The new problems that now require investigating are in what way this change takes place, how radically or how incompletely it is carried out, and what the different possibilities are which present themselves in the course of this development.

[1931b, 4592]

Quite different are the effects of the castration complex in the female. She acknowledges the fact of her castration, and with it, too, the superiority of the male and her own inferiority; but she rebels against this unwelcome state of affairs. From this divided attitude three lines of development open up. The first leads to a general revulsion from sexuality. The little girl, frightened by the comparison with boys, grows dissatisfied with her clitoris, and gives up her phallic activity and with it her sexuality in general as well as a good part of her masculinity in other fields. The second line leads her to cling with defiant self-assertiveness to her threatened masculinity. To an incredibly late age she clings to the hope of getting a penis some time. That hope becomes her life's aim; and the phantasy of being a man in spite of everything often persists as a formative factor over long periods. This 'masculinity complex' in women can also result in a manifest homosexual choice of object. Only if her development follows the third, very circuitous, path does she reach the final normal female attitude, in which she takes her father as her object and so finds her way to the feminine form of the Oedipus complex. Thus in women the Oedipus complex is the end-result of a fairly lengthy development. It is not destroyed, but created, by the influence of castration; it escapes the strongly hostile influences which, in the male, have a destructive effect on it, and indeed it is all too often not surmounted by the female at all. For this reason, too, the cultural consequences of its break-up are smaller and of less importance in her. We should probably not be wrong in saying that it is this difference in the reciprocal relation between the Oedipus and the castration complex which gives its special stamp to the character of females as social beings.¹

[1931b, 4594]

We see, then, that the phase of exclusive attachment to the mother, which may be called the pre-Oedipus phase, possesses a far greater importance in women than it can have in men. Many phenomena of female sexual life which were not properly understood before can be fully explained by reference to this phase. Long ago, for instance, we noticed that many women who have chosen their husband on the model of their father, or have put him in their father's place, nevertheless repeat towards him, in their married life, their bad relations with their mother. The husband of such a woman was meant to be the inheritor of her relation to her father, but in reality he became the inheritor of her relation to her mother. This is easily explained as an obvious case of regression. Her relation to her mother was the original one, and her attachment to her father was built up on it, and now, in marriage, the original relation emerges from repression. For the main content of her development to womanhood lay in the carrying over of her affective object attachments from her mother to her father.

[1931b, 4595]
With many women we have the impression that their years of maturity are occupied by a struggle with their husband, just as their youth was spent in a struggle with their mother. In the light of the previous discussions we shall conclude that their hostile attitude to their mother is not a consequence of the rivalry implicit in the Oedipus complex, but originates from the preceding phase and has merely been reinforced and exploited in the Oedipus situation. And actual analytic examination confirms this view. Our interest must be directed to the mechanisms that are at work in her turning away from the mother who was an object so intensely and exclusively loved. We are prepared to find, not a single factor, but a whole number of them operating together towards the same end.

[1931b, 4595]

Among these factors are some which are determined by the circumstances of infantile sexuality in general, and so hold good equally for the erotic life of boys. First and foremost we may mention jealousy of other people - of brothers and sisters, rivals, among whom the father too has a place. Childhood love is boundless; it demands exclusive possession, it is not content with less than all. But it has a second characteristic: it has, in point of fact, no aim and is incapable of obtaining complete satisfaction; and principally for that reason it is doomed to end in disappointment and to give place to a hostile attitude. Later on in life the lack of an ultimate satisfaction may favour a different result. This very factor may ensure the uninterrupted continuance of the libidinal cathexis, as happens with love-relations that are inhibited in their aim. But in the stress of the processes of development it regularly happens that the libido abandons its unsatisfying position in order to find a new one.

[1931b, 4595]

Another, much more specific motive for turning away from the mother arises from the effect of the castration complex on the creature who is without a penis. At some time or other the little girl makes the discovery of her organic inferiority - earlier and more easily, of course, if there are brothers or other boys about. We have already taken note of the three paths which diverge from this point: (a) the one which leads to a cessation of her whole sexual life, (b) the one which leads to a defiant over-emphasis of her masculinity, and (c) the first steps towards definitive femininity. It is not easy to determine the exact timing here or the typical course of events. Even the point of time when the discovery of castration is made varies, and a number of other factors seem to be inconstant and to depend on chance. The state of the girl's own phallic activity plays a part; and so too does the question whether this activity was found out or not, and how much interference with it she experienced afterwards.

[1931b, 4596]

We shall return to the part played by the clitoris; let us now turn to the second task with which a girl's development is burdened. A boy's mother is the first object of his love, and she remains so too during the formation of his Oedipus complex and, in essence, all through his life. For a girl too her first object must be her mother (and the figures of wet-nurses and foster-mothers that merge into her). The first object-cathexes occur in attachment to the satisfaction of the major and simple vital needs, and the circumstances of the care of children are the same for both sexes. But in the Oedipus situation the girl's father has become her love-object, and we expect that in the normal course of development she will find her way from this paternal object to her final choice of an object. In the course of time, therefore, a girl has to change her erotogenic zone and her object - both of which a boy retains. The question then arises of how this happens: in particular, how does a girl pass from her mother to an attachment to her father? or, in other words, how does she pass from her masculine phase to the feminine one to which she is biologically destined?

[1933a, 4720]
We will now turn our interest on to the single question of what it is that brings this powerful attachment of the girl to her mother to an end. This, as we know, is its usual fate: it is destined to make room for an attachment to her father. Here we come upon a fact which is a pointer to our further advance. This step in development does not involve only a simple change of object. The turning away from the mother is accompanied by hostility; the attachment to the mother ends in hate. A hate of that kind may become very striking and last all through life; it may be carefully overcompensated later on; as a rule one part of it is overcome while another part persists. Events of later years naturally influence this greatly. We will restrict ourselves, however, to studying it at the time at which the girl turns to her father and to enquiring into the motives for it. We are then given a long list of accusations and grievances against the mother which are supposed to justify the child's hostile feelings; they are of varying validity which we shall not fail to examine. A number of them are obvious rationalizations and the true sources of enmity remain to be found. I hope you will be interested if on this occasion I take you through all the details of a psycho-analytic investigation.

[1933a, 4723]

With the transference of the wish for a penis-baby on to her father, the girl has entered the situation of the Oedipus complex. Her hostility to her mother, which did not need to be freshly created, is now greatly intensified, for she becomes the girl's rival, who receives from her father everything that she desires from him. For a long time the girl's Oedipus complex concealed her pre-Oedipus attachment to her mother from our view, though it is nevertheless so important and leaves such lasting fixations behind it. For girls the Oedipus situation is the outcome of a long and difficult development; it is a kind of preliminary solution, a position of rest which is not soon abandoned, especially as the beginning of the latency period is not far distant. And we are now struck by a difference between the two sexes, which is probably momentous, in regard to the relation of the Oedipus complex to the castration complex. In a boy the Oedipus complex, in which he desires his mother and would like to get rid of his father as being a rival, develops naturally from the phase of his phallic sexuality. The threat of castration compels him, however, to give up that attitude. Under the impression of the danger of losing his penis, the Oedipus complex is abandoned, repressed and, in the most normal cases, entirely destroyed, and a severe super-ego is set up as its heir. What happens with a girl is almost the opposite. The castration complex prepares for the Oedipus complex instead of destroying it; the girl is driven out of her attachment to her mother through the influence of her envy for the penis and she enters the Oedipus situation as though into a haven of refuge. In the absence of fear of castration the chief motive is lacking which leads boys to surmount the Oedipus complex. Girls remain in it for an indeterminate length of time; they demolish it late and, even so, incompletely. In these circumstances the formation of the super-ego must suffer; it cannot attain the strength and independence which give it its cultural significance, and feminists are not pleased when we point out to them the effects of this factor upon the average feminine character.

[1933a, 4731]
It is not my intention to pursue the further behaviour of femininity through puberty to the period of maturity. Our knowledge, moreover, would be insufficient for the purpose. But I will bring a few features together in what follows. Taking its prehistory as a starting-point, I will only emphasize here that the development of femininity remains exposed to disturbance by the residual phenomena of the early masculine period. Regressions to the fixations of the pre-Oedipus phases very frequently occur; in the course of some women's lives there is a repeated alternation between periods in which masculinity or femininity gains the upper hand. Some portion of what we men call 'the enigma of women' may perhaps be derived from this expression of bisexuality in women's lives. But another question seems to have become ripe for judgement in the course of these researches. We have called the motive force of sexual life 'the libido'. Sexual life is dominated by the polarity of masculine-feminine; thus the notion suggests itself of considering the relation of the libido to this antithesis. It would not be surprising if it were to turn out that each sexuality had its own special libido appropriated to it, so that one sort of libido would pursue the aims of a masculine sexual life and another sort those of a feminine one. But nothing of the kind is true. There is only one libido, which serves both the masculine and the feminine sexual functions. To it itself we cannot assign any sex; if, following the conventional equation of activity and masculinity, we are inclined to describe it as masculine, we must not forget that it also covers trends with a passive aim. Nevertheless the juxtaposition 'feminine libido' is without any justification. Furthermore, it is our impression that more constraint has been applied to the libido when it is pressed into the service of the feminine function, and that - to speak teleologically - Nature takes less careful account of its demands than in the case of masculinity. And the reason for this may lie - thinking once again teleologically - in the fact that the accomplishment of the aim of biology has been entrusted to the aggressiveness of men and has been made to some extent independent of women's consent.

[1933a, 4733]

A woman's identification with her mother allows us to distinguish two strata: the pre-Oedipus one which rests on her affectionate attachment to her mother and takes her as a model, and the later one from the Oedipus complex which seeks to get rid of her mother and take her place with her father. We are no doubt justified in saying that much of both of them is left over for the future and that neither of them is adequately surmounted in the course of development. But the phase of the affectionate pre-Oedipus attachment is the decisive one for a woman's future: during it preparations are made for the acquisition of the characteristics with which she will later fulfil her role in the sexual function and perform her invaluable social tasks. It is in this identification too that she acquires her attractiveness to a man, whose Oedipus attachment to his mother it kindles into passion. How often it happens, however, that it is only his son who obtains what he himself aspired to! One gets an impression that a man's love and a woman's are a phase apart psychologically.

[1933a, 4736]

With the phallic phase and in the course of it the sexuality of early childhood reaches its height and approaches its dissolution. Thereafter boys and girls have different histories. Both have begun to put their intellectual activity at the service of sexual researches; both start off from the premiss of the universal presence of the penis. But now the paths of the sexes diverge. The boy enters the Oedipus phase; he begins to manipulate his penis and simultaneously has phantasies of carrying out some sort of activity with it in relation to his mother, till, owing to the combined effect of a threat of castration and the sight of the absence of a penis in females, he experiences the greatest trauma of his life and this introduces the period of latency with all its consequences. The girl, after vainly attempting to do the same as the boy, comes to recognize her lack of a penis or rather the inferiority of her clitoris, with permanent effects on the development of her character; as a result of this first disappointment in rivalry, she often begins by turning away altogether from sexual life.

[1940a [1938], 4965]
It is an interesting thing that the relation between the Oedipus complex and the castration complex should take such a different shape - an opposite one, in fact - in the case of females as compared to that of males. In males, as we have seen, the threat of castration brings the Oedipus complex to an end; in females we find that, on the contrary, it is their lack of a penis that forces them into their Oedipus complex. It does little harm to a woman if she remains in her feminine Oedipus attitude. (The term 'Electra complex' has been proposed for it.) She will in that case choose her husband for his paternal characteristics and be ready to recognize his authority. Her longing to possess a penis, which is in fact unappeasable, may find satisfaction if she can succeed in completing her love for the organ by extending it to the bearer of the organ, just as happened earlier when she progressed from her mother's breast to her mother as a whole person.

[1940a [1938], 5001]
I have learnt to look upon unconscious love relations like this (which are marked by their abnormal consequences) - between a father and a daughter, or between a mother and a son - as a revival of germs of feeling in infancy. I have shown at length elsewhere⁠¹ at what an early age sexual attraction makes itself felt between parents and children, and I have explained that the legend of Oedipus is probably to be regarded as a poetical rendering of what is typical in these relations. Distinct traces are probably to be found in most people of an early partiality of this kind - on the part of a daughter for her father, or on the part of a son for his mother; but it must be assumed to be more intense from the very first in the case of those children whose constitution marks them down for a neurosis, who develop prematurely and have a craving for love. At this point certain other influences, which need not be discussed here, come into play, and lead to a fixation of this rudimentary feeling of love or to a reinforcement of it; so that it turns into something (either while the child is still young or not until it has reached the age of puberty) which must be put on a par with a sexual inclination and which, like the latter, has the forces of the libido at its command.² The nature of her disposition had always drawn her towards her father, and his numerous illnesses were bound to have increased her affection for him. In some of these illnesses he would allow no one but her to discharge the lighter duties of nursing. He had been so proud of the early growth of her intelligence that he had made her his confidante while she was still a child. It was really she and not her mother whom Frau K.'s appearance had driven out of more than one position.

[1905e, 1393]

When I told Dora that I could not avoid supposing that her affection for her father must at a very early moment have amounted to her being completely in love with him, she of course gave me her usual reply: 'I don't remember that.' But she immediately went on to tell me something analogous about a seven-year-old girl who was her cousin (on her mother's side) and in whom she often thought she saw a kind of reflection of her own childhood. This little girl had (not for the first time) been the witness of a heated dispute between her parents, and, when Dora happened to come in on a visit soon afterwards, whispered in her ear: 'You can't think how I hate that person!' (pointing to her mother), 'and when she's dead I shall marry Daddy.' I am in the habit of regarding associations such as this, which bring forward something that agrees with the content of an assertion of mine, as a confirmation from the unconscious of what I have said. No other kind of 'Yes' can be extracted from the unconscious; there is no such thing at all as an unconscious 'No'.¹

[1905e, 1394]
It is in the world of ideas, however, that the choice of an object is accomplished at first; and the sexual life of maturing youth is almost entirely restricted to indulging in phantasies, that is, in ideas that are not destined to be carried into effect.¹ In these phantasies the infantile tendencies invariably emerge once more, but this time with intensified pressure from somatic sources. Among these tendencies the first place is taken with uniform frequency by the child's sexual impulses towards his parents, which are as a rule already differentiated owing to the attraction of the opposite sex - the son being drawn towards his mother and the daughter towards her father.² At the same time as these plainly incestuous phantasies are overcome and repudiated, one of the most significant, but also one of the most painful, psychical achievements of the pubertal period is completed: detachment from parental authority, a process that alone makes possible the opposition, which is so important for the progress of civilization, between the new generation and the old. At every stage in the course of development through which all human beings ought by rights to pass, a certain number are held back; so there are some who have never got over their parents' authority and have withdrawn their affection from them either very incompletely or not at all. They are mostly girls, who, to the delight of their parents, have persisted in all their childish love far beyond puberty. It is most instructive to find that it is precisely these girls who in their later marriage lack the capacity to give their husbands what is due to them; they make cold wives and remain sexually anaesthetic. We learn from this that sexual love and what appears to be non-sexual love for parents are fed from the same sources; the latter, that is to say, merely corresponds to an infantile fixation of the libido.

[1905d, 1539]

Thus she tells us plainly enough what with the years had become of their childhood friendship. In her it grew until she was thoroughly in love, for a girl must have something to which she can give her heart. Fräulein Zoe, the embodiment of cleverness and clarity, makes her own mind quite transparent to us. While it is in any case the general rule for a normally constituted girl to turn her affection towards her father in the first instance, Zoe, who had no one in her family but her father, was especially ready to do so. But her father had nothing left over for her; all his interest was engrossed by the objects of his science. So she was obliged to cast her eyes around upon other people, and became especially attached to her young playmate. When he too ceased to have any eyes for her, her love was not shaken by it but rather increased, for he had become like her father, was, like him, absorbed by science and held apart by it from life and from Zoe. Thus it was made possible for her to remain faithful in her unfaithfulness - to find her father once more in her loved one, to include both of them with the same emotion, or, as we may say, to identify both of them in her feeling. What is our justification for this piece of psychological analysis, which might well seem arbitrary? The author has presented us with it in a single, but highly characteristic, detail. When Zoe described the transformation in her former playmate which had so greatly disturbed her, she abused him by comparing him to an archaeopteryx, the bird-like monstrosity which belongs to the archaeology of zoology. In that way she found a single concrete expression of the identity of the two figures. Her complaint applies with the same word to the man she loved and to her father. The archaeopteryx is, we might say, a compromise idea or an intermediate idea in which her thought about the folly of the man she loved coincided with the analogous thought about her father.

[1907a, 1836]
However, this motive does not go deep enough either; besides, being bound up with civilized conditions, it fails to provide a satisfactory connection with the state of affairs among primitive people. All the more important, therefore, is the next factor, which is based on the evolution of the libido. We have learnt from analytic researches how universal and how powerful the earliest allocations of libido are. In these we are concerned with infantile sexual wishes which are clung to (in women usually a fixation of the libido on the father or a brother who takes his place) - wishes which frequently enough were directed towards other things than intercourse, or included it only as a dimly perceived goal. The husband is almost always so to speak only a substitute, never the right man; it is another man - in typical cases the father - who has first claim to a woman's love, the husband at most takes second place. It depends on how intense this fixation is and on how obstinately it is maintained whether the substitute is rejected as unsatisfying. Frigidity is thus among the genetic determinants of neuroses. The more powerful the psychological element in a woman's sexual life is, the greater will be the capacity for resistance shown by her distribution of libido to the upheaval of the first sexual act, and the less overpowering will be the effect which bodily possession of her can produce. Frigidity may then become established as a neurotic inhibition or provide the foundation for the development of other neuroses and even a moderate diminution of potency in the man will greatly contribute to help this process.

[1918a, 2358]

Both the child's lies were instigated by the same complex. As the eldest of five children, the little girl early developed an unusually strong attachment to her father, which was destined when she was grown up to wreck her happiness in life. But she could not long escape the discovery that her beloved father was not so great a personage as she was inclined to think him. He had to struggle against money difficulties; he was not so powerful or so distinguished as she had imagined. But she could not put up with this departure from her ideal. Since, as women do, she based all her ambition on the man she loved, she became too strongly dominated by the motive of supporting her father against the world. So she boasted to her school-fellows, in order not to have to belittle her father. When, later on, she learned to translate ice for dinner by ‘glace’, her self-reproaches about this reminiscence led her by an easy path into a pathological dread of pieces or splinters of glass.

[1913g, 2619]

Her father was an excellent draughtsman, and had often enough excited the delight and admiration of the children by exhibitions of his skill. It was as an identification of herself with her father that she had drawn the circle at school - which she could only do successfully by deceitful methods. It was as though she wanted to boast: 'Look at what my father can do!' The sense of guilt that was attached to her excessive fondness for her father found its expression in connection with her attempted deception; an admission was impossible for the same reason that was given in the first of these observations: it would inevitably have been an admission of her hidden incestuous love.

[1913g, 2619]
This relation is undoubtedly a more favourable one, from the children's point of view as well. That is what our expectations demand; we find an absence of love far more repellent between parents and children than between brothers and sisters. In the former case we have, as it were, made something sacred which in the latter we have left profane. Yet daily observation can show us how frequently the emotional relations between parents and their grown-up children fall behind the ideal set up by society, how much hostility is ready to hand and would be expressed if it were not held back by admixtures of filial piety and affectionate impulses. The motives for this hostility are generally known and their tendency is to divide those of the same sex - the daughter from the mother and the father from the son. The daughter finds in her mother the authority which restricts her will and which is entrusted with the task of imposing on her the renunciation of sexual freedom which society demands; in a few instances she even finds in her a competitor who struggles against being supplanted. The same thing is repeated between the son and his father still more glaringly. In the son's eyes his father embodies every unwillingly tolerated social restraint; his father prevents him from exercising his will, from early sexual pleasure and, where there is common property in the family, from enjoying it. In the case of an heir to the throne this waiting for a father's death reaches an almost tragic height. There seems less danger to the relation between father and daughter or mother and son. This last provides the purest examples of an unchangeable affection, unimpaired by any egoistic considerations.

What I have in mind is rivalry in love, with a clear emphasis on the subject's sex. While he is still a small child, a son will already begin to develop a special affection for his mother, whom he regards as belonging to him; he begins to feel his father as a rival who disputes his sole possession. And in the same way a little girl looks on her mother as a person who interferes with her affectionate relation to her father and who occupies a position which she herself could very well fill. Observation shows us to what early years these attitudes go back. We refer to them as the 'Oedipus complex', because the legend of Oedipus realizes, with only a slight softening, the two extreme wishes that arise from the son's situation - to kill his father and take his mother to wife. I do not wish to assert that the Oedipus complex exhausts the relation of children to their parents: it can easily be far more complicated. The Oedipus complex can, moreover, be developed to a greater or less strength, it can even be reversed; but it is a regular and very important factor in a child's mental life, and there is more danger of our under estimating rather than over-estimating its influence and that of the developments which proceed from it. Incidentally, children often react in their Oedipus attitude to a stimulus coming from their parents, who are frequently led in their preferences by difference of sex, so that the father will choose his daughter and the mother her son as a favourite, or, in case of a cooling-off in the marriage, as a substitute for a love-object that has lost its value.
The affections of the little girl are fixed on her father, who has probably done all he could to win her love, and in this way has sown the seeds of an attitude of hatred and rivalry towards her mother. This attitude exists side by side with a current of affectionate dependence on her, and as years go on it may be destined to come into consciousness more and more clearly and forcibly, or else to give an impetus to an excessive reaction of devotion to her. But it is not with the girl's relation to her mother that the beating-phantasy is connected. There are other children in the nursery, only a few years older or younger, who are disliked on all sorts of other grounds, but chiefly because the parents' love has to be shared with them, and for this reason they are repelled with all the wild energy characteristic of the emotional life of those years. If the child in question is a younger brother or sister (as in three of my four cases) it is despised as well as hated; yet it attracts to itself the share of affection which the blinded parents are always ready to give the youngest child, and this is a spectacle the sight of which cannot be avoided. One soon learns that being beaten, even if it does not hurt very much, signifies a deprivation of love and a humiliation. And many children who believed themselves securely enthroned in the unshakable affection of their parents have by a single blow been cast down from all the heavens of their imaginary omnipotence. The idea of the father beating this hateful child is therefore an agreeable one, quite apart from whether he has actually been seen doing so. It means: 'My father does not love this other child, he loves only me.'

We find here for the first time, too, something like a constancy of sex in the persons who play a part in the phantasy. The children who are being beaten are almost invariably boys, in the phantasies of boys just as much as in those of girls. This characteristic is naturally not to be explained by any rivalry between the sexes, as otherwise of course in the phantasies of boys it would be girls who would be being beaten; and it has nothing to do with the sex of the child who was hated in the first phase. But it points to a complication in the case of girls. When they turn away from their incestuous love for their father, with its genital significance, they easily abandon their feminine role. They spur their 'masculinity complex' (van Ophuijsen, 1917) into activity, and from that time forward only want to be boys. For that reason the whipping-boys who represent them are boys too. In both the cases of day-dreaming - one of which almost rose to the level of a work of art - the heroes were always young men; indeed women used not to come into these creations at all, and only made their first appearance after many years, and then in minor parts.

[1919e, 3649]

[1919e, 3652]
After this highly discursive introduction I am only able to present a very concise summary of the sexual history of the case under consideration. In childhood the girl had passed through the normal attitude characteristic of the feminine Oedipus complex¹ in a way that was not at all remarkable, and had later also begun to substitute for her father a brother slightly older than herself. She did not remember any sexual traumas in early life, nor were any discovered by the analysis. Comparison of her brother's genital organs and her own, which took place about the beginning of the latency period (at five years old or perhaps a little earlier), left a strong impression on her and had far-reaching after-effects. There were very few signs pointing to infantile masturbation, or else the analysis did not go far enough to throw light on this point. The birth of a second brother when she was between five and six years old exercised no special influence upon her development. During the pre-pubertal years at school she gradually became acquainted with the facts of sex, and she received this knowledge with mixed feelings of lasciviousness and frightened aversion, in a way which may be called normal and was not exaggerated in degree. This amount of information about her seems meagre enough, nor can I guarantee that it is complete. It may be that the history of her youth was much richer in experiences; I do not know. As I have already said, the analysis was broken off after a short time, and therefore yielded an anamnesis not much more reliable than the other anamneses of homosexuals, which there is good cause to question. Further, the girl had never been neurotic, and came to the analysis without even one hysterical symptom, so that opportunities for investigating the history of her childhood did not present themselves so readily as usual. [1920a, 3845]

Correctly speaking, this dream has no right whatever to be called 'telepathic'. It did not inform the dreamer of anything which (outside his normal knowledge) was taking place elsewhere. What the dream did relate was something quite different from the event reported in the telegram received on the second day after the night of the dream. The dream and the actual occurrence diverge at a particularly important point; but they agree, apart from the coincidence of time, in another very interesting element. In the dream the dreamer's wife had twins. The occurrence, however, was that his daughter had given birth to twins in her distant home. The dreamer did not overlook this difference; he did not seem to know any way of getting over it and, as according to his own account he had no leaning towards the occult, he only asked quite tentatively whether the coincidence between dream and occurrence on the point of the twin-birth could be more than an accident. The psycho-analytic interpretation of dreams, however, does away with this difference between the dream and the event, and gives both the same content. If we consult the associative material to this dream, it shows, in spite of its sparseness, that an intimate bond of feeling existed between the father and daughter, a bond of feeling which is so usual and so natural that we ought to cease to be ashamed of it, one that in daily life merely finds expression as a tender interest and is only pushed to its logical conclusion in dreams. The father knew that his daughter clung to him, he was convinced that she often thought of him during her labour. In his heart I think he grudged her to his son-in-law, to whom in one letter he makes a few disparaging references. On the occasion of her confinement (whether expected or communicated by telepathy) the unconscious wish became active in the repressed part of his mind: 'she ought to be my (second) wife instead'; it was this wish that had distorted the dream-thoughts and was the cause of the difference between the manifest content of the dream and the event. We are entitled to replace the second wife in the dream by the daughter. If we possessed more associations to the dream, we could undoubtedly verify and deepen this interpretation. [1922a, 3886]
Who then is the man, by whom the dreamer wishes to have a child, or of whose likeness she
would like to be the mother? She often tried to see his face, but the dream never allowed her
to; the man had to remain incognito. We know from countless analyses what this concealment
means, and the conclusion we should base on analogy is verified by another statement of the
dreamer's. Under the influence of paraldehyde she once recognized the face of the man in the
dream as that of the hospital physician who was treating her, and who meant nothing more to
her conscious emotional life. The original thus never divulged its identity, but this impression of
it in 'transference' establishes the conclusion that earlier it must always have been her father.
Ferenczi is perfectly right in pointing out that these 'dreams of the unsuspecting' are valuable
sources of information, as confirming the conjectures of analysis. Our dreamer was the eldest of
twelve children; how often must she have suffered the pangs of jealousy and disappointment
when it was not she but her mother who obtained from her father the child she longed for!
[1922a, 3892]

Here is another of our dreamer's 'visions' which will probably become more intelligible in the
light of analytic knowledge. Women friends obviously had a great significance in her emotional
life. Only recently the death of one of them was conveyed to her by a knocking at night on the
bed of a room-mate in the sanatorium. Another friend had many years before married a widower
with several (five) children. On the occasion of her visits to their house she regularly saw the
apparition of a lady, who she could not help supposing was the husband's first wife; this did not
at first permit of confirmation, and only became a matter of certainty with her seven years later,
on the discovery of a fresh photograph of the dead woman. This achievement in the way of a
vision on the part of our correspondent had the same intimate dependence on the family
complexes familiar to us as had her presentiment of her brother's death. By identifying herself
with her friend she could in the person of the latter find the fulfilment of her own wishes; for
every eldest daughter of a numerous family builds up in her unconscious the phantasy of
becoming her father's second wife by the death of her mother. If the mother is ill or dies, the
eldest daughter takes her place as a matter of course in relation to her younger brothers and
sisters, and may even take over some part of the functions of the wife in respect to the father.
The unconscious wish fills in the other part.
[1922a, 3896]
A prediction had been made, then, to the enquirers (at a strange place and by a strange fortune-teller, who was at the same time carrying out some, presumably irrelevant, ritual) that something would happen to them at a particular time, which in fact did not come true. The date at which the prophecy should have been fulfilled was long past. It was striking that those concerned reported their experience not with derision or disappointment but with obvious satisfaction. Included among what had been told them there were certain quite definite details which seemed capricious and unintelligible and would only have been justified if they had hit the mark. Thus, for instance, the palmist told a woman who was twenty-seven (though she looked much younger) and who had taken off her wedding-ring, that she would be married and have two children before she was thirty-two. The woman was forty-three when, now seriously ill, she told me the story in her analysis: she had remained childless. If one knew her private history (of which the 'Professor' in the lounge of the Paris hotel was certainly ignorant) one could understand the two numbers included in the prophecy. The girl had married after an unusually intense attachment to her father and had then had a passionate longing for children, so as to be able to put her husband in the place of her father. After years of disappointment, when she was on the brink of a neurosis, she obtained the prophecy, which promised her - the lot of her mother. For it was a fact that the latter had had two children by the time she was thirty-two. Thus it was only by the help of psycho-analysis that it was possible to give a significant interpretation of the peculiarities of this pretended message from without. But there was then no better explanation of the whole, unequivocally determined chain of events than to suppose that a strong wish on the part of the questioner - the strongest unconscious wish, in fact, of her whole emotional life and the motive force of her impending neurosis - had made itself manifest to the fortune-teller by being directly transferred to him while his attention was being distracted by the performances he was going through.

[1925i, 4054]

To an ever-increasing extent the Oedipus complex reveals its importance as the central phenomenon of the sexual period of early childhood. After that, its dissolution takes place; it succumbs to repression, as we say, and is followed by the latency period. It has not yet become clear, however, what it is that brings about its destruction. Analyses seem to show that it is the experience of painful disappointments. The little girl likes to regard herself as what her father loves above all else; but the time comes when she has to endure a harsh punishment from him and she is cast out of her fool's paradise. The boy regards his mother as his own property; but he finds one day that she has transferred her love and solicitude to a new arrival. Reflection must deepen our sense of the importance of those influences, for it will emphasize the fact that distressing experiences of this sort, which act in opposition to the content of the complex, are inevitable. Even when no special events occur, like those we have mentioned as examples, the absence of the satisfaction hoped for, the continued denial of the desired baby, must in the end lead the small lover to turn away from his hopeless longing. In this way the Oedipus complex would go to its destruction from its lack of success, from the effects of its internal impossibility.

[1924d, 4085]
To an ever-increasing extent the Oedipus complex reveals its importance as the central phenomenon of the sexual period of early childhood. After that, its dissolution takes place; it succumbs to repression, as we say, and is followed by the latency period. It has not yet become clear, however, what it is that brings about its destruction. Analyses seem to show that it is the experience of painful disappointments. The little girl likes to regard herself as what her father loves above all else; but the time comes when she has to endure a harsh punishment from him and she is cast out of her fool's paradise. The boy regards his mother as his own property; but he finds one day that she has transferred her love and solicitude to a new arrival. Reflection must deepen our sense of the importance of those influences, for it will emphasize the fact that distressing experiences of this sort, which act in opposition to the content of the complex, are inevitable. Even when no special events occur, like those we have mentioned as examples, the absence of the satisfaction hoped for, the continued denial of the desired baby, must in the end lead the small lover to turn away from his hopeless longing. In this way the Oedipus complex would go to its destruction from its lack of success, from the effects of its internal impossibility. [1924d, 4085]

The fear of castration being thus excluded in the little girl, a powerful motive also drops out for the setting-up of a super-ego and for the breaking-off of the infantile genital organization. In her, far more than in the boy, these changes seem to be the result of upbringing and of intimidation from outside which threatens her with a loss of love. The girl's Oedipus complex is much simpler than that of the small bearer of the penis; in my experience, it seldom goes beyond the taking of her mother's place and the adopting of a feminine attitude towards her father. Renunciation of the penis is not tolerated by the girl without some attempt at compensation. She slips - along the line of a symbolic equation, one might say - from the penis to a baby. Her Oedipus complex culminates in a desire, which is long retained, to receive a baby from her father as a gift - to bear him a child. One has an impression that the Oedipus complex is then gradually given up because this wish is never fulfilled. The two wishes - to possess a penis and a child - remain strongly cathexed in the unconscious and help to prepare the female creature for her later sexual role. The comparatively lesser strength of the sadistic contribution to her sexual instinct, which we may no doubt connect with the stunted growth of her penis, makes it easier in her case for the direct sexual trends to be transformed into aim-inhibited trends of an affectionate kind. It must be admitted, however, that in general our insight into these developmental processes in girls is unsatisfactory, incomplete and vague. [1924d, 4090]

Every analyst has come across certain women who cling with especial intensity and tenacity to the bond with their father and to the wish in which it culminates of having a child by him. We have good reason to suppose that the same wishful phantasy was also the motive force of their infantile masturbation, and it is easy to form an impression that at this point we have been brought up against an elementary and unanalysable fact of infantile sexual life. But a thorough analysis of these very cases brings something different to light - namely, that here the Oedipus complex has a long prehistory and is in some respects a secondary formation. [1925j, 4149]
So far there has been no question of the Oedipus complex, nor has it up to this point played any part. But now the girl's libido slips into a new position along the line - there is no other way of putting it - of the equation 'penis-child'. She gives up her wish for a penis and puts in place of it a wish for a child: and with that purpose in view she takes her father as a love object. Her mother becomes the object of her jealousy. The girl has turned into a little woman. If I am to credit a single analytic instance, this new situation can give rise to physical sensations which would have to be regarded as a premature awakening of the female genital apparatus. When the girl's attachment to her father comes to grief later on and has to be abandoned, it may give place to an identification with him and the girl may thus return to her masculinity complex and perhaps remain fixated in it.

[1925j, 4154]

The process of arriving at an object, which plays such an important part in mental life, takes place alongside of the organization of the libido. After the stage of auto-erotism, the first love-object in the case of both sexes is the mother; and it seems probable that to begin with a child does not distinguish its mother's organ of nutrition from its own body. Later, but still in the first years of infancy, the relation known as the Oedipus complex becomes established: boys concentrate their sexual wishes upon their mother and develop hostile impulses against their father as being a rival, while girls adopt an analogous attitude.¹ All of the different variations and consequences of the Oedipus complex are important; and the innately bisexual constitution of human beings makes itself felt and increases the number of simultaneously active tendencies. Children do not become clear for quite a long time about the differences between the sexes; and during this period of sexual researches they produce typical sexual theories which, being circumscribed by the incompleteness of their authors' own physical development, are a mixture of truth and error and fail to solve the problems of sexual life (the riddle of the Sphinx - that is, the question of where babies come from). We see, then, that a child's first object-choice is an incestuous one. The whole course of development that I have described is run through rapidly. For the most remarkable feature of the sexual life of man is its diphasic onset, its onset in two waves, with an interval between them. It reaches a first climax in the fourth or fifth year of a child's life. But thereafter this early efflorescence of sexuality passes off; the sexual impulses which have shown such liveliness are overcome by repression, and a period of latency follows, which lasts until puberty and during which the reaction-formations of morality, shame, and disgust are built up.² Of all living creatures man alone seems to show this diphasic onset of sexual growth, and it may perhaps be the biological determinant of his predisposition to neuroses. At puberty the impulses and object-relations of a child's early years become re-animated, and amongst them the emotional ties of its Oedipus complex. In the sexual life of puberty there is a struggle between the urges of early years and the inhibitions of the latency period. Before this, and while the child is at the highest point of its infantile sexual development, a genital organization of a sort is established; but only the male genitals play a part in it, and the female ones remain undiscovered. (I have described this as the period of phallic primacy.) At this stage the contrast between the sexes is not stated in terms of 'male' or 'female' but of 'possessing a penis' or 'castrated'. The castration complex which arises in this connection is of the profoundest importance in the formation alike of character and of neuroses.

