But may one not take objection to the findings of an enquiry which ascribes to accidental circumstances of his parental constellation so decisive an influence on a person's fate - which, for example, makes Leonardo's fate depend on his illegitimate birth and on the barrenness of his first stepmother Donna Albiera? I think one has no right to do so. If one considers chance to be unworthy of determining our fate, it is simply a relapse into the pious view of the Universe which Leonardo himself was on the way to overcoming when he wrote that the sun does not move. We naturally feel hurt that a just God and a kindly providence do not protect us better from such influences during the most defenceless period of our lives. At the same time we are all too ready to forget that in fact everything to do with our life is chance, from our origin out of the meeting of spermatozoon and ovum onwards - chance which nevertheless has a share in the law and necessity of nature, and which merely lacks any connection with our wishes and illusions. The apportioning of the determining factors of our life between the 'necessities' of our constitution and the 'chances' of our childhood may still be uncertain in detail; but in general it is no longer possible to doubt the importance precisely of the first years of our childhood. We all still show too little respect for Nature which (in the obscure words of Leonardo which recall Hamlet's lines) 'is full of countless causes ["ragioni"] that never enter experience'.¹

¹[1910c, 2304]
In place of a single sick person let us put society - suffering as a whole from neuroses, though composed of sick and healthy members; and in place of individual acceptance in the one case let us put general recognition in the other. A little reflection will then show you that this substitution cannot in any way alter the outcome. The success which the treatment can have with the individual must occur equally with the community. Sick people will not be able to let their various neuroses become known - their anxious over-tenderness which is meant to conceal their hatred, their agoraphobia which tells of disappointed ambition, their obsessive actions which represent self-reproaches for evil intentions and precautions against them - if all their relatives and every stranger from whom they wish to conceal their mental processes know the general meaning of such symptoms, and if they themselves know that in the manifestations of their illness they are producing nothing that other people cannot instantly interpret. The effect, however, will not be limited to the concealment of the symptoms which, incidentally, it is often impossible to carry out; for this necessity for concealment destroys the use of being ill. Disclosure of the secret will have attacked, at its most sensitive point, the 'aetiological equation' from which neuroses arise - it will have made the gain from the illness illusory; and consequently the final outcome of the changed situation brought about by the physician's indiscretion can only be that the production of the illness will be brought to a stop.

[1910d, 2312]

Yet another line of thought extending into organic research branches off from psycho-analysis. We may ask ourselves whether the suppression of sexual component instincts which is brought about by environmental influences is sufficient in itself to call up functional disturbances in organs, or whether special constitutional conditions must be present in order that the organs may be led to an exaggeration of their erotogenic role and consequently provoke repression of the instincts. We should have to see in those conditions the constitutional part of the disposition to fall ill of psychogenic and neurotic disorders. This is the factor to which, as applied to hysteria, I gave the provisional name of 'somatic compliance'.

[1910i, 2371]

It must be understood that each individual, through the combined operation of his innate disposition and the influences brought to bear on him during his early years, has acquired a specific method of his own in his conduct of his erotic life - that is, in the preconditions to falling in love which he lays down, in the instincts he satisfies and the aims he sets himself in the course of it. This produces what might be described as a stereotype plate (or several such), which is constantly repeated - constantly reprinted afresh - in the course of the person's life, so far as external circumstances and the nature of the love objects accessible to him permit, and which is certainly not entirely insusceptible to change in the face of recent experiences. Now, our observations have shown that only a portion of these impulses which determine the course of erotic life have passed through the full process of psychical development. That portion is directed towards reality, is at the disposal of the conscious personality, and forms a part of it. Another portion of the libidinal impulses has been held up in the course of development; it has been kept away from the conscious personality and from reality, and has either been prevented from further expansion except in phantasy or has remained wholly in the unconscious so that it is unknown to the personality's consciousness. If someone's need for love is not entirely satisfied by reality, he is bound to approach every new person whom he meets with libidinal anticipatory ideas; and it is highly probable that both portions of his libido, the portion that is capable of becoming conscious as well as the unconscious one, have a share in forming that attitude.

[1912b, 2457]
I take this opportunity of defending myself against the mistaken charge of having denied the importance of innate (constitutional) factors because I have stressed that of infantile impressions. A charge such as this arises from the restricted nature of what men look for in the field of causation: in contrast to what ordinarily holds good in the real world, people prefer to be satisfied with a single causative factor. Psycho-analysis has talked a lot about the accidental factors in aetiology and little about the constitutional ones; but that is only because it was able to contribute something fresh to the former, while, to begin with, it knew no more than was commonly known about the latter. We refuse to posit any contrast in principle between the two sets of aetiological factors; on the contrary, we assume that the two sets regularly act jointly in bringing about the observed result. Δαιμων και Τυχη [Endowment and Chance] determine a man’s fate - rarely or never one of these powers alone. The amount of aetiological effectiveness to be attributed to each of them can only be arrived at in every individual case separately. These cases may be arranged in a series according to the varying proportion in which the two factors are present, and this series will no doubt have its extreme cases. We shall estimate the share taken by constitution or experience differently in individual cases according to the stage reached by our knowledge; and we shall retain the right to modify our judgement along with changes in our understanding. Incidentally, one might venture to regard constitution itself as a precipitate from the accidental effects produced on the endlessly long chain of our ancestors.

[1912b, 2457]

Our work on the question of the disposition to neurotic affections has added the ‘infantile’ factor to the somatic and hereditary ones hitherto recognized. Psycho-analysis was obliged to trace back patients’ mental life to their early infancy, and the conclusion was reached that inhibitions of mental development (‘infantilisms’) present a disposition to neurosis. In particular, we have learnt from our investigations of sexual life that there really is such a thing as ‘infantile sexuality’, that the sexual instinct is made up of many components and passes through a complicated course of development, the final outcome of which, after many restrictions and transformations, is the ‘normal’ sexuality of adults. The puzzling perversions of the sexual instinct which occur in adults appear to be either inhibitions of development, fixations or lop-sided growths. Thus neuroses are the negative of perversions.

[1913m, 2547]

A young man who has hitherto satisfied his libido by means of phantasies ending in masturbation, and who now seeks to replace a régime approximating to auto-erotism by the choice of a real object - or a girl who has given her whole affection to her father or brother and who must now, for the sake of a man who is courting her, allow her hitherto unconscious incestuous libidinal wishes to become conscious - or a married woman who would like to renounce her polygamous inclinations and phantasies of prostitution so as to become a faithful consort to her husband and a perfect mother to her child - all of these fall ill from the most laudable efforts, if the earlier fixations of their libido are powerful enough to resist a displacement; and this point will be decided, once again, by the factors of disposition, constitution and infantile experience. All of them, it might be said, meet with the fate of the little tree in the Grimms’ fairy tale, which wished it had different leaves. From the hygienic point of view - which, to be sure, is not the only one to be taken into account - one could only wish for them that they had continued to be undeveloped, as inferior and as useless as they were before they fell ill. The change which the patients strive after, but bring about only imperfectly or not at all, invariably has the value of a step forward from the point of view of real life. It is otherwise if we apply ethical standards: we see people falling ill just as often when they discard an ideal as when they seek to attain it.

[1912c, 2562]
A certain practical importance may readily be allowed to these types of onset. They are to be met with in their pure form, indeed, in individual cases; we should not have noticed the third and fourth types if they had not in some subjects constituted the sole precipitating causes of the illness. The first type keeps before our eyes the extraordinarily powerful influence of the external world, and the second the no less important influence - which opposes the former one - of the subject's peculiar individuality. Pathology could not do justice to the problem of the precipitating factors in the neuroses so long as it was merely concerned with deciding whether those affections were of an 'endogenous' or 'exogenous' nature. It was bound to meet every observation which pointed to the importance of abstinence (in the widest sense of the word) as a precipitating cause with the objection that other people tolerate the same experiences without falling ill. If, however, it sought to lay stress on the peculiar individuality of the subject as being the essential factor decisive between illness and health, it was obliged to put up with the proviso that people possessing such a peculiarity can remain healthy indefinitely, just so long as they are able to retain that peculiarity. Psycho-analysis has warned us that we must give up the unfruitful contrast between external and internal factors, between experience and constitution, and has taught us that we shall invariably find the cause of the onset of neurotic illness in a particular psychical situation which can be brought about in a variety of ways.

Like the majority of you, I am inclined to refuse to give a general answer to the question. It partly coincides with another, more comprehensive question: when does sexual activity in general become pathogenic for particular people? If we put this consideration on one side, we are left with a question of detail relating to the characteristics of masturbation in so far as it represents a special manner and form of sexual satisfaction. Here it would be to the point to repeat what is already known to us and has been discussed in other connections - to assess the influence of the quantitative factor and of the combined operation of several pathogenic factors. Above all, however, we should have to leave a wide field for what are known as an individual's constitutional dispositions. But it must be confessed that dealing with these is an awkward business. For we are in the habit of forming our opinion of individual dispositions ex post facto: we attribute this or that disposition to people after the event, when they have already fallen ill. We have no method of discovering it beforehand. We behave, in fact, like the Scottish King in one of Victor Hugo's novels, who boasted of an infallible method of recognizing witchcraft. He had the accused woman stewed in boiling water and then tasted the broth. He then judged according to the taste: 'Yes, that was a witch', or 'No, that was not one.'

What do we know so far about this problem? Strictly speaking, only one single general proposition can be asserted on the subject with certainty. It will be recalled that we divide the pathogenic determinants concerned in the neuroses into those which a person brings along with him into his life and those which life brings to him - the constitutional and the accidental - by whose combined operation alone the pathogenic determinant is as a rule established. The general proposition, then, which I have alluded to above, lays it down that the grounds for determining the choice of neurosis are entirely of the former kind - that is, that they are in the nature of dispositions and are independent of experiences which operate pathogenically.
There is yet another way in which philosophy can derive a stimulus from psycho-analysis, and that is by itself becoming a subject of psycho-analytic research. Philosophical theories and systems have been the work of a small number of men of striking individuality. In no other science does the personality of the scientific worker play anything like so large a part as in philosophy. And now for the first time psycho-analysis enables us to construct a 'psychography' of a personality. (See the sociological section below, p. 2824.) It teaches us to recognize the affective units - the complexes dependent on instincts - whose presence is to be presumed in each individual, and it introduces us to the study of the transformations and end-products arising from these instinctual forces. It reveals the relations of a person's constitutional disposition and the events of his life to the achievements open to him owing to his peculiar gifts. It can conjecture with more or less certainty from an artist's work the intimate personality that lies behind it. In the same way, psycho-analysis can indicate the subjective and individual motives behind philosophical theories which have ostensibly sprung from impartial logical work, and can draw a critic's attention to the weak spots in the system. It is not the business of psycho-analysis, however, to undertake such criticism itself, for, as may be imagined, the fact that a theory is psychologically determined does not in the least invalidate its scientific truth. [1913j, 2815]

On the other hand, psycho-analysis has fully demonstrated the part played by social conditions and requirements in the causation of neurosis. The forces which, operating from the ego, bring about the restriction and repression of instinct owe their origin essentially to compliance with the demands of civilization. A constitution and a set of childhood experiences which, in other cases, would inevitably lead to a neurosis will produce no such result where this compliance is absent or where these demands are not made by the social circle in which the particular individual is placed. The old assertion that the increase in nervous disorders is a product of civilization is at least a half-truth. Young people are brought into contact with the demands of civilization by upbringing and example; and if instinctual repression occurs independently of these two factors, it is a plausible hypothesis to suppose that a primaeval and prehistoric demand has at last become part of the organized and inherited endowment of mankind. A child who produces instinctual repressions spontaneously is thus merely repeating a part of the history of civilization. What is today an act of internal restraint was once an external one, imposed, perhaps, by the necessities of the moment; and, in the same way, what is now brought to bear upon every growing individual as an external demand of civilization may some day become an internal disposition to repression. [1913j, 2824]

With this sexual activity of the first years of childhood the inherited constitution of the individual also came into its own. Disposition and experience are here linked up in an indissoluble aetiological unity. For disposition exaggerates impressions which would otherwise have been completely commonplace and have had no effect, so that they become traumas giving rise to stimulations and fixations; while experiences awaken factors in the disposition which, without them, might have long remained dormant and perhaps never have developed. The last word on the subject of traumatic aetiology was spoken later by Abraham, when he pointed out that the sexual constitution which is peculiar to children is precisely calculated to provoke sexual experiences of a particular kind - namely traumas. [1914d, 2887]
I take the opportunity here of warning you against taking sides in a quite unnecessary dispute. In scientific matters people are very fond of selecting one portion of the truth, putting it in the place of the whole and of then disputing the rest, which is no less true, in favour of this one portion. In just this way a number of schools of opinion have already split off from the psychoanalytic movement, some of which recognize the egoistic instincts while disavowing the sexual ones, and others attribute importance to the influence of the real tasks of life while overlooking the individual's past - and others besides. Now here we have a similar occasion for pointing a contrast and starting a controversy. Are neuroses exogenous or endogenous illnesses? Are they the inevitable result of a particular constitution or the product of certain detrimental (traumatic) experiences in life? More particularly, are they brought about by fixation of the libido (and the other features of the sexual constitution) or by the pressure of frustration? This dilemma seems to me no more sensible on the whole than another that I might put to you: does a baby come about through being begotten by its father or conceived by its mother? Both determinants are equally indispensable, as you will justly reply. In the matter of the causation of the neuroses the relation, if not precisely the same, is very similar. As regards their causation, instances of neurotic illness fall into a series within which the two factors - sexual constitution and experience, or, if you prefer it, fixation of the libido and frustration - are represented in such a manner that if there is more of the one there is less of the other. At one end of the series are the extreme cases of which you could say with conviction: these people, in consequence of the singular development of their libido, would have fallen ill in any case, whatever they had experienced and however carefully their lives had been sheltered. At the other end there are the cases, as to which, on the contrary, you would have had to judge that they would certainly have escaped falling ill if their lives had not brought them into this or that situation. In the cases lying within the series a greater or lesser amount of predisposition in the sexual constitution is combined with a lesser or greater amount of detrimental experience in their lives. Their sexual constitution would not have led them into a neurosis if they had not had these experiences, and these experiences would not have had a traumatic effect on them if their libido had been otherwise disposed. In this series I can perhaps allow a certain preponderance in significance to the predisposing factors; but even that admission depends on how far you choose to extend the frontiers of neurotic illness.

I propose, Gentlemen, that we should name a series of this kind a 'complemental series', and I forewarn you that we shall have occasion to construct others of the same kind.
Where, then, does the libido find the fixations which it requires in order to break through the repressions? In the activities and experiences of infantile sexuality, in the abandoned component trends, in the objects of childhood which have been given up. It is to them, accordingly, that the libido returns. The significance of this period of childhood is twofold: on the one hand, during it the instinctual trends which the child has inherited with his innate disposition first become manifest, and secondly, others of his instincts are for the first time awakened and made active by external impressions and accidental experiences. There is no doubt, I think, that we are justified in making this twofold division. The manifestation of the innate disposition is indeed not open to any critical doubts, but analytic experience actually compels us to assume that purely chance experiences in childhood are able to leave fixations of the libido behind them. Nor do I see any theoretical difficulty in this. Constitutional dispositions are also undoubtedly after-effects of experiences by ancestors in the past; they too were once acquired. Without such acquisition there would be no heredity. And is it conceivable that acquisition such as this, leading to inheritance, would come to an end precisely with the generation we are considering? The significance of infantile experiences should not be totally neglected, as people like doing, in comparison with the experiences of the subject's ancestors and of his own maturity; on the contrary, they call for particular consideration. They are all the more momentous because they occur in times of incomplete development and are for that very reason liable to have traumatic effects. The studies on developmental mechanics by Roux and others have shown that the prick of a needle into an embryonic germinial layer in the act of cell-division results in a severe disturbance of development. The same injury inflicted on a larval or fully grown animal would do no damage. [1916-1917, 3419]

Thus fixation of the libido in the adult, which we introduced into the aetiological equation of neurosis as representing the constitutional factor, now falls, for our purposes, into two further parts: the inherited constitution and the disposition acquired in early childhood. As we all know, a diagram is certain of a sympathetic reception from students. So I will summarize the position diagrammatically:

Causation of neurosis = Disposition due to Fixation of Libido + Accidental Experience (Traumatic)

Sexual Constitution                                          Infantile Experience
(Prehistoric Experience)

[1916-1917, 3420]

The hereditary sexual constitution presents us with a great variety of dispositions, according as one component instinct or another, alone or in combination with others, is inherited in particular strength. The sexual constitution forms once again, together with the factor of infantile experience, a 'complementary series' exactly similar to the one we first came to know between disposition and the accidental experience of the adult. In both of them we find the same extreme cases and the same relations between the two factors concerned. And here the question suggests itself of whether the most striking kinds of libidinal regressions - those to earlier stages of the sexual organization - may not be predominantly determined by the hereditary constitutional factor. But it is best to postpone answering this question till we have been able to take a wider range of forms of neurotic illness into account. [1916-1917, 3420]
These facts have a certain interest from the point of view of education, which plans the prevention of neuroses by intervening at an early stage in children's sexual development. So long as one focuses attention principally on infantile sexual experiences, one must suppose that one has done everything for the prophylaxis of nervous illnesses by taking care that the child's development is delayed and that it is spared experiences of the sort. We already know, however, that the preconditions for the causation of neuroses are complex and cannot be influenced in general if we take account of only a single factor. Strict protection of the young loses value because it is powerless against the constitutional factor. Besides, it is more difficult to carry out than educationists imagine and it brings with it two fresh dangers which must not be underestimated: the fact that it may achieve too much - that it may encourage an excess of sexual repression, with damaging results, and the fact that it may send the child out into life without any defence against the onrush of sexual demands that is to be looked for at puberty. Thus it remains extremely doubtful how far prophylaxis in childhood can be carried with advantage and whether an altered attitude to the immediate situation may not offer a better angle of approach for the prevention of neuroses.

The only impression we gain is that these events of childhood are somehow demanded as a necessity, that they are among the essential elements of a neurosis. If they have occurred in reality, so much to the good; but if they have been withheld by reality, they are put together from hints and supplemented by phantasy. The outcome is the same, and up to the present we have not succeeded in pointing to any difference in the consequences, whether phantasy or reality has had the greater share in these events of childhood. Here we simply have once again one of the complemental relations that I have so often mentioned; moreover it is the strangest of all we have met with. Whence comes the need for these phantasies and the material for them? There can be no doubt that their sources lie in the instincts; but it has still to be explained why the same phantasies with the same content are created on every occasion. I am prepared with an answer which I know will seem daring to you. I believe these primal phantasies, as I should like to call them, and no doubt a few others as well, are a phylogenetic endowment. In them the individual reaches beyond his own experience into primeval experience at points where his own experience as been too rudimentary. It seems to me quite possible that all the things that are told to us to-day in analysis as phantasy - the seduction of children, the inflaming of sexual excitement by observing parental intercourse, the threat of castration (or rather castration itself) - were once real occurrences in the primeval times of the human family, and that children in their phantasies are simply filling in the gaps in individual truth with prehistoric truth. I have repeatedly been led to suspect that the psychology of the neuroses has stored up in it more of the antiquities of human development than any other source.
You will no doubt have observed that in these last discussions I have introduced a fresh factor into the structure of the aetiological chain - namely the quantity, the magnitude, of the energies concerned. We have still to take this factor into account everywhere. A purely qualitative analysis of the aetiological determinants is not enough. Or, to put it another way, a merely dynamic view of these mental processes is insufficient; an economic line of approach is also needed. We must tell ourselves that the conflict between two trends does not break out till certain intensities of cathexis have been reached, even though the determinants for it have long been present so far as their subject-matter is concerned. In the same way, the pathogenic significance of the constitutional factors must be weighed according to how much more of one component instinct than of another is present in the inherited disposition. It may even be supposed that the disposition of all human beings is qualitatively alike and that they differ only owing to these quantitative conditions. The quantitative factor is no less decisive as regards capacity to resist neurotic illness. It is a matter of what quota of unemployed libido a person is able to hold in suspension and of how large a fraction of his libido he is able to divert from sexual to sublimated aims. The ultimate aim of mental activity, which may be described qualitatively as an endeavour to obtain pleasure and avoid unpleasure, emerges, looked at from the economic point of view, as the task of mastering the amounts of excitation (mass of stimuli) operating in the mental apparatus and of keeping down their accumulation which creates unpleasure.

If, then, there are children who come some way to meet this education in anxiety, and who go on to find dangers themselves that they have not been warned against, this is sufficiently explained by the fact that they have a greater amount of innate libidinal need in their constitution or have been prematurely spoiled by libidinal satisfaction. It is not to be wondered at if such children include, too, the later neurotics: as we know, what most facilitates the development of a neurosis is an incapacity to tolerate a considerable damming-up of libido over any great length of time. You will observe that here once more the constitutional factor comes into its rights - and these, indeed, we have never sought to dispute. We are only on our guard against those who in its favour neglect all other claims, and who introduce the constitutional factor at points at which the combined results of observation and analysis show that it does not belong or must take the last place.
Think it over! You have learnt all that is essential about the determinants of falling ill as well as all the factors that come into effect after the patient has fallen ill. Where do these leave room for any therapeutic influence? In the first place there is hereditary disposition. We have not talked about it very often because it is emphatically stressed from other directions and we have nothing new to say about it. But do not suppose that we underestimate it; precisely as therapists we come to realize its power clearly enough. In any case we can do nothing to alter it; we too must take it as something given, which sets a limit to our efforts. Next there is the influence of early experiences in childhood, to which we are in the habit of giving prominence in analysis: they belong to the past and we cannot undo them. Then comes everything that we have summarized as ‘real frustration’ - the misfortunes of life from which arise deprivation of love, poverty, family quarrels, ill-judged choice of a partner in marriage, unfavourable social circumstances, and the strictness of the ethical standards to whose pressure the individual is subject. Here, to be sure, there would be handles enough for a very effective therapy, but it would have to be of the kind which Viennese folklore attributes to the Emperor Joseph - the benevolent interference of a powerful personage before whose will people bow and difficulties vanish. But who are we, that we should be able to adopt benevolence of this kind as an instrument of our therapy? Poor ourselves and socially powerless, and compelled to earn our livelihood from our medical activity, we are not even in a position to extend our efforts to people without means, as other doctors with other methods of treatment are after all able to do. Our therapy is too time-consuming and too laborious for that to be possible. Perhaps, however, you are clutching at one of the factors I have mentioned and believe that there you have found the point at which our influence can make its attack. If the ethical restrictions demanded by society play a part in the deprivation imposed on the patient, treatment can, after all, give him the courage, or perhaps a direct injunction, to disregard those barriers and achieve satisfaction and recovery while forgoing the fulfilment of an ideal that is exalted, but so often not adhered to, by society. The patient will thus become healthy by ‘living a full life’ sexually. This, it is true, casts a shadow on analytic treatment for not serving general morality. What it has given to the individual it will have taken from the community.

[1916-1917, 3475]

The distinction between nervous health and neurosis is thus reduced to a practical question and is decided by the outcome - by whether the subject is left with a sufficient amount of capacity for enjoyment and of efficiency. It probably goes back to the relative sizes of the quota of energy that remains free and of that which is bound by repression, and is of a quantitative not of a qualitative nature. I need not tell you that this discovery is the theoretical justification for our conviction that neuroses are in principle curable in spite of their being based on constitutional disposition.

[1916-1917, 3496]
I should like at this point to break off the story of my patient's childhood and say something of this sister, of her development and later fortunes, and of the influence she had on him. She was two years older than he was, and had always remained ahead of him. As a child she was boyish and unmanageable, but she then entered upon a brilliant intellectual development and distinguished herself by her acute and realistic powers of mind; she inclined in her studies to the natural sciences, but also produced imaginative writings of which her father had a high opinion. She was mentally far superior to her numerous early admirers, and used to make jokes at their expense. In her early twenties, however, she began to be depressed, complained that she was not good-looking enough, and withdrew from all society. She was sent to travel in the company of an acquaintance, an elderly lady, and after her return told a number of most improbable stories of how she had been ill-treated by her companion, but remained with her affections obviously fixed upon her alleged tormentor. While she was on a second journey, soon afterwards, she poisoned herself and died far away from her home. Her disorder is probably to be regarded as the beginning of a dementia praecox. She was one of the proofs of the conspicuously neuropathic heredity in her family, but by no means the only one. An uncle, her father's brother, died after long years of life as an eccentric, with indications pointing to the presence of a severe obsessional neurosis; while a good number of collateral relatives were and are afflicted with less serious nervous complaints.

[1918b, 3514]

At an earlier stage in the discussion we were brought up against an ambiguity in regard to the patient's predilection for female nates and for sexual intercourse in the posture in which they are especially prominent. It seemed necessary to trace this predilection back to the intercourse which he had observed between his parents, while at the same time a preference of this kind is a general characteristic of archaic constitutions which are predisposed to an obsessional neurosis. But the contradiction is easily resolved if we regard it as a case of overdetermination. The person who was the subject of his observation of this posture during intercourse was, after all, his father in the flesh, and it may also have been from him that he had inherited this constitutional predilection. Neither his father's subsequent illness nor his family history contradicts this; as has been mentioned already, a brother of his father's died in a condition which must be regarded as the outcome of a severe obsessional disorder.

[1918b, 3542]

Once we have admitted the idea of a fusion of the two classes of instincts with each other, the possibility of a - more or less complete - 'defusion' of them forces itself upon us. The sadistic component of the sexual instinct would be a classical example of a serviceable instinctual fusion; and the sadism which has made itself independent as a perversion would be typical of a defusion, though not of one carried to extremes. From this point we obtain a view of a great domain of facts which has not before been considered in this light. We perceive that for purposes of discharge the instinct of destruction is habitually brought into the service of Eros; we suspect that the epileptic fit is a product and indication of an instinctual defusion; and we come to understand that instinctual defusion and the marked emergence of the death instinct call for particular consideration among the effects of some severe neuroses - for instance, the obsessional neuroses. Making a swift generalization, we might conjecture that the essence of a regression of libido (e.g. from the genital to the sadistic-anal phase) lies in a defusion of instincts, just as, conversely, the advance from the earlier phase to the definitive genital one would be conditioned by an accession of erotic components. The question also arises whether ordinary ambivalence, which is so often unusually strong in the constitutional disposition to neurosis, should not be regarded as the product of a defusion; ambivalence, however, is such a fundamental phenomenon that it more probably represents an instinctual fusion that has not been completed.

[1923b, 3975]
It remains to be seen whether this construction will turn out to be serviceable. Although it arose from a desire to fix some of the most important theoretical ideas of psycho-analysis, it goes far beyond psycho-analysis. I have repeatedly heard it said contemptuously that it is impossible to take a science seriously whose most general concepts are as lacking in precision as those of libido and of instinct in psycho-analysis. But this reproach rests on a complete misconception of the facts. Clear basic concepts and sharply drawn definitions are only possible in the mental sciences in so far as the latter seek to fit a region of facts into the frame of a logical system. In the natural sciences, of which psychology is one, such clear-cut general concepts are superfluous and indeed impossible. Zoology and Botany did not start from correct and adequate definitions of an animal and a plant; to this very day biology has been unable to give any certain meaning to the concept of life. Physics itself, indeed, would never have made any advance if it had had to wait until its concepts of matter, force, gravitation, and so on, had reached the desirable degree of clarity and precision. The basic ideas or most general concepts in any of the disciplines of science are always left indeterminate at first and are only explained to begin with by reference to the realm of phenomena from which they were derived; it is only by means of a progressive analysis of the material of observation that they can be made clear and can find a significant and consistent meaning. I have always felt it as a gross injustice that people have refused to treat psycho-analysis like any other science. This refusal found an expression in the raising of the most obstinate objections. Psycho-analysis was constantly reproached for its incompleteness and insufficiencies; though it is plain that a science based upon observation has no alternative but to work out its findings piecemeal and to solve its problems step by step. Again, when I endeavoured to obtain for the sexual function the recognition which had so long been withheld from it, psycho-analytic theory was branded as 'pan-sexualism'. And when I laid stress on the hitherto neglected importance of the part played by the accidental impressions of early youth, I was told that psycho-analysis was denying constitutional and hereditary factors - a thing which I had never dreamt of doing. It was a case of contradiction at any price and by any methods. [1925d, 4233]

Obsessional neurosis is unquestionably the most interesting and repaying subject of analytic research. But as a problem it has not yet been mastered. It must be confessed that, if we endeavour to penetrate more deeply into its nature, we still have to rely upon doubtful assumptions and unconfirmed suppositions. Obsessional neurosis originates, no doubt, in the same situation as hysteria, namely, the necessity of fending off the libidinal demands of the Oedipus complex. Indeed, every obsessional neurosis seems to have a substratum of hysterical symptoms that have been formed at a very early stage. But it is subsequently shaped along quite different lines owing to a constitutional factor. The genital organization of the libido turns out to be feeble and insufficiently resistant, so that when the ego begins its defensive efforts the first thing it succeeds in doing is to throw back the genital organization (of the phallic phase), in whole or in part, to the earlier sadistic-anal level. This fact of regression is decisive for all that follows. [1926d, 4272]

Another possibility has to be considered. Perhaps regression is the result not of a constitutional factor but of a time-factor. It may be that regression is rendered possible not because the genital organization of the libido is too feeble but because the opposition of the ego begins too early, while the sadistic phase is at its height. I am not prepared to express a definite opinion on this point, but I may say that analytic observation does not speak in favour of such an assumption. It shows rather that, by the time an obsessional neurosis is entered upon, the phallic stage has already been reached. Moreover, the onset of this neurosis belongs to a later time of life than that of hysteria - to the second period of childhood, after the latency period has set in. In a woman patient whose case I was able to study and who was overtaken by this disorder at a very late date, it became clear that the determining cause of her regression and of the emergence of her obsessional neurosis was a real occurrence through which her genital life, which had up till then been intact, lost all its value.¹ [1926d, 4272]
It is not our business to criticize Rank's hypothesis in detail here. We have only to consider whether it helps to solve our particular problem. His formula - that those people become neurotic in whom the trauma of birth was so strong that they have never been able completely to abreact it - is highly disputable from a theoretical point of view. We do not rightly know what is meant by abreacting the trauma. Taken literally, it implies that the more frequently and the more intensely a neurotic person reproduces the effect of anxiety the more closely will he approach to mental health - an untenable conclusion. It was because it did not tally with the facts that I gave up the theory of abreaction which had played such a large part in the cathartic method. To lay so much stress, too, on the variability in the strength of the birth trauma is to leave no room for the legitimate claims of hereditary constitution as an aetiological factor. For this variability is an organic factor which operates in an accidental fashion in relation to the constitution and is itself dependent on many influences which might be called accidental - as, for instance, on timely assistance in child-birth. Rank's theory completely ignores constitutional factors as well as phylogenetic ones. If, however, we were to try to find a place for the constitutional factor by qualifying his statement with the proviso, let us say, that what is really important is the extent to which the individual reacts to the variable intensity of the trauma of birth, we should be depriving his theory of its significance and should be relegating the new factor introduced by him to a position of minor importance: the factor which decided whether a neurosis should supervene or not would lie in a different, and once more in an unknown, field.

[1926d, 4305]

Only let us hold fast to this: the nodal point and pivot of the whole situation is the relative strength of the ego organization. We shall then find it easy to complete our aetiological survey. As what may be called the normal causes of neurotic illness we already know the feebleness of the childhood ego, the task of dealing with the early sexual impulses and the effects of the more or less chance experiences of childhood. Is it not possible, however, that yet other factors play a part, derived from the time before the beginning of the child's life? For instance, an innate strength and unruliness of the instinctual life in the id, which from the outset sets the ego tasks too hard for it? Or a special developmental feebleness of the ego due to unknown reasons? Such factors must of course acquire an aetiological importance, in some cases a transcendent one. We have invariably to reckon with the instinctual strength of the id; if it has developed to excess, the prospects of our therapy are poor. We still know too little of the causes of a developmental inhibition of the ego. These then would be the cases of neurosis with an essentially constitutional basis. Without some such constitutional, congenital favouring factors a neurosis can, no doubt, scarcely come about.

[1926e, 4383]
(2) For cultural reasons the most intense repression falls upon the sexual instincts; but it is precisely in connection with them that repression most easily miscarries, so that neurotic symptoms are found to be substitutive satisfactions of repressed sexuality. The belief that in man sexual life begins only at puberty is incorrect. On the contrary, signs of it can be detected from the beginning of extra-uterine existence; it reaches a first culminating point at or before the fifth year ('early period'), after which it is inhibited or interrupted ('latency period') until the age of puberty, which is the second climax of its development. This diphasic onset of sexual development seems to be distinctive of the genus Homo. All experiences during the first period of childhood are of the greatest importance to the individual, and in combination with his inherited sexual constitution form the dispositions for the subsequent development of character and disease. It is wrong to make sexuality coincide with 'genitality'. The sexual instincts pass through a complicated course of development, and it is only at the end of it that the 'primacy of the genital zones' is attained. Before this there are a number of 'pregenital' organizations of the libido - points at which it may become 'fixated' and to which, in the event of subsequent repression, it will return ('regression'). The infantile fixations of the libido are what determine the form of any later neurosis. Thus the neuroses are to be regarded as inhibitions in the development of the libido. There are no specific causes of nervous disorders; the question whether a conflict finds a healthy solution or leads to a neurotic inhibition of function depends upon quantitative considerations.

[1926f, 4405]

Which of these two views is correct? The earlier one, which genetically seemed so unassailable, or the newer one, which rounds off the theory in such a welcome fashion? Clearly, and by the evidence, too, of direct observations, both are justified. They do not contradict each other, and they even coincide at one point, for the child's revengeful aggressiveness will be in part determined by the amount of punitive aggression which he expects from his father. Experience shows, however, that the severity of the super-ego which a child develops in no way corresponds to the severity of treatment which he has himself met with.¹ The severity of the former seems to be independent of that of the latter. A child who has been very leniently brought up can acquire a very strict conscience. But it would also be wrong to exaggerate this independence; it is not difficult to convince oneself that severity of upbringing does also exert a strong influence on the formation of the child's super-ego. What it amounts to is that in the formation of the super-ego and the emergence of a conscience innate constitutional factors and influences from the real environment act in combination. This is not at all surprising; on the contrary, it is a universal aetiological condition for all such processes.²

[1930a, 4520]

Fenichel (1930) rightly emphasizes the difficulty of recognizing in the material produced in analysis what parts of it represent the unchanged content of the pre-Oedipus phase and what parts have been distorted by regression (or in other ways). He does not accept Jeanne Lampl-de Groot's assertion of the little girl's active attitude in the phallic phase. He also rejects the 'displacement backwards' of the Oedipus complex proposed by Melanie Klein (1928), who places its beginnings as early as the commencement of the second year of life. This dating of it, which would also necessarily imply a modification of our view of all the rest of the child's development, does not in fact correspond to what we learn from the analyses of adults, and it is especially incompatible with my findings as to the long duration of the girl's pre-Oedipus attachment to her mother. A means of softening this contradiction is afforded by the reflection that we are not as yet able to distinguish in this field between what is rigidly fixed by biological laws and what is open to movement and change under the influence of accidental experience. The effect of seduction has long been familiar to us and in just the same way other factors - such as the date at which the child's brothers and sisters are born or the time when it discovers the difference between the sexes, or again its direct observations of sexual intercourse or its parents' behaviour in encouraging or repelling it - may hasten the child's sexual development and bring it to maturity.

[1931b, 4606]
One cannot very well doubt the importance of envy for the penis. You may take it as an instance of male injustice if I assert that envy and jealousy play an even greater part in the mental life of women than of men. It is not that I think these characteristics are absent in men or that I think they have no other roots in women than envy for the penis; but I am inclined to attribute their greater amount in women to this latter influence. Some analysts, however, have shown an inclination to depreciate the importance of this first instalment of penis-envy in the phallic phase. They are of opinion that what we find of this attitude in women is in the main a secondary structure which has come about on the occasion of later conflicts by regression to this early infantile impulse. This, however, is a general problem of depth psychology. In many pathological - or even unusual - instinctual attitudes (for instance, in all sexual perversions) the question arises of how much of their strength is to be attributed to early infantile fixations and how much to the influence of later experiences and developments. In such cases it is almost always a matter of complemental series such as we put forward in our discussion of the aetiology of the neuroses. Both factors play a part in varying amounts in the causation; a less on the one side is balanced by a more on the other. The infantile factor sets the pattern in all cases but does not always determine the issue, though it often does. Precisely in the case of penis-envy I should argue decidedly in favour of the preponderance of the infantile factor.

[1933a, 4727]
The recognition that most of our children pass through a neurotic phase in the course of their development carries with it the germ of a hygienic challenge. The question may be raised whether it would not be expedient to come to a child's help with an analysis even if he shows no signs of a disturbance, as a measure for safeguarding his health, just as to-day we inoculate healthy children against diphtheria without waiting to see if they fall ill of it. The discussion of this question has only an academic interest at present, but I may venture to consider it here. The mere suggestion would seem to the great bulk of our contemporaries to be a monstrous outrage, and in view of the attitude towards analysis of most people in a parental position any hope of putting through such an idea must be abandoned for the time being. Prophylaxis such as this against neurotic illness, which would probably be very effective, also presupposes a quite other constitution of society. The watchword for the application of psycho-analysis to education is to be found to-day elsewhere. Let us make ourselves clear as to what the first task of education is. The child must learn to control his instincts. It is impossible to give him liberty to carry out all his impulses without restriction. To do so would be a very instructive experiment for child-psychologists; but life would be impossible for the parents and the children themselves would suffer grave damage, which would show itself partly at once and partly in later years. Accordingly, education must inhibit, forbid and suppress, and this it has abundantly seen to in all periods of history. But we have learnt from analysis that precisely this suppression of instincts involves the risk of neurotic illness. As you will remember, we have examined in detail how this occurs. Thus education has to find its way between the Scylla of non-interference and the Charybdis of frustration. Unless this problem is entirely insoluble, an optimum must be discovered which will enable education to achieve the most and damage the least. It will therefore be a matter of deciding how much to forbid, at what times and by what means. And in addition we have to take into account the fact that the objects of our educational influence have very different innate constitutional dispositions, so that it is quite impossible that the same educational procedure can be equally good for all children. A moment's reflection tells us that hitherto education has fulfilled its task very badly and has done children great damage. If it discovers the optimum and carries out its task ideally, it can hope to wipe out one of the factors in the aetiology of falling ill - the influence of the accidental traumas of childhood. It cannot in any case get rid of the other factor - the power of an insubordinate instinctual constitution. If now we consider the difficulties that confront the educator - how he has to recognize the child's constitutional individuality, to infer from small indications what is going on in his immature mind, to give him the right amount of love and yet to maintain an effective degree of authority - we shall tell ourselves that the only appropriate preparation for the profession of educator is a thorough psycho-analytic training. It would be best that he should have been analysed himself, for, when all is said and done, it is impossible to assimilate analysis without experiencing it personally. The analysis of teachers and educators seems to be a more efficacious prophylactic measure than the analysis of children themselves, and there are less difficulties in the way of putting it into practice.

[1933a, 4749]
Compared with the other psychotherapeutic procedures psycho-analysis is beyond any doubt the most powerful. It is just and fair, too, that this should be so for it is also the most laborious and time-consuming; it would not be used on slight cases. In suitable cases it is possible by its means to get rid of disturbances and bring about changes for which in pre-analytic times one would not have ventured to hope. But it has its very appreciable limits. The therapeutic ambition of some of my adherents has made the greatest efforts to overcome these obstacles so that every sort of neurotic disorder might be curable by psycho-analysis. They have endeavoured to compress the work of analysis into a shorter duration, to intensify transference so that it may be able to overcome any resistance, to unite other forms of influence with it so as to compel a cure. These efforts are certainly praiseworthy, but, in my opinion, they are vain. They bring with them, too, a danger of being oneself forced away from analysis and drawn into a boundless course of experimentation. The expectation that every neurotic phenomenon can be cured may, I suspect, be derived from the layman's belief that the neuroses are something quite unnecessary which have no right whatever to exist. Whereas in fact they are severe, constitutionally fixed illnesses, which rarely restrict themselves to only a few attacks but persist as a rule over long periods or throughout life. Our analytic experience that they can be extensively influenced, if the historical precipitating causes and accidental auxiliary factors of the illness can be dealt with, has led us to neglect the constitutional factor in our therapeutic practice, and in any case we can do nothing about it; but in theory we ought always to bear it in mind. The radical inaccessibility of the psychoses to analytic treatment should, in view of their close relationship to the neuroses, restrict our pretensions in regard to these latter. The therapeutic effectiveness of psycho-analysis remains cramped by a number of weighty and scarcely assailable factors. In the case of children, where one might count on the greatest successes, the difficulties are the external ones connected with their relation to their parents, though these difficulties are after all a necessary part of being a child. In the case of adults the difficulties arise in the first instance from two factors: the amount of psychical rigidity present and the form of the illness with all that that covers in the way of deeper determinants.

[1933a, 4752]

We give the name of traumas to those impressions, experienced early and later forgotten, to which we attach such great importance in the aetiology of the neuroses. We may leave on one side the question of whether the aetiology of the neuroses in general may be regarded as traumatic. The obvious objection to this is that it is not possible in every case to discover a manifest trauma in the neurotic subject's earliest history. We must often resign ourselves to saying that all we have before us is an unusual, abnormal reaction to experiences and demands which affect everyone, but are worked over and dealt with by other people in another manner which may be called normal. When we have nothing else at our disposal for explaining a neurosis but hereditary and constitutional dispositions, we are naturally tempted to say that it was not acquired but developed.

[1939a, 4898]
But in this connection two points must be stressed. Firstly, the genesis of a neurosis invariably goes back to very early impressions in childhood.¹ Secondly, it is true that there are cases which are distinguished as being 'traumatic' because their effects go back unmistakably to one or more powerful impressions in these early times - impressions which have escaped being dealt with normally, so that one is inclined to judge that if they had not occurred the neurosis would not have come about either. It would be enough for our purposes if we were obliged to restrict the analogy we are in search of to these traumatic cases. But the gap between the two groups appears not to be unbridgeable. It is quite possible to unite the two aetiological determinants under a single conception; it is merely a question of how one defines 'traumatic'. If we may assume that the experience acquires its traumatic character only as a result of a quantitative factor - that is to say, that in every case it is an excess in demand that is responsible for an experience evoking unusual pathological reactions - then we can easily arrive at the expedient of saying that something acts as a trauma in the case of one constitution but in the case of another would have no such effect. In this way we reach the concept of a sliding ‘complemental series’ as it is called, in which two factors converge in fulfilling an aetiological requirement. A less of one factor is balanced by a more of the other; as a rule both factors operate together and it is only at the two ends of the series that there can be any question of a simple motive being at work. After mentioning this, we can disregard the distinction between traumatic and non-traumatic aetiologies as irrelevant to the analogy we are in search of.

The immediate and most certain answer is that it consists in certain dispositions such as are characteristic of all living organisms: in the capacity and tendency, that is, to enter particular lines of development and to react in a particular manner to certain excitations, impressions and stimuli. Since experience shows that there are distinctions in this respect between individuals of the human species, the archaic heritage must include these distinctions; they represent what we recognize as the constitutional factor in the individual. Now, since all human beings, at all events in their early days, have approximately the same experiences, they react to them, too, in a similar manner; a doubt was therefore able to arise whether we should not include these reactions, along with their individual distinctions, in the archaic heritage. This doubt should be put on one side: our knowledge of the archaic heritage is not enlarged by the fact of this similarity.

We need not be at a loss to find an answer to this question. Quantitative disharmonies are what must be held responsible for the inadequacy and sufferings of neurotics. The determining cause of all the forms taken by human mental life, is, indeed, to be sought in the reciprocal action between innate dispositions and accidental experiences. Now a particular instinct may be too strong or too weak innately, or a particular capacity may be stunted or insufficiently developed in life. On the other hand, external impressions and experiences may make demands of differing strength on different people; and what one person's constitution can deal with may prove an unmanageable task for another's. These quantitative differences will determine the variety of the results.
Every analyst will have treated a few cases which have had this gratifying outcome. He has succeeded in clearing up the patient's neurotic disturbance, and it has not returned and has not been replaced by any other such disturbance. Nor are we without some insight into the determinants of these successes. The patient's ego had not been noticeably altered and the aetiology of his disturbance had been essentially traumatic. The aetiology of every neurotic disturbance is, after all, a mixed one. It is a question either of the instincts being excessively strong - that is to say, recalcitrant to taming by the ego - or of the effects of early (i.e. premature) traumas which the immature ego was unable to master. As a rule there is a combination of both factors, the constitutional and the accidental. The stronger the constitutional factor, the more readily will a trauma lead to a fixation and leave behind a developmental disturbance; the stronger the trauma, the more certainly will its injurious effects become manifest even when the instinctual situation is normal. There is no doubt that an aetiology of the traumatic sort offers by far the more favourable field for analysis. Only when a case is a predominantly traumatic one will analysis succeed in doing what it is so superlatively able to do; only then will it, thanks to having strengthened the patient's ego, succeed in replacing by a correct solution the inadequate decision made in his early life. Only in such cases can one speak of an analysis having been definitively ended. In them, analysis has done all that it should and does not need to be continued. It is true that, if the patient who has been restored in this way never produces another disorder calling for analysis, we do not know how much his immunity may not be due to a kind fate which has spared him ordeals that are too severe.

A constitutional strength of instinct and an unfavourable alteration of the ego acquired in its defensive struggle in the sense of its being dislocated and restricted - these are the factors which are prejudicial to the effectiveness of analysis and which may make its duration interminable. One is tempted to make the first factor - strength of instinct - responsible as well for the emergence of the second - the alteration of the ego; but it seems that the latter too has an aetiology of its own. And, indeed, it must be admitted that our knowledge of these matters is as yet insufficient. They are only now becoming the subject of analytic study. In this field the interest of analysts seems to me to be quite wrongly directed. Instead of an enquiry into how a cure by analysis comes about (a matter which I think has been sufficiently elucidated) the question should be asked of what are the obstacles that stand in the way of such a cure.
(1) Whether a neurotic illness occurs at all depends upon a quantitative factor - upon the total load on the nervous system as compared with the latter's capacity for resistance. Everything which can keep this quantitative factor below a certain threshold-value, or can bring it back to that level, has a therapeutic effect, since by so doing it keeps the aetiological equation unsatisfied. [1895f, 365]

What is to be understood by the 'total load' and by the 'capacity for resistance' of the nervous system, could no doubt be more clearly explained on the basis of certain hypotheses regarding the function of the nerves. [1895f, 365]

Thus the action of heredity is comparable to that of a multiplier in an electric circuit, which exaggerates the visible deviation of the needle, but which cannot determine its direction. [1896a, 371]
Nor can we leave the subject of regression in dreams without setting down in words a notion by which we have already repeatedly been struck and which will recur with fresh intensity when we have entered more deeply into the study of the psycho-neuroses: namely that dreaming is on the whole an example of regression to the dreamer's earliest condition, a revival of his childhood, of the instinctual impulses which dominated it and of the methods of expression which were then available to him. Behind this childhood of the individual we are promised a picture of a phylogenetic childhood - a picture of the development of the human race, of which the individual's development is in fact an abbreviated recapitulation influenced by the chance circumstances of life. We can guess how much to the point is Nietzsche's assertion that in dreams 'some primaeval relic of humanity is at work which we can now scarcely reach any longer by a direct path'; and we may expect that the analysis of dreams will lead us to a knowledge of man's archaic heritage, of what is psychically innate in him. Dreams and neuroses seem to have preserved more mental antiquities than we could have imagined possible; so that psycho-analysis may claim a high place among the sciences which are concerned with the reconstruction of the earliest and most obscure periods of the beginnings of the human race.

[1900a, 981]

¹ [Footnote added 1920:] The phantasies of the pubertal period have as their starting-point the infantile sexual researches that were abandoned in childhood. No doubt, too, they are also present before the end of the latency period. They may persist wholly, or to a great extent, unconsciously and for that reason it is often impossible to date them accurately. They are of great importance in the origin of many symptoms, since they precisely constitute preliminary stages of these symptoms and thus lay down the forms in which the repressed libidinal components find satisfaction. In the same way, they are the prototypes of the nocturnal phantasies which become conscious as dreams. Dreams are often nothing more than revivals of pubertal phantasies of this kind under the influence of, and in relation to, some stimulus left over from the waking life of the previous day (the 'day's residues'). Some among the sexual phantasies of the pubertal period are especially prominent, and are distinguished by their very general occurrence and by being to a great extent independent of individual experience. Such are the adolescent's phantasies of overhearing his parents in sexual intercourse, of having been seduced at an early age by someone he loves and of having been threatened with castration; such, too, are his phantasies of being in the womb, and even of experiences there, and the so-called 'Family Romance', in which he reacts to the difference between his attitude towards his parents now and in his childhood. The close relations existing between these phantasies and myths has been demonstrated in the case of the last instance by Otto Rank (1909).

[1905d, 1539]

The power which makes it difficult or impossible for women, and to a lesser degree for men as well, to enjoy undisguised obscenity is termed by us 'repression'; and we recognize in it the same psychical process which, in cases of serious illness, keeps whole complexes of impulses, together with their derivatives, away from consciousness, and which has turned out to be the main factor in the causation of what are known as psycho-neuroses. It is our belief that civilization and higher education have a large influence in the development of repression, and we suppose that, under such conditions, the psychical organization undergoes an alteration (that can also emerge as an inherited disposition) as a result of which what was formerly felt as agreeable now seems unacceptable and is rejected with all possible psychical force. The repressive activity of civilization brings it about that primary possibilities of enjoyment, which have now, however, been repudiated by the censorship in us, are lost to us. But to the human psyche all renunciation is exceedingly difficult, and so we find that tendentious jokes provide a means of undoing the renunciation and retrieving what was lost. When we laugh at a refined obscene joke, we are laughing at the same thing that makes a peasant laugh at a coarse piece of smut. In both cases the pleasure springs from the same source. We, however, could never bring ourselves to laugh at the coarse smut; we should feel ashamed or it would seem to us disgusting. We can only laugh when a joke has come to our help.

[1905c, 1697]
I take this opportunity of defending myself against the mistaken charge of having denied the importance of innate (constitutional) factors because I have stressed that of infantile impressions. A charge such as this arises from the restricted nature of what men look for in the field of causation: in contrast to what ordinarily holds good in the real world, people prefer to be satisfied with a single causative factor.

Psycho-analysis has talked a lot about the accidental factors in aetiology and little about the constitutional ones; but that is only because it was able to contribute something fresh to the former, while, to begin with, it knew no more than was commonly known about the latter. We refuse to posit any contrast in principle between the two sets of aetiological factors; on the contrary, we assume that the two sets regularly act jointly in bringing about the observed result. Δαιμον και Τύχη [Endowment and Chance] determine a man's fate - rarely or never one of these powers alone. The amount of aetiological effectiveness to be attributed to each of them can only be arrived at in every individual case separately. These cases may be arranged in a series according to the varying proportion in which the two factors are present, and this series will no doubt have its extreme cases. We shall estimate the share taken by constitution or experience differently in individual cases according to the stage reached by our knowledge; and we shall retain the right to modify our judgement along with changes in our understanding. Incidentally, one might venture to regard constitution itself as a precipitate from the accidental effects produced on the endlessly long chain of our ancestors.

[1912b, 2457]

In the first place, then, it must be said that there is no sense in asking savages to tell us the real reason for their prohibitions - the origin of taboo. It follows from our postulates that they cannot answer, since their real reason must be 'unconscious'. We can, however, reconstruct the history of taboo as follows on the model of obsessional prohibitions. Taboos, we must suppose, are prohibitions of primeval antiquity which were at some time externally imposed upon a generation of primitive men; they must, that is to say, no doubt have been impressed on them violently by the previous generation. These prohibitions must have concerned activities towards which there was a strong inclination. They must then have persisted from generation to generation, perhaps merely as a result of tradition transmitted through parental and social authority. Possibly, however, in later generations they may have become 'organized' as an inherited psychical endowment. Who can decide whether such things as 'innate ideas' exist, or whether in the present instance they have operated, either alone or in conjunction with education, to bring about the permanent fixing of taboos? But one thing would certainly follow from the persistence of the taboo, namely that the original desire to do the prohibited thing must also still persist among the tribes concerned. They must therefore have an ambivalent attitude towards their taboos. In their unconscious there is nothing they would like more than to violate them, but they are afraid to do so; they are afraid precisely because they would like to, and the fear is stronger than the desire. The desire is unconscious, however, in every individual member of the tribe just as it is in neurotics.

[1912-1913, 2679]
If we follow the changing relations between survivors and the dead through the course of ages, it becomes obvious that there has been an extraordinary diminution in ambivalence. It is now quite easy to keep down the unconscious hostility to the dead (though its existence can still be traced) without any particular expenditure of psychical energy. Where, in earlier times, satisfied hatred and pained affection fought each other, we now find that a kind of scar has been formed in the shape of piety, which declares "de mortuis nil nisi bonum". It is only neurotics whose mourning for the loss of those dear to them is still troubled by obsessive self-reproaches - the secret of which is revealed by psycho-analysis as the old emotional ambivalence. We need not discuss here how this alteration came about or how much share in it is due to a constitutional modification and how much to a real improvement in family relations. But this example suggests the probability that the psychical impulses of primitive peoples were characterized by a higher amount of ambivalence than is to be found in modern civilized man. It is to be supposed that as this ambivalence diminished, taboo (a symptom of the ambivalence and a compromise between two conflicting impulses) slowly disappeared. Neurotics, who are obliged to reproduce the struggle and the taboo resulting from it, may be said to have inherited an archaic constitution as an atavistic vestige; the need to compensate for this at the behest of civilization is what drives them to their immense expenditure of mental energy.

No one can have failed to observe, in the first place, that I have taken as the basis of my whole position the existence of a collective mind, in which mental processes occur just as they do in the mind of an individual. In particular, I have supposed that the sense of guilt for an action has persisted for many thousands of years and has remained operative in generations which can have had no knowledge of that action. I have supposed that an emotional process, such as might have developed in generations of sons who were ill-treated by their father, has extended to new generations which were exempt from such treatment for the very reason that their father had been eliminated. It must be admitted that these are grave difficulties; and any explanation that could avoid presumptions of such a kind would seem to be preferable.