[1925d, 4212]
Parallel with this first great difference there is the other, concerned with the finding of the object. In the case of a male, his mother becomes his first love-object as a result of her feeding him and looking after him, and she remains so until she is replaced by someone who resembles her or is derived from her. A female's first object, too, must be her mother: the primary conditions for a choice of object are, of course, the same for all children. But at the end of her development, her father - a man - should have become her new love-object. In other words, to the change in her own sex there must correspond a change in the sex of her object. The new problems that now require investigating are in what way this change takes place, how radically or how incompletely it is carried out, and what the different possibilities are which present themselves in the course of this development.

In regard to the passive impulses of the phallic phase, it is noteworthy that girls regularly accuse their mother of seducing them. This is because they necessarily received their first, or at any rate their strongest, genital sensations when they were being cleaned and having their toilet attended to by their mother (or by someone such as a nurse who took her place). Mothers have often told me, as a matter of observation, that their little daughters of two and three years old enjoy these sensations and try to get their mothers to make them more intense by repeated touching and rubbing. The fact that the mother thus unavoidably initiates the child into the phallic phase is, I think, the reason why, in phantasies of later years, the father so regularly appears as the sexual seducer. When the girl turns away from her mother, she also makes over to her father her introduction into sexual life.

An examination of the analytic literature on the subject shows that everything that has been said by me here is already to be found in it. It would have been superfluous to publish this paper if it were not that in a field of research which is so difficult of access every account of first-hand experiences or personal views may be of value. Moreover, there are a number of points which I have defined more sharply and isolated more carefully. In some of the other papers on the subject the description is obscured because they deal at the same time with the problems of the super-ego and the sense of guilt. This I have avoided doing. Also, in describing the various outcomes of this phase of development, I have refrained from discussing the complications which arise when a child, as a result of disappointment from her father, returns to the attachment to her mother which she had abandoned, or when, in the course of her life, she repeatedly changes over from one position to the other. But precisely because my paper is only one contribution among others, I may be spared an exhaustive survey of the literature, and I can confine myself to bringing out the more important points on which I agree or disagree with these other writings.
The methods of representation employed by the dream-work - fascinating material, scarcely capable of exhaustion - have been made more and more familiar to us by closer study. I will give you a few examples of them. Thus, for instance, dreams represent the relation of frequency by a multiplication of similar things. Here is a young girl's remarkable dream. She dreamt she came into a great hall and found some one in it sitting on a chair; this was repeated six or eight times or more, but each time it was her father. This is easy to understand when we discover, from accessory details in the interpretation, that this room stood for the womb. The dream then becomes equivalent to the phantasy, familiarly found in girls, of having met their rather already during their intra-uterine life when he visited the womb while their mother was pregnant. You should not be confused by the fact that something is reversed in the dream - that her father's 'coming-in' is displaced on to herself; incidentally, this has a special meaning of its own as well. The multiplication of the figure of the father can only express the fact that the event in question occurred repeatedly. After all, it must be allowed that the dream is not taking very much on itself in expressing frequency by multiplicity. It has only needed to go back to the original significance of the former word; to-day it means to us a repetition in time, but it is derived from an accumulation in space. In general, indeed, where it is possible, the dream-work changes temporal relations into spatial ones and represents them as such. In a dream, for instance, one may see a scene between two people who look very small and a long way off, as though one were seeing them through the wrong end of a pair of opera-glasses. Here, both the smallness and the remoteness in space have the same significance: what is meant is remoteness in time and we are to understand that the scene is from the remote past.

[1933a, 4638]

We shall return to the part played by the clitoris; let us now turn to the second task with which a girl's development is burdened. A boy's mother is the first object of his love, and she remains so too during the formation of his Oedipus complex and, in essence, all through his life. For a girl too her first object must be her mother (and the figures of wet-nurses and foster-mothers that merge into her). The first object-cathexes occur in attachment to the satisfaction of the major and simple vital needs, and the circumstances of the care of children are the same for both sexes. But in the Oedipus situation the girl's father has become her love-object, and we expect that in the normal course of development she will find her way from this paternal object to her final choice of an object. In the course of time, therefore, a girl has to change her erotogenic zone and her object - both of which a boy retains. The question then arises of how this happens: in particular, how does a girl pass from her mother to an attachment to her father? or, in other words, how does she pass from her masculine phase to the feminine one to which she is biologically destined?

[1933a, 4720]
It would be a solution of ideal simplicity if we could suppose that from a particular age onwards the elementary influence of the mutual attraction between the sexes makes itself felt and impels the small woman towards men, while the same law allows the boy to continue with his mother. We might suppose in addition that in this the children are following the pointer given them by the sexual preference of their parents. But we are not going to find things so easy; we scarcely know whether we are to believe seriously in the power of which poets talk so much and with such enthusiasm but which cannot be further dissected analytically. We have found an answer of quite another sort by means of laborious investigations, the material for which at least was easy to arrive at. For you must know that the number of women who remain till a late age tenderly dependent on a paternal object, or indeed on their real father, is very great. We have established some surprising facts about these women with an intense attachment of long duration to their father. We knew, of course, that there had been a preliminary stage of attachment to the mother, but we did not know that it could be so rich in content and so long-lasting, and could leave behind so many opportunities for fixations and dispositions. During this time the girl's father is only a troublesome rival; in some cases the attachment to her mother lasts beyond the fourth year of life. Almost everything that we find later in her relation to her father was already present in this earlier attachment and has been transferred subsequently on to her father. In short, we get an impression that we cannot understand women unless we appreciate this phase of their pre-Oedipus attachment to their mother.

[1933a, 4721]

We shall be glad, then, to know the nature of the girl's libidinal relations to her mother. The answer is that they are of very many different kinds. Since they persist through all three phases of infantile sexuality, they also take on the characteristics of the different phases and express themselves by oral, sadistic-anal and phallic wishes. These wishes represent active as well as passive impulses; if we relate them to the differentiation of the sexes which is to appear later - though we should avoid doing so as far as possible - we may call them masculine and feminine. Besides this, they are completely ambivalent, both affectionate and of a hostile and aggressive nature. The latter often only come to light after being changed into anxiety ideas. It is not always easy to point to a formulation of these early sexual wishes; what is most clearly expressed is a wish to get the mother with child and the corresponding wish to bear her a child - both belonging to the phallic period and sufficiently surprising, but established beyond doubt by analytic observation. The attractiveness of these investigations lies in the surprising detailed findings which they bring us. Thus, for instance, we discover the fear of being murdered or poisoned, which may later form the core of a paranoic illness, already present in this pre-Oedipus period, in relation to the mother. Or another case: you will recall an interesting episode in the history of analytic research which caused me many distressing hours. In the period in which the main interest was directed to discovering infantile sexual traumas, almost all my women patients told me that they had been seduced by their father. I was driven to recognize in the end that these reports were untrue and so came to understand that hysterical symptoms are derived from phantasies and not from real occurrences. It was only later that I was able to recognize in this phantasy of being seduced by the father the expression of the typical Oedipus complex in women. And now we find the phantasy of seduction once more in the pre-Oedipus prehistory of girls; but the seducer is regularly the mother. Here, however, the phantasy touches the ground of reality, for it was really the mother who by her activities over the child's bodily hygiene inevitably stimulated, and perhaps even roused for the first time, pleasurable sensations in her genitals.

[1933a, 4722]
Along with the abandonment of clitoridal masturbation a certain amount of activity is renounced. Passivity now has the upper hand, and the girl's turning to her father is accomplished principally with the help of passive instinctual impulses. You can see that a wave of development like this, which clears the phallic activity out of the way, smooths the ground for femininity. If too much is not lost in the course of it through repression, this femininity may turn out to be normal. The wish with which the girl turns to her father is no doubt originally the wish for the penis which her mother has refused her and which she now expects from her father. The feminine situation is only established, however, if the wish for a penis is replaced by one for a baby, if, that is, a baby takes the place of a penis in accordance with an ancient symbolic equivalence. It has not escaped us that the girl has wished for a baby earlier, in the undisturbed phallic phase: that, of course, was the meaning of her playing with dolls. But that play was not in fact an expression of her femininity; it served as an identification with her mother with the intention of substituting activity for passivity. She was playing the part of her mother and the doll was herself: now she could do with the baby everything that her mother used to do with her. Not until the emergence of the wish for a penis does the doll-baby become a baby from the girl's father, and thereafter the aim of the most powerful feminine wish. Her happiness is great if later on this wish for a baby finds fulfilment in reality, and quite especially so if the baby is a little boy who brings the longed-for penis with him. Often enough in her combined picture of 'a baby from her father' the emphasis is laid on the baby and her father left unstressed. In this way the ancient masculine wish for the possession of a penis is still faintly visible through the femininity now achieved. But perhaps we ought rather to recognize this wish for a penis as being par excellence a feminine one.

With the transference of the wish for a penis-baby on to her father, the girl has entered the situation of the Oedipus complex. Her hostility to her mother, which did not need to be freshly created, is now greatly intensified, for she becomes the girl's rival, who receives from her father everything that she desires from him. For a long time the girl's Oedipus complex concealed her pre-Oedipus attachment to her mother from our view, though it is nevertheless so important and leaves such lasting fixations behind it. For girls the Oedipus situation is the outcome of a long and difficult development; it is a kind of preliminary solution, a position of rest which is not soon abandoned, especially as the beginning of the latency period is not far distant. And we are now struck by a difference between the two sexes, which is probably momentous, in regard to the relation of the Oedipus complex to the castration complex. In a boy the Oedipus complex, in which he desires his mother and would like to get rid of his father as being a rival, develops naturally from the phase of his phallic sexuality. The threat of castration compels him, however, to give up that attitude. Under the impression of the danger of losing his penis, the Oedipus complex is abandoned, repressed and, in the most normal cases, entirely destroyed, and a severe super-ego is set up as its heir. What happens with a girl is almost the opposite. The castration complex prepares for the Oedipus complex instead of destroying it; the girl is driven out of her attachment to her mother through the influence of her envy for the penis and she enters the Oedipus situation as though into a haven of refuge. In the absence of fear of castration the chief motive is lacking which leads boys to surmount the Oedipus complex. Girls remain in it for an indeterminate length of time; they demolish it late and, even so, incompletely. In these circumstances the formation of the super-ego must suffer; it cannot attain the strength and independence which give it its cultural significance, and feminists are not pleased when we point out to them the effects of this factor upon the average feminine character.
The determinants of women's choice of an object are often made unrecognizable by social conditions. Where the choice is able to show itself freely, it is often made in accordance with the narcissistic ideal of the man whom the girl had wished to become. If the girl has remained in her attachment to her mother - that is, in the Oedipus complex - her choice is made according to the paternal type. Since, when she turned from her mother to her father, the hostility of her ambivalent relation remained with her mother, a choice of this kind should guarantee a happy marriage. But very often the outcome is of a kind that presents a general threat to such a settlement of the conflict due to ambivalence. The hostility that has been left behind follows in the train of the positive attachment and spreads over on to the new object. The woman's husband, who to begin with inherited from her father, becomes after a time her mother's heir as well. So it may easily happen that the second half of a woman's life may be filled by the struggle against her husband, just as the shorter first half was filled by her rebellion against her mother. When this reaction has been lived through, a second marriage may easily turn out very much more satisfying. Another alteration in a woman's nature, for which lovers are unprepared, may occur in a marriage after the first child is born. Under the influence of a woman's becoming a mother herself, an identification with her own mother may be revived, against which she had striven up till the time of her marriage, and this may attract all the available libido to itself, so that the compulsion to repeat reproduces an unhappy marriage between her parents. The difference in a mother's reaction to the birth of a son or a daughter shows that the old factor of lack of a penis has even now not lost its strength. A mother is only brought unlimited satisfaction by her relation to a son; this is altogether the most perfect, the most free from ambivalence of all human relationships. A mother can transfer to her son the ambition which she has been obliged to suppress in herself, and she can expect from him the satisfaction of all that has been left over in her of her masculinity complex. Even a marriage is not made secure until the wife has succeeded in making her husband her child as well and in acting as a mother to him. [1933a, 4735]

If a little girl persists in her first wish - to grow into a boy - in extreme cases she will end as a manifest homosexual, and otherwise she will exhibit markedly masculine traits in the conduct of her later life, will choose a masculine vocation, and so on. The other path leads by way of abandoning the mother she has loved: the daughter, under the influence of her envy for the penis, cannot forgive her mother for having sent her into the world so insufficiently equipped. In her resentment over this she gives up her mother and puts someone else in her place as the object of her love - her father. If one has lost a love-object, the most obvious reaction is to identify oneself with it, to replace it from within, as it were, by identification. This mechanism now comes to the little girl's help. Identification with her mother can take the place of attachment to her mother. The little daughter puts herself in her mother's place, as she has always done in her games; she tries to take her mother's place with her father, and begins to hate the mother she used to love, and from two motives: from jealousy as well as from mortification over the penis she has been denied. Her new relation to her father may start by having as its content a wish to have his penis at her disposal, but it culminates in another wish - to have a baby from him as a gift. The wish for a baby has thus taken the place of the wish for a penis, or has at all events split off from it. [1940a [1938], 5000]
Occasions for conflict between a daughter and her mother arise when the daughter begins to grow up and long for sexual liberty, but finds herself under her mother's tutelage; while the mother, on the other hand, is warned by her daughter's growth that the time has come when she herself must abandon her claims to sexual satisfaction.

[1900a, 736]

ANALYSIS. - It is no easy matter to give a complete interpretation of the dream. It formed part of a cycle of dreams and can only be fully understood if it is taken in connection with the others. There is difficulty in obtaining in sufficient isolation the material necessary for establishing the symbolism. - In the first place, the patient declared that the train journey was to be interpreted historically, as an allusion to a journey she had taken when she was leaving a sanatorium for nervous diseases, with whose director, needless to say, she had been in love. Her mother had fetched her away, and the doctor had appeared at the station and handed her a bouquet of flowers as a parting present. It had been very awkward that her mother should have witnessed this tribute. At this point, then, her mother figured as interfering with her attempts at a love affair; and this had in fact been the part played by that severe lady during the patient's girlhood. - Her next association related to the sentence: 'she looked round to see whether the parts could not be seen from behind.' The façade of the dream would of course lead one to think of the parts of her little daughter who had been run over and mangled. But her association led in quite another direction. She recollected having once seen her father naked in the bath room from behind; she went on to talk of the distinctions between the sexes, and laid stress on the fact that a man's genitals can be seen even from behind but a woman's cannot. In this connection she herself interpreted 'the little one' as meaning the genitals and 'her little one' - she had a four-year-old daughter - as her own genitals. She reproached her mother with having expected her to live as though she had no genitals, and pointed out that the same reproach was expressed in the opening sentence of the dream: 'her mother sent her little one away, so that she had to go by herself.' In her imagination 'going by herself in the streets' meant not having a man, not having any sexual relations ('coire' in Latin means literally 'to go with') - and she disliked that. Her accounts all went to show that when she was a girl she had in fact suffered from her mother's jealousy owing to the preference shown her by her father.

[1900a, 825]

The deeper interpretation of this dream was shown by another dream of the same night, in which the dreamer identified herself with her brother. She had actually been a boyish girl, and had often been told that she should have been a boy. This identification with her brother made it particularly clear that 'the little one' meant a genital organ. Her mother was threatening him (or her) with castration, which could only have been a punishment for playing with her penis; thus the identification also proved that she herself had masturbated as a child - a memory which till then she had only had as applied to her brother. The information supplied by the second dream showed that she must have come to know about the male organ at an early age and have afterwards forgotten it. Further, the second dream alluded to the infantile sexual theory according to which girls are boys who have been castrated. When I suggested to her that she had had this childish belief, she at once confirmed the fact by telling me that she had heard the anecdote of the little boy's saying to the little girl: 'Cut off?' and of the little girl's replying: 'No, always been like that.'

[1900a, 825]
'That is to say, you knew that it was so. - The meaning of the dream is now becoming even clearer. You said to yourself: "This man is persecuting me; he wants to force his way into my room. My 'jewel-case' is in danger, and if anything happens it will be Father's fault." For that reason in the dream you chose a situation which expresses the opposite - a danger from which your father is saving you. In this part of the dream everything is turned into its opposite; you will soon discover why. As you say, the mystery turns upon your mother. You ask how she comes into the dream? She is, as you know, your former rival in your father's affections. In the incident of the bracelet, you would have been glad to accept what your mother had rejected. Now let us just put "give" instead of "accept" and "withhold" instead of "reject". Then it means that you were ready to give your father what your mother withheld from him; and the thing in question was connected with jewellery.¹ Now bring your mind back to the jewel-case which Herr K. gave you. You have there the starting-point for a parallel line of thoughts, in which Herr K. is to be put in the place of your father just as he was in the matter of standing beside your bed. He gave you a jewel-case; so you are to give him your jewel-case. That was why I spoke just now of a "return-present". In this line of thoughts your mother must be replaced by Frau K. (You will not deny that she, at any rate, was present at the time.) So you are ready to give Herr K., what his wife withholds from him. That is the thought which has had to be repressed with so much energy, and which has made it necessary for every one of its elements to be turned into its opposite. The dream confirms once more what I had already told you before you dreamt it - that you are summoning up your old love for your father in order to protect yourself against your love for Herr K. But what do all these efforts show? Not only that you are afraid of Herr K., but that you are still more afraid of yourself, and of the temptation you feel to yield to him. In short, these efforts prove once more how deeply you loved him.'²

¹[1905e, 1407]

The two groups of ideas met in this one thought: 'Mother got both things from father: the sexual wetness and the dirtying discharge.' Dora's jealousy of her mother was inseparable from the group of thoughts relating to her infantile love for her father which she summoned up for her protection. But this material was not yet capable of representation. If, however, a recollection could be found which was equally closely connected with both the groups related to the word 'wet', but which avoided any offensiveness, then such a recollection would be able to take over the representation in the dream of the material in question.

²[1905e, 1426]

A recollection of this sort was furnished by the episode of the 'drops' - the jewellery ['Schmuck'] that Dora's mother wanted to have. In appearance the connection between this reminiscence and the two groups of thoughts relating to sexual wetness and to being dirtied was a purely external and superficial one, of a verbal character. For 'drops' was used ambiguously as a 'switch-word', while 'jewellery' ['Schmuck'] was taken as an equivalent to 'clean', and thus as a rather forced contrary of 'dirtied'.¹ But in reality the most substantial connections can be shown to have existed between the things denoted themselves. The recollection originated from the material connected with Dora's jealousy of her mother, which, though its roots were infantile, had persisted far beyond that period. By means of these two verbal bridges it was possible to transfer on to the single reminiscence of the 'jewel-drops' the whole of the significance attaching to the ideas of her parents' sexual intercourse, and of her mother's gonorrhoea and tormenting passion for cleanliness.

¹[1905e, 1426]
Let us return to the sexual development of children. We have some arrears to make up owing to our having paid more attention to the somatic than to the mental phenomena of sexual life. The child's first choice of an object, which derives from its need for help, claims our further interest. Its choice is directed in the first instance to all those who look after it, but these soon give place to its parents. Children's relations to their parents, as we learn alike from direct observations of children and from later analytic examination of adults, are by no means free from elements of accompanying sexual excitation. The child takes both of its parents, and more particularly one of them, as the object of its erotic wishes. In so doing, it usually follows some indication from its parents, whose affection bears the clearest characteristics of a sexual activity, even though of one that is inhibited in its aims. As a rule a father prefers his daughter and a mother her son; the child reacts to this by wishing, if he is a son, to take his father's place, and, if she is a daughter, her mother's. The feelings which are aroused in these relations between parents and children and in the resulting ones between brothers and sisters are not only of a positive or affectionate kind but also of a negative or hostile one. The complex which is thus formed is doomed to early repression; but it continues to exercise a great and lasting influence from the unconscious. It is to be suspected that, together with its extensions, it constitutes the *nuclear complex* of every neurosis, and we may expect to find it no less actively at work in other regions of mental life. The myth of King Oedipus, who killed his father and took his mother to wife, reveals, with little modification, the infantile wish, which is later opposed and repudiated by the *barrier against incest*. Shakespeare's *Hamlet* is equally rooted in the soil of the incest-complex, but under a better disguise.

When a mother hinders or arrests a daughter's sexual activity, she is fulfilling a normal function whose lines are laid down by events in childhood, which has powerful, unconscious motives, and has received the sanction of society. It is the daughter's business to emancipate herself from this influence and to decide for herself on broad and rational grounds what her share of enjoyment or denial of sexual pleasure shall be. If in the attempt to emancipate herself she falls a victim to a neurosis it implies the presence of a mother-complex which is as a rule over-powerful, and is certainly unmastered. The conflict between this complex and the new direction taken by the libido is dealt with in the form of one neurosis or another, according to the subject's disposition. The manifestation of the neurotic reaction will always be determined, however, not by her present-day relation to her actual mother but by her infantile relations to her earliest image of her mother.
This relation is undoubtedly a more favourable one, from the children's point of view as well. That is what our expectations demand; we find an absence of love far more repellent between parents and children than between brothers and sisters. In the former case we have, as it were, made something sacred which in the latter we have left profane. Yet daily observation can show us how frequently the emotional relations between parents and their grown-up children fall behind the ideal set up by society, how much hostility is ready to hand and would be expressed if it were not held back by admixtures of filial piety and affectionate impulses. The motives for this hostility are generally known and their tendency is to divide those of the same sex - the daughter from the mother and the father from the son. The daughter finds in her mother the authority which restricts her will and which is entrusted with the task of imposing on her the renunciation of sexual freedom which society demands; in a few instances she even finds in her a competitor who struggles against being supplanted. The same thing is repeated between the son and his father still more glaringly. In the son's eyes his father embodies every unwillingly tolerated social restraint; his father prevents him from exercising his will, from early sexual pleasure and, where there is common property in the family, from enjoying it. In the case of an heir to the throne this waiting for a father's death reaches an almost tragic height. There seems less danger to the relation between father and daughter or mother and son. This last provides the purest examples of an unchangeable affection, unimpaired by any egoistic considerations. [1916-1917, 3294]

What I have in mind is rivalry in love, with a clear emphasis on the subject's sex. While he is still a small child, a son will already begin to develop a special affection for his mother, whom he regards as belonging to him; he begins to feel his father as a rival who disputes his sole possession. And in the same way a little girl looks on her mother as a person who interferes with her affectionate relation to her father and who occupies a position which she herself could very well fill. Observation shows us to what early years these attitudes go back. We refer to them as the 'Oedipus complex', because the legend of Oedipus realizes, with only a slight softening, the two extreme wishes that arise from the son's situation - to kill his father and take his mother to wife. I do not wish to assert that the Oedipus complex exhausts the relation of children to their parents: it can easily be far more complicated. The Oedipus complex can, moreover, be developed to a greater or less strength, it can even be reversed; but it is a regular and very important factor in a child's mental life, and there is more danger of our under estimating rather than over-estimating its influence and that of the developments which proceed from it. Incidentally, children often react in their Oedipus attitude to a stimulus coming from their parents, who are frequently led in their preferences by difference of sex, so that the father will choose his daughter and the mother her son as a favourite, or, in case of a cooling-off in the marriage, as a substitute for a love-object that has lost its value. [1916-1917, 3295]
What, then, can be gathered about the Oedipus complex from the direct observation of children at the time of their making their choice of an object before the latency period? Well, it is easy to see that the little man wants to have his mother all to himself, that he feels the presence of his father as a nuisance, that he is resentful if his father indulges in any signs of affection towards his mother and that he shows satisfaction when his father has gone on a journey or is absent. He will often express his feelings directly in words and promise his mother to marry her. It will be thought that this amounts to little compared to the deeds of Oedipus; but in fact it is enough, it is the same thing at root. Observation is often obscured by the circumstance that on other occasions the same child will simultaneously give evidence of great affection for his father. But contrary - or, as it is better to say, 'ambivalent' - emotional attitudes, which in adults would lead to a conflict, remain compatible with each other for a long time in children, just as later they find a permanent place beside each other in the unconscious. It will also be objected that the little boy's conduct arises from egoistic motives and gives no grounds for postulating an erotic complex: the child's mother attends to all his needs, so that he has an interest in preventing her from looking after anyone else. This also is true; but it will soon become clear that in this situation as in similar ones the egoistic interest is merely affording a point of support to which the erotic trend is attached. The little boy may show the most undisguised sexual curiosity about his mother, he may insist upon sleeping beside her at night, he may force his presence on her while she is dressing or may even make actual attempts at seducing her, as his mother will often notice and report with amusement - all of which puts beyond doubt the erotic nature of his tie with his mother. Nor must it be forgotten that the mother devotes the same attention to a little daughter without producing the same result and that the father often competes with her in looking after the boy and yet fails to gain the same significance as she does. In short, the factor of sexual preference cannot be eliminated from the situation by any criticism. From the standpoint of egoistic interest it would be simply foolish of the little man not to prefer to put up with having two people in his service rather than only one of them.

The affections of the little girl are fixed on her father, who has probably done all he could to win her love, and in this way has sown the seeds of an attitude of hatred and rivalry towards her mother. This attitude exists side by side with a current of affectionate dependence on her, and as years go on it may be destined to come into consciousness more and more clearly and forcibly, or else to give an impetus to an excessive reaction of devotion to her. But it is not with the girl's relation to her mother that the beating-phantasy is connected. There are other children in the nursery, only a few years older or younger, who are disliked on all sorts of other grounds, but chiefly because the parents' love has to be shared with them, and for this reason they are repelled with all the wild energy characteristic of the emotional life of those years. If the child in question is a younger brother or sister (as in three of my four cases) it is despised as well as hated; yet it attracts to itself the share of affection which the blinded parents are always ready to give the youngest child, and this is a spectacle the sight of which cannot be avoided. One soon learns that being beaten, even if it does not hurt very much, signifies a deprivation of love and a humiliation. And many children who believed themselves securely enthroned in the unshakable affection of their parents have by a single blow been cast down from all the heavens of their imaginary omnipotence. The idea of the father beating this hateful child is therefore an agreeable one, quite apart from whether he has actually been seen doing so. It means: 'My father does not love this other child, he loves only me.'
Let us disentangle identification as it occurs in the structure of a neurotic symptom from its rather complicated connections. Supposing that a little girl (and we will keep to her for the present) develops the same painful symptom as her mother - for instance, the same tormenting cough. This may come about in various ways. The identification may come from the Oedipus complex; in that case it signifies a hostile desire on the girl's part to take her mother's place, and the symptom expresses her object-love towards her father, and brings about a realization, under the influence of a sense of guilt, of her desire to take her mother's place: 'You wanted to be your mother, and now you are - anyhow so far as your sufferings are concerned.' This is the complete mechanism of the structure of a hysterical symptom. Or, on the other hand, the symptom may be the same as that of the person who is loved; so, for instance, Dora¹ imitated her father's cough. In that case we can only describe the state of things by saying that identification has appeared instead of object-choice, and that object-choice has regressed to identification. We have heard that identification is the earliest and original form of emotional tie; it often happens that under the conditions in which symptoms are constructed, that is, where there is repression and where the mechanisms of the unconscious are dominant, object-choice is turned back into identification - the ego assumes the characteristics of the object. It is noticeable that in these identifications the ego sometimes copies the person who is not loved and sometimes the one who is loved. It must also strike us that in both cases the identification is a partial and extremely limited one and only borrows a single trait from the person who is its object.

[1921c, 3798]
The little series of reminiscences must engage our attention for a while longer. I have stated elsewhere that such scenes of childhood are 'screen memories' selected at a later period, put together, and not infrequently falsified in the process. This subsequent remodelling serves a purpose that is sometimes easy to guess. In our case one can almost hear the writer's ego glorifying or soothing itself by means of this series of recollections. 'I was from infancy a particularly noble and compassionate creature. I learnt quite early that animals have souls as we have, and could not endure cruelty to animals. The sins of the flesh were far from me and I preserved my chastity till late in life.' With declarations such as these she was loudly contradicting the inferences that we have to make about her early childhood on the basis of our analytical experience, namely, that she had an abundance of premature sexual impulses and violent feelings of hatred for her mother and her younger brothers and sisters. (Besides the genital significance I have just assigned to it, the little bird may also be a symbol of a child, like all small animals; her recollection thus accentuated very insistently the fact that this small creature had the same right to exist as she herself.) Hence the short series of recollections furnishes a very nice example of a mental structure with a twofold aspect. Viewed superficially, we may find in it the expression of an abstract idea, here, as usually, with an ethical reference. In Silberer's nomenclature the structure has an anagogic content. On deeper investigation it reveals itself as a chain of phenomena belonging to the region of the repressed life of the instincts - it displays its psycho-analytic content. As you know, Silberer, who was among the first to issue a warning to us not to lose sight of the nobler side of the human soul, has put forward the view that all or nearly all dreams permit such a twofold interpretation, a purer, anagogic one beside the ignoble, psycho-analytic one. This is, however, unfortunately not so. On the contrary, an over-interpretation of this kind is rarely possible. To my knowledge no valid example of such a dream-analysis with a double meaning has been published up to the present time. But observations of this kind can often be made upon the series of associations that our patients produce during analytic treatment. On the one hand the successive ideas are linked by a line of association which is plain to the eye, while on the other hand you become aware of an underlying theme which is kept secret but which at the same time plays a part in all these ideas. The contrast between the two themes that dominate the same series of ideas is not always one between the lofty anagogic and the low psycho-analytic, but one rather between offensive and respectable or indifferent ideas - a fact that easily explains why such a chain of associations with a twofold determination arises. In our present example it is of course not accidental that the anagogic and the psycho-analytic interpretations stood in such a sharp contrast to each other; both related to the same material, and the later trend was no other than that of the reaction-formations which had been erected against the disowned instinctual impulses.

Here is another of our dreamer's 'visions' which will probably become more intelligible in the light of analytic knowledge. Women friends obviously had a great significance in her emotional life. Only recently the death of one of them was conveyed to her by a knocking at night on the bed of a room-mate in the sanatorium. Another friend had many years before married a widower with several (five) children. On the occasion of her visits to their house she regularly saw the apparition of a lady, who she could not help supposing was the husband's first wife; this did not at first permit of confirmation, and only became a matter of certainty with her seven years later, on the discovery of a fresh photograph of the dead woman. This achievement in the way of a vision on the part of our correspondent had the same intimate dependence on the family complexes familiar to us as had her presentiment of her brother's death. By identifying herself with her friend she could in the person of the latter find the fulfilment of her own wishes; for every eldest daughter of a numerous family builds up in her unconscious the phantasy of becoming her father's second wife by the death of her mother. If the mother is ill or dies, the eldest daughter takes her place as a matter of course in relation to her younger brothers and sisters, and may even take over some part of the functions of the wife in respect to the father. The unconscious wish fills in the other part.
A third consequence of penis-envy seems to be a loosening of the girl's relation with her mother as a love-object. The situation as a whole is not very clear, but it can be seen that in the end the girl's mother, who sent her into the world so insufficiently equipped, is almost always held responsible for her lack of a penis. The way in which this comes about historically is often that soon after the girl has discovered that her genitals are unsatisfactory she begins to show jealousy of another child on the ground that her mother is fonder of it than of her, which serves as a reason for her giving up her affectionate relation to her mother. It will fit in with this if the child which has been preferred by her mother is made into the first object of the beating-phantasy which ends in masturbation.

So far there has been no question of the Oedipus complex, nor has it up to this point played any part. But now the girl's libido slips into a new position along the line - there is no other way of putting it - of the equation 'penis-child'. She gives up her wish for a penis and puts in place of it a wish for a child: and with that purpose in view she takes her father as a love object. Her mother becomes the object of her jealousy. The girl has turned into a little woman. If I am to credit a single analytic instance, this new situation can give rise to physical sensations which would have to be regarded as a premature awakening of the female genital apparatus. When the girl's attachment to her father comes to grief later on and has to be abandoned, it may give place to an identification with him and the girl may thus return to her masculinity complex and perhaps remain fixated in it.

[1925], 4152
The process of arriving at an object, which plays such an important part in mental life, takes place alongside of the organization of the libido. After the stage of auto-erotism, the first love-object in the case of both sexes is the mother; and it seems probable that to begin with a child does not distinguish its mother's organ of nutrition from its own body. Later, but still in the first years of infancy, the relation known as the Oedipus complex becomes established: boys concentrate their sexual wishes upon their mother and develop hostile impulses against their father as being a rival, while girls adopt an analogous attitude.¹ All of the different variations and consequences of the Oedipus complex are important; and the innately bisexual constitution of human beings makes itself felt and increases the number of simultaneously active tendencies. Children do not become clear for quite a long time about the differences between the sexes; and during this period of sexual researches they produce typical sexual theories which, being circumscribed by the incompleteness of their authors' own physical development, are a mixture of truth and error and fail to solve the problems of sexual life (the riddle of the Sphinx - that is, the question of where babies come from). We see, then, that a child's first object-choice is an incestuous one. The whole course of development that I have described is run through rapidly. For the most remarkable feature of the sexual life of man is its diphasic onset, its onset in two waves, with an interval between them. It reaches a first climax in the fourth or fifth year of a child's life. But thereafter this early efflorescence of sexuality passes off; the sexual impulses which have shown such liveliness are overcome by repression, and a period of latency follows, which lasts until puberty and during which the reaction-formations of morality, shame, and disgust are built up.² Of all living creatures man alone seems to show this diphasic onset of sexual growth, and it may perhaps be the biological determinant of his predisposition to neuroses. At puberty the impulses and object-relations of a child's early years become re-animated, and amongst them the emotional ties of its Oedipus complex. In the sexual life of puberty there is a struggle between the urges of early years and the inhibitions of the latency period. Before this, and while the child is at the highest point of its infantile sexual development, a genital organization of a sort is established; but only the male genitals play a part in it, and the female ones remain undiscovered. (I have described this as the period of phallic primacy.) At this stage the contrast between the sexes is not stated in terms of 'male' or 'female' but of 'possessing a penis' or 'castrated'. The castration complex which arises in this connection is of the profoundest importance in the formation alike of character and of neuroses.

¹ (Footnote added 1935:) The information about infantile sexuality was obtained from the study of men and the theory deduced from it was concerned with male children. It was natural enough to expect to find a complete parallel between the two sexes; but this turned out not to hold. Further investigations and reflections revealed profound differences between the sexual development of men and women. The first sexual object of a baby girl (just as of a baby boy) is her mother; and before a woman can reach the end of her normal development she has to change not only her sexual object but also her leading genital zone. From this circumstance difficulties arise and possibilities of inhibition which are not present in the case of men.

² (1925d, 4212) Parallel with this first great difference there is the other, concerned with the finding of the object. In the case of a male, his mother becomes his first love-object as a result of her feeding him and looking after him, and she remains so until she is replaced by someone who resembles her or is derived from her. A female's first object, too, must be her mother: the primary conditions for a choice of object are, of course, the same for all children. But at the end of her development, her father - a man - should have become her new love-object. In other words, to the change in her own sex there must correspond a change in the sex of her object. The new problems that now require investigating are in what way this change takes place, how radically or how incompletely it is carried out, and what the different possibilities are which present themselves in the course of this development.
With many women we have the impression that their years of maturity are occupied by a struggle with their husband, just as their youth was spent in a struggle with their mother. In the light of the previous discussions we shall conclude that their hostile attitude to their mother is not a consequence of the rivalry implicit in the Oedipus complex, but originates from the preceding phase and has merely been reinforced and exploited in the Oedipus situation. And actual analytic examination confirms this view. Our interest must be directed to the mechanisms that are at work in her turning away from the mother who was an object so intensely and exclusively loved. We are prepared to find, not a single factor, but a whole number of them operating together towards the same end.

Another, much more specific motive for turning away from the mother arises from the effect of the castration complex on the creature who is without a penis. At some time or other the little girl makes the discovery of her organic inferiority - earlier and more easily, of course, if there are brothers or other boys about. We have already taken note of the three paths which diverge from this point: (a) the one which leads to a cessation of her whole sexual life, (b) the one which leads to a defiant over-emphasis of her masculinity, and (c) the first steps towards definitive femininity. It is not easy to determine the exact timing here or the typical course of events. Even the point of time when the discovery of castration is made varies, and a number of other factors seem to be inconstant and to depend on chance. The state of the girl's own phallic activity plays a part; and so too does the question whether this activity was found out or not, and how much interference with it she experienced afterwards.

A prohibition of masturbation, as we have seen, becomes an incentive for giving it up; but it also becomes a motive for rebelling against the person who prohibits it - that is to say, the mother, or the mother-substitute who later regularly merges with her. A defiant persistence in masturbation appears to open the way to masculinity. Even where the girl has not succeeded in suppressing her masturbation, the effect of the apparently vain prohibition is seen in her later efforts to free herself at all costs from a satisfaction which has been spoilt for her. When she reaches maturity her object-choice may still be influenced by this persisting purpose. Her resentment at being prevented from free sexual activity plays a big part in her detachment from her mother. The same motive comes into operation again after puberty, when her mother takes up her duty of guarding her daughter's chastity. We shall, of course, not forget that the mother is similarly opposed to a boy's masturbating and thus provides him, too, with a strong motive for rebellion.

However this may be, at the end of this first phase of attachment to the mother, there emerges, as the girl's strongest motive for turning away from her, the reproach that her mother did not give her a proper penis - that is to say, brought her into the world as a female. A second reproach, which does not reach quite so far back, is rather a surprising one. It is that her mother did not give her enough milk, did not suckle her long enough. Under the conditions of modern civilization this may be true often enough, but certainly not so often as is asserted in analyses. It would seem rather that this accusation gives expression to the general dissatisfaction of children, who, in our monogamous civilization, are weaned from the breast after six or nine months, whereas the primitive mother devotes herself exclusively to her child for two or three years. It is as though our children had remained for ever unsated, as though they had never sucked long enough at their mother's breast. But I am not sure whether, if one analysed children who had been suckled as long as the children of primitive peoples, one would not come upon the same complaint. Such is the greed of a child's libido!
When we survey the whole range of motives for turning away from the mother which analysis brings to light - that she failed to provide the little girl with the only proper genital, that she did not feed her sufficiently, that she compelled her to share her mother's love with others, that she never fulfilled all the girl's expectations of love, and, finally, that she first aroused her sexual activity and then forbade it - all these motives seem nevertheless insufficient to justify the girl's final hostility. Some of them follow inevitably from the nature of infantile sexuality; others appear like rationalizations devised later to account for the uncomprehended change in feeling. Perhaps the real fact is that the attachment to the mother is bound to perish, precisely because it was the first and was so intense; just as one can often see happen in the first marriages of young women which they have entered into when they were most passionately in love. In both situations the attitude of love probably comes to grief from the disappointments that are unavoidable and from the accumulation of occasions for aggression. As a rule, second marriages turn out much better.

[1931b, 4598]

We cannot go so far as to assert that the ambivalence of emotional cathexes is a universally valid law, and that it is absolutely impossible to feel great love for a person without its being accompanied by a hatred that is perhaps equally great, or vice versa. Normal adults do undoubtedly succeed in separating those two attitudes from each other, and do not find themselves obliged to hate their love-objects and to love their enemy as well as hate him. But this seems to be the result of later developments. In the first phases of erotic life, ambivalence is evidently the rule. Many people retain this archaic trait all through their lives. It is characteristic of obsessional neurotics that in their object-relationships love and hate counterbalance each other. In primitive races, too, we may say that ambivalence predominates. We shall conclude, then, that the little girl's intense attachment to her mother is strongly ambivalent, and that it is in consequence precisely of this ambivalence that (with the assistance of the other factors we have adduced) her attachment is forced away from her mother - once again, that is to say, in consequence of a general characteristic of infantile sexuality.

[1931b, 4599]

A further question arises: 'What does the little girl require of her mother? What is the nature of her sexual aims during the time of exclusive attachment to her mother?' The answer we obtain from the analytic material is just what we should expect. The girl's sexual aims in regard to her mother are active as well as passive and are determined by the libidinal phases through which the child passes. Here the relation of activity to passivity is especially interesting. It can easily be observed that in every field of mental experience, not merely that of sexuality, when a child receives a passive impression it has a tendency to produce an active reaction. It tries to do itself what has just been done to it. This is part of the work imposed on it of mastering the external world and can even lead to its endeavouring to repeat an impression which it would have reason to avoid on account of its distressing content. Children's play, too, is made to serve this purpose of supplementing a passive experience with an active piece of behaviour and of thus, as it were, annulling it. When a doctor has opened a child's mouth, in spite of his resistance, to look down his throat, the same child, after the doctor has gone, will play at being the doctor himself, and will repeat the assault upon some small brother or sister who is as helpless in his hands as he was in the doctor's. Here we have an unmistakable revolt against passivity and a preference for the active role. This swing-over from passivity to activity does not take place with the same regularity or vigour in all children; in some it may not occur at all. A child's behaviour in this respect may enable us to draw conclusions as to the relative strength of the masculinity and femininity that it will exhibit in its sexuality.

[1931b, 4600]
The first sexual and sexually coloured experiences which a child has in relation to its mother are naturally of a passive character. It is suckled, fed, cleaned, and dressed by her, and taught to perform all its functions. A part of its libido goes on clinging to those experiences and enjoys the satisfactions bound up with them; but another part strives to turn them into activity. In the first place, being suckled at the breast gives place to active sucking. As regards the other experiences the child contents itself either with becoming self-sufficient - that is, with itself successfully carrying out what had hitherto been done for it - or with repeating its passive experiences in an active form in play; or else it actually makes its mother into the object and behaves as the active subject towards her. For a long time I was unable to credit this last behaviour, which takes place in the field of real action, until my observations removed all doubts on the matter.

[1931b, 4600]

We seldom hear of a little girl's wanting to wash or dress her mother, or tell her to perform her excretory functions. Sometimes, it is true, she says: 'Now let's play that I'm the mother and you're the child'; but generally she fulfils these active wishes in an indirect way, in her play with her doll, in which she represents the mother and the doll the child. The fondness girls have for playing with dolls, in contrast to boys, is commonly regarded as a sign of early awakened femininity. Not unjustly so; but we must not overlook the fact that what finds expression here is the active side of femininity, and that the little girl's preference for dolls is probably evidence of the exclusiveness of her attachment to her mother, with complete neglect of her father-object.

[1931b, 4601]

The very surprising sexual activity of little girls in relation to their mother is manifested chronologically in oral, sadistic, and finally even in phallic trends directed towards her. It is difficult to give a detailed account of these because they are often obscure instinctual impulses which it was impossible for the child to grasp psychically at the time of their occurrence, which were therefore only interpreted by her later, and which then appear in the analysis in forms of expression that were certainly not the original ones. Sometimes we come across them as transferences on to the later, father-object, where they do not belong and where they seriously interfere with our understanding of the situation. We find the little girl's aggressive oral and sadistic wishes in a form forced on them by early repression, as a fear of being killed by her mother - a fear which, in turn, justifies her death-wish against her mother, if that becomes conscious. It is impossible to say how often this fear of the mother is supported by an unconscious hostility on the mother's part which is sensed by the girl. (Hitherto, it is only in men that I have found the fear of being eaten up. This fear is referred to the father, but it is probably the product of a transformation of oral aggressivity directed to the mother. The child wants to eat up its mother from whom it has had its nourishment; in the case of the father there is no such obvious determinant for the wish.)

[1931b, 4601]

The women patients showing a strong attachment to their mother in whom I have been able to study the pre-Oedipus phase have all told me that when their mother gave them enemas or rectal douches they used to offer the greatest resistance and react with fear and screams of rage. This behaviour may be very frequent or even the habitual thing in children. I only came to understand the reason for such a specially violent opposition from a remark made by Ruth Mack Brunswick, who was studying these problems at the same time as I was, to the effect that she was inclined to compare the outbreak of anger after an enema to the orgasm following genital excitation. The accompanying anxiety should, she thought, be construed as a transformation of the desire for aggression which had been stirred up. I believe that this is really so and that, at the sadistic-anal level, the intense passive stimulation of the intestinal zone is responded to by an outbreak of desire for aggression which is manifested either directly as rage, or, in consequence of its suppression, as anxiety. In later years this reaction seems to die away.

[1931b, 4602]
In regard to the passive impulses of the phallic phase, it is noteworthy that girls regularly accuse their mother of seducing them. This is because they necessarily received their first, or at any rate their strongest, genital sensations when they were being cleaned and having their toilet attended to by their mother (or by someone such as a nurse who took her place). Mothers have often told me, as a matter of observation, that their little daughters of two and three years old enjoy these sensations and try to get their mothers to make them more intense by repeated touching and rubbing. The fact that the mother thus unavoidably initiates the child into the phallic phase is, I think, the reason why, in phantasies of later years, the father so regularly appears as the sexual seducer. When the girl turns away from her mother, she also makes over to her father her introduction into sexual life.

Lastly, intense active wishful impulses directed towards the mother also arise during the phallic phase. The sexual activity of this period culminates in clitoridal masturbation. This is probably accompanied by ideas of the mother, but whether the child attaches a sexual aim to the idea, and what that aim is, I have not been able to discover from my observations. It is only when all her interests have received a fresh impetus through the arrival of a baby brother or sister that we can clearly recognize such an aim. The little girl wants to believe that she has given her mother the new baby, just as the boy wants to; and her reaction to this event and her behaviour to the baby is exactly the same as his. No doubt this sounds quite absurd, but perhaps that is only because it sounds so unfamiliar.

The turning-away from her mother is an extremely important step in the course of a little girl's development. It is more than a mere change of object. We have already described what takes place in it and the many motives put forward for it; we may now add that hand in hand with it there is to be observed a marked lowering of the active sexual impulses and a rise of the passive ones. It is true that the active trends have been affected by frustration more strongly; they have proved totally unrealizable and are therefore abandoned by the libido more readily. But the passive trends have not escaped disappointment either. With the turning-away from the mother clitoridal masturbation frequently ceases as well; and often enough when the small girl represses her previous masculinity a considerable portion of her sexual trends in general is permanently injured too. The transition to the father-object is accomplished with the help of the passive trends in so far as they have escaped the catastrophe. The path to the development of femininity now lies open to the girl, to the extent to which it is not restricted by the remains of the pre-Oedipus attachment to her mother which she has surmounted.

An examination of the analytic literature on the subject shows that everything that has been said by me here is already to be found in it. It would have been superfluous to publish this paper if it were not that in a field of research which is so difficult of access every account of first-hand experiences or personal views may be of value. Moreover, there are a number of points which I have defined more sharply and isolated more carefully. In some of the other papers on the subject the description is obscured because they deal at the same time with the problems of the super-ego and the sense of guilt. This I have avoided doing. Also, in describing the various outcomes of this phase of development, I have refrained from discussing the complications which arise when a child, as a result of disappointment from her father, returns to the attachment to her mother which she had abandoned, or when, in the course of her life, she repeatedly changes over from one position to the other. But precisely because my paper is only one contribution among others, I may be spared an exhaustive survey of the literature, and I can confine myself to bringing out the more important points on which I agree or disagree with these other writings.
Abraham's (1921) description of the manifestations of the castration complex in the female is still unsurpassed; but one would be glad if it had included the factor of the girl's original exclusive attachment to her mother. I am in agreement with the principal points in Jeanne Lampl-de Groot's¹ (1927) important paper. In this the complete identity of the pre-Oedipus phase in boys and girls is recognized, and the girl's sexual (phallic) activity towards her mother is affirmed and substantiated by observations. The turning-away from the mother is traced to the influence of the girl's recognition of castration, which obliges her to give up her sexual object, and often masturbation along with it. The whole development is summed up in the formula that the girl goes through a phase of the 'negative' Oedipus complex before she can enter the positive one. A point on which I find the writer's account inadequate is that it represents the turning-away from the mother as being merely a change of object and does not discuss the fact that it is accompanied by the plainest manifestations of hostility. To this hostility full justice is done in Helene Deutsch's latest paper, on feminine masochism and its relation to frigidity (1930), in which she also recognizes the girl's phallic activity and the intensity of her attachment to her mother. Helene Deutsch states further that the girl's turning towards her father takes place viâ her passive trends (which have already been awakened in relation to her mother). In her earlier book (1925) the author had not yet set herself free from the endeavour to apply the Oedipus pattern to the pre-Oedipus phase, and she therefore interpreted the little girl's phallic activity as an identification with her father.

Fenichel (1930) rightly emphasizes the difficulty of recognizing in the material produced in analysis what parts of it represent the unchanged content of the pre-Oedipus phase and what parts have been distorted by regression (or in other ways). He does not accept Jeanne Lampl-de Groot's assertion of the little girl's active attitude in the phallic phase. He also rejects the 'displacement backwards' of the Oedipus complex proposed by Melanie Klein (1928), who places its beginnings as early as the commencement of the second year of life. This dating of it, which would also necessarily imply a modification of our view of all the rest of the child's development, does not in fact correspond to what we learn from the analyses of adults, and it is especially incompatible with my findings as to the long duration of the girl's pre-Oedipus attachment to her mother. A means of softening this contradiction is afforded by the reflection that we are not as yet able to distinguish in this field between what is rigidly fixed by biological laws and what is open to movement and change under the influence of accidental experience. The effect of seduction has long been familiar to us and in just the same way other factors - such as the date at which the child's brothers and sisters are born or the time when it discovers the difference between the sexes, or again its direct observations of sexual intercourse or its parents' behaviour in encouraging or repelling it - may hasten the child's sexual development and bring it to maturity.

We shall return to the part played by the clitoris; let us now turn to the second task with which a girl's development is burdened. A boy's mother is the first object of his love, and she remains so too during the formation of his Oedipus complex and, in essence, all through his life. For a girl too her first object must be her mother (and the figures of wet-nurses and foster-mothers that merge into her). The first object-cathexes occur in attachment to the satisfaction of the major and simple vital needs, and the circumstances of the care of children are the same for both sexes. But in the Oedipus situation the girl's father has become her love-object, and we expect that in the normal course of development she will find her way from this paternal object to her final choice of an object. In the course of time, therefore, a girl has to change her erotogenic zone and her object - both of which a boy retains. The question then arises of how this happens: in particular, how does a girl pass from her mother to an attachment to her father? or, in other words, how does she pass from her masculine phase to the feminine one to which she is biologically destined?
It would be a solution of ideal simplicity if we could suppose that from a particular age onwards the elementary influence of the mutual attraction between the sexes makes itself felt and impels the small woman towards men, while the same law allows the boy to continue with his mother. We might suppose in addition that in this the children are following the pointer given them by the sexual preference of their parents. But we are not going to find things so easy; we scarcely know whether we are to believe seriously in the power of which poets talk so much and with such enthusiasm but which cannot be further dissected analytically. We have found an answer of quite another sort by means of laborious investigations, the material for which at least was easy to arrive at. For you must know that the number of women who remain till a late age tenderly dependent on a paternal object, or indeed on their real father, is very great. We have established some surprising facts about these women with an intense attachment of long duration to their father. We knew, of course, that there had been a preliminary stage of attachment to the mother, but we did not know that it could be so rich in content and so long-lasting, and could leave behind so many opportunities for fixations and dispositions. During this time the girl's father is only a troublesome rival; in some cases the attachment to her mother lasts beyond the fourth year of life. Almost everything that we find later in her relation to her father was already present in this earlier attachment and has been transferred subsequently on to her father. In short, we get an impression that we cannot understand women unless we appreciate this phase of their pre-Oedipus attachment to their mother.

We shall be glad, then, to know the nature of the girl's libidinal relations to her mother. The answer is that they are of very many different kinds. Since they persist through all three phases of infantile sexuality, they also take on the characteristics of the different phases and express themselves by oral, sadistic-anal and phallic wishes. These wishes represent active as well as passive impulses; if we relate them to the differentiation of the sexes which is to appear later - though we should avoid doing so as far as possible - we may call them masculine and feminine. Besides this, they are completely ambivalent, both affectionate and of a hostile and aggressive nature. The latter often only come to light after being changed into anxiety ideas. It is not always easy to point to a formulation of these early sexual wishes; what is most clearly expressed is a wish to get the mother with child and the corresponding wish to bear her a child - both belonging to the phallic period and sufficiently surprising, but established beyond doubt by analytic observation. The attractiveness of these investigations lies in the surprising detailed findings which they bring us. Thus, for instance, we discover the fear of being murdered or poisoned, which may later form the core of a paranoic illness, already present in this pre-Oedipus period, in relation to the mother. Or another case: you will recall an interesting episode in the history of analytic research which caused me many distressing hours. In the period in which the main interest was directed to discovering infantile sexual traumas, almost all my women patients told me that they had been seduced by their father. I was driven to recognize in the end that these reports were untrue and so came to understand that hysterical symptoms are derived from phantasies and not from real occurrences. It was only later that I was able to recognize in this phantasy of being seduced by the father the expression of the typical Oedipus complex in women. And now we find the phantasy of seduction once more in the pre-Oedipus prehistory of girls; but the seducer is regularly the mother. Here, however, the phantasy touches the ground of reality, for it was really the mother who by her activities over the child's bodily hygiene inevitably stimulated, and perhaps even roused for the first time, pleasurable sensations in her genitals.
I have no doubt you are ready to suspect that this portrayal of the abundance and strength of a little girl's sexual relations with her mother is very much overdrawn. After all, one has opportunities of seeing little girls and notices nothing of the sort. But the objection is not to the point. Enough can be seen in the children if one knows how to look. And besides, you should consider how little of its sexual wishes a child can bring to preconscious expression or communicate at all. Accordingly we are only within our rights if we study the residues and consequences of this emotional world in retrospect, in people in whom these processes of development had attained a specially clear and even excessive degree of expansion. Pathology has always done us the service of making discernible by isolation and exaggeration conditions which would remain concealed in a normal state. And since our investigations have been carried out on people who were by no means seriously abnormal, I think we should regard their outcome as deserving belief.

[1933a, 4723]

We will now turn our interest on to the single question of what it is that brings this powerful attachment of the girl to her mother to an end. This, as we know, is its usual fate: it is destined to make room for an attachment to her father. Here we come upon a fact which is a pointer to our further advance. This step in development does not involve only a simple change of object. The turning away from the mother is accompanied by hostility; the attachment to the mother ends in hate. A hate of that kind may become very striking and last all through life; it may be carefully overcompensated later on; as a rule one part of it is overcome while another part persists. Events of later years naturally influence this greatly. We will restrict ourselves, however, to studying it at the time at which the girl turns to her father and to enquiring into the motives for it. We are then given a long list of accusations and grievances against the mother which are supposed to justify the child's hostile feelings; they are of varying validity which we shall not fail to examine. A number of them are obvious rationalizations and the true sources of enmity remain to be found. I hope you will be interested if on this occasion I take you through all the details of a psycho-analytic investigation.

[1933a, 4723]

The reproach against the mother which goes back furthest is that she gave the child too little milk - which is construed against her as lack of love. Now there is some justification for this reproach in our families. Mothers often have insufficient nourishment to give their children and are content to suckle them for a few months, for half or three-quarters of a year. Among primitive peoples children are fed at their mother's breast for two or three years. The figure of the wet-nurse who suckles the child is as a rule merged into the mother; when this has not happened, the reproach is turned into another one - that the nurse, who fed the child so willingly, was sent away by the mother too early. But whatever the true state of affairs may have been, it is impossible that the child's reproach can be justified as often as it is met with. It seems, rather, that the child's avidity for its earliest nourishment is altogether insatiable, that it never gets over the pain of losing its mother's breast. I should not be surprised if the analysis of a primitive child, who could still suck at its mother's breast when it was already able to run about and talk, were to bring the same reproach to light. The fear of being poisoned is also probably connected with the withdrawal of the breast. Poison is nourishment that makes one ill. Perhaps children trace back their early illnesses too to this frustration. A fair amount of intellectual education is a prerequisite for believing in chance; primitive people and uneducated ones, and no doubt children as well, are able to assign a ground for everything that happens. Perhaps originally it was a reason on animistic lines. Even to-day in some strata of our population no one can die without having been killed by someone else - preferably by the doctor. And the regular reaction of a neurotic to the death of someone closely connected with him is to put the blame on himself for having caused the death.

[1933a, 4724]
The next accusation against the child's mother flares up when the next baby appears in the nursery. If possible the connection with oral frustration is preserved: the mother could not or would not give the child any more milk because she needed the nourishment for the new arrival. In cases in which the two children are so close in age that lactation is prejudiced by the second pregnancy, this reproach acquires a real basis, and it is a remarkable fact that a child, even with an age difference of only 11 months, is not too young to take notice of what is happening. But what the child grudges the unwanted intruder and rival is not only the suckling but all the other signs of maternal care. It feels that it has been dethroned, despised, prejudiced in its rights; it casts a jealous hatred upon the new baby and develops a grievance against the faithless mother which often finds expression in a disagreeable change in its behaviour. It becomes 'naughty', perhaps, irritable and disobedient and goes back on the advances it has made towards controlling its excretions. All of this has been very long familiar and is accepted as self-evident; but we rarely form a correct idea of the strength of these jealous impulses, of the tenacity with which they persist and of the magnitude of their influence on later development. Especially as this jealousy is constantly receiving fresh nourishment in the later years of childhood and the whole shock is repeated with the birth of each new brother or sister. Nor does it make much difference if the child happens to remain the mother's preferred favourite. A child's demands for love are immoderate, they make exclusive claims and tolerate no sharing.

An abundant source of a child's hostility to its mother is provided by its multifarious sexual wishes, which alter according to the phase of the libido and which cannot for the most part be satisfied. The strongest of these frustrations occur at the phallic period, if the mother forbids pleasurable activity with the genitals - often with severe threats and every sign of displeasure - activity to which, after all, she herself had introduced the child. One would think these were reasons enough to account for a girl's turning away from her mother. One would judge, if so, that the estrangement follows inevitably from the nature of children's sexuality, from the immoderate character of their demand for love and the impossibility of fulfilling their sexual wishes. It might be thought indeed that this first love-relation of the child's is doomed to dissolution for the very reason that it is the first, for these early object-cathexes are regularly ambivalent to a high degree. A powerful tendency to aggressiveness is always present beside a powerful love, and the more passionately a child loves its object the more sensitive does it become to disappointments and frustrations from that object; and in the end the love must succumb to the accumulated hostility. Or the idea that there is an original ambivalence such as this in erotic cathexes may be rejected, and it may be pointed out that it is the special nature of the mother-child relation that leads, with equal inevitability, to the destruction of the child's love; for even the mildest upbringing cannot avoid using compulsion and introducing restrictions, and any such intervention in the child's liberty must provoke as a reaction an inclination to rebelliousness and aggressiveness. A discussion of these possibilities might, I think, be most interesting; but an objection suddenly emerges which forces our interest in another direction. All these factors - the slights, the disappointments in love, the jealousy, the seduction followed by prohibition - are, after all, also in operation in the relation of a boy to his mother and are yet unable to alienate him from the maternal object. Unless we can find something that is specific for girls and is not present or not in the same way present in boys, we shall not have explained the termination of the attachment of girls to their mother.

[1933a, 4726]
The essential content of the first is as follows: the little girl has hitherto lived in a masculine way, has been able to get pleasure by the excitation of her clitoris and has brought this activity into relation with her sexual wishes directed towards her mother, which are often active ones; now, owing to the influence of her penis-envy, she loses her enjoyment in her phallic sexuality. Her self-love is mortified by the comparison with the boy's far superior equipment and in consequence she renounces her masturbatory satisfaction from her clitoris, repudiates her love for her mother and at the same time not infrequently represses a good part of her sexual trends in general. No doubt her turning away from her mother does not occur all at once, for to begin with the girl regards her castration as an individual misfortune, and only gradually extends it to other females and finally to her mother as well. Her love was directed to her phallic mother; with the discovery that her mother is castrated it becomes possible to drop her as an object, so that the motives for hostility, which have long been accumulating, gain the upper hand. This means, therefore, that as a result of the discovery of women's lack of a penis they are debased in value for girls just as they are for boys and later perhaps for men.

[1933a, 4728]

You all know the immense aetiological importance attributed by our neurotic patients to their masturbation. They make it responsible for all their troubles and we have the greatest difficulty in persuading them that they are mistaken. In fact, however, we ought to admit to them that they are right, for masturbation is the executive agent of infantile sexuality, from the faulty development of which they are indeed suffering. But what neurotics mostly blame is the masturbation of the period of puberty; they have mostly forgotten that of early infancy, which is what is really in question. I wish I might have an opportunity some time of explaining to you at length how important all the factual details of early masturbation become for the individual's subsequent neurosis or character: whether or not it was discovered, how the parents struggled against it or permitted it, or whether he succeeded in suppressing it himself. All of this leaves permanent traces on his development. But I am on the whole glad that I need not do this. It would be a hard and tedious task and at the end of it you would put me in an embarrassing situation by quite certainly asking me to give you some practical advice as to how a parent or educator should deal with the masturbation of small children. From the development of girls, which is what my present lecture is concerned with, I can give you the example of a child herself trying to get free from masturbating. She does not always succeed in this. If envy for the penis has provoked a powerful impulse against clitoridial masturbation but this nevertheless refuses to give way, a violent struggle for liberation ensues in which the girl, as it were, herself takes over the role of her deposed mother and gives expression to her entire dissatisfaction with her inferior clitoris in her efforts against obtaining satisfaction from it. Many years later, when her masturbatory activity has long since been suppressed, an interest still persists which we must interpret as a defence against a temptation that is still dreaded. It manifests itself in the emergence of sympathy for those to whom similar difficulties are attributed, it plays a part as a motive in contracting a marriage and, indeed, it may determine the choice of a husband or lover. Disposing of early infantile masturbation is truly no easy or indifferent business.

[1933a, 4729]
Along with the abandonment of clitorial masturbation a certain amount of activity is renounced. Passivity now has the upper hand, and the girl's turning to her father is accomplished principally with the help of passive instinctual impulses. You can see that a wave of development like this, which clears the phallic activity out of the way, smooths the ground for femininity. If too much is not lost in the course of it through repression, this femininity may turn out to be normal. The wish with which the girl turns to her father is no doubt originally the wish for the penis which her mother has refused her and which she now expects from her father. The feminine situation is only established, however, if the wish for a penis is replaced by one for a baby, if, that is, a baby takes the place of a penis in accordance with an ancient symbolic equivalence. It has not escaped us that the girl has wished for a baby earlier, in the undisturbed phallic phase: that, of course, was the meaning of her playing with dolls. But that play was not in fact an expression of her femininity; it served as an identification with her mother with the intention of substituting activity for passivity. She was playing the part of her mother and the doll was herself: now she could do with the baby everything that her mother used to do with her. Not until the emergence of the wish for a penis does the doll-baby become a baby from the girl's father, and thereafter the aim of the most powerful feminine wish. Her happiness is great if later on this wish for a baby finds fulfilment in reality, and quite especially so if the baby is a little boy who brings the longed-for penis with him. Often enough in her combined picture of 'a baby from her father' the emphasis is laid on the baby and her father left unstressed. In this way the ancient masculine wish for the possession of a penis is still faintly visible through the femininity now achieved. But perhaps we ought rather to recognize this wish for a penis as being par excellence a feminine one.

[1933a, 4730]

With the transference of the wish for a penis-baby on to her father, the girl has entered the situation of the Oedipus complex. Her hostility to her mother, which did not need to be freshly created, is now greatly intensified, for she becomes the girl's rival, who receives from her father everything that she desires from him. For a long time the girl's Oedipus complex concealed her pre-Oedipus attachment to her mother from our view, though it is nevertheless so important and leaves such lasting fixations behind it. For girls the Oedipus situation is the outcome of a long and difficult development; it is a kind of preliminary solution, a position of rest which is not soon abandoned, especially as the beginning of the latency period is not far distant. And we are now struck by a difference between the two sexes, which is probably momentous, in regard to the relation of the Oedipus complex to the castration complex. In a boy the Oedipus complex, in which he desires his mother and would like to get rid of his father as being a rival, develops naturally from the phase of his phallic sexuality. The threat of castration compels him, however, to give up that attitude. Under the impression of the danger of losing his penis, the Oedipus complex is abandoned, repressed and, in the most normal cases, entirely destroyed, and a severe super-ego is set up as its heir. What happens with a girl is almost the opposite. The castration complex prepares for the Oedipus complex instead of destroying it; the girl is driven out of her attachment to her mother through the influence of her envy for the penis and she enters the Oedipus situation as though into a haven of refuge. In the absence of fear of castration the chief motive is lacking which leads boys to surmount the Oedipus complex. Girls remain in it for an indeterminate length of time; they demolish it late and, even so, incompletely. In these circumstances the formation of the super-ego must suffer; it cannot attain the strength and independence which give it its cultural significance, and feminists are not pleased when we point out to them the effects of this factor upon the average feminine character.

[1933a, 4731]
The determinants of women's choice of an object are often made unrecognizable by social conditions. Where the choice is able to show itself freely, it is often made in accordance with the narcissistic ideal of the man whom the girl had wished to become. If the girl has remained in her attachment to her father - that is, in the Oedipus complex - her choice is made according to the paternal type. Since, when she turned from her mother to her father, the hostility of her ambivalent relation remained with her mother, a choice of this kind should guarantee a happy marriage. But very often the outcome is of a kind that presents a general threat to such a settlement of the conflict due to ambivalence. The hostility that has been left behind follows in the train of the positive attachment and spreads over on to the new object. The woman's husband, who to begin with inherited from her father, becomes after a time her mother's heir as well. So it may easily happen that the second half of a woman's life may be filled by the struggle against her husband, just as the shorter first half was filled by her rebellion against her mother. When this reaction has been lived through, a second marriage may easily turn out very much more satisfying. Another alteration in a woman's nature, for which lovers are unprepared, may occur in a marriage after the first child is born. Under the influence of a woman's becoming a mother herself, an identification with her own mother may be revived, against which she had striven up till the time of her marriage, and this may attract all the available libido to itself, so that the compulsion to repeat reproduces an unhappy marriage between her parents. The difference in a mother's reaction to the birth of a son or a daughter shows that the old factor of lack of a penis has even now not lost its strength. A mother is only brought unlimited satisfaction by her relation to a son; this is altogether the most perfect, the most free from ambivalence of all human relationships. A mother can transfer to her son the ambition which she has been obliged to suppress in herself, and she can expect from him the satisfaction of all that has been left over in her of her masculinity complex. Even a marriage is not made secure until the wife has succeeded in making her husband her child as well and in acting as a mother to him.

A woman's identification with her mother allows us to distinguish two strata: the pre-Oedipus one which rests on her affectionate attachment to her mother and takes her as a model, and the later one from the Oedipus complex which seeks to get rid of her mother and take her place with her father. We are no doubt justified in saying that much of both of them is left over for the future and that neither of them is adequately surmounted in the course of development. But the phase of the affectionate pre-Oedipus attachment is the decisive one for a woman's future: during it preparations are made for the acquisition of the characteristics with which she will later fulfill her role in the sexual function and perform her invaluable social tasks. It is in this identification too that she acquires her attractiveness to a man, whose Oedipus attachment to his mother it kindles into passion. How often it happens, however, that it is only his son who obtains what he himself aspired to! One gets an impression that a man's love and a woman's are a phase apart psychologically.

[1933a, 4735]

[1933a, 4736]
From the mass of material I shall first bring forward some cases which relate to the development of character. Take, for instance, the girl who has reached a state of the most decided opposition to her mother. She has cultivated all those characteristics which she has seen that her mother lacked, and has avoided everything that reminded her of her mother. We may supplement this by saying that in her early years, like every female child, she adopted an identification with her mother and that she is now rebelling against this energetically. But when this girl marries and herself becomes a wife and a mother, we need not be surprised to find that she begins to grow more and more like the mother to whom she was so antagonistic, till finally the identification with her which she surmounted is unmistakably re-established. The same thing happens too with boys; and even the great Goethe, who in the period of his genius certainly looked down upon his unbending and pedantic father, in his old age developed traits which formed a part of his father's character. The outcome can become even more striking when the contrast between the two personalities is sharper. A young man whose fate it was to grow up beside a worthless father, began by developing, in defiance of him, into a capable, trustworthy and honourable person. In the prime of life his character was reversed, and thenceforward he behaved as though he had taken this same father as a model. In order not to miss the connection with our theme, we must keep in mind the fact that at the beginning of such a course of events there is always an identification with the father in early childhood. This is afterwards repudiated, and even overcompensated, but in the end establishes itself once more.

[1939a, 4943]

A child's first erotic object is the mother's breast that nourishes it; love has its origin in attachment to the satisfied need for nourishment. There is no doubt that, to begin with, the child does not distinguish between the breast and its own body; when the breast has to be separated from the body and shifted to the 'outside' because the child so often finds it absent, it carries with it as an 'object' a part of the original narcissistic libidinal cathexis. This first object is later completed into the person of the child's mother, who not only nourishes it but also looks after it and thus arouses in it a number of other physical sensations, pleasurable and unpleasurable. By her care of the child's body she becomes its first seducer. In these two relations lies the root of a mother's importance, unique, without parallel, established unalterably for a whole lifetime as the first and strongest love-object and as the prototype of all later love-relations - for both sexes. In all this the phylogenetic foundation has so much the upper hand over personal accidental experience that it makes no difference whether a child has really sucked at the breast or has been brought up on the bottle and never enjoyed the tenderness of a mother's care. In both cases the child's development takes the same path; it may be that in the second case its later longing grows all the greater. And for however long it is fed at its mother's breast, it will always be left with a conviction after it has been weaned that its feeding was too short and too little.