Further reflection, however, will show that I am not alone in the responsibility for this bold procedure. Without the assumption of a collective mind, which makes it possible to neglect the interruptions of mental acts caused by the extinction of the individual, social psychology in general cannot exist. Unless psychical processes were continued from one generation to another, if each generation were obliged to acquire its attitude to life anew, there would be no progress in this field and next to no development. This gives rise to two further questions: how much can we attribute to psychical continuity in the sequence of generations? and what are the ways and means employed by one generation in order to hand on its mental states to the next one? I shall not pretend that these problems are sufficiently explained or that direct communication and tradition - which are the first things that occur to one - are enough to account for the process. Social psychology shows very little interest, on the whole, in the manner in which the required continuity in the mental life of successive generations is established. A part of the problem seems to be met by the inheritance of psychical dispositions which, however, need to be given some sort of impetus in the life of the individual before they can be roused into actual operation. This may be the meaning of the poet's words:
On the other hand, psycho-analysis has fully demonstrated the part played by social conditions and requirements in the causation of neurosis. The forces which, operating from the ego, bring about the restriction and repression of instinct owe their origin essentially to compliance with the demands of civilization. A constitution and a set of childhood experiences which, in other cases, would inevitably lead to a neurosis will produce no such result where this compliance is absent or where these demands are not made by the social circle in which the particular individual is placed. The old assertion that the increase in nervous disorders is a product of civilization is at least a half-truth. Young people are brought into contact with the demands of civilization by upbringing and example; and if instinctual repression occurs independently of these two factors, it is a plausible hypothesis to suppose that a primaeval and prehistoric demand has at last become part of the organized and inherited endowment of mankind. A child who produces instinctual repressions spontaneously is thus merely repeating a part of the history of civilization. What is to-day an act of internal restraint was once an external one, imposed, perhaps, by the necessities of the moment; and, in the same way, what is now brought to bear upon every growing individual as an external demand of civilization may some day become an internal disposition to repression.

[1913j, 2824]

The content of the Ucs. may be compared with an aboriginal population in the mind. If inherited mental formations exist in the human being - something analogous to instinct¹ in animals - these constitute the nucleus of the Ucs. Later there is added to them what is discarded during childhood development as unserviceable; and this need not differ in its nature from what is inherited. A sharp and final division between the content of the two systems does not, as a rule, take place till puberty.

[1915e, 3017]

The transformation of 'bad' instincts is brought about by two factors working in the same direction, an internal and an external one. The internal factor consists in the influence exercised on the bad (let us say, the egoistic) instincts by erotism - that is, by the human need for love, taken in its widest sense. By the admixture of erotic components the egoistic instincts are transformed into social ones. We learn to value being loved as an advantage for which we are willing to sacrifice other advantages. The external factor is the force exercised by upbringing, which represents the claims of our cultural environment, and this is continued later by the direct pressure of that environment. Civilization has been attained through the renunciation of instinctual satisfaction, and it demands the same renunciation from each newcomer in turn. Throughout an individual's life there is a constant replacement of external by internal compulsion. The influences of civilization cause an ever-increasing transformation of egoistic trends into altruistic and social ones by an admixture of erotic elements. In the last resort it may be assumed that every internal compulsion which makes itself felt in the development of human beings was originally - that is, in the history of mankind - only an external one. Those who are born to-day bring with them as an inherited organization some degree of tendency (disposition) towards the transformation of egoistic into social instincts, and this disposition is easily stimulated into bringing about that result. A further portion of this instinctual transformation has to be accomplished during the life of the individual himself. So the human being is subject not only to the pressure of his immediate cultural environment, but also to the influence of the cultural history of his ancestors.

[1915b, 3074]
In the first place we are faced by the fact that the dreamer has a symbolic mode of expression at his disposal which he does not know in waking life and does not recognize. This is as extraordinary as if you were to discover that your housemaid understood Sanskrit, though you know that she was born in a Bohemian village and never learnt it. It is not easy to account for this fact by the help of our psychological views. We can only say that the knowledge of symbolism is unconscious to the dreamer, that it belongs to his unconscious mental life. But even with this assumption we do not meet the point. Hitherto it has only been necessary for us to assume the existence of unconscious endeavours - endeavours, that is, of which, temporarily or permanently, we know nothing. Now, however, it is a question of more than this, of unconscious pieces of knowledge, of connections of thought, of comparisons between different objects which result in its being possible for one of them to be regularly put in place of the other. These comparisons are not freshly made on each occasion; they lie ready to hand and are complete, once and for all. This is implied by the fact of their agreeing in the case of different individuals - possibly, indeed, agreeing in spite of differences of language. What can be the origin of these symbolic relations? Linguistic usage covers only a small part of them. The multiplicity of parallels in other spheres of knowledge are mostly unknown to the dreamer; we ourselves have been obliged to collect them laboriously.

So we are now faced by the depressing discovery that, though we can give a satisfactory explanation of the individual neurotic symptoms by their connection with experiences, our skill leaves us in the lurch when we come to the far more frequent typical symptoms. Furthermore, I am far from having made you acquainted with all the difficulties that arise when consistently pursuing the historical interpretation of symptoms. Nor do I intend to do so; for, though it is my intention not to gloss things over to you or conceal them, I cannot throw you into perplexity and confusion at the very beginning of our common studies. It is true that we have only made a beginning with our efforts at understanding the significance of symptoms; but we will hold fast to what we have achieved and pursue our way step by step to a mastery of what we have not yet understood. I will try to console you, therefore, with the reflection that any fundamental distinction between one kind of symptom and the other is scarcely to be assumed. If the individual symptoms are so unmistakably dependent on the patient's experience, it remains possible that the typical symptoms may go back to an experience which is in itself typical - common to all human beings. Other features which recur regularly in neuroses may be general reactions which are imposed on the patients by the nature of their pathological change, like the repetitions or doubts in obsessional neurosis. In short, we have no grounds for premature despair; we shall see what remains to be seen.

The meaning of psychical conflict can be adequately expressed in another way by saying that for an external frustration to become pathogenic an internal frustration must be added to it. In that case, of course, the external and internal frustration relate to different paths and objects. The external frustration removes one possibility of satisfaction and the internal frustration seeks to exclude another possibility, about which the conflict then breaks out. I prefer this way of representing the matter because it has a secret content. For it hints at the probability that the internal impediments arose from real external obstacles during the prehistoric periods of human development.
I will dwell for a little to-day on yet another point in ego development, partly because I have some remoter aims in view, but also because what follows is precisely calculated to justify the sharp separation between the ego-instincts and the sexual instincts which we favour but which is not self-evident. In forming our judgement of the two courses of development both of the ego and of the libido - we must lay emphasis on a consideration which has not often hitherto been taken into account. For both of them are at bottom heritages, abbreviated recapitulations of the development which all mankind has passed through from its præmaeval days over long periods of time. In the case of the development of the libido, this phylegetic origin is, I venture to think, immediately obvious. Consider how in one class of animals the genital apparatus is brought into the closest relation to the mouth, while in another it cannot be distinguished from the excretory apparatus, and in yet others it is linked to the motor organs - all of which you will find attractively set out in W. Böltsche's valuable book. Among animals one can find, so to speak in petrified form, every species of perversion of the sexual organization. In the case of human beings, however, this phylegetic point of view is partly veiled by the fact that what is at bottom inherited is nevertheless freshly acquired in the development of the individual, probably because the same conditions which originally necessitated its acquisition persist and continue to operate upon each individual. I should like to add that originally the operation of these conditions was creative but that it is now evocative. Besides this, there is no doubt that the prescribed course of development can be disturbed and altered in each individual by recent external influences. But we know the power which forced a development of this kind upon humanity and maintains its pressure in the same direction to-day. It is, once again, frustration by reality, or, if we are to give it its true, grand name, the pressure of vital needs - Necessity (Άνάγκη). She has been a strict educator and has made much out of us. The neurotics are among those of her children to whom her strictness has brought evil results; but that is a risk with all education. This appreciation of the necessities of life need not, incidentally, weigh against the importance, of 'internal developmental trends', if such can be shown to be present.

Where, then, does the libido find the fixations which it requires in order to break through the repressions? In the activities and experiences of infantile sexuality, in the abandoned component trends, in the objects of childhood which have been given up. It is to them, accordingly, that the libido returns. The significance of this period of childhood is twofold: on the one hand, during it the instinctual trends which the child has inherited with his innate disposition first become manifest, and secondly, others of his instincts are for the first time awakened and made active by external impressions and accidental experiences. There is no doubt, I think, that we are justified in making this twofold division. The manifestation of the innate disposition is indeed not open to any critical doubts, but analytic experience actually compels us to assume that purely chance experiences in childhood are able to leave fixations of the libido behind them. Nor do I see any theoretical difficulty in this. Constitutional dispositions are also undoubtedly after-effects of experiences by ancestors in the past; they too were once acquired. Without such acquisition there would be no heredity. And is it conceivable that acquisition such as this, leading to inheritance, would come to an end precisely with the generation we are considering? The significance of infantile experiences should not be totally neglected, as people like doing, in comparison with the experiences of the subject's ancestors and of his own maturity; on the contrary, they call for particular consideration. They are all the more momentous because they occur in times of incomplete development and are for that very reason liable to have traumatic effects. The studies on developmental mechanics by Roux and others have shown that the prick of a needle into an embryonic germinal layer in the act of cell-division results in a severe disturbance of development. The same injury inflicted on a larval or fully grown animal would do no damage.

[1916-1917, 3414]
The only impression we gain is that these events of childhood are somehow demanded as a necessity, that they are among the essential elements of a neurosis. If they have occurred in reality, so much to the good; but if they have been withheld by reality, they are put together from hints and supplemented by phantasy. The outcome is the same, and up to the present we have not succeeded in pointing to any difference in the consequences, whether phantasy or reality has had the greater share in these events of childhood. Here we simply have once again one of the complemental relations that I have so often mentioned; moreover it is the strangest of all we have met with. Whence comes the need for these phantasies and the material for them? There can be no doubt that their sources lie in the instincts; but it has still to be explained why the same phantasies with the same content are created on every occasion. I am prepared with an answer which I know will seem daring to you. I believe these primal phantasies, as I should like to call them, and no doubt a few others as well, are a phylogenetic endowment. In them the individual reaches beyond his own experience into primaeval experience at points where his own experience has been too rudimentary. It seems to me quite possible that all the things that are told to us to-day in analysis as phantasy - the seduction of children, the inflaming of sexual excitement by observing parental intercourse, the threat of castration (or rather castration itself) - were once real occurrences in the primaeval times of the human family, and that children in their phantasies are simply filling in the gaps in individual truth with prehistoric truth. I have repeatedly been led to suspect that the psychology of the neuroses has stored up in it more of the antiquities of human development than any other source.

[1916-1917, 3427]

A certain ambiguity and indefiniteness in the use of the word 'Angst' will not have escaped you. By 'anxiety' we usually understand the subjective state into which we are put by perceiving the 'generation of anxiety' and we call this an affect. And what is an affect in the dynamic sense? It is in any case something highly composite. An affect includes in the first place particular motor innervations or discharges and secondly certain feelings; the latter are of two kinds - perceptions of the motor actions that have occurred and the direct feelings of pleasure and unpleasure which, as we say, give the affect its keynote. But I do not think that with this enumeration we have arrived at the essence of an affect. We seem to see deeper in the case of some affects and to recognize that the core which holds the combination we have described together is the repetition of some particular significant experience. This experience could only be a very early impression of a very general nature, placed in the prehistory not of the individual but of the species. To make myself more intelligible - an affective state would be constructed in the same way as a hysterical attack; and, like it, would be the precipitate of a reminiscence. A hysterical attack may thus be likened to a freshly constructed individual affect, and a normal affect to the expression of a general hysteria which has become a heritage.

[1916-1917, 3444]

¹ It is very remarkable that the reaction of shame should be so intimately connected with involuntary emptying of the bladder (whether in the day-time or at night) and not equally so, as one would have expected, with incontinence of the bowels. Experience leaves no room for doubt upon the point. The regular relation that is found to exist between incontinence of the bladder and fire also provides matter for reflection. It is possible that these reactions and relations represent precipitates from the history of human civilization derived from a lower stratum than anything that is preserved for us in the traces surviving in myths or folklore.

[1918b, 3574]
I will now turn from this unsatisfactory conclusion to a consideration of the problem which I have attempted in my Introductory Lectures on Psycho-Analysis. I should myself be glad to know whether the primal scene in my present patient's case was a phantasy or a real experience; but, taking other similar cases into account, I must admit that the answer to this question is not in fact a matter of very great importance. These scenes of observing parental intercourse, of being seduced in childhood, and of being threatened with castration are unquestionably an inherited endowment, a phylogenetic heritage, but they may just as easily be acquired by personal experience. With my patient, his seduction by his elder sister was an indisputable reality; why should not the same have been true of his observation of his parents' intercourse?

I fully agree with Jung¹ in recognizing the existence of this phylogenetic heritage; but I regard it as a methodological error to seize on a phylogenetic explanation before the ontogenetic possibilities have been exhausted. I cannot see any reason for obstinately disputing the importance of infantile prehistory while at the same time freely acknowledging the importance of ancestral prehistory. Nor can I overlook the fact that phylogenetic motives and productions themselves stand in need of elucidation, and that in quite a number of instances this is afforded by factors in the childhood of the individual. And, finally, I cannot feel surprised that what was originally produced by certain circumstances in prehistoric times and was then transmitted in the shape of a predisposition to its re-acquirement should, since the same circumstances persist, emerge once more as a concrete event in the experience of the individual.

I have now come to the end of what I had to say about this case. There remain two problems, of the many that it raises, which seem to me to deserve special emphasis. The first relates to the phylogenetically inherited schemata, which, like the categories of philosophy, are concerned with the business of 'placing' the impressions derived from actual experience. I am inclined to take the view that they are precipitates from the history of human civilization. The Oedipus complex, which comprises a child's relation to his parents, is one of them - is, in fact, the best known member of the class. Wherever experiences fail to fit in with the hereditary schema, they become remodelled in the imagination - a process which might very profitably be followed out in detail. It is precisely such cases that are calculated to convince us of the independent existence of the schema. We are often able to see the schema triumphing over the experience of the individual; as when in our present case the boy's father became the castrator and the menace of his infantile sexuality in spite of what was in other respects an inverted Oedipus complex. A similar process is at work where a nurse comes to play the mother's part or where the two become fused together. The contradictions between experience and the schema seem to supply the conflicts of childhood with an abundance of material.

¹[1918b, 3577]
If human beings too possessed an instinctive endowment such as this, it would not be surprising that it should be very particularly concerned with the processes of sexual life, even though it could not be by any means confined to them. This instinctive factor would then be the nucleus of the unconscious, a primitive kind of mental activity, which would later be dethroned and overlaid by human reason, when that faculty came to be acquired, but which in some people, perhaps in every one, would retain the power of drawing down to it the higher mental processes. Repression would be the return to this instinctive stage, and man would thus be paying for his great new acquisition with his liability to neurosis, and would be bearing witness by the possibility of the neuroses to the existence of those earlier, instinct-like, preliminary stages. The significance of the traumas of early childhood would lie in their contributing material to this unconscious which would save it from being worn away by the subsequent course of development.

[1918b, 3595]

I am aware that expression has been given in many quarters to thoughts like these, which emphasize the hereditary, phylogenetically acquired factor in mental life. In fact, I am of opinion that people have been far too ready to find room for them and ascribe importance to them in psycho-analysis. I consider that they are only admissible when psycho-analysis strictly observes the correct order of precedence, and, after forcing its way through the strata of what has been acquired by the individual, comes at last upon traces of what has been inherited.¹

[1918b, 3596]

If, however, the derivation of perversions from the Oedipus complex can be generally established, our estimate of its importance will have gained added strength. For in our opinion the Oedipus complex is the actual nucleus of neuroses, and the infantile sexuality which culminates in this complex is the true determinant of neuroses. What remains of the complex in the unconscious represents the disposition to the later development of neuroses in the adult. In this way the beating-phantasy and other analogous perverse fixations would also only be precipitates of the Oedipus complex, scars, so to say, left behind after the process has ended, just as the notorious 'sense of inferiority' corresponds to a narcissistic scar of the same sort. In taking this view of the matter I must express my unreserved agreement with Marcinowski (1918), who has recently put it forward most happily. As is well known, this neurotic delusion of inferiority is only a partial one, and is completely compatible with the existence of a self-overvaluation derived from other sources. The origin of the Oedipus complex itself, and the destiny which compels man, probably alone among all animals, to begin his sexual life twice over, first like all other creatures in his early childhood, and then after a long interruption once more at the age of puberty - all the problems that are connected with man's 'archaic heritage' - have been discussed by me elsewhere, and I have no intention of going into them in this place.

[1919e, 3654]

The theory of psycho-analysis (a theory based on observation) holds firmly to the view that the motive forces of repression must not be sexualized. Man's archaic heritage forms the nucleus of the unconscious mind; and whatever part of that heritage has to be left behind in the advance to later phases of development, because it is unserviceable or incompatible with what is new and harmful to it, falls a victim to the process of repression. This selection is made more successfully with one group of instincts than with the other. In virtue of special circumstances which have often been pointed out already, the latter group, that of the sexual instincts, are able to defeat the intentions of repression, and to enforce their representation by substitutive formations of a disturbing kind. For this reason infantile sexuality, which is held under repression, acts as the chief motive force in the formation of symptoms; and the essential part of its content, the Oedipus complex, is the nuclear complex of neuroses. I hope that in this paper I have raised an expectation that the sexual aberrations of childhood, as well as those of mature life, are ramifications of the same complex.

[1919e, 3662]
Let us answer first what is easiest to answer. The differentiation between ego and id must be attributed not only to primitive man but even to much simpler organisms, for it is the inevitable expression of the influence of the external world. The super-ego, according to our hypothesis, actually originated from the experiences that led to totemism. The question whether it was the ego or the id that experienced and acquired these things soon comes to nothing. Reflection at once shows us that no external vicissitudes can be experienced or undergone by the id, except by way of the ego, which is the representative of the external world to the id. Nevertheless it is not possible to speak of direct inheritance in the ego. It is here that the gulf between an actual individual and the concept of a species becomes evident. Moreover, one must not take the difference between ego and id in too hard-and-fast a sense, nor forget that the ego is a specially differentiated part of the id. The experiences of the ego seem at first to be lost for inheritance; but, when they have been repeated often enough and with sufficient strength in many individuals in successive generations, they transform themselves, so to say, into experiences of the id, the impressions of which are preserved by heredity. Thus in the id, which is capable of being inherited, are harboured residues of the existences of countless egos; and, when the ego forms its super-ego out of the id, it may perhaps only be reviving shapes of former egos and be bringing them to resurrection.

[1923b, 3972]

But the derivation of the super-ego from the first object-cathexes of the id, from the Oedipus complex, signifies even more for it. This derivation, as we have already shown, brings it into relation with the phylogenetic acquisitions of the id and makes it a reincarnation of former ego-structures which have left their precipitates behind in the id. Thus the super-ego is always close to the id and can act as its representative vis-à-vis the ego. It reaches deep down into the id and for that reason is farther from consciousness than the ego is.¹

[1923b, 3982]

We see from what has been said that quantitative relations - relations which are not directly observable but which can only be inferred - are what determine whether or not old situations of danger shall be preserved, repressions on the part of the ego maintained and childhood neuroses find a continuation. Among the factors that play a part in the causation of neuroses and that have created the conditions under which the forces of the mind are pitted against one another, three emerge into prominence: a biological, a phylogenetic and a purely psychological factor.

[1926d, 4308]

The existence of the second, phylogenetic, factor, is based only upon inference. We have been led to assume its existence by a remarkable feature in the development of the libido. We have found that the sexual life of man, unlike that of most of the animals nearly related to him, does not make a steady advance from birth to maturity, but that, after an early efflorescence up till the fifth year, it undergoes a very decided interruption; and that it then starts on its course once more at puberty, taking up again the beginnings broken off in early childhood. This has led us to suppose that something momentous must have occurred in the vicissitudes of the human species which has left behind this interruption in the sexual development of the individual as a historical precipitate. This factor owes its pathogenic significance to the fact that the majority of the instinctual demands of this infantile sexuality are treated by the ego as dangers and fended off as such, so that the later sexual impulses of puberty, which in the natural course of things would be ego-syntonic, run the risk of succumbing to the attraction of their infantile prototypes and following them into repression. It is here that we come upon the most direct aetiology of the neuroses. It is a curious thing that early contact with the demands of sexuality should have a similar effect on the ego to that produced by premature contact with the external world.

[1926d, 4309]
In this connection the puzzling phobias of early childhood deserve to be mentioned once again. We have been able to explain some of them, such as the fear of being alone or in the dark or with strangers, as reactions to the danger of losing the object. Others, like the fear of small animals, thunder storms, etc., might perhaps be accounted for as vestigial traces of the congenital preparedness to meet real dangers which is so strongly developed in other animals. In man, only that part of this archaic heritage is appropriate which has reference to the loss of the object. If childhood phobias become fixed and grow stronger and persist into later years, analysis shows that their content has become associated with instinctual demands and has come to stand for internal dangers as well. [1926d, 4320]

The impressions of early traumas, from which we started out, are either not translated into the preconscious or are quickly put back by repression into the id-condition. Their mnemonic residues are in that case unconscious and operate from the id. We believe we can easily follow their further vicissitudes so long as it is a question of what has been experienced by the subject himself. But a fresh complication arises when we become aware of the probability that what may be operative in an individual's psychical life may include not only what he has experienced himself but also things that were innately present in him at his birth, elements with a phylogenetic origin - an archaic heritage. The questions then arise of what this consists in, what it contains and what is the evidence for it. [1939a, 4920]

The immediate and most certain answer is that it consists in certain dispositions such as are characteristic of all living organisms: in the capacity and tendency, that is, to enter particular lines of development and to react in a particular manner to certain excitations, impressions and stimuli. Since experience shows that there are distinctions in this respect between individuals of the human species, the archaic heritage must include these distinctions; they represent what we recognize as the constitutional factor in the individual. Now, since all human beings, at all events in their early days, have approximately the same experiences, they react to them, too, in a similar manner; a doubt was therefore able to arise whether we should not include these reactions, along with their individual distinctions, in the archaic heritage. This doubt should be put on one side: our knowledge of the archaic heritage is not enlarged by the fact of this similarity. [1939a, 4920]
Nevertheless, analytic research has brought us a few results which give us cause for thought. There is, in the first place, the universality of symbolism in language. The symbolic representation of one object by another - the same thing applies to actions - is familiar to all our children and comes to them, as it were, as a matter of course. We cannot show in regard to them how they have learnt it and must admit that in many cases learning it is impossible. It is a question of an original knowledge which adults afterwards forget. It is true that an adult makes use of the same symbols in his dreams, but he does not understand them unless an analyst interprets them to him, and even then he is reluctant to believe the translation. If he makes use of one of the very common figures of speech in which this symbolism is recorded, he is obliged to admit that its true sense has completely escaped him. Moreover, symbolism disregards differences of language; investigations would probably show that it is ubiquitous - the same for all peoples. Here, then, we seem to have an assured instance of an archaic heritage dating from the period at which language developed. But another explanation might still be attempted. It might be said that we are dealing with thought-connections between ideas - connections which had been established during the historical development of speech and which have to be repeated now every time the development of speech has to be gone through in an individual. It would thus be a case of the inheritance of an intellectual disposition similar to the ordinary inheritance of an instinctual disposition - and once again it would be no contribution to our problem.

[1939a, 4920]

The work of analysis has, however, brought something else to light which exceeds in its importance what we have so far considered. When we study the reactions to early traumas, we are quite often surprised to find that they are not strictly limited to what the subject himself has really experienced but diverge from it in a way which fits in much better with the model of a phylogenetic event and, in general, can only be explained by such an influence. The behaviour of neurotic children towards their parents in the Oedipus and castration complex abounds in such reactions, which seem unjustified in the individual case and only become intelligible phylogenetically - by their connection with the experience of earlier generations. It would be well worth while to place this material, which I am able to appeal to here, before the public in a collected form. Its evidential value seems to me strong enough for me to venture on a further step and to posit the assertion that the archaic heritage of human beings comprises not only dispositions but also subject-matter - memory-traces of the experience of earlier generations. In this way the compass as well as the importance of the archaic heritage would be significantly extended.

[1939a, 4921]

On further reflection I must admit that I have behaved for a long time as though the inheritance of memory-traces of the experience of our ancestors, independently of direct communication and of the influence of education by the setting of an example, were established beyond question. When I spoke of the survival of a tradition among a people or of the formation of a people's character, I had mostly in mind an inherited tradition of this kind and not one transmitted by communication. Or at least I made no distinction between the two and was not clearly aware of my audacity in neglecting to do so. My position, no doubt, is made more difficult by the present attitude of biological science, which refuses to hear of the inheritance of acquired characters by succeeding generations. I must, however, in all modesty confess that nevertheless I cannot do without this factor in biological evolution. The same thing is not in question, indeed, in the two cases: in the one it is a matter of acquired characters which are hard to grasp, in the other of memory-traces of external events - something tangible, as it were. But it may well be that at bottom we cannot imagine one without the other.

[1939a, 4921]
If we assume the survival of these memory-traces in the archaic heritage, we have bridged the gulf between individual and group psychology: we can deal with peoples as we do with an individual neurotic. Granted that at the time we have no stronger evidence for the presence of memory-traces in the archaic heritage than the residual phenomena of the work of analysis which call for a phylogenetic derivation, yet this evidence seems to us strong enough to postulate that such is the fact. If it is not so, we shall not advance a step further along the path we entered on, either in analysis or in group psychology. The audacity cannot be avoided.

And by this assumption we are effecting something else. We are diminishing the gulf which earlier periods of human arrogance had torn too wide apart between mankind and the animals. If any explanation is to be found of what are called the instincts of animals, which allow them to behave from the first in a new situation in life as though it were an old and familiar one - if any explanation at all is to be found of this instinctive life of animals, it can only be that they bring the experiences of their species with them into their own new existence - that is, that they have preserved memories of what was experienced by their ancestors. The position in the human animal would not at bottom be different. His own archaic heritage corresponds to the instincts of animals even though it is different in its compass and contents.

After this discussion I have no hesitation in declaring that men have always known (in this special way) that they once possessed a primal father and killed him.

Two further questions must now be answered. First, under what conditions does a memory of this kind enter the archaic heritage? And, secondly, in what circumstances can it become active - that is, can it advance to consciousness from its unconscious state in the id, even though in an altered and distorted shape? The answer to the first question is easy to formulate: the memory enters the archaic heritage if the event was important enough, or repeated often enough, or both. In the case of parricide both conditions are fulfilled. On the second question there is this to be said. A whole number of influences may be concerned, not all of which are necessarily known. A spontaneous development is also conceivable, on the analogy of what happens in some neuroses. What is certainly of decisive importance, however, is the awakening of the forgotten memory trace by a recent real repetition of the event. The murder of Moses was a repetition of this kind and, later, the supposed judicial murder of Christ: so that these events come into the foreground as causes. It seems as though the genesis of monotheism could not do without these occurrences. We are reminded of the poet's words:

And lastly a remark which brings up a psychological argument. A tradition that was based only on communication could not lead to the compulsive character that attaches to religious phenomena. It would be listened to, judged, and perhaps dismissed, like any other piece of information from outside; it would never attain the privilege of being liberated from the constraint of logical thought. It must have undergone the fate of being repressed, the condition of lingering in the unconscious, before it is able to display such powerful effects on its return, to bring the masses under its spell, as we have seen with astonishment and hitherto without comprehension in the case of religious tradition. And this consideration weighs heavily in favour of our believing that things really happened in the way we have tried to picture them or at least in some similar way.
We have heard how the weak and immature ego of the first period of childhood is permanently damaged by the stresses put upon it in its efforts to fend off the dangers that are peculiar to that period of life. Children are protected against the dangers that threaten them from the external world by the solicitude of their parents; they pay for this security by a fear of loss of love which would deliver them over helpless to the dangers of the external world. This factor exerts a decisive influence on the outcome of the conflict when a boy finds himself in the situation of the Oedipus complex, in which the threat to his narcissism by the danger of castration, reinforced from primal sources, takes possession of him. Driven by the combined operation of these two influences, the contemporary real danger and the remembered one with its phylogenetic basis, the child embarks on his attempts at defence - repressions - which are effective for the moment but nevertheless turn out to be psychologically inadequate when the later re-animation of sexual life brings a reinforcement to the instinctual demands which have been repudiated in the past. If this is so, it would have to be said from a biological standpoint that the ego comes to grief over the task of mastering the excitations of the early sexual period, at a time when its immaturity makes it incompetent to do so. It is in this lagging of ego development behind libidinal development that we see the essential precondition of neurosis; and we cannot escape the conclusion that neuroses could be avoided if the childish ego were spared this task - if, that is to say, the child’s sexual life were allowed free play, as happens among many primitive peoples. It may be that the aetiology of neurotic illnesses is more complicated than we have here described it; if so, we have at least brought out one essential part of the aetiological complex. Nor should we forget the phylogenetic influences, which are represented in some way in the id in forms that we are not yet able to grasp, and which must certainly act upon the ego more powerfully in that early period than later. On the other hand, the realization dawns on us that such an early attempt at damming up the sexual instinct, so decided a partisanship by the young ego in favour of the external as opposed to the internal world, brought about by the prohibition of infantile sexuality, cannot be without its effect on the individual's later readiness for culture. The instinctual demands forced away from direct satisfaction are compelled to enter on new paths leading to substitutive satisfaction, and in the course of these détours they may become desexualized and their connection with their original instinctual aims may become looser. And at this point we may anticipate the thesis that many of the highly valued assets of our civilization were acquired at the cost of sexuality and by the restriction of sexual motive forces.

[1940a [1938], 5006]
The next question we come to is whether every alteration of the ego - in our sense of the term - is acquired during the defensive struggles of the earliest years. There can be no doubt about the answer. We have no reason to dispute the existence and importance of original, innate distinguishing characteristics of the ego. This is made certain by the single fact that each person makes a selection from the possible mechanisms of defence, that he always uses a few only of them and always the same ones. This would seem to indicate that each ego is endowed from the first with individual dispositions and trends, though it is true that we cannot specify their nature or what determines them. Moreover, we know that we must not exaggerate the difference between inherited and acquired characters into an antithesis; what was acquired by our forefathers certainly forms an important part of what we inherit. When we speak of an 'archaic heritage' we are usually thinking only of the id and we seem to assume that at the beginning of the individual's life no ego is as yet in existence. But we shall not overlook the fact that id and ego are originally one; nor does it imply any mystical overvaluation of heredity if we think it credible that, even before the ego has come into existence, the lines of development, trends and reactions which it will later exhibit are already laid down for it. The psychological peculiarities of families, races and nations, even in their attitude to analysis, allow of no other explanation. Indeed, more than this: analytic experience has forced on us a conviction that even particular psychical contents, such as symbolism, have no other sources than hereditary transmission, and researches in various fields of social anthropology, make it plausible to suppose that other, equally specialized precipitates left by early human development are also present in the archaic heritage.

With the recognition that the properties of the ego which we meet with in the form of resistances can equally well be determined by heredity as acquired in defensive struggles, the topographical distinction between what is ego and what is id loses much of its value for our investigation. If we advance a step further in our analytic experience, we come upon resistances of another kind, which we can no longer localize and which seem to depend on fundamental conditions in the mental apparatus. I can only give a few examples of this type of resistance; the whole field of enquiry is still bewilderingly strange and insufficiently explored. We come across people, for instance, to whom we should be inclined to attribute a special 'adhesiveness of the libido'. The processes which the treatment sets in motion in them are so much slower than in other people because, apparently, they cannot make up their minds to detach libidinal cathexes from one object and displace them on to another, although we can discover no special reason for this cathetic loyalty. One meets with the opposite type of person, too, in whom the libido seems particularly mobile; it enters readily upon the new cathexes suggested by analysis, abandoning its former ones in exchange for them. The difference between the two types is comparable to the one felt by a sculptor, according to whether he works in hard stone or soft clay. Unfortunately, in this second type the results of analysis often turn out to be very impermanent: the new cathexes are soon given up once more, and we have an impression, not of having worked in clay, but of having written on water. In the words of the proverb: 'Soon got, soon gone.'
In other cases this equilibrium is very unstable. The attack makes its appearance as a manifestation of the residue of the hypnoid consciousness whenever the normal personality is exhausted and incapacitated. The possibility cannot be dismissed that here the attack may have been divested of its original meaning and may be recurring as a motor reaction without any content.

[1895d, 18]

I must confess, too, that I can see no sign in Frau von N.'s history of the 'psychical inefficiency' to which Janet attributes the genesis of hysteria. According to him the hysterical disposition consists in an abnormal restriction of the field of consciousness (due to hereditary degeneracy) which results in a disregard of whole groups of ideas and, later, to a disintegration of the ego and the organization of secondary personalities. If this were so, what remains of the ego after the withdrawal of the hysterically-organized psychical groups would necessarily also be less efficient than a normal ego; and in fact, according to Janet, the ego in hysteria is afflicted by psychical stigmata, condemned to mono-ideism and incapable of the volitional acts of ordinary life. Janet, I think, has made the mistake here of promoting what are after-effects of changes in consciousness due to hysteria to the rank of primary determinants of hysteria. The subject is one that deserves further consideration elsewhere; but in Frau non N. there was no sign of any such inefficiency. During the times of her worst states she was and remained capable of playing her part in the management of a large industrial business, of keeping a constant eye on the education of her children, of carrying on her correspondence with prominent people in the intellectual world - in short, of fulfilling her obligations well enough for the fact of her illness to remain concealed. I am inclined to believe, then, that all this involved a considerable excess of efficiency, which could perhaps not be kept up in the long run and was bound to lead to exhaustion - to a secondary 'misère psychologique' ['psychological impoverishment']. It seems likely that disturbances of this kind in her efficiency were beginning to make themselves felt at the time when I first saw her; but however that may be, severe hysteria had been present for many years before the appearance of the symptoms of exhaustion.¹

[1895d, 94]

(β) The last of the aetiological conditions I have to bring forward appears at first sight not to be of a sexual nature at all. Anxiety neurosis also arises - and in both sexes - as a result of the factor of overwork or exhausting exertion - as, for instance, after night-watching, sick-nursing, or even after severe illness.

[1895b, 339]
Observations of this sort, which can be multiplied at will, positively thrust a sexual aetiology on the doctor for a certain category of cases. And other cases, which would otherwise remain unintelligible, can at least be understood and classified without inconsistency by employing that aetiology as a key. I have in mind those very numerous cases in which, it is true, everything is present that has been found in the previous category - on the one hand the manifestations of anxiety neurosis, and on the other the specific factor of coitus interruptus - but in which something else as well intrudes itself: namely, a long interval between the presumed aetiology and its effects, and also perhaps aetiological factors that are not of a sexual nature. Take, for instance, a man who, on receiving news of his father's death, had a heart attack and from that moment fell a victim to an anxiety neurosis. The case is not comprehensible, for, till then, the man was not neurotic. The death of his father, who was well advanced in years, did not take place under in any way special circumstances, and it will be admitted that the normal and expected decease of an aged father is not one of those experiences which usually cause a healthy adult to fall ill. Perhaps the aetiological analysis will become clearer if I add that this man had been practising coitus interruptus for eleven years, with due consideration for his wife's satisfaction. The clinical symptoms are, at least, exactly the same as those which appear in other people after only a short sexual noxa of the same kind, and without the interpolation of any other trauma. A similar assessment must be made of the case of a woman whose anxiety neurosis broke out after the loss of her child, or of the student whose preparatory studies for his final examination were interfered with by an anxiety neurosis. I think that in these instances, too, the effect is not explained by the ostensible aetiology. One is not necessarily 'overworked' by study, and a healthy mother as a rule reacts only with normal grief to the loss of a child. Above all, however, I should have expected the student, as a result of his overwork, to acquire cephalasthenia, and the mother, as a result of her bereavement, hysteria. That both should have been overtaken by anxiety neurosis leads me to attach importance to the fact that the mother had been living for eight years in conditions of marital coitus interruptus, and that the student had for three years had an ardent love affair with a 'respectable' girl whom he had to avoid making pregnant.

These considerations lead us to the conclusion that the specific sexual noxa of coitus interruptus, even when it is not able on its own account to provoke an anxiety neurosis in the subject, does at least provoke him to acquire it. The anxiety neurosis breaks out as soon as there is added to the latent effect of the specific factor the effect of another, stock noxa. The latter can act in the sense of the specific factor quantitatively but cannot replace it qualitatively. The specific factor always remains decisive for the form taken by the neurosis. I hope to be able to prove this assertion concerning the aetiology of the neuroses more comprehensively too.

The two last aetiological conditions on our list seem to fall into place without difficulty. The tendency to anxiety in masturbators who have become neurasthenic is explained by the fact that it is very easy for them to pass into a state of 'abstinence' after they have been accustomed for so long to discharging even the smallest quantity of somatic excitation, faulty though that discharge is. Finally, the last case, - the generation of anxiety neurosis through severe illness, overwork, exhausting sick-nursing, etc., - finds an easy interpretation when brought into relation with the effects of coitus interruptus. Here the psyche, on account of its deflection, would seem to be no longer capable of mastering the somatic excitation, a task on which, as we know, it is continuously engaged. We are aware to what a low level libido can sink under these conditions; and we have here a good example of a neurosis which, although it exhibits no sexual aetiology, nevertheless exhibits a sexual mechanism.
But there is doubt about their interpretation. Are we to accept the post hoc ergo propter hoc conclusion straight away and spare ourselves any critical consideration of the raw material? There are examples enough in which the final, releasing cause has not, in the face of critical analysis, maintained its position as the causa efficiens. One has only to think, for instance, of the relationship between trauma and gout. The role of a trauma in provoking an attack of gout in the injured limb is probably no different from the role it plays in the aetiology of tabes and general paralysis of the insane; only in the case of gout it is clear to the meanest capacity that it is absurd to suppose that the trauma has ‘caused’ the gout instead of having merely provoked it. It is bound to make us thoughtful when we come across aetiological factors of this sort - ‘stock’ factors, as I should like to call them - in the aetiology of the most varied forms of illness. Emotion, fright, is also a stock factor of this kind. Fright can provoke chorea, apoplexy, paralysis agitans and many other things just as well as it can provoke anxiety neurosis. I must not go on to argue, of course, that, because of their ubiquity, the stock causes do not satisfy our requirements and that there must be specific causes as well; to do so would be to beg the question in favour of the proposition I want to prove. But I am justified in drawing the following conclusion: if the same specific cause can be shown to exist in the aetiology of all, or the great majority, of cases of anxiety neurosis, our view of the matter need not be shaken by the fact that the illness does not break out until one or other stock factor, such as emotion, has come into operation.

[1895f, 356]

So it was with my cases of anxiety neurosis. Let us take the man who, after receiving the news of his father’s death, fell ill so inexplicably. (I add ‘inexplicably’ because the death was not unexpected and did not occur in unusual or shattering circumstances.) This man had carried out coitus interruptus for eleven years with his wife, whom he tried for the most part to satisfy. Again, the young man who was not equal to the quarrels between his wife and his mother, had practised withdrawal with his young wife from the first, in order to spare himself the burden of children. Then we have the student who acquired an anxiety neurosis from overwork, instead of the cerebral neurasthenia that was to be expected: he had maintained a relationship for three years with a girl whom it was not permissible for him to make pregnant. Again, there was the woman who, childless herself, was overtaken by an anxiety neurosis about a niece’s illness: she was married to an impotent man and had never been sexually satisfied. And so on. Not all these cases are equally clear or equally good evidence for my thesis; but when I add them to the very considerable number of cases in which the aetiology shows nothing but the specific factor, they fit without contradiction into the theory I have put forward and they allow of an extension of our aetiological understanding beyond the boundaries hitherto in force.

[1895f, 357]
I, too, have made exactly the same observation, without, however, being misled by it. I myself have caused anxiety attacks to disappear by means of psychical treatment, improvement of the patient's general health, and so on; but I have naturally not concluded from this that what had caused the anxiety attack was a lack of treatment. Not that I should like to foist a conclusion of this sort upon Löwenfeld. My joking remark is only intended to show that the state of affairs may easily be complicated enough to render Löwenfeld's objection quite invalid. I have not found it difficult to reconcile the fact brought forward here with my assertion that anxiety neurosis has a specific aetiology. It will readily be granted that there are aetiological factors which, in order to exercise their effect, must operate with a certain intensity (or quantity) and over a certain period of time - which, that is to say, become summated. The effects of alcohol are a standard example of causation like this through summation. It follows that there must be a period of time in which the specific aetiology is at work but in which its effect is not yet manifest. During this time the subject is not ill as yet, but he is predisposed to a particular illness - in our case, to anxiety neurosis - and now the addition of a stock noxa will be able to set the neurosis off, just as would a further intensification of the operation of the specific noxa. The situation may also be expressed as follows: it is not enough for the specific noxa to be present; it must also reach a definite amount; and, in the process of reaching that limit, a quantity of specific noxa can be replaced by a quota of stock noxa. If the latter is removed once more, we find ourselves below a certain threshold and the clinical symptoms depart once more. The whole therapy of the neuroses rests upon the fact that the total load upon the nervous system, to which it has succumbed, can be brought below this threshold by influencing the aetiological mixture in a great variety of ways. From these circumstances we can draw no conclusion as to the existence or non-existence of a specific aetiology. These considerations are surely indisputable and assured. But anyone who does not think them sufficient may be influenced by the following argument. According to the views of Löwenfeld and very many others, the aetiology of anxiety states is to be found in heredity. Now heredity is certainly immune to alteration; thus if anxiety neurosis is curable by treatment, we should have to conclude according to Löwenfeld's argument that its aetiology cannot reside in heredity.

For the rest, I might have been spared having to defend myself against these two objections of Löwenfeld's, if my respected opponent had paid greater attention to my paper itself. In it, both these objections are anticipated and answered. I have only been able to repeat here what I said there; and I have even purposely analysed the same cases over again. Moreover the aetiological formulas on which I have just laid weight are contained in the text of my paper. I will repeat them once more. I maintain that there exists a specific aetiological factor for anxiety neurosis which can be replaced in its operation by stock noxae in a QUANTITATIVE sense, but not in a QUALITATIVE one; I furthermore maintain that this specific factor determines above all the FORM of the neurosis; whether a neurotic illness occurs at all depends on the total load upon the nervous system (in proportion to its capacity to carry the load). As a rule the neuroses are overdetermined; that is to say, several factors operate together in their aetiology.

Besides this, there are plenty of cases in which a single anxiety-state is provoked by the extra addition of a stock factor, by an excitement of some kind or other. The same holds good, therefore, for the aetiology of the individual anxiety attack as for the causation of the whole neurosis. It is not very strange that the anxiety of the phobias should obey different conditions; they have a more complicated structure than purely somatic anxiety attacks. In phobias the anxiety is linked to a definite ideational or perceptual content, and the arousal of this psychical content is the chief condition for the emergence of the anxiety. When this happens, anxiety is 'generated', just as for instance sexual tension is generated by the arousal of libidinal ideas. The connection of this process, however, with the theory of anxiety neurosis has not yet been elucidated.
Auxiliary Causes: Any stock noxae - emotion, fright, and also physical exhaustion through illness or over-exertion.

If I consider this aetiological formula for anxiety neurosis in detail, I am able to add the following remarks. Whether a special personal constitution (which need not be produced by heredity) is absolutely necessary for the production of an anxiety neurosis, or whether any normal person can be made to have an anxiety neurosis by some given quantitative increase of the specific factor - this I am not able to decide with certainty; but I incline strongly to the latter view. -Hereditary disposition is the most important precondition for anxiety neurosis; but it is not an indispensable one, since it is absent in a class of borderline cases. -The presence of the specific sexual factor can, in the majority of cases, be demonstrated with certainty. In one series of cases (congenital ones) this factor is not separated from the precondition of heredity, but is fulfilled with the help of it. That is to say, in some patients this peculiarity of the vita sexualis - psychical inadequacy in mastering somatic sexual tension - is innate in the form of a stigma whereas ordinarily it is via that peculiarity that they acquire the neurosis. In another class of borderline cases the specific cause is contained in a contributory one. This is when the psychical inadequacy which I have just mentioned is brought about by exhaustion and such causes. All these cases fall into classes which melt into one another and do not form separate categories. In all of them, moreover, we find that the sexual tension undergoes the same vicissitudes; and for most of them the distinction between precondition, specific and auxiliary cause holds good, in conformity with the solution of the aetiological equation which I have given above.

As concurrent (or auxiliary) causes of neuroses may be enumerated all the stock agents met with elsewhere: emotional disturbance, physical exhaustion, acute illnesses, intoxications, traumatic accidents, intellectual overwork, etc. I maintain that none of these, not even the last, enters into the aetiology of the neuroses regularly or necessarily, and I am aware that to declare this opinion is to put oneself in direct opposition to a theory which is looked upon as universally accepted and irreproachable. Since Beard declared that neurasthenia was the fruit of our modern civilization, he has only met with believers; but I find it impossible to accept this view. A laborious study of the neuroses has taught me that the specific aetiology of the neuroses has escaped Beard's notice.

Stock concurrent causes can replace the specific aetiology in respect of quantity, but can never take its place entirely. There are numerous cases in which all the aetiological influences are represented by the hereditary precondition and the specific cause, stock causes being absent. In the other cases indispensable aetiological factors are not in themselves sufficient in quantity to bring about an outbreak of neurosis; a state of apparent health may be maintained for a long time, though it is in reality a state of predisposition to neurosis. It is then enough for a stock cause to come into action as well, and the neurosis becomes manifest. But it must be clearly pointed out that under these conditions the nature of the stock cause which supervenes is a matter of complete indifference - whether it is an emotion, a trauma, an infectious illness or anything else. The pathological effect will not be modified according to this variation; the nature of the neurosis will always be dominated by the pre-existing specific cause.
It is the prolonged and intense action of this pernicious sexual satisfaction which is enough on its own account to provoke a neurasthenic neurosis or which imposes on the subject the special neurasthenic stamp that is manifested later under the influence of an incidental accessory cause. I have also come across people presenting the indications of a neurasthenic constitution in whom I have not succeeded in bringing to light the aetiology I have mentioned; but I have at least shown that the sexual function has never developed to its normal level in these patients; they seemed to have been endowed by heredity with a sexual constitution analogous to what is brought about in a neurasthenic as a result of masturbation. [1896a, 374]

Obsessions similarly presuppose a sexual experience in childhood (though one of a different nature from that found in hysteria). The aetiology of the two neuro-psychoses of defence is related as follows to the aetiology of the two simple neuroses, neurasthenia and anxiety neurosis. Both the latter disorders are direct effects of the sexual noxae themselves, as I have shown in my paper on anxiety neurosis (1895b); both the defence neuroses are indirect consequences of sexual noxae which have occurred before the advent of sexual maturity - are consequences, that is, of the psychical memory-traces of those noxae. The current causes which produce neurasthenia and anxiety neurosis often at the same time play the part of exciting causes of the neuroses of defence; on the other hand, the specific causes of a defence neurosis - the traumas of childhood - can at the same time lay the foundations for a later development of neurasthenia. Finally, it not infrequently happens, too, that neurasthenia or anxiety neurosis is maintained, not by current sexual noxae, but, instead, solely by the persisting effect of a memory of childhood traumas.¹ [1896b, 388]

A reply to objections made by Löwenfeld to the content of No. XXXII. The problem of the aetiology of the pathology of the neuroses is dealt with here, to justify the division into three categories of the aetiological factors that appear: (a) preconditions, (b) specific causes and (c) concurrent or auxiliary causes. What are called preconditions are the factors which, though they are indispensable for producing the effect, cannot by themselves produce it but need in addition the specific causes. The specific causes are distinguished from the preconditions by the fact that they figure in only a few aetiological formulas, while the preconditions play the same part in numerous affections. Auxiliary causes are such as neither need invariably be present nor are able by themselves to produce the effect in question. - In the case of neuroses it is possible that the precondition may be heredity; the specific cause lies in sexual factors; everything else that is brought up apart from these as forming the aetiology of the neuroses (overwork, emotion, physical illness) is an auxiliary cause and can never entirely take the place of the specific factor, though it can no doubt serve as a substitute for it in the matter of quantity. The form of a neurosis depends on the nature of the specific sexual cause; whether there shall be a neurasthenic illness at all is determined by factors operating quantitatively; heredity works like a multiplier inserted in an electric circuit. [1897b, 448]
There may perhaps be some, however, who are quite willing to recognize the sexual aetiology in their neurasthenic patients, but who nevertheless blame it as one-sidedness if they are not asked to pay attention as well to the other factors which are always mentioned by the authorities as causes of neurasthenia. Now it would never occur to me to substitute a sexual aetiology in neuroses for every other aetiology, and so to assert that the latter have no operative force. This would be a misunderstanding. What I think is rather that in addition to all the familiar aetiological factors which have been recognized - and probably correctly so - by the authorities as leading to neurasthenia, the sexual factors, which have not hitherto been sufficiently appreciated, should also be taken into account. In my opinion, however, these sexual factors deserve to be given a special place in the aetiological series. For they alone are never absent in any case of neurasthenia, they alone are capable of producing the neurosis without any further assistance, so that those other factors seem to be reduced to the role of an auxiliary and supplementary aetiology, and they alone allow the physician to recognize firm relations between their manifold nature and the multiplicity of the clinical pictures. If, on the other hand, I group together all the patients who have ostensibly become neurasthenic from overwork, emotional agitation, as an after-effect of typhoid fever, and so on, they show me nothing in common in their symptoms. The nature of their aetiology gives me no idea of what kind of symptoms to expect, any more than, conversely, does the clinical picture they present enable me to infer what aetiology is at work in them.

The sexual causes, too, are the ones which most readily offer the physician a foothold for his therapeutic influence. Heredity is no doubt an important factor, when it is present; it enables a strong pathological effect to come about where otherwise only a very slight one would have resulted. But heredity is inaccessible to the physician's influence; everyone is born with his own hereditary tendencies to illness, and we can do nothing to change them. Nor should we forget that it is precisely in regard to the aetiology of the neurasthenias that we must necessarily deny the first place to heredity. Neurasthenia (in both its forms) is one of those affections which anyone may easily acquire without having any hereditary taint. If it were otherwise, the enormous increase in neurasthenia, of which all the authorities complain, would be unthinkable. In what concerns civilization, among whose sins people so often include responsibility for neurasthenia, these authorities may indeed be right (although the way in which this comes about is probably quite different from what they imagine). Yet the state of our civilization is, once again, something that is unalterable for the individual. Moreover this factor, being common to all the members of the same society, can never explain the fact of selectivity in the incidence of the illness. The physician who is not neurasthenic is exposed to the same influence of an allegedly detrimental civilization as the neurasthenic patient whom he has to treat. Subject to these limitations, the factors of exhaustion retain their significance. But the element of 'overwork', which physicians are so fond of producing to their patients as the cause of their neurosis, is too often unduly misused. It is quite true that anyone who, owing to sexual noxae, has made himself disposed to neurasthenia, tolerates intellectual work and the psychical exigencies of life badly; but no one ever becomes neurotic through work or excitement alone. Intellectual work is rather a protection against falling ill of neurasthenia; it is precisely the most unremitting intellectual workers who remain exempt from neurasthenia, and what neurasthenics complain of as 'overwork that is making them ill' does not as a rule deserve to be called 'intellectual work' at all, either in its quality or quantity. Physicians will have to become accustomed to explaining to an office-worker who has been 'overworked' at his desk or to a housewife for whom her domestic activities have become too heavy, that they have fallen ill, not because they have tried to carry out duties which are in fact easily performed by a civilized brain, but because all the while they have been grossly neglecting and damaging their sexual life.
For such cases it has quite correctly come to be the therapeutic practice to disregard the psychoneurotic components in the clinical picture and to treat the 'actual neurosis' exclusively. In very many cases it is possible to overcome the neurosis as well as it has brought along with it, provided that the neurasthenia is effectively dealt with. But a different view must be taken in those cases of psychoneurosis which either appear spontaneously or remain behind as an independent entity after an illness composed of neurasthenia and psychoneurosis has run its course. When I speak of a 'spontaneous' appearance of a psychoneurosis, I do not mean that anamnestic investigation shows us no aetiological element whatever. It may do so, no doubt; but it may also happen that our attention is directed to some indifferent factor - an emotional state, an enfeeblement owing to physical illness, and so on. It must, however, be borne in mind in all these cases that the true aetiology of the psychoneuroses does not lie in such precipitating causes, but remains beyond the reach of ordinary anamnestic examination.

[1897b, 471]

In the case of anyone who is predisposed to hysteria, the onset of his illness is precipitated when, either as a result of his own progressive maturity or of the external circumstances of his life, he finds himself faced by the demands of a real sexual situation. Between the pressure of the instinct and his antagonism to sexuality, illness offers him a way of escape. It does not solve his conflict, but seeks to evade it by transforming his libidinal impulses into symptoms. The exception is only an apparent one when a hysterical - a male patient it may be - falls ill as a result of some trivial emotion, some conflict which does not centre around any sexual interest. In such cases psycho-analysis is regularly able to show that the illness has been made possible by the sexual component of the conflict, which has prevented the mental processes from reaching a normal issue.

[1905d, 1490]

INTELLECTUAL WORK Finally, it is an unmistakable fact that concentration of the attention upon an intellectual task and intellectual strain in general produce a concomitant sexual excitation in many young people as well as adults. This is no doubt the only justifiable basis for what is in other respects the questionable practice of ascribing nervous disorders to intellectual 'overwork'.

[1905d, 1521]

But in view of the close connections between the psychoneuroses and the simple neuroses, which go so far, indeed, that a differential diagnosis is not always easy for inexperienced observers, it could not be long before the knowledge arrived at in the one field was extended to the other. Moreover, apart from this consideration, a deeper investigation of the psychical mechanism of hysterical symptoms led to the same result. For if the psychical traumas from which the hysterical symptoms were derived were pursued further and further by means of the 'cathartic' procedure initiated by Breuer and me, experiences were eventually reached which belonged to the patient's childhood and related to his sexual life. And this was so, even in cases in which the onset of the illness had been brought about by some commonplace emotion of a non-sexual kind. Unless these sexual traumas of childhood were taken into account it was impossible either to elucidate the symptoms (to understand the way in which they were determined) or to prevent their recurrence. In this way the unique significance of sexual experiences in the aetiology of the psychoneuroses seemed to be established beyond a doubt; and this fact remains to this day one of the corner-stones of my theory.