[1940a [1938], 4996]
If a little girl persists in her first wish - to grow into a boy - in extreme cases she will end as a manifest homosexual, and otherwise she will exhibit markedly masculine traits in the conduct of her later life, will choose a masculine vocation, and so on. The other path leads by way of abandoning the mother she has loved: the daughter, under the influence of her envy for the penis, cannot forgive her mother for having sent her into the world so insufficiently equipped. In her resentment over this she gives up her mother and puts someone else in her place as the object of her love - her father. If one has lost a love-object, the most obvious reaction is to identify oneself with it, to replace it from within, as it were, by identification. This mechanism now comes to the little girl's help. Identification with her mother can take the place of attachment to her mother. The little daughter puts herself in her mother's place, as she has always done in her games; she tries to take her mother's place with her father, and begins to hate the mother she used to love, and from two motives: from jealousy as well as from mortification over the penis she has been denied. Her new relation to her father may start by having as its content a wish to have his penis at her disposal, but it culminates in another wish - to have a baby from him as a gift. The wish for a baby has thus taken the place of the wish for a penis, or has at all events split off from it.

[1940a [1938], 5000]

It is an interesting thing that the relation between the Oedipus complex and the castration complex should take such a different shape - an opposite one, in fact - in the case of females as compared to that of males. In males, as we have seen, the threat of castration brings the Oedipus complex to an end; in females we find that, on the contrary, it is their lack of a penis that forces them into their Oedipus complex. It does little harm to a woman if she remains in her feminine Oedipus attitude. (The term 'Electra complex' has been proposed for it.) She will in that case choose her husband for his paternal characteristics and be ready to recognize his authority. Her longing to possess a penis, which is in fact unappeasable, may find satisfaction if she can succeed in completing her love for the organ by extending it to the bearer of the organ, just as happened earlier when she progressed from her mother's breast to her mother as a whole person.

[1940a [1938], 5001]
What I have in mind is rivalry in love, with a clear emphasis on the subject's sex. While he is still a small child, a son will already begin to develop a special affection for his mother, whom he regards as belonging to him; he begins to feel his father as a rival who disputes his sole possession. And in the same way a little girl looks on her mother as a person who interferes with her affectionate relation to her father and who occupies a position which she herself could very well fill. Observation shows us to what early years these attitudes go back. We refer to them as the 'Oedipus complex', because the legend of Oedipus realizes, with only a slight softening, the two extreme wishes that arise from the son's situation - to kill his father and take his mother to wife. I do not wish to assert that the Oedipus complex exhausts the relation of children to their parents: it can easily be far more complicated. The Oedipus complex can, moreover, be developed to a greater or less strength, it can even be reversed; but it is a regular and very important factor in a child's mental life, and there is more danger of our underestimating rather than over-estimating its influence and that of the developments which proceed from it. Incidentally, children often react in their Oedipus attitude to a stimulus coming from their parents, who are frequently led in their preferences by difference of sex, so that the father will choose his daughter and the mother her son as a favourite, or, in case of a cooling-off in the marriage, as a substitute for a love-object that has lost its value.

[1916-1917, 3295]

As you may imagine, Gentlemen, I have passed very cursorily over a great number of considerations of both practical and theoretical importance connected with the Oedipus complex. Nor shall I enter into its variations or its possible reversal. Among its remoter connections I will only give you a further hint that it has turned out to have a highly important effect on literary production. In a valuable work Otto Rank has shown that dramatists of every period have chosen their material in the main from the Oedipus and incest complex and its variations and disguises. Nor should it be allowed to pass unnoticed that the two criminal wishes of the Oedipus complex were recognized as the true representatives of the uninhibited life of the instincts long before the time of psycho-analysis. Among the writings of the Encyclopaedist Diderot you will find a celebrated dialogue, *Le neveu Rameau*, which was rendered into German by no less a person than Goethe. There you may read this remarkable sentence: 'Si le petit sauvage était abandonné à lui-même, qu'il conservât toute son imbécillité, et qu'il réunît au peu de raison de l'enfant au berceau la violence des passions de l'homme de trente ans, il tordrait le col à son père et coucherait avec sa mère.'¹

[1916-1917, 3402]

It would appear, therefore, that in both sexes the relative strength of the masculine and feminine sexual dispositions is what determines whether the outcome of the Oedipus situation shall be an identification with the father or with the mother. This is one of the ways in which bisexuality takes a hand in the subsequent vicissitudes of the Oedipus complex. The other way is even more important. For one gets an impression that the simple Oedipus complex is by no means its commonest form, but rather represents a simplification or schematization which, to be sure, is often enough justified for practical purposes. Closer study usually discloses the more complete Oedipus complex, which is twofold, positive and negative, and is due to the bisexuality originally present in children: that is to say, a boy has not merely an ambivalent attitude towards his father and an affectionate object-choice towards his mother, but at the same time he also behaves like a girl and displays an affectionate feminine attitude to his father and a corresponding jealousy and hostility towards his mother. It is this complicating element introduced by bisexuality that makes it so difficult to obtain a clear view of the facts in connection with the earliest object-choices and identifications, and still more difficult to describe them intelligibly. It may even be that the ambivalence displayed in the relations to the parents should be attributed entirely to bisexuality and that it is not, as I have represented above, developed out of identification in consequence of rivalry.

[1923b, 3967]
In my opinion it is advisable in general, and quite especially where neurotics are concerned, to assume the existence of the complete Oedipus complex. Analytic experience then shows that in a number of cases one or the other constituent disappears, except for barely distinguishable traces; so that the result is a series with the normal positive Oedipus complex at one end and the inverted negative one at the other, while its intermediate members exhibit the complete form with one or other of its two components preponderating. At the dissolution of the Oedipus complex the four trends of which it consists will group themselves in such a way as to produce a father-identification and a mother-identification. The father-identification will preserve the object-relation to the mother which belonged to the positive complex and will at the same time replace the object-relation to the father which belonged to the inverted complex: and the same will be true, *mutatis mutandis*, of the mother-identification. The relative intensity of the two identifications in any individual will reflect the preponderance in him of one or other of the two sexual dispositions.

[1923b, 3967]

In boys the situation of the Oedipus complex is the first stage that can be recognized with certainty. It is easy to understand, because at that stage a child retains the same object which he previously cathedcted with his libido - not as yet a genital one - during the preceding period while he was being suckled and nursed. The fact, too, that in this situation he regards his father as a disturbing rival and would like to get rid of him and take his place is a straightforward consequence of the actual state of affairs. I have shown elsewhere¹ how the Oedipus attitude in little boys belongs to the phallic phase, and how its destruction is brought about by the fear of castration - that is, by narcissistic interest in their genitals. The matter is made more difficult to grasp by the complicating circumstance that even in boys the Oedipus complex has a double orientation, active and passive, in accordance with their bisexual constitution; a boy also wants to take his *mother's place* as the love-object of his *father* - a fact which we describe as the feminine attitude.

[1925j, 4147]
As regards the prehistory of the Oedipus complex in boys we are far from complete clarity. We know that that period includes an identification of an affectionate sort with the boy's father, an identification which is still free from any sense of rivalry in regard to his mother. Another element of that stage is invariably, I believe, a masturbatory activity in connection with the genitals, the masturbation of early childhood, the more or less violent suppression of which by those in charge of the child sets the castration complex in action. It is to be assumed that this masturbation is attached to the Oedipus complex and serves as a discharge for the sexual excitation belonging to it. It is, however, uncertain whether the masturbation has this character from the first, or whether on the contrary it makes its first appearance spontaneously as an activity of a bodily organ and is only brought into relation with the Oedipus complex at some later date; this second possibility is by far the more probable. Another doubtful question is the part played by bed-wetting and by the breaking of that habit through the intervention of training measures. We are inclined to make the simple connection that continued bed-wetting is a result of masturbation and that its suppression is regarded by boys as an inhibition of their genital activity - that is, as having the meaning of a threat of castration; but whether we are always right in supposing this remains to be seen. Finally, analysis shows us in a shadowy way how the fact of a child at a very early age listening to his parents copulating may set up his first sexual excitation, and how that event may, owing to its after-effects, act as a starting-point for the child's whole sexual development. Masturbation, as well as the two attitudes in the Oedipus complex, later on become attached to this early experience, the child having subsequently interpreted its meaning. It is impossible, however, to suppose that these observations of coitus are of universal occurrence, so that at this point we are faced with the problem of 'primal phantasies'. Thus the prehistory of the Oedipus complex, even in boys, raises all of these questions for sifting and explanation; and there is the further problem of whether we are to suppose that the process invariably follows the same course, or whether a great variety of different preliminary stages may not converge upon the same terminal situation.

In little girls the Oedipus complex raises one problem more than in boys. In both cases the mother is the original object; and there is no cause for surprise that boys retain that object in the Oedipus complex. But how does it happen that girls abandon it and instead take their father as an object? In pursuing this question I have been able to reach some conclusions which may throw light precisely on the prehistory of the Oedipus relation in girls.

Let us go back again to infantile phobias of animals; for, when all is said and done, we understand them better than any other cases. In animal phobias, then, the ego has to oppose a libidinal object-cathexis coming from the id - a cathexis that belongs either to the positive or the negative Oedipus complex - because it believes that to give way to it would entail the danger of castration. This question has already been discussed, but there still remains a doubtful point to clear up. In 'Little Hans's' case - that is, in the case of a positive Oedipus complex - was it his fondness for his mother or was it his aggressiveness towards his father which called out the defence by the ego? In practice it seems to make no difference, especially as each set of feelings implies the other; but the question has a theoretical interest, since it is only the feeling of affection for the mother which can count as a purely erotic one. The aggressive impulse flows mainly from the destructive instinct; and we have always believed that in a neurosis it is against the demands of the libido and not against those of any other instinct that the ego is defending itself. In point of fact we know that after 'Hans's' phobia had been formed, his tender attachment to his mother seemed to disappear, having been completely disposed of by repression, while the formation of the symptom (the substitutive formation) took place in relation to his aggressive impulses. In the 'Wolf Man' the situation was simpler. The impulse that was repressed - his feminine attitude towards his father - was a genuinely erotic one; and it was in relation to that impulse that the formation of his symptoms took place.
Nothing, however, deserves more notice than the fact that children regularly direct their sexual wishes towards their nearest relatives - in the first place, therefore, towards their father and mother, and afterwards towards their brothers and sisters. The first object of a boy's love is his mother, and of a girl's her father (except in so far as an innate bisexual disposition favours the simultaneous presence of the contrary attitude). The other parent is felt as a disturbing rival and not infrequently viewed with strong hostility. You must understand me aright. What I mean to say is not that the child wants to be treated by its favourite parent merely with the kind of affection which we adults like to regard as the essence of the parent-child relation. No, analysis leaves us in no doubt that the child's wishes extend beyond such affection to all that we understand by sensual satisfaction - so far, that is, as the child's powers of imagination allow. It is easy to see that the child never guesses the actual facts of sexual intercourse; he replaces them by other notions derived from his own experience and feelings. As a rule his wishes culminate in the intention to bear, or in some in definable way, to procreate a baby. Boys, too, in their ignorance, do not exclude themselves from the wish to bear a baby. We give the whole of this mental structure the name of 'Oedipus complex', after the familiar Greek legend. With the end of the early sexual period it should normally be given up, should radically disintegrate and become transformed; and the results of this transformation are destined for important functions in later mental life. But as a rule this is not effected radically enough, in which case puberty brings about a revival of the complex, which may have serious consequences.

[1926e, 4355]

A further complication arises when the constitutional factor we call bisexuality is comparatively strongly developed in a child. For then, under the threat to the boy's masculinity by castration, his inclination becomes strengthened to diverge in the direction of femininity, to put himself instead in his mother's place and take over her role as object of his father's love. But the fear of castration makes this solution impossible as well. The boy understands that he must also submit to castration if he wants to be loved by his father as a woman. Thus both impulses, hatred of the father and being in love with the father, undergo repression. There is a certain psychological distinction in the fact that the hatred of the father is given up on account of fear of an external danger (castration), while the being in love with the father is treated as an internal instinctual danger, though fundamentally it goes back to the same external danger.

[1928b, 4559]

What makes hatred of the father unacceptable is fear of the father; castration is terrible, whether as a punishment or as the price of love. Of the two factors which repress hatred of the father, the first, the direct fear of punishment and castration, may be called the normal one; its pathogenic intensification seems to come only with the addition of the second factor, the fear of the feminine attitude. Thus a strong innate bisexual disposition becomes one of the preconditions or reinforcements of neurosis. Such a disposition must certainly be assumed in Dostoevsky, and it shows itself in a viable form (as latent homosexuality) in the important part played by male friendships in his life, in his strangely tender attitude towards rivals in love and in his remarkable understanding of situations which are explicable only by repressed homosexuality, as many examples from his novels show.

[1928b, 4560]
During the phase of the normal Oedipus complex we find the child tenderly attached to the parent of the opposite sex, while its relation to the parent of its own sex is predominantly hostile. In the case of a boy there is no difficulty in explaining this. His first love-object was his mother. She remains so; and, with the strengthening of his erotic desires and his deeper insight into the relations between his father and mother, the former is bound to become his rival. With the small girl it is different. Her first object, too, was her mother. How does she find her way to her father? How, when and why does she detach herself from her mother? We have long understood that the development of female sexuality is complicated by the fact that the girl has the task of giving up what was originally her leading genital zone the clitoris - in favour of a new zone - the vagina. But it now seems to us that there is a second change of the same sort which is no less characteristic and important for the development of the female: the exchange of her original object - her mother - for her father. The way in which the two tasks are connected with each other is not yet clear to us.

Since this phase allows room for all the fixations and repressions from which we trace the origin of the neuroses, it would seem as though we must retract the universality of the thesis that the Oedipus complex is the nucleus of the neuroses. But if anyone feels reluctant about making this correction, there is no need for him to do so. On the one hand, we can extend the content of the Oedipus complex to include all the child's relations to both parents; or, on the other, we can take due account of our new findings by saying that the female only reaches the normal positive Oedipus situation after she has surmounted a period before it that is governed by the negative complex. And indeed during that phase a little girl's father is not much else for her than a troublesome rival, although her hostility towards him never reaches the pitch which is characteristic of boys. We have, after all, long given up any expectation of a neat parallelism between male and female sexual development.

Our insight into this early, pre-Oedipus, phase in girls comes to us as a surprise, like the discovery, in another field, of the Minoan-Mycenean civilization behind the civilization of Greece.

Everything in the sphere of this first attachment to the mother seemed to me so difficult to grasp in analysis - so grey with age and shadowy and almost impossible to revivify - that it was as if it had succumbed to an especially inexorable repression. But perhaps I gained this impression because the women who were in analysis with me were able to cling to the very attachment to the father in which they had taken refuge from the early phase that was in question. It does indeed appear that women analysts - as, for instance, Jeanne Lampl-de Groot and Helene Deutsch - have been able to perceive these facts more easily and clearly because they were helped in dealing with those under their treatment by the transference to a suitable mother-substitute. Nor have I succeeded in seeing my way though any case completely, and I shall therefore confine myself to reporting the most general findings and shall give only a few examples of the new ideas which I have arrived at. Among these is a suspicion that this phase of attachment to the mother is especially intimately related to the aetiology of hysteria, which is not surprising when we reflect that both the phase and the neurosis are characteristically feminine, and further, that in this dependence on the mother we have the germ of later paranoia in women.¹ For this germ appears to be the surprising, yet regular, fear of being killed (? devoured) by the mother. It is plausible to assume that this fear corresponds to a hostility which develops in the child towards her mother in consequence of the manifold restrictions imposed by the latter in the course of training and bodily care and that the mechanism of projection is favoured by the early age of the child's psychical organization.

[1931b, 4590]

[1931b, 4591]
I began by stating the two facts which have struck me as new: that a woman's strong dependence on her father merely takes over the heritage of an equally strong attachment to her mother, and that this earlier phase has lasted for an unexpectedly long period of time. I shall now go back a little in order to insert these new findings into the picture of female sexual development with which we are familiar. In doing this, a certain amount of repetition will be inevitable. It will help our exposition if, as we go along, we compare the state of things in women with that in men.

[1931b, 4592]

Abraham's (1921) description of the manifestations of the castration complex in the female is still unsurpassed; but one would be glad if it had included the factor of the girl's original exclusive attachment to her mother. I am in agreement with the principal points in Jeanne Lampl-de Groot's¹ (1927) important paper. In this the complete identity of the pre-Oedipus phase in boys and girls is recognized, and the girl's sexual (phallic) activity towards her mother is affirmed and substantiated by observations. The turning-away from the mother is traced to the influence of the girl's recognition of castration, which obliges her to give up her sexual object, and often masturbation along with it. The whole development is summed up in the formula that the girl goes through a phase of the 'negative' Oedipus complex before she can enter the positive one. A point on which I find the writer's account inadequate is that it represents the turning-away from the mother as being merely a change of object and does not discuss the fact that it is accompanied by the plainest manifestations of hostility. To this hostility full justice is done in Helene Deutsch's latest paper, on feminine masochism and its relation to frigidity (1930), in which she also recognizes the girl's phallic activity and the intensity of her attachment to her mother. Helene Deutsch states further that the girl's turning towards her father takes place via her passive trends (which have already been awakened in relation to her mother). In her earlier book (1925) the author had not yet set herself free from the endeavour to apply the Oedipus pattern to the pre-Oedipus phase, and she therefore interpreted the little girl's phallic activity as an identification with her father.

[1931b, 4605]

And now for the other side of the situation. Since the transference reproduces the patient's relation with his parents, it takes over the ambivalence of that relation as well. It almost inevitably happens that one day his positive attitude towards the analyst changes over into the negative, hostile one. This too is as a rule a repetition of the past. His obedience to his father (if it is his father that is in question), his courting of his father's favour, had its roots in an erotic wish directed towards him. Some time or other that demand will press its way forward in the transference as well and insist on being satisfied. In the analytic situation it can only meet with frustration. Real sexual relations between patients and analysts are out of the question, and even the subtler methods of satisfaction, such as the giving of preference, intimacy and so on, are only sparingly granted by the analyst. A rejection of this kind is taken as the occasion for the change-over; probably things happened in the same way in the patient's childhood.

[1940a [1938], 4986]
I have learnt to look upon unconscious love relations like this (which are marked by their abnormal consequences) - between a father and a daughter, or between a mother and a son - as a revival of germs of feeling in infancy. I have shown at length elsewhere¹ at what an early age sexual attraction makes itself felt between parents and children, and I have explained that the legend of Oedipus is probably to be regarded as a poetical rendering of what is typical in these relations. Distinct traces are probably to be found in most people of an early partiality of this kind - on the part of a daughter for her father, or on the part of a son for his mother; but it must be assumed to be more intense from the very first in the case of those children whose constitution marks them down for a neurosis, who develop prematurely and have a craving for love. At this point certain other influences, which need not be discussed here, come into play, and lead to a fixation of this rudimentary feeling of love or to a reinforcement of it; so that it turns into something (either while the child is still young or not until it has reached the age of puberty) which must be put on a par with a sexual inclination and which, like the latter, has the forces of the libido at its command.² The nature of her disposition had always drawn her towards her father, and his numerous illnesses were bound to have increased her affection for him. In some of these illnesses he would allow no one but her to discharge the lighter duties of nursing. He had been so proud of the early growth of her intelligence that he had made her his confidante while she was still a child. It was really she and not her mother whom Frau K.'s appearance had driven out of more than one position.

[1905e, 1393]

When I told Dora that I could not avoid supposing that her affection for her father must at a very early moment have amounted to her being completely in love with him, she of course gave me her usual reply: 'I don't remember that.' But she immediately went on to tell me something analogous about a seven-year-old girl who was her cousin (on her mother's side) and in whom she often thought she saw a kind of reflection of her own childhood. This little girl had (not for the first time) been the witness of a heated dispute between her parents, and, when Dora happened to come in on a visit soon afterwards, whispered in her ear: 'You can't think how I hate that person!' (pointing to her mother), 'and when she's dead I shall marry Daddy.' I am in the habit of regarding associations such as this, which bring forward something that agrees with the content of an assertion of mine, as a confirmation from the unconscious of what I have said. No other kind of 'Yes' can be extracted from the unconscious; there is no such thing at all as an unconscious 'No'.¹

[1905e, 1394]

Although the diphasic nature of object-choice comes down in essentials to no more than the operation of the latency period, it is of the highest importance in regard to disturbances of that final outcome. The resultants of infantile object-choice are carried over into the later period. They either persist as such or are revived at the actual time of puberty. But as a consequence of the repression which has developed between the two phases they prove unutilizable. Their sexual aims have become mitigated and they now represent what may be described as the 'affectionate current' of sexual life. Only psycho-analytic investigation can show that behind this affection, admiration and respect there lie concealed the old sexual longings of the infantile component instincts which have now become unserviceable. The object-choice of the pubertal period is obliged to dispense with the objects of childhood and to start afresh as a 'sensual current'. Should these two currents fail to converge, the result is often that one of the ideals of sexual life, the focusing of all desires upon a single object, will be unattainable.

[1905d, 1518]
THE SEXUAL OBJECT DURING EARLY INFANCY  But even after sexual activity has become detached from the taking of nourishment, an important part of this first and most significant of all sexual relations is left over, which helps to prepare for the choice of an object and thus to restore the happiness that has been lost. All through the period of latency children learn to feel for other people who help them in their helplessness and satisfy their needs a love which is on the model of, and a continuation of, their relation as sucklings to their nursing mother. There may perhaps be an inclination to dispute the possibility of identifying a child’s affection and esteem for those who look after him with sexual love. I think, however, that a closer psychological examination may make it possible to establish this identity beyond any doubt. A child’s intercourse with anyone responsible for his care affords him an unending source of sexual excitation and satisfaction from his erotogenic zones. This is especially so since the person in charge of him, who, after all, is as a rule his mother, herself regards him with feelings that are derived from her own sexual life: she strokes him, kisses him, rocks him and quite clearly treats him as a substitute for a complete sexual object.¹ A mother would probably be horrified if she were made aware that all her marks of affection were rousing her child's sexual instinct and preparing for its later intensity. She regards what she does as asexual, 'pure' love, since, after all, she carefully avoids applying more excitations to the child's genitals than are unavoidable in nursery care. As we know, however, the sexual instinct is not aroused only by direct excitation of the genital zone. What we call affection will unfailingly show its effects one day on the genital zones as well. Moreover, if the mother understood more of the high importance of the part played by instincts in mental life as a whole - in all its ethical and psychical achievements - she would spare herself any self-reproaches even after her enlightenment. She is only fulfilling her task in teaching the child to love. After all, he is meant to grow up into a strong and capable person with vigorous sexual needs and to accomplish during his life all the things that human beings are urged to do by their instincts. It is true that an excess of parental affection does harm by causing precocious sexual maturity and also because, by spoiling the child, it makes him incapable in later life of temporarily doing without love or of being content with a smaller amount of it. One of the clearest indications that a child will later become neurotic is to be seen in an insatiable demand for his parents' affection. And on the other hand neuropathic parents, who are inclined as a rule to display excessive affection, are precisely those who are most likely by their caresses to arouse the child's disposition to neurotic illness. Incidentally, this example shows that there are ways more direct than inheritance by which neurotic parents can hand their disorder on to their children.

¹ Anyone who considers this 'sacrilegious' may be recommended to read Havelock Ellis's views on the relation between mother and child, which agree almost completely with mine.

[1905d, 1536]
INFANTILE ANXIETY  Children themselves behave from an early age as though their
dependence on the people looking after them were in the nature of sexual
love. Anxiety in children is originally nothing other than an expression of the fact that they are
feeling the loss of the person they love. It is for this reason that they are frightened of every
stranger. They are afraid in the dark because in the dark they cannot see the person they love;
and their fear is soothed if they can take hold of that person's hand in the dark. To attribute to
bogeys and blood-curdling stories told by nurses the responsibility for making children timid is to
over-estimate their efficacy. The truth is merely that children who are inclined to be timid are
affected by stories which would make no impression what ever upon others, and it is only
children with a sexual instinct that is excessive or has developed prematurely or has become
vociferous owing to too much petting who are inclined to be timid. In this respect a child, by
turning his libido into anxiety when he cannot satisfy it, behaves like an adult. On the other hand
an adult who has become neurotic owing to his libido being unsatisfied behaves in his anxiety
like a child: he begins to be frightened when he is alone, that is to say when he is away from
someone of whose love he had felt secure, and he seeks to assuage this fear by the most
childish measures.¹

It is in the world of ideas, however, that the choice of an object is accomplished at first; and
the sexual life of maturing youth is almost entirely restricted to indulging in phantasies, that is, in
ideas that are not destined to be carried into effect.¹ In these phantasies the infantile tendencies
invariably emerge once more, but this time with intensified pressure from somatic sources.
Among these tendencies the first place is taken with uniform frequency by the child's sexual
impulses towards his parents, which are as a rule already differentiated owing to the attraction
of the opposite sex - the son being drawn towards his mother and the daughter towards her
father.² At the same time as these plainly incestuous phantasies are overcome and repudiated,
one of the most significant, but also one of the most painful, psychical achievements of the
pubertal period is completed: detachment from parental authority, a process that alone makes
possible the opposition, which is so important for the progress of civilization, between the new
generation and the old. At every stage in the course of development through which all human
beings ought by rights to pass, a certain number are held back; so there are some who have
never got over their parents' authority and have withdrawn their affection from them either very
incompletely or not at all. They are mostly girls, who, to the delight of their parents, have
persisted in all their childish love far beyond puberty. It is most instructive to find that it is
precisely these girls who in their later marriage lack the capacity to give their husbands what is
due to them; they make cold wives and remain sexually anaesthetic. We learn from this that
sexual love and what appears to be non-sexual love for parents are fed from the same sources;
the latter, that is to say, merely corresponds to an infantile fixation of the libido.

[1905d, 1537]
The closer one comes to the deeper disturbances of psychosexual development, the more unmistakably the importance of incestuous object-choice emerges. In psychoneurotics a large portion or the whole of their psychosexual activity in finding an object remains in the unconscious as a result of their repudiation of sexuality. Girls with an exaggerated need for affection and an equally exaggerated horror of the real demands made by sexual life have an irresistible temptation on the one hand to realize the ideal of asexual love in their lives and on the other hand to conceal their libido behind an affection which they can express without self-reproaches, by holding fast throughout their lives to their infantile fondness, revived at puberty, for their parents or brothers and sisters. Psycho-analysis has no difficulty in showing persons of this kind that they are in love, in the everyday sense of the word, with these blood-relations of theirs; for, with the help of their symptoms and other manifestations of their illness, it traces their unconscious thoughts and translates them into conscious ones. In cases in which someone who has previously been healthy falls ill after an unhappy experience in love it is also possible to show with certainty that the mechanism of his illness consists in a turning-back of his libido on to those whom he preferred in his infancy.

[1905d, 1539]

Let us return to the sexual development of children. We have some arrears to make up owing to our having paid more attention to the somatic than to the mental phenomena of sexual life. The child's first choice of an object, which derives from its need for help, claims our further interest. Its choice is directed in the first instance to all those who look after it, but these soon give place to its parents. Children's relations to their parents, as we learn alike from direct observations of children and from later analytic examination of adults, are by no means free from elements of accompanying sexual excitation. The child takes both of its parents, and more particularly one of them, as the object of its erotic wishes. In so doing, it usually follows some indication from its parents, whose affection bears the clearest characteristics of a sexual activity, even though of one that is inhibited in its aims. As a rule a father prefers his daughter and a mother her son; the child reacts to this by wishing, if he is a son, to take his father's place, and, if she is a daughter, her mother's. The feelings which are aroused in these relations between parents and children and in the resulting ones between brothers and sisters are not only of a positive or affectionate kind but also of a negative or hostile one. The complex which is thus formed is doomed to early repression; but it continues to exercise a great and lasting influence from the unconscious. It is to be suspected that, together with its extensions, it constitutes the nuclear complex of every neurosis, and we may expect to find it no less actively at work in other regions of mental life. The myth of King Oedipus, who killed his father and took his mother to wife, reveals, with little modification, the infantile wish, which is later opposed and repudiated by the barrier against incest. Shakespeare's Hamlet is equally rooted in the soil of the incest-complex, but under a better disguise.

[1910a, 2232]
The affectionate current is the older of the two. It springs from the earliest years of childhood; it is formed on the basis of the interests of the self-preservative instinct and is directed to the members of the family and those who look after the child. From the very beginning it carries along with it contributions from the sexual instincts - components of erotic interest - which can already be seen more or less clearly even in childhood and in any event are uncovered in neurotics by psycho-analysis later on. It corresponds to the child's primary object-choice. We learn in this way that the sexual instincts find their first objects by attaching themselves to the valuations made by the ego-instincts, precisely in the way in which the first sexual satisfactions are experienced in attachment to the bodily functions necessary for the preservation of life. The 'affection' shown by the child's parents and those who look after him, which seldom fails to betray its erotic nature ('the child is an erotic plaything'), does a very great deal to raise the contributions made by erotism to the cathexes of his ego-instincts, and to increase them to an amount which is bound to play a part in his later development, especially when certain other circumstances lend their support.

[1912d, 2338]

I may add to these excellent arguments of Frazer's that the findings of psycho-analysis make the hypothesis of an innate aversion to incestuous intercourse totally untenable. They have shown, on the contrary, that the earliest sexual excitations of youthful human beings are invariably of an incestuous character and that such impulses when repressed play a part that can scarcely be over-estimated as motive forces of neuroses in later life.

[1912-1913, 2764]

The processes of finding an object are fairly complex and no comprehensive account has hitherto been given of them. For our purposes it may be specially pointed out that when, in the years of childhood before puberty, the process has in some respects reached a conclusion, the object that has been found turns out to be almost identical with the first object of the oral pleasure-instinct, which was reached by attachment. Though it is not actually the mother's breast, at least it is the mother. We call the mother the first love-object. For we speak of love when we bring the mental side of the sexual trends into the foreground and want to force back the underlying physical or 'sensual' instinctual demands or to forget them for a moment. At the time at which the child's mother becomes his love-object the psychical work of repression has already begun in him, which is withdrawing from his knowledge awareness of a part of his sexual aims. To his choice of his mother as a love-object everything becomes attached which, under the name of the 'Oedipus complex', has attained so much importance in the psychoanalytic explanation of the neuroses and has played no less a part, perhaps, in the resistance to psycho-analysis.

[1916-1917, 3397]
What, then, can be gathered about the Oedipus complex from the direct observation of children at the time of their making their choice of an object before the latency period? Well, it is easy to see that the little man wants to have his mother all to himself, that he feels the presence of his father as a nuisance, that he is resentful if his father indulges in any signs of affection towards his mother and that he shows satisfaction when his father has gone on a journey or is absent. He will often express his feelings directly in words and promise his mother to marry her. It will be thought that this amounts to little compared to the deeds of Oedipus; but in fact it is enough, it is the same thing at root. Observation is often obscured by the circumstance that on other occasions the same child will simultaneously give evidence of great affection for his father. But contrary - or, as it is better to say, 'ambivalent' - emotional attitudes, which in adults would lead to a conflict, remain compatible with each other for a long time in children, just as later they find a permanent place beside each other in the unconscious. It will also be objected that the little boy's conduct arises from egoistic motives and gives no grounds for postulating an erotic complex: the child's mother attends to all his needs, so that he has an interest in preventing her from looking after anyone else. This also is true; but it will soon become clear that in this situation as in similar ones the egoistic interest is merely affording a point of support to which the erotic trend is attached. The little boy may show the most undisguised sexual curiosity about his mother, he may insist upon sleeping beside her at night, he may force his presence on her while she is dressing or may even make actual attempts at seducing her, as his mother will often notice and report with amusement - all of which puts beyond doubt the erotic nature of his tie with his mother. Nor must it be forgotten that the mother devotes the same attention to a little daughter without producing the same result and that the father often competes with her in looking after the boy and yet fails to gain the same significance as she does. In short, the factor of sexual preference cannot be eliminated from the situation by any criticism. From the standpoint of egoistic interest it would be simply foolish of the little man not to prefer to put up with having two people in his service rather than only one of them.

[1916-1917, 3399]

But let us now turn from the direct observation of children to the analytic examination of adults who have become neurotic. What help does analysis give towards a further knowledge of the Oedipus complex? That can be answered in a word. Analysis confirms all that the legend describes. It shows that each of these neurotics has himself been an Oedipus or, what comes to the same thing, has, as a reaction to the complex, become a Hamlet. The analytic account of the Oedipus complex is, of course, a magnification and coarsening of the infantile sketch. The hatred of the father, the death-wishes against him, are no longer hinted at timidly, the affection for the mother admits that its aim is to possess her as a woman. Should we really attribute such blatant and extreme emotional impulses to the tender years of childhood, or is analysis deceiving us by an admixture of some new factor? It is not hard to find one. Whenever someone gives an account of a past event, even if he is a historian, we must take into account what he unintentionally puts back into the past from the present or from some intermediate time, thus falsifying his picture of it. In the case of a neurotic it is even a question whether this putting back is an entirely unintentional one; later on we shall have to discover reasons for this and have to do justice in general to the fact of 'retrospective phantasying'. We can easily see, too, that hatred of the father is reinforced by a number of factors arising from later times and circumstances and that the sexual desires towards the mother are cast into forms which must have been alien as yet to a child. But it would be a vain effort to seek to explain the whole Oedipus complex by retrospective phantasying and to attach it to later times. Its infantile core and more or less of its accessories remain as they were confirmed by the direct observation of children.

[1916-1917, 3401]
The subsequent history of this identification with the father may easily be lost sight of. It may happen that the Oedipus complex becomes inverted, and that the father is taken as the object of a feminine attitude, an object from which the directly sexual instincts look for satisfaction; in that event the identification with the father has become the precursor of an object-tie with the father. The same holds good, with the necessary substitutions, of the baby daughter as well. [1921c, 3798]

To this must be added another factor derived from the very remarkable course of development which is pursued by the erotic life of man. In its first phase, which has usually come to an end by the time a child is five years old, he has found the first object for his love in one or other of his parents, and all of his sexual instincts with their demand for satisfaction have been united upon this object. The repression which then sets in compels him to renounce the greater number of these infantile sexual aims, and leaves behind a profound modification in his relation to his parents. The child still remains tied to his parents, but by instincts which must be described as being 'inhibited in their aim'. The emotions which he feels henceforward towards these objects of his love are characterized as 'affectionate'. It is well known that the earlier 'sensual' tendencies remain more or less strongly preserved in the unconscious, so that in a certain sense the whole of the original current continues to exist.¹ [1921c, 3803]

The development of the libido in children has made us acquainted with the first but also the best example of sexual instincts which are inhibited in their aims. All the feelings which a child has towards its parents and those who look after it pass by an easy transition into the wishes which give expression to the child's sexual impulsions. The child claims from these objects of its love all the signs of affection which it knows of; it wants to kiss them, touch them, and look at them; it is curious to see their genitals, and to be with them when they perform their intimate excretory functions; it promises to marry its mother or nurse - whatever it may understand by marriage; it proposes to itself to bear its father a child, etc. Direct observation, as well as the subsequent analytic investigation of the residues of childhood, leave no doubt as to the complete fusion of tender and jealous feelings and of sexual intentions, and show us in what a fundamental way the child makes the person it loves into the object of all its still not properly centred sexual trends.¹ [1921c, 3828]

This first configuration of the child's love, which in typical cases takes the shape of the Oedipus complex, succumbs, as we know, from the beginning of the period of latency onwards to a wave of repression. Such of it as is left over shows itself as a purely affectionate emotional tie, relating to the same people, but no longer to be described as 'sexual'. Psycho-analysis, which illuminates the depths of mental life, has no difficulty in showing that the sexual ties of the earliest years of childhood also persist, though repressed and unconscious. It gives us courage to assert that wherever we come across an affectionate feeling it is successor to a completely 'sensual' object-tie with the person in question or rather with that person's prototype (or imago). It cannot indeed disclose to us without a special investigation whether in a given case this former complete sexual current still exists under repression or whether it has already been exhausted. To speak still more precisely: it is quite certain that this current is still there as a form and possibility, and can always be cathetted and put into activity again by means of regression; the only question is (and it cannot always be answered) what degree of cathexis and operative force it still has at the present moment. Equal care must be taken in this connection to avoid two sources of error - the Scylla of underestimating the importance of the repressed unconscious, and the Charybdis of judging the normal entirely by the standards of the pathological. [1921c, 3829]
Aim-inhibited Sexual Impulses. - The social instincts belong to a class of instinctual impulses which need not be described as sublimated, though they are closely related to these. They have not abandoned their directly sexual aims, but they are held back by internal resistances from attaining them; they rest content with certain approximations to satisfaction and for that very reason lead to especially firm and permanent attachments between human beings. To this class belong in particular the affectionate relations between parents and children, which were originally fully sexual, feelings of friendship, and the emotional ties in marriage which had their origin in sexual attraction.