[1906a, 1576]
I think it is worth emphasizing the fact that, whatever modifications my views on the aetiology of the psychoneuroses have passed through, there are two positions which I have never repudiated or abandoned - the importance of sexuality and of infantilism. Apart from this, accidental influences have been replaced by constitutional factors and 'defence' in the purely psychological sense has been replaced by organic 'sexual repression'. The question may, however, be raised of where convincing evidence is to be found in favour of the alleged aetiological importance of sexual factors in the psychoneuroses, in view of the fact that the onset of these illnesses may be observed in response to the most commonplace emotions or even to somatic precipitating causes, and since I have had to abandon a specific aetiology depending on the particular form of the childhood experiences concerned. To such a question I would reply that the psycho-analytic examination of neurotics is the source from which this disputed conviction of mine is derived. If we make use of that irreplaceable method of research, we discover that the patient's symptoms constitute his sexual activity (whether wholly or in part), which arises from the sources of the normal or perverse component instincts of sexuality. Not only is a large part of the symptomatology of hysteria derived directly from expressions of sexual excitement, not only do a number of erotogenic zones attain the significance of genitals during neuroses owing to an intensification of infantile characteristics, but the most complicated symptoms are themselves revealed as representing, by means of 'conversion', phantasies which have a sexual situation as their subject-matter. Anyone who knows how to interpret the language of hysteria will recognize that the neurosis is concerned only with the patient's repressed sexuality. The sexual function must, however, be understood in its true extent, as it is laid down by disposition in infancy. Wherever some commonplace emotion must be included among the determinants of the onset of the illness, analysis invariably shows that it is the sexual component of the traumatic experience - a component that is never lacking which has produced the pathogenic result.

[1906a, 1582]

Accordingly, the aetiology of the neuroses comprises everything which can act in a detrimental manner upon the processes serving the sexual function. In the forefront, then, are to be ranked the noxae which affect the sexual function itself - in so far as these are regarded as injurious by the sexual constitution, varying as it does with different degrees of culture and education. In the next place comes every other kind of noxa and trauma which, by causing general damage to the organism, may lead secondarily to injury to its sexual processes. It should not, however, be forgotten that the aetiological problem in the case of the neuroses is at least as complicated as the causative factors of any other illness. A single pathogenic influence is scarcely ever sufficient; in the large majority of cases a number of aetiological factors are required, which support one another and must therefore not be regarded as being in mutual opposition. For this reason a state of neurotic illness cannot be sharply differentiated from health. The onset of the illness is the product of a summation and the necessary total of aetiological determinants can be completed from any direction. To look for the aetiology of the neuroses exclusively in heredity or in the constitution would be just as one-sided as to attribute that aetiology solely to the accidental influences brought to bear upon sexuality in the course of the subject's life - whereas better insight shows that the essence of these illnesses lies solely in a disturbance of the organism's sexual processes.

[1906a, 1583]
Even at that time I could not fail to notice that the causation of the illness did not always point to sexual life. One person, it was true, fell ill directly from a sexual noxa; but another did so because he had lost his fortune or had been through an exhausting organic illness. The explanation of these varieties came later, when we gained an insight into the suspected interrelations between the ego and the libido, and the explanation became the more satisfactory the deeper that insight extended. A person only falls ill of a neurosis if his ego has lost the capacity to allocate his libido in some way. The stronger is his ego, the easier will it be for it to carry out that task. Any weakening of his ego from whatever cause must have the same effect as an excessive increase in the claims of the libido and will thus make it possible for him to fall ill of a neurosis. There are other and more intimate relations between the ego and the libido; but these have not yet come within our scope, so I will not bring them up as part of my present explanation. What remains essential and makes things clear to us is that, in every case and no matter how the illness is set going, the symptoms of the neurosis are sustained by the libido and are consequently evidence that it is being employed abnormally.

[1916-1917, 3438]

If now we take up our first question once more, we find that our new line of approach inevitably leads us to a particular conclusion. The question was whether it is possible to dispose of an instinctual conflict permanently and definitively - i.e. to 'tame' an instinctual demand in that fashion. Formulated in these terms, the question makes no mention at all of the strength of the instinct; but it is precisely on this that the outcome depends. Let us start from the assumption that what analysis achieves for neurotics is nothing other than what normal people bring about for themselves without its help. Everyday experience, however, teaches us that in a normal person any solution of an instinctual conflict only holds good for a particular strength of instinct, or, more correctly, only for a particular relation between the strength of the instinct and the strength of the ego.¹ If the strength of the ego diminishes, whether through illness or exhaustion, or from some similar cause, all the instincts which have so far been successfully tamed may renew their demands and strive to obtain substitutive satisfactions in abnormal ways.² Irrefutable proof of this statement is supplied by our nightly dreams; they react to the sleeping attitude assumed by the ego with an awakening of instinctual demands.

[1937c, 5023]

² Here we have a justification of the claim to aetiological importance of such non-specific factors as overwork, shock, etc. These factors have always been assured of general recognition, but have had to be pushed into the background precisely by psycho-analysis. It is impossible to define health except in metapsychological terms: i.e. by reference to the dynamic relations between the agencies of the mental apparatus which have been recognized - or (if that is preferred) inferred or conjectured - by us.

[1937c, 5023]
The biological factor is the long period of time during which the young of the human species is in a condition of helplessness and dependence. Its intra-uterine existence seems to be short in comparison with that of most animals, and it is sent into the world in a less finished state. As a result, the influence of the real external world upon it is intensified and an early differentiation between the ego and the id is promoted. Moreover, the dangers of the external world have a greater importance for it, so that the value of the object which can alone protect it against them and take the place of its former intra-uterine life is enormously enhanced. The biological factor, then, establishes the earliest situations of danger and creates the need to be loved which will accompany the child through the rest of its life.
[1926d, 4308]
If we consider once more the origin of the super-ego as we have described it, we shall recognize that it is the outcome of two highly important factors, one of a biological and the other of a historical nature: namely, the lengthy duration in man of his childhood helplessness and dependence, and the fact of his Oedipus complex, the repression of which we have shown to be connected with the interruption of libidinal development by the latency period and so with the diphasic onset of man's sexual life. According to one psycho-analytic hypothesis, the last-mentioned phenomenon, which seems to be peculiar to man, is a heritage of the cultural development necessitated by the glacial epoch. We see, then, that the differentiation of the super-ego from the ego is no matter of chance; it represents the most important characteristics of the development both of the individual and of the species; indeed, by giving permanent expression to the influence of the parents it perpetuates the existence of the factors to which it owes its origin.

[1923b, 3969]

And now, as a third point, psycho-analysis has shown us, to our growing astonishment, the enormously important part played by what is known as the 'Oedipus complex' - that is, the emotional relation of a child to its two parents - in the mental life of human beings. Our astonishment diminishes when we realize that the Oedipus complex is the psychical correlate of two fundamental biological facts: the long period of the human child's dependence, and the remarkable way in which its sexual life reaches a first climax in the third to fifth years of life, and then, after a period of inhibition, sets in again at puberty. And here, the discovery was made that a third and extremely serious part of human intellectual activity, the part which has created the great institutions of religion, law, ethics, and all forms of civic life, has as its fundamental aim the enabling of the individual to master his Oedipus complex and to divert his libido from its infantile attachments into the social ones that are ultimately desired. The applications of psycho-analysis to the science of religion and sociology (e. g. by the present writer, Theodor Reik and Oskar Pfister), which have led to these findings, are still young and insufficiently appreciated; but it cannot be doubted that further studies will only confirm the certainty of these important conclusions.

[1924f, 4117]

The biological factor is the long period of time during which the young of the human species is in a condition of helplessness and dependence. Its intra-uterine existence seems to be short in comparison with that of most animals, and it is sent into the world in a less finished state. As a result, the influence of the real external world upon it is intensified and an early differentiation between the ego and the id is promoted. Moreover, the dangers of the external world have a greater importance for it, so that the value of the object which can alone protect it against them and take the place of its former intra-uterine life is enormously enhanced. The biological factor, then, establishes the earliest situations of danger and creates the need to be loved which will accompany the child through the rest of its life.

[1926d, 4308]
We can speak with a fair degree of certainty about the part played by the period of life. It seems that neuroses are acquired only in early childhood (up to the age of six), even though their symptoms may not make their appearance till much later. The childhood neurosis may become manifest for a short time or may even be overlooked. In every case the later neurotic illness links up with the prelude in childhood. It is possible that what are known as traumatic neuroses (due to excessive fright or severe somatic shocks, such as railway collisions, burial under falls of earth, and so on) are an exception to this: their relations to determinants in childhood have hitherto eluded investigation. There is no difficulty in accounting for this aetiological preference for the first period of childhood. The neuroses are, as we know, disorders of the ego; and it is not to be wondered at if the ego, so long as it is feeble, immature and incapable of resistance, fails to deal with tasks which it could cope with later on with the utmost ease. In these circumstances instinctual demands from within, no less than excitations from the external world, operate as 'traumas', particularly if they are met half way by certain innate dispositions. The helpless ego fends them off by means of attempts at flight (*repression*), which later turn out to be inefficient and which involve permanent restrictions on further development. The damage inflicted on the ego by its first experiences gives us the appearance of being disproportionately great; but we have only to take as an analogy the differences in the results produced by the prick of a needle into a mass of cells in the act of cell-division (as in Roux's experiments) and into the fully grown animal which eventually develops out of them. No human individual is spared such traumatic experiences; none escapes the repressions to which they give rise. These questionable reactions on the part of the ego may perhaps be indispensable for the attainment of another aim which is set for the same period of life: in the space of a few years the little primitive creature must turn into a civilized human being; he must pass through an immensely long stretch of human cultural development in an almost uncannily abbreviated form. This is made possible by hereditary disposition; but it can almost never be achieved without the additional help of upbringing, of parental influence, which, as a precursor of the super-ego, restricts the ego's activity by prohibitions and punishments, and encourages or compels the setting-up of repressions. We must therefore not forget to include the influence of civilization among the determinants of neurosis. It is easy, as we can see, for a barbarian to be healthy; for a civilized man the task is hard. The desire for a powerful, uninhibited ego may seem to us intelligible; but, as we are taught by the times we live in, it is in the profoundest sense hostile to civilization. And since the demands of civilization are represented by family upbringing, we must bear in mind the part played by this biological characteristic of the human species - the prolonged period of its childhood dependence - in the aetiology of the neuroses.

However instructive cases of this kind may be, a still higher degree of interest must attach to the influence of a situation which every child is destined to pass through and which follows inevitably from the factor of the prolonged period during which a child is cared for by other people and lives with his parents. I am thinking of the *Oedipus complex*, so named because its essential substance is to be found in the Greek legend of King Oedipus, which has fortunately been preserved for us in a version by a great dramatist. The Greek hero killed his father and took his mother to wife. That he did so unwittingly, since he did not know them as his parents, is a deviation from the analytic facts which we can easily understand and which, indeed, we shall recognize as inevitable.
The fact that the onset of sexual development in human beings occurs in two phases, i.e. that the development is interrupted by the period of latency, seemed to call for particular notice. This appears to be one of the necessary conditions of the aptitude of men for developing a higher civilization, but also of their tendency to neurosis. So far as we know, nothing analogous is to be found in man's animal relatives. It would seem that the origin of this peculiarity of man must be looked for in the prehistory of the human species.

[1905d, 1545]

Neurosis stands outside this series. It also is based upon a peculiarity in the development of the human libido - the twice repeated start made by the directly sexual function, with an intervening period of latency.¹ To this extent it resembles hypnosis and group formation in having the character of a regression, which is absent from being in love. It makes its appearance wherever the advance from directly sexual instincts to those that are inhibited in their aims has not been wholly successful; and it represents a conflict between those portions of the instincts which have been received into the ego after having passed through this development and those portions of them which, springing from the repressed unconscious, strive - as do other, completely repressed, instinctual impulses - to attain direct satisfaction. Neuroses are extraordinarily rich in content, for they embrace all possible relations between the ego and the object - both those in which the object is retained and others in which it is abandoned or erected inside the ego itself - and also the conflicting relations between the ego and its ego ideal.

[1921c, 3834]

If we consider once more the origin of the super-ego as we have described it, we shall recognize that it is the outcome of two highly important factors, one of a biological and the other of a historical nature: namely, the lengthy duration in man of his childhood helplessness and dependence, and the fact of his Oedipus complex, the repression of which we have shown to be connected with the interruption of libidinal development by the latency period and so with the biphasic onset of man's sexual life. According to one psycho-analytic hypothesis, the last-mentioned phenomenon, which seems to be peculiar to man, is a heritage of the cultural development necessitated by the glacial epoch. We see, then, that the differentiation of the super-ego from the ego is no matter of chance; it represents the most important characteristics of the development both of the individual and of the species; indeed, by giving permanent expression to the influence of the parents it perpetuates the existence of the factors to which it owes its origin.

[1923b, 3969]

And now, as a third point, psycho-analysis has shown us, to our growing astonishment, the enormously important part played by what is known as the 'Oedipus complex' - that is, the emotional relation of a child to its two parents - in the mental life of human beings. Our astonishment diminishes when we realize that the Oedipus complex is the psychical correlate of two fundamental biological facts: the long period of the human child's dependence, and the remarkable way in which its sexual life reaches a first climax in the third to fifth years of life, and then, after a period of inhibition, sets in again at puberty. And here, the discovery was made that a third and extremely serious part of human intellectual activity, the part which has created the great institutions of religion, law, ethics, and all forms of civic life, has as its fundamental aim the enabling of the individual to master his Oedipus complex and to divert his libido from its infantile attachments into the social ones that are ultimately desired. The applications of psycho-analysis to the science of religion and sociology (e. g. by the present writer, Theodor Reik and Oskar Pfister), which have led to these findings, are still young and insufficiently appreciated; but it cannot be doubted that further studies will only confirm the certainty of these important conclusions.

[1924f, 4117]
The process of arriving at an object, which plays such an important part in mental life, takes place alongside of the organization of the libido. After the stage of auto-erotism, the first love-object in the case of both sexes is the mother; and it seems probable that to begin with a child does not distinguish its mother's organ of nutrition from its own body. Later, but still in the first years of infancy, the relation known as the Oedipus complex becomes established: boys concentrate their sexual wishes upon their mother and develop hostile impulses against their father as being a rival, while girls adopt an analogous attitude.¹ All of the different variations and consequences of the Oedipus complex are important; and the innately bisexual constitution of human beings makes itself felt and increases the number of simultaneously active tendencies. Children do not become clear for quite a long time about the differences between the sexes; and during this period of sexual researches they produce typical sexual theories which, being circumscribed by the incompleteness of their authors' own physical development, are a mixture of truth and error and fail to solve the problems of sexual life (the riddle of the Sphinx - that is, the question of where babies come from). We see, then, that a child's first object-choice is an incestuous one. The whole course of development that I have described is run through rapidly. For the most remarkable feature of the sexual life of man is its diphasic onset, its onset in two waves, with an interval between them. It reaches a first climax in the fourth or fifth year of a child's life. But thereafter this early efflorescence of sexuality passes off; the sexual impulses which have shown such liveliness are overcome by repression, and a period of latency follows, which lasts until puberty and during which the reaction-formations of morality, shame, and disgust are built up.² Of all living creatures man alone seems to show this diphasic onset of sexual growth, and it may perhaps be the biological determinant of his predisposition to neuroses. At puberty the impulses and object-relations of a child's early years become re-animated, and amongst them the emotional ties of its Oedipus complex. In the sexual life of puberty there is a struggle between the urges of early years and the inhibitions of the latency period. Before this, and while the child is at the highest point of its infantile sexual development, a genital organization of a sort is established; but only the male genitals play a part in it, and the female ones remain undiscovered. (I have described this as the period of phallic primacy.) At this stage the contrast between the sexes is not stated in terms of 'male' or 'female' but of 'possessing a penis' or 'castrated'. The castration complex which arises in this connection is of the profoundest importance in the formation alike of character and of neuroses.

¹[1925d, 4212]

²[1926d, 4309]
Then I will pursue the subject further; in any case it is not easy for me to get away from it. I will tell you, then, that the most remarkable thing about the sexual life of children seems to me that it passes through the whole of its very far-reaching development in the first five years of life. From then onwards until puberty there stretches what is known as the period of latency. During it sexuality normally advances no further; on the contrary, the sexual urges diminish in strength and many things are given up and forgotten which the child did and knew. During that period of life, after the early efflorescence of sexuality has withered, such attitudes of the ego as shame, disgust and morality arise, which are destined to stand up against the later tempest of puberty and to lay down the path of the freshly awakening sexual desires. This 'diphasic onset', as it is named, of sexual life has a great deal to do with the genesis of neurotic illnesses. It seems to occur only in human beings, and it is perhaps one of the determinants of the human privilege of becoming neurotic. The prehistory of sexual life was just as much overlooked before psycho-analysis as, in another department, the background to conscious mental life. You will rightly suspect that the two are intimately connected.

[1926e, 4353]

These three points - the very early appearance of these experiences (during the first five years of life), the fact of their being forgotten and their sexual-aggressive content - are closely interconnected. The traumas are either experiences on the subject's own body or sense perceptions, mostly of something seen and heard - that is, experiences or impressions. The interconnection of these three points is established by a theory, a product of the work of analysis which alone can bring about a knowledge of the forgotten experiences, or, to put it more vividly but also more incorrectly, bring them back to memory. The theory is that, in contrast to popular opinion, the sexual life of human beings (or what corresponds to it later on) exhibits an early efflorescence which comes to an end at about the fifth year and is followed by what is known as the period of latency (till puberty) in which there is no further development of sexuality and indeed what has been attained undergoes a retrogression. This theory is confirmed by the anatomical investigation of the growth of the internal genitalia; it leads us to suppose that the human race is descended from a species of animal which reached sexual maturity in five years and rouses a suspicion that the postponement of sexual life and its diphasic onset are intimately connected with the history of hominization. Human beings appear to be the only animal organisms with a latency period and sexual retardation of this kind. Investigations on the primates (which, so far as I know, are not available) would be indispensable for testing this theory. It cannot be a matter of indifference psychologically that the period of infantile amnesia coincides with this early period of sexuality. It may be that this state of things provides the true determinant for the possibility of neurosis, which is in a sense a human prerogative and from this point of view appears as a vestige - a 'survival' - of primaeval times like certain portions of our bodily anatomy.

[1939a, 4900]
Another mental need, which is also shared by obsessional neurotics and which is in some respects related to the one just mentioned, is the need for uncertainty in their life, or for doubt. An enquiry into this characteristic leads deep into the investigation of instinct. The creation of uncertainty is one of the methods employed by the neurosis for drawing the patient away from reality and isolating him from the world - which is among the objects of every psychoneurotic disorder. Again, it is only too obvious what efforts are made by the patients themselves in order to be able to avoid certainty and remain in doubt. Some of them, indeed, give a vivid expression to this tendency in a dislike of clocks and watches (for these at least make the time of day certain), and in the unconscious artifices which they employ in order to render these doubt removing instruments innocuous. Our present patient had developed a peculiar talent for avoiding a knowledge of any facts which would have helped him in deciding his conflict. Thus he was in ignorance upon those matters relating to his lady which were the most relevant to the question of his marriage: he was ostensibly unable to say who had operated upon her and whether the operation had been unilateral or bilateral. He had to be forced into remembering what he had forgotten and into finding out what he had overlooked.

[1909d, 2182]

LADIES AND GENTLEMEN, - With the discovery of infantile sexuality and the tracing back of neurotic symptoms to erotic instinctual components we have arrived at some unexpected formulas concerning the nature and purposes of neurotic illnesses. We see that human beings fall ill when, as a result of external obstacles or of an internal lack of adaptation, the satisfaction of their erotic needs in reality frustrated. We see that they then take flight into illness in order that by its help they may find a satisfaction to take the place of what has been frustrated. We recognize that the pathological symptoms constitute a portion of the subject's sexual activity or even the whole of his sexual life, and we find that the withdrawal from reality is the main purpose of the illness but also the main damage caused by it. We suspect that our patients' resistance to recovery is no simple one, but compounded of several motives. Not only does the patient's ego rebel against giving up the repressions by means of which it has risen above its original disposition, but the sexual instincts are unwilling to renounce their substitutive satisfaction so long as it is uncertain whether reality will offer them anything better.

[1910a, 2234]
The deeper you penetrate into the pathogenesis of nervous illness, the more you will find revealed the connection between the neuroses and other productions of the human mind, including the most valuable. You will be taught that we humans, with the high standards of our civilization and under the pressure of our internal repressions, find reality unsatisfying quite generally, and for that reason entertain a life of phantasy in which we like to make up for the insufficiencies of reality by the production of wish-fulfillments. These phantasies include a great deal of the true constitutional essence of the subject's personality as well as of those of his impulses which are repressed where reality is concerned. The energetic and successful man is one who succeeds by his efforts in turning his wishful phantasies into reality. Where this fails, as a result of the resistances of the external world and of the subject's own weakness, he begins to turn away from reality and withdraws into his more satisfying world of phantasy, the content of which is transformed into symptoms should he fall ill. In certain favourable circumstances, it still remains possible for him to find another path leading from these phantasies to reality, instead of becoming permanently estranged from it by regressing to infancy. If a person who is at loggerheads with reality possesses an artistic gift (a thing that is still a psychological mystery to us), he can transform his phantasies into artistic creations instead of into symptoms. In this manner he can escape the doom of neurosis and by this roundabout path regain his contact with reality. (Cf. Rank, 1907.) If there is persistent rebellion against the real world and if this precious gift is absent or insufficient, it is almost inevitable that the libido, keeping to the sources of the phantasies, will follow the path of regression, and will revive infantile wishes and end in neurosis. To-day neurosis takes the place of the monasteries which used to be the refuge of all whom life had disappointed or who felt too weak to face it. [1910a, 2235]

Two factors will decide whether this advance in the developmental path of the libido is to fail. First, there is the amount of frustration in reality, which opposes the new object-choice and reduces its value for the person concerned. There is after all no point in embarking upon an object-choice if no choice is to be allowed at all or if there is no prospect of being able to choose anything suitable. Secondly, there is the amount of attraction which the infantile objects that have to be relinquished are able to exercise, and which is in proportion to the erotic cathexis attaching to them in childhood. If these two factors are sufficiently strong, the general mechanism by which the neuroses are formed comes into operation. The libido turns away from reality, is taken over by imaginative activity (the process of introversion), strengthens the images of the first sexual objects and becomes fixated to them. The obstacle raised against incest, however, compels the libido that has turned to these objects to remain in the unconscious. The masturbatory activity carried out by the sensual current, which is now part of the unconscious, makes its own contribution in strengthening this fixation. Nothing is altered in this state of affairs if the advance which has miscarried in reality is now completed in phantasy, and if in the phantasy-situations that lead to masturbatory satisfaction the original sexual objects are replaced by different ones. As a result of this substitution the phantasies become admissible to consciousness, but no progress is made in the allocation of the libido in reality. In this way it can happen that the whole of a young man's sensuality becomes tied to incestuous objects in the unconscious, or to put it another way, becomes fixated to unconscious incestuous phantasies. The result is then total impotence, which is perhaps further ensured by the simultaneous onset of an actual weakening of the organs that perform the sexual act. [1912d, 2339]
We have long observed that every neurosis has as its result, and probably therefore as its purpose, a forcing of the patient out of real life, an alienating of him from reality. Nor could a fact such as this escape the observation of Pierre Janet; he spoke: of a loss of 'la fonction du réel' ['the function of reality'] as being a special characteristic of neurotics, but without discovering the connection of this disturbance with the fundamental determinants of neurosis.¹ By introducing the process of repression into the genesis of the neuroses we have been able to gain some insight into this connection. Neurotics turn away from reality because they find it unbearable - either the whole or parts of it. The most extreme type of this turning away from reality is shown by certain cases of hallucinatory psychosis which seek to deny the particular event that occasioned the outbreak of their insanity (Griesinger). But in fact every neurotic does the same with some fragment of reality.² And we are now confronted with the task of investigating the development of the relation of neurotics and of mankind in general to reality, and in this way of bringing the psychological significance of the real external world into the structure of our theories.

[1911b, 2552]

Where these are present and sufficiently strongly developed, there is a risk of the libido becoming 'introverted'.¹ It turns away from reality, which, owing to the obstinate frustration, has lost its value for the subject, and turns towards the life of phantasy, in which it creates new wishful structures and revives the traces of earlier, forgotten ones. In consequence of the intimate connection between the activity of phantasy and material present in everyone which is infantile and repressed and has become unconscious, and thanks to the exceptional position enjoyed by the life of phantasy in regard to reality-testing,² the libido may thenceforward move on a backward course; it may follow the path of regression along infantile lines, and strive after aims that correspond with them. If these strivings, which are incompatible with the subject's present-day individuality, acquire enough intensity, a conflict must result between them and the other portion of his personality, which has maintained its relation to reality. This conflict is resolved by the formation of symptoms, and is followed by the onset of manifest illness. The fact that the whole process originated from frustration in the real world is reflected in the resulting event that the symptoms, in which the ground of reality is reached once more, represent substitutive satisfactions.

[1912c, 2560]

The asocial nature of neuroses has its genetic origin in their most fundamental purpose, which is to take flight from an unsatisfying reality into a more pleasurable world of phantasy. The real world, which is avoided in this way by neurotics, is under the sway of human society and of the institutions collectively created by it. To turn away from reality is at the same time to withdraw from the community of man.

[1912-1913, 2717]

It is true that psycho-analysis has taken the individual mind as its subject, but in investigating the individual it could not avoid dealing with the emotional basis of the relation of the individual to society. It has found that the social feelings invariably contain an erotic element - an element which, if it is over-emphasized and then repressed, becomes one of the marks of a particular group of mental disorders. Psycho-analysis has recognized that in general the neuroses are asocial in their nature and that they always aim at driving the individual out of society and at replacing the safe monastic seclusion of earlier days by the isolation of illness. The intense feeling of guilt which dominates so many neuroses has been shown to be a social modification of neurotic anxiety.

[1913, 2824]
A pressing motive for occupying ourselves with the conception of a primary and normal narcissism arose when the attempt was made to subsume what we know of dementia praecox (Kraepelin) or schizophrenia (Bleuler) under the hypothesis of the libido theory. Patients of this kind, whom I have proposed to term paraphrenics, display two fundamental characteristics: megalomania and diversion of their interest from the external world - from people and things. In consequence of the latter change, they become inaccessible to the influence of psycho-analysis and cannot be cured by our efforts. But the paraphrenic’s turning away from the external world needs to be more precisely characterized. A patient suffering from hysteria or obsessional neurosis has also, as far as his illness extends, given up his relation to reality. But analysis shows that he has by no means broken off his erotic relations to people and things. He still retains them in phantasy; i.e. he has, on the one hand, substituted for real objects imaginary ones from his memory, or has mixed the latter with the former; and on the other hand, he has renounced the initiation of motor activities for the attainment of his aims in connection with those objects. Only to this condition of the libido may we legitimately apply the term ‘introversion’ of the libido which is used by Jung indiscriminately. It is otherwise with the paraphrenic. He seems really to have withdrawn his libido from people and things in the external world, without replacing them by others in phantasy. When he does so replace them, the process seems to be a secondary one and to be part of an attempt at recovery, designed to lead the libido back to objects.¹

To take the first of these. Both patients give us an impression of having been ‘fixed’ to a particular portion of their past, as though they could not manage to free themselves from it and were for that reason alienated from the present and the future. They then remained lodged in their illness in the sort of way in which in earlier days people retreated into a monastery in order to bear the burden there of their ill-fated lives. What had brought this fate upon our first patient was the marriage which she had in real life abandoned. By means of her symptoms she continued to carry on her dealings with her husband. We learnt to understand the voices that pleaded for him, that excused him, that put him on a pedestal and that lamented his loss. Although she was young and desirable to other men, she had taken every precaution, real and imaginary (magical), to remain faithful to him. She did not show herself to strangers and she neglected her personal appearance; furthermore, once she had sat down in a chair she was unable to get out of it quickly, she refused to sign her name, and she could not make any presents, on the ground that no one ought to receive anything from her.

We cannot dismiss the question of why, in what way and for what motive a person can arrive at such a remarkable attitude to life and one that is so inexpedient - assuming that this attitude is a general characteristic of neuroses and not a special peculiarity of these two patients. And in fact it is a general feature, of great practical importance, in every neurosis. Breuer’s first hysterical patient was similarly fixated to the period when she was nursing her father in a serious illness. In spite of her recovery, in a certain respect she remained cut off from life; she remained healthy and efficient but avoided the normal course of a woman’s life. In every one of our patients, analysis shows us that they have been carried back to some particular period of their past by the symptoms of their illness or their consequences. In the majority of cases, indeed, a very early phase of life is chosen for the purpose - a period of their childhood or even, laughable as this may sound, of their existence as an infant at the breast.
But this does not at all agree with the observation which all of us can make that every neurosis disturbs the patient's relation to reality in some way, that it serves him as a means of withdrawing from reality, and that, in its severe forms, it actually signifies a flight from real life. This contradiction seems a serious one; but it is easily resolved, and the explanation of it will in fact help us to understand neuroses.

We might expect that when a psychosis comes into being, something analogous to the process in a neurosis occurs, though, of course, between different agencies of the mind; thus we might expect that in a psychosis, too, two steps could be discerned, of which the first would drag the ego away, this time from reality, while the second would try to make good the damage done and re-establish the subject's relations to reality at the expense of the id. And, in fact, some analogy of the sort can be observed in a psychosis. Here, too, there are two steps, the second of which has the character of a reparation. But beyond that the analogy gives way to a far more extensive similarity between the two processes. The second step of the psychosis is indeed intended to make good the loss of reality, not, however, at the expense of a restriction of the id - as happens in neurosis at the expense of the relation to reality - but in another, more autocratic manner, by the creation of a new reality which no longer raises the same objections as the old one that has been given up. The second step, therefore, both in neurosis and psychosis, is supported by the same trends. In both cases it serves the desire for power of the id, which will not allow itself to be dictated to by reality. Both neurosis and psychosis are thus the expression of a rebellion on the part of the id against the external world, of its unwillingness - or, if one prefers, its incapacity - to adapt itself to the exigencies of reality, to 'Αυτόχτωνη [Necessity]. Neurosis and psychosis differ from each other far more in their first, introductory, reaction than in the attempt at reparation which follows it.

Accordingly, the initial difference is expressed thus in the final outcome: in neurosis a piece of reality is avoided by a sort of flight, whereas in psychosis it is remodelled. Or we might say: in psychosis, the initial flight is succeeded by an active phase of remodelling; in neurosis, the initial obedience is succeeded by a deferred attempt at flight. Or again, expressed in yet another way: neurosis does not disavow the reality, it only ignores it; psychosis disavows it and tries to replace it. We call behaviour 'normal' or 'healthy', if it combines certain features of both reactions - if it disavows the reality as little as does a neurosis, but if it then exerts itself, as does a psychosis, to effect an alteration of that reality. Of course, this expedient, normal, behaviour leads to work being carried out on the external world; it does not stop, as in psychosis, at effecting internal changes. It is no longer autoplastic but alloplastic.

A neurosis usually contents itself with avoiding the piece of reality in question and protecting itself against coming into contact with it. The sharp distinction between neurosis and psychosis, however, is weakened by the circumstance that in neurosis, too, there is no lack of attempts to replace a disagreeable reality by one which is more in keeping with the subject's wishes. This is made possible by the existence of a world of phantasy, of a domain which became separated from the real external world at the time of the introduction of the reality principle. This domain has since been kept free from the demands of the exigencies of life, like a kind of 'reservation'; it is not inaccessible to the ego, but is only loosely attached to it. It is from this world of phantasy that the neurosis draws the material for its new wishful constructions, and it usually finds that material along the path of regression to a more satisfying real past.
It can hardly be doubted that the world of phantasy plays the same part in psychosis and that there, too, it is the storehouse from which the materials or the pattern for building the new reality are derived. But whereas the new, imaginary external world of a psychosis attempts to put itself in the place of external reality, that of a neurosis, on the contrary, is apt, like the play of children, to attach itself to a piece of reality - a different piece from the one against which it has to defend itself - and to lend that piece a special importance and a secret meaning which we (not always quite appropriately) call a symbolic one. Thus we see that both in neurosis and psychosis there comes into consideration the question not only of a loss of reality but also of a substitute for reality.

[1924e, 4098]

These last two features - the rejection of the claims of reality and the putting thought of the pleasure principle - bring humour near to the regressive or reactionary processes which engage our attention so extensively in psychopathology. Its fending off of the possibility of suffering places it among the great series of methods which the human mind has constructed in order to evade the compulsion to suffer - a series which begins with neurosis and culminates in madness and which includes intoxication, self-absorption and ecstasy. Thanks to this connection, humour possesses a dignity which is wholly lacking, for instance, in jokes, for jokes either serve simply to obtain a yield of pleasure or place the yield of pleasure that has been obtained in the service of aggression. In what, then, does the humorous attitude consist, an attitude by means of which a person refuses to suffer, emphasizes the invincibility of his ego by the real world, victoriously maintains the pleasure principle - and all this, in contrast to other methods having the same purposes, without overstepping the bounds of mental health? The two achievements seem incompatible.

[1927d, 4543]
¹ [Footnote added 1923:] This is not quite right. The statement that the motives of illness are not present at the beginning of the illness, but only appear secondarily to it, cannot be maintained. In the very next paragraph motives for being ill are mentioned which were in existence before the outbreak of illness, and were partly responsible for that outbreak. I subsequently found a better way of meeting the facts, by introducing a distinction between the primary advantage derived from the illness and the secondary one. The motive for being ill is, of course, invariably the gaining of some advantage. What follows in the later sentences of this paragraph applies to the secondary gain. But in every neurotic illness a primary gain has also to be recognized. In the first place, falling ill involves a saving of psychical effort; it emerges as being economically the most convenient solution where there is a mental conflict (we speak of a 'flight into illness'), even though in most cases the ineffectiveness of such an escape becomes manifest at a later stage. This element in the primary gain may be described as the internal or psychological one, and it is, so to say, a constant one. But beyond this, external factors (such as in the instance given of the situation of a woman subjugated by her husband) may contribute motives for falling ill; and these will constitute the external element in the primary gain.

[1905e, 1380]

Years have again gone by since her visit. In the meantime the girl has married, and indeed - unless all the signs mislead me - she has married the young man who came into her associations at the beginning of the analysis of the second dream. Just as the first dream represented her turning away from the man she loved to her father - that is to say, her flight from life into disease - so the second dream announced that she was about to tear herself free from her father and had been reclaimed once more by the realities of life.

[1905e, 1456]

In the case of anyone who is predisposed to hysteria, the onset of his illness is precipitated when, either as a result of his own progressive maturity or of the external circumstances of his life, he finds himself faced by the demands of a real sexual situation. Between the pressure of the instinct and his antagonism to sexuality, illness offers him a way of escape. It does not solve his conflict, but seeks to evade it by transforming his libidinal impulses into symptoms. The exception is only an apparent one when a hysteric - a male patient it may be - falls ill as a result of some trivial emotion, some conflict which does not centre around any sexual interest. In such cases psycho-analysis is regularly able to show that the illness has been made possible by the sexual component of the conflict, which has prevented the mental processes from reaching a normal issue.

[1905d, 1490]
This obscure region of the story is made intelligible to us by some explanations which we derive from the later remarks of Zoe Bertgang. It was in fact the original of Gradiva, Fräulein Zoe herself, whom Hanold saw out of his window walking past in the street (89.) and whom he nearly overtook. If this had happened, the information given him by the dream - that she was in fact living at the same time and in the same town as he was - would by a lucky chance have received an irresistible confirmation, which would have brought about the collapse of his internal struggle. But the canary, whose singing sent Hanold off on his distant journey, belonged to Zoe, and its cage stood in her window diagonally across the street from Hanold's house. (135.) Hanold, who, according to the girl's accusation, had the gift of 'negative hallucination', who possessed the art of not seeing and not recognizing people who were actually present, must from the first have had an unconscious knowledge of what we only learned later. The indications of Zoe's proximity (her appearance in the street and her bird's singing so near his window) intensified the effect of the dream, and in this position, so perilous for his resistance to his erotic feelings, he took to flight. His journey was a result of his resistance gathering new strength after the surge forward of his erotic desires in the dream; it was an attempt at flight from the physical presence of the girl he loved. In a practical sense it meant a victory for repression, just as his earlier activity, his 'pedestrian researches' upon women and girls, had meant a victory for erotism. But everywhere in these oscillations in the struggle the compromise character of the outcome was preserved: the journey to Pompeii, which was supposed to lead him away from the living Zoe, led him at least to her surrogate, to Gradiva. The journey which was undertaken in defiance of the latent dream-thoughts, was nevertheless following the path to Pompeii that was pointed out by the manifest content of the dream. Thus at every fresh struggle between erotism and resistance we find the delusion triumphant.

[1907a, 1862]

These considerations have been based so far on the requirement laid down by the second of the stages of civilization which we have postulated, the requirement that every sexual activity of the kind described as perverse is prohibited, while what is called normal sexual intercourse is freely permitted. We have found that even when the line between sexual freedom and restriction is drawn at this point, a number of individuals are ruled out as perverts, and a number of others, who make efforts not to be perverts whilst constitutionally they should be so, are forced into nervous illness. It is easy to predict the result that will follow if sexual freedom is still further circumscribed and the requirements of civilization are raised to the level of the third stage, which bans all sexual activity outside legal marriage. The number of strong natures who openly oppose the demands of civilization will increase enormously, and so will the number of weaker ones who, faced with the conflict between the pressure of cultural influences and the resistance of their constitution, take flight into neurotic illness.

[1908d, 1955]
This brings us to the question whether sexual intercourse in legal marriage can offer full compensation for the restrictions imposed before marriage. There is such an abundance of material supporting a reply in the negative that we can give only the briefest summary of it. It must above all be borne in mind that our cultural sexual morality restricts sexual intercourse even in marriage itself, since it imposes on married couples the necessity of contenting themselves, as a rule, with a very few procreative acts. As a consequence of this consideration, satisfying sexual intercourse in marriage takes place only for a few years; and we must subtract from this, of course, the intervals of abstention necessitated by regard for the wife's health. After these three, four or five years, the marriage becomes a failure in so far as it has promised the satisfaction of sexual needs. For all the devices hitherto invented for preventing conception impair sexual enjoyment, hurt the fine susceptibilities of both partners and even actually cause illness. Fear of the consequences of sexual intercourse first brings the married couple's physical affection to an end; and then, as a remoter result, it usually puts a stop as well to the mental sympathy between them, which should have been the successor to their original passionate love. The spiritual disillusionment and bodily deprivation to which most marriages are thus doomed puts both partners back in the state they were in before their marriage, except for being the poorer by the loss of an illusion, and they must once more have recourse to their fortitude in mastering and deflecting their sexual instinct. We need not enquire how far men, by then in their maturer years, succeed in this task. Experience shows that they very frequently avail themselves of the degree of sexual freedom which is allowed them - although only with reluctance and under a veil of silence - by even the strictest sexual code. The 'double' sexual morality which is valid for men in our society is the plainest admission that society itself does not believe in the possibility of enforcing the precepts which it itself has laid down. But experience shows as well that women, who, as being the actual vehicle of the sexual interests of mankind, are only endowed in a small measure with the gift of sublimating their instincts, and who, though they may find a sufficient substitute for the sexual object in an infant at the breast, do not find one in a growing child - experience shows, I repeat, that women, when they are subjected to the disillusionments of marriage, fall ill of severe neuroses which permanently darken their lives. Under the cultural conditions of to-day, marriage has long ceased to be a panacea for the nervous troubles of women; and if we doctors still advise marriage in such cases, we are nevertheless aware that, on the contrary, a girl must be very healthy if she is to be able to tolerate it, and we urgently advise our male patients not to marry any girl who has had nervous trouble before marriage. On the contrary, the cure for nervous illness arising from marriage would be marital unfaithfulness. But the more strictly a woman has been brought up and the more sternly she has submitted to the demands of civilization, the more she is afraid of taking this way out; and in the conflict between her desires and her sense of duty, she once more seeks refuge in a neurosis. Nothing protects her virtue as securely as an illness. Thus the married state, which is held out as a consolation to the sexual instinct of the civilized person in his youth, proves to be inadequate even to the demands of the actual period of life covered by it. There is no question of its being able to compensate for the deprivation which precedes it. [1908d, 1957]

The onset of hysterical attacks follows laws that are easily understandable. Since the repressed complex consists of a libidinal cathexis and an ideational content (the phantasy), the attack can be evoked (1) associatively, when the content of the complex (if sufficiently cathected) is touched on by something connected with it in conscious life; (2) organically, when, for internal somatic reasons and as a result of psychical influences from outside, the libidinal cathexis rises above a certain degree; (3) in the service of the primary purpose - as an expression of a 'flight into illness', when reality becomes distressing or frightening - that is, as a consolation; (4) in the service of the secondary purposes, with which the illness allies itself, as soon as, by producing an attack, the patient can achieve an aim that is useful to him. In the last case the attack is directed at particular individuals; it can be put off till they are present, and it gives an impression of being consciously simulated. [1909a, 1983]
But I must now return to a more detailed examination of the precipitating cause of our present patient's illness. His mother was brought up in a wealthy family with which she was distantly connected. This family carried on a large industrial concern. His father, at the time of his marriage, had been taken into the business, and had thus by his marriage made himself a fairly comfortable position. The patient had learnt from some chaff exchanged between his parents (whose marriage was an extremely happy one) that his father, some time before making his mother's acquaintance, had made advances to a pretty but penniless girl of humble birth. So much by way of introduction. After his father's death the patient's mother told him one day that she had been discussing his future with her rich relations, and that one of her cousins had declared himself ready to let him marry one of his daughters when his education was completed; a business connection with the firm would offer him a brilliant opening in his profession. This family plan stirred up in him a conflict as to whether he should remain faithful to the lady he loved in spite of her poverty, or whether he should follow in his father's footsteps and marry the lovely, rich, and well-connected girl who had been assigned to him. And he resolved this conflict, which was in fact one between his love and the persisting influence of his father's wishes, by falling ill; or, to put it more correctly, by falling ill he avoided the task of resolving it in real life.¹

¹ It is worth emphasizing that his flight into illness was made possible by his identifying himself with his father. The identification enabled his affects to regress on to the residue of his childhood.

LADIES AND GENTLEMEN, - With the discovery of infantile sexuality and the tracing back of neurotic symptoms to erotic instinctual components we have arrived at some unexpected formulas concerning the nature and purposes of neurotic illnesses. We see that human beings fall ill when, as a result of external obstacles or of an internal lack of adaptation, the satisfaction of their erotic needs in reality frustrated. We see that they then take flight into illness in order that by its help they may find a satisfaction to take the place of what has been frustrated. We recognize that the pathological symptoms constitute a portion of the subject's sexual activity or even the whole of his sexual life, and we find that the withdrawal from reality is the main purpose of the illness but also the main damage caused by it. We suspect that our patients' resistance to recovery is no simple one, but compounded of several motives. Not only does the patient's ego rebel against giving up the repressions by means of which it has risen above its original disposition, but the sexual instincts are unwilling to renounce their substitutive satisfaction so long as it is uncertain whether reality will offer them anything better.

The flight from unsatisfactory reality into what, on account of the biological damage involved, we call illness (though it is never without an immediate yield of pleasure to the patient) takes place along the path of involution, of regression, of a return to earlier phases of sexual life, phases from which at one time satisfaction was not withheld. This regression appears to be a twofold one: a temporal one, in so far as the libido, the erotic needs, hark back to stages of development that are earlier in time, and a formal one, in that the original and primitive methods of psychical expression are employed in manifesting those needs. Both these kinds of regression, however, lead back to childhood and unite in bringing about an infantile condition of sexual life.
Let us return to our more serious case. A certain number of people, faced in their lives by conflicts which they have found too difficult to solve, have taken flight into neurosis and in this way won an unmistakable, although in the long run too costly, gain from illness. What will these people have to do if their flight into illness is barred by the indiscreet revelations of psycho-analysis? They will have to be honest, confess to the instincts that are at work in them, face the conflict, fight for what they want, or go without it; and the tolerance of society, which is bound to ensue as a result of psycho-analytic enlightenment, will help them in their task.

[1910d, 2314]

Let us remember, however, that our attitude to life ought not to be that of a fanatic for hygiene or therapy. We must admit that the ideal prevention of neurotic illnesses which we have in mind would not be of advantage to every individual. A good number of those who now take flight into illness would not, under the conditions we have assumed, support the conflict but would rapidly succumb or would cause a mischief greater than their own neurotic illness. Neuroses have in fact their biological function as a protective contrivance and they have their social justification: the 'gain from illness' they provide is not always a purely subjective one. Is there one of you who has not at some time looked into the causation of a neurosis and had to allow that it was the mildest possible outcome of the situation? And should such heavy sacrifices be made in order to eradicate the neuroses in particular, when the world is full of other unavoidable misery?

[1910d, 2314]

Where these are present and sufficiently strongly developed, there is a risk of the libido becoming 'introverted'. It turns away from reality, which, owing to the obstinate frustration, has lost its value for the subject, and turns towards the life of phantasy, in which it creates new wishful structures and revives the traces of earlier, forgotten ones. In consequence of the intimate connection between the activity of phantasy and material present in everyone which is infantile and repressed and has become unconscious, and thanks to the exceptional position enjoyed by the life of phantasy in regard to reality-testing, the libido may thenceforward move on a backward course; it may follow the path of regression along infantile lines, and strive after aims that correspond with them. If these strivings, which are incompatible with the subject's present-day individuality, acquire enough intensity, a conflict must result between them and the other portion of his personality, which has maintained its relation to reality. This conflict is resolved by the formation of symptoms, and is followed by the onset of manifest illness. The fact that the whole process originated from frustration in the real world is reflected in the resulting event that the symptoms, in which the ground of reality is reached once more, represent substitutive satisfactions.

[1912c, 2560]

The asocial nature of neuroses has its genetic origin in their most fundamental purpose, which is to take flight from an unsatisfying reality into a more pleasurable world of phantasy. The real world, which is avoided in this way by neurotics, is under the sway of human society and of the institutions collectively created by it. To turn away from reality is at the same time to withdraw from the community of man.

[1912-1913, 2717]
It is true that psycho-analysis has taken the individual mind as its subject, but in investigating the individual it could not avoid dealing with the emotional basis of the relation of the individual to society. It has found that the social feelings invariably contain an erotic element - an element which, if it is over-emphasized and then repressed, becomes one of the marks of a particular group of mental disorders. Psycho-analysis has recognized that in general the neuroses are asocial in their nature and that they always aim at driving the individual out of society and at replacing the safe monastic seclusion of earlier days by the isolation of illness. The intense feeling of guilt which dominates so many neuroses has been shown to be a social modification of neurotic anxiety.

[1913, 2824]

The ego takes a similar interest, however, in the development and maintenance of the neurosis in every other case. I have already shown that symptoms are supported by the ego, too, because they have a side with which they offer satisfaction to the repressing purpose of the ego. Moreover, settling the conflict by constructing a symptom is the most convenient way out and the one most agreeable to the pleasure principle: it unquestionably spares the ego a large amount of internal work which is felt as distressing. Indeed there are cases in which even the physician must admit that for a conflict to end in neurosis is the most harmless and socially tolerable solution. You must not be surprised to hear that even the physician may occasionally take the side of the illness he is combating. It is not his business to restrict himself in every situation in life to being a fanatic in favour of health. He knows that there is not only neurotic misery in the world but real, irremovable suffering as well, that necessity may even require a person to sacrifice his health; and he learns that a sacrifice of this kind made by a single person can prevent immeasurable unhappiness for many others. If we may say, then, that whenever a neurotic is faced by a conflict he takes flight into illness, yet we must allow that in some cases that flight is fully justified, and a physician who has recognized how the situation lies will silently and solicitously withdraw.

[1916-1917, 3435]

But this episode, though it is now closed, was not without an important influence on the spread of psycho-analysis. Medical men who had hitherto held back from any approach to psycho-analytic theories were brought into closer contact with them when, in the course of their duties as army doctors, they were obliged to deal with war neuroses. The reader will be able to gather from Ferenczi's paper with what hesitations and under what disguises these closer contacts were made. Some of the factors which psycho-analysis had recognized and described long before as being at work in peace-time neuroses - the psychogenic origin of the symptoms, the importance of unconscious instinctual impulses, the part played in dealing with mental conflicts by the primary gain from being ill ('the flight into illness') - were observed to be present equally in the war neuroses and were accepted almost universally. Simmel's studies show, too, what successes could be achieved by treating war neurotics by the method of catharsis, which, as we know, was the first step towards the psycho-analytic technique.

[1919d, 3665]
The World War, which broke up so many other organizations, could do nothing against our 'International'. The first meeting after the war took place in 1920, at The Hague, on neutral ground. It was moving to see how hospitably the Dutch welcomed the starving and impoverished subjects of the Central European states; and I believe this was the first occasion in a ruined world on which Englishmen and Germans sat at the same table for the friendly discussion of scientific interests. Both in Germany and in the countries of Western Europe the war had actually stimulated interest in psycho-analysis. The observation of war neuroses had at last opened the eyes of the medical profession to the importance of psychogenesis in neurotic disturbances, and some of our psychological conceptions, such as the 'gain from illness' and the 'flight into illness', quickly became popular. The last Congress before the German collapse, which was held at Budapest in 1918, was attended by official representatives of the allied governments of the Central European powers, and they agreed to the establishment of psycho-analytic Centres for the treatment of war neuroses. But this point was never reached. Similarly too the comprehensive plans made by one of our leading members, Dr. Anton von Freund, for establishing in Budapest a centre for analytic study and treatment came to grief as a result of the political upheavals that followed soon afterwards and of the premature death of their irreplaceable author. At a later date some of his ideas were put into execution by Max Eitingon, who in 1920 founded a psycho-analytical clinic in Berlin. During the brief period of Bolshevik rule in Hungary, Ferenczi was still able to carry on a successful course of instruction as the official representative of psycho-analysis at the University of Budapest. After the war our opponents were pleased to announce that events had produced a conclusive argument against the validity of the theses of analysis. The war neuroses, they said, had proved that sexual factors were unnecessary to the aetiology of neurotic disorders. But their triumph was frivolous and premature. For on the one hand no one had been able to carry out a thorough analysis of a case of war neurosis, so that in fact nothing whatever was known for certain as to their motivation and no conclusions could be drawn from this uncertainty; while on the other hand psycho-analysis had long before arrived at the concept of narcissism and of narcissistic neuroses, in which the subject's libido is attached to his own ego instead of to an object. Though on other occasions, therefore, the charge was brought against psycho-analysis of having made an unjustifiable extension of the concept of sexuality, yet, when it became convenient for controversial ends, this crime was forgotten and we were once more held down to the narrowest meaning of the word.

[1925d, 4229]
In spite of the incompleteness, I will venture on a few remarks as a conclusion to our enquiry. The programme of becoming happy, which the pleasure principle imposes on us, cannot be fulfilled; yet we must not - indeed, we cannot - give up our efforts to bring it nearer to fulfilment by some means or other. Very different paths may be taken in that direction, and we may give priority either to the positive aspect of the aim, that of gaining pleasure, or to its negative one, that of avoiding unpleasure. By none of these paths can we attain all that we desire. Happiness, in the reduced sense in which we recognize it as possible, is a problem of the economics of the individual's libido. There is no golden rule which applies to everyone: every man must find out for himself in what particular fashion he can be saved. All kinds of different factors will operate to direct his choice. It is a question of how much real satisfaction he can expect to get from the external world, how far he is led to make himself independent of it, and, finally, how much strength he feels he has for altering the world to suit his wishes. In this, his psychical constitution will play a decisive part, irrespectively of the external circumstances. The man who is predominantly erotic will give first preference to his emotional relationships to other people; the narcissistic man, who inclines to be self-sufficient, will seek his main satisfactions in his internal mental processes; the man of action will never give up the external world on which he can try out his strength. As regards the second of these types, the nature of his talents and the amount of instinctual sublimation open to him will decide where he shall locate his interests. Any choice that is pushed to an extreme will be penalized by exposing the individual to the dangers which arise if a technique of living that has been chosen as an exclusive one should prove inadequate. Just as a cautious business-man avoids tying up all his capital in one concern, so, perhaps, worldly wisdom will advise us not to look for the whole of our satisfaction from a single aspiration. Its success is never certain, for that depends on the convergence of many factors, perhaps on none more than on the capacity of the psychical constitution to adapt its function to the environment and then to exploit that environment for a yield of pleasure. A person who is born with a specially unfavourable instinctual constitution, and who has not properly undergone the transformation and rearrangement of his libidinal components which is indispensable for later achievements, will find it hard to obtain happiness from his external situation, especially if he is faced with tasks of some difficulty. As a last technique of living, which will at least bring him substitutive satisfactions, he is offered that of a flight into neurotic illness - a flight which he usually accomplishes when he is still young. The man who sees his pursuit of happiness come to nothing in later years can still find consolation in the yield of pleasure of chronic intoxication; or he can embark on the desperate attempt at rebellion seen in a psychosis.¹

[1930a, 4482]
This girl, who was bubbling over with intellectual vitality, led an extremely monotonous existence in her puritanically-minded family. She embellished her life in a manner which probably influenced her decisively in the direction of her illness, by indulging in systematic day-dreaming, which she described as her 'private theatre'. While everyone thought she was attending, she was living through fairy tales in her imagination; but she was always on the spot when she was spoken to, so that no one was aware of it. She pursued this activity almost continuously while she was engaged on her household duties, which she discharged unexceptionably. I shall presently have to describe the way in which this habitual day-dreaming while she was well passed over into illness without a break.

[1895d, 22]

There is in general no guarantee of the data produced by our memory. But I am ready to agree with you that the scene is genuine. If so, you selected it from innumerable others of a similar or another kind because, on account of its content (which in itself was indifferent) it was well adapted to represent the two phantasies, which were important enough to you. A recollection of this kind, whose value lies in the fact that it represents in the memory impressions and thoughts of a later date whose content is connected with its own by symbolic or similar links, may appropriately be called a 'screen memory'. In any case you will cease to feel any surprise that this scene should so often recur to your mind. It can no longer be regarded as an innocent one since, as we have discovered, it is calculated to illustrate the most momentous turning-points in your life, the influence of the two most powerful motive forces - hunger and love.