[1923a, 3934]

I have described elsewhere how this turning away takes place. The object-cathexes are given up and replaced by identifications. The authority of the father or the parents is introjected into the ego, and there it forms the nucleus of the super-ego, which takes over the severity of the father and perpetuates his prohibition against incest, and so secures the ego from the return of the libidinal object-cathexis. The libidinal trends belonging to the Oedipus complex are in part desexualized and sublimated (a thing which probably happens with every transformation into an identification) and in part inhibited in their aim and changed into impulses of affection. The whole process has, on the one hand, preserved the genital organ - has averted the danger of its loss - and, on the other, has paralysed it - has removed its function. This process ushers in the latency period, which now interrupts the child's sexual development.

[1924d, 4088]

By its theory of the instincts psycho-analysis offended the feelings of individuals in so far as they regarded themselves as members of the social community; another branch of its theory was calculated to hurt every single person at the tenderest point of his own psychical development. Psycho-analysis disposed once and for all of the fairy tale of an asexual childhood. It demonstrated the fact that sexual interests and activities occur in small children from the beginning of their lives. It showed what transformations those activities pass through, how at about the age of five they succumb to inhibition and how from puberty onwards they enter the service of the reproductive function. It recognized that early infantile sexual life reaches its peak in what is known as the Oedipus complex (an emotional attachment of the child to the parent of the opposite sex accompanied by an attitude of rivalry to the parent of the same sex) and that at that period of life this impulsion extends uninhibited into a straightforward sexual desire. This can be confirmed so easily that only the greatest efforts could make it possible to overlook it. Every individual has in fact gone through this phase but has afterwards energetically repressed its purport and succeeded in forgetting it. A horror of incest and an enormous sense of guilt are left over from this prehistoric epoch of the individual's existence. It may be that something quite similar occurred in the prehistoric epoch of the human species as a whole and that the beginnings of morality, religion and social order were intimately connected with the surmounting of that primaeval era. To adults their prehistory seems so inglorious that they refuse to allow themselves to be reminded of it: they were infuriated when psycho-analysis tried to lift the veil of amnesia from their years of childhood. There was only one way out: what psycho-analysis asserted must be false and what posed as a new science must be a tissue of fancies and distortions.

[1925e, 4128]
The process of arriving at an object, which plays such an important part in mental life, takes place alongside of the organization of the libido. After the stage of auto-erotism, the first love-object in the case of both sexes is the mother; and it seems probable that to begin with a child does not distinguish its mother's organ of nutrition from its own body. Later, but still in the first years of infancy, the relation known as the Oedipus complex becomes established: boys concentrate their sexual wishes upon their mother and develop hostile impulses against their father as being a rival, while girls adopt an analogous attitude.¹ All of the different variations and consequences of the Oedipus complex are important; and the innately bisexual constitution of human beings makes itself felt and increases the number of simultaneously active tendencies. Children do not become clear for quite a long time about the differences between the sexes; and during this period of sexual researches they produce typical sexual theories which, being circumscribed by the incompleteness of their authors' own physical development, are a mixture of truth and error and fail to solve the problems of sexual life (the riddle of the Sphinx - that is, the question of where babies come from). We see, then, that a child's first object-choice is an incestuous one. The whole course of development that I have described is run through rapidly. For the most remarkable feature of the sexual life of man is its diphasic onset, its onset in two waves, with an interval between them. It reaches a first climax in the fourth or fifth year of a child's life. But thereafter this early efflorescence of sexuality passes off; the sexual impulses which have shown such liveliness are overcome by repression, and a period of latency follows, which lasts until puberty and during which the reaction-formations of morality, shame, and disgust are built up.² Of all living creatures man alone seems to show this diphasic onset of sexual growth, and it may perhaps be the biological determinant of his predisposition to neuroses. At puberty the impulses and object-relations of a child's early years become reanimated, and amongst them the emotional ties of its Oedipus complex. In the sexual life of puberty there is a struggle between the urges of early years and the inhibitions of the latency period. Before this, and while the child is at the highest point of its infantile sexual development, a genital organization of a sort is established; but only the male genitals play a part in it, and the female ones remain undiscovered. (I have described this as the period of phallic primacy.) At this stage the contrast between the sexes is not stated in terms of 'male' or 'female' but of 'possessing a penis' or 'castrated'. The castration complex which arises in this connection is of the profoundest importance in the formation alike of character and of neuroses.

¹ (Footnote added 1935:) The information about infantile sexuality was obtained from the study of men and the theory deduced from it was concerned with male children. It was natural enough to expect to find a complete parallel between the two sexes; but this turned out not to hold. Further investigations and reflections revealed profound differences between the sexual development of men and women. The first sexual object of a baby girl (just as of a baby boy) is her mother; and before a woman can reach the end of her normal development she has to change not only her sexual object but also her leading genital zone. From this circumstance difficulties arise and possibilities of inhibition which are not present in the case of men.

² [1925d, 4212]
The idea of being devoured by the father is typical age-old childhood material. It has familiar parallels in mythology (e.g. the myth of Kronos) and in the animal kingdom. Yet in spite of this confirmation the idea is so strange to us that we can hardly credit its existence in a child. Nor do we know whether it really means what it seems to say, and we cannot understand how it can have become the subject of a phobia. Analytic observation supplies the requisite information. It shows that the idea of being devoured by the father gives expression, in a form that has undergone regressive degradation, to a passive, tender impulse to be loved by him in a genital-erotic sense. Further investigation of the case history leaves no doubt of the correctness of this explanation. The genital impulse, it is true, betrays no sign of its tender purpose when it is expressed in the language belonging to the superseded transitional phase between the oral and sadistic organizations of the libido. Is it, moreover, a question merely of the replacement of the representative by a regressive form of expression or is it a question of a genuine regressive degradation of the genitally-directed impulse in the id? It is not at all easy to make certain. The case history of the Russian 'Wolf Man' gives very definite support to the second, more serious, view; for, from the time of the decisive dream onward, the boy became naughty, tormenting and sadistic, and soon afterwards developed a regular obsessional neurosis. At any rate, we can see that repression is not the only means which the ego can employ for the purpose of defence against an unwelcome instinctual impulse. If it succeeds in making an instinct regress, it will actually have done it more injury than it could have by repressing it. Sometimes, indeed, after forcing an instinct to regress in this way, it goes on to repress it. [1926d, 4265]

Nothing, however, deserves more notice than the fact that children regularly direct their sexual wishes towards their nearest relatives - in the first place, therefore, towards their father and mother, and afterwards towards their brothers and sisters. The first object of a boy's love is his mother, and of a girl's her father (except in so far as an innate bisexual disposition favours the simultaneous presence of the contrary attitude). The other parent is felt as a disturbing rival and not infrequently viewed with strong hostility. You must understand me aright. What I mean to say is not that the child wants to be treated by its favourite parent merely with the kind of affection which we adults like to regard as the essence of the parent-child relation. No, analysis leaves us in no doubt that the child's wishes extend beyond such affection to all that we understand by sensual satisfaction - so far, that is, as the child's powers of imagination allow. It is easy to see that the child never guesses the actual facts of sexual intercourse; he replaces them by other notions derived from his own experience and feelings. As a rule his wishes culminate in the intention to bear, or in some in definable way, to procreate a baby. Boys, too, in their ignorance, do not exclude themselves from the wish to bear a baby. We give the whole of this mental structure the name of 'Oedipus complex', after the familiar Greek legend. With the end of the early sexual period it should normally be given up, should radically disintegrate and become transformed; and the results of this transformation are destined for important functions in later mental life. But as a rule this is not effected radically enough, in which case puberty brings about a revival of the complex, which may have serious consequences. [1926e, 4355]
The methods of representation employed by the dream-work - fascinating material, scarcely capable of exhaustion - have been made more and more familiar to us by closer study. I will give you a few examples of them. Thus, for instance, dreams represent the relation of frequency by a multiplication of similar things. Here is a young girl's remarkable dream. She dreamt she came into a great hall and found some one in it sitting on a chair; this was repeated six or eight times or more, but each time it was her father. This is easy to understand when we discover, from accessory details in the interpretation, that this room stood for the womb. The dream then becomes equivalent to the phantasy, familiarly found in girls, of having met their rather already during their intra-uterine life when he visited the womb while their mother was pregnant. You should not be confused by the fact that something is reversed in the dream - that her father's 'coming-in' is displaced on to herself; incidentally, this has a special meaning of its own as well. The multiplication of the figure of the father can only express the fact that the event in question occurred repeatedly. After all, it must be allowed that the dream is not taking very much on itself in expressing frequency by multiplicity. It has only needed to go back to the original significance of the former word; to-day it means to us a repetition in time, but it is derived from an accumulation in space. In general, indeed, where it is possible, the dream-work changes temporal relations into spatial ones and represents them as such. In a dream, for instance, one may see a scene between two people who look very small and a long way off, as though one were seeing them through the wrong end of a pair of opera-glasses. Here, both the smallness and the remoteness in space have the same significance: what is meant is remoteness in time and we are to understand that the scene is from the remote past.

This preface is not superfluous, for it can heighten our realization of the intensity of the Oedipus complex. When a boy (from the age of two or three) has entered the phallic phrase of his libidinal development, is feeling pleasurable sensations in his sexual organ and has learnt to procure these at will by manual stimulation, he becomes his mother's lover. He wishes to possess her physically in such ways as he has divined from his observations and intuitions about sexual life, and he tries to seduce her by showing her the male organ which he is proud to own. In a word, his early awakened masculinity seeks to take his father's place with her; his father has hitherto in any case been an envied model to the boy, owing to the physical strength he perceives in him and the authority with which he finds him clothed. His father now becomes a rival who stands in his way and whom he would like to get rid of. If while his father is away he is allowed to share his mother's bed and if when his father returns he is once more banished from it, his satisfaction when his father disappears and his disappointment when he emerges again are deeply felt experiences. This is the subject of the Oedipus complex, which the Greek legend has translated from the world of a child's phantasy into pretended reality. Under the conditions of our civilization it is invariably doomed to a frightening end.

The boy's mother has understood quite well that his sexual excitation relates to herself. Sooner or later she reflects that it is not right to allow it to continue. She thinks she is doing the correct thing in forbidding him to handle his genital organ. Her prohibition has little effect; at the most it brings about some modification in his method of obtaining satisfaction. At last his mother adopts the severest measures; she threatens to take away from him the thing he is defying her with. Usually, in order to make the threat more frightening and more credible, she delegates its execution to the boy's father, saying that she will tell him and that he will cut the penis off. Strange to say, this threat operates only if another condition is fulfilled before or afterwards. In itself it seems too inconceivable to the boy that such a thing could happen. But if at the time of the threat he can recall the appearance of female genitals or if shortly afterwards he has a sight of them - of genitals, that is to say, which really lack this supremely valued part, then he takes what he has heard seriously and, coming under the influence of the castration complex, experiences the severest trauma of his young life.¹

¹[1940a [1938], 4997]
In my experience, which is already extensive, the chief part in the mental lives of all children who later become psychoneurotics is played by their parents. Being in love with the one parent and hating the other are among the essential constituents of the stock of psychical impulses which is formed at that time and which is of such importance in determining the symptoms of the later neurosis. It is not my belief, however, that psychoneurotics differ sharply in this respect from other human beings who remain normal - that they are able, that is, to create something absolutely new and peculiar to themselves. It is far more probable - and this is confirmed by occasional observations on normal children - that they are only distinguished by exhibiting on a magnified scale feelings of love and hatred to their parents which occur less obviously and less intensely in the minds of most children.

If *Oedipus Rex* moves a modern audience no less than it did the contemporary Greek one, the explanation can only be that its effect does not lie in the contrast between destiny and human will, but is to be looked for in the particular nature of the material on which that contrast is exemplified. There must be something which makes a voice within us ready to recognize the compelling force of destiny in the *Oedipus*, while we can dismiss as merely arbitrary such dispositions as are laid down in *Die Ahnfrau* or other modern tragedies of destiny. And a factor of this kind is in fact involved in the story of King Oedipus. His destiny moves us only because it might have been ours - because the oracle laid the same curse upon us before our birth as upon him. It is the fate of all of us, perhaps, to direct our first sexual impulse towards our mother and our first hatred and our first murderous wish against our father. Our dreams convince us that that is so. King Oedipus, who slew his father Laius and married his mother Jocasta, merely shows us the fulfilment of our own childhood wishes. But, more fortunate than he, we have meanwhile succeeded, in so far as we have not become psychoneurotics, in detaching our sexual impulses from our mothers and in forgetting our jealousy of our fathers. Here is one in whom these primaeval wishes of our childhood have been fulfilled, and we shrink back from him with the whole force of the repression by which those wishes have since that time been held down within us. While the poet, as he unravels the past, brings to light the guilt of Oedipus, he is at the same time compelling us to recognize our own inner minds, in which those same impulses, though suppressed, are still to be found. The contrast with which the closing Chorus leaves us confronted -

There is an unmistakable indication in the text of Sophocles' tragedy itself that the legend of Oedipus sprang from some primaeval dream-material which had as its content the distressing disturbance of a child's relation to his parents owing to the first stirrings of sexuality. At a point when Oedipus, though he is not yet enlightened, has begun to feel troubled by his recollection of the oracle, Jocasta consoles him by referring to a dream which many people dream, though, as she thinks, it has no meaning:
In attempting to analyse this small mistake I first thought of the phrase 'sich an der Alten vergreifen',¹ which provided a short cut to the solution. I was under the influence of a dream which had been told me by a young man the previous evening and the content of which could only point to sexual intercourse with his own mother.² The strange fact that the legend finds nothing objectionable in Queen Jocasta's age seemed to me to fit in well with the conclusion that in being in love with one's own mother one is never concerned with her as she is in the present but with her youthful mnemonic image carried over from one's childhood. Such incongruities always appear when a phantasy that fluctuates between two periods is made conscious and so becomes definitely attached to one of the two periods. While absorbed in thoughts of this kind I came to my patient, who is over ninety, and I must have been on the way to grasping the universal human application of the Oedipus myth as correlated with the Fate which is revealed in the oracles; for at that point I did violence to or committed a blunder on 'the old woman'. Here again the bungled action was a harmless one; of the two possible errors, using the morphine solution for the eye or the eye lotion for the injection, I had chosen by far the more harmless one. This still leaves the question open of whether we may admit the possibility of an unconscious intention in mistakes that can cause serious harm, in the same way as in the cases which I have discussed.

[1901b, 1258]

It has justly been said that the Oedipus complex is the nuclear complex of the neuroses, and constitutes the essential part of their content. It represents the peak of infantile sexuality, which, through its after-effects, exercises a decisive influence on the sexuality of adults. Every new arrival on this planet is faced by the task of mastering the Oedipus complex; anyone who fails to do so falls a victim to neurosis. With the progress of psycho-analytic studies the importance of the Oedipus complex has become more and more clearly evident; its recognition has become the shibboleth that distinguishes the adherents of psycho-analysis from its opponents.

[1905d, 1539]

The first of these modern dramas is Hamlet. It has as its subject the way in which a man who has so far been normal becomes neurotic owing to the peculiar nature of the task by which he is faced, a man, that is, in whom an impulse that has hitherto been successfully suppressed endeavours to make its way into action. Hamlet is distinguished by three characteristics which seem important in connection with our present discussion. (1) The hero is not psychopathic, but only becomes psychopathic in the course of the action of the play. (2) The repressed impulse is one of those which are similarly repressed in all of us, and the repression of which is part and parcel of the foundations of our personal evolution. It is this repression which is shaken up by the situation in the play. As a result of these two characteristics it is easy for us to recognize ourselves in the hero: we are susceptible to the same conflict as he is, since 'a person who does not lose his reason under certain conditions can have no reason to lose'. (3) It appears as a necessary precondition of this form of art that the impulse that is struggling into consciousness, however clearly it is recognizable, is never given a definite name; so that in the spectator too the process is carried through with his attention averted, and he is in the grip of his emotions instead of taking stock of what is happening. A certain amount of resistance is no doubt saved in this way, just as, in an analytic treatment, we find derivatives of the repressed material reaching consciousness, owing to a lower resistance, while the repressed material itself is unable to do so. After all, the conflict in Hamlet is so effectively concealed that it was left to me to unearth it.

[1942a [1905], 1611]
In his attitude towards his father and mother Hans confirms in the most concrete and uncompromising manner what I have said in my *Interpretation of Dreams* and in my *Three Essays* with regard to the sexual relations of a child to his parents. Hans really was a little Oedipus who wanted to have his father ‘out of the way’, to get rid of him, so that he might be alone with his beautiful mother and sleep with her. This wish had originated during his summer holidays, when the alternating presence and absence of his father had drawn Hans's attention to the condition upon which depended the intimacy with his mother which he longed for. At that time the form taken by the wish had been merely that his father should 'go away'; and at a later stage it became possible for his fear of being bitten by a white horse to attach itself directly on to this form of the wish, owing to a chance impression which he received at the moment of some one else's departure. But subsequently (probably not until they had moved back to Vienna, where his father's absences were no longer to be reckoned on) the wish had taken the form that his father should be *permanently* away - that he should be 'dead'. The fear which sprang from this death-wish against his father, and which may thus be said to have had a normal motive, formed the chief obstacle to the analysis until it was removed during the conversation in my consulting-room.¹

We have reduced psychical impotence to the failure of the affectionate and the sensual currents in love to combine, and this developmental inhibition has in turn been explained as being due to the influences of strong childhood fixations and of later frustration in reality through the intervention of the barrier against incest. There is one principal objection to the theory we advance; it does too much. It explains why certain people suffer from psychical impotence, but it leaves us with the apparent mystery of how others have been able to escape this disorder. Since we must recognize that all the relevant factors known to us - the strong childhood fixation, the incest-barrier and the frustration in the years of development after puberty - are to be found in practically all civilized human beings, we should be justified in expecting psychical impotence to be a universal affliction under civilization and not a disorder confined to some individuals.²

It cannot be said that the world has shown much gratitude to psycho-analytic research for its revelation of the Oedipus complex. On the contrary, the discovery has provoked the most violent opposition among adults; and those who had neglected to take part in the repudiation of this proscribed and tabooed emotional relationship made up for their fault later by depriving the complex of its value through twisted re-interpretations. It is my unaltered conviction that there is nothing in this to be disavowed or glossed over. We must reconcile ourselves to the fact which was recognized by the Greek legend itself as an inevitable fate. It is once again an interesting fact that the Oedipus complex, which has been rejected from real life, has been left to imaginative writing, has been placed freely, as it were, at its disposal. Otto Rank has shown in a careful study how the Oedipus complex has provided dramatic authors with a wealth of themes in endless modifications, softenings and disguises - in distortions, that is to say, of the kind which we are already familiar with as the work of a censorship. We may therefore also ascribe this Oedipus complex to dreamers who have been fortunate enough to escape conflicts with their parents in later life. And, intimately linked with it, we find what we call the 'castration complex', the reaction to the threats against the child aimed at putting a stop to his early sexual activities and attributed to his father.

[1909b, 2096]

[1912d, 2341]

[1916-1917, 3296]
Among these forbidden wishes special emphasis deserves to be further laid on the incestuous ones - that is, on those aiming at sexual intercourse with parents and brothers and sisters. You know what horror is felt, or at least professed, in human society at such intercourse, and what stress is laid on the prohibitions directed against it. Tremendous efforts have been made to explain this horror of incest. Some people have supposed that breeding considerations on the part of Nature have found psychical representation in this prohibition, since inbreeding would impair racial characters. Others have maintained that, as a result of living together from early childhood onwards, sexual desire has been diverted from the people in question. In both these cases, it may be remarked, an avoidance of incest would be secured automatically, and it would not be clear why such severe prohibitions were called for, which would point rather to the presence of a strong desire for it. Psycho-analytic researches have shown unmistakably that the choice of an incestuous love-object is, on the contrary, the first and invariable one, and that it is not until later that resistance to it sets in; it is no doubt impossible to trace back this resistance to *individual* psychology.

[1916-1917, 3298]

It is a surprising thing that the tragedy of Sophocles does not call up indignant repudiation in his audience - a reaction similar to that of our simple-minded army doctor but far better justified. For fundamentally it is an amoral work: it absolves men from moral responsibility, exhibits the gods as promoters of crime and shows the impotence of the moral impulses of men which struggle against crime. It might easily be supposed that the material of the legend had in view an indictment of the gods and of fate; and in the hands of Euripides, the critic and enemy of the gods, it would probably have become such an indictment. But with the devout Sophocles there is no question of an application of that kind. The difficulty is overcome by the pious sophistry that to bow to the will of the gods is the highest morality even when it promotes crime. I cannot think that this morality is a strong point of the play, but it has no influence on its effect. It is not to it that the auditor reacts but to the secret sense and content of the legend. He reacts as though by self-analysis he had recognized the Oedipus complex in himself and had unveiled the will of the gods and the oracle as exalted disguises of his own unconscious. It is as though he was obliged to remember the two wishes - to do away with his father and in place of him to take his mother to wife - and to be horrified at them. And he understands the dramatist's voice as though it were saying to him: 'You are struggling in vain against your responsibility and are protesting in vain of what you have done in opposition to these criminal intentions. You are guilty, for you have not been able to destroy them; they still persist in you unconsciously.' And there is psychological truth contained in this. Even if a man has repressed his evil impulses into the unconscious and would like to tell himself afterwards that he is not responsible for them, he is nevertheless bound to be aware of this responsibility as a sense of guilt whose basis is unknown to him.

[1916-1917, 3398]
The clinical fact which meets us behind the form of the Oedipus complex as it is established by analysis is of the highest practical significance. We learn that at puberty, when the sexual instinct first makes its demands in full strength, the old familiar incestuous objects are taken up again and freshly cathexed with libido. The infantile object-choice was only a feeble one, but it was a prelude, pointing the direction for the object-choice at puberty. At this point, then, very intense emotional processes come into play, following the direction of the Oedipus complex or reacting against it, processes which, however, since their premisses have become intolerable, must to a large extent remain apart from consciousness. From this time onwards, the human individual has to devote himself to the great task of detaching himself from his parents, and not until that task is achieved can he cease to be a child and become a member of the social community. For the son this task consists in detaching his libidinal wishes from his mother and employing them for the choice of a real outside love-object, and in reconciling himself with his father if he has remained in opposition to him, or in freeing himself from his pressure if, as a reaction to his infantile rebelliousness, he has become subservient to him. These tasks are set to everyone; and it is remarkable how seldom they are dealt with in an ideal manner - that is, in one which is correct both psychologically and socially. By neurotics, however, no solution at all is arrived at: the son remains all his life bowed beneath his father's authority and he is unable to transfer his libido to an outside sexual object. With the relationship changed round, the same fate can await the daughter. In this sense the Oedipus complex may justly be regarded as the nucleus of the neuroses.

But there is something else that I cannot pass by. The reminder of dreams given to us by the mother and wife of Oedipus must not be allowed to remain fruitless. Do you recall the outcome of our dream-analyses - how the wishes that construct dreams are so often of a perverse or incestuous nature or reveal an unsuspected hostility to those who are nearest and dearest to the dreamer? At that time we gave no explanation of the origin of these evil impulses. Now you can find it for yourselves. They are allocations of the libido and object-cathexes which date from early infancy and have long since been abandoned as far as conscious life is concerned, but which prove still to be present at night-time and to be capable of functioning in a certain sense. Since, however, everyone, and not only neurotics, experiences these perverse, incestuous and murderous dreams, we may conclude that people who are normal to-day have passed along a path of development that has led through the perversions and object-cathexes of the Oedipus complex, that is the path of normal development and that neurotics merely exhibit to us in a magnified and coarsened form what the analysis of dreams reveals to us in healthy people as well. And this is one of the reasons why I dealt with the study of dreams before that of neurotic symptoms.

In the very earliest years of childhood (approximately between the ages of two and five) a convergence of the sexual impulses occurs of which, in the case of boys, the object is the mother. This choice of an object, in conjunction with a corresponding attitude of rivalry and hostility towards the father, provides the content of what is known as the Oedipus complex, which in every human being is of the greatest importance in determining the final shape of his erotic life. It has been found to be characteristic of a normal individual that he learns to master his Oedipus complex, whereas the neurotic subject remains involved in it.
By its theory of the instincts psycho-analysis offended the feelings of individuals in so far as they regarded themselves as members of the social community; another branch of its theory was calculated to hurt every single person at the tenderest point of his own psychical development. Psycho-analysis disposed once and for all of the fairy tale of an asexual childhood. It demonstrated the fact that sexual interests and activities occur in small children from the beginning of their lives. It showed what transformations those activities pass through, how at about the age of five they succumb to inhibition and how from puberty onwards they enter the service of the reproductive function. It recognized that early infantile sexual life reaches its peak in what is known as the Oedipus complex (an emotional attachment of the child to the parent of the opposite sex accompanied by an attitude of rivalry to the parent of the same sex) and that at that period of life this impulsion extends uninhibited into a straightforward sexual desire. This can be confirmed so easily that only the greatest efforts could make it possible to overlook it. Every individual has in fact gone through this phase but has afterwards energetically repressed its purport and succeeded in forgetting it. A horror of incest and an enormous sense of guilt are left over from this prehistoric epoch of the individual's existence. It may be that something quite similar occurred in the prehistoric epoch of the human species as a whole and that the beginnings of morality, religion and social order were intimately connected with the surmounting of that primitive era. To adults their prehistory seems so inglorious that they refuse to allow themselves to be reminded of it: they were infuriated when psycho-analysis tried to lift the veil of amnesia from their years of childhood. There was only one way out: what psycho-analysis asserted must be false and what posed as a new science must be a tissue of fancies and distortions.

A number of suggestions came to me out of the Oedipus complex, the ubiquity of which gradually dawned on me. The poet's choice, or his invention, of such a terrible subject seemed puzzling; and so too did the overwhelming effect of its dramatic treatment, and the general nature of such tragedies of destiny. But all of this became intelligible when one realized that a universal law of mental life had here been captured in all its emotional significance. Fate and the oracle were no more than materializations of an internal necessity; and the fact of the hero's sinning without his knowledge and against his intentions was evidently a right expression of the unconscious nature of his criminal tendencies. From understanding this tragedy of destiny it was only a step further to understanding a tragedy of character - Hamlet, which had been admired for three hundred years without its meaning being discovered or its author's motives guessed. It could scarcely be a chance that this neurotic creation of the poet should have come to grief, like his numberless fellows in the real world, over the Oedipus complex. For Hamlet was faced with the task of taking vengeance on another for the two deeds which are the subject of the Oedipus desires; and before that task his arm was paralysed by his own obscure sense of guilt. Shakespeare wrote Hamlet very soon after his father's death.¹ The suggestions made by me for the analysis of this tragedy were fully worked out later on by Ernest Jones. And the same example was afterwards used by Otto Rank as the starting-point for his investigation of the choice of material made by dramatists. In his large volume on the incest theme (Rank, 1912) he was able to show how often imaginative writers have taken as their subject the themes of the Oedipus situation, and traced in the different literatures of the world the way in which the material has been transformed, modified, and softened.

¹[1925e, 4128]

[1925d, 4237]
I am surprised that you are still silent. That can scarcely mean consent. - In asserting that a child's first choice of an object is, to use the technical term, an incestuous one, analysis no doubt once more hurt the most sacred feelings of humanity, and might well be prepared for a corresponding amount of disbelief, contradiction and attack. And these it has received in abundance. Nothing has damaged it more in the good opinion of its contemporaries than its hypothesis of the Oedipus complex as a structure universally bound to human destiny. The Greek myth, incidentally, must have had the same meaning; but the majority of men to-day, learned and unlearned alike, prefer to believe that Nature has laid down an innate abhorrence in us as a guard against the possibility of incest.

[1926e, 4355]

But let us first summon history to our aid. When Caius Julius Caesar landed in Egypt, he found the young Queen Cleopatra (who was soon to become so important to him) married to her still younger brother Ptolemy. In an Egyptian dynasty there was nothing peculiar in this; the Ptolemies, who were of Greek origin, had merely carried on the custom which had been practised by their predecessors, the ancient Pharaohs, for a few thousand years. This, however, was merely brother-and-sister incest, which even at the present time is not judged so harshly. So let us turn to our chief witness in matters concerning primaeval times - mythology. It informs us that the myths of every people, and not only of the Greeks, are filled with examples of love-affairs between fathers and daughters and even between mothers and sons. Cosmology, no less than the genealogy of royal races, is founded upon incest. For what purpose do you suppose these legends were created? To brand gods and kings as criminals? to fasten on them the abhorrence of the human race? Rather, surely, because incestuous wishes are a primordial human heritage and have never been fully overcome, so that their fulfilment was still granted to gods and their descendants when the majority of common humans were already obliged to renounce them. It is in complete harmony with these lessons of history and mythology that we find incestuous wishes still present and operative in the childhood of the individual.

[1926e, 4356]

The most important conflict with which a small child is faced is his relation to his parents, the 'Oedipus complex'; it is in attempting to grapple with this problem that those destined to suffer from a neurosis habitually come to grief. The reactions against the instinctual demands of the Oedipus complex are the source of the most precious and socially important achievements of the human mind; and this holds true not only in the life of individuals but probably also in the history of the human species as a whole. The super-ego, too, the moral agency which dominates the ego, has its origin in the process of overcoming the Oedipus complex.

[1926f, 4406]
Parricide, according to a well-known view, is the principal and primal crime of humanity as well as of the individual. (See my *Totem and Taboo* 1912-13.) It is in any case the main source of the sense of guilt, though we do not know if it is the only one: researches have not yet been able to establish with certainty the mental origin of guilt and the need for expiation. But it is not necessary for it to be the only one. The psychological situation is complicated and requires elucidation. The relation of a boy to his father is, as we say, an 'ambivalent' one. In addition to the hate which seeks to get rid of the father as a rival, a measure of tenderness for him is also habitually present. The two attitudes of mind combine to produce identification with the father; the boy wants to be in his father's place because he admires him and wants to be like him, and also because he wants to put him out of the way. This whole development now comes up against a powerful obstacle. At a certain moment the child comes to understand that an attempt to remove his father as a rival would be punished by him with castration. So from fear of castration - that is, in the interests of preserving his masculinity - he gives up his wish to possess his mother and get rid of his father. In so far as this wish remains in the unconscious it forms the basis of the sense of guilt. We believe that what we have here been describing are normal processes, the normal fate of the so-called 'Oedipus complex'; nevertheless it requires an important amplification.

The Oedipus complex, as far as we know, is present in childhood in all human beings, undergoes great alterations during the years of development and in many individuals is found in varying degrees of strength even at a mature age. Its essential characteristics, its universality, its content and its fate were recognized, long before the days of psycho-analysis, by that acute thinker Diderot, as is shown by a passage in his famous dialogue, *Le neveu de Rameau*: 'Si le petit sauvage était abandonné à lui-même, qu'il conservât tout son imbécillité, et qu'il réunît au peu de raison de l'enfant au berceau la violence des passions de l'homme de trente ans, il tordrait le cou à son père, et coucherait avec sa mère.'

If it had been objectively demonstrated that Philipp Halsmann murdered his father, there would at all events be some grounds for introducing the Oedipus complex to provide a motive for an otherwise unexplained deed. Since no such proof has been adduced, mention of the Oedipus complex has a misleading effect; it is at the least idle. Such disagreements as have been uncovered by the investigation in the Halsmann family between the father and son are altogether inadequate to provide a foundation for assuming in the son a bad relationship towards his father. Even if it were otherwise, we should be obliged to say that it is a far cry from there to the causation of such a deed. Precisely because it is always present, the Oedipus complex is not suited to provide a decision on the question of guilt. The situation envisaged in a well-known anecdote might easily be brought about. There was a burglary. A man who had a jemmy in his possession was found guilty of the crime. After the verdict had been given and he had been asked if he had anything to say, he begged to be sentenced for adultery at the same time - since he was carrying the tool for that on him as well.