[1899a, 496]

² If anyone is curious to know, I may add that the dream concealed a phantasy of my behaving in an improper and sexually provocative manner, and of the patient putting up a defence against my conduct. If this interpretation seems incredible, I need only point to the numerous instances in which doctors have charges of the same kind brought against them by hysterical women. But in such cases the phantasy emerges into consciousness undisguised and in the form of a delusion, instead of being distorted and appearing only as a dream. - [Added 1909:] This dream occurred at the beginning of the patient's psycho-analytic treatment. It was not until later that I learnt that she had been repeating in it the initial trauma from which her neurosis had arisen. I have since then come across the same behaviour in other patients; having been exposed to a sexual assault in their childhood, they seek, as it were, to bring about a repetition of it in their dreams.

[1900a, 671]
Indeed, when we look into the matter more closely, we must recognize the fact that the dream-work is doing nothing original in making substitutions of this kind. In order to gain its ends - in this case the possibility of a representation hampered by censorship - it merely follows the paths which it finds already laid down in the unconscious; and it gives preference to those transformations of the repressed material which can also become conscious in the form of jokes or allusions and of which the phantasies of neurotic patients are so full. At this point we suddenly reach an understanding of Scherner's dream interpretations, whose essential correctness I have defended elsewhere. The imagination's preoccupation with the subject's own body is by no means peculiar to dreams or characteristic only of them. My analyses have shown me that it is habitually present in the unconscious thoughts of neurotics, and that it is derived from sexual curiosity, which, in growing youths or girls, is directed to the genitals of the other sex, and to those of their own as well. Nor, as Scherner and Volkelt have rightly insisted, is a house the only circle of ideas employed for symbolizing the body; and this is equally true of dreams and of the unconscious phantasies of neurosis. It is true that I know patients who have retained an architectural symbolism for the body and the genitals. (Sexual interest ranges far beyond the sphere of the external genitalia.) For these patients pillars and columns represent the legs (as they do in the Song of Solomon), every gateway stands for one of the bodily orifices ('hole'), every water-pipe is a reminder of the urinary apparatus, and so on. But the circle of ideas centring round plant-life or the kitchen may just as readily be chosen to conceal sexual images.¹ In the former case the way has been well prepared by linguistic usage, itself the precipitate of imaginative similes reaching back to remote antiquity: e.g. the Lord's vineyard, the seed, and the maiden's garden in the Song of Solomon. The ugliest as well as the most intimate details of sexual life may be thought and dreamt of in seemingly innocent allusions to activities in the kitchen; and the symptoms of hysteria could never be interpreted if we forgot that sexual symbolism can find its best hiding-place behind what is commonplace and inconspicuous. There is a valid sexual meaning behind the neurotic child's intolerance of blood or raw meat, or his nausea at the sight of eggs or macaroni, and behind the enormous exaggeration in neurotics of the natural human dread of snakes. Wherever neuroses make use of such disguises they are following paths along which all humanity passed in the earliest periods of civilization - paths of whose continued existence today, under the thinnest of veils, evidence is to be found in linguistic usages, superstitions and customs.

[1900a, 815]
I do not wish to deny categorically that this fourth power in dream-construction - which we shall soon recognize as all old acquaintance, since in fact it is the only one of the four with which we are familiar in other connections - I do not wish to deny that this fourth factor has the capacity to create new contributions to dreams. It is certain, however, that, like the others, it exerts its influence principally by its preferences and selections from psychical material in the dream-thoughts that has already been formed. Now there is one case in which it is to a great extent spared the labour of, as it were, building up a façade for the dream - the case, namely, in which a formation of that kind already exists, available for use in the material of the dream-thoughts. I am in the habit of describing the element in the dream-thoughts which I have in mind as a 'phantasy.' I shall perhaps avoid misunderstanding if I mention the 'day-dream' as something analogous to it in waking life.¹ The part played in our mental life by these structures has not yet been fully recognized and elucidated by psychiatrists, though M. Benedikt has made what seems to me a very promising start in that direction. The importance of day-dreams has not escaped the unerring vision of imaginative writers; there is, for instance, a well-known account by Alphonse Daudet in Le Nabab of the day-dreams of one of the minor characters in that story. The study of the psychoneuroses leads to the surprising discovery that these phantasies or day-dreams are the immediate forerunners of hysterical symptoms, or at least of a whole number of them. Hysterical symptoms are not attached to actual memories, but to phantasies erected on the basis of memories. The frequent occurrence of conscious daytime phantasies brings these structures to our knowledge; but just as there are phantasies of this kind which are conscious, so, too, there are unconscious ones in great numbers, which have to remain unconscious on account of their content and of their origin from repressed material. Closer investigation of the characteristics of these day-time phantasies shows us how right it is that these formations should bear the same name as we give to the products of our thought during the night - the name, that is, of 'dreams.' They share a large number of their properties with night-dreams, and their investigation might, in fact, have served as the shortest and best approach to an understanding of night-dreams.

[1900a, 931]
The function of 'secondary revision', which we have attributed to the fourth of the factors concerned in shaping the content of dreams, shows us in operation once more the activity which is able to find free vent in the creation of day-dreams without being inhibited by any other influences. We might put it simply by saying that this fourth factor of ours seeks to mould the material offered to it into something like a day-dream. If, however, a day-dream of this kind has already been formed within the nexus of the dream-thoughts, this fourth factor in the dream-work will prefer to take possession of the ready-made day-dream and seek to introduce it into the content of the dream. There are some dreams which consist merely in the repetition of a day-time phantasy which may perhaps have remained unconscious: such, for instance, as the boy's dream of driving in a war-chariot with the heroes of the Trojan War. In my 'Autodidasker' dream the second part at all events was a faithful reproduction of a daytime phantasy, innocent in itself, of a conversation with Professor N. In view of the complicated conditions which a dream has to satisfy when it comes into existence, it happens more frequently that the ready-made phantasy forms only a portion of the dream, or that only a portion of the phantasy forces its way into the dream. Thereafter, the phantasy is treated in general like any other portion of the latent material, though it often remains recognizable as an entity in the dream. There are often parts of my dreams which stand out as producing a different impression from the rest. They strike me as being, as it were, more fluent, more connected and at the same time more fleeting than other parts of the same dream. These, I know, are unconscious phantasies which have found their way into the fabric of the dream, but I have never succeeded in pinning down a phantasy of this kind. Apart from this, these phantasies, like any other component of the dream-thoughts, are compressed, condensed, superimposed on one another, and so on. There are, however, transitional cases, between the case in which they constitute the content (or at least the façade) of the dream unaltered and the extreme opposite in which they are represented in the content of the dream only by one of their elements or by a distant allusion. What happens to phantasies present in the dream-thoughts is evidently also determined by any advantages they may have to offer the requirements of the censorship and of the urge towards condensation.

Now that the old antithesis between conscious life and dream life has been reduced to its proper proportions by the establishment of unconscious psychical reality, a number of dream-problems with which earlier writers were deeply concerned have lost their significance. Thus some of the activities whose successful performance in dreams excited astonishment are now no longer to be attributed to dreams but to unconscious thinking, which is active during the day no less than at night. If, as Scherner has said, dreams appear to engage in making symbolic representations of the body, we now know that those representations are the product of certain unconscious phantasies (deriving, probably, from sexual impulses) which find expression not only in dreams but also in hysterical phobias and other symptoms. If a dream carries on the activities of the day and completes them and even brings valuable fresh ideas to light, all we need do is to strip it of the dream disguise, which is the product of dream-work and the mark of assistance rendered by obscure forces from the depths of the mind (cf. the Devil in Tartini's sonata dream); the intellectual achievement is due to the same mental forces which produce every similar result during the daytime. We are probably inclined greatly to over-estimate the conscious character of intellectual and artistic production as well. Accounts given us by some of the most highly productive men, such as Goethe and Helmholtz, show rather that what is essential and new in their creations came to them without premeditation and as an almost ready-made whole. There is nothing strange if in other cases, where a concentration of every intellectual faculty was needed, conscious activity also contributed its share. But it is the much-abused privilege of conscious activity, wherever it plays a part, to conceal every other activity from our eyes.

[1900a, 932]

[1900a, 1038]
It would be a mistake, however, to suppose that these dream-facades are nothing other than mistaken and somewhat arbitrary revisions of the dream-content by the conscious agency of our mental life. In the erection of a dream-façade use is not infrequently made of wishful phantasies which are present in the dream-thoughts in a pre-constructed form, and are of the same character as the appropriately named 'day-dreams' familiar to us in waking life. The wishful phantasies revealed by analysis in night-dreams often turn out to be repetitions or modified versions of scenes from infancy; thus in some cases the facade of the dream directly reveals the dream's actual nucleus, distorted by an admixture of other material.

[1901a, 1081]

As regards the second kind of emotional reaction, which is not directed against me this time, but against my patient - supposing that my view of her is correct - and which regards the perverse nature of her phantasies as horrible, I should like to say emphatically that a medical man has no business to indulge in such passionate condemnation. I may also remark in passing that it seems to me superfluous for a physician who is writing upon the aberrations of the sexual instincts to seize every opportunity of inserting into the text expressions of his personal repugnance at such revolting things. We are faced by a fact; and it is to be hoped that we shall grow accustomed to it, when we have put our own tastes on one side. We must learn to speak without indignation of what we call the sexual perversions - instances in which the sexual function has extended its limits in respect either to the part of the body concerned or to the sexual object chosen. The uncertainty in regard to the boundaries of what is to be called normal sexual life, when we take different races and different epochs into account, should in itself be enough to cool the zealot's ardour. We surely ought not to forget that the perversion which is the most repellent to us, the sensual love of a man for a man, was not only tolerated by a people so far our superiors in cultivation as were the Greeks, but was actually entrusted by them with important social functions. The sexual life of each one of us extends to a slight degree - now in this direction, now in that - beyond the narrow lines imposed as the standard of normality. The perversions are neither bestial nor degenerate in the emotional sense of the word. They are a development of germs all of which are contained in the undifferentiated sexual disposition of the child, and which, by being suppressed or by being diverted to higher, asexual aims - by being 'sublimated' - are destined to provide the energy for a great number of our cultural achievements. When, therefore, any one has become a gross and manifest pervert, it would be more correct to say that he has remained one, for he exhibits a certain stage of inhibited development. All psychoneurotics are persons with strongly marked perverse tendencies, which have been repressed in the course of their development and have become unconscious. Consequently their unconscious phantasies show precisely the same content as the documentarily recorded actions of perverts - even though they have not read Krafft-Ebing's *Psychopathia Sexualis*, to which simple-minded people attribute such a large share of the responsibility for the production of perverse tendencies. Psychoneuroses, so to speak, the negative of perversions. In neurotics their sexual constitution, under which the effects of heredity are included, operates in combination with any accidental influences in their life which may disturb the development of normal sexuality. A stream of water which meets with an obstacle in the river-bed is dammed up and flows back into old channels which had formerly seemed fated to run dry. The motive forces leading to the formation of hysterical symptoms draw their strength not only from repressed normal sexuality but also from unconscious perverse activities.¹

[1905e, 1387]
Nor do I know whether Herr K. would have done any better if it had been revealed to him that
the slap Dora gave him by no means signified a final 'No' on her part, but that it expressed the
jealousy which had lately been roused in her, while her strongest feelings were still on his side.
If he had disregarded that first 'No', and had continued to press his suit with a passion which left
room for no doubts, the result might very well have been a triumph of the girl's affection for him
over all her internal difficulties. But I think she might just as well have been merely provoked into
satisfying her craving for revenge upon him all the more thoroughly. It is never possible to
calculate towards which side the decision will incline in such a conflict of motives: whether
towards the removal of the repression or towards its reinforcement. Incapacity for meeting a real
erotic demand is one of the most essential features of a neurosis. Neurotics are dominated by
the opposition between reality and phantasy. If what they long for the most intensely in their
phantasies is presented to them in reality, they none the less flee from it; and they abandon
themselves to their phantasies the most readily where they need no longer fear to see them
realized. Nevertheless, the barrier erected by repression can fall before the onslaught of a
violent emotional excitement produced by a real cause; it is possible for a neurosis to be
overcome by reality. But we have no general means of calculating through what person or what
event such a cure can be effected.¹

[1905e, 1445]

Though even to-day I do not consider these assertions incorrect, it is not to be wondered at
that, in the course of ten years of continuous effort at reaching an understanding of these
phenomena, I have made a considerable step forward from the views I then held, and now
believe that I am in a position, on the basis of deeper experience, to correct the insufficiencies,
the displacements and the misunderstandings under which my theory then laboured. At that
time my material was still scanty, and it happened by chance to include a disproportionately
large number of cases in which sexual seduction by an adult or by older children played the
chief part in the history of the patient's childhood. I thus over-estimated the frequency of such
events (though in other respects they were not open to doubt). Moreover, I was at that period
unable to distinguish with certainty between falsifications made by hysterics in their memories of
childhood and traces of real events. Since then I have learned to explain a number of
phantasies of seduction as attempts at fending off memories of the subject's own sexual activity
( infantile masturbation). When this point had been clarified, the 'traumatic' element in the
sexual experiences of childhood lost its importance and what was left was the realization that
infantile sexual activity (whether spontaneous or provoked ) prescribes the direction that will be
taken by later sexual life after maturity. The same clarification (which corrected the most
important of my early mistakes) also made it necessary to modify my view of the mechanism of
hysterical symptoms. They were now no longer to be regarded as direct derivatives of the
repressed memories of childhood experiences; but between the symptoms and the childish
impressions there were inserted the patient's phantasies (or imaginary memories), mostly
produced during the years of puberty, which on the one side were built up out of and over the
childhood memories and on the other side were transformed directly into the symptoms. It was
only after the introduction of this element of hysterical phantasies that the texture of the
neurosis and its relation to the patient's life became intelligible; a surprising analogy came to
light, too, between these unconscious phantasies of hysterics and the imaginary creations of
paranoics which become conscious as delusions.

[1906a, 1578]
The interest taken by the hero of the story in this relief is the basic psychological fact in the narrative. It was not immediately explicable. 'Dr. Norbert Hanold, Lecturer in Archaeology, did not in fact find in the relief anything calling for special notice from the point of view of his branch of science.' (3.)¹ 'He could not explain to himself what there was in it that had provoked his attention. He only knew that he had been attracted by something and that the effect had continued unchanged ever since.' But his imagination was occupied with the sculpture without ceasing. He found something 'of to-day' about it, as though the artist had had a glimpse in the street and captured it 'from the life'. He gave the girl thus pictured as she stepped along the name of 'Gradiva' - 'the girl who steps along'. He made up a story that she was no doubt the daughter of an aristocratic family, perhaps 'of a patrician aedile, who carried out his office in the service of Ceres', and that she was on her way to the goddess's temple. Then he found it hard to fit her quiet, calm nature into the busy life of a capital city. He convinced himself, rather, that she must be transported to Pompeii, and that somewhere there she was stepping across the curious stepping-stones which have been dug up and which made it possible to cross dry-foot from one side of the street to the other in rainy weather, though allowing carriage-wheels to pass between them as well. Her features struck him as having a Greek look and he had no doubt that she was of Hellenic origin. Little by little he brought the whole of his archaeological learning into the service of these and other phantasies relating to the original who had been the model for the relief.

[1907a, 1816]
The first manifestations of the process that had been set going in Hanold by the relief were phantasies, which played around the figure represented in it. The figure seemed to him to have something 'of to-day' about her, in the best sense of the words, and it was as though the artist had captured her 'from the life' stepping along the street. He gave the girl in the ancient relief the name of 'Gradiva', which he constructed on the model of an epithet of the war-god striding into battle - 'Mars Gradivus'. He endowed her personality with more and more characteristics. She may have been the daughter of a respected personage, of a patrician, perhaps, who was connected with the temple service of a deity. He thought he could trace a Greek origin in her features; and finally he felt compelled to remove her from the busy life of a capital and to transport her to the more peaceful Pompeii, and there he made her step across the lava stepping-stones which made it possible to cross from one side of the street to the other. These products of his phantasy seem arbitrary enough, but at the same time innocently unsuspicious. And, indeed, even when for the first time they gave rise to an incitement to action - when the archaeologist, obsessed by the problem of whether this posture of the feet corresponded to reality, began to make observations from life in order to examine the feet of contemporary women and girls - even this action was screened by conscious scientific motives, as though all his interest in the sculpture of Gradiva had sprung from the soil of his professional concern with archaeology. The women and girls in the street, whom he chose as the subjects of his investigation, must, of course, have taken another, crudely erotic view of his behaviour, and we cannot but think them right. We ourselves can be in no doubt that Hanold was as much in ignorance of the motives of his researches as he was of the origin of his phantasies about Gradiva. These, as we learned later, were echoes of his memories of his youthful love, derivatives of those memories, transformations and distortions of them, after they had failed to make their way into his consciousness in an unmodified form. The ostensibly aesthetic judgement that the sculpture had something 'of to-day' about it took the place of his knowledge that a gait of that kind belonged to a girl whom he knew and who stepped across the street at the present time. Behind the impression of the sculpture being 'from the life' and the phantasy of its subject being Greek lay his memory of the name Zoe, which means 'life' in Greek. 'Gradiva', as we learn from our hero himself at the end of the story, after he has been cured of his delusion, is a good translation of the surname 'Bertgang' which means something like 'someone who steps along brilliantly or splendidly'. The details about Gradiva's father originated from Hanold's knowledge that Zoe Bertgang was the daughter of a respected teacher at the University, which can well be translated into classical terms as 'temple-service'. Finally, his phantasy transported her to Pompeii, not 'because her quiet, calm nature seemed to demand it', but because no other or better analogy could be found in his science for his remarkable state, in which he became aware of his memories of his childhood friendship through obscure channels of information. Once he had made his own childhood coincide with the classical past (which it was so easy for him to do), there was a perfect similarity between the burial of Pompeii - the disappearance of the past combined with its preservation - and repression, of which he possessed a knowledge through what might be described as 'endopsychic' perception. In this he was employing the same symbolism that the author makes the girl use consciously towards the conclusion of the story: 'I told myself I should be able to dig out something interesting here even by myself. Of course I hadn't counted on making the find that I have . . .' (124.) And at the very end she replied to Hanold's plan for their honeymoon with a reference to 'her childhood friend who had also in a sense been dug out of the ruins again'. (150.) [1907a, 1849]
Let us recall all that we have heard about the nature and origin of the phantasies which are the precursors of delusions. They are substitutes for and derivatives of repressed memories which a resistance will not allow to enter consciousness unaltered, but which can purchase the possibility of becoming conscious by taking account, by means of changes and distortions, of the resistance's censorship. When this compromise has been accomplished, the memories have turned into the phantasies, which can easily be misunderstood by the conscious personality - that is, understood so as to fit in with the dominant psychical current. Now let us suppose that dream-images are what might be described as the creations of people's physiological delusions - the products of the compromise in the struggle between what is repressed and what is dominant which is probably present in every human being, including those who in the day-time are perfectly sound in mind. We shall then understand that dream-images have to be regarded as something distorted, behind which something else must be looked for, something not distorted, but in some sense objectionable, like Hanold's repressed memories behind his phantasies. We can give expression to the contrast which we have thus recognized, by distinguishing what the dreamer remembers when he wakes up as the manifest content of the dream from what constituted the basis of the dream before the distortion imposed by the censorship - namely, the latent dream-thoughts. Thus, interpreting a dream consists in translating the manifest content of the dream into the latent dream-thoughts, in undoing the distortion which the dream-thoughts have had to submit to from the censorship of the resistance. If we apply these notions to the dream we are concerned with, we shall find that its latent dream-thoughts can only have been: 'the girl you are looking for with the graceful gait is really living in this town with you.' But in that form the thought could not become conscious. It was obstructed by the fact that a phantasy had laid it down, as the result of an earlier compromise, that Gradiva was a Pompeian; consequently, if the real fact that she was living in the same place and at the same time was to be affirmed, there was no choice but to adopt the distortion: 'You are living at Pompeii at the time of Gradiva.' This then was the idea which was realized by the manifest content of the dream, and was represented as a present event actually being experienced.

[1907a, 1855]

But, you will ask, if people make such a mystery of their phantasying, how is it that we know such a lot about it? Well, there is a class of human beings upon whom, not a god, indeed, but a stern goddess - Necessity - has allotted the task of telling what they suffer and what things give them happiness. These are the victims of nervous illness, who are obliged to tell their phantasies, among other things, to the doctor by whom they expect to be cured by mental treatment. This is our best source of knowledge, and we have since found good reason to suppose that our patients tell us nothing that we might not also hear from healthy people.

[1908e, 1924]

There is a great deal more that could be said about phantasies; but I will only allude as briefly as possible to certain points. If phantasies become over-luxuriant and over-powerful, the conditions are laid for an onset of neurosis or psychosis. Phantasies, moreover, are the immediate mental precursors of the distressing symptoms complained of by our patients. Here a broad by-path branches off into pathology.

[1908e, 1925]
We are all familiar with the delusional imaginings of the paranoic, which are concerned with the
greatness and the sufferings of his own self and which appear in forms that are quite typical and
almost monotonous. We have also become acquainted, through numerous accounts, with the
strange performances with which certain perverts stage their sexual satisfaction, whether in
idea or reality. Nevertheless, it may be new to some readers to hear that quite analogous
psychical structures are regularly present in all the psychoneuroses, particularly in hysteria, and
that these latter - which are known as hysterical phantasies - can be seen to have important
connections with the causation of the neurotic symptoms.

[1908a, 1932]

These day-dreams are cathected with a large amount of interest; they are carefully cherished
by the subject and usually concealed with a great deal of sensitivity, as though they were
among the most intimate possessions of his personality. It is easy to recognize a person who is
absorbed in day-dreaming in the street, however, by his sudden, as it were absent-minded,
smile, his way of talking to himself, or by the hastening of his steps which marks the climax of
the imagined situation. Every hysterical attack which I have been able to investigate up to the
present has proved to be an involuntary irruption of day-dreams of this kind. For our
observations no longer leave any room for doubt that such phantasies may be unconscious just
as well as conscious; and as soon as the latter have become unconscious they may also
become pathogenic - that is, they may express themselves in symptoms and attacks. In
favourable circumstances, the subject can still capture an unconscious phantasy of this sort in
consciousness. After I had drawn the attention of one of my patients to her phantasies, she told
me that on one occasion she had suddenly found herself in tears in the street and that, rapidly
considering what it was she was actually crying about, she had got hold of a phantasy to the
following effect. In her imagination she had formed a tender attachment to a pianist who was
well known in the town (though she was not personally acquainted with him); she had had a
child by him (she was in fact childless); and he had then deserted her and her child and left
them in poverty. It was at this point in her romance that she had burst into tears.

[1908a, 1933]

Unconscious phantasies have either been unconscious all along and have been formed in the
unconscious; or - as is more often the case - they were once conscious phantasies, day-
dreams, and have since been purposely forgotten and have become unconscious through
'repression'. Their content may afterwards either have remained the same or have undergone
alterations, so that the present unconscious phantasies are derivatives of the once conscious
ones. Now an unconscious phantasy has a very important connection with the subject's sexual
life; for it is identical with the phantasy which served to give him sexual satisfaction during a
period of masturbation. At that time the masturbatory act (in the widest sense of the term) was
compounded of two parts. One was the evocation of a phantasy and the other some active
behaviour for obtaining self-gratification at the height of the phantasy. This compound, as we
know, was itself merely soldered together.¹ Originally the action was a purely auto-erotic
procedure for the purpose of obtaining pleasure from some particular part of the body, which
could be described as erotogenic. Later, this action became merged with a wishful idea from the
sphere of object-love and served as a partial realization of the situation in which the phantasy
culminated. When, subsequently, the subject renounces this type of satisfaction, composed of
masturbation and phantasy, the action is given up, while the phantasy, from being conscious,
becomes unconscious. If no other mode of sexual satisfaction supervenes, the subject remains
abstinent; and if he does not succeed in sublimating his libido - that is, in deflecting his sexual
excitation to higher aims -, the condition is now fulfilled for his unconscious phantasy to be
revived and to proliferate, and, at least as regards some part of its content, to put itself into
effect, with the whole force of his need for love, in the form of a pathological symptom.

[1908a, 1934]
Owing, probably, to the difficulties which the unconscious phantasies meet with in their endeavour to find expression, the relationship of the phantasies to the symptoms is not simple, but on the contrary, complicated in many ways.¹ As a rule - when, that is, the neurosis is fully developed and has persisted for some time - a particular symptom corresponds, not to a single unconscious phantasy, but to several such phantasies; and it does so not in an arbitrary manner but in accordance with a regular pattern. At the beginning of the illness these complications are, no doubt, not all fully developed.

[1908a, 1936]

This connection between symptoms and phantasies makes it easy to arrive from a psycho-analysis of the former at a knowledge of the components of the sexual instincts which dominate the individual, as I have demonstrated in my 《Three Essays on the Theory of Sexuality》. In some cases, however, investigation by this means yields an unexpected result. It shows that there are many symptoms where the uncovering of a sexual phantasy (or of a number of phantasies, one of which, the most significant and the earliest, is of a sexual nature) is not enough to bring about a resolution of the symptoms. To resolve it one has to have two sexual phantasies, of which one has a masculine and the other a feminine character. Thus one of these phantasies springs from a homosexual impulse. This new finding does not alter our seventh formula. It remains true that a hysterical symptom must necessarily represent a compromise between a libidinal and a repressing impulse; but it may also represent a union of two libidinal phantasies of an opposite sexual character.

[1908a, 1937]

The bisexual nature of hysterical symptoms, which can in any event be demonstrated in numerous cases, is an interesting confirmation of my view that the postulated existence of an innate bisexual disposition in man is especially clearly visible in the analysis of psychoneurotics.² An exactly analogous state of affairs occurs in the same field when a person who is masturbating tries in his conscious phantasies to have the feelings both of the man and of the woman in the situation which he is picturing. Further counterparts are to be found in certain hysterical attacks in which the patient simultaneously plays both parts in the underlying sexual phantasy. In one case which I observed, for instance, the patient pressed her dress up against her body with one hand (as the woman), while she tried to tear it off with the other (as the man). This simultaneity of contradictory actions serves to a large extent to obscure the situation, which is otherwise so plastically portrayed in the attack, and it is thus well suited to conceal the unconscious phantasy that is at work.

[1908a, 1938]
In considering the question of abstinence, the distinction is not nearly strictly enough made between two forms of it - namely abstention from any sexual activity whatever and abstention from sexual intercourse with the opposite sex. Many people who boast of succeeding in being abstinent have only been able to do so with the help of masturbation and similar satisfactions which are linked with the auto-erotic sexual activities of early childhood. But precisely because of this connection such substitutive means of sexual satisfaction are by no means harmless; they predispose to the numerous varieties of neuroses and psychoses which are conditional on an involution of sexual life to its infantile forms. Masturbation, moreover, is far from meeting the ideal demands of civilized sexual morality, and consequently drives young people into the same conflicts with the ideals of education which they hoped to escape by abstinence. Furthermore, it vitiates the character through indulgence, and this in more than one way. In the first place, it teaches people to achieve important aims without taking trouble and by easy paths instead of through an energetic exertion of force - that is, it follows the principle that sexuality lays down the pattern of behaviour; secondly, in the phantasies that accompany satisfaction the sexual object is raised to a degree of excellence which is not easily found again in reality. A witty writer (Karl Kraus in the Vienna paper Die Fackel) once expressed this truth in reverse by cynically remarking: 'Copulation is no more than an unsatisfying substitute for masturbation.'

When one carries out the psycho-analysis of a hysterical woman patient whose complaint is manifested in attacks, one soon becomes convinced that these attacks are nothing else but phantasies translated into the motor sphere, projected on to motility and portrayed in pantomime. It is true that the phantasies are unconscious; but apart from this they are of the same nature as the phantasies which can be observed directly in day-dreams or which can be elicited by interpretation from dreams at night. Often a dream takes the place of an attack, and still more often it explains it, since the same phantasy finds a different expression in a dream and in an attack. We might expect then that by observing an attack we should be able to get to know the phantasy represented in it; but this is seldom possible. As a rule, owing to the influence of the censorship, the pantomimic portrayal of the phantasy has undergone distortions which are completely analogous to the hallucinatory distortions of a dream, so that both of them have, in the first resort, become unintelligible to the subject's own consciousness as well as to the observer's comprehension. A hysterical attack, therefore, needs to be subjected to the same interpretative revision as we employ for night-dreams. But not only are the forces from which the distortion proceeds and the purpose of the distortion the same as those we have come to know through the interpretation of dreams; the technique employed in the distortion is the same too.

(1) The attack becomes unintelligible through the fact that it represents several phantasies in the same material simultaneously - that is to say through condensation. The elements common to the two (or more) phantasies constitute the nucleus of the representation, as they do in dreams. The phantasies which are thus made to coincide are often of quite a different nature. They may, for instance, be a recent wish and the re-activation of an infantile impression. The same innervations are in that case made to serve both purposes, often in a most ingenious way. Hysterical patients who make a very extensive use of condensation may find a single form of attack sufficient; others express their numerous pathogenic phantasies by a multiplication of the forms of attack.
The later stage in the development of the neurotic's estrangement from his parents, begun in this manner, might be described as 'the neurotic's family romance'. It is seldom remembered consciously but can almost always be revealed by psycho-analysis. For a quite peculiarly marked imaginative activity is one of the essential characteristics of neurotics and also of all comparatively highly gifted people. This activity emerges first in children's play, and then, starting roughly from the period before puberty, takes over the topic of family relations. A characteristic example of this peculiar imaginative activity is to be seen in the familiar day-dreaming¹ which persists far beyond puberty. If these day-dreams are carefully examined, they are found to serve as the fulfilment of wishes and as a correction of actual life. They have two principal aims, an erotic and an ambitious one - though an erotic aim is usually concealed behind the latter too. At about the period I have mentioned, then, the child's imagination becomes engaged in the task of getting free from the parents of whom he now has a low opinion and of replacing them by others, who, as a rule, are of higher social standing. He will make use in this connection of any opportune coincidences from his actual experience, such as his becoming acquainted with the Lord of the Manor or some landed proprietor if he lives in the country or with some member of the aristocracy if he lives in town. Chance occurrences of this kind arouse the child's envy, which finds expression in a phantasy in which both his parents are replaced by others of better birth. The technique used in developing phantasies like this (which are, of course, conscious at this period) depends upon the ingenuity and the material which the child has at his disposal. There is also the question of whether the phantasies are worked out with greater or less effort to obtain verisimilitude. This state is reached at a time at which the child is still in ignorance of the sexual determinants of procreation.

Moreover the motive of revenge and retaliation, which was in the foreground at the earlier state, is also to be found at the later one. It is, as a rule, precisely these neurotic children who were punished by their parents for sexual naughtiness and who now revenge themselves on their parents by means of phantasies of this kind.

Moreover, this event and the feelings that were revived by it gave a new direction to his wishes. In his triumphant final phantasy he summed up all of his erotic wishes, both those derived from his auto-erotic phase and those connected with his object-love. In that phantasy he was married to his beautiful mother and had innumerable children whom he could look after in his own way.

I had expressed a suspicion that Hans's repressed wish might now be that he wanted at all costs to see his mother's widdler. As his behaviour to a new maid fitted in with this hypothesis, his father gave him his first piece of enlightenment, namely, that women have no widdlers. He reacted to this first effort at helping him by producing a phantasy that he had seen his mother showing her widdler.¹ This phantasy and a remark made by him in conversation, to the effect that his widdler was 'fixed in, of course', allow us our first glimpse into the patient's unconscious mental processes. The fact was that the threat of castration made to him by his mother some fifteen months earlier was now having a deferred effect upon him. For his phantasy that his mother was doing the same as he had done (the familiar \textit{tu quoque} repartee of inculpated children) was intended to serve as a piece of self-justification; it was a protective or defensive phantasy. At the same time we must remark that it was Hans's parents who had extracted from the pathogenic material operating in him the particular theme of his interest in widdlers. Hans followed their lead in this matter, but he had not yet taken any line of his own in the analysis. And no therapeutic success was to be observed. The analysis had passed far away from the subject of horses; and the information that women have no widdlers was calculated, if anything, to increase his concern for the preservation of his own.
The arrival of his sister brought into Hans's life many new elements, which from that time on gave him no rest. In the first place he was obliged to submit to a certain degree of privation: to begin with, a temporary separation from his mother, and later a permanent diminution in the amount of care and attention which he had received from her and which thenceforward he had to grow accustomed to sharing with his sister. In the second place, he experienced a revival of the pleasures he had enjoyed when he was looked after as an infant; for they were called up by all that he saw his mother doing for the baby. As a result of these two influences his erotic needs became intensified, while at the same time they began to obtain insufficient satisfaction. He made up for the loss which his sister's arrival had entailed on him by imagining that he had children of his own; and so long as he was at Gmunden - on his second visit there - and could really play with these children, he found a sufficient outlet for his affections. But after his return to Vienna he was once more alone, and set all his hopes upon his mother. He had meanwhile suffered another privation, having been exiled from his parents' bedroom at the age of four and a half. His intensified erotic excitability now found expression in phantasies, by which in his loneliness he conjured up his playmates of the past summer, and in regular auto-erotic satisfaction obtained by a masturbatory stimulation of his genitals.

[1909b, 2112]
He then went on to say that he would like to speak of a criminal act, whose author he did not recognize as himself, though he quite clearly recollected committing it. He quoted a saying of Nietzsche's:² "I did this," says my Memory. "I cannot have done this," says my Pride and remains inexorable. In the end - Memory yields. 'Well,' he continued, 'my memory has not yielded on this point.' - 'That is because you derive pleasure from your self-reproaches as a means of self-punishment.' - 'My younger brother - I am really very fond of him now, and he is causing me a great deal of worry just at present, for he wants to make what I consider a preposterous match; I have thought before now of going and killing the person concerned so as to prevent his marrying her - well, my younger brother and I used to fight a lot when we were children. We were very fond of each other at the same time, and were inseparable; but I was plainly filled with jealousy, as he was the stronger and better-looking of the two and consequently the favourite.' - 'Yes. You have already given me a description of a scene of jealousy in connection with Fräulein Lina.' - 'Very well then, on some such occasion (it was certainly before I was eight years old, for I was not going to school yet, which I began to do when I was eight) - on some such occasion, this is what I did. We both had toy guns of the usual make. I loaded mine with the ram rod and told him that if he looked up the barrel he would see something. Then, while he was looking in, I pulled the trigger. He was hit on the forehead and not hurt; but I had meant to hurt him very much indeed. Afterwards I was quite beside myself, and threw myself on the ground and asked myself however I could have done such a thing. But I did do it.' - I took the opportunity of urging my case. If he had preserved the recollection of an action so foreign to him as this, he could not, I maintained, deny the possibility of something similar, which he had now forgotten entirely, having happened at a still earlier age in relation to his father. - He then told me he was aware of having felt other vindictive impulses, this time towards the lady he admired so much, of whose character he painted a glowing picture. It might be true, he said, that she could not love easily; but she was reserving her whole self for the one man to whom she would some day belong. She did not love him. When he had become certain of that, a conscious phantasy had taken shape in his mind of how he should grow very rich and marry some one else, and should then take her to call on the lady in order to hurt her feelings. But at that point the phantasy had broken down, for he had been obliged to own to himself that the other woman, his wife, was completely indifferent to him; then his thoughts had become confused, till finally it had been clearly borne in upon him that this other woman would have to die. In this phantasy, just as in his attempt upon his brother, he recognized the quality of cowardice which was so particularly horrible to him.³ - In the further course of our conversation I pointed out to him that he ought logically to consider himself as in no way responsible for any of these traits in his character; for all of these reprehensible impulses originated from his infancy, and were only derivatives of his infantile character surviving in his unconscious; and he must know that moral responsibility could not be applied to children. It was only by a process of development, I added, that a man, with his moral responsibility, grew up out of the sum of his infantile predispositions.⁴ He expressed a doubt, however, whether all his evil impulses had originated from that source. But I promised to prove it to him in the course of the treatment.

[1909d, 2146]
The mutual antagonism between his feelings for his lady was too marked to have escaped his conscious perception entirely, although we may conclude from the obsessions in which it was manifested that he did not rightly appreciate the depth of his negative impulses. The lady had refused his first proposal, ten years earlier. Since then he had to his own knowledge passed through alternating periods, in which he either believed that he loved her intensely, or felt indifferent to her. Whenever in the course of the treatment he was faced by the necessity of taking some step which would bring him nearer the successful end of his courtship, his resistance usually began by taking the form of a conviction that after all he did not very much care for her - though this resistance, it is true, used soon to break down. Once when she was lying seriously ill in bed and he was most deeply concerned about her, there crossed his mind as he looked at her a wish that she might lie like that for ever. He explained this idea by an ingenious piece of sophistry: maintaining that he had only wished her to be permanently ill so that he might be relieved of his intolerable fear that she would have a repeated succession of attacks¹. Now and then he used to occupy his imagination with day-dreams, which he himself recognized as 'phantasies of revenge' and felt ashamed of. Believing, for instance, that the lady set great store by the social standing of a suitor, he made up a phantasy in which she was married to a man of that kind, who was in some government office. He himself then entered the same department, and rose much more rapidly than her husband, who eventually became his subordinate. One day, his phantasy proceeded, this man committed some act of dishonesty. The lady threw herself at his feet and implored him to save her husband. He promised to do so, and informed her that it had only been for love of her that he had entered the service, because he had foreseen that such a moment would occur; and now that her husband was saved, his own mission was fulfilled and he would resign his post.

¹ [1909d, 2153]

He produced other phantasies in which he did the lady some great service without her knowing that it was he who was doing it. In these he only recognized his affection, without sufficiently appreciating the origin and aim of his magnanimity, which was designed to repress his thirst for revenge, after the manner of Dumas' Count of Monte-Cristo. Moreover he admitted that occasionally he was overcome by quite distinct impulses to do some mischief to the lady he admired. These impulses were mostly in abeyance when she was there, and only appeared in her absence.

¹ [1909d, 2153]
¹ In psycho-analyses we frequently come across occurrences of this kind, dating back to the earliest years of the patient's childhood, in which his infantile sexual activity appears to reach its climax and often comes to a catastrophic end owing to some misfortune or punishment. Such occurrences are apt to appear in a shadowy way in dreams. Often they will become so clear that the analyst thinks he has a firm hold of them, and will nevertheless evade any final elucidation; and unless he proceeds with the greatest skill and caution he may be compelled to leave it undecided whether the scene in question actually took place or not. It will help to put us upon the right track in interpreting it, if we recognize that more than one version of the scene (each often differing greatly from the other) may be detected in the patient's unconscious phantasies. If we do not wish to go astray in our judgement of their historical reality, we must above all bear in mind that people's 'childhood memories' are only consolidated at a later period, usually at the age of puberty; and that this involves a complicated process of remodelling, analogous in every way to the process by which a nation constructs legends about its early history. It at once becomes evident that in his phantasies about his infancy the individual as he grows up endeavours to efface the recollection of his auto-erotic activities; and this he does by exalting their memory-traces to the level of object-love, just as a real historian will view the past in the light of the present. This explains why these phantasies abound in seductions and assaults, where the facts will have been confined to auto-erotic activities and the caresses or punishments that stimulated them. Furthermore, it becomes clear that in constructing phantasies about his childhood the individual sexualizes his memories; that is, he brings commonplace experiences into relation with his sexual activity, and extends his sexual interest to them - though in doing this he is probably following upon the traces of a really existing connection. No one who remembers my 'Analysis of a Phobia in a Five-Year-Old Boy' will need to be told that it is not my intention in these remarks to detract from the importance which I have hitherto attached to infantile sexuality by reducing it to nothing more than sexual interest at the age of puberty. I merely wish to give some technical advice that may help to clear up a class of phantasy which is calculated to falsify the picture of infantile sexual activity.

It is seldom that we are in the fortunate position of being able, as in the present instance, to establish the facts upon which these tales of the individual's prehistoric past are based, by recourse to the unimpeachable testimony of a grown-up person. Even so, the statement made by our patient's mother leaves the way open to various possibilities. That she did not proclaim the sexual character of the offence for which the child was punished may have been due to the activity of her own censorship; for with all parents it is precisely this sexual element in their children's past that their own censorship is most anxious to eliminate. But it is just as possible that the child was reproved by his nurse or by his mother herself for some commonplace piece of naughtiness of a non-sexual nature, and that his reaction was so violent that he was castigated by his father. In phantasies of this kind nurses and servants are regularly replaced by the superior figure of the mother. A deeper interpretation of the patient's dreams in relation to this episode revealed the clearest traces of the presence in his mind of an imaginative production of a positively epic character. In this his sexual desires for his mother and sister and his sister's premature death were linked up with the young hero's chastisement at his father's hand. It was impossible to unravel this tissue of phantasy thread by thread; the therapeutic success of the treatment was precisely what stood in the way of this. The patient recovered, and his ordinary life began to assert its claims: there were many tasks before him, which he had already neglected far too long, and which were incompatible with a continuation of the treatment. I am not to be blamed, therefore, for this gap in the analysis. The scientific results of psycho-analysis are at present only a by-product of its therapeutic aims, and for that reason it is often just in those cases where treatment fails that most discoveries are made.
A discussion of this childhood scene will be found in the footnote, and here I will only remark that its emergence shook the patient for the first time in his refusal to believe that at some prehistoric period in his childhood he had been seized with fury (which had subsequently become latent) against the father whom he loved so much. I must confess that I had expected it to have a greater effect, for the incident had been described to him so often - even by his father himself - that there could be no doubt of its objective reality. But, with that capacity for being illogical which never fails to bewilder one in such highly intelligent people as obsessional neurotics, he kept urging against the evidential value of the story the fact that he himself could not remember the scene. And so it was only along the painful road of transference that he was able to reach a conviction that his relation to his father really necessitated the postulation of this unconscious complement. Things soon reached a point at which, in his dreams, his waking phantasies, and his associations, he began heaping the grossest and filthiest abuse upon me and my family, though in his deliberate actions he never treated me with anything but the greatest respect. His demeanor as he repeated these insults to me was that of a man in despair. 'How can a gentleman like you, sir,' he used to ask, 'let yourself be abused in this way by a low, good-for-nothing fellow like me? You ought to turn me out: that's all I deserve.' While he talked like this, he would get up from the sofa and roam about the room, - a habit which he explained at first as being due to delicacy of feeling: he could not bring himself, he said, to utter such horrible things while he was lying there so comfortably. But soon he himself found a more cogent explanation, namely, that he was avoiding my proximity for fear of my giving him a beating. If he stayed on the sofa he behaved like some one in desperate terror trying to save himself from castigations of terrific violence; he would bury his head in his hands, cover his face with his arm, jump up suddenly and rush away, his features distorted with pain, and so on. He recalled that his father had had a passionate temper, and sometimes in his violence had not known where to stop. Thus, little by little, in this school of suffering, the patient won the sense of conviction which he had lacked - though to any disinterested mind the truth would have been almost self-evident.

The deeper you penetrate into the pathogenesis of nervous illness, the more you will find revealed the connection between the neuroses and other productions of the human mind, including the most valuable. You will be taught that we humans, with the high standards of our civilization and under the pressure of our internal repressions, find reality unsatisfying quite generally, and for that reason entertain a life of phantasy in which we like to make up for the insufficiencies of reality by the production of wish-fulfilments. These phantasies include a great deal of the true constitutional essence of the subject's personality as well as of those of his impulses which are repressed where reality is concerned. The energetic and successful man is one who succeeds by his efforts in turning his wishful phantasies into reality. Where this fails, as a result of the resistances of the external world and of the subject's own weakness, he begins to turn away from reality and withdraws into his more satisfying world of phantasy, the content of which is transformed into symptoms should he fall ill. In certain favourable circumstances, it still remains possible for him to find another path leading from these phantasies to reality, instead of becoming permanently estranged from it by regressing to infancy. If a person who is at loggerheads with reality possesses an artistic gift (a thing that is still a psychological mystery to us), he can transform his phantasies into artistic creations instead of into symptoms. In this manner he can escape the doom of neurosis and by this roundabout path regain his contact with reality. (Cf. Rank, 1907.) If there is persistent rebellion against the real world and if this precious gift is absent or insufficient, it is almost inevitable that the libido, keeping to the sources of the phantasies, will follow the path of regression, and will revive infantile wishes and end in neurosis. To-day neurosis takes the place of the monasteries which used to be the refuge of all whom life had disappointed or who felt too weak to face it.

[1909d, 2163]

[1910a, 2235]
To these phantasies which have succeeded in dominating the man's love in real life, the urge to rescue the loved one seems to bear merely a loose and superficial relation, and one that is fully accounted for by conscious reasons. By her propensity to be fickle and unfaithful the loved one brings herself into dangerous situations, and thus it is understandable that the lover should be at pains to protect her from these dangers by watching over her virtue and counteracting her bad inclinations. However, the study of people's screen-memories, phantasies and nocturnal dreams shows that we have here a particularly felicitous 'rationalization' of an unconscious motive, a process which may be compared to a successful secondary revision of a dream. In actual fact the 'rescue-motif' has a meaning and history of its own, and is an independent derivative of the mother-complex, or more accurately, of the parental complex. When a child hears that he owes his life to his parents, or that his mother gave him life, his feelings of tenderness unite with impulses which strive at power and independence, and they generate the wish to return this gift to the parents and to repay them with one of equal value. It is as though the boy's defiance were to make him say: 'I want nothing from my father; I will give him back all I have cost him.' He then forms the phantasy of rescuing his father from danger and saving his life; in this way he puts his account square with him. This phantasy is commonly enough displaced on to the emperor, king or some other great man; after being thus distorted it becomes admissible to consciousness, and may even be made use of by creative writers. In its application to a boy's father it is the defiant meaning in the idea of rescuing which is by far the most important; where his mother is concerned it is usually its tender meaning. The mother gave the child life, and it is not easy to find a substitute, of equal value for this unique gift. With a slight change of meaning, such as is easily effected in the unconscious and is comparable to the way in which in consciousness concepts shade into one another, rescuing his mother takes on the significance of giving her a child or making a child for her - needless to say, one like himself. This is not too remote from the original sense of rescuing, and the change in meaning is not an arbitrary one. His mother gave him a life - his own life - and in exchange he gives her another life, that of a child which has the greatest resemblance to himself. The son shows his gratitude by wishing to have by his mother a son who is like himself: in other words, in the rescue-phantasy he is completely identifying himself with his father. All his instincts, those of tenderness, gratitude, lustfulness, defiance and independence, find satisfaction in the single wish to be his own father. Even the element of danger has not been lost in the change of meaning; for the act of birth itself is the danger from which he was saved by his mother's efforts. Birth is both the first of all dangers to life and the prototype of all the later ones that cause us to feel anxiety, and the experience of birth has probably left behind in us the expression of affect which we call anxiety. Macduff of the Scottish legend, who was not born of his mother but ripped from her womb, was for that reason unacquainted with anxiety. [1910h, 2333]
Two factors will decide whether this advance in the developmental path of the libido is to fail. First, there is the amount of frustration in reality, which opposes the new object-choice and reduces its value for the person concerned. There is after all no point in embarking upon an object-choice if no choice is to be allowed at all or if there is no prospect of being able to choose anything suitable. Secondly, there is the amount of attraction which the infantile objects that have to be relinquished are able to exercise, and which is in proportion to the erotic cathexis attaching to them in childhood. If these two factors are sufficiently strong, the general mechanism by which the neuroses are formed comes into operation. The libido turns away from reality, is taken over by imaginative activity (the process of introversion), strengthens the images of the first sexual objects and becomes fixated to them. The obstacle raised against incest, however, compels the libido that has turned to these objects to remain in the unconscious. The masturbatory activity carried out by the sensual current, which is now part of the unconscious, makes its own contribution in strengthening this fixation. Nothing is altered in this state of affairs if the advance which has miscarried in reality is now completed in phantasy, and if in the phantasy-situations that lead to masturbatory satisfaction the original sexual objects are replaced by different ones. As a result of this substitution the phantasies become admissible to consciousness, but no progress is made in the allocation of the libido in reality. In this way it can happen that the whole of a young man's sensuality becomes tied to incestuous objects in the unconscious, or to put it another way, becomes fixated to unconscious incestuous phantasies. The result is then total impotence, which is perhaps further ensured by the simultaneous onset of an actual weakening of the organs that perform the sexual act.

We can now understand the motives behind the boy's phantasies mentioned in the first of these 'Contributions' (above, p. 2331), which degrade the mother to the level of a prostitute. They are efforts to bridge the gulf between the two currents in love, at any rate in phantasy, and by debasing the mother to acquire her as an object of sensuality.

A short while ago I saw a patient, about twenty years of age, who gave an unmistakable picture (confirmed by other opinions) of a dementia praecox (hebephrenia). During the initial stages of his illness he had exhibited periodic changes of mood and had made a considerable improvement. While he was in this favourable condition he was removed from the institution by his parents and for about a week he was regaled with entertainments of every kind to celebrate his supposed recovery. His relapse followed immediately upon this week of festivities. When he was brought back to the institution, he said that the consulting physician had advised him 'to flirt with his mother a little'. There can be no doubt that in this delusory parnnesia he was giving expression to the excitement which had been provoked in him by being in his mother's company and which had been the immediate provocation of his relapse.

More than ten years ago, at a time when the findings and hypotheses of psycho-analysis were known to only a few people, the following events were reported to me from a trustworthy source. A girl, who was the daughter of a medical man, fell ill of hysteria with local symptoms. Her father denied that it was hysteria and arranged for various somatic treatments to be initiated, which brought little improvement. One day a woman friend of the patient's said to her: 'Have you never thought of consulting Dr. F.?' To which the patient replied: 'What good would that be? I know he'd say to me: "Have you ever had the idea of having sexual intercourse with your father?"' - It seems unnecessary for me to say explicitly that it has never been my practice and is not my practice to-day to ask such questions. But it is worth remarking that much of what patients report of the words and actions of their physicians may be understood as revelations of their own pathogenic phantasies.
The sun, therefore, is nothing but another sublimated symbol for the father; and in pointing this out I must disclaim all responsibility for the monotony of the solutions provided by psycho-analysis. In this instance symbolism overrides grammatical gender - at least so far as German goes,¹ for in most other languages the sun is masculine. Its counterpart in this picture of the two parents is 'Mother Earth' as she is generally called. We frequently come upon confirmations of this assertion in resolving the pathogenic phantasies of neurotics by psycho-analysis. I can make no more than the barest allusion to the relation of all this to cosmic myths. One of my patients, who had lost his father at a very early age, was always seeking to rediscover him in what was grand and sublime in Nature. Since I have known this, it has seemed to me probable that Nietzsche's hymn 'Vor Sonnenaufgang' ['Before Sunrise'] is an expression of the same longing.² Another patient, who became neurotic after his father's death, was seized with his first attack of anxiety and giddiness while the sun shone upon him as he was working in the garden with a spade. He spontaneously put forward as an interpretation that he had become frightened because his father had looked at him while he was at work upon his mother with a sharp instrument. When I ventured upon a mild remonstrance, he gave an air of greater plausibility to his view by telling me that even in his father's lifetime he had compared him with the sun, though then it had been in a satirical sense. Whenever he had been asked where his father was going to spend the summer he had replied in these sonorous words from the 'Prologue in Heaven':  

[1911c, 2426]  

Perhaps I may be allowed to add a few words with a view to establishing the causes of this conflict that broke out in relation to the feminine wishful phantasy. As we know, when a wishful phantasy makes its appearance, our business is to bring it into connection with some frustration, some privation in real life. Now Schreber admits having suffered a privation of the kind. His marriage, which he describes as being in other respects a happy one, brought him no children; and in particular it brought him no son who might have consoled him for the loss of his father and brother and upon whom he might have drained off his unsatisfied homosexual affections.¹ His family line threatened to die out, and it seems that he felt no little pride in his birth and lineage. 'Both the Flechsigs and the Schrebers were members of "the highest nobility of Heaven", as the phrase went. The Schrebers in particular bore the title of "Margraves of Tuscany and Tasmania"; for souls, urged by some sort of personal vanity, have a custom of adorning themselves with somewhat high-sounding titles borrowed from this world.'² (24.) The great Napoleon obtained a divorce from Josephine (though only after severe internal struggles) because she could not propagate the dynasty.³ Dr. Schreber may have formed a phantasy that if he were a woman he would manage the business of having children more successfully; and he may thus have found his way back into the feminine attitude towards his father which he had exhibited in the earliest years of his childhood. If that were so, then his delusion that as a result of his emasculation the world was to be peopled with 'a new race of men, born from the spirit of Schreber' (288) - a delusion the realization of which he was continually postponing to a more and more remote future - would also be designed to offer him an escape from his childlessness. If the 'little men' whom Schreber himself finds so puzzling were children, then we should have no difficulty in understanding why they were collected in such great numbers on his head (158): they were in truth the 'children of his spirit'.⁴

[1911c, 2428]
It would be convenient if we could say 'it has recathedcted his infantile complexes'. But this would be incorrect: the only justifiable way of putting it would be 'the unconscious portions of those complexes'. The topics dealt with in this paper are so extraordinarily involved that it is tempting to embark on a number of contiguous problems whose clarification would in point of fact be necessary before it would be possible to speak in unambiguous terms of the psychical processes that are to be described here. These problems include the drawing of a line of distinction between introversion and regression, the fitting of the theory of complexes into the libido theory, the relations of phantasying to the conscious and the unconscious as well as to reality - and others besides. I need not apologize for having resisted this temptation in the present paper.

[1912b, 2459]

In consequence of these conditions, a closer connection arises, on the one hand, between the sexual instinct and phantasy and, on the other hand, between the ego-instincts and the activities of consciousness. Both in healthy and in neurotic people this connection strikes us as very intimate, although the considerations of genetic psychology which have just been put forward lead us to recognize it as a secondary one. The continuance of auto-erotism is what makes it possible to retain for so long the easier momentary and imaginary satisfaction in relation to the sexual object in place of real satisfaction, which calls for effort and postponement. In the realm of phantasy, repression remains all-powerful; it brings about the inhibition of ideas in statu nascendi before they can be noticed by consciousness, if their cathexis is likely to occasion a release of unpleasure. This is the weak spot in our psychical organization: and it can be employed to bring back under the dominance of the pleasure principle thought-processes which had already become rational. An essential part of the psychical disposition to neurosis thus lies in the delay in educating the sexual instincts to pay regard to reality and, as a corollary, in the conditions which make this delay possible.

[1911b, 2555]

(8) The strangest characteristic of unconscious (repressed) processes, to which no investigator can become accustomed without the exercise of great self-discipline, is due to their entire disregard of reality-testing; they equate reality of thought with external actuality, and wishes with their fulfilment - with the event - just as happens automatically under the dominance of the ancient pleasure principle. Hence also the difficulty of distinguishing unconscious phantasies from memories which have become unconscious. But one must never allow oneself to be misled into applying the standards of reality to repressed psychical structures, and on that account, perhaps, into undervaluing the importance of phantasies in the formation of symptoms on the ground that they are not actualities, or into tracing a neurotic sense of guilt back to some other source because there is no evidence that any actual crime has been committed. One is bound to employ the currency that is in use in the country one is exploring - in our case a neurotic currency. Suppose, for instance, that one is trying to solve a dream such as this. A man who had once nursed his father through a long and painful mortal illness, told me that in the months following his father's death he had repeatedly dreamt that his father was alive once more and that he was talking to him in his usual way. But he felt it exceedingly painful that his father had really died, only without knowing it. The only way of understanding this apparently nonsensical dream is by adding 'as the dreamer wished' or 'in consequence of his wish' after the words 'that his father had really died', and by further adding 'that he wished it' to the last words. The dream-thought then runs: it was a painful memory for him that he had been obliged to wish for his father's death (as a release) while he was still alive, and how terrible it would have been if his father had had any suspicion of it! What we have here is thus the familiar case of self-reproaches after the loss of someone loved, and in this instance the self-reproach went back to the infantile significance of death-wishes against the father.

[1911b, 2557]
Where these are present and sufficiently strongly developed, there is a risk of the libido becoming 'introverted'.¹ It turns away from reality, which, owing to the obstinate frustration, has lost its value for the subject, and turns towards the life of phantasy, in which it creates new wishful structures and revives the traces of earlier, forgotten ones. In consequence of the intimate connection between the activity of phantasy and material present in everyone which is infantile and repressed and has become unconscious, and thanks to the exceptional position enjoyed by the life of phantasy in regard to reality-testing,² the libido may thenceforward move on a backward course; it may follow the path of regression along infantile lines, and strive after aims that correspond with them. If these strivings, which are incompatible with the subject's present-day individuality, acquire enough intensity, a conflict must result between them and the other portion of his personality, which has maintained its relation to reality. This conflict is resolved by the formation of symptoms, and is followed by the onset of manifest illness. The fact that the whole process originated from frustration in the real world is reflected in the resulting event that the symptoms, in which the ground of reality is reached once more, represent substitutive satisfactions.
[1912c, 2560]

A young man who has hitherto satisfied his libido by means of phantasies ending in masturbation, and who now seeks to replace a régime approximating to auto-erotism by the choice of a real object - or a girl who has given her whole affection to her father or brother and who must now, for the sake of a man who is courting her, allow her hitherto unconscious incestuous libidinal wishes to become conscious - or a married woman who would like to renounce her polygamous inclinations and phantasies of prostitution so as to become a faithful consort to her husband and a perfect mother to her child - all of these fall ill from the most laudable efforts, if the earlier fixations of their libido are powerful enough to resist a displacement; and this point will be decided, once again, by the factors of disposition, constitution and infantile experience. All of them, it might be said, meet with the fate of the little tree in the Grimms' fairy tale, which wished it had different leaves. From the hygienic point of view - which, to be sure, is not the only one to be taken into account - one could only wish for them that they had continued to be as undeveloped, as inferior and as useless as they were before they fell ill. The change which the patients strive after, but bring about only imperfectly or not at all, invariably has the value of a step forward from the point of view of real life. It is otherwise if we apply ethical standards: we see people falling ill just as often when they discard an ideal as when they seek to attain it.
[1912c, 2562]

(c) A fixation of infantile sexual aims may be made possible, and a persistence of psychical infantilism. Here we have the disposition for the occurrence of a neurosis. As psycho-analysts we cannot fail to be greatly interested in this result of masturbation - which in this case means, of course, masturbation occurring at puberty and continued afterwards. We must keep in mind the significance which masturbation acquires as a carrying into effect of phantasy - that half-way region interpolated between life in accordance with the pleasure principle and life in accordance with the reality principle; and we must remember how masturbation makes it possible to bring about sexual developments and sublimations in phantasy, which are nevertheless not advances but injurious compromises - though it is true, as an important remark of Stekel's has pointed out, that this same compromise renders severe perverse inclinations harmless and averts the worst consequences of abstinence.
[1912f, 2573]
However, contradictions of a certain kind - replacements by the precise opposite - offer no serious difficulty to the work of analytic interpretation. We shall not appeal here to the fact that contraries are so often represented by one and the same element in the modes of expression used by the unconscious, as for instance in dreams. But we shall remember that there are motive forces in mental life which bring about replacement by the opposite in the form of what is known as reaction-formation; and it is precisely in the revelation of such hidden forces as these that we look for the reward of this enquiry. The Moerae were created as a result of a discovery that warned man that he too is a part of nature and therefore subject to the immutable law of death. Something in man was bound to struggle against this subjection, for it is only with extreme unwillingness that he gives up his claim to an exceptional position. Man, as we know, makes use of his imaginative activity in order to satisfy the wishes that reality does not satisfy. So his imagination rebelled against the recognition of the truth embodied in the myth of the Moerae, and constructed instead the myth derived from it, in which the Goddess of Death was replaced by the Goddess of Love and by what was equivalent to her in human shape. The third of the sisters was no longer Death; she was the fairest, best, most desirable and most lovable of women. Nor was this substitution in any way technically difficult: it was prepared for by an ancient ambivalence, it was carried out along a primaeval line of connection which could not long have been forgotten. The Goddess of Love herself, who now took the place of the Goddess of Death, had once been identical with her. Even the Greek Aphrodite had not wholly relinquished her connection with the underworld, although she had long surrendered her chthonic role to other divine figures, to Persephone, or to the tri-form Artemis-Hecate. The great Mother-goddesses of the oriental peoples, however, all seem to have been both creators and destroyers - both goddesses of life and fertility and goddesses of death. Thus the replacement by a wishful opposite in our theme harks back to a primaeval identity.

At this point a portion of our case history fits in, which I have so far kept back. The patient's sexual life began in her earliest childhood with beating-phantasies. After they were suppressed, an unusually long period of latency set in, during which the girl passed through a period of exalted moral growth, without any awakening of female sexual feelings. Her marriage, which took place at an early age, opened a time of normal sexual activity. This period, during which she was a happy wife, continued for a number of years, until her first great frustration brought on the hysterical neurosis. When this was followed by her genital life losing all its value, her sexual life, as I have said, returned to the infantile stage of sadism.

I can see nothing against the presumption that it is precisely this incestuous factor in the relation that provides savages with the motive for their rules of avoidance between son-in-law and mother-in-law. Thus the explanation which we should adopt for these strictly enforced avoidances among primitive peoples is that put forward by Fison, which regards them merely as a further protection against possible incest. The same explanation holds good of all other avoidances, between both blood and tribal relations. The only difference would be that in the case of blood relations the possibility of incest is an immediate one and the intention to prevent it may be conscious; in the other cases, including that of a man's relation to his mother-in-law, the possibility of incest would seem to be a temptation in phantasy set in motion through the agency of unconscious connecting links.

The asocial nature of neuroses has its genetic origin in their most fundamental purpose, which is to take flight from an unsatisfying reality into a more pleasurable world of phantasy. The real world, which is avoided in this way by neurotics, is under the sway of human society and of the institutions collectively created by it. To turn away from reality is at the same time to withdraw from the community of man.
It is in obsessional neuroses that the survival of the omnipotence of thoughts is most clearly visible and that the consequences of this primitive mode of thinking come closest to consciousness. But we must not be misled into supposing that it is a distinguishing feature of this particular neurosis, for analytic investigation reveals the same thing in the other neuroses as well. In all of them what determines the formation of symptoms is the reality not of experience but of thought. Neurotics live in a world apart, where, as I have said elsewhere, only 'neurotic currency' is legal tender; that is to say, they are only affected by what is thought with intensity and pictured with emotion, whereas agreement with external reality is a matter of no importance. What hysterics repeat in their attacks and fix by means of their symptoms are experiences which have occurred in that form only in their imagination though it is true that in the last resort those imagined experiences go back to actual events or are based upon them. To attribute the neurotic sense of guilt to real misdeeds would show an equal misunderstanding. An obsessional neurotic may be weighed down by a sense of guilt that would be appropriate in a mass-murderer, while in fact, from his childhood onwards, he has behaved to his fellow-men as the most considerate and scrupulous member of society. Nevertheless, his sense of guilt has a justification: it is founded on the intense and frequent death wishes against his fellows which are unconsciously at work in him. It has a justification if what we take into account are unconscious thoughts and not intentional deeds. Thus the omnipotence of thoughts, the overvaluation of mental processes as compared with reality, is seen to have unrestricted play in the emotional life of neurotic patients and in everything that derives from it. If one of them undergoes psychoanalytic treatment, which makes what is unconscious in him conscious, he will be unable to believe that thoughts are free and will constantly be afraid of expressing evil wishes, as though their expression would lead inevitably to their fulfilment. This behaviour, as well as the superstitions which he practises in ordinary life, reveals his resemblance to the savages who believe they can alter the external world by mere thinking.

[1912-1913, 2729]

In just the same way, an inhibition upon movement (an abasia or an agoraphobia) will gradually become more complete and more detailed, when once that system has succeeded in installing itself as a representative of an unconscious wish and of the defence against the wish. Whatever other unconscious phantasies and operative reminiscences may be present in the patient force their way to expression as symptoms along this same path, once it has been opened, and group themselves into an appropriate new arrangement within the framework of the inhibition upon movement. Thus it would be a vain and indeed a foolish task to attempt to understand the complexities and details of the symptoms of (for example) an agoraphobia on the basis of its underlying premises; for the whole consistency and strictness of the combination are merely apparent. Just as with the façades of dreams, if we look more attentively we find the most blatant inconsistency and arbitrariness in the structure of symptoms. The real reason for the details of a systematic phobia of this kind lies in concealed determinants, which need have nothing to do with an inhibition upon movement; and that, too, is why these phobias take such various and contradictory shapes in different people.

[1912-1913, 2738]
Another product of this sort was the hypothesis of infantile sexuality. This, however, was made at a much later date. In the early days of tentative investigation by analysis no such thing was thought of. At first it was merely observed that the effects of present-day experiences had to be traced back to something in the past. But enquirers often find more than they bargain for. One was drawn further and further back into the past; one hoped at last to be able to stop at puberty, the period in which the sexual impulses are traditionally supposed to awake. But in vain; the tracks led still further back into childhood and into its earlier years. On the way, a mistaken idea had to be overcome which might have been almost fatal to the young science. Influenced by Charcot's view of the traumatic origin of hysteria, one was readily inclined to accept as true and aetiologically significant the statements made by patients in which they ascribed their symptoms to passive sexual experiences in the first years of childhood - to put it bluntly, to seduction. When this aetiology broke down under the weight of its own improbability and contradiction in definitely ascertainable circumstances, the result at first was helpless bewilderment. Analysis had led back to these infantile sexual traumas by the right path, and yet they were not true. The firm ground of reality was gone. At that time I would gladly have given up the whole work, just as my esteemed predecessor, Breuer, had done when he made his unwelcome discovery. Perhaps I persevered only because I no longer had any choice and could not then begin again at anything else. At last came the reflection that, after all, one had no right to despair because one has been deceived in one's expectations; one must revise those expectations. If hysterical subjects trace back their symptoms to traumas that are fictitious, then the new fact which emerges is precisely that they create such scenes in phantasy, and this psychical reality requires to be taken into account alongside practical reality. This reflection was soon followed by the discovery that these phantasies were intended to cover up the auto-erotic activity of the first years of childhood, to embellish it and raise it to a higher plane. And now, from behind the phantasies, the whole range of a child's sexual life came to light.

Psycho-analysis is obliged to give its backing to the second constituent of Adler's theory as it would to something of its own. And in fact it is nothing else than psycho-analytic knowledge, which that author extracted from sources open to everyone during ten years of work in common and which he has now labelled as his own by a change in nomenclature. I myself consider 'safeguarding [Sicherung]', for instance, a better term than 'protective measure [Schutzmassregel]' which is the one I employ; but I cannot discover any difference in their meaning. Again, a host of familiar features come to light in Adler's propositions when one restores the earlier 'phantasied' and 'phantasy' in place of 'feigned [fingiert]', 'fictive' and 'fiction'. The identity of these terms would be insisted upon by psycho-analysis even if their author had not taken part in our common work over a period of many years.

Psycho-analysis is able to show us other things as well which are important for understanding the effects of repression in the psychoneuroses. It shows us, for instance, that the instinctual representation develops with less interference and more profusely if it is withdrawn by repression from conscious influence. It proliferates in the dark, as it were, and takes on extreme forms of expression, which when they are translated and presented to the neurotic are not only bound to seem alien to him, but frighten him by giving him the picture of an extraordinary and dangerous strength of instinct. This deceptive strength of instinct is the result of an uninhibited development in phantasy and of the damming-up consequent on frustrated satisfaction. The fact that this last result is bound up with repression points the direction in which the true significance of repression has to be looked for.
Among the derivatives of the Ucs. instinctual impulses, of the sort we have described, there are some which unite in themselves characters of an opposite kind. On the one hand, they are highly organized, free from self-contradiction, have made use of every acquisition of the system Cs. and would hardly be distinguished in our judgement from the formations of that system. On the other hand, they are unconscious and are incapable of becoming conscious. Thus qualitatively they belong to the system Pcs., but factually to the Ucs. Their origin is what decides their fate. We may compare them with individuals of mixed race who, taken all round, resemble white men, but who betray their coloured descent by some striking feature or other, and on that account are excluded from society and enjoy none of the privileges of white people. Of such a nature are those phantasies of normal people as well as of neurotics which we have recognized as preliminary stages in the formation both of dreams and of symptoms and which, in spite of their high degree of organization, remain repressed and therefore cannot become conscious. They draw near to consciousness and remain undisturbed so long as they do not have an intense cathexis, but as soon as they exceed a certain height of cathexis they are thrust back. Substitutive formations, too, are highly organized derivatives of the Ucs. of this kind; but these succeed in breaking through into consciousness, when circumstances are favourable - for example, if they happen to join forces with an anticathexis from the Pcs.

Lying partly undressed on the sofa beside her lover, she heard a noise like a click or beat. She did not know its cause, but she arrived at an interpretation of it after meeting two men on the staircase, one of whom was carrying something that looked like a covered box. She became convinced that someone acting on instructions from her lover had watched and photographed her during their intimate tête à tête. I do not for a moment imagine, of course, that if the unlucky noise had not occurred the delusion would not have been formed; on the contrary, something inevitable is to be seen behind this accidental circumstance, something which was bound to assert itself compulsively in the patient, just as when she supposed that there was a liaison between her lover and the elderly superior, her mother-substitute. Among the store of unconscious phantasies of all neurotics, and probably of all human beings, there is one which is seldom absent and which can be disclosed by analysis: this is the phantasy of watching sexual intercourse between the parents. I call such phantasies - of the observation of sexual intercourse between the parents, of seduction, of castration, and others - 'primal phantasies'; and I shall discuss in detail elsewhere their origin and their relation to individual experience. The accidental noise was thus merely playing the part of a provoking factor which activated the typical phantasy of overhearing which is a component of the parental complex. Indeed, it is doubtful whether we can rightly call the noise 'accidental'. As Otto Rank has remarked to me, such noises are on the contrary an indispensible part of the phantasy of listening, and they reproduce either the sounds which betray parental intercourse or those by which the listening child fears to betray itself. But now we know at once where we stand. The patient's lover was still her father, but she herself had taken her mother's place. The part of the listener had then to be allotted to a third person. We can see by what means the girl had freed herself from her homosexual dependence on her mother. It was by means of a small piece of regression: instead of choosing her mother as a love-object, she identified herself with her - she herself became her mother. The possibility of this regression points to the narcissistic origin of her homosexual object-choice and thus to the paranoic disposition in her. One might sketch a train of thought which would bring about the same result as this identification: 'If my mother does it, I may do it too; I've just as good a right as she has.'
Let us consider again the outstanding fact that the patient protected herself against her love for a man by means of a paranoid delusion. The key to the understanding of this is to be found in the history of the development of the delusion. As we might have expected, the latter was at first aimed against the woman. But now, on this paranoid basis, the advance from a female to a male object was accomplished. Such an advance is unusual in paranoia; as a rule we find that the victim of persecution remains fixated to the same persons, and therefore to the same sex to which his love-objects belonged before the paranoid transformation took place. But neurotic disorder does not preclude an advance of this kind, and our observation may be typical of many others. There are many similar processes occurring outside paranoia which have not yet been looked at from this point of view, amongst them some which are very familiar. For instance, the so-called neurasthenic's unconscious attachment to incestuous love-objects prevents him from choosing a strange woman as his object and restricts his sexual activity to phantasy. But within the limits of phantasy he achieves the progress which is denied him, and he succeeds in replacing mother and sister by extraneous objects. Since the veto of the censorship does not come into action with these objects, he can become conscious in his phantasies of his choice of these substitute-figures.

The contradiction between such experiences and the rule that what induces illness is frustration is not insoluble. It disappears if we make a distinction between an external and an internal frustration. If the object in which the libido can find its satisfaction is withheld in reality, this is an external frustration. In itself it is inoperative, not pathogenic, until an internal frustration is joined to it. This latter must proceed from the ego, and must dispute the access by the libido to other objects, which it now seeks to get hold of. Only then does a conflict arise, and the possibility of a neurotic illness, i.e. of a substitutive satisfaction reached circuitously by way of the repressed unconscious. Internal frustration is potentially present, therefore, in every case, only it does not come into operation until external, real frustration has prepared the ground for it. In those exceptional cases in which people are made ill by success, the internal frustration has operated by itself; indeed it has only made its appearance after an external frustration has been replaced by fulfilment of a wish. At first sight there is something strange about this; but on closer consideration we shall reflect that it is not at all unusual for the ego to tolerate a wish as harmless so long as it exists in phantasy alone and seems remote from fulfilment, whereas the ego will defend itself hotly against such a wish as soon as it approaches fulfilment and threatens to become a reality. The distinction between this and familiar situations in neurosis-formation is merely that ordinarily it is internal intensifications of the libidinal cathexis that turn the phantasy, which has hitherto been thought little of and tolerated, into a dreaded opponent; while in these cases of ours the signal for the outbreak of conflict is given by a real external change.

Wild thoughts, you will say, to be running through an unmarried girl's head. I admit that is so. But you must not forget that I did not make these things but only interpreted them. A sleep-ceremonial like this is a strange thing too, and you will not fail to see how the ceremonial corresponds to the phantasies which are revealed by the interpretation. But I attach more importance to your noticing that what was seen in the ceremonial was a precipitate not of a single phantasy but of a number of them, though they had a nodal point somewhere, and, further, that the rules laid down by the ceremonial reproduced the patient's sexual wishes at one point positively and at another negatively - in part they represented them, but in part they served as a defence against them.
I have warned you that we still have something new to learn; it is indeed something surprising and perplexing. By means of analysis, as you know, starting from the symptoms, we arrive at a knowledge of the infantile experiences to which the libido is fixated and out of which the symptoms are made. Well, the surprise lies in the fact that these scenes from infancy are not always true. Indeed, they are not true in the majority of cases, and in a few of them they are the direct opposite of the historical truth. As you will see, this discovery is calculated more than any other to discredit either analysis, which has led to this result, or the patients, on whose statements the analysis and our whole understanding of the neuroses are founded. But there is something else remarkably perplexing about it. If the infantile experiences brought to light by analysis were invariably real, we should feel that we were standing on firm ground; if they were regularly falsified and revealed as inventions, as phantasies of the patient, we should be obliged to abandon this shaky ground and look for salvation elsewhere. But neither of these things is the case: the position can be shown to be that the childhood experiences constructed or remembered in analysis are sometimes indisputably false and sometimes equally certainly correct, and in most cases compounded of truth and falsehood. Sometimes, then, symptoms represent events which really took place and to which we may attribute an influence on the fixation of the libido, and sometimes they represent phantasies of the patient's which are not, of course, suited to playing an aetiological role. It is difficult to find one's way about in this. We can make a first start, perhaps, with a similar discovery - namely, that the isolated childhood memories that people have possessed consciously from time immemorial and before there was any such thing as analysis may equally be falsified or at least may combine truth and falsehood in plenty. In their case there is seldom any difficulty in showing their incorrectness; so we at least have the reassurance of knowing that the responsibility for this unexpected disappointment lies, not with analysis, but in some way with the patients.

[1916-1917, 3424]

After a little reflection we shall easily understand what it is about this state of things that perplexes us so much. It is the low valuation of reality, the neglect of the distinction between it and phantasy. We are tempted to feel offended at the patient's having taken up our time with invented stories. Reality seems to us something worlds apart from invention, and we set a very different value on it. Moreover the patient, too, looks at things in this light in his normal thinking. When he brings up the material which leads from behind his symptoms to the wishful situations modelled on his infantile experiences, we are in doubt to begin with whether we are dealing with reality or phantasies. Later, we are enabled by certain indications to come to a decision and we are faced by the task of conveying it to the patient. This, however, invariably gives rise to difficulties. If we begin by telling him straight away that he is now engaged in bringing to light the phantasies with which he has disguised the history of his childhood (just as every nation disguises its forgotten prehistory by constructing legends), we observe that his interest in pursuing the subject further suddenly diminishes in an undesirable fashion. He too wants to experience realities and despises everything that is merely 'imaginary'. If, however, we leave him, till this piece of work is finished, in the belief that we are occupied in investigating the real events of his childhood, we run the risk of his later on accusing us of being mistaken and laughing at us for our apparent credulity. It will be a long time before he can take in our proposal that we should equate phantasy and reality and not bother to begin with whether the childhood experiences under examination are the one or the other. Yet this is clearly the only correct attitude to adopt towards these mental productions. They too possess a reality of a sort. It remains a fact that the patient has created these phantasies for himself, and this fact is of scarcely less importance for his neurosis than if he had really experienced what the phantasies contain. The phantasies possess psychical as contrasted with material reality, and we gradually learn to understand that in the world of the neuroses it is psychical reality which is the decisive kind.
[1916-1917, 3425]
Among the occurrences which recur again and again in the youthful history of neurotics - which are scarcely ever absent - there are a few of particular importance, which also deserve, on that account, I think, to be brought into greater prominence than the rest. As specimens of this class I will enumerate these: observation of parental intercourse, seduction by an adult and threat of being castrated. It would be a mistake to suppose that they are never characterized by material reality; on the contrary, this is often established incontestably through enquiries from older members of the patient's family. It is by no means a rare thing, for instance, for a little boy, who is beginning to play with his penis in a naughty way and is not yet aware that one must conceal such activities, to be threatened by a parent or nurse with having his penis or his sinful hand cut off. Parents will often admit this when they are asked, since they think they have done something useful in making such a threat; a number of people have a correct conscious memory of such a threat, especially if it was made at a somewhat later period. If the threat is delivered by the mother or some other female she usually shifts its performance on to the father or the doctor. In *Struwwelpeter*, the famous work of the Frankfurt paediatrician Hoffmann (which owes its popularity precisely to an understanding of the sexual and other complexes of childhood), you will find castration softened into a cutting-off of the thumbs as a punishment for obstinate sucking. But it is highly improbable that children are threatened with castration as often as it appears in the analyses of neurotics. We shall be satisfied by realizing that the child puts a threat of this kind together in his imagination on the basis of hints, helped out by a knowledge that auto-erotic satisfaction is forbidden and under the impression of his discovery of the female genitals. Nor is it only in proletarian families that it is perfectly possible for a child, while he is not yet credited with possessing an understanding or a memory, to be a witness of the sexual act between his parents or other grown-up people; and the possibility cannot be rejected that he will be able to understand and react to the impression in retrospect. If, however, the intercourse is described with the most minute details, which would be difficult to observe, or if, as happens most frequently, it turns out to have been intercourse from behind *more ferarum* [in the manner of animals], there can be no remaining doubt that the phantasy is based on an observation of intercourse between animals (such as dogs) and that its motive was the child's unsatisfied scopophilia during puberty. The extreme achievement on these lines is a phantasy of observing parental intercourse while one is still an unborn baby in the womb. Phantasies of being seduced are of particular interest, because so often they are not phantasies but real memories. Fortunately, however, they are nevertheless not real as often as seemed at first to be shown by the findings of analysis. Seduction by an older child or by one of the same age is even more frequent than by an adult; and if in the case of girls who produce such an event in the story of their childhood their father figures fairly regularly as the seducer, there can be no doubt either of the imaginary nature of the accusation or of the motive that has led to it. A phantasy of being seduced when no seduction has occurred is usually employed by a child to screen the auto-erotic period of his sexual activity. He spares himself shame about masturbation by retrospectively phantasying a desired object into these earliest times. You must not suppose, however, that sexual abuse of a child by its nearest male relatives belongs entirely to the realm of phantasy. Most analysts will have treated cases in which such events were real and could be unimpeachably established; but even so they related to the later years of childhood and had been transposed into earlier times.

[1916-1917, 3426]
The only impression we gain is that these events of childhood are somehow demanded as a necessity, that they are among the essential elements of a neurosis. If they have occurred in reality, so much to the good; but if they have been withheld by reality, they are put together from hints and supplemented by phantasy. The outcome is the same, and up to the present we have not succeeded in pointing to any difference in the consequences, whether phantasy or reality has had the greater share in these events of childhood. Here we simply have once again one of the complemental relations that I have so often mentioned; moreover it is the strangest of all we have met with. Whence comes the need for these phantasies and the material for them? There can be no doubt that their sources lie in the instincts; but it has still to be explained why the same phantasies with the same content are created on every occasion. I am prepared with an answer which I know will seem daring to you. I believe these *primal phantasies*, as I should like to call them, and no doubt a few others as well, are a phylogenetic endowment. In them the individual reaches beyond his own experience into primaeval experience at points where his own experience has been too rudimentary. It seems to me quite possible that all the things that are told to us to-day in analysis as phantasy - the seduction of children, the inflaming of sexual excitement by observing parental intercourse, the threat of castration (or rather castration itself) - were once real occurrences in the primaeval times of the human family, and that children in their phantasies are simply filling in the gaps in individual truth with prehistoric truth. I have repeatedly been led to suspect that the psychology of the neuroses has stored up in it more of the antiquities of human development than any other source.

[1916-1917, 3427]

The things I have just been discussing, Gentlemen, compel me to enter more closely into the origin and significance of the mental activity which is described as 'phantasy'. As you are aware, it enjoys a universally high reputation, without its position in mental life having become clear. I have the following remarks to make about it. The human ego is, as you know, slowly educated by the pressure of external necessity to appreciate reality and obey the reality principle; in the course of this process it is obliged to renounce, temporarily or permanently, a variety of the objects and aims at which its striving for pleasure, and not only for sexual pleasure, is directed. But men have always found it hard to renounce pleasure; they cannot bring themselves to do it without some kind of compensation. They have therefore retained a mental activity in which all these abandoned sources of pleasure and methods of achieving pleasure are granted a further existence - a form of existence in which they are left free from the claims of reality and of what we call 'reality-testing'. Every desire takes before long the form of picturing its own fulfilment; there is no doubt that dwelling upon imaginary wish-fulfilments brings satisfaction with it, although it does not interfere with a knowledge that what is concerned is not real. Thus in the activity of phantasy human beings continue to enjoy the freedom from external compulsion which they have long since renounced in reality. They have contrived to alternate between remaining an animal of pleasure and being once more a creature of reason. Indeed, they cannot subsist on the scanty satisfaction which they can extort from reality. 'We cannot do without auxiliary constructions', as Theodor Fontane once said. The creation of the mental realm of phantasy finds a perfect parallel in the establishment of 'reservations' or 'nature reserves' in places where the requirements of agriculture, communications and industry threaten to bring about changes in the original face of the earth which will quickly make it unrecognizable. A nature reserve preserves its original state which everywhere else has to our regret been sacrificed to necessity. Everything, including what is useless and even what is noxious, can grow and proliferate there as it pleases. The mental realm of phantasy is just such a reservation withdrawn from the reality principle.

[1916-1917, 3427]
The best-known productions of phantasy are the so-called 'day-dreams', which we have already come across, imagined satisfactions of ambitious, megalomanic, erotic wishes, which flourish all the more exuberantly the more reality counsels modesty and restraint. The essence of the happiness of phantasy - making the obtaining of pleasure free once more from the assent of reality - is shown in them unmistakably. We know that such day-dreams are the nucleus and prototype of night-dreams. A night-dream is at bottom nothing other than a day-dream that has been made utilizable owing the liberation of the instinctual impulses at night, and that has been distorted by the form assumed by mental activity at night. We have already become familiar with the idea that even a day-dream is not necessarily conscious - that there are unconscious day-dreams, as well. Such unconscious day-dreams are thus the source not only of night-dreams but also of neurotic symptoms.

The importance of the part played by phantasy in the formation of symptoms will be made clear to you by what I have to tell you. I have explained how in the case of frustration the libido cathects regressively the positions which it has given up but to which some quotas of it have remained adhering. I shall not withdraw this or correct it, but I have to insert a connecting link. How does the libido find its way to these points of fixation? All the objects and trends which the libido has given up have not yet been given up in every sense. They or their derivatives are still retained with a certain intensity in phantasies. Thus the libido need only withdraw on to phantasies in order to find the path open to every repressed fixation. These phantasies have enjoyed a certain amount of toleration: they have not come into conflict with the ego, however sharp the contrasts between them may have been, so long as a particular condition is observed. This condition is of a quantitative nature and it is now upset by the backward flow of libido on to the phantasies. As a result of this surplus, the energic cathexis of the phantasies is so much increased that they begin to raise claims, that they develop a pressure in the direction of becoming realized. But this makes a conflict between them and the ego inevitable. Whether they were previously preconscious or conscious, they are now subjected to repression from the direction of the ego and are at the mercy of attraction from the direction of the unconscious. From what are now unconscious phantasies the libido travels back to their origins in the unconscious - to its own points of fixation.

The libido's retreat to phantasy is an intermediate stage on the path to the formation of symptoms and it seem to call for a special name. C. G. Jung coined the very appropriate one of 'introversion', but then most inexpediently gave it another meaning as well. We will continue to take it that introversion denotes the turning away of the libido from the possibilities of real satisfaction and the hypercathexis of phantasies which have hitherto been tolerated as innocent. An introvert is not yet a neurotic, but he is in an unstable situation: he is sure to develop symptoms at the next shift of forces, unless he finds some other outlets for his dammed-up libido. The unreal character of neurotic satisfaction and the neglect of the distinction between phantasy and reality are on the other hand already determined by the fact of lingering at the stage of introversion.
It is easy to understand that the first suspicion fell upon the English governess, for the change in the boy made its appearance while she was there. Two screen memories had persisted, which were incomprehensible in themselves, and which related to her. On one occasion, as she was walking along in front of them, she said: 'Do look at my little tail!' Another time, when they were on a drive, her hat flew away, to the two children's great satisfaction. This pointed to the castration complex, and might permit of a construction being made to the effect that a threat uttered by her against the boy had been largely responsible for originating his abnormal conduct. There is no danger at all in communicating constructions of this kind to the person under analysis; they never do any damage to the analysis if they are mistaken; but at the same time they are not put forward unless there is some prospect of reaching a nearer approximation to the truth by means of them. The first effect of this supposition was the appearance of some dreams, which it was not possible to interpret completely, but all of which seemed to centre around the same material. As far as they could be understood, they were concerned with aggressive actions on the boy's part against his sister or against the governess and with energetic reproofs and punishments on account of them. It was as though . . . after her bath . . . he had tried . . . to undress his sister . . . to tear off her coverings . . . or veils - and so on. But it was not possible to get at any firm content from the interpretation; and since these dreams gave an impression of always working over the same material in various different ways, the correct reading of these ostensible reminiscences became assured: it could only be a question of phantasies, which the dreamer had made on the subject of his childhood at some time or other, probably at the age of puberty, and which had now come to the surface again in this unrecognizable form.

[1918b, 3512]

Here, then, was the explanation of the phantasies whose existence we had already divined. They were meant to efface the memory of an event which later on seemed offensive to the patient's masculine self-esteem, and they reached this end by putting an imaginary and desirable converse in the place of the historical truth. According to these phantasies it was not he who had played the passive part towards his sister; but, on the contrary, he had been aggressive, had tried to see his sister undressed, had been rejected and punished, and had for that reason got into the rage which the family tradition talked of so much. It was also appropriate to weave the governess into this imaginative composition, since the chief responsibility for his fits of rage had been ascribed to her by his mother and grandmother. These phantasies, therefore, corresponded exactly to the legends by means of which a nation that has become great and proud tries to conceal the insignificance and failure of its beginnings.

[1918b, 3513]
I must here turn for a moment to the history of the treatment. When once the Grusha scene had been assimilated - the first experience that he could really remember, and one which he had remembered without any conjectures or intervention on my part - the problem of the treatment had every appearance of having been solved. From that time forward there were no more resistances; all that remained to be done was to collect and to co-ordinate. The old trauma theory of the neuroses, which was after all built up upon impressions gained from psychoanalytic practice, had suddenly come to the front once more. Out of critical interest I made one more attempt to force upon the patient another view of his story, which might commend itself more to sober common sense. It was true that there could be no doubt about the scene with Grusha, but, I suggested, in itself that scene meant nothing; it had been emphasized \textit{ex post facto} by a regression from the circumstances of his object choice, which, as a result of his intention to debase, had been diverted from his sister on to servant girls. On the other hand, his observation of intercourse, I argued, was a phantasy of his later years; its historical nucleus may perhaps have been an observation or an experience by the patient of the administration of an innocent enema. Some of my readers will possibly be inclined to think that with such hypotheses as these I was for the first time beginning to approach an understanding of the case; but the patient looked at me uncomprehendingly and a little contemptuously when I put this view before him, and he never reacted to it again. I have already stated my own arguments against any such rationalization at their proper point in the discussion.

On these issues I can venture upon no decision. I must confess, however, that I regard it as greatly to the credit of psycho-analysis that it should even have reached the stage of raising such questions as these. Nevertheless, I cannot deny that the scene with Grusha, the part it played in the analysis, and the effects that followed from it in the patient's life can be most naturally and completely explained if we consider that the primal scene, which may in other cases be a phantasy, was a reality in the present one. After all, there is nothing impossible about it; and the hypothesis of its reality is entirely compatible with the inciting action of the observations upon animals which are indicated by the sheep-dogs in the dream-picture.

I will now turn from this unsatisfactory conclusion to a consideration of the problem which I have attempted in my \textit{Introductory Lectures on Psycho-Analysis}. I should myself be glad to know whether the primal scene in my present patient's case was a phantasy or a real experience; but, taking other similar cases into account, I must admit that the answer to this question is not in fact a matter of very great importance. These scenes of observing parental intercourse, of being seduced in childhood, and of being threatened with castration are unquestionably an inherited endowment, a phylogenetic heritage, but they may just as easily be acquired by personal experience. With my patient, his seduction by his elder sister was an indisputable reality; why should not the same have been true of his observation of his parents' intercourse?
I admit that this is the most delicate question in the whole domain of psycho-analysis. I did not require the contributions of Adler or Jung to induce me to consider the matter with a critical eye, and to bear in mind the possibility that what analysis puts forward as being forgotten experiences of childhood (and of an improbably early childhood) may on the contrary be based upon phantasies created on occasions occurring late in life. According to this view, wherever we seemed in analyses to see traces of the after-effects of an infantile impression of the kind in question, we should rather have to assume that we were faced by the manifestation of some constitutional factor or of some disposition that had been phylogenetically maintained. On the contrary, no doubt has troubled me more; no other uncertainty has been more decisive in holding me back from publishing my conclusions. I was the first - a point to which none of my opponents have referred - to recognize both the part played by phantasies in symptom-formation and also the 'retrospective phantasying' of late impressions into childhood and their sexualization after the event. (See my Interpretation of Dreams (1900a), First Edition, p. 559, and Notes upon a Case of Obsessional Neurosis', (1909d).) If, in spite of this, I have held to the more difficult and more improbable view, it has been as a result of arguments such as are forced upon the investigator by the case described in these pages or by any other infantile neurosis - arguments which I once again lay before my readers for their decision.

We have pointed out that this predominance of the life of phantasy and of the illusion born of an unfulfilled wish is the ruling factor in the psychology of neuroses. We have found that what neurotics are guided by is not ordinary objective reality but psychological reality. A hysterical symptom is based upon phantasy instead of upon the repetition of real experience, and the sense of guilt in an obsessional neurosis is based upon the fact of an evil intention which was never carried out. Indeed, just as in dreams and in hypnosis, in the mental operations of a group the function for testing the reality of things falls into the background in comparison with the strength of wishful impulses with their affective cathexis.

The analytic researches carried out by the writer fell, to begin with, into the error of greatly overestimating the importance of seduction as a source of sexual manifestations in children and as a root for the formation of neurotic symptoms. This misapprehension was corrected when it became possible to appreciate the extraordinarily large part played in the mental life of neurotics by the activities of phantasy, which clearly carried more weight in neurosis than did external reality. Behind these phantasies there came to light the material which allows us to draw the picture which follows of the development of the sexual function.
The number nine is well known to us from neurotic phantasies. It is the number of the months of pregnancy, and wherever it appears it directs our attention to a phantasy of pregnancy. In our painter’s case, to be sure, the number refers to years, not months; and it will be objected that nine is a significant number in other ways as well. But who knows whether it may not in general owe a good deal of its sanctity to the part it plays in pregnancy? Nor need we be disconcerted by the change from nine months to nine years. We know from dreams what liberties 'unconscious mental activity' takes with numbers. If, for instance, the number five occurs in a dream, this can invariably be traced back to a five that is important in waking life; but whereas in waking life the five was a five years' difference in age or a company of five people, it appeared in the dream as five bank-notes or five fruits. That is to say, the number is kept, but its denominator is changed according to the requirements of condensation and displacement. Nine years in a dream could thus easily correspond to nine months in real life. The dream-work plays about with the numbers of waking life in another way, too, for it shows a sovereign disregard for noughts and does not treat them as numbers at all. Five dollars in a dream can stand for fifty or five hundred or five thousand dollars in reality.

[1923d, 4013]

This revolt against castration or a feminine attitude has been torn out of its organic context by Alfred Adler. He has linked it superficially or falsely with the longing for power, and has postulated it as an independent 'masculine protest'. Since a neurosis can only arise from a conflict between two trends, it is as justifiable to see the cause of 'every' neurosis in the masculine protest as it is to see it in the feminine attitude against which the protest is being made. It is quite true that this masculine protest plays a regular part in the formation of character - in some types of people a very large part - and that we meet it in the analysis of neurotic men as a vigorous resistance. Psycho-analysis has attached due importance to the masculine protest in connection with the castration complex, without being able to accept its omnipotence or its omnipresence in neuroses. The most marked case of a masculine protest with all its manifest reactions and character-traits that I have met with in analysis was that of a patient who came to me for treatment on account of an obsessional neurosis in whose symptoms the unresolved conflict between a masculine and a feminine attitude (fear of castration and desire for castration) found clear expression. In addition, the patient had developed masochistic phantasies which were wholly derived from a wish to accept castration; and he had even gone beyond these phantasies to real satisfaction in perverse situations. The whole of his state rested - like Adler's theory itself - on the repression and denial of early infantile fixations of love.

[1923d, 4016]

The situation takes a favourable turn if the analysis of a corroborative dream of this sort, which 'tags along behind', is immediately followed by feelings of remembering what has hitherto been forgotten. But even then the sceptic can fall back upon an assertion that the recollections are illusory. Moreover, such feelings are for the most part absent. The repressed material is only allowed through bit by bit; and every lack of completeness inhibits or delays the forming of a sense of conviction. Furthermore, what we are dealing with may not be the reproduction of a real and forgotten event but the bringing forward of an unconscious phantasy, about which no feeling of memory is ever to be expected, though the possibility may sometimes remain of a sense of subjective conviction.

[1923c, 4036]
A neurosis usually contents itself with avoiding the piece of reality in question and protecting itself against coming into contact with it. The sharp distinction between neurosis and psychosis, however, is weakened by the circumstance that in neurosis, too, there is no lack of attempts to replace a disagreeable reality by one which is more in keeping with the subject's wishes. This is made possible by the existence of a world of phantasy, of a domain which became separated from the real external world at the time of the introduction of the reality principle. This domain has since been kept free from the demands of the exigencies of life, like a kind of 'reservation'; it is not inaccessible to the ego, but is only loosely attached to it. It is from this world of phantasy that the neurosis draws the material for its new wishful constructions, and it usually finds that material along the path of regression to a more satisfying real past.

[1924e, 4097]

It can hardly be doubted that the world of phantasy plays the same part in psychosis and that there, too, it is the storehouse from which the materials or the pattern for building the new reality are derived. But whereas the new, imaginary external world of a psychosis attempts to put itself in the place of external reality, that of a neurosis, on the contrary, is apt, like the play of children, to attach itself to a piece of reality - a different piece from the one against which it has to defend itself - and to lend that piece a special importance and a secret meaning which we (not always quite appropriately) call a symbolic one. Thus we see that both in neurosis and psychosis there comes into consideration the question not only of a loss of reality but also of a substitute for reality.

[1924e, 4098]

Before going further into the question of infantile sexuality I must mention an error into which I fell for a while and which might well have had fatal consequences for the whole of my work. Under the influence of the technical procedure which I used at that time, the majority of my patients reproduced from their childhood scenes in which they were sexually seduced by some grown-up person. With female patients the part of seducer was almost always assigned to their father. I believed these stories, and consequently supposed that I had discovered the roots of the subsequent neurosis in these experiences of sexual seduction in childhood. My confidence was strengthened by a few cases in which relations of this kind with a father, uncle, or elder brother had continued up to an age at which memory was to be trusted. If the reader feels inclined to shake his head at my credulity, I cannot altogether blame him; though I may plead that this was at a time when I was intentionally keeping my critical faculty in abeyance so as to preserve an unprejudiced and receptive attitude towards the many novelties which were coming to my notice every day. When, however, I was at last obliged to recognize that these scenes of seduction had never taken place, and that they were only phantasies which my patients had made up or which I myself had perhaps forced on them, I was for some time completely at a loss. My confidence alike in my technique and in its results suffered a severe blow; it could not be disputed that I had arrived at these scenes by a technical method which I considered correct, and their subject-matter was unquestionably related to the symptoms from which my investigation had started. When I had pulled myself together, I was able to draw the right conclusions from my discovery: namely, that the neurotic symptoms were not related directly to actual events but to wishful phantasies, and that as far as the neurosis was concerned psychical reality was of more importance than material reality. I do not believe even now that I forced the seduction-phantasies on my patients, that I 'suggested' them. I had in fact stumbled for the first time upon the Oedipus complex, which was later to assume such an overwhelming importance, but which I did not recognize as yet in its disguise of phantasy. Moreover, seduction during childhood retained a certain share, though a humbler one, in the aetiology of neuroses. But the seducers turned out as a rule to have been older children.

[1925d, 4210]
The more generalized inhibitions of the ego obey a different mechanism of a simple kind. When the ego is involved in a particularly difficult psychical task, as occurs in mourning, or when there is some tremendous suppression of affect or when a continual flood of sexual phantasies has to be kept down, it loses so much of the energy at its disposal that it has to cut down the expenditure of it at many points at once. It is in the position of a speculator whose money has become tied up in his various enterprises. I came across an instructive example of this kind of intense, though short-lived, general inhibition. The patient, an obsessional neurotic, used to be overcome by a paralysing fatigue which lasted for one or more days whenever something occurred which should obviously have thrown him into a rage. We have here a point from which it should be possible to reach an understanding of the condition of general inhibition which characterizes states of depression, including the gravest form of them, melancholia. [1926d, 4251]
A special kind of symbolism must, no doubt, have lain behind the toad, but I unfortunately neglected to enquire into it.

Hypnosis. - She had had some fearful dreams. The legs and arms of the chairs were all turned into snakes; a monster with a vulture's beak was tearing and eating at her all over her body; other wild animals leapt upon her, etc. She then passed on to other animal-deliria, which, however, she qualified with the addition "That was real" (not a dream): how (on an earlier occasion) she had been going to pick up a ball of wool, and it was a mouse and ran away; how she had been on a walk, and a big toad suddenly jumped out at her, and so on. I saw that my general prohibition had been ineffective and that I should have to take her frightening impressions away from her one by one.¹ I took an opportunity of asking her, too, why she had gastric pains and what they came from. (I believe that all her attacks of zoöpsia are accompanied by gastric pains.) Her answer, which she gave rather grudgingly, was that she did not know. I requested her to remember by tomorrow. She then said in a definitely grumbling tone that I was not to keep on asking her where this and that came from, but to let her tell me what she had to say, I fell in with this, and she went on without preface: 'When they carried him out, I could not believe he was dead.' (So she was talking of her husband again, and I saw now that the cause of her ill-humour was that she had been suffering from the residues of this story which had been kept back.) After this, she said, she had hated her child for three years, because she always told herself that she might have been able to nurse her husband back to health if she had not been in bed on account of the child. And then after her husband's death, there had been nothing but insults and agitations. His relatives, who had always been against the marriage and had then been angry because they had been so happy together, had spread a rumour that she had poisoned him, so that she had wanted to demand an enquiry. Her relatives had involved her in all kinds of legal proceedings with the help of a shady journalist. The wretch had sent round agents to stir people up against her. He got the local papers to print libellous articles about her, and then sent her the cuttings. This had been the origin of her unsociability and her hatred of all strangers. After I had spoken some calming words about what she had told me, she said she felt easier.

¹ I unfortunately failed to enquire into the significance of Frau Emmy's animal visions - to distinguish, for instance, what was symbolic in her fear of animals from what was primary horror, such as is characteristic of many neuropaths from youth onwards.

Hypnosis. - Yesterday evening it had suddenly occurred to her why the small animals she saw grew so enormous. It happened to her for the first time at D-- during a theatrical performance in which a huge lizard appeared on the stage. This memory had tormented her a great deal yesterday as well.

¹
I tried to disentangle the confusion of her mind under hypnosis. I asked her what it was that frightened her. She repeated the story of the mouse with every sign of terror, and added that as she went down the steps she saw a dreadful animal lying there, which vanished at once. I said that these were hallucinations and told her not to be frightened of mice; it was only drunkards who saw them (she disliked drunkards intensely). I told her the story of Bishop Hatto. She knew it too, and listened to it with extreme horror. - 'How did you come to think of the circus?' I went on to ask. She said that she had clearly heard the horses stamping in their stables near-by and getting tied up in their halters, which might injure them. When this happened Johann used to go out and untie them. I denied that there were stables near-by or that anyone in the next room had groaned. Did she know where she was? She said she knew now, but had thought earlier that she was in Rügen. I asked her how she got on to this memory. They had been talking in the garden, she said, of how hot it was in one part of it, and all at once the thought had come to her of the shadeless terrace in Rügen. Well then, I asked, what were her unhappy memories of her stay in Rügen? She produced a series of them. She had had the most frightful pains there in her legs and arms; when she was out on excursions there she had several times been caught in a fog and lost her way; twice, while she was on a walk, a bull had come after her, and so on. How was it that she had had this attack to-day? - How (she answered)? She had written a great many letters; it had taken her three hours and had given her a bad head. - I could assume, accordingly, that her attack of delirium was brought on by fatigue and that its content was determined by associations from such things as the shadeless place in the garden, etc. I repeated all the lessons I have been in the habit of giving her and left her composed to sleep.

[1895d, 68]

In this way, firstly, the painful region had been extended by the addition of adjacent areas: every fresh theme which had a pathogenic effect had cathected a new region in the legs; secondly, each of the scenes which made a powerful impression on her had left a trace behind it, bringing about lasting and constantly accumulating cathexis of the various functions of the legs, a linking of these functions with her feelings of pain. But a third mechanism had unmistakably been involved in the building up of her astasia-abasia. The patient ended her description of a whole series of episodes by complaining that they had made the fact of her 'standing alone' painful to her. In another series of episodes, which comprised her unsuccessful attempts to establish a new life for her family, she was never tired of repeating that what was painful about them had been her feeling of helplessness, the feeling that she could not 'take a single step forward'. In view of this, I was forced to suppose that among the influences that went to the building up of her abasia, these reflections of hers played a part; I could not help thinking that the patient had done nothing more nor less than look for a symbolic expression of her painful thoughts and that she had found it in the intensification of her sufferings. The fact that somatic symptoms of hysteria can be brought about by symbolization of this kind was already asserted in our 'Preliminary Communication'. In the Discussion on the present case I shall bring forward two or three conclusive instances of this. This psychical mechanism of symbolization did not play a prominent part with Fräulein Elisabeth von R. It did not create her abasia. But everything goes to show that the abasia which was already present received considerable reinforcement in this way. Accordingly, this abasia, at the stage of development at which I came across it, was to be equated not only with a functional paralysis based on psychical associations but also with one based on symbolization.

[1895d, 138]
Now that the old antithesis between conscious life and dream life has been reduced to its proper proportions by the establishment of unconscious psychical reality, a number of dream-problems with which earlier writers were deeply concerned have lost their significance. Thus some of the activities whose successful performance in dreams excited astonishment are now no longer to be attributed to dreams but to unconscious thinking, which is active during the day no less than at night. If, as Scherner has said, dreams appear to engage in making symbolic representations of the body, we now know that those representations are the product of certain unconscious phantasies (deriving, probably, from sexual impulses) which find expression not only in dreams but also in hysterical phobias and other symptoms. If a dream carries on the activities of the day and completes them and even brings valuable fresh ideas to light, all we need do is to strip it of the dream disguise, which is the product of dream-work and the mark of assistance rendered by obscure forces from the depths of the mind (cf. the Devil in Tartini’s sonata dream); the intellectual achievement is due to the same mental forces which produce every similar result during the daytime. We are probably inclined greatly to over-estimate the conscious character of intellectual and artistic production as well. Accounts given us by some of the most highly productive men, such as Goethe and Helmholtz, show rather that what is essential and new in their creations came to them without premeditation and as an almost ready-made whole. There is nothing strange if in other cases, where a concentration of every intellectual faculty was needed, conscious activity also contributed its share. But it is the much-abused privilege of conscious activity, wherever it plays a part, to conceal every other activity from our eyes.

¹ Hans only confirmed the interpretation of the two giraffes as his father and mother, and not the sexual symbolism, according to which the giraffe itself represented the penis. This symbolism was probably correct, but we really cannot ask more of Hans.

The Professor only knows that the game which Hans intended to play with the loaded carts must have stood in the relation of a symbolic substitute to some other wish as to which he had so far uttered no word. But, if it did not seem too daring, this wish might already, even at this stage, be constructed.

¹ Hans was now going off into a phantasy. As we can see, a box and a bath have the same meaning for him: they both represent the space which contains the babies. We must bear in mind Hans's repeated assurances on this point.

What can be the meaning of the boy's obstinate persistence in all this nonsense? Oh no, it was no nonsense: it was parody, it was Hans's revenge upon his father. It was as much as to say: 'If you really expect me to believe that the stork brought Hanna in October, when even in the summer, while we were travelling to Gmunden, I'd noticed how big Mother's stomach was, - then I expect you to believe my lies.' What can be the meaning of the assertion that even the summer before the last Hanna had travelled with them to Gmunden 'in the box', except that he knew about his mother's pregnancy? His holding out the prospect of a repetition of this journey in the box in each successive year exemplifies a common way in which unconscious thoughts from the past emerge into consciousness; or it may have special reasons and express his dread of seeing a similar pregnancy repeated on their next summer holiday. We now see, moreover, what the circumstances were that had made him take a dislike to the journey to Gmunden, as his second phantasy had indicated.
¹ The box was of course the womb. (Hans's father was trying to let him know that he understood this.)
And the same is true of the caskets in which so many of the heroes of mythology were exposed, from the
time of King Sargon of Agade onwards. - [Added 1923:] Cf. Rank's study, Der Mythus von der Geburt des
Helden, 1909.
[1909b, 2057]

'In the light of this, we may review the interpretation of Hans's earlier phantasy to the effect
that the plumber had come and unscrewed the bath and had stuck a borer into his stomach.
The big bath meant a "behind", the borer or screwdriver was (as was explained at the time) a
widdler.¹ The two phantasies are identical. Moreover, a new light is thrown upon Hans's fear of
the big bath. (This, by the way, has already diminished.) He dislikes his "behind" being too small
for the big bath.'
[1909b, 2084]

¹ It is quite certain that Hans's two associations, 'raspberry syrup' and 'a gun for shooting people dead
with' must have had more than one set of determinants. They probably had just as much to do with his
hatred of his father as with his constipation complex. His father, who himself guessed the latter connection,
also suggested that 'raspberry syrup' might be related to 'blood'.
[1909b, 2096]

But the patient was also familiar with the fact that rats are carriers of dangerous infectious
diseases; he could therefore employ them as symbols of his dread (justifiable enough in the
army) of syphilitic infection. This dread concealed all sorts of doubts as to the kind of life his
father had led during his term of military service. Again, in another sense, the penis itself is a
carrier of syphilitic infection; and in this way he could consider the rat as a male organ of sex. It
had a further title to be so regarded; for a penis (especially a child's penis) can easily be
compared to a worm, and the captain's story had been about rats burrowing in some one's
anus, just as the large round-worms had in his when he was a child. Thus the penis significance
of rats was based, once more, upon anal erotism. And apart from this, the rat is a dirty animal,
feeding upon excrement and living in sewers.¹ It is perhaps unnecessary to point out how great
an extension of the rat delirium became possible owing to this new meaning. For instance, 'So
many rats, so many florins' could serve as an excellent characterization of a certain female
profession which he particularly detested. On the other hand, it is certainly not a matter of
indifference that the substitution of a penis for a rat in the captain's story resulted in a situation
of intercourse per anum, which could not fail to be especially revolting to him when brought into
connection with his father and the woman he loved. And when we consider that the same
situation was reproduced in the compulsive threat which had formed in his mind after the
captain had made his request, we shall be forcibly reminded of certain curses in use among the
Southern Slavs.² Moreover, all of this material, and more besides, was woven into the fabric of
the rat discussions behind the screen-association 'heiraten' ['to marry'].
[1909d, 2167]
The story of the rat punishment, as was shown by the patient's own account of the matter and by his facial expression as he repeated the story to me, had fanned into a flame all his prematurely suppressed impulses of cruelty, egoistic and sexual alike. Yet, in spite of all this wealth of material, no light was thrown upon the meaning of his obsessional idea until one day the Rat-Wife in Ibsen's *Little Eyolf* came up in the analysis, and it became impossible to escape the inference that in many of the shapes assumed by his obsessional deliria rats had another meaning still - namely, that of children.¹ Enquiry into the origin of this new meaning at once brought me up against some of the earliest and most important roots. Once when the patient was visiting his father's grave he had seen a big beast, which he had taken to be a rat, gliding along over the grave.² He assumed that it had actually come out of his father's grave, and had just been having a meal off his corpse. The notion of a rat is inseparably bound up with the fact that it has sharp teeth with which it gnaws and bites.³ But rats cannot be sharp-toothed, greedy and dirty with impunity: they are cruelly persecuted and mercilessly put to death by man, as the patient had often observed with horror. He had often pitied the poor creatures. But he himself had been just such a nasty, dirty little wretch, who was apt to bite people when he was in a rage, and had been fearfully punished for doing so (p. 2162). He could truly be said to find 'a living likeness of himself' in the rat. It was almost as though Fate, when the captain told him his story, had been putting him through an association test: she had called out a 'complex stimulus-word', and he had reacted to it with his obsessional idea.