However instructive cases of this kind may be, a still higher degree of interest must attach to the influence of a situation which every child is destined to pass through and which follows inevitably from the factor of the prolonged period during which a child is cared for by other people and lives with his parents. I am thinking of the *Oedipus complex*, so named because its essential substance is to be found in the Greek legend of King Oedipus, which has fortunately been preserved for us in a version by a great dramatist. The Greek hero killed his father and took his mother to wife. That he did so unwittingly, since he did not know them as his parents, is a deviation from the analytic facts which we can easily understand and which, indeed, we shall recognize as inevitable.
It is no doubt true that the impact of the threat of castration upon a boy's budding sexual life does not always have these dreaded consequences. It will depend once again on quantitative relations how much damage is done and how much avoided. The whole occurrence, which may probably be regarded as the central experience of the years of childhood, the greatest problem of early life and the strongest source of later inadequacy, is so completely forgotten that its reconstruction during the work of analysis is met in adults by the most decided disbelief. Indeed, aversion to it is so great that people try to silence any mention of the proscribed subject and the most obvious reminders of it are overlooked by a strange intellectual blindness. One may hear it objected, for instance, that the legend of King Oedipus has in fact no connection with the construction made by analysis: the cases are quite different, since Oedipus did not know that it was his father that he killed and his mother that he married. What is overlooked in this is that a distortion of this kind is inevitable if an attempt is made at a poetic handling of the material, and that there is no introduction of extraneous material but only a skilful employment of the factors presented by the theme. The ignorance of Oedipus is a legitimate representation of the unconscious state into which, for adults, the whole experience has fallen; and the coercive power of the oracle, which makes or should make the hero innocent, is a recognition of the inevitability of the fate which has condemned every son to live through the Oedipus complex. Again it was pointed out from psycho-analytic quarters how easily the riddle of another dramatic hero, Shakespeare's procrastinator, Hamlet, can be solved by reference to the Oedipus complex, since the prince came to grief over the task of punishing someone else for what coincided with the substance of his own Oedipus wish - whereupon the general lack of understanding on the part of the literary world showed how ready is the mass of mankind to hold fast to its infantile repressions.¹

[1940a [1938], 4999]
Let us return to the sexual development of children. We have some arrears to make up owing to our having paid more attention to the somatic than to the mental phenomena of sexual life. The child's first choice of an object, which derives from its need for help, claims our further interest. Its choice is directed in the first instance to all those who look after it, but these soon give place to its parents. Children's relations to their parents, as we learn alike from direct observations of children and from later analytic examination of adults, are by no means free from elements of accompanying sexual excitation. The child takes both of its parents, and more particularly one of them, as the object of its erotic wishes. In so doing, it usually follows some indication from its parents, whose affection bears the clearest characteristics of a sexual activity, even though of one that is inhibited in its aims. As a rule a father prefers his daughter and a mother her son; the child reacts to this by wishing, if he is a son, to take his father's place, and, if she is a daughter, her mother's. The feelings which are aroused in these relations between parents and children and in the resulting ones between brothers and sisters are not only of a positive or affectionate kind but also of a negative or hostile one. The complex which is thus formed is doomed to early repression; but it continues to exercise a great and lasting influence from the unconscious. It is to be suspected that, together with its extensions, it constitutes the *nuclear complex* of every neurosis, and we may expect to find it no less actively at work in other regions of mental life. The myth of King Oedipus, who killed his father and took his mother to wife, reveals, with little modification, the infantile wish, which is later opposed and repudiated by the *barrier against incest*. Shakespeare's *Hamlet* is equally rooted in the soil of the incest-complex, but under a better disguise.

[1910a, 2232]

But the time comes when this early blossoming is nipped by the frost. None of these incestuous loves can avoid the fate of repression. They may succumb to it on the occasion of some discoverable external event which leads to disillusionment - such as unexpected slights, the unwelcome birth of a new brother or sister (which is felt as faithlessness), etc.; or the same thing may happen owing to internal conditions apart from any such events, perhaps simply because their yearning remains unsatisfied too long. It is unquestionably true that such events are not the *effective* causes, but that these love-affairs are bound to come to grief sooner or later, though we cannot say on what particular stumbling block. Most probably they pass away because their time is over, because the children have entered upon a new phase of development in which they are compelled to recapitulate from the history of mankind the repression of an incestuous object-choice, just as at an earlier stage they were obliged to effect an object-choice of that very sort.¹ In the new phase no mental product of the incestuous love-impulses that is present unconsciously is taken over by consciousness; and anything that has already come into consciousness is expelled from it. At the same time as this process of repression takes place, a sense of guilt appears. This is also of unknown origin, but there is no doubt whatever that it is connected with the incestuous wishes, and that it is justified by the persistence of those wishes in the unconscious.²

[1919e, 3650]
The early efflorescence of infantile sexual life is doomed to extinction because its wishes are incompatible with reality and with the inadequate stage of development which the child has reached. That efflorescence comes to an end in the most distressing circumstances and to the accompaniment of the most painful feelings. Loss of love and failure leave behind them a permanent injury to self-regard in the form of a narcissistic scar, which in my opinion, as well as in Marcinowski's (1918), contributes more than anything to the 'sense of inferiority' which is so common in neurotics. The child's sexual researches, on which limits are imposed by his physical development, lead to no satisfactory conclusion; hence such later complaints as 'I can't accomplish anything; I can't succeed in anything'. The tie of affection, which binds the child as a rule to the parent of the opposite sex, succumbs to disappointment, to a vain expectation of satisfaction or to jealousy over the birth of a new baby - unmistakable proof of the infidelity of the object of the child's affections. His own attempt to make a baby himself, carried out with tragic seriousness, fails shamefully. The lessening amount of affection he receives, the increasing demands of education, hard words and an occasional punishment - these show him at last the full extent to which he has been scorned. These are a few typical and constantly recurring instances of the ways in which the love characteristic of the age of childhood is brought to a conclusion.

This preface is not superfluous, for it can heighten our realization of the intensity of the Oedipus complex. When a boy (from the age of two or three) has entered the phallic phrase of his libidinal development, is feeling pleasurable sensations in his sexual organ and has learnt to procure these at will by manual stimulation, he becomes his mother's lover. He wishes to possess her physically in such ways as he has divined from his observations and intuitions about sexual life, and he tries to seduce her by showing her the male organ which he is proud to own. In a word, his early awakened masculinity seeks to take his father's place with her; his father has hitherto in any case been an envied model to the boy, owing to the physical strength he perceives in him and the authority with which he finds him clothed. His father now becomes a rival who stands in his way and whom he would like to get rid of. If while his father is away he is allowed to share his mother's bed and if when his father returns he is once more banished from it, his satisfaction when his father disappears and his disappointment when he emerges again are deeply felt experiences. This is the subject of the Oedipus complex, which the Greek legend has translated from the world of a child's phantasy into pretended reality. Under the conditions of our civilization it is invariably doomed to a frightening end.

[1920g, 3725]

[1940a [1938], 4997]
If *Oedipus Rex* moves a modern audience no less than it did the contemporary Greek one, the explanation can only be that its effect does not lie in the contrast between destiny and human will, but is to be looked for in the particular nature of the material on which that contrast is exemplified. There must be something which makes a voice within us ready to recognize the compelling force of destiny in the *Oedipus*, while we can dismiss as merely arbitrary such dispositions as are laid down in *Die Ahnfrau* or other modern tragedies of destiny. And a factor of this kind is in fact involved in the story of King Oedipus. His destiny moves us only because it might have been ours - because the oracle laid the same curse upon us before our birth as upon him. It is the fate of all of us, perhaps, to direct our first sexual impulse towards our mother and our first hatred and our first murderous wish against our father. Our dreams convince us that that is so. King Oedipus, who slew his father Laïus and married his mother Jocasta, merely shows us the fulfilment of our own childhood wishes. But, more fortunate than he, we have meanwhile succeeded, in so far as we have not become psychoneurotics, in detaching our sexual impulses from our mothers and in forgetting our jealousy of our fathers. Here is one in whom these primaeval wishes of our childhood have been fulfilled, and we shrink back from him with the whole force of the repression by which those wishes have since that time been held down within us. While the poet, as he unravels the past, brings to light the guilt of Oedipus, he is at the same time compelling us to recognize our own inner minds, in which those same impulses, though suppressed, are still to be found. The contrast with which the closing Chorus leaves us confronted -

[1900a, 741]

² [Footnote added 1915:] The barrier against incest is probably among the historical acquisitions of mankind, and, like other moral taboos, has no doubt already become established in many persons by organic inheritance. (Cf. my *Totem and Taboo*, 1912-13.) Psycho-analytic investigation shows, however, how intensely the individual struggles with the temptation to incest during his period of growth and how frequently the barrier is transgressed in phantasies and even in reality.

[1905d, 1538]

It is in the world of ideas, however, that the choice of an object is accomplished at first; and the sexual life of maturing youth is almost entirely restricted to indulging in phantasies, that is, in ideas that are not destined to be carried into effect.¹ In these phantasies the infantile tendencies invariably emerge once more, but this time with intensified pressure from somatic sources. Among these tendencies the first place is taken with uniform frequency by the child's sexual impulses towards his parents, which are as a rule already differentiated owing to the attraction of the opposite sex - the son being drawn towards his mother and the daughter towards her father.² At the same time as these plainly incestuous phantasies are overcome and repudiated, one of the most significant, but also one of the most painful, psychical achievements of the pubertal period is completed: detachment from parental authority, a process that alone makes possible the opposition, which is so important for the progress of civilization, between the new generation and the old. At every stage in the course of development through which all human beings ought by rights to pass, a certain number are held back; so there are some who have never got over their parents' authority and have withdrawn their affection from them either very incompletely or not at all. They are mostly girls, who, to the delight of their parents, have persisted in all their childish love far beyond puberty. It is most instructive to find that it is precisely these girls who in their later marriage lack the capacity to give their husbands what is due to them; they make cold wives and remain sexually anaesthetic. We learn from this that sexual love and what appears to be non-sexual love for parents are fed from the same sources; the latter, that is to say, merely corresponds to an infantile fixation of the libido.

[1905d, 1539]
It has justly been said that the Oedipus complex is the nuclear complex of the neuroses, and constitutes the essential part of their content. It represents the peak of infantile sexuality, which, through its after-effects, exercises a decisive influence on the sexuality of adults. Every new arrival on this planet is faced by the task of mastering the Oedipus complex; anyone who fails to do so falls a victim to neurosis. With the progress of psycho-analytic studies the importance of the Oedipus complex has become more and more clearly evident; its recognition has become the shibboleth that distinguishes the adherents of psycho-analysis from its opponents.

[1905d, 1539]

It is inevitable and perfectly normal that a child should take his parents as the first objects of his love. But his libido should not remain fixated to these first objects; later on, it should merely take them as a model, and should make a gradual transition from them on to extraneous people when the time for the final choice of an object arrives. The detachment of the child from his parents is thus a task that cannot be evaded if the young individual's social fitness is not to be endangered. During the time at which repression is making its selection among the component instincts, and later, when there should be a slackening of the parents' influence, which is essentially responsible for the expenditure of energy on these repressions, the task of education meets with great problems, which at the present time are certainly not always dealt with in an understanding and unobjectionable manner.

[1910a, 2233]

The clinical fact which meets us behind the form of the Oedipus complex as it is established by analysis is of the highest practical significance. We learn that at puberty, when the sexual instinct first makes its demands in full strength, the old familiar incestuous objects are taken up again and freshly cathected with libido. The infantile object-choice was only a feeble one, but it was a prelude, pointing the direction for the object-choice at puberty. At this point, then, very intense emotional processes come into play, following the direction of the Oedipus complex or reacting against it, processes which, however, since their premisses have become intolerable, must to a large extent remain apart from consciousness. From this time onwards, the human individual has to devote himself to the great task of detaching himself from his parents, and not until that task is achieved can he cease to be a child and become a member of the social community. For the son this task consists in detaching his libidinal wishes from his mother and employing them for the choice of a real outside love-object, and in reconciling himself with his father if he has remained in opposition to him, or in freeing himself from his pressure if, as a reaction to his infantile rebelliousness, he has become subservient to him. These tasks are set to everyone; and it is remarkable how seldom they are dealt with in an ideal manner - that is, in one which is correct both psychologically and socially. By neurotics, however, no solution at all is arrived at: the son remains all his life bowed beneath his father's authority and he is unable to transfer his libido to an outside sexual object. With the relationship changed round, the same fate can await the daughter. In this sense the Oedipus complex may justly be regarded as the nucleus of the neuroses.

[1916-1917, 3402]
But the time comes when this early blossoming is nipped by the frost. None of these incestuous loves can avoid the fate of repression. They may succumb to it on the occasion of some discoverable external event which leads to disillusionment - such as unexpected slights, the unwelcome birth of a new brother or sister (which is felt as faithlessness), etc.; or the same thing may happen owing to internal conditions apart from any such events, perhaps simply because their yearning remains unsatisfied too long. It is unquestionably true that such events are not the effective causes, but that these love-affairs are bound to come to grief sooner or later, though we cannot say on what particular stumbling block. Most probably they pass away because their time is over, because the children have entered upon a new phase of development in which they are compelled to recapitulate from the history of mankind the repression of an incestuous object-choice, just as at an earlier stage they were obliged to effect an object-choice of that very sort. In the new phase no mental product of the incestuous love-impulses that is present unconsciously is taken over by consciousness; and anything that has already come into consciousness is expelled from it. At the same time as this process of repression takes place, a sense of guilt appears. This is also of unknown origin, but there is no doubt whatever that it is connected with the incestuous wishes, and that it is justified by the persistence of those wishes in the unconscious.

[1919e, 3650]

In 1913 Otto Rank and Hanns Sachs, in an extremely interesting work, brought together the results which had been achieved up to that time in the application of psycho-analysis to the mental sciences. The most easily accessible branches of those sciences seem to be mythology and the history of literature and religion. No final formula has yet been found enabling us to give an appropriate place to myths in this connection. Otto Rank, in a large volume on the incest complex (1912), has produced evidence of the surprising fact that the choice of subject matter, especially for dramatic works, is principally determined by the ambit of what psycho-analysis has termed the 'Oedipus complex'. By working it over with the greatest variety of modifications, distortions and disguises, the dramatist seeks to deal with his own most personal relations to this emotional theme. It is in attempting to master the Oedipus complex - that is to say, a person's emotional attitude towards his family, or in a narrower sense towards his father and mother - that individual neurotics come to grief, and for this reason that complex habitually forms the nucleus of their neuroses. It does not owe its importance to any unintelligible conjunction; the emphasis laid upon the relation of children to their parents is an expression of the biological facts that the young of the human race pass through a long period of dependence and are slow in reaching maturity, as well as that their capacity for love undergoes a complicated course of development. Consequently, the overcoming of the Oedipus complex coincides with the most efficient way of mastering the archaic, animal heritage of humanity. It is true that that heritage comprises all the forces that are required for the subsequent cultural development of the individual, but they must first be sorted out and worked over. This archaic heirloom is not fit to be used for the purposes of civilized social life in the form in which it is inherited by the individual.

[1919g, 3704]
To this must be added another factor derived from the very remarkable course of development which is pursued by the erotic life of man. In its first phase, which has usually come to an end by the time a child is five years old, he has found the first object for his love in one or other of his parents, and all of his sexual instincts with their demand for satisfaction have been united upon this object. The repression which then sets in compels him to renounce the greater number of these infantile sexual aims, and leaves behind a profound modification in his relation to his parents. The child still remains tied to his parents, but by instincts which must be described as being 'inhibited in their aim'. The emotions which he feels henceforward towards these objects of his love are characterized as 'affectionate'. It is well known that the earlier 'sensual' tendencies remain more of less strongly preserved in the unconscious, so that in a certain sense the whole of the original current continues to exist.¹

In the very earliest years of childhood (approximately between the ages of two and five) a convergence of the sexual impulses occurs of which, in the case of boys, the object is the mother. This choice of an object, in conjunction with a corresponding attitude of rivalry and hostility towards the father, provides the content of what is known as the Oedipus complex, which in every human being is of the greatest importance in determining the final shape of his erotic life. It has been found to be characteristic of a normal individual that he learns to master his Oedipus complex, whereas the neurotic subject remains involved in it.

Along with the demolition of the Oedipus complex, the boy's object-cathexis of his mother must be given up. Its place may be filled by one of two things: either an identification with his mother or an intensification of his identification with his father. We are accustomed to regard the latter outcome as the more normal; it permits the affectionate relation to the mother to be in a measure retained. In this way the dissolution of the Oedipus complex would consolidate the masculinity in a boy's character. In a precisely analogous way, the outcome of the Oedipus attitude in a little girl may be an intensification of her identification with her mother (or the setting up of such an identification for the first time) - a result which will fix the child's feminine character.

These identifications are not what we should have expected, since they do not introduce the abandoned object into the ego; but this alternative outcome may also occur, and is easier to observe in girls than in boys. Analysis very often shows that a little girl, after she has had to relinquish her father as a love-object, will bring her masculinity into prominence and identify herself with her father (that is, with the object which has been lost), instead of with her mother. This will clearly depend on whether the masculinity in her disposition - whatever that may consist in - is strong enough.
It would appear, therefore, that in both sexes the relative strength of the masculine and feminine sexual dispositions is what determines whether the outcome of the Oedipus situation shall be an identification with the father or with the mother. This is one of the ways in which bisexuality takes a hand in the subsequent vicissitudes of the Oedipus complex. The other way is even more important. For one gets an impression that the simple Oedipus complex is by no means its commonest form, but rather represents a simplification or schematization which, to be sure, is often enough justified for practical purposes. Closer study usually discloses the more complete Oedipus complex, which is twofold, positive and negative, and is due to the bisexuality originally present in children: that is to say, a boy has not merely an ambivalent attitude towards his father and an affectionate object-choice towards his mother, but at the same time he also behaves like a girl and displays an affectionate feminine attitude to his father and a corresponding jealousy and hostility towards his mother. It is this complicating element introduced by bisexuality that makes it so difficult to obtain a clear view of the facts in connection with the earliest object-choices and identifications, and still more difficult to describe them intelligibly. It may even be that the ambivalence displayed in the relations to the parents should be attributed entirely to bisexuality and that it is not, as I have represented above, developed out of identification in consequence of rivalry.

In my opinion it is advisable in general, and quite especially where neurotics are concerned, to assume the existence of the complete Oedipus complex. Analytic experience then shows that in a number of cases one or the other constituent disappears, except for barely distinguishable traces; so that the result is a series with the normal positive Oedipus complex at one end and the inverted negative one at the other, while its intermediate members exhibit the complete form with one or other of its two components preponderating. At the dissolution of the Oedipus complex the four trends of which it consists will group themselves in such a way as to produce a father-identification and a mother-identification. The father-identification will preserve the object-relation to the mother which belonged to the positive complex and will at the same time replace the object-relation to the father which belonged to the inverted complex: and the same will be true, mutatis mutandis, of the mother-identification. The relative intensity of the two identifications in any individual will reflect the preponderance in him of one or other of the two sexual dispositions.

The broad general outcome of the sexual phase dominated by the Oedipus complex may, therefore, be taken to be the forming of a precipitate in the ego, consisting of these two identifications in some way united with each other. This modification of the ego retains its special position; it confronts the other contents of the ego as an ego ideal or super-ego.

[1923b, 3967]
The super-ego is, however, not simply a residue of the earliest object-choices of the id; it also represents an energetic reaction-formation against those choices. Its relation to the ego is not exhausted by the precept: 'You ought to be like this (like your father).'</sup>1 It also comprises the prohibition: 'You may not be like this (like your father) - that is, you may not do all that he does; some things are his prerogative.' This double aspect of the ego ideal derives from the fact that the ego ideal had the task of repressing the Oedipus complex; indeed, it is to that revolutionary event that it owes its existence. Clearly the repression of the Oedipus complex was no easy task. The child's parents, and especially his father, were perceived as the obstacle to a realization of his Oedipus wishes; so his infantile ego fortified itself for the carrying out of the repression by erecting this same obstacle within itself. It borrowed strength to do this, so to speak, from the father, and this loan was an extraordinarily momentous act. The super-ego retains the character of the father, while the more powerful the Oedipus complex was and the more rapidly it succumbed to repression (under the influence of authority, religious teaching, schooling and reading), the stricter will be the domination of the super-ego over the ego later on - in the form of conscience or perhaps of an unconscious sense of guilt. I shall presently bring forward a suggestion about the source of its power to dominate in this way - the source, that is, of its compulsive character which manifests itself in the form of a categorical imperative.

[1923b, 3968]

The way in which the super-ego came into being explains how it is that the early conflicts of the ego with the object-cathexes of the id can be continued in conflicts with their heir, the super-ego. If the ego has not succeeded in properly mastering the Oedipus complex, the energetic cathexis of the latter, springing from the id, will come into operation once more in the reaction-formation of the ego ideal. The abundant communication between the ideal and these Ucs. instinctual impulses solves the puzzle of how it is that the ideal itself can to a great extent remain unconscious and inaccessible to the ego. The struggle which once raged in the deepest strata of the mind, and was not brought to an end by rapid sublimation and identification, is now continued in a higher region, like the Battle of the Huns in Kaulbach's painting.

[1923b, 3973]

To an ever-increasing extent the Oedipus complex reveals its importance as the central phenomenon of the sexual period of early childhood. After that, its dissolution takes place; it succumbs to repression, as we say, and is followed by the latency period. It has not yet become clear, however, what it is that brings about its destruction. Analyses seem to show that it is the experience of painful disappointments. The little girl likes to regard herself as what her father loves above all else; but the time comes when she has to endure a harsh punishment from him and she is cast out of her fool's paradise. The boy regards his mother as his own property; but he finds one day that she has transferred her love and solicitude to a new arrival. Reflection must deepen our sense of the importance of those influences, for it will emphasize the fact that distressing experiences of this sort, which act in opposition to the content of the complex, are inevitable. Even when no special events occur, like those we have mentioned as examples, the absence of the satisfaction hoped for, the continued denial of the desired baby, must in the end lead the small lover to turn away from his hopeless longing. In this way the Oedipus complex would go to its destruction from its lack of success, from the effects of its internal impossibility.

[1924d, 4085]

Another view is that the Oedipus complex must collapse because the time has come for its disintegration, just as the milk-teeth fall out when the permanent ones begin to grow. Although the majority of human beings go through the Oedipus complex as an individual experience, it is nevertheless a phenomenon which is determined and laid down by heredity and which is bound to pass away according to programme when the next pre-ordained phase of development sets in. This being so, it is of no great importance what the occasions are which allow this to happen, or, indeed, whether any such occasions can be discovered at all.

[1924d, 4085]
We should not be as short-sighted as the person in charge of the child who threatens him with castration, and we must not overlook the fact that at this time masturbation by no means represents the whole of his sexual life. As can be clearly shown, he stands in the Oedipus attitude to his parents; his masturbation is only a genital discharge of the sexual excitation belonging to the complex, and throughout his later years will owe its importance to that relationship. The Oedipus complex offered the child two possibilities of satisfaction, an active and a passive one. He could put himself in his father's place in a masculine fashion and have intercourse with his mother as his father did, in which case he would soon have felt the latter as a hindrance; or he might want to take the place of his mother and be loved by his father, in which case his mother would become superfluous. The child may have had only very vague notions as to what constitutes a satisfying erotic intercourse; but certainly the penis must play a part in it, for the sensations in his own organ were evidence of that. So far he had had no occasion to doubt that women possessed a penis. But now his acceptance of the possibility of castration, his recognition that women were castrated, made an end of both possible ways of obtaining satisfaction from the Oedipus complex. For both of them entailed the loss of his penis - the masculine one as a resulting punishment and the feminine one as a precondition. If the satisfaction of love in the field of the Oedipus complex is to cost the child his penis, a conflict is bound to arise between his narcissistic interest in that part of his body and the libidinal cathexis of his parental objects. In this conflict the first of these forces normally triumphs: the child's ego turns away from the Oedipus complex.

I have described elsewhere how this turning away takes place. The object-cathexes are given up and replaced by identifications. The authority of the father or the parents is introjected into the ego, and there it forms the nucleus of the super-ego, which takes over the severity of the father and perpetuates his prohibition against incest, and so secures the ego from the return of the libidinal object-cathexis. The libidinal trends belonging to the Oedipus complex are in part desexualized and sublimated (a thing which probably happens with every transformation into an identification) and in part inhibited in their aim and changed into impulses of affection. The whole process has, on the one hand, preserved the genital organ - has averted the danger of its loss - and, on the other, has paralysed it - has removed its function. This process ushers in the latency period, which now interrupts the child's sexual development.

I see no reason for denying the name of a 'repression' to the ego's turning away from the Oedipus complex, although later repressions come about for the most part with the participation of the super-ego, which in this case is only just being formed. But the process we have described is more than a repression. It is equivalent, if it is ideally carried out, to a destruction and an abolition of the complex. We may plausibly assume that we have here come upon the borderline - never a very sharply drawn one - between the normal and the pathological. If the ego has in fact not achieved much more than a repression of the complex, the latter persists in an unconscious state in the id and will later manifest its pathogenic effect.

Analytic observation enables us to recognize or guess these connections between the phallic organization, the Oedipus complex, the threat of castration, the formation of the super-ego and the latency period. These connections justify the statement that the destruction of the Oedipus complex is brought about by the threat of castration. But this does not dispose of the problem; there is room for a theoretical speculation which may upset the results we have come to or put them in a new light. Before we start along this new path, however, we must turn to a question which has arisen in the course of this discussion and has so far been left on one side. The process which has been described refers, as has been expressly said, to male children only. How does the corresponding development take place in little girls?
At this point our material - for some incomprehensible reason - becomes far more obscure and full of gaps. The female sex, too, develops an Oedipus complex, a super-ego and a latency period. May we also attribute a phallic organization and a castration complex to it? The answer is in the affirmative; but these things cannot be the same as they are in boys. Here the feminist demand for equal rights for the sexes does not take us far, for the morphological distinction is bound to find expression in differences of psychical development. 'Anatomy is Destiny', to vary a saying of Napoleon's. The little girl's clitoris behaves just like a penis to begin with; but, when she makes a comparison with a playfellow of the other sex, she perceives that she has 'come off badly' and she feels this as a wrong done to her and as a ground for inferiority. For a while still she consoles herself with the expectation that later on, when she grows older, she will acquire just as big an appendage as the boy's. Here the masculinity complex of women branches off. A female child, however, does not understand her lack of a penis as being a sex character; she explains it by assuming that at some earlier date she had possessed an equally large organ and had then lost it by castration. She seems not to extend this inference from herself to other, adult females, but, entirely on the lines of the phallic phase, to regard them as possessing large and complete - that is to say, male - genitals. The essential difference thus comes about that the girl accepts castration as an accomplished fact, whereas the boy fears the possibility of its occurrence.

[1924d, 4090]

I have no doubt that the chronological and causal relations described here between the Oedipus complex, sexual intimidation (the threat of castration), the formation of the super-ego and the beginning of the latency period are of a typical kind; but I do not wish to assert that this type is the only possible one. Variations in the chronological order and in the linking-up of these events are bound to have a very important bearing on the development of the individual.

[1924d, 4091]

And now, as a third point, psycho-analysis has shown us, to our growing astonishment, the enormously important part played by what is known as the 'Oedipus complex' - that is, the emotional relation of a child to its two parents - in the mental life of human beings. Our astonishment diminishes when we realize that the Oedipus complex is the psychical correlate of two fundamental biological facts: the long period of the human child's dependence, and the remarkable way in which its sexual life reaches a first climax in the third to fifth years of life, and then, after a period of inhibition, sets in again at puberty. And here, the discovery was made that a third and extremely serious part of human intellectual activity, the part which has created the great institutions of religion, law, ethics, and all forms of civic life, has as its fundamental aim the enabling of the individual to master his Oedipus complex and to divert his libido from its infantile attachments into the social ones that are ultimately desired. The applications of psycho-analysis to the science of religion and sociology (e. g. by the present writer, Theodor Reik and Oskar Pfister), which have led to these findings, are still young and insufficiently appreciated; but it cannot be doubted that further studies will only confirm the certainty of these important conclusions.

[1924f, 4117]
The Oedipus complex, however, is such an important thing that the manner in which one enters and leaves it cannot be without its effects. In boys (as I have shown at length in the paper to which I have just referred and to which all of my present remarks are closely related) the complex is not simply repressed, it is literally smashed to pieces by the shock of threatened castration. Its libidinal cathexes are abandoned, desexualized and in part sublimated; its objects are incorporated into the ego, where they form the nucleus of the super-ego and give that new structure its characteristic qualities. In normal, or, it is better to say, in ideal cases, the Oedipus complex exists no longer, even in the unconscious; the super-ego has become its heir. Since the penis (to follow Ferenczi) owes its extraordinarily high narcissistic cathexis to its organic significance for the propagation of the species, the catastrophe to the Oedipus complex (the abandonment of incest and the institution of conscience and morality) may be regarded as a victory of the race over the individual. This is an interesting point of view when one considers that neurosis is based upon a struggle of the ego against the demands of the sexual function. But to leave the standpoint of individual psychology is not of any immediate help in clarifying this complicated situation.

[1925j, 4155]

In girls the motive for the demolition of the Oedipus complex is lacking. Castration has already had its effect, which was to force the child into the situation of the Oedipus complex. Thus the Oedipus complex escapes the fate which it meets with in boys: it may be slowly abandoned or dealt with by repression, or its effects may persist far into women's normal mental life. I cannot evade the notion (though I hesitate to give it expression) that for women the level of what is ethically normal is different from what it is in men. Their super-ego is never so inexorable, so impersonal, so independent of its emotional origins as we require it to be in men. Character traits which critics of every epoch have brought up against women - that they show less sense of justice than men, that they are less ready to submit to the great exigencies of life, that they are more often influenced in their judgements by feelings of affection or hostility - all these would be amply accounted for by the modification in the formation of their super-ego which we have inferred above. We must not allow ourselves to be deflected from such conclusions by the denials of the feminists, who are anxious to force us to regard the two sexes as completely equal in position and worth; but we shall, of course, willingly agree that the majority of men are also far behind the masculine ideal and that all human individuals, as a result of their bisexual disposition and of cross-inheritance, combine in themselves both masculine and feminine characteristics, so that pure masculinity and femininity remain theoretical constructions of uncertain content.

[1925j, 4155]
In enforcing regression, the ego scores its first success in its defensive struggle against the demands of the libido. (In this connection it is of advantage to distinguish the more general notion of 'defence' from 'repression'. Repression is only one of the mechanisms which defence makes use of.) It is perhaps in obsessional cases more than in normal or hysterical ones that we can most clearly recognize that the motive force of defence is the castration complex and that what is being fended off are the trends of the Oedipus complex. We are at present dealing with the beginning of the latency period, a period which is characterized by the dissolution of the Oedipus complex, the creation or consolidation of the super-ego and the erection of ethical and aesthetic barriers in the ego. In obsessional neuroses these processes are carried further than is normal. In addition to the destruction of the Oedipus complex a regressive degradation of the libido takes place, the super-ego becomes exceptionally severe and unkind, and the ego, in obedience to the super-ego, produces strong reaction-formations in the shape of conscientiousness, pity and cleanliness. Implacable, though not always on that account successful, severity is shown in condemning the temptation to continue early infantile masturbation, which now attaches itself to regressive (sadistic-anal) ideas but which nevertheless represents the unsubjugated part of the phallic organization. There is an inherent contradiction about this state of affairs, in which, precisely in the interests of masculinity (that is to say, from fear of castration), every activity belonging to masculinity is stopped. But here, too, obsessional neurosis is only overdoing the normal method of getting rid of the Oedipus complex. We once more find here an illustration of the truth that every exaggeration contains the seed of its own undoing. For, under the guise of obsessional acts, the masturbation that has been suppressed approaches ever more closely to satisfaction.

¹ Since the differentiation of the ego and the id, our interest in the problems of repression, too, was bound to receive a fresh impetus. Up till then we had been content to confine our interest to those aspects of repression which concerned the ego - the keeping away from consciousness and from motility, and the formation of substitutes (symptoms). With regard to the repressed instinctual impulses themselves, we assumed that they remained unaltered in the unconscious for an indefinite length of time. But now our interest is turned to the vicissitudes of the repressed and we begin to suspect that it is not self-evident, perhaps not even usual, that those impulses should remain unaltered and unalterable in this way. There is no doubt that the original impulses have been inhibited and deflected from their aim through repression. But has the portion of them in the unconscious maintained itself and been proof against the influences of life that tend to alter and depreciate them? In other words, do the old wishes, about whose former existence analysis tells us, still exist? The answer seems ready to hand and certain. It is that the old, repressed wishes must still be present in the unconscious since we still find their derivatives, the symptoms, in operation. But this answer is not sufficient. It does not enable us to decide between two possibilities: either that the old wish is now operating only through its derivatives, having transferred the whole of its cathetic energy to them, or that it is itself still in existence too. If its fate has been to exhaust itself in cathecting its derivatives, there is yet a third possibility. In the course of the neurosis it may have become re-animated by regression, anachronistic though it may now be. These are no idle speculations. There are many things about mental life, both normal and pathological, which seem to call for the raising of such questions. In my paper, 'The Dissolution of the Oedipus Complex' (1924), I had occasion to notice the difference between the mere repression and the real removal of an old wishful impulse.

[1926d, 4273]
Nothing, however, deserves more notice than the fact that children regularly direct their sexual wishes towards their nearest relatives - in the first place, therefore, towards their father and mother, and afterwards towards their brothers and sisters. The first object of a boy's love is his mother, and of a girl's her father (except in so far as an innate bisexual disposition favours the simultaneous presence of the contrary attitude). The other parent is felt as a disturbing rival and not infrequently viewed with strong hostility. You must understand me aright. What I mean to say is not that the child wants to be treated by its favourite parent merely with the kind of affection which we adults like to regard as the essence of the parent-child relation. No, analysis leaves us in no doubt that the child's wishes extend beyond such affection to all that we understand by sensual satisfaction - so far, that is, as the child's powers of imagination allow. It is easy to see that the child never guesses the actual facts of sexual intercourse; he replaces them by other notions derived from his own experience and feelings. As a rule his wishes culminate in the intention to bear, or in some in definable way, to procreate a baby. Boys, too, in their ignorance, do not exclude themselves from the wish to bear a baby. We give the whole of this mental structure the name of 'Oedipus complex', after the familiar Greek legend. With the end of the early sexual period it should normally be given up, should radically disintegrate and become transformed; and the results of this transformation are destined for important functions in later mental life. But as a rule this is not effected radically enough, in which case puberty brings about a revival of the complex, which may have serious consequences.

[1926e, 4355]

When I described the relation between the ego and the id to you, I suppressed an important part of the theory of the mental apparatus. For we have been obliged to assume that within the ego itself a particular agency has become differentiated, which we name the super-ego. This super-ego occupies a special position between the ego and the id. It belongs to the ego and shares its high degree of psychological organization; but it has a particularly intimate connection with the id. It is in fact a precipitate of the first object-cathexes of the id and is the heir to the Oedipus complex after its demise. This super-ego can confront the ego and treat it like an object; and it often treats it very harshly. It is as important for the ego to remain on good terms with the super-ego as with the id. Estrangements between the ego and the super-ego are of great significance in mental life. You will already have guessed that the super-ego is the vehicle of the phenomenon that we call conscience. Mental health very much depends on the super-ego's being normally developed - that is, on its having become sufficiently impersonal. And that is precisely what it is not in neurotics, whose Oedipus complex has not passed through the correct process of transformation. Their super-ego still confronts their ego as a strict father confronts a child; and their morality operates in a primitive fashion in that the ego gets itself punished by the super-ego. Illness is employed as an instrument for this 'self-punishment', and neurotics have to behave as though they were governed by a sense of guilt which, in order to be satisfied, needs to be punished by illness.

[1926e, 4365]

This rift between them seems unavoidable. The reason for it is not immediately recognizable. It expresses itself at first as a conflict between the family and the larger community to which the individual belongs. We have already perceived that one of the main endeavours of civilization is to bring people together into large unities. But the family will not give the individual up. The more closely the members of a family are attached to one another, the more often do they tend to cut themselves off from others, and the more difficult is it for them to enter into the wider circle of life. The mode of life in common which is phylogenetically the older, and which is the only one that exists in childhood, will not let itself be superseded by the cultural mode of life which has been acquired later. Detaching himself from his family becomes a task that faces every young person, and society often helps him in the solution of it by means of puberty and initiation rites. We get the impression that these are difficulties which are inherent in all psychical - and, indeed, at bottom, in all organic - development.