It was only then that it became possible to understand the inexplicable process by which his obsessional idea had been formed. With the assistance of our knowledge of infantile sexual theories and of symbolism (as learnt from the interpretation of dreams) the whole thing could be translated and given a meaning. When, at the afternoon halt (during which he had lost his pince-nez), the captain had told him about the rat punishment, the patient had only been struck at first by the combined cruelty and lasciviousness of the situation depicted. But immediately afterwards a connection had been set up with the scene from his childhood in which he himself had bitten some one. The captain - a man who could defend such punishments - had become a substitute for his father, and had thus drawn down upon himself a part of the reviving animosity which had burst out, on the original occasion, against his cruel father. The idea which came into his consciousness for a moment, to the effect that something of the sort might happen to some one he was fond of, is probably to be translated into a wish such as 'You ought to have the same thing done to you!' aimed at the teller of the story, but through him at his father. A day and a half later,¹ when the captain had handed him the packet upon which the charges were due and had requested him to pay back the 3.80 kronen to Lieutenant A., he had already been aware that his 'cruel superior' was making a mistake, and that the only person he owed anything to was the young lady at the post office. It might easily, therefore, have occurred to him to think of some derisive reply, such as, 'Will I, though?' or 'Pay your grandmother!' or 'Yes! You bet I'll pay him back the money!' - answers which would have been subject to no compulsive force. But instead, out of the stirrings of his father-complex and out of his memory of the scene from his childhood, there formed in his mind some such answer as: 'Yes! I'll pay back the money!' when my father and the lady have children!' or 'As sure as my father and the lady can have children, I'll pay him back the money!' In short, a derisive affirmation attached to an absurd condition which could never be fulfilled.²

[1909d, 2168]

[1909d, 2169]
The sun, therefore, is nothing but another sublimated symbol for the father; and in pointing this out I must disclaim all responsibility for the monotony of the solutions provided by psycho-analysis. In this instance symbolism overrides grammatical gender - at least so far as German goes,¹ for in most other languages the sun is masculine. Its counterpart in this picture of the two parents is 'Mother Earth' as she is generally called. We frequently come upon confirmations of this assertion in resolving the pathogenic phantasies of neurotics by psycho-analysis. I can make no more than the barest allusion to the relation of all this to cosmic myths. One of my patients, who had lost his father at a very early age, was always seeking to rediscover him in what was grand and sublime in Nature. Since I have known this, it has seemed to me probable that Nietzsche's hymn 'Vor Sonnenaufgang' ['Before Sunrise'] is an expression of the same longing.² Another patient, who became neurotic after his father's death, was seized with his first attack of anxiety and giddiness while the sun shone upon him as he was working in the garden with a spade. He spontaneously put forward as an interpretation that he had become frightened because his father had looked at him while he was at work upon his mother with a sharp instrument. When I ventured upon a mild remonstrance, he gave an air of greater plausibility to his view by telling me that even in his father's lifetime he had compared him with the sun, though then it had been in a satirical sense. Whenever he had been asked where his father was going to spend the summer he had replied in these sonorous words from the 'Prologue in Heaven':

[1911c, 2426]

6 "For this reason attempts were made to pump out my spinal cord. This was done by means of so-called "little men" who were placed in my feet. I shall have more to say presently on the subject of these "little men", who showed some resemblance to the phenomena of the same name which I have already discussed in Chapter VI. There used as a rule to be two of them - a "little Flechsig" and a "little von W." - And I used to hear their voices, too, in my feet.' (154.) Von W. was the man who was supposed to have accused Schreber of masturbation. The 'little men' are described by Schreber himself as being among the most remarkable and, in some respects, the most puzzling phenomena of his illness (157). It looks as though they were the product of a condensation of children and - spermatozoa.

[1911c, 2427]

In dealing with the case history of Senatspräsident Schreber I purposely restricted myself to a minimum of interpretation and I feel confident that every reader with a knowledge of psycho-analysis will have learned from the material which I presented more than was explicitly stated by me, and that he will have found no difficulty in drawing the threads closer and in reaching conclusions at which I no more than hinted. By a happy chance the same issue of this periodical as that in which my own paper appeared showed that the attention of some other contributors had been directed to Schreber's autobiography, and made it easy to guess how much more material remains to be gathered from the symbolic content of the phantasies and delusions of this gifted paranoic.¹

[1911c, 2445]

The eagle, then, who makes his young look into the sun and requires of them that they shall not be dazzled by its light, is behaving as though he were himself a descendant of the sun and were submitting his children to a test of their ancestry. And when Schreber boasts that he can look into the sun unscathed and undazzled, he has rediscovered the mythological method of expressing his filial relation to the sun, and has confirmed us once again in our view that the sun is a symbol of the father. It will be remembered that during his illness Schreber gave free expression to his family pride,² and that we discovered in the fact of his childlessness a human motive for his having fallen ill with a feminine wishful phantasy. Thus the connection between his delusional privilege and the basis of his illness becomes evident.

[1911c, 2446]
I am quite sure, however, that this opposition between our views had nothing to do with the breach in our relations which followed shortly after. This had deeper causes, but it came about in such a way that at first I did not understand it; it was only later that I learnt from many clear indications how to interpret it. It will be remembered that Breuer said of his famous first patient that the element of sexuality was astonishingly undeveloped in her and had contributed nothing to the very rich clinical picture of the case. I have always wondered why the critics did not more often cite this assertion of Breuer's as an argument against my contention of a sexual aetiology in the neuroses, and even to-day I do not know whether I ought to regard the omission as evidence of tact or of carelessness on their part. Anyone who reads the history of Breuer's case now in the light of the knowledge gained in the last twenty years will at once perceive the symbolism in it - the snakes, the stiffening, the paralysis of the arm - and, on taking into account the situation at the bedside of the young woman's sick father, will easily guess the real interpretation of her symptoms; his opinion of the part played by sexuality in her mental life will therefore be very different from that of her doctor. In his treatment of her case, Breuer was able to make use of a very intense suggestive rapport with the patient, which may serve us as a complete prototype of what we call 'transference' to-day. Now I have strong reasons for suspecting that after all her symptoms had been relieved Breuer must have discovered from further indications the sexual motivation of this transference, but that the universal nature of this unexpected phenomenon escaped him, with the result that, as though confronted by an 'untoward event',¹ he broke off all further investigation. He never said this to me in so many words, but he told me enough at different times to justify this reconstruction of what happened. When I later began more and more resolutely to put forward the significance of sexuality in the aetiology of neuroses, he was the first to show the reaction of distaste and repudiation which was later to become so familiar to me, but which at that time I had not yet learnt to recognize as my inevitable fate.

[1914d, 2881]

Incidentally, I have said nothing at all to you yet as to the circumstances in which we can obtain our deepest insight into the hypothetical 'primal language' and as to the field in which most of it has survived. Until you know this you cannot form an opinion of its whole significance. For this field is that of the neuroses and its material is the symptoms and other manifestations of neurotic patients, for the explanation and treatment of which psycho-analysis was, indeed, created.

[1916-1917, 3261]
Our patient gradually came to learn that it was as symbols of the female genitals that clocks were banished from her equipment for the night. Clocks and watches - though elsewhere we have found other symbolic interpretations for them - have arrived at a genital role owing to their relation to periodic processes and equal intervals of time. A woman may boast that her menstruation behaves with the regularity of clockwork. Our patient's anxiety, however, was directed in particular against being disturbed in her sleep by the ticking of a clock. The ticking of a clock may be compared with the knocking or throbbing in the clitoris during sexual excitement. She had in fact been repeatedly woken from her sleep by this sensation, which had now become distressing to her; and she gave expression to this fear of an erection in the rule that all clocks and watches that were going should be removed from her neighbourhood at night.

Flower-pots and vases, like all vessels, are also female symbols. Taking precautions against their falling and being broken at night was thus not without its good sense. We know the widespread custom of breaking a vessel or plate at betrothal ceremonies. Each man present gets hold of a fragment, and we may regard this as a sign of his resigning the claims he had upon the bride in virtue of a marriage-regulation dating from before the establishment of monogamy. In connection with this part of her ceremonial the girl produced a recollection and several associations. Once when she was a child she had fallen down while she was carrying a glass or china vase and had cut her finger and bled profusely. When she grew up and came to know the facts about sexual intercourse she formed an anxious idea that on her wedding-night she would not bleed and would thus fail to show that she was a virgin. Her precautions against vases being broken thus meant a repudiation of the whole complex concerned with virginity and bleeding at the first intercourse - a repudiation equally of the fear of bleeding and of the contrary fear of not bleeding. These precautions, which she subsumed under her avoidance of noise, had only a remote connection with it.

If a pillow was a woman, then the shaking of the eiderdown till all the feathers were at the bottom and caused a swelling there had a sense as well. It meant making a woman pregnant; but she never failed to smooth away the pregnancy again, for she had for years been afraid that her parents' intercourse would result in another child and so present her with a competitor. On the other hand, if the big pillow was a woman, the mother, then the small top-pillow could only stand for the daughter. Why did this pillow have to be placed diamond-wise and her head precisely along its centre line? It was easy to recall to her that this diamond shape is the inscription scribbled on every wall to represent the open female genitals. If so, she herself was playing the man and replacing the male organ by her head. (Cf. the symbolism of beheading for castrating.)
Let us turn to the obsessional neuroses in the hope of learning more about the formation of symptoms. The symptoms belonging to this neurosis fall, in general, into two groups, each having an opposite trend. They are either prohibitions, precautions and expiations - that is, negative in character - or they are, on the contrary, substitutive satisfactions which often appear in symbolic disguise. The negative, defensive group of symptoms is the older of the two; but as illness is prolonged, the satisfactions, which scoff at all defensive measures, gain the upper hand. The symptom-formation scores a triumph if it succeeds in combining the prohibition with satisfaction so that what was originally a defensive command or prohibition acquires the significance of a satisfaction as well; and in order to achieve this end it will often make use of the most ingenious associative paths. Such an achievement demonstrates the tendency of the ego to synthesize, which we have already observed. In extreme cases the patient manages to make most of his symptoms acquire, in addition to their original meaning, a directly contrary one. This is a tribute to the power of ambivalence, which, for some unknown reason, plays such a large part in obsessional neuroses. In the crudest instance the symptom is diphasic: an action which carries out a certain injunction is immediately succeeded by another action which stops or undoes the first one even if it does not go quite so far as to carry out its opposite.

[1926d, 4271]

Just a moment! Things are not quite as bad as that. Why do you choose to except your own mental processes from the rule of law which you recognize in other people's? When you have attained some degree of self-discipline and have certain knowledge at your disposal, your interpretations will be independent of your personal characteristics and will hit the mark. I am not saying that the analyst's personality is a matter of indifference for this portion of his task. A kind of sharpness of hearing for what is unconscious and repressed, which is not possessed equally by everyone, has a part to play. And here, above all, we are brought to the analyst's obligation to make himself capable, by a deep-going analysis of his own, of the unprejudiced reception of the analytic material. Something, it is true, still remains over: something comparable to the 'personal equation' in astronomical observations. This individual factor will always play a larger part in psycho-analysis than elsewhere. An abnormal person can become an accurate physicist; as an analyst he will be hampered by his own abnormality from seeing the pictures of mental life undistorted. Since it is impossible to demonstrate to anyone his own abnormality, general agreement in matters of depth-psychology will be particularly hard to reach. Some psychologists, indeed, think it is quite impossible and that every fool has an equal right to give out his folly as wisdom. I confess that I am more of an optimist about this. After all, our experiences show that fairly satisfactory agreements can be reached even in psychology. Every field of research has its particular difficulty which we must try to eliminate. And, moreover, even in the interpretative art of analysis there is much that can be learnt like any other material of study: for instance, in connection with the peculiar method of indirect representation through symbols.

[1926e, 4362]
On the other hand, he (the patient) was the material which was being used for the analysis (or synthesis). What was in question was the success of the treatment. The reference to his legs in the dream reminded him of an experience of the previous evening. He had been having a dancing-lesson and had met a lady of whom he had been eager to make a conquest. He clasped her to himself so tightly that on one occasion she gave a scream. As he relaxed his pressure against her legs, he felt her strong responsive pressure against the lower part of his thighs as far down as his knees - the point mentioned in his dream. So that in this connection it was the woman who was the magnesium in the retort - things were working at last. He was feminine in relation to me, just as he was masculine in relation to the woman. If it was working with the lady it was working with him in the treatment. His feeling himself and the sensations in his knees pointed to masturbation and fitted in with his fatigue on the previous day. -His appointment with the lady had in fact been for half-past eleven. His wish to miss it by oversleeping and to stay with his sexual objects at home (that is, to keep to masturbation) corresponded to his resistance.

[1900a, 840]

The significance of enuresis in the early history of neurotics is worth going into thoroughly. For the sake of clearness I will confine myself to remarking that Dora's case of bed-wetting was not the usual one. The disorder was not simply that the habit had persisted beyond what is considered the normal period, but, according to her explicit account, it had begun by disappearing and had then returned at a relatively late age - after her sixth year. Bed-wetting of this kind has, to the best of my knowledge, no more likely cause than masturbation, a habit whose importance in the aetiology of bed-wetting in general is still insufficiently appreciated. In my experience, the children concerned have themselves at one time been very well aware of this connection, and all its psychological consequences follow from it as though they had never forgotten it. Now, at the time when Dora reported the dream, we were engaged upon a line of enquiry which led straight towards an admission that she had masturbated in childhood. A short while before, she had raised the question of why it was that precisely she had fallen ill, and, before I could answer, had put the blame on her father. The justification for this was forthcoming not out of her unconscious thoughts but from her conscious knowledge. It turned out, to my astonishment, that the girl knew what the nature of her father's illness had been. After his return from consulting me she had overheard a conversation in which the name of the disease had been mentioned. At a still earlier period - at the time of the detached retina - an oculist who was called in must have hinted at a luetic aetiology; for the inquisitive and anxious girl overheard an old aunt of hers saying to her mother: 'He was ill before his marriage, you know,' and adding something which she could not understand, but which she subsequently connected in her mind with improper subjects.

[1905e, 1411]
I then understood that behind the train of thought in which she brought these open accusations against her father there lay concealed as usual a *self*-accusation. I met her half-way by assuring her that in my view the occurrence of leucorrhoea in young girls pointed primarily to masturbation, and I considered that all the other causes which were commonly assigned to that complaint were put in the background by masturbation.¹ I added that she was now on the way to finding an answer to her own question of why it was that precisely she had fallen ill - by confessing that she had masturbated, probably in childhood. Dora denied flatly that she could remember any such thing. But a few days later she did something which I could not help regarding as a further step towards the confession. For on that day she wore at her waist - a thing she never did on any other occasion before or after - a small reticule of a shape which had just come into fashion; and, as she lay on the sofa and talked, she kept playing with it - opening it, putting a finger into it, shutting it again, and so on. I looked on for some time, and then explained to her the nature of a 'symptomatic act'.² I give the name of symptomatic acts to those acts which people perform, as we say, automatically, unconsciously, without attending to them, or as if in a moment of distraction. They are actions to which people would like to deny any significance, and which, if questioned about them, they would explain as being indifferent and accidental. Closer observation, however, will show that these actions, about which consciousness knows nothing or wishes to know nothing, in fact give expression to unconscious thoughts and impulses, and are therefore most valuable and instructive as being manifestations of the unconscious which have been able to come to the surface. There are two sorts of conscious attitudes possible towards these symptomatic acts. If we can ascribe inconspicuous motives to them we recognize their existence; but if no such pretext can be found for conscious use we usually fail altogether to notice that we have performed them. Dora found no difficulty in producing a motive: 'Why should I not wear a reticule like this, as it is now the fashion to do?' But a justification of this kind does not dismiss the possibility of the action in question having an unconscious origin. Though on the other hand the existence of such an origin and the meaning attributed to the act cannot be conclusively established. We must content ourselves with recording the fact that such a meaning fits in quite extraordinarily well with the situation as a whole and with the programme laid down by the unconscious.
[1905e, 1413]
The reproaches against her father for having made her ill, together with the self-reproach underlying them, the leucorrhoea, the playing with the reticule, the bed-wetting after her sixth year, the secret which she would not allow the doctors to tear from her - the circumstantial evidence of her having masturbated in childhood seems to me complete and without a flaw. In the present case I had begun to suspect the masturbation when she had told me of her cousin's gastric pains, and had then identified herself with her by complaining for days together of similar painful sensations. It is well known that gastric pains occur especially often in those who masturbate. According to a personal communication made to me by Wilhelm Fliess, it is precisely gastralgias of this character which can be interrupted by an application of cocaine to the 'gastric spot' discovered by him in the nose, and which can be cured by the cauterization of the same spot. In confirmation of my suspicion Dora gave me two facts from her conscious knowledge: she herself had frequently suffered from gastric pains, and she had good reasons for believing that her cousin was a masturbator. It is a very common thing for patients to recognize in other people a connection which, on account of their emotional resistances, they cannot perceive in themselves. And, indeed, Dora no longer denied my supposition, although she still remembered nothing. Even the date which she assigned to the bed-wetting, when she said that it lasted 'till a short time before the appearance of the nervous asthma', appears to me to be of clinical significance. Hysterical symptoms hardly ever appear so long as children are masturbating, but only afterwards, when a period of abstinence has set in;¹ they form a substitute for masturbatory satisfaction, the desire for which continues to persist in the unconscious until another and more normal kind of satisfaction appears - where that is still attainable. For upon whether it is still attainable or not depends the possibility of a hysteria being cured by marriage and normal sexual intercourse. But if the satisfaction afforded in marriage is again removed - as it may be owing to coitus interruptus, psychological estrangement, or other causes - then the libido flows back again into its old channel and manifests itself once more in hysterical symptoms.

¹ [Footnote added 1915:] The problem of why the sense of guilt of neurotics is, as Bleuler recently recognized, regularly attached to the memory of some masturbatory activity, usually at puberty, still awaits an exhaustive analytic explanation. [Added 1920:] The most general and most important factor concerned must no doubt be that masturbation represents the executive agency of the whole of infantile sexuality and is, therefore, able to take over the sense of guilt attaching to it.
Unconscious phantasies have either been unconscious all along and have been formed in the unconscious; or - as is more often the case - they were once conscious phantasies, day-dreams, and have since been purposely forgotten and have become unconscious through 'repression'. Their content may afterwards either have remained the same or have undergone alterations, so that the present unconscious phantasies are derivatives of the once conscious ones. Now an unconscious phantasy has a very important connection with the subject's sexual life; for it is identical with the phantasy which served to give him sexual satisfaction during a period of masturbation. At that time the masturbatory act (in the widest sense of the term) was compounded of two parts. One was the evocation of a phantasy and the other some active behaviour for obtaining self-gratification at the height of the phantasy. This compound, as we know, was itself merely soldered together.¹ Originally the action was a purely auto-erotic procedure for the purpose of obtaining pleasure from some particular part of the body, which could be described as erotogenic. Later, this action became merged with a wishful idea from the sphere of object-love and served as a partial realization of the situation in which the phantasy culminated. When, subsequently, the subject renounces this type of satisfaction, composed of masturbation and phantasy, the action is given up, while the phantasy, from being conscious, becomes unconscious. If no other mode of sexual satisfaction supervenes, the subject remains abstinent; and if he does not succeed in sublimating his libido - that is, in deflecting his sexual excitation to higher aims - the condition is now fulfilled for his unconscious phantasy to be revived and to proliferate, and, at least as regards some part of its content, to put itself into effect, with the whole force of his need for love, in the form of a pathological symptom.

Our present patient's behaviour in the matter of masturbation was most remarkable. He did not practise it during puberty and therefore, according to one set of views, he might have expected to be exempt from neurosis. On the other hand, an impulsion towards masturbatory activities came over him in his twenty-first year, shortly after his father's death. He felt very much ashamed of himself each time he gave way to this kind of gratification, and soon foreswore the habit. From that time onwards it reappeared only upon rare and extraordinary occasions. It was provoked, he told me, when he experienced especially fine moments, or when he read especially fine passages. It occurred once, for instance, on a lovely summer's afternoon when, in the middle of Vienna, he heard a postilion blowing his horn in the most wonderful way - until a policeman stopped him, because blowing horns is not allowed in the centre of the town. And another time it happened when he read in Dichtung und Warheit how the young Goethe had freed himself in a burst of tenderness from the effects of a curse which a jealous mistress had pronounced upon the next woman who should kiss his lips after her; he had long, almost superstitiously, suffered the curse to hold him back, but now he broke his bonds and kissed his love joyfully again and again.

It seemed to the patient not a little strange that he should be impelled to masturbate precisely upon such beautiful and uplifting occasions as these. But I could not help pointing out that these two occasions had something in common - a prohibition, and the defiance of a command.
Starting from these indications and from other data of a similar kind, I ventured to put forward a construction to the effect that when he was a child of under six he had been guilty of some sexual misdemeanour connected with masturbation and had been soundly castigated for it by his father. This punishment, according to my hypothesis, had, it was true, put an end to his masturbating, but on the other hand it had left behind it an ineradicable grudge against his father and had established him for all time in his role of an interferer with the patient's sexual enjoyment.¹ To my great astonishment the patient then informed me that his mother had repeatedly described to him an occurrence of this kind which dated from his earliest childhood and had evidently escaped being forgotten by her on account of its remarkable consequences. He himself, however, had no recollection of it whatever. The tale was as follows. When he was very small - it became possible to establish the date more exactly owing to its having coincided with the fatal illness of an elder sister - he had done something naughty, for which his father had given him a beating. The little boy had flown into a terrible rage and had hurled abuse at his father even while he was under his blows. But as he knew no bad language, he had called him all the names of common objects that he could think of, and had screamed: 'You lamp! You towel! You plate!' and so on. His father, shaken by such an outburst of elemental fury, had stopped beating him, and had declared: 'The child will be either a great man or a great criminal!'² The patient believed that the scene made a permanent impression upon himself as well as upon his father. His father, he said, never beat him again; and he also attributed to this experience a part of the change which came over his own character. From that time forward he was a coward - out of fear of the violence of his own rage. His whole life long, moreover, he was terribly afraid of blows, and used to creep away and hide, filled with terror and indignation, when one of his brothers or sisters was beaten.

Thus in the case of Schreber we find ourselves once again on the familiar ground of the father-complex.¹ The patient's struggle with Flechsig became revealed to him as a conflict with God, and we must therefore construe it as an infantile conflict with the father whom he loved; the details of that conflict (of which we know nothing) are what determined the content of his delusions. None of the material which in other cases of the sort is brought to light by analysis is absent in the present one: every element is hinted at in one way or another. In infantile experiences such as this the father appears as an interferer with the satisfaction which the child is trying to obtain; this is usually of an auto-erotic character, though at a later date it is often replaced in phantasy by some other satisfaction of a less inglorious kind.² In the final stage of Schreber's delusion a magnificent victory was scored by the infantile sexual urge; for voluptuousness became God-fearing, and God Himself (his father) never tired of demanding it from him. His father's most dreaded threat, castration, actually provided the material for his wishful phantasy (at first resisted but later accepted) of being transformed into a woman. His allusion to an offence covered by the surrogate idea 'soul-murder' could not be more transparent. The chief attendant was discovered to be identical with his neighbour von W., who, according to the voices, had falsely accused him of masturbation (108). The voices said, as though giving grounds for the threat of castration: 'For you are to be represented as being given over to voluptuous excesses.'³ (127-8.) Finally, we come to the enforced thinking (47) to which the patient submitted himself because he supposed that God would believe he had become an idiot and would withdraw from him if he ceased thinking for a moment. This is a reaction (with which we are also familiar in other connections) to the threat or fear of losing one's reason as a result of indulging in sexual practices and especially in masturbation. Considering the enormous number of delusional ideas of a hypochondriacal nature which the patient developed, no great importance should perhaps be attached to the fact that some of them coincide word for word with the hypochondriacal fears of masturbators.⁶
With your permission I will set before you a summary of the points on which we seem to be agreed or divided.

We are all _agreed_, I feel,

(a) on the importance of the phantasies which accompany or represent the act of masturbation,
(b) on the importance of the sense of guilt, whatever its source may be, which is attached to masturbation, and
(c) on the impossibility of assigning a qualitative determinant for the injurious effects of masturbation. (On this last point agreement is not unanimous.)

_Unresolved differences of opinion_ have appeared

(a) in respect to a denial of a somatic factor in the effects of masturbation,
(b) in respect to a general denial of the injurious effects of masturbation,
(c) with regard to the origin of the sense of guilt, which some of you wish to attribute directly to lack of satisfaction, while others adduce social factors in addition, or the attitude of the subject's personality at the moment, and
(d) with regard to the ubiquity of masturbation in children.

Lastly, significant _uncertainties_ exist

(a) as to the mechanism of the injurious effects of masturbation, if there are any, and
(b) as to the aetiological relation of masturbation to the 'actual neuroses'.

[1912f, 2568]

There is another question that I might draw your attention to, which has been dealt with too little in our discussions: that of 'unconscious' masturbation. I mean masturbation during sleep, during abnormal states, or fits. You will recall the many hysterical fits in which masturbatory acts recur in a disguised or unrecognizable way, after the subject has renounced that form of satisfaction, and the many symptoms in obsessional neurosis which seek to replace and repeat this kind of sexual activity, which has formerly been forbidden. We may also speak of a therapeutic return of masturbation. A number of you will have found on occasion, as I have, that it represents a great advance if during the treatment the patient ventures to take up masturbation once more, though he may have no intention of making a permanent stop at that infantile halting-place. In this connection I may remind you that a considerable number of precisely the most severe sufferers from neurosis have avoided all recollection of masturbation during historic times, while psycho-analysis is able to prove that that species of sexual activity had by no means been strange to them during the forgotten earliest period of their lives.

[1912f, 2574]
In enforcing regression, the ego scores its first success in its defensive struggle against the
demands of the libido. (In this connection it is of advantage to distinguish the more general
notion of 'defence' from 'repression'. Repression is only one of the mechanisms which defence
makes use of.) It is perhaps in obsessional cases more than in normal or hysterical ones that
we can most clearly recognize that the motive force of defence is the castration complex and
that what is being fended off are the trends of the Oedipus complex. We are at present dealing
with the beginning of the latency period, a period which is characterized by the dissolution of the
Oedipus complex, the creation or consolidation of the super-ego and the erection of ethical and
aesthetic barriers in the ego. In obsessional neuroses these processes are carried further than
is normal. In addition to the destruction of the Oedipus complex a regressive degradation of the
libido takes place, the super-ego becomes exceptionally severe and unkind, and the ego, in
obedience to the super-ego, produces strong reaction-formations in the shape of
conscientiousness, pity and cleanliness. Implacable, though not always on that account
successful, severity is shown in condemning the temptation to continue early infantile
masturbation, which now attaches itself to regressive (sadistic-anal) ideas but which
nevertheless represents the unsubjugated part of the phallic organization. There is an inherent
contradiction about this state of affairs, in which, precisely in the interests of masculinity (that is
to say, from fear of castration), every activity belonging to masculinity is stopped. But here, too,
obessional neurosis is only overdoing the normal method of getting rid of the Oedipus
complex. We once more find here an illustration of the truth that every exaggeration contains
the seed of its own undoing. For, under the guise of obsessional acts, the masturbation that has
been suppressed approaches ever more closely to satisfaction.
[1926d, 4273]

... I have read your critical review of my Dostoevsky study with great pleasure. All your
objections deserve consideration and must be recognized as in a sense apt. I can bring forward
a little in my defence. But of course it will not be a question of who is right or who is wrong.
[1928b, 4569]

I think you are applying too high a standard to this triviality. It was written as a favour to
someone and written reluctantly. I always write reluctantly nowadays. No doubt you noticed this
about it. This is not meant, of course, to excuse hasty or false judgements, but merely the
careless architecture of the essay as a whole. I cannot dispute the unharmonious effect
produced by the addition of the Zweig analysis; but deeper examination will perhaps show some
justification for it. If I had not been hampered by considerations of the place where my essay
was to appear, I should certainly have written: 'We may expect that in the history of a neurosis
accompanied by such a severe sense of guilt a special part will be played by the struggle
against masturbation. This expectation is completely fulfilled by Dostoevsky's pathological
addiction to gambling. For, as we can see from a short story of Zweig's . . . etc.' That is to say,
the amount of space given to the short story corresponds not to the relation: Zweig-Dostoevsky,
but to the other one: masturbation-neurosis. All the same, the outcome was clumsy.
[1928b, 4569]
You all know the immense aetiological importance attributed by our neurotic patients to their masturbation. They make it responsible for all their troubles and we have the greatest difficulty in persuading them that they are mistaken. In fact, however, we ought to admit to them that they are right, for masturbation is the executive agent of infantile sexuality, from the faulty development of which they are indeed suffering. But what neurotics mostly blame is the masturbation of the period of puberty; they have mostly forgotten that of early infancy, which is what is really in question. I wish I might have an opportunity some time of explaining to you at length how important all the factual details of early masturbation become for the individual’s subsequent neurosis or character: whether or not it was discovered, how the parents struggled against it or permitted it, or whether he succeeded in suppressing it himself. All of this leaves permanent traces on his development. But I am on the whole glad that I need not do this. It would be a hard and tedious task and at the end of it you would put me in an embarrassing situation by quite certainly asking me to give you some practical advice as to how a parent or educator should deal with the masturbation of small children. From the development of girls, which is what my present lecture is concerned with, I can give you the example of a child herself trying to get free from masturbating. She does not always succeed in this. If envy for the penis has provoked a powerful impulse against clitoral masturbation but this nevertheless refuses to give way, a violent struggle for liberation ensues in which the girl, as it were, herself takes over the role of her deposed mother and gives expression to her entire dissatisfaction with her inferior clitoris in her efforts against obtaining satisfaction from it. Many years later, when her masturbatory activity has long since been suppressed, an interest still persists which we must interpret as a defence against a temptation that is still dreaded. It manifests itself in the emergence of sympathy for those to whom similar difficulties are attributed, it plays a part as a motive in contracting a marriage and, indeed, it may determine the choice of a husband or lover. Disposing of early infantile masturbation is truly no easy or indifferent business. [1933a, 4729]
I should like to go back once more to the instinctual life of obsessional neurotics and add one more remark upon it. It turned out that our patient, besides all his other characteristics, was a renifleur. By his own account, when he was a child he had recognized every one by their smell, like a dog; and even when he was grown up he was more susceptible to sensations of smell than most people.¹ I have met with the same characteristic in other neurotics, both in hysterical and in obsessional patients, and I have come to recognize that a tendency to taking pleasure in smell, which has become extinct since childhood, may play a part in the genesis of neurosis.² And here I should like to raise the general question whether the atrophy of the sense of smell (which was an inevitable result of man’s assumption of an erect posture) and the consequent organic repression of his pleasure in smell may not have had a considerable share in the origin of his susceptibility to nervous disease. This would afford us some explanation of why, with the advance of civilization, it is precisely the sexual life that must fall a victim to repression. For we have long known the intimate connection in the animal organization between the sexual instinct and the function of the olfactory organ.

² For instance, in certain forms of fetishism.

¹ I may add that in his childhood he had been subject to strong coprophilic propensities. In this connection his anal erotism has already been noticed (p. 2166).

² For instance, in certain forms of fetishism.

The conjecture which goes deepest, however, is the one which takes its start from what I have said above (p. 4495) in my footnote. It is to the effect that, with the assumption of an erect posture by man and with the depreciation of his sense of smell, it was not only his anal erotism which threatened to fall a victim to organic repression, but the whole of his sexuality; so that since this, the sexual function has been accompanied by a repugnance which cannot further be accounted for, and which prevents its complete satisfaction and forces it away from the sexual aim into sublimations and libidinal displacements. I know that Bleuler (1913) once pointed to the existence of a primary repelling attitude like this towards sexual life. All neurotics, and many others besides, take exception to the fact that ‘inter urinas et faeces nascimur’. The genitals, too, give rise to strong sensations of smell which many people cannot tolerate and which spoil sexual intercourse for them. Thus we should find that the deepest root of the sexual repression which advances along with civilization is the organic defence of the new form of life achieved with man’s erect gait against his earlier animal existence. This result of scientific research coincides in a remarkable way with commonplace prejudices that have often made themselves heard. Nevertheless, these things are at present no more than unconfirmed possibilities which have not been substantiated by science. Nor should we forget that, in spite of the undeniable depreciation of olfactory stimuli, there exist even in Europe people among whom the strong genital odours which are so repellent to us are highly prized as sexual stimulants and who refuse to give them up. (Cf. the collections of folklore obtained from Iwan Bloch’s questionnaire on the sense of smell in sexual life published in different volumes of Friedrich S. Krauss’s Anthropophyteia.)
In the case of anyone who is predisposed to hysteria, the onset of his illness is precipitated when, either as a result of his own progressive maturity or of the external circumstances of his life, he finds himself faced by the demands of a real sexual situation. Between the pressure of the instinct and his antagonism to sexuality, illness offers him a way of escape. It does not solve his conflict, but seeks to evade it by transforming his libidinal impulses into symptoms. The exception is only an apparent one when a hysteric - a male patient it may be - falls ill as a result of some trivial emotion, some conflict which does not centre around any sexual interest. In such cases psycho-analysis is regularly able to show that the illness has been made possible by the sexual component of the conflict, which has prevented the mental processes from reaching a normal issue.

[1905d, 1490]

Further information now became available relating to people who had remained normal; and this led to the unexpected finding that the sexual history of their childhood did not necessarily differ in essentials from that of neurotics, and, in particular, that the part played by seduction was the same in both cases. As a consequence, accidental influences receded still further into the background as compared with 'repression' (as I now began to say instead of 'defence'). Thus it was no longer a question of what sexual experiences a particular individual had had in his childhood, but rather of his reaction to those experiences - of whether he had reacted to them by 'repression' or not. It could be shown how in the course of development a spontaneous infantile sexual activity was often broken off by an act of repression. Thus a mature neurotic individual was invariably pursued by a certain amount of 'sexual repression' from his childhood; this found expression when he was faced by the demands of real life, and the psycho-analyses of hysterics showed that they fell ill as a result of the conflict between their libido and their sexual repression and that their symptoms were in the nature of compromises between the two mental currents.

[1906a, 1580]

I think it is worth emphasizing the fact that, whatever modifications my views on the aetiology of the psychoneuroses have passed through, there are two positions which I have never repudiated or abandoned - the importance of sexuality and of infantilism. Apart from this, accidental influences have been replaced by constitutional factors and 'defence' in the purely psychological sense has been replaced by organic 'sexual repression'. The question may, however, be raised of where convincing evidence is to be found in favour of the alleged aetiological importance of sexual factors in the psychoneuroses, in view of the fact that the onset of these illnesses may be observed in response to the most commonplace emotions or even to somatic precipitating causes, and since I have had to abandon a specific aetiology depending on the particular form of the childhood experiences concerned. To such a question I would reply that the psycho-analytic examination of neurotics is the source from which this disputed conviction of mine is derived. If we make use of that irreplaceable method of research, we discover that *the patient's symptoms constitute his sexual activity* (whether wholly or in part), which arises from the sources of the normal or perverse component instincts of sexuality. Not only is a large part of the symptomatology of hysteria derived directly from expressions of sexual excitement, not only do a number of erotogenic zones attain the significance of genitals during neuroses owing to an intensification of infantile characteristics, but the most complicated symptoms are themselves revealed as representing, by means of 'conversion', phantasies which have a sexual situation as their subject-matter. Anyone who knows how to interpret the language of hysteria will recognize that the neurosis is concerned only with the patient's repressed sexuality. The sexual function must, however, be understood in its true extent, as it is laid down by disposition in infancy. Wherever some commonplace emotion must be included among the determinants of the onset of the illness, analysis invariably shows that it is the sexual component of the traumatic experience - a component that is never lacking which has produced the pathogenic result.

[1906a, 1582]
Accordingly, the aetiology of the neuroses comprises everything which can act in a detrimental manner upon the processes serving the sexual function. In the forefront, then, are to be ranked the noxae which affect the sexual function itself - in so far as these are regarded as injurious by the sexual constitution, varying as it does with different degrees of culture and education. In the next place comes every other kind of noxa and trauma which, by causing general damage to the organism, may lead secondarily to injury to its sexual processes. It should not, however, be forgotten that the aetiological problem in the case of the neuroses is at least as complicated as the causative factors of any other illness. A single pathogenic influence is scarcely ever sufficient; in the large majority of cases a number of aetiological factors are required, which support one another and must therefore not be regarded as being in mutual opposition. For this reason a state of neurotic illness cannot be sharply differentiated from health. The onset of the illness is the product of a summation and the necessary total of aetiological determinants can be completed from any direction. To look for the aetiology of the neuroses exclusively in heredity or in the constitution would be just as one-sided as to attribute that aetiology solely to the accidental influences brought to bear upon sexuality in the course of the subject's life - whereas better insight shows that the essence of these illnesses lies solely in a disturbance of the organism's sexual processes.

[1906a, 1583]

The first of these modern dramas is *Hamlet*. It has as its subject the way in which a man who has so far been normal becomes neurotic owing to the peculiar nature of the task by which he is faced, a man, that is, in whom an impulse that has hitherto been successfully suppressed endeavours to make its way into action. *Hamlet* is distinguished by three characteristics which seem important in connection with our present discussion. (1) The hero is not psychopathic, but only becomes psychopathic in the course of the action of the play. (2) The repressed impulse is one of those which are similarly repressed in all of us, and the repression of which is part and parcel of the foundations of our personal evolution. It is this repression which is shaken up by the situation in the play. As a result of these two characteristics it is easy for us to recognize ourselves in the hero: we are susceptible to the same conflict as he is, since 'a person who does not lose his reason under certain conditions can have no reason to lose'. (3) It appears as a necessary precondition of this form of art that the impulse that is struggling into consciousness, however clearly it is recognizable, is never given a definite name; so that in the spectator too the process is carried through with his attention averted, and he is in the grip of his emotions instead of taking stock of what is happening. A certain amount of resistance is no doubt saved in this way, just as, in an analytic treatment, we find derivatives of the repressed material reaching consciousness, owing to a lower resistance, while the repressed material itself is unable to do so. After all, the conflict in *Hamlet* is so effectively concealed that it was left to me to unearth it.

[1942a [1905], 1611]

The onset of hysterical attacks follows laws that are easily understandable. Since the repressed complex consists of a libidinal cathexis and an ideational content (the phantasy), the attack can be evoked (1) associatively, when the content of the complex (if sufficiently cathected) is touched on by something connected with it in conscious life; (2) organically, when, for internal somatic reasons and as a result of psychical influences from outside, the libidinal cathexis rises above a certain degree; (3) in the service of the primary purpose - as an expression of a 'flight into illness', when reality becomes distressing or frightening - that is, as a consolation; (4) in the service of the secondary purposes, with which the illness allies itself, as soon as, by producing an attack, the patient can achieve an aim that is useful to him. In the last case the attack is directed at particular individuals; it can be put off till they are present, and it gives an impression of being consciously simulated.

[1909a, 1983]
Investigation of the childhood history of hysterical patients shows that the hysterical attack is designed to take the place of an *auto-erotic* satisfaction previously practised and since given up. In a great number of cases this satisfaction (masturbation by contact or by pressure of the thighs, or, again, by movements of the tongue, and so on) recurs during the attack itself, while the subject's consciousness is deflected. Moreover, the onset of an attack that is due to an increase of libido and is in the service of the primary purpose - as a consolation - exactly repeats the conditions under which, at the earlier time, the patient had intentionally sought this auto-erotic satisfaction. The anamnesis of the patient shows the following stages: (a) auto-erotic satisfaction, without ideational content; (b) the same satisfaction, connected with a phantasy which leads to the act of satisfaction; (c) renunciation of the act, with retention of the phantasy; (d) repression of the phantasy, which then comes into effect as a hysterical attack, either in an unchanged form, or in a modified one and adapted to new environmental impressions. Furthermore, (e) the phantasy may even reinstate the act of satisfaction belonging to it which had ostensibly been given up. This is a typical cycle of infantile sexual activity: repression, failure of repression, and return of the repressed.

[1909a, 1983]

Our second problem - the problem of why transference appears in psycho-analysis as resistance - has been left for the moment untouched; and we must now approach it more closely. Let us picture the psychological situation during the treatment. An invariable and indispensable precondition of every onset of a psychoneurosis is the process to which Jung has given the appropriate name of 'introversion'.¹ That is to say: the portion of libido which is capable of becoming conscious and is directed towards reality is diminished, and the portion which is directed away from reality and is unconscious, and which, though it may still feed the subject's phantasies, nevertheless belongs to the unconscious, is proportionately increased. The libido (whether wholly or in part) has entered on a regressive course and has revived the subject's infantile imagos.² The analytic treatment now proceeds to follow it; it seeks to track down the libido, to make it accessible to consciousness and, in the end, serviceable for reality. Where the investigations of analysis come upon the libido withdrawn into its hiding-place, a struggle is bound to break out; all the forces which have caused the libido to regress will rise up as 'resistances' against the work of analysis, in order to conserve the new state of things. For if the libido's introversion or regression had not been justified by a particular relation between the subject and the external world - stated in the most general terms, by the frustration of satisfaction - and if it had not for the moment even become expedient, it could never have taken place at all. But the resistances from this source are not the only ones or indeed the most powerful. The libido at the disposal of the subject's personality had always been under the influence of the attraction of his unconscious complexes (or more correctly, of the portions of those complexes belonging to the unconscious), and it entered on a regressive course because the attraction of reality had diminished. In order to liberate it, this attraction of the unconscious has to be overcome; that is, the repression of the unconscious instincts and of their productions, which has meanwhile been set up in the subject, must be removed. This is responsible for by far the largest part of the resistance, which so often causes the illness to persist even after the turning away from reality has lost its temporary justification. The analysis has to struggle against the resistances from both these sources. The resistance accompanies the treatment step by step. Every single association, every act of the person under treatment must reckon with the resistance and represents a compromise between the forces that are striving towards recovery and the opposing ones which I have described.

[1912b, 2459]
Another temptation arises out of the educative activity which, in psycho-analytic treatment, devolves on the doctor without any deliberate intention on his part. When the developmental inhibitions are resolved, it happens of itself that the doctor finds himself in a position to indicate new aims for the trends that have been liberated. It is then no more than a natural ambition if he endeavours to make something specially excellent of a person whom he has been at such pains to free from his neurosis and if he prescribes high aims for his wishes. But here again the doctor should hold himself in check, and take the patient's capacities rather than his own desires as guide. Not every neurotic has a high talent for sublimation; one can assume of many of them that they would not have fallen ill at all if they had possessed the art of sublimating their instincts. If we press them unduly towards sublimation and cut them off from the most accessible and convenient instinctual satisfactions, we shall usually make life even harder for them than they feel it in any case. As a doctor, one must above all be tolerant to the weakness of a patient, and must be content if one has won back some degree of capacity for work and enjoyment for a person even of only moderate worth. Educative ambition is of as little use as therapeutic ambition. It must further be borne in mind that many people fall ill precisely from an attempt to sublimate their instincts beyond the degree permitted by their organization and that in those who have a capacity for sublimation the process usually takes place of itself as soon as their inhibitions have been overcome by analysis. In my opinion, therefore, efforts invariably to make use of the analytic treatment to bring about sublimation of instinct are, though no doubt always laudable, far from being in every case advisable.

In the pages which follow, I shall describe, on the basis of impressions arrived at empirically, the changes which conditions must undergo in order to bring about the outbreak of a neurotic illness in a person with a disposition to it. I shall thus be dealing with the question of the precipitating factors of illnesses and shall have little to say about their forms. The present discussion of the precipitating causes will differ from others in that the changes to be enumerated will relate exclusively to the subject's libido. For psycho-analysis has taught us that the vicissitudes of the libido are what decide in favour of nervous health or sickness. Nor are words to be wasted in this connection on the concept of disposition. It is precisely psycho-analytic research which has enabled us to show that neurotic disposition lies in the history of the development of the libido, and to trace back the operative factors in that development to innate varieties of sexual constitution and to influences of the external world experienced in early childhood.

Thus with this type, to which, no doubt, the majority of human beings on the whole belong, the possibility of falling ill arises only when there is abstinence. And it may be judged from this what an important part in the causation of neuroses may be played by the limitation imposed by civilization on the field of accessible satisfactions. Frustration has a pathogenic effect because it dams up libido, and so submits the subject to a test as to how long he can tolerate this increase in psychical tension and as to what methods he will adopt for dealing with it. There are only two possibilities for remaining healthy when there is a persistent frustration of satisfaction in the real world. The first is by transforming the psychical tension into active energy which remains directed towards the external world and eventually extorts a real satisfaction of the libido from it. The second is by renouncing libidinal satisfaction, sublimating the dammed-up libido and turning it to the attainment of aims which are no longer erotic and which escape frustration. That these two possibilities are realized in men's lives proves that unhappiness does not coincide with neurosis and that frustration does not alone decide whether its victim remains healthy or falls ill. The immediate effect of frustration lies in its bringing into play the dispositional factors which have hitherto been inoperative.
It is advisable to draw a sharp distinction between the two types of onset of illness - a sharper distinction than observation as a rule permits. In the first type what is prominent is a change in the external world; in the second type the accent falls on an internal change. In the first type the subject falls ill from an experience; in the second type it is from a developmental process. In the first case he is faced by the task of renouncing satisfaction, and he falls ill from his incapacity for resistance; in the second case his task is to exchange one kind of satisfaction for another, and he breaks down from his inflexibility. In the second case the conflict, which is between the subject's effort to remain as he is and the effort to change himself in order to meet fresh purposes and fresh demands from reality, is present from the first. In the former case the conflict only arises after the dammed-up libido has chosen other, and incompatible, possibilities of satisfaction. The part played by the conflict and the previous fixation of the libido is incomparably more obvious in the second type than in the first, in which such unserviceable fixations may perhaps only emerge as a result of the external frustration.

In spite of the very clear differences between the two types of onset of illness that we have described, they nevertheless coincide in essentials and can without difficulty be brought together into a unity. Falling ill from frustration may also be regarded as incapacity for adaptation to reality - in the particular case, that is, in which reality frustrates satisfaction of libido. Falling ill under the conditions of the second type leads directly to a special case of frustration. It is true that reality does not here frustrate every kind of satisfaction; but it frustrates the one kind which the subject declares is the only possible one. Nor does the frustration come immediately from the external world, but primarily from certain trends in the subject's ego. Nevertheless, frustration remains the common factor and the more inclusive one. In consequence of the conflict which immediately sets in in the second type, both kinds of satisfaction - the habitual one as well as the one aimed at - are equally inhibited; a damming-up of libido, with all its consequences, comes about just as it does in the first case. The psychical events leading to the formation of symptoms are if anything easier to follow in the second type than in the first; for in the second type the pathogenic fixations of the libido do not need to be freshly established, but have already been in force while the subject was healthy. A certain amount of introversion of libido is, as a rule, already present; and there is a saving of some part of the subject's regression to the infantile stage, owing to the fact that his forward development has not yet completed its course.

(c) The next type, which I shall describe as falling ill from an inhibition in development, looks like an exaggeration of the second one - falling ill from the demands of reality. There is no theoretical reason for distinguishing it, but only a practical one; for those we are here concerned with are people who fall ill as soon as they get beyond the irresponsible age of childhood, and who have thus never reached a phase of health - a phase, that is, of capacity for achievement and enjoyment which is on the whole unrestricted. The essential feature of the dispositional process is in these cases quite plain. Their libido has never left its infantile fixations; the demands of reality are not suddenly made upon a wholly or partly mature person, but arise from the very fact of growing older, since it is obvious that they constantly alter with the subject's increasing age. Thus conflict falls into the background in comparison with insufficiency. But here, too, all our other experience leads us to postulate an effort at overcoming the fixations of childhood; for otherwise the outcome of the process could never be neurosis but only a stationary infantilism.
(d) Just as the third type has brought the dispositional determinant before us almost in isolation, so the fourth type, which now follows, draws our attention to another factor, which comes into consideration in every single case and might easily for that very reason be overlooked in a theoretical discussion. We see people fall ill who have hitherto been healthy, who have met with no fresh experience and whose relation to the external world has undergone no change, so that the onset of their illness inevitably gives an impression of spontaneity. A closer consideration of such cases, however, shows us that none the less a change has taken place in them whose importance we must rate very highly as a cause of illness. As a result of their having reached a particular period of life, and in conformity with regular biological processes, the quantity of libido in their mental economy has experienced an increase which is in itself enough to upset the equilibrium of their health and to set up the necessary conditions for a neurosis. It is well known that more or less sudden increases of libido of this kind are habitually associated with puberty and the menopause - with the attainment of a certain age in women; in some people they may in addition be manifested in periodicities that are still unknown. Here the damming-up of libido is the primary factor; it becomes pathogenic as a consequence of a relative frustration on the part of the external world, which would still have granted satisfaction to a smaller claim by the libido. The unsatisfied and dammed-up libido can once again open up paths to regression and kindle the same conflicts which we have demonstrated in the case of absolute external frustration. We are reminded in this way that the quantitative factor should not be left out of account in any consideration of the precipitating causes of illness. All the other factors - frustration, fixation, developmental inhibition - remain ineffective unless they affect a certain amount of libido and bring about a damming-up of libido of a certain height. It is true that we are unable to measure this amount of libido which seems to us indispensable for a pathogenic effect; we can only postulate it after the resulting illness has started. There is only one direction in which we can determine it more precisely. We may assume that it is not a question of an absolute quantity, but of the relation between the quota of libido in operation and the quantity of libido which the individual ego is able to deal with - that is, to hold under tension, to sublimate or to employ directly. For this reason a relative increase in the quantity of libido may have the same effects as an absolute one. An enfeeblement of the ego owing to organic illness or owing to some special demand upon its energy will be able to cause the emergence of neuroses which would otherwise have remained latent in spite of any disposition that might be present.

[1912c, 2563]

It remains to say a few words on the relation of these types to the facts of observation. If I survey the set of patients on whose analysis I am at the moment engaged, I must record that not one of them is a pure example of any of the four types of onset. In each of them, rather, I find a portion of frustration operating alongside of a portion of incapacity to adapt to the demands of reality; inhibition in development, which coincides, of course, with inflexibility of fixations, has to be reckoned with in all of them, and, as I have already said, the importance of quantity of libido must never be neglected. I find, indeed, that in several of these patients their illness has appeared in successive waves, between which there have been healthy intervals, and that each of these waves has been traceable to a different type of precipitating cause. Thus the erection of these four types cannot lay claim to any high theoretical value; they are merely different ways of establishing a particular pathogenic constellation in the mental economy - namely the damming-up of libido, which the ego cannot, with the means at its command, ward off without damage. But this situation itself only becomes pathogenic as a result of a quantitative factor; it does not come as a novelty to mental life and is not created by the impact of what is spoken of as a 'cause of illness'.

[1912c, 2564]
A certain practical importance may readily be allowed to these types of onset. They are to be met with in their pure form, indeed, in individual cases; we should not have noticed the third and fourth types if they had not in some subjects constituted the sole precipitating causes of the illness. The first type keeps before our eyes the extraordinarily powerful influence of the external world, and the second the no less important influence - which opposes the former one - of the subject's peculiar individuality. Pathology could not do justice to the problem of the precipitating factors in the neuroses so long as it was merely concerned with deciding whether those affections were of an 'endogenous' or 'exogenous' nature. It was bound to meet every observation which pointed to the importance of abstinence (in the widest sense of the word) as a precipitating cause with the objection that other people tolerate the same experiences without falling ill. If, however, it sought to lay stress on the peculiar individuality of the subject as being the essential factor decisive between illness and health, it was obliged to put up with the proviso that people possessing such a peculiarity can remain healthy indefinitely, just so long as they are able to retain that peculiarity. Psycho-analysis has warned us that we must give up the unfruitful contrast between external and internal factors, between experience and constitution, and has taught us that we shall invariably find the cause of the onset of neurotic illness in a particular psychical situation which can be brought about in a variety of ways.

I shall now take my footing once more on the clinical observation of an individual case. Over a long period I studied a woman patient whose neurosis underwent an unusual change. It began, after a traumatic experience, as a straightforward anxiety hysteria and retained that character for a few years. One day, however, it suddenly changed into an obsessional neurosis of the severest type. A case of this kind could not fail to become significant in more than one direction. On the one hand, it might perhaps claim to be looked upon like a bilingual document and to show how an identical content could be expressed by the two neuroses in different languages. On the other hand, it threatened to contradict completely our theory that disposition arises from developmental inhibition, unless we were prepared to accept the supposition that a person could innately possess more than one weak spot in his libidinal development. I told myself that we had no right to dismiss this latter possibility; but I was greatly interested to arrive at an understanding of the case.

It is not difficult to determine the characteristic which distinguishes this case of obsessional neurosis from those more frequent ones which start at an early age and thereafter run a chronic course with exacerbations of a more or less striking kind. In these other cases, once the sexual organization which contains the disposition to obsessional neurosis is established it is never afterwards completely surmounted; in our case it was replaced to begin with by the higher stage of development, and was then re-activated by regression from the latter.
At this point, our curiosity will of course raise the question why this damming-up of libido in the ego should have to be experienced as unpleasurable. I shall content myself with the answer that unpleasure is always the expression of a higher degree of tension, and that therefore what is happening is that a quantity in the field of material events is being transformed here as elsewhere into the psychical quality of unpleasure. Nevertheless it may be that what is decisive for the generation of unpleasure is not the absolute magnitude of the material event, but rather some particular function of that absolute magnitude. Here we may even venture to touch on the question of what makes it necessary at all for our mental life to pass beyond the limits of narcissism and to attach the libido to objects. The answer which would follow from our line of thought would once more be that this necessity arises when the cathexis of the ego with libido exceeds a certain amount. A strong egoism is a protection against falling ill, but in the last resort we must begin to love in order not to fall ill, and we are bound to fall ill if, in consequence of frustration, we are unable to love. This follows somewhat on the lines of Heine's picture of the psychogenesis of the Creation:

[1914c, 2940]

So much the more surprising, and indeed bewildering, must it appear when as a doctor one makes the discovery that people occasionally fall ill precisely when a deeply-rooted and long-cherished wish has come to fulfilment. It seems then as though they were not able to tolerate their happiness; for there can be no question that there is a causal connection between their success and their falling ill.

[1916d, 3104]

Different as these two cases are in other respects, they yet agree in this one point: the illness followed close upon the fulfilment of a wish and put an end to all enjoyment of it.

[1916d, 3105]

The contradiction between such experiences and the rule that what induces illness is frustration is not insoluble. It disappears if we make a distinction between an external and an internal frustration. If the object in which the libido can find its satisfaction is withheld in reality, this is an external frustration. In itself it is inoperative, not pathogenic, until an internal frustration is joined to it. This latter must proceed from the ego, and must dispute the access by the libido to other objects, which it now seeks to get hold of. Only then does a conflict arise, and the possibility of a neurotic illness, i.e. of a substitutive satisfaction reached circuitously by way of the repressed unconscious. Internal frustration is potentially present, therefore, in every case, only it does not come into operation until external, real frustration has prepared the ground for it. In those exceptional cases in which people are made ill by success, the internal frustration has operated by itself; indeed it has only made its appearance after an external frustration has been replaced by fulfilment of a wish. At first sight there is something strange about this; but on closer consideration we shall reflect that it is not at all unusual for the ego to tolerate a wish as harmless so long as it exists in phantasy alone and seems remote from fulfilment, whereas the ego will defend itself hotly against such a wish as soon as it approaches fulfilment and threatens to become a reality. The distinction between this and familiar situations in neurosis-formation is merely that ordinarily it is internal intensifications of the libidinal cathexis that turn the phantasy, which has hitherto been thought little of and tolerated, into a dreaded opponent; while in these cases of ours the signal for the outbreak of conflict is given by a real external change.

[1916d, 3105]
Analytic work has no difficulty in showing us that it is forces of conscience which forbid the subject to gain the long hoped for advantage from the fortunate change in reality. It is a difficult task, however, to discover the essence and origin of these judging and punishing trends, which so often surprise us by their existence where we do not expect to find them. For the usual reasons I shall not discuss what we know or conjecture on the point in relation to cases of clinical observation, but in relation to figures which great writers have created from the wealth of their knowledge of the mind.

[1916d, 3106]

After this long digression into literature, let us return to clinical experience - but only to establish in a few words the complete agreement between them. Psycho-analytic work teaches that the forces of conscience which induce illness in consequence of success, instead of, as normally, in consequence of frustration, are closely connected with the Oedipus complex, the relation to father and mother - as perhaps, indeed, is our sense of guilt in general.

[1916d, 3117]

Thus the problem of the causation of the neuroses seems to grow more complicated. In fact, psycho-analytic investigation makes us acquainted with a fresh factor, which is not taken into account in our aetiological series and which we can recognize easiest in cases in which what has hitherto been a healthy condition is suddenly disturbed by an onset of neurotic illness. In such people we regularly find indications of a contention between wishful impulses or, as we are in the habit of saying, a psychical conflict. One part of the personality champions certain wishes while another part opposes them and fends them off. Without such a conflict there is no neurosis. There would not seem to be anything peculiar in this. Our mental life is, as you know, perpetually agitated by conflicts which we have to settle. No doubt, therefore, special conditions must be fulfilled if such a conflict is to become pathogenic. We must ask what these conditions are, between what mental powers these pathogenic conflicts are played out, and what the relation is between the conflict and the other causative factors.

[1916-1917, 3411]

Even at that time I could not fail to notice that the causation of the illness did not always point to sexual life. One person, it was true, fell ill directly from a sexual noxa; but another did so because he had lost his fortune or had been through an exhausting organic illness. The explanation of these varieties came later, when we gained an insight into the suspected interrelations between the ego and the libido, and the explanation became the more satisfactory the deeper that insight extended. A person only falls ill of a neurosis if his ego has lost the capacity to allocate his libido in some way. The stronger is his ego, the easier will it be for it to carry out that task. Any weakening of his ego from whatever cause must have the same effect as an excessive increase in the claims of the libido and will thus make it possible for him to fall ill of a neurosis. There are other and more intimate relations between the ego and the libido; but these have not yet come within our scope, so I will not bring them up as part of my present explanation. What remains essential and makes things clear to us is that, in every case and no matter how the illness is set going, the symptoms of the neurosis are sustained by the libido and are consequently evidence that it is being employed abnormally.

[1916-1917, 3438]
The preceding discussion may perhaps have placed the sexuality of psychoneurotics in a false light. It may have given the impression that, owing to their disposition, psychoneurotics approximate closely to perverts in their sexual behaviour and are proportionately remote from normal people. It may indeed very well be that the constitutional disposition of these patients (apart from their exaggerated degree of sexual repression and the excessive intensity of their sexual instinct) includes an unusual tendency to perversion, using that word in its widest sense. Nevertheless, investigation of comparatively slight cases shows that this last assumption is not absolutely necessary, or at least that in forming a judgement on these pathological developments there is a factor to be considered which weighs in the other direction. Most psychoneurotics only fall ill after the age of puberty as a result of the demands made upon them by normal sexual life. (It is most particularly against the latter that repression is directed.) Or else illnesses of this kind set in later, when the libido fails to obtain satisfaction along normal lines. In both these cases the libido behaves like a stream whose main bed has become blocked. It proceeds to fill up collateral channels which may hitherto have been empty. Thus, in the same way, what appears to be the strong tendency (though, it is true, a negative one) of psychoneurotics to perversion may be collaterally determined, and must, in any case, be collaterally intensified. The fact is that we must put sexual repression as an internal factor alongside such external factors as limitation of freedom, inaccessibility of a normal sexual object, the dangers of the normal sexual act, etc., which bring about perversions in persons who might perhaps otherwise have remained normal.

SECOND PHASE OF INFANTILE MSTURBATION   The masturbation of early infancy seems to disappear after a short time; but it may persist uninterruptedly until puberty, and this would constitute the first great deviation from the course of development laid down for civilized men. At some point of childhood after early infancy, as a rule before the fourth year, the sexual instinct belonging to the genital zone usually revives and persists again for a time until it is once more suppressed, or it may continue without interruption. This second phase of infantile sexual activity may assume a variety of different forms which can only be determined by a precise analysis of individual cases. But all its details leave behind the deepest (unconscious) impressions in the subject's memory, determine the development of his character, if he is to remain healthy, and the symptomatology of his neurosis, if he is to fall ill after puberty.¹ In the latter case we find that this sexual period has been forgotten and that the conscious memories that bear witness to it have been displaced. (I have already mentioned that I am also inclined to relate normal infantile amnesia to this infantile sexual activity.) Psycho-analytic investigation enables us to make what has been forgotten conscious and thus do away with a compulsion that arises from the unconscious psychical material.

¹ [1905d, 1509]
Already a few years back we ventured, with the help of these hypotheses, to approach the problem of choice of neurosis. Our method of work, which aims at discovering normal conditions by studying their disturbances, led us to adopt a very singular and unexpected line of attack. The order in which the main forms of psychoneurosis are usually enumerated - Hysteria, Obsessional Neurosis, Paranoia, Dementia Praecox - corresponds (even though not quite exactly) to the order of the ages at which the onset of these disorders occurs. Hysterical forms of illness can be observed even in earliest childhood; obsessional neurosis usually shows its first symptoms in the second period of childhood (between the ages of six and eight); while the two other psychoneuroses, which I have brought together under the heading of 'paraphrenia', do not appear until after puberty and during adult life. It is these disorders - the last to emerge - which were the first to show themselves accessible to our enquiry into the dispositions that result in the choice of neurosis. The characteristics peculiar to both of them - megalomania, turning away from the world of objects, increased difficulty in transference - have obliged us to conclude that their dispositional fixation is to be looked for in a stage of libidinal development before object-choice has been established - that is in the phase of auto-erotism and of narcissism. Thus these forms of illness, which make their appearance so late, go back to very early inhibitions and fixations.

Another possibility has to be considered. Perhaps regression is the result not of a constitutional factor but of a time-factor. It may be that regression is rendered possible not because the genital organization of the libido is too feeble but because the opposition of the ego begins too early, while the sadistic phase is at its height. I am not prepared to express a definite opinion on this point, but I may say that analytic observation does not speak in favour of such an assumption. It shows rather that, by the time an obsessional neurosis is entered upon, the phallic stage has already been reached. Moreover, the onset of this neurosis belongs to a later time of life than that of hysteria - to the second period of childhood, after the latency period has set in. In a woman patient whose case I was able to study and who was overtaken by this disorder at a very late date, it became clear that the determining cause of her regression and of the emergence of her obsessional neurosis was a real occurrence through which her genital life, which had up till then been intact, lost all its value.¹

[1913i, 2624]

[1926d, 4272]
In nervous pathology there is similar heredity and what is known as dissimilar heredity. No objection can be made to the former; it is in fact a very remarkable thing that in the disorders which depend on similar heredity (Thomson's disease, Friedreich's disease, the myopathies, Huntington's chorea, etc.) we never come across a trace of any other accessory aetiological influence. But dissimilar heredity, which is much more important than the other, leaves gaps which would have to be filled before a satisfactory solution of aetiological problems could be reached. Dissimilar heredity consists in the fact that the members of the same family are found to be affected by the most various nervous disorders, functional and organic, without its being possible to discover any law determining the replacement of one illness by another or the order of their succession through the generations. Alongside of the sick members of these families there are others who remain healthy; and the theory of dissimilar heredity does not tell us why one person tolerates the same hereditary load without succumbing to it or why another person, who is sick, should choose this particular nervous affection from among all the illnesses which make up the great family of nervous diseases instead of choosing another one - hysteria instead of epilepsy or insanity, and so on. Since there is no such thing as chance in neurotic pathogenesis any more than anywhere else, it must be allowed that it is not heredity that presides over the choice of the particular nervous disorder which is to develop in the predisposed member of a family, but that there are grounds for suspecting the existence of other aetiological influences, of a less incomprehensible nature, which would then deserve to be called the specific aetiology of such and such a nervous affection. Without the existence of this special aetiological factor, heredity could have done nothing; it would have lent itself to the production of another nervous disorder if the specific aetiology in question had been replaced by some other influence.

The importance of the active element in sexual life as a cause of obsessions, and of sexual passivity for the pathogenesis of hysteria, even seems to unveil the reason for the more intimate connection of hysteria with the female sex and the preference of men for obsessional neurosis. One sometimes comes across a pair of neurotic patients who were a pair of little lovers in their earliest childhood - the man suffering from obsessions and the woman from hysteria. If they are a brother and sister, one might mistake for a result of nervous heredity what is in fact the consequence of precocious sexual experiences.

As regards nervous heredity, I am far from being able to estimate correctly its influence in the aetiology of the psychoneuroses. I admit that its presence is indispensable for severe cases; I doubt if it is necessary for slight ones; but I am convinced that nervous heredity by itself is unable to produce psychoneuroses if their specific aetiology, precocious sexual excitation, is missing. I even believe that the decision as to which of the neuroses, hysteria or obsessions, will develop in a given case, is not decided by heredity but a special characteristic of the sexual event in earliest childhood.

I have found this specific determinant of hysteria - sexual passivity during the pre-sexual period - in every case of hysteria (including two male cases) which I have analysed. How greatly the claims of hereditary disposition are diminished by the establishment in this way of accidental aetiological factors as a determinant needs no more than a mention. Furthermore, a path is laid open to an understanding of why hysteria is far and away more frequent in members of the female sex; for even in childhood they are more liable to provoke sexual attacks.
It is not at all rare for both of the two children to fall ill later on of a defence neurosis - the brother with obsessions and the sister with hysteria. This naturally gives the appearance of a familial neurotic disposition. Occasionally, however, this pseudo-heredity is resolved in a surprising fashion. In one of my cases a brother, a sister, and a somewhat older male cousin were all of them ill. From the analysis which I carried out on the brother, I learnt that he was suffering from self-reproaches for being the cause of his sister's illness. He himself had been seduced by his cousin, and the latter, it was known in the family, had been the victim of his nursemaid.
[1896b, 386]

Sexual experiences of early childhood have the same significance in the aetiology of obsessional neurosis as they have in that of hysteria. Here, however, it is no longer a question of sexual passivity, but of acts of aggression carried out with pleasure and of pleasurable participation in sexual acts - that is to say, of sexual activity. This difference in the aetiological circumstances is bound up with the fact that obsessional neurosis shows a visible preference for the male sex.
[1896b, 388]

I am not yet in a position, Gentlemen, to give a reliable answer to this question. The number of cases I have analysed is not large enough nor have the determining factors in them been sufficiently various. So far, I have observed that obsessions can be regularly shown by analysis to be disguised and transformed self-reproaches about acts of sexual aggression in childhood, and are therefore more often met with in men than in women, and that men develop obsessions more often than hysteria. From this I might conclude that the character of the infantile scenes - whether they were experienced with pleasure or only passively - has a determining influence on the choice of the later neurosis; but I do not want to underestimate the significance of the age at which these childhood actions occur, and other factors as well. Only a discussion of further analyses can throw light on these points. But when it becomes clear which are the decisive factors in the choice between the possible forms of the neuro-psychoses of defence, the question of what the mechanism is in virtue of which that particular form takes shape will once again be a purely psychological problem.
[1896c, 433]

After I had made this correction, 'infantile sexual traumas' were in a sense replaced by the 'infantilism of sexuality'. A second modification of the original theory lay not far off. Along with the supposed frequency of seduction in childhood, I ceased also to lay exaggerated stress on the accidental influencing of sexuality on to which I had sought to thrust the main responsibility for the causation of the illness, though I had not on that account denied the constitutional and hereditary factors. I had even hoped to solve the problem of choice of neurosis (the decision to which form of psychoneurosis the patient is to fall a victim) by reference to the details of the sexual experiences of childhood. I believed at that time - though with reservations - that a passive attitude in these scenes produced a predisposition to hysteria and, on the other hand, an active one a predisposition to obsessional neurosis. Later on I was obliged to abandon this view entirely, even though some facts demand that in some way or other the supposed correlation between passivity and hysteria and between activity and obsessional neurosis shall be maintained. Accidental influences derived from experience having thus receded into the background, the factors of constitution and heredity necessarily gained the upper hand once more; but there was this difference between my views and those prevailing in other quarters, that on my theory the 'sexual constitution' took the place of a 'general neuropathic disposition'. In my recently published Three Essays on the Theory of Sexuality (1905d ) I have tried to give a picture of the variegated nature of this sexual constitution as well as of the composite character of the sexual instinct in general and its derivation from contributory sources from different parts of the organism.
[1906a, 1579]
If we consider a number of analyses of obsessional neurotics we shall find it impossible to escape the impression that a relation between love and hatred such as we have found in our present patient is among the most frequent, the most marked, and probably, therefore, the most important characteristics of obsessional neurosis. But however tempting it may be to bring the problem of the 'choice of neurosis' into connection with instinctual life, there are reasons enough for avoiding such a course. For we must remember that in every neurosis we come upon the same suppressed instincts behind the symptoms. After all, hatred, kept suppressed in the unconscious by love, plays a great part in the pathogenesis of hysteria and paranoia. We know too little of the nature of love to be able to arrive at any definite conclusion here; and, in particular, the relation between the negative factor¹ in love and the sadistic components of the libido remains completely obscure. What follows is therefore to be regarded as no more than a provisional explanation. We may suppose, then, that in the cases of unconscious hatred with which we are concerned the sadistic components of love have, from constitutional causes, been exceptionally strongly developed, and have consequently undergone a premature and all too thorough suppression, and that the neurotic phenomena we have observed arise on the one hand from conscious feelings of affection which have become exaggerated as a reaction, and on the other hand from sadism persisting in the unconscious in the form of hatred.

[1909d, 2187]

It is easy to see that this discussion is beginning to trench upon the problem of 'choice of neurosis', which, however, cannot be taken in hand until preliminary work of another kind has been accomplished. Let us bear in mind for the present that we have already dealt with fixation, and that we have postponed the subject of symptom-formation; and let us restrict ourselves to the question of whether the analysis of Schreber's case throws any light upon the mechanism of repression proper which predominates in paranoia.

[1911c, 2436]

(7) While the ego goes through its transformation from a pleasure-ego into a reality-ego, the sexual instincts undergo the changes that lead them from their original auto-erotism through various intermediate phases to object-love in the service of procreation. If we are right in thinking that each step in these two courses of development may become the site of a disposition to later neurotic illness, it is plausible to suppose that the form taken by the subsequent illness (the choice of neurosis) will depend on the particular phase of the development of the ego and of the libido in which the dispositional inhibition of development has occurred. Thus unexpected significance attaches to the chronological features of the two developments (which have not yet been studied), and to possible variations in their synchronization.

[1911b, 2556]

The problem of why and how a person may fall ill of a neurosis is certainly among those to which psycho-analysis should offer a solution. But it will probably be necessary to find a solution first to another and narrower problem - namely, why it is that this or that person must fall ill of a particular neurosis and of none other. This is the problem of 'choice of neurosis'.

[1913i, 2623]
Already a few years back we ventured, with the help of these hypotheses, to approach the problem of choice of neurosis. Our method of work, which aims at discovering normal conditions by studying their disturbances, led us to adopt a very singular and unexpected line of attack. The order in which the main forms of psychoneurosis are usually enumerated - Hysteria, Obsessional Neurosis, Paranoia, Dementia Praecox - corresponds (even though not quite exactly) to the order of the ages at which the onset of these disorders occurs. Hysterical forms of illness can be observed even in earliest childhood; obsessional neurosis usually shows its first symptoms in the second period of childhood (between the ages of six and eight); while the two other psychoneuroses, which I have brought together under the heading of 'paraphrenia', do not appear until after puberty and during adult life. It is these disorders - the last to emerge - which were the first to show themselves accessible to our enquiry into the dispositions that result in the choice of neurosis. The characteristics peculiar to both of them - megalomania, turning away from the world of objects, increased difficulty in transference - have obliged us to conclude that their dispositional fixation is to be looked for in a stage of libidinal development before object-choice has been established - that is in the phase of auto-erotism and of narcissism. Thus these forms of illness, which make their appearance so late, go back to very early inhibitions and fixations.

This would accordingly lead us to suppose that the disposition to hysteria and obsessional neurosis, the two transference neuroses proper, which produce their symptoms at an early age, lies in later phases of libidinal development. But at what point in them should we find a developmental inhibition? and, above all, what would be the difference in phases that would determine a disposition to obsessional neurosis as contrasted with hysteria? For a long time nothing was to be learned about this; and my earlier attempts at discovering these two dispositions - the notion, for instance, that hysteria might be determined by passivity and obsessional neurosis by activity in infantile experience - had soon to be abandoned as incorrect.

When in the course of the analysis this came about, I was forced to see that the situation was quite different from what I had imagined. The obsessional neurosis was not a further reaction to the same trauma which had first provoked the anxiety hysteria; it was a reaction to a second experience, which had completely wiped out the first. (Here, then, we have an exception - though, it is true, a not indubitable one - to our proposition affirming that choice of neurosis is independent of experience.)

On the other hand, it is not hard to show that another regression to an earlier level occurs in hysteria too. The sexuality of female children, is, as we know, dominated and directed by a masculine organ (the clitoris) and often behaves like the sexuality of boys. This masculine sexuality has to be got rid of by a last wave of development at puberty, and the vagina, an organ derived from the cloaca, has to be raised into the dominant erotogenic zone. Now, it is very common in hysterical neurosis for this repressed masculine sexuality to be re-activated and then for the defensive struggle on the part of the ego-syntonic instincts to be directed against it. But it seems to me too early to enter here into a discussion of the problems of the disposition to hysteria.
With this as a starting-point we go on to make our first important discovery. We learn that, when we try to understand neurotic disorders, by far the greater significance attaches to the sexual instincts; that in fact neuroses are the specific disorders, so to speak, of the sexual function; that in general whether or not a person develops a neurosis depends on the quantity of his libido, and on the possibility of satisfying it and of discharging it through satisfaction; that the form taken by the disease is determined by the way in which the individual passes through the course of development of his sexual function, or, as we put it, by the fixations his libido has undergone in the course of its development; and, further, that by a special, not very simple technique for influencing the mind we are able to throw light on the nature of some groups of neuroses and at the same time to do away with them. Our therapeutic efforts have their greatest success with a certain class of neuroses which proceed from a conflict between the ego-instincts and the sexual instincts. For in human beings it may happen that the demands of the sexual instincts, whose reach of course extends far beyond the individual, seem to the ego to constitute a danger which threatens its self-preservation or its self-esteem. The ego then assumes the defensive, denies the sexual instincts the satisfaction they desire and forces them into those by-paths of substitutive satisfaction which become manifest as nervous symptoms.

The sexual function, as I found, is in existence from the very beginning of the individual's life, though at first it is attached to the other vital functions and does not become independent of them until later; it has to pass through a long and complicated process of development before it becomes what we are familiar with as the normal sexual life of the adult. It begins by manifesting itself in the activity of a whole number of component instincts. These are dependent upon erotogenic zones in the body; some of them make their appearance in pairs of opposite impulses (such as sadism and masochism or the impulses to look and to be looked at); they operate independently of one another in a search for pleasure, and they find their object for the most part in the subject's own body. Thus at first the sexual function is non-centralized and predominantly auto-erotic. Later, syntheses begin to appear in it; a first stage of organization is reached under the dominance of the oral components, an anal-sadistic stage follows, and it is only after the third stage has at last been reached that the primacy of the genitals is established and that the sexual function begins to serve the ends of reproduction. In the course of this process of development a number of elements of the various component instincts turn out to be unserviceable for this last end and are therefore left on one side or turned to other uses, while others are diverted from their aims and carried over into the genital organization. I gave the name of libido to the energy of the sexual instincts and to that form of energy alone. I was next driven to suppose that the libido does not always pass through its prescribed course of development smoothly. As a result either of the excessive strength of certain of the components or of experiences involving premature satisfaction, fixations of the libido may occur at various points in the course of its development. If subsequently a repression takes place, the libido flows back to these points (a process described as regression), and it is from them that the energy breaks through in the form of a symptom. Later on it further became clear that the localization of the point of fixation is what determines the choice of neurosis, that is, the form in which the subsequent illness makes its appearance.

It seems easy to infer that when people of the erotic type fall ill they will develop hysteria, just as those of the obsessional type will develop obsessional neurosis; but these inferences, too, share the uncertainty which I have just stressed. People of the narcissistic type who are exposed to a frustration from the external world, though otherwise independent, are peculiarly disposed to psychosis; and they also present essential preconditions for criminality.
If we prefer to suppose, nevertheless, that a particularly strongly developed tendency to perversion is among the characteristics of psychoneurotic constitutions, we have before us the prospect of being able to distinguish a number of such constitutions according to the innate preponderance of one or the other of the erotogenic zones or of one or the other of the component instincts. The question whether a special relation holds between the perverse disposition and the particular form of illness adopted, has, like so much else in this field, not yet been investigated.

[1905d, 1494]
This, to tell the truth, is no new, unheard-of proposition. Sexual disorders have always been admitted among the causes of nervous illness, but they have been subordinated to heredity - and co-ordinated with the other *agents provocateurs*; their aetiological influence has been restricted to a limited number of observed cases. Physicians had even fallen into the habit of not investigating them unless the patient brought them up himself. What gives its distinctive character to my line of approach is that I elevate these sexual influences to the rank of specific causes, that I recognize their action in every case of neurosis, and finally that I trace a regular parallelism, a proof of a special aetiological relation between the nature of the sexual influence and the pathological species of the neurosis.

[1896a, 373]

Exhaustive researches during the last few years have led me to recognize that the most immediate and, for practical purposes, the most significant causes of every case of neurotic illness are to be found in factors arising from sexual life. This theory is not entirely new. A certain amount of importance has been allowed to sexual factors in the aetiology of the neuroses from time immemorial and by every writer on the subject. In certain marginal regions of medicine a cure for 'sexual complaints' and for 'nervous weakness' has always been promised in the same breath. When once the validity of the theory ceases to be denied, therefore, it will not be hard to dispute its originality.

[1897b, 455]

Nor is it true that patients put insuperable obstacles in the way of an investigation into their sexual life. After some slight hesitation, adults usually adjust themselves to the situation by saying: 'After all, I'm at the doctor's; I can say anything to him.' A great many women who find it difficult enough to go through life concealing their sexual feelings, are relieved to find that with the doctor no other consideration outweighs that of their recovery, and they are grateful to him that for once they are allowed to behave quite humanly about sexual things. A dim knowledge of the overwhelming importance of sexual factors in the production of neuroses (a knowledge which I am trying to capture afresh for science) seems never to have been lost in the consciousness of laymen. How often do we witness scenes like this: A married couple, one of whom is suffering from a neurosis, comes to us for consultation. After we have made a great many introductory remarks and apologies to the effect that no conventional barriers should exist between them and the doctor who wants to be of use in such cases, and so on, we tell them that we suspect that the cause of the illness lies in the unnatural and detrimental form of sexual intercourse which they must have chosen since the wife's last confinement. We tell them that doctors do not as a rule concern themselves with such matters, but that that is reprehensible of them, even though the patients do not want to be told about things like that, etc. Then upon one of the couple nudges the other and says: 'You see! I told you all along it would make me ill.' And the other answers: 'Well, I know, I thought so too; but what is one to do?'

[1897b, 457]
When I published the paper I have mentioned, I was under no illusion as to its power to carry conviction. In the first place, I was aware that the account I had given was only a brief and incomplete one and even in places hard to understand - just enough, perhaps, to arouse the reader's expectations. Then, too, I had scarcely brought forward any examples and given no figures. Nor had I touched on the technique of collecting anamneses or done anything to prevent misunderstandings. I had not given consideration to any but the most obvious objections; and, as regards the theory itself, I had laid stress only on its main proposition and not on its qualifications. Accordingly, each reader was in fact at liberty to form his own opinion as to the binding force of the whole hypothesis. I could, moreover, reckon upon another difficulty in the way of its acceptance. I know very well that in putting forward my 'sexual aetiology' of the neuroses, I have brought up nothing new, and that undercurrents in medical literature taking these facts into account have never been absent. I know, too, that official academic medicine has in fact also been aware of them. But it has acted as if it knew nothing about the matter. It has made no use of its knowledge and has drawn no inferences from it. Such behaviour must have a deep-seated cause, originating perhaps in a kind of reluctance to look squarely at sexual matters in a reaction against older attempts at an explanation, which are regarded as obsolete. At all events, one had to be prepared to meet with resistance in venturing upon an attempt to make something credible to other people which they could without any trouble have discovered for themselves.

This, to tell the truth, is no new, unheard-of proposition. Sexual disorders have always been admitted among the causes of nervous illness, but they have been subordinated to heredity - and co-ordinated with the other agents provocateurs; their aetiological influence has been restricted to a limited number of observed cases. Physicians had even fallen into the habit of not investigating them unless the patient brought them up himself. What gives its distinctive character to my line of approach is that I elevate these sexual influences to the rank of specific causes, that I recognize their action in every case of neurosis, and finally that I trace a regular parallelism, a proof of a special aetiological relation between the nature of the sexual influence and the pathological species of the neurosis.
Originally my theory related only to the clinical pictures comprised under the term 'neurasthenia', among which I was particularly struck by two, which occasionally appear as pure types and which I described as 'neurasthenia proper' and 'anxiety neurosis'. It had, to be sure, always been a matter of common knowledge that sexual factors may play a part in the causation of these forms of illness; but those factors were not regarded as invariably operative, nor was there any idea of giving them precedence over other aetiological influences. I was surprised to begin with at the frequency of gross disturbances in the vita sexualis of nervous patients; the more I set about looking for such disturbances - bearing in mind the fact that everyone hides the truth in matters of sex - and the more skilful I became at pursuing my enquiries in the face of a preliminary denial, the more regularly was I able to discover pathogenic factors in sexual life, till little seemed to stand in the way of my assuming their universal occurrence. It was necessary, however, to presuppose from the start that sexual irregularities occurred with similar frequency in our ordinary society under the pressure of social conditions; and a doubt might remain as to the degree of deviation from normal sexual functioning which should be regarded as pathogenic. I was therefore obliged to attach less importance to the invariable evidence of sexual noxae than to a second discovery which seemed to me less ambiguous. It emerged that the form taken by the illness - neurasthenia or anxiety neurosis - bore a constant relation to the nature of the sexual noxa involved. In typical cases of neurasthenia a history of regular masturbation or persistent emissions was found; in anxiety neurosis factors appeared such as coitus interruptus, 'unconsummated excitation', and other conditions - in all of which there seemed to be the common element of an insufficient discharge of the libido that had been produced. It was only after this discovery, which was easy to make and could be confirmed as often as one liked, that I had the courage to claim a preferential position for sexual influences in the aetiology of the neuroses. Furthermore, in the mixed forms of neurasthenia and anxiety neurosis which are so common it was possible to trace a combination of the aetiologies which I had assumed for the two pure forms. Moreover, this twofold form assumed by the neurosis seemed to tally with the polar (i.e. the masculine and feminine) character of sexuality.

[1906a, 1575]
There is no longer anything contradictory to us in the notion that a psychical process which develops anxiety can nevertheless be the fulfilment of a wish. We know that it can be explained by the fact that the wish belongs to one system, the Ucs., while it has been repudiated and suppressed by the other system, the Pcs.¹ Even where psychical health is perfect, the subjugation of the Ucs. by the Pcs. is not complete; the measure of suppression indicates the degree of our psychical normality. Neurotic symptoms show that the two systems are in conflict with each other; they are the products of a compromise which brings the conflict to an end for the time being. On the one hand, they allow the Ucs. an outlet for the discharge of its excitation, and provide it with a kind of sally-port, while, on the other hand they make it possible for the Pcs. to control the Ucs. to some extent. It is instructive to consider, for instance, the significance of a hysterical phobia or an agoraphobia. Let us suppose that a neurotic patient is unable to cross the street alone - a condition which we rightly regard as a 'symptom.' If we remove this symptom by compelling him to carry out the act of which he believes himself incapable, the consequence will be an attack of anxiety; and indeed the occurrence of an anxiety-attack in the street is often the precipitating cause of the onset of an agoraphobia. We see, therefore, that the symptom has been constructed in order to avoid an outbreak of anxiety; the phobia is erected like a frontier fortification against the anxiety.

[1900a, 1009]

We shall not be able to form a correct picture of the strange psychical work which brings about the occurrence of both parapraxes and dream images until we have learnt that psychoneurotic symptoms, and especially the psychical formations of hysteria and obsessional neurosis, repeat in their mechanism all the essential features of this mode of working. This is therefore the starting-point for the continuation of our researches. For us, however, there is yet another special interest in considering parapraxes, chance actions and symptomatic actions in the light of this last analogy. If we compare them to the products of the psychoneuroses, to neurotic symptoms, two frequently repeated statements - namely, that the borderline between the normal and the abnormal in nervous matters is a fluid one, and that we are all a little neurotic - acquire meaning and support. Without any medical experience we can construct various types of nervous illness of this kind which are merely hinted at - formes frustres¹ - of the neuroses: cases in which the symptoms are few, or occur rarely or not severely - in other words, cases whose comparative mildness is located in the number, intensity and duration of their pathological manifestations. But we might perhaps never arrive by conjecture at precisely the type that appears most frequently to form the transition between health and illness. For the type we are considering, whose pathological manifestations are parapraxes and symptomatic acts, is characterized by the fact that the symptoms are located in the least important psychical functions, while everything that can lay claim to higher psychical value remains free from disturbance. Where the symptoms are distributed in the reverse way - that is, where they make their appearance in the most important individual and social functions and are able to disturb nutrition, sexual intercourse, professional work and social life - this is the mark of severe cases of neurosis and is more characteristic of them than, for example, are the variety and vigour of their pathological manifestations.

[1901b, 1347]
From the third year of life a child's sexual life shows much agreement with an adult's. It differs from the latter, as we already know, in lacking a firm organization under the primacy of the genitals, in its inevitable traits of perversion and also, of course, in the far lesser intensity of the whole trend. But from the point of view of theory the most interesting phases of sexual, or, as we will say, of libidinal, development lie earlier than this point of time. This course of development takes place so rapidly that we should probably never have succeeded in getting a firm hold of its fleeting pictures by direct observation. It was only with the help of the psycho-analytic investigation of the neuroses that it became possible to discern the still earlier phases of the development of the libido. These are nothing but constructions, to be sure, but, if you carry out psycho-analyses in practice, you will find that they are necessary and useful constructions. You will soon learn how it comes about that pathology can here put us in possession of conditions which we should inevitably overlook in a normal subject.

[1916-1917, 3394]

The Interpretation of Parapraxes and Haphazard Acts. - It was a triumph for the interpretative art of psycho-analysis when it succeeded in demonstrating that certain common mental acts of normal people, for which no one had hitherto attempted to put forward a psychological explanation, were to be regarded in the same light as the symptoms of neurotics: that is to say, they had a meaning, which was unknown to the subject but which could easily be discovered by analytic means. The phenomena in question were such events as the temporary forgetting of familiar words and names, forgetting to carry out prescribed tasks, everyday slips of the tongue and of the pen, misreadings, losses and mislayings of objects, certain errors, instances of apparently accidental self-injury, and finally habitual movements carried out seemingly without intention or in play, tunes hummed ‘thoughtlessly’, and so on. All of these were shorn of their physiological explanation, if any such had ever been attempted, were shown to be strictly determined and were revealed as an expression of the subject’s suppressed intentions or as a result of a clash between two intentions one of which was permanently or temporarily unconscious. The importance of this contribution to psychology was of many kinds. The range of mental determinism was extended by it in an unforeseen manner; the supposed gulf between normal and pathological mental events was narrowed; in many cases a useful insight was afforded into the play of mental forces that must be suspected to lie behind the phenomena. Finally, a class of material was brought to light which is calculated better than any other to stimulate a belief in the existence of unconscious mental acts even in people to whom the hypothesis of something at once mental and unconscious seems strange and even absurd. The study of one’s own parapraxes and haphazard acts, for which most people have ample opportunities, is even to-day the best preparation for an approach to psycho-analysis. In analytic treatment, the interpretation of parapraxes retains a place as a means of uncovering the unconscious, alongside the immeasurably more important interpretation of associations.

[1923a, 3917]

It has been worth while to enter in some detail into the explanation of dreams, since analytic work has shown that the dynamics of the formation of dreams are the same as those of the formation of symptoms. In both cases we find a struggle between two trends, of which one is unconscious and ordinarily repressed and strives towards satisfaction - that is, wish-fulfilment - while the other, belonging probably to the conscious ego, is disapproving and repressive. The outcome of this conflict is a compromise-formation (the dream or the symptom) in which both trends have found an incomplete expression. The theoretical importance of this conformity between dreams and symptoms is illuminating. Since dreams are not pathological phenomena, the fact shows that the mental mechanisms which produce the symptoms of illness are equally present in normal mental life, that the same uniform law embraces both the normal and the abnormal and that the findings of research into neurotics or psychotics cannot be without significance for our understanding of the healthy mind.

[1923a, 3919]
In order to remain faithful to our customary phraseology, we shall have to speak, not of transposing the psychical accent, but of displacing large amounts of cathexis. The question then is whether we are entitled to picture extensive displacements like this from one agency of the mental apparatus to another. It looks like a new hypothesis constructed ad hoc. Yet we may remind ourselves that we have repeatedly (even though not sufficiently often) taken a factor of this kind into account in our attempts at a metapsychological picture of mental events. Thus, for instance, we supposed that the difference between an ordinary erotic object-cathexis and the state of being in love is that in the latter incomparably more cathexis passes over to the object and that the ego empties itself as it were in favour of the object. In studying some cases of paranoia I was able to establish the fact that ideas of persecution are formed early and exist for a long time without any perceptible effect, until, as the result of some particular precipitating event, they receive sufficient amounts of cathexis to cause them to become dominant. The cure, too, of such paranoic attacks would lie not so much in a resolution and correction of the delusional ideas as in a withdrawal from them of the cathexis which has been lent to them. The alternations between melancholia and mania, between a cruel suppression of the ego by the super-ego and a liberation of the ego after that pressure, suggests a shift of cathexis of this kind; such a shift, moreover, would have to be brought in to explain a whole number of phenomena belonging to normal mental life. If this has been done hitherto only to a very limited extent, that is on account of our usual caution - something which deserves only praise. The region in which we feel secure is that of the pathology of mental life; it is here that we make our observations and acquire our convictions. For the present we venture to form a judgement on the normal mind only in so far as we can discern what is normal in the isolations and distortions of the pathological material. When once we have overcome this hesitancy we shall recognize what a large contribution is made to the understanding of mental processes by the static conditions as well as by the dynamic changes in the quantity of energic cathexis.

The normal processes in the formation of conscience must be similar to the abnormal ones described here. We have not yet succeeded in fixing the boundary line between them. It will be observed that here the largest share in the outcome is ascribed to the passive component of repressed femininity. In addition, it must be of importance as an accidental factor whether the father, who is feared in any case, is also especially violent in reality. This was true in Dostoevsky's case, and we can trace back the fact of his extraordinary sense of guilt and of his masochistic conduct of life to a specially strong feminine component. Thus the formula for Dostoevsky is as follows: a person with a specially strong innate bisexual disposition, who can defend himself with special intensity against dependence on a specially severe father. This characteristic of bisexuality comes as an addition to the components of his nature that we have already recognized. His early symptoms of death-like attacks can thus be understood as a father-identification on the part of his ego, which is permitted by his super-ego as a punishment. 'You wanted to kill your father in order to be your father yourself. Now you are your father, but a dead father' - the regular mechanism of hysterical symptoms. And further: 'Now your father is killing you.' For the ego the death symptom is a satisfaction in phantasy of the masculine wish and at the same time a masochistic satisfaction; for the super-ego it is a punitive satisfaction - that is, a sadistic satisfaction. Both of them, the ego and the super-ego, carry on the role of father.

[1927d, 4544]

[1928b, 4561]
My life's work has been directed to a single aim. I have observed the more subtle disturbances of mental function in healthy and sick people and have sought to infer - or, if you prefer it, to guess - from signs of this kind how the apparatus which serves these functions is constructed and what concurrent and mutually opposing forces are at work in it. What we - I, my friends and collaborators - have managed to learn in following this path has seemed to us of importance for the construction of a mental science which makes it possible to understand both normal and pathological processes as parts of the same natural course of events.

[1930, 4578]

It is doubtful whether we are as yet in a position to discover types to fulfil this requirement - as we shall no doubt be able to do later, on some basis of which we are still ignorant. If we confine our effort to setting up purely psychological types, the libidinal situation will have a first claim to serve as a basis for our classification. It may fairly be demanded that this classification should not merely be deduced from our knowledge or our hypotheses about the libido, but that it should be easily confirmed in actual experience and that it should contribute to the clarification of the mass of our observations and help us to grasp them. It may at once be admitted that these libidinal types need not be the only possible ones even in the psychical field, and that, if we proceeded from other qualities, we might perhaps establish a whole set of other psychological types. But it must be required of all such types that they shall not coincide with clinical pictures. On the contrary, they must comprehend all the variations which according to our practical judgement fall within the limits of the normal. In their extreme developments, however, they may well approximate to clinical pictures and in that way help to bridge the gulf that is supposed to lie between the normal and the pathological.

[1931a, 4585]

It is a familiar fact that the aetiological preconditions of neurosis are not yet known with certainty. The precipitating causes of it are frustrations and internal conflicts: conflicts between the three major psychical agencies, conflicts arising within the libidinal economy in consequence of our bisexual disposition and conflicts between the erotic and the aggressive instinctual components. It is the endeavour of the psychology of the neuroses to discover what makes these processes, which belong to the normal course of mental life, become pathogenic.

[1931a, 4587]

The situation in which we find ourselves at the beginning of our enquiry may be expected itself to point the way for us. We wish to make the ego the matter of our enquiry, our very own ego. But is that possible? After all, the ego is in its very essence a subject; how can it be made into an object? Well, there is no doubt that it can be. The ego can take itself as an object, can treat itself like other objects, can observe itself, criticize itself, and do Heaven knows what with itself. In this, one part of the ego is setting itself over against the rest. So the ego can be split; it splits itself during a number of its functions - temporally at least. Its parts can come together again afterwards. That is not exactly a novelty, though it may perhaps be putting an unusual emphasis on what is generally known. On the other hand, we are familiar with the notion that pathology, by making things larger and coarser, can draw our attention to normal conditions which would otherwise have escaped us. Where it points to a breach or a rent, there may normally be an articulation present. If we throw a crystal to the floor, it breaks; but not into haphazard pieces. It comes apart along its lines of cleavage into fragments whose boundaries, though they were invisible, were predetermined by the crystal's structure. Mental patients are split and broken structures of this same kind. Even we cannot withhold from them something of the reverential awe which peoples of the past felt for the insane. They have turned away from external reality, but for that very reason they know more about internal, psychical reality and can reveal a number of things to us that would otherwise be inaccessible to us.

[1933a, 4667]
One of the first applications of psycho-analysis was to teach us to understand the opposition offered to us by our contemporaries because we practised psycho-analysis. Other applications, of an objective nature, may claim a more general interest. Our first purpose, of course, was to understand the disorders of the human mind, because a remarkable experience had shown that here understanding and cure almost coincide, that a traversable road leads from the one to the other. And for a long time it was our only purpose. Then, however, we perceived the close relations, the internal identity indeed, between pathological processes and what are known as normal ones. Psycho-analysis became a depth-psychology; and, since nothing that men make or do is understandable without the co-operation of psychology, the applications of psycho-analysis to numerous fields of knowledge, in particular to those of the mental sciences, came about of their own accord, pushed their way to the front and called for ventilation. These tasks unluckily came up against obstacles which, rooted as they were in the circumstances, have not yet been overcome even to-day. An application of this kind presupposes specialized knowledge which an analyst does not possess, while those who possess it, the specialists, know nothing of analysis and perhaps want to know nothing. The result has been that analysts, as amateurs with an equipment of greater or less adequacy, often hastily scraped together, have made excursions into such fields of knowledge as mythology, the history of civilization, ethnology, the science of religion and so on. They were no better treated by the experts resident in those fields than are trespassers in general: their methods and their findings, in so far as they attracted attention, were in the first instance rejected. But these conditions are constantly improving, and in every region there is a growing number of people who study psycho-analysis in order to make use of it in their special subject, and in order, as colonists, to replace the pioneers. Here we may expect a rich harvest of new discoveries. Applications of analysis are always confirmations of it as well. There, too, where scientific work is further removed from practical activity, the inevitable differences of opinion will no doubt take a less embittered form.

[1933a, 4745]

There are a quantity of similar processes among those which the analytic investigation of mental life has taught us to know. Some of them are described as pathological, others are counted among the diversity of normal events. But that matters little, since the boundaries between the two are not sharply drawn, their mechanisms are to a large extent the same, and it is of far more importance whether the alterations in question take place in the ego itself or whether they confront it as alien to it - in which case they are known as symptoms.

[1939a, 4943]

We shall very soon feel, however, that this explanation is unsatisfactory: it is too general, it explains too much. The aetiology put forward applies to every case of mental suffering, misery and disablement, but not every such state can be termed neurotic. The neuroses have specific characteristics, they are miseries of a particular kind. So we must after all expect to find particular causes for them. Or we may adopt the supposition that, among the tasks with which mental life has to deal, there are a few on which it can especially easily come to grief; so that the peculiarity of the phenomena of neurosis, which are often so very remarkable, would follow from this without our needing to withdraw our earlier assertions. If it remains true that the neuroses do not differ in any essential respect from the normal, their study promises to yield us valuable contributions to our knowledge of the normal. It may be that we shall thus discover the 'weak points' in a normal organization.

[1940a [1938], 4992]
But let us for the moment keep to psychology. We have seen that it is not scientifically feasible to draw a line of demarcation between what is psychically normal and abnormal; so that that distinction, in spite of its practical importance, possesses only a conventional value. We have thus established a right to arrive at an understanding of the normal life of the mind from a study of its disorders - which would not be admissible if these pathological states, neuroses and psychoses, had specific causes operating in the manner of foreign bodies.

[1940a [1938], 5002]
By analysing dreams we can take a step forward in our understanding of the composition of that most marvellous and most mysterious of all instruments. Only a small step, no doubt; but a beginning. And this beginning will enable us to proceed further with its analysis, on the basis of other structures which must be termed pathological. For illnesses - those, at least, which are rightly named 'functional' - do not presuppose the disintegration of the apparatus or the production of fresh splits in its interior. They are to be explained on a dynamic basis - by the strengthening and weakening of the various components in the interplay of forces, so many of whose effects are hidden from view while functions are normal. I hope to be able to show elsewhere how the compounding of the apparatus out of two agencies makes it possible for the normal mind too to function with greater delicacy than would be possible with only one of them.²

[1900a, 1035]

It is not until we have studied pathological phenomena that we can get an insight into normal ones. Many things which had long been known of the influence of the mind on the body were only now brought into their true perspective. The commonest, everyday example of the mind's action on the body, and one that is to be observed in everyone, is offered by what is known as the 'expression of the emotions'. A man's states of mind are manifested, almost without exception, in the tensions and relaxations of his facial muscles, in the adaptations of his eyes, in the amount of blood in the vessels of his skin, in the modifications in his vocal apparatus and in the movements of his limbs and in particular of his hands. These concomitant physical changes are for the most part of no advantage to the person concerned; on the contrary, they often stand in his way if he wishes to conceal his mental processes from other people. But they serve these other people as trustworthy indications from which his mental processes can be inferred and in which more confidence can be placed than in any simultaneous verbal expressions that may be made deliberately. If we are able to submit anyone to a more accurate examination during certain of his mental activities, we come upon further physical consequences, in the shape of changes in his heart-action, alterations in the distribution of blood in his body, and so on.

[1890a, 1588]

Certain special difficulties seem to me to lie in the way of a direct study of narcissism. Our chief means of access to it will probably remain the analysis of the paraphrenias. Just as the transference neuroses have enabled us to trace the libidinal instinctual impulses, so dementia praecox and paranoia will give us an insight into the psychology of the ego. Once more, in order to arrive at an understanding of what seems so simple in normal phenomena, we shall have to turn to the field of pathology with its distortions and exaggerations. At the same time, other means of approach remain open to us, by which we may obtain a better knowledge of narcissism. These I shall now discuss in the following order: the study of organic disease, of hypochondria and of the erotic life of the sexes.

[1914c, 2938]
An investigation of normal, stable states, in which the frontiers of the ego are safeguarded against the id by resistances (anticathexes) and have held firm, and in which the super-ego is not distinguished from the ego, because they work together harmoniously - an investigation of that kind would teach us little. The only thing that can help us are states of conflict and uproar, when the contents of the unconscious id have a prospect of forcing their way into the ego and into consciousness and the ego puts itself once more on the defensive against this invasion. It is only under these conditions that we can make such observations as will confirm or correct our statements about the two partners. Now, our nightly sleep is precisely a state of this sort, and for that reason psychical activity during sleep, which we perceive as dreams, is our most favourable object of study. In that way, too, we avoid the familiar reproach that we base our constructions of normal mental life on pathological findings; for dreams are regular events in the life of a normal person, however much their characteristics may differ from the productions of our waking life. Dreams, as everyone knows, may be confused, unintelligible or positively nonsensical, what they say may contradict all that we know of reality, and we behave in them like insane people, since, so long as we are dreaming, we attribute objective reality to the contents of the dream.

[1940a [1938], 4975]
Nor is it my purpose to exaggerate the differences, sufficiently large as they are, between the psycho-analytic and the popular view of parapraxes. I would rather call attention to cases in which these differences lose much of their sharpness. As regards the simplest and most inconspicuous examples of slips made by the tongue or the pen - in which, perhaps, words are merely contracted, or words and letters left out - the more complicated interpretations come to nothing. From the point of view of psycho-analysis we must maintain that some disturbance of intention has revealed its existence in these cases, but we cannot say from what the disturbance derived and what its aim was. In fact it has achieved nothing apart from demonstrating its existence. In such cases we can also see how a parapraxis is encouraged by phonetic resemblances and close psychological associations: this is a fact that we have never disputed. It is, however, a reasonable scientific demand that such rudimentary cases of slips of the tongue or slips of the pen should be judged on the basis of the more clearly marked cases, whose investigation yields such unambiguous conclusions as to the way in which parapraxes are caused.

[1901b, 1340]

A comparative examination of my examples of misreading and slips of the pen leads to the same conclusions. As with slips of the tongue, certain cases appear to owe their origin to a work of condensation which has no further motivation (e.g. the ‘Apfe’). It would however be satisfactory to learn whether special conditions may not have to be fulfilled if such a condensation, which is normal in dream-work but a fault in our waking thought, is to take place. No information on this problem can be obtained from the examples themselves. I should however refuse to conclude from this that there are in fact no conditions other than, for instance, a relaxation of conscious attention, since I know from other sources that it is precisely automatic activities which are characterized by correctness and reliability. I should prefer to stress the fact that here, as so often in biology, normal circumstances or those approaching the normal are less favourable subjects for investigation than pathological ones. I expect that what remains obscure in the elucidation of these very slight disturbances will be illuminated by the explanation of serious disturbances.

[1901b, 1342]

Already a few years back we ventured, with the help of these hypotheses, to approach the problem of choice of neurosis. Our method of work, which aims at discovering normal conditions by studying their disturbances, led us to adopt a very singular and unexpected line of attack. The order in which the main forms of psychoneurosis are usually enumerated - Hysteria, Obsessional Neurosis, Paranoia, Dementia Praecox - corresponds (even though not quite exactly) to the order of the ages at which the onset of these disorders occurs. Hysterical forms of illness can be observed even in earliest childhood; obsessional neurosis usually shows its first symptoms in the second period of childhood (between the ages of six and eight); while the two other psychoneuroses, which I have brought together under the heading of ‘paraphrenia’, do not appear until after puberty and during adult life. It is these disorders - the last to emerge - which were the first to show themselves accessible to our enquiry into the dispositions that result in the choice of neurosis. The characteristics peculiar to both of them - megalomania, turning away from the world of objects, increased difficulty in transference - have obliged us to conclude that their dispositional fixation is to be looked for in a stage of libidinal development before object-choice has been established - that is in the phase of auto-erotism and of narcissism. Thus these forms of illness, which make their appearance so late, go back to very early inhibitions and fixations.

[1913i, 2624]
I have no doubt you are ready to suspect that this portrayal of the abundance and strength of a little girl's sexual relations with her mother is very much overdrawn. After all, one has opportunities of seeing little girls and notices nothing of the sort. But the objection is not to the point. Enough can be seen in the children if one knows how to look. And besides, you should consider how little of its sexual wishes a child can bring to preconscious expression or communicate at all. Accordingly we are only within our rights if we study the residues and consequences of this emotional world in retrospect, in people in whom these processes of development had attained a specially clear and even excessive degree of expansion. Pathology has always done us the service of making discernible by isolation and exaggeration conditions which would remain concealed in a normal state. And since our investigations have been carried out on people who were by no means seriously abnormal, I think we should regard their outcome as deserving belief.

[1933a, 4723]
And now let us enquire about latency, which, in view of the analogy, is bound to interest us especially. A trauma in childhood may be followed immediately by a neurotic outbreak, an infantile neurosis, with an abundance of efforts at defence, and accompanied by the formation of symptoms. This neurosis may last a considerable time and cause marked disturbances, but it may also run a latent course and be overlooked. As a rule defence retains the upper hand in it; in any case alterations of the ego, comparable to scars, are left behind. It is only rarely that an infantile neurosis continues without interruption into an adult one. Far more often it is succeeded by a period of apparently undisturbed development - a course of things which is supported or made possible by the intervention of the physiological period of latency. Not until later does the change take place with which the definitive neurosis becomes manifest as a belated effect of the trauma. This occurs either at the irruption of puberty or some while later. In the former case it happens because the instincts, intensified by physical maturation, are able now to take up the struggle again in which they were at first defeated by the defence. In the latter case it happens because the reactions and alterations of the ego brought about by the defence now prove a hindrance in dealing with the new tasks of life, so that severe conflicts come about between the demands of the real external world and the ego, which seeks to maintain the organization which it has painstakingly achieved in its defensive struggle. The phenomenon of a latency of the neurosis between the first reactions to the trauma and the later outbreak of the illness must be regarded as typical. This latter illness may also be looked upon as an attempt at cure - as an effort once more to reconcile with the rest those portions of the ego that have been split off by the influence of the trauma and to unite them into a powerful whole vis-à-vis the external world. An attempt of this kind seldom succeeds, however, unless the work of analysis comes to its help, and even then not always; it ends often enough in a complete devastation or fragmentation of the ego or in its being overwhelmed by the portion which was early split off and which is dominated by the trauma.