[1930a, 4497]
The contradiction between this statement and what we have previously said about the genesis of conscience is in point of fact not so very great, and we see a way of further reducing it. In order to make our exposition easier, let us take as our example the aggressive instinct, and let us assume that the renunciation in question is always a renunciation of aggression. (This, of course, is only to be taken as a temporary assumption.) The effect of instinctual renunciation on the conscience then is that every piece of aggression whose satisfaction the subject gives up is taken over by the super-ego and increases the latter's aggressiveness (against the ego). This does not harmonize well with the view that the original aggressiveness of conscience is a continuance of the severity of the external authority and therefore has nothing to do with renunciation. But the discrepancy is removed if we postulate a different derivation for this first instalment of the super-ego's aggressivity. A considerable amount of aggressiveness must be developed in the child against the authority which prevents him from having his first, but none the less his most important, satisfactions, whatever the kind of instinctual deprivation that is demanded of him may be; but he is obliged to renounce the satisfaction of this revengeful aggressiveness. He finds his way out of this economically difficult situation with the help of familiar mechanisms. By means of identification he takes the unattackable authority into himself. The authority now turns into his super-ego and enters into possession of all the aggressiveness which a child would have liked to exercise against it. The child's ego has to content itself with the unhappy role of the authority - the father - who has been thus degraded. Here, as so often, the situation is reversed: 'If I were the father and you were the child, I should treat you badly.' The relationship between the super-ego and the ego is a return, distorted by a wish, of the real relationships between the ego, as yet undivided, and an external object. That is typical, too. But the essential difference is that the original severity of the super-ego does not - or does not so much - represent the severity which one has experienced from it, or which one attributes to it; it represents rather one's own aggressiveness towards it. If this is correct, we may assert truly that in the beginning conscience arises through the suppression of an aggressive impulse, and that it is subsequently reinforced by fresh suppressions of the same kind.

[1930a, 4519]

I myself am far from satisfied with these remarks on identification; but it will be enough if you can grant me that the installation of the super-ego can be described as a successful instance of identification with the parental agency. The fact that speaks decisively for this view is that this new creation of a superior agency within the ego is most intimately linked with the destiny of the Oedipus complex, so that the super-ego appears as the heir of that emotional attachment which is of such importance for childhood. With his abandonment of the Oedipus complex a child must, as we can see, renounce the intense object-cathexes which he has deposited with his parents, and it is as a compensation for this loss of objects that there is such a strong intensification of the identifications with his parents which have probably long been present in his ego. Identifications of this kind as precipitates of object-cathexes that have been given up will be repeated often enough later in the child's life; but it is entirely in accordance with the emotional importance of this first instance of such a transformation that a special place in the ego should be found for its outcome. Close investigation has shown us, too, that the super-ego is stunted in its strength and growth if the surmounting of the Oedipus complex is only incompletely successful. In the course of development the super-ego also takes on the influences of those who have stepped into the place of parents - educators, teachers, people chosen as ideal models. Normally it departs more and more from the original parental figures; it becomes, so to say, more impersonal. Nor must it be forgotten that a child has a different estimate of its parents at different periods of its life. At the time at which the Oedipus complex gives place to the super-ego they are something quite magnificent; but later they lose much of this. Identifications then come about with these later parents as well, and indeed they regularly make important contributions to the formation of character; but in that case they only affect the ego, they no longer influence the super-ego, which has been determined by the earliest parental imagos.

[1933a, 4673]
Now let us go back and turn to the id. It is not so easy to guess what occurs during repression in connection with the instinctual impulse that is being fought against. The main question which our interest raises is as to what happens to the energy, to the libidinal charge, of that excitation - how is it employed? You recollect that the earlier hypothesis was that it is precisely this that is transformed by repression into anxiety. We no longer feel able to say that. The modest reply will rather be that what happens to it is probably not always the same thing. There is probably an intimate correspondence which we ought to get to know about between what is occurring at the time in the ego and in the id in connection with the repressed impulse. For since we have decided that the pleasure-unpleasure principle, which is set in action by the signal of anxiety, plays a part in repression, we must alter our expectations. That principle exercises an entirely unrestricted dominance over what happens in the id. We can rely on its bringing about quite profound changes in the instinctual impulse in question. We are prepared to find that repression will have very various consequences, more or less far-reaching. In some cases the repressed instinctual impulse may retain its libidinal cathexis, and may persist in the id unchanged, although subject to constant pressure from the ego. In other cases what seems to happen is that it is totally destroyed, while its libido is permanently diverted along other paths. I expressed the view that this is what happens when the Oedipus complex is dealt with normally - in this desirable case, therefore, being not simply repressed but destroyed in the id. Clinical experience has further shown us that in many cases, instead of the customary result of repression, a degradation of the libido takes place - a regression of the libidinal organization to an earlier stage. This can, of course, only occur in the id, and if it occurs it will be under the influence of the same conflict which was introduced by the signal of anxiety. The most striking example of this kind is provided by the obsessional neurosis, in which libidinal regression and repression operate together.

[1933a, 4698]
It is, I may say, a matter of daily experience that sexual intercourse between adults strikes any children who may observe it as something uncanny and that it arouses anxiety in them. I have explained this anxiety by arguing that what we are dealing with is a sexual excitation with which their understanding is unable to cope and which they also, no doubt, repudiate because their parents are involved in it, and which is therefore transformed into anxiety. At a still earlier period of life sexual excitations directed towards a parent of the opposite sex have not yet met with repression and, as we have seen, are freely expressed. (See p. 735 ff.)

³ [Footnote added 1920:] As regards the origin of the perversions, I will add a word in anticipation of what is to come. There is reason to suppose that, just as in the case of fetishism, abortive beginnings of normal sexual development occur before the perversions become fixated. Analytic investigation has already been able to show in a few cases that perversions are a residue of development towards the Oedipus complex and that after the repression of that complex the components of the sexual instinct which are strongest in the disposition of the individual concerned emerge once more.

But the time comes when this early blossoming is nipped by the frost. None of these incestuous loves can avoid the fate of repression. They may succumb to it on the occasion of some discoverable external event which leads to disillusionment - such as unexpected slights, the unwelcome birth of a new brother or sister (which is felt as faithlessness), etc.; or the same thing may happen owing to internal conditions apart from any such events, perhaps simply because their yearning remains unsatisfied too long. It is unquestionably true that such events are not the effective causes, but that these love-affairs are bound to come to grief sooner or later, though we cannot say on what particular stumbling block. Most probably they pass away because their time is over, because the children have entered upon a new phase of development in which they are compelled to recapitulate from the history of mankind the repression of an incestuous object-choice, just as at an earlier stage they were obliged to effect an object-choice of that very sort.¹ In the new phase no mental product of the incestuous love-impulses that is present unconsciously is taken over by consciousness; and anything that has already come into consciousness is expelled from it. At the same time as this process of repression takes place, a sense of guilt appears. This is also of unknown origin, but there is no doubt whatever that it is connected with the incestuous wishes, and that it is justified by the persistence of those wishes in the unconscious.²

To this must be added another factor derived from the very remarkable course of development which is pursued by the erotic life of man. In its first phase, which has usually come to an end by the time a child is five years old, he has found the first object for his love in one or other of his parents, and all of his sexual instincts with their demand for satisfaction have been united upon this object. The repression which then sets in compels him to renounce the greater number of these infantile sexual aims, and leaves behind a profound modification in his relation to his parents. The child still remains tied to his parents, but by instincts which must be described as being 'inhibited in their aim'. The emotions which he feels henceforward towards these objects of his love are characterized as 'affectionate'. It is well known that the earlier 'sensual' tendencies remain of less strongly preserved in the unconscious, so that in a certain sense the whole of the original current continues to exist.¹
This first configuration of the child's love, which in typical cases takes the shape of the Oedipus complex, succumbs, as we know, from the beginning of the period of latency onwards to a wave of repression. Such of it as is left over shows itself as a purely affectionate emotional tie, relating to the same people, but no longer to be described as 'sexual'. Psycho-analysis, which illuminates the depths of mental life, has no difficulty in showing that the sexual ties of the earliest years of childhood also persist, though repressed and unconscious. It gives us courage to assert that wherever we come across an affectionate feeling it is successor to a completely 'sensual' object-tie with the person in question or rather with that person's prototype (or *imago*). It cannot indeed disclose to us without a special investigation whether in a given case this former complete sexual current still exists under repression or whether it has already been exhausted. To speak still more precisely: it is quite certain that this current is still there as a form and possibility, and can always be cathected and put into activity again by means of regression; the only question is (and it cannot always be answered) what degree of cathexis and operative force it still has at the present moment. Equal care must be taken in this connection to avoid two sources of error - the Scylla of underestimating the importance of the repressed unconscious, and the Charybdis of judging the normal entirely by the standards of the pathological.

[1921c, 3829]

The super-ego is, however, not simply a residue of the earliest object-choices of the id; it also represents an energetic reaction-formation against those choices. Its relation to the ego is not exhausted by the precept: 'You *ought* to be like this (like your father).' It also comprises the prohibition: 'You *may not* be like this (like your father) - that is, you may not do all that he does; some things are his prerogative.' This double aspect of the ego ideal derives from the fact that the ego ideal had the task of repressing the Oedipus complex; indeed, it is to that revolutionary event that it owes its existence. Clearly the repression of the Oedipus complex was no easy task. The child's parents, and especially his father, were perceived as the obstacle to a realization of his Oedipus wishes; so his infantile ego fortified itself for the carrying out of the repression by erecting this same obstacle within itself. It borrowed strength to do this, so to speak, from the father, and this loan was an extraordinarily momentous act. The super-ego retains the character of the father, while the more powerful the Oedipus complex was and the more rapidly it succumbed to repression (under the influence of authority, religious teaching, schooling and reading), the stricter will be the domination of the super-ego over the ego later on - in the form of conscience or perhaps of an unconscious sense of guilt. I shall presently bring forward a suggestion about the source of its power to dominate in this way - the source, that is, of its compulsive character which manifests itself in the form of a categorical imperative.

[1923b, 3968]

To an ever-increasing extent the Oedipus complex reveals its importance as the central phenomenon of the sexual period of early childhood. After that, its dissolution takes place; it succumbs to repression, as we say, and is followed by the latency period. It has not yet become clear, however, what it is that brings about its destruction. Analyses seem to show that it is the experience of painful disappointments. The little girl likes to regard herself as what her father loves above all else; but the time comes when she has to endure a harsh punishment from him and she is cast out of her fool's paradise. The boy regards his mother as his own property; but he finds one day that she has transferred her love and solicitude to a new arrival. Reflection must deepen our sense of the importance of those influences, for it will emphasize the fact that distressing experiences of this sort, which act in opposition to the content of the complex, are inevitable. Even when no special events occur, like those we have mentioned as examples, the absence of the satisfaction hoped for, the continued denial of the desired baby, must in the end lead the small lover to turn away from his hopeless longing. In this way the Oedipus complex would go to its destruction from its lack of success, from the effects of its internal impossibility.

[1924d, 4085]
I see no reason for denying the name of a 'repression' to the ego's turning away from the Oedipus complex, although later repressions come about for the most part with the participation of the super-ego, which in this case is only just being formed. But the process we have described is more than a repression. It is equivalent, if it is ideally carried out, to a destruction and an abolition of the complex. We may plausibly assume that we have here come upon the borderline - never a very sharply drawn one - between the normal and the pathological. If the ego has in fact not achieved much more than a repression of the complex, the latter persists in an unconscious state in the id and will later manifest its pathogenic effect.

By its theory of the instincts psycho-analysis offended the feelings of individuals in so far as they regarded themselves as members of the social community; another branch of its theory was calculated to hurt every single person at the tenderest point of his own psychical development. Psycho-analysis disposed once and for all of the fairy tale of an asexual childhood. It demonstrated the fact that sexual interests and activities occur in small children from the beginning of their lives. It showed what transformations those activities pass through, how at about the age of five they succumb to inhibition and how from puberty onwards they enter the service of the reproductive function. It recognized that early infantile sexual life reaches its peak in what is known as the Oedipus complex (an emotional attachment of the child to the parent of the opposite sex accompanied by an attitude of rivalry to the parent of the same sex) and that at that period of life this impulsion extends uninhibited into a straightforward sexual desire. This can be confirmed so easily that only the greatest efforts could make it possible to overlook it. Every individual has in fact gone through this phase but has afterwards energetically repressed its purport and succeeded in forgetting it. A horror of incest and an enormous sense of guilt are left over from this prehistoric epoch of the individual's existence. It may be that something quite similar occurred in the prehistoric epoch of the human species as a whole and that the beginnings of morality, religion and social order were intimately connected with the surmounting of that primaeval era. To adults their prehistory seems so inglorious that they refuse to allow themselves to be reminded of it: they were infuriated when psycho-analysis tried to lift the veil of amnesia from their years of childhood. There was only one way out: what psycho-analysis asserted must be false and what posed as a new science must be a tissue of fancies and distortions.

In girls the motive for the demolition of the Oedipus complex is lacking. Castration has already had its effect, which was to force the child into the situation of the Oedipus complex. Thus the Oedipus complex escapes the fate which it meets with in boys: it may be slowly abandoned or dealt with by repression, or its effects may persist far into women's normal mental life. I cannot evade the notion (though I hesitate to give it expression) that for women the level of what is ethically normal is different from what it is in men. Their super-ego is never so inexorable, so impersonal, so independent of its emotional origins as we require it to be in men. Character-traits which critics of every epoch have brought up against women - that they show less sense of justice than men, that they are less ready to submit to the great exigencies of life, that they are more often influenced in their judgements by feelings of affection or hostility - all these would be amply accounted for by the modification in the formation of their super-ego which we have inferred above. We must not allow ourselves to be deflected from such conclusions by the denials of the feminists, who are anxious to force us to regard the two sexes as completely equal in position and worth; but we shall, of course, willingly agree that the majority of men are also far behind the masculine ideal and that all human individuals, as a result of their bisexual disposition and of cross-inheritance, combine in themselves both masculine and feminine characteristics, so that pure masculinity and femininity remain theoretical constructions of uncertain content.
The process of arriving at an object, which plays such an important part in mental life, takes place alongside of the organization of the libido. After the stage of auto-erotism, the first love-object in the case of both sexes is the mother; and it seems probable that to begin with a child does not distinguish its mother's organ of nutrition from its own body. Later, but still in the first years of infancy, the relation known as the Oedipus complex becomes established: boys concentrate their sexual wishes upon their mother and develop hostile impulses against their father as being a rival, while girls adopt an analogous attitude.¹ All of the different variations and consequences of the Oedipus complex are important; and the innately bisexual constitution of human beings makes itself felt and increases the number of simultaneously active tendencies. Children do not become clear for quite a long time about the differences between the sexes; and during this period of sexual researches they produce typical sexual theories which, being circumscribed by the incompleteness of their authors' own physical development, are a mixture of truth and error and fail to solve the problems of sexual life (the riddle of the Sphinx - that is, the question of where babies come from). We see, then, that a child's first object-choice is an incestuous one. The whole course of development that I have described is run through rapidly. For the most remarkable feature of the sexual life of man is its diphasic onset, its onset in two waves, with an interval between them. It reaches a first climax in the fourth or fifth year of a child's life. But thereafter this early efflorescence of sexuality passes off; the sexual impulses which have shown such liveliness are overcome by repression, and a period of latency follows, which lasts until puberty and during which the reaction-formations of morality, shame, and disgust are built up.² Of all living creatures man alone seems to show this diphasic onset of sexual growth, and it may perhaps be the biological determinant of his predisposition to neuroses. At puberty the impulses and object-relations of a child's early years become re-animated, and amongst them the emotional ties of its Oedipus complex. In the sexual life of puberty there is a struggle between the urges of early years and the inhibitions of the latency period. Before this, and while the child is at the highest point of its infantile sexual development, a genital organization of a sort is established; but only the male genitals play a part in it, and the female ones remain undiscovered. (I have described this as the period of phallic primacy.) At this stage the contrast between the sexes is not stated in terms of 'male' or 'female' but of 'possessing a penis' or 'castrated'. The castration complex which arises in this connection is of the profoundest importance in the formation alike of character and of neuroses.

[1925d, 4212]

Let us go back again to infantile phobias of animals; for, when all is said and done, we understand them better than any other cases. In animal phobias, then, the ego has to oppose a libidinal object-cathexis coming from the id - a cathexis that belongs either to the positive or the negative Oedipus complex - because it believes that to give way to it would entail the danger of castration. This question has already been discussed, but there still remains a doubtful point to clear up. In 'Little Hans's' case - that is, in the case of a positive Oedipus complex - was it his fondness for his mother or was it his aggressiveness towards his father which called out the defence by the ego? In practice it seems to make no difference, especially as each set of feelings implies the other; but the question has a theoretical interest, since it is only the feeling of affection for the mother which can count as a purely erotic one. The aggressive impulse flows mainly from the destructive instinct; and we have always believed that in a neurosis it is against the demands of the libido and not against those of any other instinct that the ego is defending itself. In point of fact we know that after 'Hans's' phobia had been formed, his tender attachment to his mother seemed to disappear, having been completely disposed of by repression, while the formation of the symptom (the substitutive formation) took place in relation to his aggressive impulses. In the 'Wolf Man' the situation was simpler. The impulse that was repressed - his feminine attitude towards his father - was a genuinely erotic one; and it was in relation to that impulse that the formation of his symptoms took place.

[1926d, 4282]
Since the differentiation of the ego and the id, our interest in the problems of repression, too, was bound to receive a fresh impetus. Up till then we had been content to confine our interest to those aspects of repression which concerned the ego - the keeping away from consciousness and from motility, and the formation of substitutes (symptoms). With regard to the repressed instinctual impulses themselves, we assumed that they remained unaltered in the unconscious for an indefinite length of time. But now our interest is turned to the vicissitudes of the repressed and we begin to suspect that it is not self-evident, perhaps not even usual, that those impulses should remain unaltered and unalterable in this way. There is no doubt that the original impulses have been inhibited and deflected from their aim through repression. But has the portion of them in the unconscious maintained itself and been proof against the influences of life that tend to alter and depreciate them? In other words, do the old wishes, about whose former existence analysis tells us, still exist? The answer seems ready to hand and certain. It is that the old, repressed wishes must still be present in the unconscious since we still find their derivatives, the symptoms, in operation. But this answer is not sufficient. It does not enable us to decide between two possibilities: either that the old wish is now operating only through its derivatives, having transferred the whole of its cathetic energy to them, or that it is itself still in existence too. If its fate has been to exhaust itself in cathecting its derivatives, there is yet a third possibility. In the course of the neurosis it may have become re-animated by regression, anachronistic though it may now be. These are no idle speculations. There are many things about mental life, both normal and pathological, which seem to call for the raising of such questions. In my paper, 'The Dissolution of the Oedipus Complex' (1924), I had occasion to notice the difference between the mere repression and the real removal of an old wishful impulse.

We may suppose, therefore, that this was the way in which things happened. The sight of a woman's dead body, naked or on the point of being stripped, reminded the young man of his mother. It roused in him a longing for his mother which sprang from his Oedipus complex, and this was immediately completed by a feeling of indignation against his father. His ideas of 'father' and 'God' had not yet become widely separated; so that his desire to destroy his father could become conscious as doubt in the existence of God and could seek to justify itself in the eyes of reason as indignation about the ill-treatment of a mother object. It is of course typical for a child to regard what his father does to his mother in sexual intercourse as ill-treatment. The new impulse, which was displaced into the sphere of religion, was only a repetition of the Oedipus situation and consequently soon met with a similar fate. It succumbed to a powerful opposing current. During the actual conflict the level of displacement was not maintained: there is no mention of arguments in justification of God, nor are we told what the infallible signs were by which God proved his existence to the doubter. The conflict seems to have been unfolded in the form of a hallucinatory psychosis: inner voices were heard which uttered warnings against resistance to God. But the outcome of the struggle was displayed once again in the sphere of religion and it was of a kind predetermined by the fate of the Oedipus complex: complete submission to the will of God the Father. The young man became a believer and accepted everything he had been taught since his childhood about God and Jesus Christ. He had had a religious experience and had undergone a conversion.

All of this is so simple and straightforward that we cannot but ask ourselves whether by understanding this case we have thrown any light at all on the psychology of conversion in general. I may refer the reader to an admirable volume on the subject by Sante de Sanctis (1924), which incidentally takes all the findings of psycho-analysis into account. Study of this work confirms our expectation that by no means every case of conversion can be understood so easily as this one. In no respect, however, does our case contradict the views arrived at on the subject by modern research. The point which our present observation throws into relief is the manner in which the conversion was attached to a particular determining event, which caused the subject's scepticism to flare up for a last time before being finally extinguished.
A further complication arises when the constitutional factor we call bisexuality is comparatively strongly developed in a child. For then, under the threat to the boy's masculinity by castration, his inclination becomes strengthened to diverge in the direction of femininity, to put himself instead in his mother's place and take over her role as object of his father's love. But the fear of castration makes this solution impossible as well. The boy understands that he must also submit to castration if he wants to be loved by his father as a woman. Thus both impulses, hatred of the father and being in love with the father, undergo repression. There is a certain psychological distinction in the fact that the hatred of the father is given up on account of fear of an external danger (castration), while the being in love with the father is treated as an internal instinctual danger, though fundamentally it goes back to the same external danger.

What makes hatred of the father unacceptable is fear of the father; castration is terrible, whether as a punishment or as the price of love. Of the two factors which repress hatred of the father, the first, the direct fear of punishment and castration, may be called the normal one; its pathogenic intensification seems to come only with the addition of the second factor, the fear of the feminine attitude. Thus a strong innate bisexual disposition becomes one of the preconditions or reinforcements of neurosis. Such a disposition must certainly be assumed in Dostoevsky, and it shows itself in a viable form (as latent homosexuality) in the important part played by male friendships in his life, in his strangely tender attitude towards rivals in love and in his remarkable understanding of situations which are explicable only by repressed homosexuality, as many examples from his novels show.

But what has been said so far does not exhaust the consequences of the repression of the hatred of the father in the Oedipus complex. There is something fresh to be added: namely that in spite of everything the identification with the father finally makes a permanent place for itself in the ego. It is received into the ego, but establishes itself there as a separate agency in contrast to the rest of the content of the ego. We then give it the name of super-ego and ascribe to it, the inheritor of the parental influence, the most important functions. If the father was hard, violent and cruel, the super-ego takes over those attributes from him and, in the relations between the ego and it, the passivity which was supposed to have been repressed is re-established. The super-ego has become sadistic, and the ego becomes masochistic - that is to say, at bottom passive in a feminine way. A great need for punishment develops in the ego, which in part offers itself as a victim to Fate, and in part finds satisfaction in ill-treatment by the super-ego (that is, in the sense of guilt). For every punishment is ultimately castration and, as such, a fulfilment of the old passive attitude towards the father. Even Fate is, in the last resort, only a later projection of the father.
The results of the threat of castration are multifarious and incalculable; they affect the whole of a boy's relations with his father and mother and subsequently with men and women in general. As a rule the child's masculinity is unable to stand up to this first shock. In order to preserve his sexual organ he renounces the possession of his mother more or less completely; his sexual life often remains permanently encumbered by the prohibition. If a strong feminine component, as we call it, is present in him, its strength is increased by this intimidation of his masculinity. He falls into a passive attitude to his father, such as he attributes to his mother. It is true that as a result of the threat he has given up masturbation, but not the activities of his imagination accompanying it. On the contrary, since these are now the only form of sexual satisfaction remaining to him, he indulges in them more than before and in these phantasies, though he still continues to identify himself with his father, he also does so, simultaneously and perhaps predominantly, with his mother. Derivatives and modified products of these early masturbatory phantasies usually make their way into his later ego and play a part in the formation of his character. Apart from this encouragement of his femininity, fear and hatred of his father gain greatly in intensity. The boy's masculinity withdraws, as it were, into a defiant attitude towards his father, which will dominate his later behaviour in human society in a compulsive fashion. A residue of his erotic fixation to his mother is often left in the form of an excessive dependence on her, and this persists as a kind of bondage to women. He no longer ventures to love his mother, but he cannot risk not being loved by her, for in that case he would be in danger of being betrayed by her to his father and handed over to castration. The whole experience, with all its antecedents and consequences, of which my account has only been able to give a selection, is subjected to a highly energetic repression, and, as is made possible by the laws operating in the unconscious id, all the mutually contending emotional impulses and reactions which are set going at that time are preserved in the unconscious and ready to disturb the later development of the ego after puberty. When the somatic process of sexual maturation puts fresh life into the old libidinal fixations which had apparently been surmounted, sexual life will turn out to be inhibited, without homogeneity and fallen apart into mutually conflicting urges.

It is no doubt true that the impact of the threat of castration upon a boy's budding sexual life does not always have these dreaded consequences. It will depend once again on quantitative relations how much damage is done and how much avoided. The whole occurrence, which may probably be regarded as the central experience of the years of childhood, the greatest problem of early life and the strongest source of later inadequacy, is so completely forgotten that its reconstruction during the work of analysis is met in adults by the most decided disbelief. Indeed, aversion to it is so great that people try to silence any mention of the proscribed subject and the most obvious reminders of it are overlooked by a strange intellectual blindness. One may hear it objected, for instance, that the legend of King Oedipus has in fact no connection with the construction made by analysis: the cases are quite different, since Oedipus did not know that it was his father that he killed and his mother that he married. What is overlooked in this is that a distortion of this kind is inevitable if an attempt is made at a poetic handling of the material, and that there is no introduction of extraneous material but only a skilful employment of the factors presented by the theme. The ignorance of Oedipus is a legitimate representation of the unconscious state into which, for adults, the whole experience has fallen; and the coercive power of the oracle, which makes or should make the hero innocent, is a recognition of the inevitability of the fate which has condemned every son to live through the Oedipus complex. Again it was pointed out from psycho-analytic quarters how easily the riddle of another dramatic hero, Shakespeare's procrastinator, Hamlet, can be solved by reference to the Oedipus complex, since the prince came to grief over the task of punishing someone else for what coincided with the substance of his own Oedipus wish - whereupon the general lack of understanding on the part of the literary world showed how ready is the mass of mankind to hold fast to its infantile repressions.

[1940a [1938], 4998]
Yet more than a century before the emergence of psycho-analysis the French philosopher Diderot bore witness to the importance of the Oedipus complex by expressing the difference between the primitive and civilized worlds in this sentence: 'Si le petit sauvage était abandonné à lui-même, qu'il conservât toute son imbécillité, et qu'il réunît au peu de raison de l'enfant au berceau la violence des passions de l'homme de trente ans, il tordrait le col à son père et coucherait avec sa mère.'² I venture to say that if psycho-analysis could boast of no other achievement than the discovery of the repressed Oedipus complex, that alone would give it a claim to be included among the precious new acquisitions of mankind.

[1940a [1938], 4999]
We should not be as short-sighted as the person in charge of the child who threatens him with castration, and we must not overlook the fact that at this time masturbation by no means represents the whole of his sexual life. As can be clearly shown, he stands in the Oedipus attitude to his parents; his masturbation is only a genital discharge of the sexual excitation belonging to the complex, and throughout his later years will owe its importance to that relationship. The Oedipus complex offered the child two possibilities of satisfaction, an active and a passive one. He could put himself in his father's place in a masculine fashion and have intercourse with his mother as his father did, in which case he would soon have felt the latter as a hindrance; or he might want to take the place of his mother and be loved by his father, in which case his mother would become superfluous. The child may have had only very vague notions as to what constitutes a satisfying erotic intercourse; but certainly the penis must play a part in it, for the sensations in his own organ were evidence of that. So far he had had no occasion to doubt that women possessed a penis. But now his acceptance of the possibility of castration, his recognition that women were castrated, made an end of both possible ways of obtaining satisfaction from the Oedipus complex. For both of them entailed the loss of his penis - the masculine one as a resulting punishment and the feminine one as a precondition. If the satisfaction of love in the field of the Oedipus complex is to cost the child his penis, a conflict is bound to arise between his narcissistic interest in that part of his body and the libidinal cathexis of his parental objects. In this conflict the first of these forces normally triumphs: the child's ego turns away from the Oedipus complex.

I have described elsewhere how this turning away takes place. The object-cathexes are given up and replaced by identifications. The authority of the father or the parents is introjected into the ego, and there it forms the nucleus of the super-ego, which takes over the severity of the father and perpetuates his prohibition against incest, and so secures the ego from the return of the libidinal object-cathexis. The libidinal trends belonging to the Oedipus complex are in part desexualized and sublimated (a thing which probably happens with every transformation into an identification) and in part inhibited in their aim and changed into impulses of affection. The whole process has, on the one hand, preserved the genital organ - has averted the danger of its loss - and, on the other, has paralysed it - has removed its function. This process ushers in the latency period, which now interrupts the child's sexual development.

Analytic observation enables us to recognize or guess these connections between the phallic organization, the Oedipus complex, the threat of castration, the formation of the super-ego and the latency period. These connections justify the statement that the destruction of the Oedipus complex is brought about by the threat of castration. But this does not dispose of the problem; there is room for a theoretical speculation which may upset the results we have come to or put them in a new light. Before we start along this new path, however, we must turn to a question which has arisen in the course of this discussion and has so far been left on one side. The process which has been described refers, as has been expressly said, to male children only. How does the corresponding development take place in little girls?

[1924d, 4088]
At this point our material - for some incomprehensible reason - becomes far more obscure and full of gaps. The female sex, too, develops an Oedipus complex, a super-ego and a latency period. May we also attribute a phallic organization and a castration complex to it? The answer is in the affirmative; but these things cannot be the same as they are in boys. Here the feminist demand for equal rights for the sexes does not take us far, for the morphological distinction is bound to find expression in differences of psychical development. 'Anatomy is Destiny', to vary a saying of Napoleon's. The little girl's clitoris behaves just like a penis to begin with; but, when she makes a comparison with a playfellow of the other sex, she perceives that she has 'come off badly' and she feels this as a wrong done to her and as a ground for inferiority. For a while still she consoles herself with the expectation that later on, when she grows older, she will acquire just as big an appendage as the boy's. Here the masculinity complex of women branches off. A female child, however, does not understand her lack of a penis as being a sex character; she explains it by assuming that at some earlier date she had possessed an equally large organ and had then lost it by castration. She seems not to extend this inference from herself to other, adult females, but, entirely on the lines of the phallic phase, to regard them as possessing large and complete - that is to say, male - genitals. The essential difference thus comes about that the girl accepts castration as an accomplished fact, whereas the boy fears the possibility of its occurrence.

I have no doubt that the chronological and causal relations described here between the Oedipus complex, sexual intimidation (the threat of castration), the formation of the super-ego and the beginning of the latency period are of a typical kind; but I do not wish to assert that this type is the only possible one. Variations in the chronological order and in the linking-up of these events are bound to have a very important bearing on the development of the individual.

Since the publication of Otto Rank's interesting study, *The Trauma of Birth*, even the conclusion arrived at by this modest investigation, to the effect that the boy's Oedipus complex is destroyed by the fear of castration, cannot be accepted without further discussion. Nevertheless, it seems to me premature to enter into such a discussion at the present time, and perhaps inadvisable to begin a criticism or an appreciation of Rank's view at this juncture.

In boys the situation of the Oedipus complex is the first stage that can be recognized with certainty. It is easy to understand, because at that stage a child retains the same object which he previously cathected with his libido - not as yet a genital one - during the preceding period while he was being suckled and nursed. The fact, too, that in this situation he regards his father as a disturbing rival and would like to get rid of him and take his place is a straightforward consequence of the actual state of affairs. I have shown elsewhere¹ how the Oedipus attitude in little boys belongs to the phallic phase, and how its destruction is brought about by the fear of castration - that is, by narcissistic interest in their genitals. The matter is made more difficult to grasp by the complicating circumstance that even in boys the Oedipus complex has a double orientation, active and passive, in accordance with their bisexual constitution; a boy also wants to take his *mother's* place as the love-object of his *father* - a fact which we describe as the feminine attitude.
As regards the prehistory of the Oedipus complex in boys we are far from complete clarity. We know that that period includes an identification of an affectionate sort with the boy's father, an identification which is still free from any sense of rivalry in regard to his mother. Another element of that stage is invariably, I believe, a masturbatory activity in connection with the genitals, the masturbation of early childhood, the more or less violent suppression of which by those in charge of the child sets the castration complex in action. It is to be assumed that this masturbation is attached to the Oedipus complex and serves as a discharge for the sexual excitation belonging to it. It is, however, uncertain whether the masturbation has this character from the first, or whether on the contrary it makes its first appearance spontaneously as an activity of a bodily organ and is only brought into relation with the Oedipus complex at some later date; this second possibility is by far the more probable. Another doubtful question is the part played by bed-wetting and by the breaking of that habit through the intervention of training measures. We are inclined to make the simple connection that continued bed-wetting is a result of masturbation and that its suppression is regarded by boys as an inhibition of their genital activity - that is, as having the meaning of a threat of castration; but whether we are always right in supposing this remains to be seen. Finally, analysis shows us in a shadowy way how the fact of a child at a very early age listening to his parents copulating may set up his first sexual excitation, and how that event may, owing to its after-effects, act as a starting-point for the child's whole sexual development. Masturbation, as well as the two attitudes in the Oedipus complex, later on become attached to this early experience, the child having subsequently interpreted its meaning. It is impossible, however, to suppose that these observations of coitus are of universal occurrence, so that at this point we are faced with the problem of 'primal phantasies'. Thus the prehistory of the Oedipus complex, even in boys, raises all of these questions for sifting and explanation; and there is the further problem of whether we are to suppose that the process invariably follows the same course, or whether a great variety of different preliminary stages may not converge upon the same terminal situation.

[1925], 4148

So far there has been no question of the Oedipus complex, nor has it up to this point played any part. But now the girl's libido slips into a new position along the line - there is no other way of putting it - of the equation 'penis-child'. She gives up her wish for a penis and puts in place of it a wish for a child: and with that purpose in view she takes her father as a love object. Her mother becomes the object of her jealousy. The girl has turned into a little woman. If I am to credit a single analytic instance, this new situation can give rise to physical sensations which would have to be regarded as a premature awakening of the female genital apparatus. When the girl's attachment to her father comes to grief later on and has to be abandoned, it may give place to an identification with him and the girl may thus return to her masculinity complex and perhaps remain fixated in it.

[1925], 4154
I have now said the essence of what I had to say; I will stop, therefore, and cast an eye over our findings. We have gained some insight into the prehistory of the Oedipus complex in girls. The corresponding period in boys is more or less unknown. In girls the Oedipus complex is a secondary formation. The operations of the castration complex precede it and prepare for it. As regards the relation between the Oedipus and castration complexes there is a fundamental contrast between the two sexes. *Whereas in boys the Oedipus complex is destroyed by the castration complex, in girls it is made possible and led up to by the castration complex.* This contradiction is cleared up if we reflect that the castration complex always operates in the sense implied in its subject-matter: it inhibits and limits masculinity and encourages femininity. The difference between the sexual development of males and females at the stage we have been considering is an intelligible consequence of the anatomical distinction between their genitals and of the psychical situation involved in it; it corresponds to the difference between a castration that has been carried out and one that has merely been threatened. In their essentials, therefore, our findings are self-evident and it should have been possible to foresee them. [1925j, 4154]

The Oedipus complex, however, is such an important thing that the manner in which one enters and leaves it cannot be without its effects. In boys (as I have shown at length in the paper to which I have just referred and to which all of my present remarks are closely related) the complex is not simply repressed, it is literally smashed to pieces by the shock of threatened castration. Its libidinal cathexes are abandoned, desexualized and in part sublimated; its objects are incorporated into the ego, where they form the nucleus of the super-ego and give that new structure its characteristic qualities. In normal, or, it is better to say, in ideal cases, the Oedipus complex exists no longer, even in the unconscious; the super-ego has become its heir. Since the penis (to follow Ferenczi) owes its extraordinarily high narcissistic cathexis to its organic significance for the propagation of the species, the catastrophe to the Oedipus complex (the abandonment of incest and the institution of conscience and morality) may be regarded as a victory of the race over the individual. This is an interesting point of view when one considers that neurosis is based upon a struggle of the ego against the demands of the sexual function. But to leave the standpoint of individual psychology is not of any immediate help in clarifying this complicated situation. [1925j, 4155]

This is as far as our investigations into the formation of symptoms take us. It is hardly worth while summing them up, for the results they have yielded are scanty and incomplete and tell us scarcely anything that we do not already know. It would be fruitless to turn our attention to symptom-formation in other disorders besides phobias, conversion hysteria and obsessional neurosis, for too little is known about them. But in reviewing those three neuroses together we are brought up against a very serious problem the consideration of which can no longer be put off. All three have as their outcome the destruction of the Oedipus complex; and in all three the motive force of the ego's opposition is, we believe, the fear of castration. Yet it is only in the phobias that this fear comes to the surface and is acknowledged. What has become of it in the other two neuroses? How has the ego spared itself this fear? The problem becomes accentuated when we recall the possibility, already referred to, that anxiety arises directly, by a kind of fermentation, from a libidinal cathexis whose processes have been disturbed. Furthermore, is it absolutely certain that fear of castration is the only motive force of repression (or defence)? If we think of neuroses in women we are bound to doubt it. For though we can with certainty establish in them the presence of a castration complex, we can hardly speak with propriety of castration anxiety where castration has already taken place. [1926d, 4281]
A further complication arises when the constitutional factor we call bisexuality is comparatively strongly developed in a child. For then, under the threat to the boy’s masculinity by castration, his inclination becomes strengthened to diverge in the direction of femininity, to put himself instead in his mother’s place and take over her role as object of his father’s love. But the fear of castration makes this solution impossible as well. The boy understands that he must also submit to castration if he wants to be loved by his father as a woman. Thus both impulses, hatred of the father and being in love with the father, undergo repression. There is a certain psychological distinction in the fact that the hatred of the father is given up on account of fear of an external danger (castration), while the being in love with the father is treated as an internal instinctual danger, though fundamentally it goes back to the same external danger.

What makes hatred of the father unacceptable is fear of the father; castration is terrible, whether as a punishment or as the price of love. Of the two factors which repress hatred of the father, the first, the direct fear of punishment and castration, may be called the normal one; its pathogenic intensification seems to come only with the addition of the second factor, the fear of the feminine attitude. Thus a strong innate bisexual disposition becomes one of the preconditions or reinforcements of neurosis. Such a disposition must certainly be assumed in Dostoevsky, and it shows itself in a viable form (as latent homosexuality) in the important part played by male friendships in his life, in his strangely tender attitude towards rivals in love and in his remarkable understanding of situations which are explicable only by repressed homosexuality, as many examples from his novels show.

With the transference of the wish for a penis-baby on to her father, the girl has entered the situation of the Oedipus complex. Her hostility to her mother, which did not need to be freshly created, is now greatly intensified, for she becomes the girl’s rival, who receives from her father everything that she desires from him. For a long time the girl’s Oedipus complex concealed her pre-Oedipus attachment to her mother from our view, though it is nevertheless so important and leaves such lasting fixations behind it. For girls the Oedipus situation is the outcome of a long and difficult development; it is a kind of preliminary solution, a position of rest which is not soon abandoned, especially as the beginning of the latency period is not far distant. And we are now struck by a difference between the two sexes, which is probably momentous, in regard to the relation of the Oedipus complex to the castration complex. In a boy the Oedipus complex, in which he desires his mother and would like to get rid of his father as being a rival, develops naturally from the phase of his phallic sexuality. The threat of castration compels him, however, to give up that attitude. Under the impression of the danger of losing his penis, the Oedipus complex is abandoned, repressed and, in the most normal cases, entirely destroyed, and a severe super-ego is set up as its heir. What happens with a girl is almost the opposite. The castration complex prepares for the Oedipus complex instead of destroying it; the girl is driven out of her attachment to her mother through the influence of her envy for the penis and she enters the Oedipus situation as though into a haven of refuge. In the absence of fear of castration the chief motive is lacking which leads boys to surmount the Oedipus complex. Girls remain in it for an indeterminate length of time; they demolish it late and, even so, incompletely. In these circumstances the formation of the super-ego must suffer; it cannot attain the strength and independence which give it its cultural significance, and feminists are not pleased when we point out to them the effects of this factor upon the average feminine character.
With the phallic phase and in the course of it the sexuality of early childhood reaches its height and approaches its dissolution. Thereafter boys and girls have different histories. Both have begun to put their intellectual activity at the service of sexual researches; both start off from the premiss of the universal presence of the penis. But now the paths of the sexes diverge. The boy enters the Oedipus phase; he begins to manipulate his penis and simultaneously has phantasies of carrying out some sort of activity with it in relation to his mother, till, owing to the combined effect of a threat of castration and the sight of the absence of a penis in females, he experiences the greatest trauma of his life and this introduces the period of latency with all its consequences. The girl, after vainly attempting to do the same as the boy, comes to recognize her lack of a penis or rather the inferiority of her clitoris, with permanent effects on the development of her character; as a result of this first disappointment in rivalry, she often begins by turning away altogether from sexual life.
[1940a [1938], 4965]

The boy's mother has understood quite well that his sexual excitation relates to herself. Sooner or later she reflects that it is not right to allow it to continue. She thinks she is doing the correct thing in forbidding him to handle his genital organ. Her prohibition has little effect; at the most it brings about some modification in his method of obtaining satisfaction. At last his mother adopts the severest measures; she threatens to take away from him the thing he is defying her with. Usually, in order to make the threat more frightening and more credible, she delegates its execution to the boy's father, saying that she will tell him and that he will cut the penis off. Strange to say, this threat operates only if another condition is fulfilled before or afterwards. In itself it seems too inconceivable to the boy that such a thing could happen. But if at the time of the threat he can recall the appearance of female genitals or if shortly afterwards he has a sight of them - of genitals, that is to say, which really lack this supremely valued part, then he takes what he has heard seriously and, coming under the influence of the castration complex, experiences the severest trauma of his young life.¹
[1940a [1938], 4997]
The clinical fact which meets us behind the form of the Oedipus complex as it is established by analysis is of the highest practical significance. We learn that at puberty, when the sexual instinct first makes its demands in full strength, the old familiar incestuous objects are taken up again and freshly cathexed with libido. The infantile object-choice was only a feeble one, but it was a prelude, pointing the direction for the object-choice at puberty. At this point, then, very intense emotional processes come into play, following the direction of the Oedipus complex or reacting against it, processes which, however, since their premisses have become intolerable, must to a large extent remain apart from consciousness. From this time onwards, the human individual has to devote himself to the great task of detaching himself from his parents, and not until that task is achieved can he cease to be a child and become a member of the social community. For the son this task consists in detaching his libidinal wishes from his mother and employing them for the choice of a real outside love-object, and in reconciling himself with his father if he has remained in opposition to him, or in freeing himself from his pressure if, as a reaction to his infantile rebelliousness, he has become subservient to him. These tasks are set to everyone; and it is remarkable how seldom they are dealt with in an ideal manner - that is, in one which is correct both psychologically and socially. By neurotics, however, no solution at all is arrived at: the son remains all his life bowed beneath his father's authority and he is unable to transfer his libido to an outside sexual object. With the relationship changed round, the same fate can await the daughter. In this sense the Oedipus complex may justly be regarded as the nucleus of the neuroses.

[1916-1917, 3402]

Along with the demolition of the Oedipus complex, the boy's object-cathexis of his mother must be given up. Its place may be filled by one of two things: either an identification with his mother or an intensification of his identification with his father. We are accustomed to regard the latter outcome as the more normal; it permits the affectionate relation to the mother to be in a measure retained. In this way the dissolution of the Oedipus complex would consolidate the masculinity in a boy's character. In a precisely analogous way, the outcome of the Oedipus attitude in a little girl may be an intensification of her identification with her mother (or the setting up of such an identification for the first time) - a result which will fix the child's feminine character.

[1923b, 3966]

It would appear, therefore, that in both sexes the relative strength of the masculine and feminine sexual dispositions is what determines whether the outcome of the Oedipus situation shall be an identification with the father or with the mother. This is one of the ways in which bisexuality takes a hand in the subsequent vicissitudes of the Oedipus complex. The other way is even more important. For one gets an impression that the simple Oedipus complex is by no means its commonest form, but rather represents a simplification or schematization which, to be sure, is often enough justified for practical purposes. Closer study usually discloses the more complete Oedipus complex, which is twofold, positive and negative, and is due to the bisexuality originally present in children: that is to say, a boy has not merely an ambivalent attitude towards his father and an affectionate object-choice towards his mother but at the same time he also behaves like a girl and displays an affectionate feminine attitude to his father and a corresponding jealousy and hostility towards his mother. It is this complicating element introduced by bisexuality that makes it so difficult to obtain a clear view of the facts in connection with the earliest object-choices and identifications, and still more difficult to describe them intelligibly. It may even be that the ambivalence displayed in the relations to the parents should be attributed entirely to bisexuality and that it is not, as I have represented above, developed out of identification in consequence of rivalry.

[1923b, 3967]
The super-ego is, however, not simply a residue of the earliest object-choices of the id; it also represents an energetic reaction-formation against those choices. Its relation to the ego is not exhausted by the precept: 'You ought to be like this (like your father).’ It also comprises the prohibition: ‘You may not be like this (like your father) - that is, you may not do all that he does; some things are his prerogative.' This double aspect of the ego ideal derives from the fact that the ego ideal had the task of repressing the Oedipus complex; indeed, it is to that revolutionary event that it owes its existence. Clearly the repression of the Oedipus complex was no easy task. The child's parents, and especially his father, were perceived as the obstacle to a realization of his Oedipus wishes; so his infantile ego fortified itself for the carrying out of the repression by erecting this same obstacle within itself. It borrowed strength to do this, so to speak, from the father, and this loan was an extraordinarily momentous act. The super-ego retains the character of the father, while the more powerful the Oedipus complex was and the more rapidly it succumbed to repression (under the influence of authority, religious teaching, schooling and reading), the stricter will be the domination of the super-ego over the ego later on - in the form of conscience or perhaps of an unconscious sense of guilt. I shall presently bring forward a suggestion about the source of its power to dominate in this way - the source, that is, of its compulsive character which manifests itself in the form of a categorical imperative.

Analytic observation enables us to recognize or guess these connections between the phallic organization, the Oedipus complex, the threat of castration, the formation of the super-ego and the latency period. These connections justify the statement that the destruction of the Oedipus complex is brought about by the threat of castration. But this does not dispose of the problem; there is room for a theoretical speculation which may upset the results we have come to or put them in a new light. Before we start along this new path, however, we must turn to a question which has arisen in the course of this discussion and has so far been left on one side. The process which has been described refers, as has been expressly said, to male children only. How does the corresponding development take place in little girls?

I have no doubt that the chronological and causal relations described here between the Oedipus complex, sexual intimidation (the threat of castration), the formation of the super-ego and the beginning of the latency period are of a typical kind; but I do not wish to assert that this type is the only possible one. Variations in the chronological order and in the linking-up of these events are bound to have a very important bearing on the development of the individual.

Since the publication of Otto Rank's interesting study, *The Trauma of Birth*, even the conclusion arrived at by this modest investigation, to the effect that the boy's Oedipus complex is destroyed by the fear of castration, cannot be accepted without further discussion. Nevertheless, it seems to me premature to enter into such a discussion at the present time, and perhaps inadvisable to begin a criticism or an appreciation of Rank's view at this juncture.
I have now said the essence of what I had to say: I will stop, therefore, and cast an eye over our findings. We have gained some insight into the prehistory of the Oedipus complex in girls. The corresponding period in boys is more or less unknown. In girls the Oedipus complex is a secondary formation. The operations of the castration complex precede it and prepare for it. As regards the relation between the Oedipus and castration complexes there is a fundamental contrast between the two sexes. *Whereas in boys the Oedipus complex is destroyed by the castration complex, in girls it is made possible and led up to by the castration complex.* This contradiction is cleared up if we reflect that the castration complex always operates in the sense implied in its subject-matter: it inhibits and limits masculinity and encourages femininity. The difference between the sexual development of males and females at the stage we have been considering is an intelligible consequence of the anatomical distinction between their genitals and of the psychical situation involved in it; it corresponds to the difference between a castration that has been carried out and one that has merely been threatened. In their essentials, therefore, our findings are self-evident and it should have been possible to foresee them.

[1925j, 4154]

The Oedipus complex, however, is such an important thing that the manner in which one enters and leaves it cannot be without its effects. In boys (as I have shown at length in the paper to which I have just referred and to which all of my present remarks are closely related) the complex is not simply repressed, it is literally smashed to pieces by the shock of threatened castration. Its libidinal cathexes are abandoned, desexualized and in part sublimated; its objects are incorporated into the ego, where they form the nucleus of the super-ego and give that new structure its characteristic qualities. In normal, or, it is better to say, in ideal cases, the Oedipus complex exists no longer, even in the unconscious; the super-ego has become its heir. Since the penis (to follow Ferenczi) owes its extraordinarily high narcissistic cathexis to its organic significance for the propagation of the species, the catastrophe to the Oedipus complex (the abandonment of incest and the institution of conscience and morality) may be regarded as a victory of the race over the individual. This is an interesting point of view when one considers that neurosis is based upon a struggle of the ego against the demands of the sexual function. But to leave the standpoint of individual psychology is not of any immediate help in clarifying this complicated situation.

[1925j, 4155]

In girls the motive for the demolition of the Oedipus complex is lacking. Castration has already had its effect, which was to force the child into the situation of the Oedipus complex. Thus the Oedipus complex escapes the fate which it meets with in boys: it may be slowly abandoned or dealt with by repression, or its effects may persist far into women's normal mental life. I cannot evade the notion (though I hesitate to give it expression) that for women the level of what is ethically normal is different from what it is in men. Their super-ego is never so inexorable, so impersonal, so independent of its emotional origins as we require it to be in men. Character-traits which critics of every epoch have brought up against women - that they show less sense of justice than men, that they are less ready to submit to the great exigencies of life, that they are more often influenced in their judgements by feelings of affection or hostility - all these would be amply accounted for by the modification in the formation of their super-ego which we have inferred above. We must not allow ourselves to be deflected from such conclusions by the denials of the feminists, who are anxious to force us to regard the two sexes as completely equal in position and worth; but we shall, of course, willingly agree that the majority of men are also far behind the masculine ideal and that all human individuals, as a result of their bisexual disposition and of cross-inheritance, combine in themselves both masculine and feminine characteristics, so that pure masculinity and femininity remain theoretical constructions of uncertain content.

[1925j, 4155]
Parricide, according to a well-known view, is the principal and primal crime of humanity as well as of the individual. (See my Totem and Taboo 1912-13.) It is in any case the main source of the sense of guilt, though we do not know if it is the only one: researches have not yet been able to establish with certainty the mental origin of guilt and the need for expiation. But it is not necessary for it to be the only one. The psychological situation is complicated and requires elucidation. The relation of a boy to his father is, as we say, an 'ambivalent' one. In addition to the hate which seeks to get rid of the father as a rival, a measure of tenderness for him is also habitually present. The two attitudes of mind combine to produce identification with the father; the boy wants to be in his father's place because he admires him and wants to be like him, and also because he wants to put him out of the way. This whole development now comes up against a powerful obstacle. At a certain moment the child comes to understand that an attempt to remove his father as a rival would be punished by him with castration. So from fear of castration - that is, in the interests of preserving his masculinity - he gives up his wish to possess his mother and get rid of his father. In so far as this wish remains in the unconscious it forms the basis of the sense of guilt. We believe that what we have here been describing are normal processes, the normal fate of the so-called 'Oedipus complex'; nevertheless it requires an important amplification.

[1928b, 4559]

We have already learned, too, that there is yet another difference between the sexes, which relates to the Oedipus complex. We have an impression here that what we have said about the Oedipus complex applies with complete strictness to the male child only and that we are right in rejecting the term 'Electra complex' which seeks to emphasize the analogy between the attitude of the two sexes. It is only in the male child that we find the fateful combination of love for the one parent and simultaneous hatred for the other as a rival. In his case it is the discovery of the possibility of castration, as proved by the sight of the female genitals, which forces on him the transformation of his Oedipus complex, and which leads to the creation of his super-ego and thus initiates all the processes that are designed to make the individual find a place in the cultural community. After the paternal agency has been internalized and become a super-ego, the next task is to detach the latter from the figures of whom it was originally the psychical representative. In this remarkable course of development it is precisely the boy's narcissistic interest in his genitals - his interest in preserving his penis - which is turned round into a curtailing of his infantile sexuality.

[1931b, 4593]
With the transference of the wish for a penis-baby on to her father, the girl has entered the situation of the Oedipus complex. Her hostility to her mother, which did not need to be freshly created, is now greatly intensified, for she becomes the girl's rival, who receives from her father everything that she desires from him. For a long time the girl's Oedipus complex concealed her pre-Oedipus attachment to her mother from our view, though it is nevertheless so important and leaves such lasting fixations behind it. For girls the Oedipus situation is the outcome of a long and difficult development; it is a kind of preliminary solution, a position of rest which is not soon abandoned, especially as the beginning of the latency period is not far distant. And we are now struck by a difference between the two sexes, which is probably momentous, in regard to the relation of the Oedipus complex to the castration complex. In a boy the Oedipus complex, in which he desires his mother and would like to get rid of his father as being a rival, develops naturally from the phase of his phallic sexuality. The threat of castration compels him, however, to give up that attitude. Under the impression of the danger of losing his penis, the Oedipus complex is abandoned, repressed and, in the most normal cases, entirely destroyed, and a severe super-ego is set up as its heir. What happens with a girl is almost the opposite. The castration complex prepares for the Oedipus complex instead of destroying it; the girl is driven out of her attachment to her mother through the influence of her envy for the penis and she enters the Oedipus situation as though into a haven of refuge. In the absence of fear of castration the chief motive is lacking which leads boys to surmount the Oedipus complex. Girls remain in it for an indeterminate length of time; they demolish it late and, even so, incompletely. In these circumstances the formation of the super-ego must suffer; it cannot attain the strength and independence which give it its cultural significance, and feminists are not pleased when we point out to them the effects of this factor upon the average feminine character.
[1933a, 4731]
Thus the sending away of the little one (of the genital organ) in the first dream was also related to the threat of castration. Her ultimate complaint against her mother was for not having given birth to her as a boy.
[1900a, 825]

The clinical fact which meets us behind the form of the Oedipus complex as it is established by analysis is of the highest practical significance. We learn that at puberty, when the sexual instinct first makes its demands in full strength, the old familiar incestuous objects are taken up again and freshly cathected with libido. The infantile object-choice was only a feeble one, but it was a prelude, pointing the direction for the object-choice at puberty. At this point, then, very intense emotional processes come into play, following the direction of the Oedipus complex or reacting against it, processes which, however, since their premisses have become intolerable, must to a large extent remain apart from consciousness. From this time onwards, the human individual has to devote himself to the great task of detaching himself from his parents, and not until that task is achieved can he cease to be a child and become a member of the social community. For the son this task consists in detaching his libidinal wishes from his mother and employing them for the choice of a real outside love-object, and in reconciling himself with his father if he has remained in opposition to him, or in freeing himself from his pressure if, as a reaction to his infantile rebelliousness, he has become subservient to him. These tasks are set to everyone; and it is remarkable how seldom they are dealt with in an ideal manner - that is, in one which is correct both psychologically and socially. By neurotics, however, no solution at all is arrived at: the son remains all his life bowed beneath his father's authority and he is unable to transfer his libido to an outside sexual object. With the relationship changed round, the same fate can await the daughter. In this sense the Oedipus complex may justly be regarded as the nucleus of the neuroses.
[1916-1917, 3402]

We find here for the first time, too, something like a constancy of sex in the persons who play a part in the phantasy. The children who are being beaten are almost invariably boys, in the phantasies of boys just as much as in those of girls. This characteristic is naturally not to be explained by any rivalry between the sexes, as otherwise of course in the phantasies of boys it would be girls who would be being beaten; and it has nothing to do with the sex of the child who was hated in the first phase. But it points to a complication in the case of girls. When they turn away from their incestuous love for their father, with its genital significance, they easily abandon their feminine role. They spur their 'masculinity complex' (Van Ophuijsen, 1917) into activity, and from that time forward only want to be boys. For that reason the whipping-boys who represent them are boys too. In both the cases of day-dreaming - one of which almost rose to the level of a work of art - the heroes were always young men; indeed women used not to come into these creations at all, and only made their first appearance after many years, and then in minor parts.
[1919e, 3652]
After this highly discursive introduction I am only able to present a very concise summary of the sexual history of the case under consideration. In childhood the girl had passed through the normal attitude characteristic of the feminine Oedipus complex¹ in a way that was not at all remarkable, and had later also begun to substitute for her father a brother slightly older than herself. She did not remember any sexual traumas in early life, nor were any discovered by the analysis. Comparison of her brother's genital organs and her own, which took place about the beginning of the latency period (at five years old or perhaps a little earlier), left a strong impression on her and had far-reaching after-effects. There were very few signs pointing to infantile masturbation, or else the analysis did not go far enough to throw light on this point. The birth of a second brother when she was between five and six years old exercised no special influence upon her development. During the pre-pubertal years at school she gradually became acquainted with the facts of sex, and she received this knowledge with mixed feelings of lasciviousness and frightened aversion, in a way which may be called normal and was not exaggerated in degree. This amount of information about her seems meagre enough, nor can I guarantee that it is complete. It may be that the history of her youth was much richer in experiences; I do not know. As I have already said, the analysis was broken off after a short time, and therefore yielded an anamnesis not much more reliable than the other anamneses of homosexuals, which there is good cause to question. Further, the girl had never been neurotic, and came to the analysis without even one hysterical symptom, so that opportunities for investigating the history of her childhood did not present themselves so readily as usual. [1920a, 3845]

Along with the demolition of the Oedipus complex, the boy's object-cathexis of his mother must be given up. Its place may be filled by one of two things: either an identification with his mother or an intensification of his identification with his father. We are accustomed to regard the latter outcome as the more normal; it permits the affectionate relation to the mother to be in a measure retained. In this way the dissolution of the Oedipus complex would consolidate the masculinity in a boy's character. In a precisely analogous way, the outcome of the Oedipus attitude in a little girl may be an intensification of her identification with her mother (or the setting up of such an identification for the first time) - a result which will fix the child's feminine character. [1923b, 3966]

These identifications are not what we should have expected, since they do not introduce the abandoned object into the ego; but this alternative outcome may also occur, and is easier to observe in girls than in boys. Analysis very often shows that a little girl, after she has had to relinquish her father as a love-object, will bring her masculinity into prominence and identify herself with her father (that is, with the object which has been lost), instead of with her mother. This will clearly depend on whether the masculinity in her disposition - whatever that may consist in - is strong enough. [1923b, 3966]
It would appear, therefore, that in both sexes the relative strength of the masculine and feminine sexual dispositions is what determines whether the outcome of the Oedipus situation shall be an identification with the father or with the mother. This is one of the ways in which bisexuality takes a hand in the subsequent vicissitudes of the Oedipus complex. The other way is even more important. For one gets an impression that the simple Oedipus complex is by no means its commonest form, but rather represents a simplification or schematization which, to be sure, is often enough justified for practical purposes. Closer study usually discloses the more complete Oedipus complex, which is twofold, positive and negative, and is due to the bisexuality originally present in children: that is to say, a boy has not merely an ambivalent attitude towards his father and an affectionate object-choice towards his mother, but at the same time he also behaves like a girl and displays an affectionate feminine attitude to his father and a corresponding jealousy and hostility towards his mother. It is this complicating element introduced by bisexuality that makes it so difficult to obtain a clear view of the facts in connection with the earliest object-choices and identifications, and still more difficult to describe them intelligibly. It may even be that the ambivalence displayed in the relations to the parents should be attributed entirely to bisexuality and that it is not, as I have represented above, developed out of identification in consequence of rivalry.
[1923b, 3967]

Analytic observation enables us to recognize or guess these connections between the phallic organization, the Oedipus complex, the threat of castration, the formation of the super-ego and the latency period. These connections justify the statement that the destruction of the Oedipus complex is brought about by the threat of castration. But this does not dispose of the problem; there is room for a theoretical speculation which may upset the results we have come to or put them in a new light. Before we start along this new path, however, we must turn to a question which has arisen in the course of this discussion and has so far been left on one side. The process which has been described refers, as has been expressly said, to male children only. How does the corresponding development take place in little girls?
[1924d, 4089]

At this point our material - for some incomprehensible reason - becomes far more obscure and full of gaps. The female sex, too, develops an Oedipus complex, a super-ego and a latency period. May we also attribute a phallic organization and a castration complex to it? The answer is in the affirmative; but these things cannot be the same as they are in boys. Here the feminist demand for equal rights for the sexes does not take us far, for the morphological distinction is bound to find expression in differences of psychical development. 'Anatomy is Destiny', to vary a saying of Napoleon's. The little girl's clitoris behaves just like a penis to begin with; but, when she makes a comparison with a playfellow of the other sex, she perceives that she has 'come off badly' and she feels this as a wrong done to her and as a ground for inferiority. For a while still she consoles herself with the expectation that later on, when she grows older, she will acquire just as big an appendage as the boy's. Here the masculinity complex of women branches off. A female child, however, does not understand her lack of a penis as being a sex character; she explains it by assuming that at some earlier date she had possessed an equally large organ and had then lost it by castration. She seems not to extend this inference from herself to other, adult females, but, entirely on the lines of the phallic phase, to regard them as possessing large and complete - that is to say, male - genitals. The essential difference thus comes about that the girl accepts castration as an accomplished fact, whereas the boy fears the possibility of its occurrence.
[1924d, 4090]
The fear of castration being thus excluded in the little girl, a powerful motive also drops out for the setting-up of a super-ego and for the breaking-off of the infantile genital organization. In her, far more than in the boy, these changes seem to be the result of upbringing and of intimidation from outside which threatens her with a loss of love. The girl's Oedipus complex is much simpler than that of the small bearer of the penis; in my experience, it seldom goes beyond the taking of her mother's place and the adopting of a feminine attitude towards her father. Renunciation of the penis is not tolerated by the girl without some attempt at compensation. She slips - along the line of a symbolic equation, one might say - from the penis to a baby. Her Oedipus complex culminates in a desire, which is long retained, to receive a baby from her father as a gift - to bear him a child. One has an impression that the Oedipus complex is then gradually given up because this wish is never fulfilled. The two wishes - to possess a penis and a child - remain strongly cathexed in the unconscious and help to prepare the female creature for her later sexual role. The comparatively lesser strength of the sadistic contribution to her sexual instinct, which we may no doubt connect with the stunted growth of her penis, makes it easier in her case for the direct sexual trends to be transformed into aim-inhibited trends of an affectionate kind. It must be admitted, however, that in general our insight into these developmental processes in girls is unsatisfactory, incomplete and vague.

[1924d, 4090]

So far there has been no question of the Oedipus complex, nor has it up to this point played any part. But now the girl's libido slips into a new position along the line - there is no other way of putting it - of the equation 'penis-child'. She gives up her wish for a penis and puts in place of it a wish for a child: and with that purpose in view she takes her father as a love object. Her mother becomes the object of her jealousy. The girl has turned into a little woman. If I am to credit a single analytic instance, this new situation can give rise to physical sensations which would have to be regarded as a premature awakening of the female genital apparatus. When the girl's attachment to her father comes to grief later on and has to be abandoned, it may give place to an identification with him and the girl may thus return to her masculinity complex and perhaps remain fixated in it.

[1925j, 4154]

I have now said the essence of what I had to say: I will stop, therefore, and cast an eye over our findings. We have gained some insight into the prehistory of the Oedipus complex in girls. The corresponding period in boys is more or less unknown. In girls the Oedipus complex is a secondary formation. The operations of the castration complex precede it and prepare for it. As regards the relation between the Oedipus and castration complexes there is a fundamental contrast between the two sexes. Whereas in boys the Oedipus complex is destroyed by the castration complex, in girls it is made possible and led up to by the castration complex. This contradiction is cleared up if we reflect that the castration complex always operates in the sense implied in its subject-matter: it inhibits and limits masculinity and encourages femininity. The difference between the sexual development of males and females at the stage we have been considering is an intelligible consequence of the anatomical distinction between their genitals and of the psychical situation involved in it; it corresponds to the difference between a castration that has been carried out and one that has merely been threatened. In their essentials, therefore, our findings are self-evident and it should have been possible to foresee them.

[1925j, 4154]
In girls the motive for the demolition of the Oedipus complex is lacking. Castration has already had its effect, which was to force the child into the situation of the Oedipus complex. Thus the Oedipus complex escapes the fate which it meets with in boys: it may be slowly abandoned or dealt with by repression, or its effects may persist far into women's normal mental life. I cannot evade the notion (though I hesitate to give it expression) that for women the level of what is ethically normal is different from what it is in men. Their super-ego is never so inexorable, so impersonal, so independent of its emotional origins as we require it to be in men. Character traits which critics of every epoch have brought up against women - that they show less sense of justice than men, that they are less ready to submit to the great exigencies of life, that they are more often influenced in their judgements by feelings of affection or hostility - all these would be amply accounted for by the modification in the formation of their super-ego which we have inferred above. We must not allow ourselves to be deflected from such conclusions by the denials of the feminists, who are anxious to force us to regard the two sexes as completely equal in position and worth; but we shall, of course, willingly agree that the majority of men are also far behind the masculine ideal and that all human individuals, as a result of their bisexual disposition and of cross-inheritance, combine in themselves both masculine and feminine characteristics, so that pure masculinity and femininity remain theoretical constructions of uncertain content.

[1925j, 4155]

The turning-away from her mother is an extremely important step in the course of a little girl's development. It is more than a mere change of object. We have already described what takes place in it and the many motives put forward for it; we may now add that hand in hand with it there is to be observed a marked lowering of the active sexual impulses and a rise of the passive ones. It is true that the active trends have been affected by frustration more strongly; they have proved totally unrealizable and are therefore abandoned by the libido more readily. But the passive trends have not escaped disappointment either. With the turning-away from the mother clitoridal masturbation frequently ceases as well; and often enough when the small girl represses her previous masculinity a considerable portion of her sexual trends in general is permanently injured too. The transition to the father-object is accomplished with the help of the passive trends in so far as they have escaped the catastrophie. The path to the development of femininity now lies open to the girl, to the extent to which it is not restricted by the remains of the pre-Oedipus attachment to her mother which she has surmounted.

[1931b, 4603]
With the transference of the wish for a penis-baby on to her father, the girl has entered the situation of the Oedipus complex. Her hostility to her mother, which did not need to be freshly created, is now greatly intensified, for she becomes the girl’s rival, who receives from her father everything that she desires from him. For a long time the girl’s Oedipus complex concealed her pre-Oedipus attachment to her mother from our view, though it is nevertheless so important and leaves such lasting fixations behind it. For girls the Oedipus situation is the outcome of a long and difficult development; it is a kind of preliminary solution, a position of rest which is not soon abandoned, especially as the beginning of the latency period is not far distant. And we are now struck by a difference between the two sexes, which is probably momentous, in regard to the relation of the Oedipus complex to the castration complex. In a boy the Oedipus complex, in which he desires his mother and would like to get rid of his father as being a rival, develops naturally from the phase of his phallic sexuality. The threat of castration compels him, however, to give up that attitude. Under the impression of the danger of losing his penis, the Oedipus complex is abandoned, repressed and, in the most normal cases, entirely destroyed, and a severe super-ego is set up as its heir. What happens with a girl is almost the opposite. The castration complex prepares for the Oedipus complex instead of destroying it; the girl is driven out of her attachment to her mother through the influence of her envy for the penis and she enters the Oedipus situation as though into a haven of refuge. In the absence of fear of castration the chief motive is lacking which leads boys to surmount the Oedipus complex. Girls remain in it for an indeterminate length of time; they demolish it late and, even so, incompletely. In these circumstances the formation of the super-ego must suffer; it cannot attain the strength and independence which give it its cultural significance, and feminists are not pleased when we point out to them the effects of this factor upon the average feminine character.

[1933a, 4731]
But, whatever the character's later capacity for resisting the influences of abandoned object-cathexes may turn out to be, the effects of the first identifications made in earliest childhood will be general and lasting. This leads us back to the origin of the ego ideal; for behind it there lies hidden an individual's first and most important identification, his identification with the father in his own personal prehistory.¹ This is apparently not in the first instance the consequence or outcome of an object-cathexis; it is a direct and immediate identification and takes place earlier than any object-cathexis. But the object-choices belonging to the first sexual period and relating to the father and mother seem normally to find their outcome in an identification of this kind, and would thus reinforce the primary one.

¹ Perhaps it would be safer to say 'with the parents'; for before a child has arrived at definite knowledge of the difference between the sexes, the lack of a penis, it does not distinguish in value between its father and its mother. I recently came across the instance of a young married woman whose story showed that, after noticing the lack of a penis in herself, she had supposed it to be absent not in all women, but only in those whom she regarded as inferior, and had still supposed that her mother possessed one. In order to simplify my presentation I shall discuss only identification with the father.

The broad general outcome of the sexual phase dominated by the Oedipus complex may, therefore, be taken to be the forming of a precipitate in the ego, consisting of these two identifications in some way united with each other. This modification of the ego retains its special position; it confronts the other contents of the ego as an ego ideal or super-ego.

The super-ego is, however, not simply a residue of the earliest object-choices of the id; it also represents an energetic reaction-formation against those choices. Its relation to the ego is not exhausted by the precept: 'You ought to be like this (like your father).' It also comprises the prohibition: 'You may not be like this (like your father) - that is, you may not do all that he does; some things are his prerogative.' This double aspect of the ego ideal derives from the fact that the ego ideal had the task of repressing the Oedipus complex; indeed, it is to that revolutionary event that it owes its existence. Clearly the repression of the Oedipus complex was no easy task. The child's parents, and especially his father, were perceived as the obstacle to a realization of his Oedipus wishes; so his infantile ego fortified itself for the carrying out of the repression by erecting this same obstacle within itself. It borrowed strength to do this, so to speak, from the father, and this loan was an extraordinarily momentous act. The super-ego retains the character of the father, while the more powerful the Oedipus complex was and the more rapidly it succumbed to repression (under the influence of authority, religious teaching, schooling and reading), the stricter will be the domination of the super-ego over the ego later on - in the form of conscience or perhaps of an unconscious sense of guilt. I shall presently bring forward a suggestion about the source of its power to dominate in this way - the source, that is, of its compulsive character which manifests itself in the form of a categorical imperative.