[1939a, 4902]
The deeper you penetrate into the pathogenesis of nervous illness, the more you will find revealed the connection between the neuroses and other productions of the human mind, including the most valuable. You will be taught that we humans, with the high standards of our civilization and under the pressure of our internal repressions, find reality unsatisfying quite generally, and for that reason entertain a life of phantasy in which we like to make up for the insufficiencies of reality by the production of wish-fulfilments. These phantasies include a great deal of the true constitutional essence of the subject's personality as well as of those of his impulses which are repressed where reality is concerned. The energetic and successful man is one who succeeds by his efforts in turning his wishful phantasies into reality. Where this fails, as a result of the resistances of the external world and of the subject's own weakness, he begins to turn away from reality and withdraws into his more satisfying world of phantasy, the content of which is transformed into symptoms should he fall ill. In certain favourable circumstances, it still remains possible for him to find another path leading from these phantasies to reality, instead of becoming permanently estranged from it by regressing to infancy. If a person who is at loggerheads with reality possesses an artistic gift (a thing that is still a psychological mystery to us), he can transform his phantasies into artistic creations instead of into symptoms. In this manner he can escape the doom of neurosis and by this roundabout path regain his contact with reality. (Cf. Rank, 1907.) If there is persistent rebellion against the real world and if this precious gift is absent or insufficient, it is almost inevitable that the libido, keeping to the sources of the phantasies, will follow the path of regression, and will revive infantile wishes and end in neurosis. To-day neurosis takes the place of the monasteries which used to be the refuge of all whom life had disappointed or who felt too weak to face it. [1910a, 2235]
We have been led on imperceptibly from the question of the causation of the psychoneuroses to the problem of their essential nature. If we are prepared to take into account what has been learnt from psycho-analysis, we can only say that the essence of these illnesses lies in disturbances of the sexual processes, the processes which determine in the organism the formation and utilization of sexual libido. It is scarcely possible to avoid picturing these processes as being in the last resort of a chemical nature; so that in what are termed the 'actual' neuroses we may recognize the somatic effects of disturbances of the sexual metabolism, and in the psychoneuroses the psychical effects of those disturbances as well. The similarity of the neuroses to the phenomena of intoxication and abstinence after the use of certain alkaloids, as well as to Graves' disease and Addison's disease, is forced upon our notice clinically. And just as these last two illnesses should no longer be described as 'nervous diseases', so also the 'neuroses' proper, in spite of their name, may soon have to be excluded from that category as well.

Accordingly, the aetiology of the neuroses comprises everything which can act in a detrimental manner upon the processes serving the sexual function. In the forefront, then, are to be ranked the noxae which affect the sexual function itself - in so far as these are regarded as injurious by the sexual constitution, varying as it does with different degrees of culture and education. In the next place comes every other kind of noxa and trauma which, by causing general damage to the organism, may lead secondarily to injury to its sexual processes. It should not, however, be forgotten that the aetiological problem in the case of the neuroses is at least as complicated as the causative factors of any other illness. A single pathogenic influence is scarcely ever sufficient; in the large majority of cases a number of aetiological factors are required, which support one another and must therefore not be regarded as being in mutual opposition. For this reason a state of neurotic illness cannot be sharply differentiated from health. The onset of the illness is the product of a summation and the necessary total of aetiological determinants can be completed from any direction. To look for the aetiology of the neuroses exclusively in heredity or in the constitution would be just as one-sided as to attribute that aetiology solely to the accidental influences brought to bear upon sexuality in the course of the subject's life - whereas better insight shows that the essence of these illnesses lies solely in a disturbance of the organism's sexual processes.

With this as a starting-point we go on to make our first important discovery. We learn that, when we try to understand neurotic disorders, by far the greater significance attaches to the sexual instincts; that in fact neuroses are the specific disorders, so to speak, of the sexual function; that in general whether or not a person develops a neurosis depends on the quantity of his libido, and on the possibility of satisfying it and of discharging it through satisfaction; that the form taken by the disease is determined by the way in which the individual passes through the course of development of his sexual function, or, as we put it, by the fixations his libido has undergone in the course of its development; and, further, that by a special, not very simple technique for influencing the mind we are able to throw light on the nature of some groups of neuroses and at the same time to do away with them. Our therapeutic efforts have their greatest success with a certain class of neuroses which proceed from a conflict between the ego-instincts and the sexual instincts. For in human beings it may happen that the demands of the sexual instincts, whose reach of course extends far beyond the individual, seem to the ego to constitute a danger which threatens its self-preservation or its self-esteem. The ego then assumes the defensive, denies the sexual instincts the satisfaction they desire and forces them into those by-paths of substitutive satisfaction which become manifest as nervous symptoms.
These minor rectifications cannot in any way alter the fact which is here under discussion, that a great many people remain infantile in their behaviour in regard to danger and do not overcome determinants of anxiety which have grown out of date. To deny this would be to deny the existence of neurosis, for it is precisely such people whom we call neurotics. But how is this possible? Why are not all neuroses episodes in the development of the individual which come to a close when the next phase is reached? Whence comes the element of persistence in these reactions to danger? Why does the affect of anxiety alone seem to enjoy the advantage over all other affects of evoking reactions which are distinguished from the rest in being abnormal and which, through their inexpediency, run counter to the movement of life? In other words, we have once more come unawares upon the riddle which has so often confronted us: whence does neurosis come - what is its ultimate, its own peculiar raison d'être? After tens of years of psycho-analytic labours, we are as much in the dark about this problem as we were at the start.

[1926d, 4303]

It is not our business to criticize Rank's hypothesis in detail here. We have only to consider whether it helps to solve our particular problem. His formula - that those people become neurotic in whom the trauma of birth was so strong that they have never been able completely to abreact it - is highly disputable from a theoretical point of view. We do not rightly know what is meant by abreacting the trauma. Taken literally, it implies that the more frequently and the more intensely a neurotic person reproduces the affect of anxiety the more closely will he approach to mental health - an untenable conclusion. It was because it did not tally with the facts that I gave up the theory of abreaction which had played such a large part in the cathartic method. To lay so much stress, too, on the variability in the strength of the birth trauma is to leave no room for the legitimate claims of hereditary constitution as an aetiological factor. For this variability is an organic factor which operates in an accidental fashion in relation to the constitution and is itself dependent on many influences which might be called accidental - as, for instance, on timely assistance in child-birth. Rank's theory completely ignores constitutional factors as well as phylogenetic ones. If, however, we were to try to find a place for the constitutional factor by qualifying his statement with the proviso, let us say, that what is really important is the extent to which the individual reacts to the variable intensity of the trauma of birth, we should be depriving his theory of its significance and should be relegating the new factor introduced by him to a position of minor importance: the factor which decided whether a neurosis should supervene or not would lie in a different, and once more in an unknown, field.

[1926d, 4305]

I do not believe, therefore, that Rank's attempt has solved the problem of the causation of neurosis; nor do I believe that we can say as yet how much it may nevertheless have contributed to such a solution. If an investigation into the effects of difficult birth on the disposition to neurosis should yield negative results, we shall rate the value of his contribution low. It is to be feared that our need to find a single, tangible 'ultimate cause' of neurotic illness will remain unsatisfied. The ideal solution, which medical men no doubt still yearn for, would be to discover some bacillus which could be isolated and bred in a pure culture and which, when injected into anyone, would invariably produce the same illness; or, to put it rather less extravagantly, to demonstrate the existence of certain chemical substances the administration of which would bring about or cure particular neuroses. But the probability of a solution of this kind seems slight.

[1926d, 4306]
That can be managed, though, if one bears in mind the complexities of living substance. In what did we find the essence of a neurosis? In the fact that the ego, the higher organization of the mental apparatus (elevated through the influence of the external world), is not able to fulfill its function of mediating between the id and reality, that in its feebleness it draws back from some instinctual portions of the id and, to make up for this, has to put up with the consequences of its renunciation in the form of restrictions, symptoms and unsuccessful reaction-formations. [1926e, 4382]
One’s first inclination is no doubt to trace back the difficulties revealed here to universal
characteristics of our organic instincts. It is no doubt also true in general that the psychical
importance of an instinct rises in proportion to its frustration. Suppose a number of totally
different human beings were all equally exposed to hunger. As their imperative need for food
mounted, all the individual differences would disappear and in their place one would see the
uniform manifestations of the one unappeased instinct. But is it also true that with the
satisfaction of an instinct its psychical value always falls just as sharply? Consider, for example,
the relation of a drinker to wine. Is it not true that wine always provides the drinker with the
same toxic satisfaction, which in poetry has so often been compared to erotic satisfaction - a
comparison acceptable from the scientific point of view as well? Has one ever heard of the
drinker being obliged constantly to change his drink because he soon grows tired of keeping to
the same one? On the contrary, habit constantly tightens the bond between a man and the kind
of wine he drinks. Does one ever hear of a drinker who needs to go to a country where wine is
dearer or drinking is prohibited, so that by introducing obstacles he can reinforce the dwindling
satisfaction that he obtains? Not at all. If we listen to what our great alcoholics, such as Böcklin,¹
say about their relation to wine, it sounds like the most perfect harmony, a model of a happy
marriage. Why is the relation of the lover to his sexual object so very different?
[1912d, 2345]
After I had in this way fixed the simple pictures of neurasthenia, anxiety neurosis and obsessional ideas, I went on to consider the cases of neurosis which are commonly included under the diagnosis of hysteria. I reflected that it was not right to stamp a neurosis as a whole as hysterical because a few hysterical signs were prominent in its complex of symptoms. I could well understand this practice, since after all hysteria is the oldest, best-known and most striking of the neuroses under consideration; but it was an abuse, for it put down to the account of hysteria so many traits of perversion and degeneracy. Whenever a hysterical sign, such as an anaesthesia or a characteristic attack, was found in a complicated case of psychical degeneracy, the whole condition was described as one of 'hysteria', so that it is not surprising that the worst and the most contradictory things were found together under this label. But just as it was certain that this diagnosis was incorrect, it was equally certain that we ought also to separate out the various neuroses; and since we were acquainted with neurasthenia, anxiety neurosis, etc., in a pure form, there was no longer any need to overlook them in the combined picture.

After making a detailed study of a number of nervous patients suffering from phobias and obsessions, I was led to attempt an explanation of those symptoms; and this enabled me afterwards to arrive successfully at the origin of pathological ideas of this sort in new and different cases. My explanation therefore seems to me to deserve publication and further examination. Simultaneously with this 'psychological theory of phobias and obsessions' my observation of patients resulted in a contribution to the theory of hysteria, or rather to a change in it, which appears to take into account an important characteristic that is common both to hysteria and to the neuroses I have just mentioned. Furthermore, I had occasion to gain insight into what is undoubtedly a form of mental disease, and I found at the same time that the point of view which I had tentatively adopted established an intelligible connection between these psychoses and the two neuroses under discussion. At the end of this paper I shall bring forward a working hypothesis which I have made use of in all three instances.

This ego-libido is, however, only conveniently accessible to analytic study when it has been put to the use of cathecting sexual objects, that is, when it has become object-libido. We can then perceive it concentrating upon objects, becoming fixed upon them or abandoning them, moving from one object to another and, from these situations, directing the subject's sexual activity, which leads to the satisfaction, that is, to the partial and temporary extinction, of the libido. The psycho-analysis of what are termed transference neuroses (hysteria and obsessional neurosis) affords us a clear insight at this point.
But the similarity between Gradiva’s procedure and the analytic method of psychotherapy is not limited to these two points - the making conscious of what has been repressed and the coinciding of explanation with cure. It also extends to what turns out to be the essence of the whole change - to the awakening of feelings. Every disorder analogous to Hanold’s delusion, what in scientific terms we are in the habit of calling ‘psychoneuroses’, has as its precondition the repression of a portion of instinctual life, or, as we can safely say, of the sexual instinct. At every attempt to introduce the unconscious and repressed causes of the illness into consciousness, the instinctual component concerned is necessarily aroused to a renewed struggle with the repressing powers, only to come to terms with them in the final outcome, often to the accompaniment of violent manifestations of reaction. The process of cure is accomplished in a relapse into love, if we combine all the many components of the sexual instinct under the term ‘love’; and such a relapse is indispensable, for the symptoms on account of which the treatment has been undertaken are nothing other than precipitates of earlier struggles connected with repression or the return of the repressed, and they can only be resolved and washed away by a fresh high tide of the same passions. Every psycho-analytic treatment is an attempt at liberating repressed love which has found a meagre outlet in the compromise of a symptom. Indeed, the agreement between such treatments and the process of cure described by the author of Gradiva reaches its climax in the further fact that in analytic psychotherapy too the re-awakened passion, whether it is love or hate, invariably chooses as its object the figure of the doctor.

[1907a, 1881]

The field I have in mind is indeed very different from yours. I am referring to the therapy employed for certain ‘nervous diseases’ - what are known as the psychoneuroses - of which hysteria and obsessional ideas may be taken as samples. The method is called ‘psycho-analysis’; it was evolved by me from the ‘cathartic’ method of therapy first practised by Josef Breuer in Vienna.¹ To combat your surprise, I must draw an analogy between the criminal and the hysteric. In both we are concerned with a secret, with something hidden. But in order not to be paradoxical I must at once point out the difference. In the case of the criminal it is a secret which he knows and hides from you, whereas in the case of the hysteric it is a secret which he himself does not know either, which is hidden even from himself. How is this possible? Now we know, through laborious research, that all these illnesses are the result of the patient’s having succeeded in repressing certain ideas and memories that are strongly cathected with affect, together with the wishes that arise from them, in such a way that they play no part in his thinking - do not enter into his consciousness - and thus remain unknown to him. But from this repressed psychical material (these ‘complexes’) are generated the somatic and psychical symptoms which plague the patient in just the same way as a guilty conscience does. In this one respect, therefore, the difference between the criminal and the hysteric is fundamental.

[1906c, 1892]
Already a few years back we ventured, with the help of these hypotheses, to approach the problem of choice of neurosis. Our method of work, which aims at discovering normal conditions by studying their disturbances, led us to adopt a very singular and unexpected line of attack. The order in which the main forms of psychoneurosis are usually enumerated - Hysteria, Obsessional Neurosis, Paranoia, Dementia Praecox - corresponds (even though not quite exactly) to the order of the ages at which the onset of these disorders occurs. Hysterical forms of illness can be observed even in earliest childhood; obsessional neurosis usually shows its first symptoms in the second period of childhood (between the ages of six and eight); while the two other psychoneuroses, which I have brought together under the heading of 'paraphrenia', do not appear until after puberty and during adult life. It is these disorders - the last to emerge - which were the first to show themselves accessible to our enquiry into the dispositions that result in the choice of neurosis. The characteristics peculiar to both of them - megalomania, turning away from the world of objects, increased difficulty in transference - have obliged us to conclude that their dispositional fixation is to be looked for in a stage of libidinal development before object-choice has been established - that is in the phase of auto-erotism and of narcissism. Thus these forms of illness, which make their appearance so late, go back to very early inhibitions and fixations.

[1913i, 2624]

The value of the concepts 'ego-libido' and 'object-libido' lies in the fact that they are derived from the study of the intimate characteristics of neurotic and psychotic processes. A differentiation of libido into a kind which is proper to the ego and one which is attached to objects is an unavoidable corollary to an original hypothesis which distinguished between sexual instincts and ego-instincts. At any rate, analysis of the pure transference neuroses (hysteria and obsessional neurosis) compelled me to make this distinction and I only know that all attempts to account for these phenomena by other means have been completely unsuccessful.

[1914c, 2934]

I have proposed that two groups of such primal instincts should be distinguished: the ego, or self-preservation, instincts and the sexual instincts. But this supposition has not the status of a necessary postulate, as has, for instance, our assumption about the biological purpose of the mental apparatus (p. 2960); it is merely a working hypothesis, to be retained only so long as it proves useful, and it will make little difference to the results of our work of description and classification if it is replaced by another. The occasion for this hypothesis arose in the course of the evolution of psycho-analysis, which was first employed upon the psychoneuroses, or, more precisely, upon the group described as 'transference neuroses' (hysteria and obsessional neurosis); these showed that at the root of all such affections there is to be found a conflict between the claims of sexuality and those of the ego. It is always possible that an exhaustive study of the other neurotic affections (especially of the narcissistic psychoneuroses, the schizophrenias) may oblige us to alter this formula and to make a different classification of the primal instincts. But for the present we do not know of any such formula, nor have we met with any argument unfavourable to drawing this contrast between sexual and ego-instincts.

[1915c, 2962]
Narcissism. - The most important theoretical advance has certainly been the application of the libido theory to the repressing ego. The ego itself came to be regarded as a reservoir of what was described as narcissistic libido, from which the libidinal cathexes of objects flowed out and into which they could be once more withdrawn. By the help of this conception it became possible to embark upon the analysis of the ego and to make a clinical distinction of the psychoneuroses into transference neuroses and narcissistic disorders. In the former (hysteria and obsessional neurosis) the subject has at his disposal a quantity of libido striving to be transferred on to extraneous objects, and use is made of this in carrying out analytic treatment; on the other hand, the narcissistic disorders (dementia praecox, paranoia, melancholia) are characterized by a withdrawal of the libido from objects and they are therefore scarcely accessible to analytic therapy. But their therapeutic inaccessibility has not prevented analysis from making the most fruitful beginnings in the deeper study of these illnesses, which are counted among the psychoses.

[1923a, 3925]

The aetiology common to the onset of a psychoneurosis and of a psychosis always remains the same. It consists in a frustration, a non-fulfilment of one of those childhood wishes which are for ever undefeated and which are so deeply rooted in our phylogenetically determined organization. This frustration is in the last resort always an external one; but in the individual case it may proceed from the internal agency (in the super-ego) which has taken over the representation of the demands of reality. The pathogenic effect depends on whether, in a conflictual tension of this kind, the ego remains true to its dependence on the external world and attempts to silence the id, or whether it lets itself be overcome by the id and thus torn away from reality. A complication is introduced into this apparently simple situation, however, by the existence of the super-ego, which, though a link that is not yet clear to us, unites in itself influences coming from the id as well as from the external world, and is to some extent an ideal model of what the whole endeavour of the ego is aiming at - a reconciliation between its various dependent relationships. The attitude of the super-ego should be taken into account - which has not hitherto been done - in every form of psychical illness. We may provisionally assume that there must also be illnesses which are based on a conflict between the ego and the super-ego. Analysis gives us a right to suppose that melancholia is a typical example of this group; and we would set aside the name of 'narcissistic psychoneuroses' for disorders of that kind. Nor will it clash with our impressions if we find reasons for separating states like melancholia from the other psychoses. We now see that we have been able to make our simple genetic formula more complete, without dropping it. Transference neuroses correspond to a conflict between the ego and the id; narcissistic neuroses, to a conflict between the ego and the super-ego; and psychoses, to one between the ego and the external world. It is true that we cannot tell at once whether we have really gained any new knowledge by this, or have only enriched our store of formulas; but I think that this possible application of the proposed differentiation of the mental apparatus into an ego, a super-ego and an id cannot fail to give us courage to keep that hypothesis steadily in view.

[1924b, 4067]
Among the hypothetical concepts which enable the doctor to deal with the analytic material, the first to be mentioned is that of 'libido'. Libido means in psycho-analysis in the first instance the force (thought of as quantitatively variable and measurable) of the sexual instincts directed towards an object - 'sexual' in the extended sense required by analytic theory. Further study showed that it was necessary to set alongside this 'object-libido' a 'narcissistic' or 'ego-libido', directed to the subject's own ego; and the interaction of these two forces has enabled us to account for a great number of normal and abnormal processes in mental life. A rough distinction was soon made between what are known as the 'transference neuroses' and the narcissistic disorders. The former (hysteria and obsessional neurosis) are the objects proper of psycho-analytic treatment, while the others, the narcissistic neuroses, though they can, it is true, be examined by the help of analysis, offer fundamental difficulties to therapeautic influence. It is true that the libido theory of psycho-analysis is by no means complete and that its relation to a general theory of the instincts is not yet clear, for psycho-analysis is a young science, quite unfinished and in a stage of rapid development. Here, however, it should be emphatically pointed out how erroneous the charge of pan-sexualism is which is so often levelled at psycho-analysis. It seeks to show that psycho-analytic theory knows of no mental motive forces other than purely sexual ones and in doing so exploits popular prejudices by using the word 'sexual' not in its analytic but in its vulgar sense.

[1924f, 4113]
Now the important decision we have to make - and this can be done with certainty in every instance if the symptoms are carefully assessed - is whether the case bears the characteristics of neurasthenia or of a psychoneurosis (hysteria, obsessions). (Mixed cases in which signs of neurasthenia are combined with signs of a psychoneurosis are of very frequent occurrence; but we will leave consideration of them till later.) It is only in neurasthenias that questioning the patient succeeds in disclosing the aetiological factors in his sexual life. These factors are, of course, known to him and belong to the present time, or, more properly, to the period of his life since sexual maturity (though this delimitation does not cover every case). In psychoneuroses questioning of this kind has little result. It may perhaps give us a knowledge of the factors which have to be recognized as precipitating ones, and these may or may not be connected with sexual life. If they are, they show themselves to be no different in kind from the aetiological factors of neurasthenia; that is, they entirely lack any specific relation to the causation of the psychoneurosis. And yet, in every instance, the aetiology of the psychoneuroses, too, lies in the field of sexuality. By a curious circuitous path, of which I shall speak later, it is possible to arrive at a knowledge of this aetiology and to understand why the patient was unable to tell us anything about it. For the events and influences which lie at the root of every psychoneurosis, belong, not to the present day, but to an epoch of life which is long past and which is, as it were, a prehistoric one-to the time of early childhood; and that is why the patient, too, knows nothing of them. He has - though only in a particular sense - forgotten them. [1897b, 459]

Thus, in every case of neurosis there is a sexual aetiology; but in neurasthenia it is an aetiology of a present-day kind, whereas in the psychoneuroses the factors are of an infantile nature. This is the first great contrast in the aetiology of the neuroses. 1 A second one emerges when we take account of a difference in the symptomatology of neurasthenia itself. Here, on the one hand, we find cases in which certain complaints characteristic of neurasthenia (intracranial pressure, proneness to fatigue, dyspepsia, constipation, spinal irritation, etc.) are prominent; in other cases these signs play a minor part and the clinical picture is composed of other symptoms, all of which exhibit a relation to the nuclear symptom, that of anxiety (free anxiousness, unrest, expectant anxiety, complete, rudimentary or supplementary anxiety attacks, locomotor vertigo, agoraphobia, insomnia, increased sensitivity to pain, and so on). I have left the name of neurasthenia to the first type, but have distinguished the second type as 'anxiety neurosis'; and I have given reasons for this separation in another place, where I have also taken account of the fact that as a rule both neuroses appear together. For the present purpose it is enough to emphasize that parallel to the difference in the symptoms of these two forms of illness there goes a difference in their aetiologies. Neurasthenia can always be traced back to a condition of the nervous system such as is acquired by excessive masturbation or arises spontaneously from frequent emissions; anxiety neurosis regularly discloses sexual influences which have in common the factor of reservation or of incomplete satisfaction - such as coitus interruptus, abstinence together with a lively libido, so-called unconsummated excitation, and so on. In my short paper intended to introduce anxiety neurosis I put forward the formula that anxiety is always libido which has been deflected from its employment. [1897b, 460]
The value of making a correct diagnostic separation of the psychoneuroses from neurasthenia is also shown by the fact that the psychoneuroses call for a different practical assessment and for special therapeutic measures. They make their appearance as a result of two kinds of determinants, either independently or in the train of the 'actual neuroses' (neurasthenia and anxiety neurosis). In the latter case we are dealing with a new type of neurosis - incidentally, a very frequent one - a mixed neurosis. The aetiology of the 'actual neuroses' has become an auxiliary aetiology of the psychoneuroses. A clinical picture arises in which, let us say, anxiety neurosis predominates but which also contains traits of genuine neurasthenia, hysteria and obsessional neurosis. When confronted with a mixture of this kind, we shall nevertheless not be wise to give up separating out the clinical pictures proper to each neurotic illness; for after all it is not difficult to explain the case to oneself in the following manner. The predominant place taken by the anxiety neurosis shows that the illness has come into being under the aetiological influence of an 'actual' sexual noxa. But the person concerned was, apart from that, disposed to one or more of the psychoneuroses owing to a special aetiology and would at some time or other have fallen ill of a psychoneurosis either spontaneously or with the advent of some other weakening factor. In this way the auxiliary aetiology for the psychoneurosis which is still lacking is supplied by the actual aetiology of the anxiety neurosis.

I will postpone until later in this paper a more thorough-going discussion of the question whether we are to regard the sexual experiences of childhood as the causes of hysteria (and obsessional neurosis), and I will now return to the form taken by the theory in some of my shorter preliminary publications during the years 1895 and 1896 (Freud, 1896b and 1896c). By laying stress on the supposed aetiological factors it was possible at that time to draw a contrast between the common neuroses as disorders with a contemporary aetiology and psychoneuroses whose aetiology was chiefly to be looked for in the sexual experiences of the remote past. The theory culminated in this thesis: if the vita sexualis is normal, there can be no neurosis.

Careful clinical observation allows us to distinguish two groups of nervous disorders: the neuroses proper and the psychoneuroses. In the former the disturbances (the symptoms), whether they show their effects in somatic or mental functioning, appear to be of a toxic nature. They behave exactly like the phenomena accompanying an excess or a deprivation of certain nerve poisons. These neuroses - which are commonly grouped together as 'neurasthenia' - can be induced by certain injurious influences in sexual life, without any hereditary taint being necessarily present; indeed, the form taken by the disease corresponds to the nature of these noxae, so that often enough the particular aetiology can at once be deduced from the clinical picture. There is a total absence, on the other hand, of any such regular correspondence between the form of a nervous illness and the other injurious influences of civilization which are blamed by the authorities. We may, therefore, regard the sexual factor as the essential one in the causation of the neuroses proper.

With the psychoneuroses, the influence of heredity is more marked and the causation less transparent. A peculiar method of investigation known as psycho-analysis has, however, enabled us to recognize that the symptoms of these disorders (hysteria, obsessional neurosis, etc.) are psychogenic and depend upon the operation of unconscious (repressed) ideational complexes. This same method has also taught us what those unconscious complexes are and has shown that, quite generally speaking, they have a sexual content. They spring from the sexual needs of people who are unsatisfied and represent for them a kind of substitutive satisfaction. We must therefore view all factors which impair sexual life, suppress its activity or distort its aims as being pathogenic factors in the psychoneuroses as well.
The value of a theoretical distinction between toxic and psychogenic neuroses is, of course, not diminished by the fact that, in most people suffering from nervous illness, disturbances arising from both sources are to be observed.

[1908d, 1951]

Psycho-analysis is unjustly reproached, Gentlemen, for leading to purely psychological theories of pathological problems. The emphasis which it lays on the pathogenic role of sexuality, which, after all, is certainly not an exclusively psychical factor should alone protect it from this reproach. Psycho-analysts never forget that the mental is based on the organic, although their work can only carry them as far as this basis and no beyond it. Thus psycho-analysis is ready to admit, and indeed to postulate, that not all disturbances of vision need be psychogenic, like those that are evoked by the repression of erotic scopophilia. If an organ which serves the two sorts of instinct increases its erotogenic role, it is in general to be expected that this will not occur without the excitability and innervation of the organ undergoing changes which will manifest themselves as disturbances of its function in the service of the ego. Indeed, if we find that an organ normally serving the purpose of sense-perception begins to behave like an actual genital when its erotogenic role is increased, we shall not regard it as improbable that toxic changes are also occurring in it. For lack of a better name we must retain the old unsuitable term of 'neurotic' disturbances for both classes of functional disturbances - those of physiological as well as those of toxic origin - which follow from an increase in the erotogenic factor. Generally speaking, the neurotic disturbances of vision stand in the same relation to the psychogenic ones as the 'actual neuroses' do to the psychoneuroses: psychogenic visual disturbances can no doubt hardly ever appear without neurotic ones, but the latter can appear without the former. These neurotic symptoms are unfortunately little appreciated and understood even today; for they are not directly accessible to psycho-analysis, and other methods of research have left the standpoint of sexuality out of account.

[1910i, 2370]

All this seems very clear, and yet it must be admitted the there is one factor which often makes it difficult to form a judgement. Some nervous states which we call the 'actual neuroses', such as typical neurasthenia and pure anxiety neurosis, obviously depend on the somatic factor in sexual life, while we have no certain picture as yet of the part played in them by the psychical factor and by repression. In such cases it is natural that the physician should first consider some 'actual' therapy, some alteration in the patient's somatic sexual activity, and he does so with perfect justification if his diagnosis is correct. The lady who consulted the young doctor complained chiefly of anxiety-states, and so he probably assumed that she was suffering from an anxiety neurosis, and felt justified in recommending a somatic therapy to her. Again a convenient misapprehension! A person suffering from anxiety is not for that reason necessarily suffering from anxiety neurosis; such a diagnosis of it cannot be based on the name; one has to know what signs constitute an anxiety neurosis, and be able to distinguish it from other pathological states which are also manifested by anxiety. My impression was that the lady in question was suffering from anxiety hysteria, and the whole value of such nosographical distinctions, one which quite justifies them, lies in the fact that they indicate a different aetiology and a different treatment. No one who took into consideration the possibility of anxiety hysteria in this case would have fallen into the error of neglecting the mental factors, as this physician did with his three alternatives.

[1910k, 2377]
On the question of the relation of masturbation and emissions to the causation of so-called 'neurasthenia', I find myself like many of you, in opposition to Stekel, and, subject to a limitation which I shall mention presently, I maintain, as against him, my former views. I see nothing that could oblige us to abandon the distinction between 'actual neuroses' and psychoneuroses, and I cannot regard the genesis of the symptoms in the case of the former as anything but toxic. Here Stekel really seems to me greatly to overstretch psychogenicity. My view is still what it was in the first instance, more than fifteen years ago: namely, that the two 'actual neuroses' - neurasthenia and anxiety neurosis (and perhaps we ought to add hypochondria proper as a third 'actual neurosis') - provide the psychoneuroses with the necessary 'somatic compliance'; they provide the excitatory material, which is then psychically selected and given a 'psychical coating', so that, speaking generally, the nucleus of the psychoneurotic symptom - the grain of sand at the centre of the pearl - is formed of a somatic sexual manifestation. This is clearer, it is true, of anxiety neurosis and its relation to hysteria than it is of neurasthenia, into which no careful psycho-analytic investigations have yet been made. In anxiety neurosis, as you have often been able to convince yourselves, it is at bottom a small fragment of undischarged excitation connected with coition which emerges as an anxiety symptom or provides the nucleus for the formation of a hysterical symptom.

Now, however, I must draw your attention to the decisive difference between the symptoms of the 'actual' neuroses and those of the psychoneuroses, the first group of which, the transference neuroses, have occupied us so much hitherto. In both cases the symptoms originate from the libido, and are thus abnormal employments of it, substitutive satisfactions. But the symptoms of the 'actual' neuroses - intracranial pressure, sensations of pain, a state of irritation in an organ, weakening or inhibition of a function - have no 'sense', no psychical meaning. They are not only manifested predominantly in the body (as are hysterical symptoms, for instance, as well), but they are also themselves entirely somatic processes, in the generating of which all the complicated mental mechanisms we have come to know are absent. Thus they really are what psychoneurotic symptoms were so long believed to be. But if so, how can they correspond to employments of the libido, which we have recognized as a force operating in the mind? Well, Gentlemen, that is a very simple matter. Let me remind you of one of the very first objections that were brought up against psycho-analysis. It was said then that it was occupied in finding a purely psychological theory of neurotic phenomena and this was quite hopeless, since psychological theories could never explain an illness. People had chosen to forget that the sexual function is not a purely psychical thing any more than it is a purely somatic one. It influences bodily and mental life alike. If in the symptoms of the psychoneuroses we have become acquainted with manifestations of disturbances in the psychical operation of the sexual function, we shall not be surprised to find in the 'actual' neuroses the direct somatic consequences of sexual disturbances.

[1912f, 2570]

[1916-1917, 3439]
And now perhaps you understand better why I did not choose to arrange my material differently. If I had promised you an 'Introduction to the Theory of the Neuroses' the correct path would certainly have led from the simple forms of the 'actual' neuroses to the more complicated psychical illnesses due to disturbance of the libido. As regards the former I should have had to collect from various sources what we have learnt or believe we know, and in connection with the psychoneuroses psycho-analysis would have come up for discussion as the most important technical aid in throwing light on those conditions. But what I intended to give and what I announced was an 'Introduction to Psycho-Analysis'. It was more important for me that you should gain an idea of psycho-analysis than that you should obtain some pieces of knowledge about the neuroses; and for that reason the 'actual' neuroses, unproductive so far as psycho-analysis is concerned, could no longer have a place in the foreground. I believe, too, that I have made the better choice for you. For, on account of the profundity of its hypotheses and the comprehensiveness of its connections, psycho-analysis deserves a place in the interest of every educated person, while the theory of the neuroses is a chapter in medicine like any other.

[1916-1917, 3440]

If we now pass over to consider neurotic anxiety, what fresh forms and situations are manifested by anxiety? There is much to be described here. In the first place we find a general apprehensiveness, a kind of freely floating anxiety which is ready to attach itself to any idea that is in any way suitable, which influences judgment, selects what is to be expected, and lies in wait for any opportunity that will allow it to justify itself. We call this state 'expectant anxiety' or 'anxious expectation'. People who are tormented by this kind of anxiety always foresee the most frightful of all possibilities, interpret every chance event as a premonition of evil and exploit every uncertainty in a bad sense. A tendency to an expectation of evil of this sort is to be found as a character trait in many people whom one cannot otherwise regard as sick; one calls them over-anxious or pessimistic. A striking amount of expectant anxiety, however, forms a regular feature of a nervous disorder to which I have given the name of 'anxiety neurosis' and which I include among the 'actual' neuroses.

[1916-1917, 3446]

The Aetiological Significance of Sexual Life. - The second novelty which emerged after the hypnotic technique had been replaced by free associations was of a clinical nature. It was discovered in the course of the prolonged search for the traumatic experiences from which hysterical symptoms appeared to be derived. The more carefully the search was pursued the more extensive seemed to be the network of aetiologically significant impressions involved, but the further back, too, did they reach into the patient's puberty or childhood. At the same time they assumed a uniform character and eventually it became inevitable to bow before the evidence and recognize that at the root of the formation of every symptom there were to be found traumatic experiences from early sexual life. Thus a sexual trauma stepped into the place of an ordinary trauma and the latter was seen to owe its aetiological significance to an associative or symbolic connection with the former, which had preceded it. An investigation of cases of common nervousness (falling into the two classes of neurasthenia and anxiety neurosis) which was simultaneously undertaken led to the conclusion that these disorders could be traced to contemporary abuses in the patients' sexual life and could be removed if these were brought to an end. It was thus easy to infer that neuroses in general are an expression of disturbances in sexual life, the so-called actual-neuroses being the consequences (by chemical agency) of contemporary injuries and the psycho-neuroses the consequences (by psychical modification) of bygone injuries to a biological function which had hitherto been gravely neglected by science. None of the theses of psycho-analysis has met with such tenacious scepticism or such embittered resistance as this assertion of the preponderating aetiological significance of sexual life in the neuroses. It should, however, be expressly remarked that, in its development up to the present day, psycho-analysis has found no reason to retreat from this opinion.

[1923a, 3920]
Thus, in every case of neurosis there is a sexual aetiology; but in neurasthenia it is an aetiology of a present-day kind, whereas in the psychoneuroses the factors are of an infantile nature. This is the first great contrast in the aetiology of the neuroses. A second one emerges when we take account of a difference in the symptomatology of neurasthenia itself. Here, on the one hand, we find cases in which certain complaints characteristic of neurasthenia (intracranial pressure, proneness to fatigue, dyspepsia, constipation, spinal irritation, etc.) are prominent; in other cases these signs play a minor part and the clinical picture is composed of other symptoms, all of which exhibit a relation to the nuclear symptom, that of anxiety (free anxiousness, unrest, expectant anxiety, complete, rudimentary or supplementary anxiety attacks, locomotor vertigo, agoraphobia, insomnia, increased sensitivity to pain, and so on). I have left the name of neurasthenia to the first type, but have distinguished the second type as 'anxiety neurosis'; and I have given reasons for this separation in another place, where I have also taken account of the fact that as a rule both neuroses appear together. For the present purpose it is enough to emphasize that parallel to the difference in the symptoms of these two forms of illness there goes a difference in their aetiology. Neurasthenia can always be traced back to a condition of the nervous system such as is acquired by excessive masturbation or arises spontaneously from frequent emissions; anxiety neurosis regularly discloses sexual influences which have in common the factor of reservation or of incomplete satisfaction - such as coitus interruptus, abstinence together with a lively libido, so-called unconsummated excitation, and so on. In my short paper intended to introduce anxiety neurosis I put forward the formula that anxiety is always libido which has been deflected from its employment.

The value of making a correct diagnostic separation of the psychoneuroses from neurasthenia is also shown by the fact that the psychoneuroses call for a different practical assessment and for special therapeutic measures. They make their appearance as a result of two kinds of determinants, either independently or in the train of the 'actual neuroses' (neurasthenia and anxiety neurosis). In the latter case we are dealing with a new type of neurosis - incidentally, a very frequent one - a mixed neurosis. The aetiology of the 'actual neuroses' has become an auxiliary aetiology of the psychoneuroses. A clinical picture arises in which, let us say, anxiety neurosis predominates but which also contains traits of genuine neurasthenia, hysteria and obsessional neurosis. When confronted with a mixture of this kind, we shall nevertheless not be wise to give up separating out the clinical pictures proper to each neurotic illness; for after all it is not difficult to explain the case to oneself in the following manner. The predominant place taken by the anxiety neurosis shows that the illness has come into being under the aetiological influence of an 'actual' sexual noxa. But the person concerned was, apart from that, disposed to one or more of the psychoneuroses owing to a special aetiology and would at some time or other have fallen ill of a psychoneurosis either spontaneously or with the advent of some other weakening factor. In this way the auxiliary aetiology for the psychoneurosis which is still lacking is supplied by the actual aetiology of the anxiety neurosis.
Originally my theory related only to the clinical pictures comprised under the term 'neurasthenia', among which I was particularly struck by two, which occasionally appear as pure types and which I described as 'neurasthenia proper' and 'anxiety neurosis'. It had, to be sure, always been a matter of common knowledge that sexual factors may play a part in the causation of these forms of illness; but those factors were not regarded as invariably operative, nor was there any idea of giving them precedence over other aetiological influences. I was surprised to begin with at the frequency of gross disturbances in the vita sexualis of nervous patients; the more I set about looking for such disturbances - bearing in mind the fact that everyone hides the truth in matters of sex - and the more skilful I became at pursuing my enquiries in the face of a preliminary denial, the more regularly was I able to discover pathogenic factors in sexual life, till little seemed to stand in the way of my assuming their universal occurrence. It was necessary, however, to presuppose from the start that sexual irregularities occurred with similar frequency in our ordinary society under the pressure of social conditions; and a doubt might remain as to the degree of deviation from normal sexual functioning which should be regarded as pathogenic. I was therefore obliged to attach less importance to the invariable evidence of sexual noxae than to a second discovery which seemed to me less ambiguous. It emerged that the form taken by the illness - neurasthenia or anxiety neurosis - bore a constant relation to the nature of the sexual noxa involved. In typical cases of neurasthenia a history of regular masturbation or persistent emissions was found; in anxiety neurosis factors appeared such as coitus interruptus, 'unconsummated excitation', and other conditions - in all of which there seemed to be the common element of an insufficient discharge of the libido that had been produced. It was only after this discovery, which was easy to make and could be confirmed as often as one liked, that I had the courage to claim a preferential position for sexual influences in the aetiology of the neuroses. Furthermore, in the mixed forms of neurasthenia and anxiety neurosis which are so common it was possible to trace a combination of the aetiologies which I had assumed for the two pure forms. Moreover, this twofold form assumed by the neurosis seemed to tally with the polar (i.e. the masculine and feminine) character of sexuality.

All this seems very clear, and yet it must be admitted the there is one factor which often makes it difficult to form a judgement. Some nervous states which we call the 'actual neuroses', such as typical neurasthenia and pure anxiety neurosis, obviously depend on the somatic factor in sexual life, while we have no certain picture as yet of the part played in them by the psychical factor and by repression. In such cases it is natural that the physician should first consider some 'actual' therapy, some alteration in the patient's somatic sexual activity, and he does so with perfect justification if his diagnosis is correct. The lady who consulted the young doctor complained chiefly of anxiety-states, and so he probably assumed that she was suffering from an anxiety neurosis, and felt justified in recommending a somatic therapy to her. Again a convenient misapprehension! A person suffering from anxiety is not for that reason necessarily suffering from anxiety neurosis; such a diagnosis of it cannot be based on the name; one has to know what signs constitute an anxiety neurosis, and be able to distinguish it from other pathological states which are also manifested by anxiety. My impression was that the lady in question was suffering from anxiety hysteria, and the whole value of such nosographical distinctions, one which quite justifies them, lies in the fact that they indicate a different aetiology and a different treatment. No one who took into consideration the possibility of anxiety hysteria in this case would have fallen into the error of neglecting the mental factors, as this physician did with his three alternatives.
The Aetiological Significance of Sexual Life. - The second novelty which emerged after the hypnotic technique had been replaced by free associations was of a clinical nature. It was discovered in the course of the prolonged search for the traumatic experiences from which hysterical symptoms appeared to be derived. The more carefully the search was pursued the more extensive seemed to be the network of aetiologically significant impressions involved, but the further back, too, did they reach into the patient's puberty or childhood. At the same time they assumed a uniform character and eventually it became inevitable to bow before the evidence and recognize that at the root of the formation of every symptom there were to be found traumatic experiences from early sexual life. Thus a sexual trauma stepped into the place of an ordinary trauma and the latter was seen to owe its aetiological significance to an associative or symbolic connection with the former, which had preceded it. An investigation of cases of common nervousness (falling into the two classes of neurasthenia and anxiety neurosis) which was simultaneously undertaken led to the conclusion that these disorders could be traced to contemporary abuses in the patients' sexual life and could be removed if these were brought to an end. It was thus easy to infer that neuroses in general are an expression of disturbances in sexual life, the so-called actual-neuroses being the consequences (by chemical agency) of contemporary injuries and the psycho-neuroses the consequences (by psychical modification) of bygone injuries to a biological function which had hitherto been gravely neglected by science. None of the theses of psycho-analysis has met with such tenacious scepticism or such embittered resistance as this assertion of the preponderating aetiological significance of sexual life in the neuroses. It should, however, be expressly remarked that, in its development up to the present day, psycho-analysis has found no reason to retreat from this opinion.

[1923a, 3920]
The appearance of there nevertheless being 'negative cases' can arise in another way as well. Sometimes an interrogation discloses the presence of a normal sexual life in a patient whose neurosis, on a superficial view, does in fact closely resemble neurasthenia or anxiety neurosis. But a more deep-going investigation regularly reveals the true state of affairs. Behind such cases, which have been taken for neurasthenia, there lies a psychoneurosis - hysteria or obsessional neurosis. Hysteria in especial, which imitates so many organic affections, can easily assume the appearance of one of the 'actual neuroses' by elevating the latter's symptoms into hysterical ones. Such hysterias in the form of neurasthenia are not even very rare. Falling back on psychoneurosis when a case of neurasthenia shows a negative sexual result, is, however, no cheap way out of the difficulty; the proof that we are right is to be obtained by the method which alone unmasks hysteria with certainty - the method of psycho-analysis, to which we shall refer presently.

With the psychoneuroses, the influence of heredity is more marked and the causation less transparent. A peculiar method of investigation known as psycho-analysis has, however, enabled us to recognize that the symptoms of these disorders (hysteria, obsessional neurosis, etc.) are *psychogenic* and depend upon the operation of unconscious (repressed) ideational complexes. This same method has also taught us what those unconscious complexes are and has shown that, quite generally speaking, they have a sexual content. They spring from the sexual needs of people who are unsatisfied and represent for them a kind of substitutive satisfaction. We must therefore view all factors which impair sexual life, suppress its activity or distort its aims as being pathogenic factors in the psychoneuroses as well.

This would accordingly lead us to suppose that the disposition to hysteria and obsessional neurosis, the two transference neuroses proper, which produce their symptoms at an early age, lies in later phases of libidinal development. But at what point in them should we find a developmental inhibition? and, above all, what would be the difference in phases that would determine a disposition to obsessional neurosis as contrasted with hysteria? For a long time nothing was to be learned about this; and my earlier attempts at discovering these two dispositions - the notion, for instance, that hysteria might be determined by passivity and obsessional neurosis by activity in infantile experience - had soon to be abandoned as incorrect.

The value of the concepts 'ego-libido' and 'object-libido' lies in the fact that they are derived from the study of the intimate characteristics of neurotic and psychotic processes. A differentiation of libido into a kind which is proper to the ego and one which is attached to objects is an unavoidable corollary to an original hypothesis which distinguished between sexual instincts and ego-instincts. At any rate, analysis of the pure transference neuroses (hysteria and obsessional neurosis) compelled me to make this distinction and I only know that all attempts to account for these phenomena by other means have been completely unsuccessful.
I have proposed that two groups of such primal instincts should be distinguished: the ego, or self-preservation, instincts and the sexual instincts. But this supposition has not the status of a necessary postulate, as has, for instance, our assumption about the biological purpose of the mental apparatus (p. 2960); it is merely a working hypothesis, to be retained only so long as it proves useful, and it will make little difference to the results of our work of description and classification if it is replaced by another. The occasion for this hypothesis arose in the course of the evolution of psycho-analysis, which was first employed upon the psychoneuroses, or, more precisely, upon the group described as 'transference neuroses' (hysteria and obsessional neurosis); these showed that at the root of all such affections there is to be found a conflict between the claims of sexuality and those of the ego. It is always possible that an exhaustive study of the other neurotic affections (especially of the narcissistic psychoneuroses, the schizophrenias) may oblige us to alter this formula and to make a different classification of the primal instincts. But for the present we do not know of any such formula, nor have we met with any argument unfavourable to drawing this contrast between sexual and ego-instincts.

Let us make a tentative effort to give a metapsychological description of the process of repression in the three transference neuroses which are familiar to us. Here we may replace 'cathexis' by 'libido', because, as we know, it is the vicissitudes of sexual impulses with which we shall be dealing.

Since the publication of a work by Abraham (1908) - which that conscientious author has attributed to my instigation - we have tried to base our characterization of Kraepelin's 'dementia praecox' (Bleuler's 'schizophrenia') on its position with reference to the antithesis between ego and object. In the transference neuroses (anxiety hysteria, conversion hysteria and obsessional neurosis) there was nothing to give special prominence to this antithesis. We knew, indeed, that frustration in regard to the object brings on the outbreak of the neurosis and that the neurosis involves a renunciation of the real object; we knew too that the libido that is withdrawn from the real object reverts first to a phantasied object and then to one that had been repressed (introversion). But in these disorders object-cathexis in general is retained with great energy, and more detailed examination of the process of repression has obliged us to assume that object-cathexis persists in the system Ucs. in spite of - or rather in consequence of - repression. Indeed, the capacity for transference, of which we make use for therapeutic purposes in these affections, presupposes an unimpaired object-cathexis.

Narcissism. - The most important theoretical advance has certainly been the application of the libido theory to the repressing ego. The ego itself came to be regarded as a reservoir of what was described as narcissistic libido, from which the libidinal cathexes of objects flowed out and into which they could be once more withdrawn. By the help of this conception it became possible to embark upon the analysis of the ego and to make a clinical distinction of the psychoneuroses into transference neuroses and narcissistic disorders. In the former (hysteria and obsessional neurosis) the subject has at his disposal a quantity of libido striving to be transferred on to extraneous objects, and use is made of this in carrying out analytic treatment; on the other hand, the narcissistic disorders (dementia praecox, paranoia, melancholia) are characterized by a withdrawal of the libido from objects and they are therefore scarcely accessible to analytic therapy. But their therapeutic inaccessibility has not prevented analysis from making the most fruitful beginnings in the deeper study of these illnesses, which are counted among the psychoses.
Contrast between Sexual and Ego Instincts. - Psycho-analysis early became aware that all mental occurrences must be regarded as built on the basis of an interplay of the forces of the elementary instincts. This, however, led to a difficult predicament, since psychology included no theory of the instincts. No one could say what an instinct really was, the question was left entirely to individual caprice, and every psychologist was in the habit of postulating any instincts in any number that he chose. The first sphere of phenomena to be studied by psycho-analysis comprised what are known as the transference neuroses (hysteria and obsessional neurosis). It was found that their symptoms came about by sexual instinctual impulses being rejected (repressed) by the subject's personality (his ego) and then finding expression by circuitous paths through the unconscious. These facts could be met by drawing a contrast between the sexual instincts and ego instincts (*instincts of self-preservation*), which was in line with the popular saying that hunger and love are what make the world go round: libido was the manifestation of the force of love in the same sense as was hunger of the self-preservation instinct. The nature of the ego instincts remained for the time being undefined and, like all the other characteristics of the ego, inaccessible to analysis. There was no means of deciding whether, and if so what, qualitative differences were to be assumed to exist between the two classes of instincts.

[1923a, 3931]

Among the hypothetical concepts which enable the doctor to deal with the analytic material, the first to be mentioned is that of 'libido'. Libido means in psycho-analysis in the first instance the force (thought of as quantitatively variable and measurable) of the sexual instincts directed towards an object - 'sexual' in the extended sense required by analytic theory. Further study showed that it was necessary to set alongside this 'object-libido' a 'narcissistic' or 'ego-libido', directed to the subject's own ego; and the interaction of these two forces has enabled us to account for a great number of normal and abnormal processes in mental life. A rough distinction was soon made between what are known as the 'transference neuroses' and the narcissistic disorders. The former (hysteria and obsessional neurosis) are the objects proper of psycho-analytic treatment, while the others, the narcissistic neuroses, though they can, it is true, be examined by the help of analysis, offer fundamental difficulties to therapeutic influence. It is true that the libido theory of psycho-analysis is by no means complete and that its relation to a general theory of the instincts is not yet clear, for psycho-analysis is a young science, quite unfinished and in a stage of rapid development. Here, however, it should be emphatically pointed out how erroneous the charge of pan-sexualism is which is so often levelled at psycho-analysis. It seeks to show that psycho-analytic theory knows of no mental motive forces other than purely sexual ones and in doing so exploits popular prejudices by using the word 'sexual' not in its analytic but in its vulgar sense.

[1924f, 4113]
Unless we have first come to a complete agreement upon the terminology involved, it is not easy to decide whether a particular case is to be reckoned as a hysteria or some other neurosis (I am speaking here of neuroses which are not of a purely neurasthenic type; and we have still to await the directing hand which shall set up boundary-marks in the region of the commonly occurring mixed neuroses and which shall bring out the features essential for their characterization. If, accordingly, we are still accustomed to diagnosing a hysteria, in the narrower sense of the term, from its similarity to familiar typical cases, we shall scarcely be able to dispute the fact that the case of Frau Emmy von N. was one of hysteria. The mildness of her deliria and hallucinations (while her other mental activities remained intact), the change in her personality and store of memories when she was in a state of artificial somnambulism, the anaesthesia in her painful leg, certain data revealed in her anamnesis, her ovarian neuralgia, etc., admit of no doubt as to the hysterical nature of the illness, or at least of the patient. That the question can be raised at all is due only to one particular feature of the case, which also provides an opportunity for a comment that is of general validity. As we have explained in the 'Preliminary Communication' which appears at the beginning of this volume, we regard hysterical symptoms as the effects and residues of excitations which have acted upon the nervous system as traumas. Residues of this kind are not left behind if the original excitation has been discharged by abreaction or thought-activity. It is impossible any longer at this point to avoid introducing the idea of quantities (even though not measurable ones). We must regard the process as though a sum of excitation impinging on the nervous system is transformed into chronic symptoms in so far as it has not been employed for external action in proportion to its amount. Now we are accustomed to find in hysteria that a considerable part of this 'sum of excitation' of the trauma is transformed into purely somatic symptoms. It is this characteristic of hysteria which has so long stood in the way of its being recognized as a psychical disorder.

After I had in this way fixed the simple pictures of neurasthenia, anxiety neurosis and obsessional ideas, I went on to consider the cases of neurosis which are commonly included under the diagnosis of hysteria. I reflected that it was not right to stamp a neurosis as a whole as hysterical because a few hysterical signs were prominent in its complex of symptoms. I could well understand this practice, since after all hysteria is the oldest, best-known and most striking of the neuroses under consideration; but it was an abuse, for it put down to the account of hysteria so many traits of perversion and degeneracy. Whenever a hysterical sign, such as an anaesthesia or a characteristic attack, was found in a complicated case of psychical degeneracy, the whole condition was described as one of 'hysteria', so that it is not surprising that the worst and the most contradictory things were found together under this label. But just as it was certain that this diagnosis was incorrect, it was equally certain that we ought also to separate out the various neuroses; and since we were acquainted with neurasthenia, anxiety neurosis, etc., in a pure form, there was no longer any need to overlook them in the combined picture.

I must add, though, that in the meantime pure hysterias have become even rarer in my experience. If it was possible for me to bring together these four cases as hysterias and if in reporting them I was able to overlook the points of view that were of importance as regards sexual neuroses, the reason is that these histories date some distance back, and that I did not at that time as yet submit such cases to a deliberate and searching investigation of their neurotic sexual foundation. And if, instead of these four, I did not report twelve cases whose analysis provides a confirmation of the psychical mechanism of hysterical phenomena put forward by us, this reticence was necessitated by the very circumstance that the analysis revealed these cases as being simultaneously sexual neuroses, although certainly no diagnostician would have refused them the name of hysteria. But an elucidation of these sexual neuroses would overstep the bounds of the present joint publication.
I should not like it to be wrongly thought that I do not wish to allow that hysteria is an independent neurotic affection, that I regard it merely as a psychical manifestation of anxiety neurosis and that I attribute to it 'ideogenic' symptoms only and am transferring the somatic symptoms (such as hyterogenic points and anaesthesias) to anxiety neurosis. Nothing of the sort. In my opinion it is possible to deal with hysteria, freed from any admixture, as something independent; and to do so in every respect except in that of therapeutics. For in therapeutics we are concerned with a practical aim, with getting rid of the pathological state as a whole. And if hysteria generally appears as a component of a mixed neurosis, the situation resembles that in which there is a mixed infection, where preserving life sets a problem which does not coincide with that of combating the operation of one particular pathogenic agent.

[1895d, 231]

It is perhaps not superfluous to point out that the three methods of defence here described and, along with them, the three forms of illness to which those methods lead, may be combined in the same person. The simultaneous appearance of phobias and hysterical symptoms which is so often observed in practice is one of the factors which render it difficult to separate hysteria clearly from other neuroses and which make it necessary to set up the category of 'mixed neuroses'. It is true that hallucinatory confusion is not often compatible with a persistence of hysteria, nor, as a rule, of obsessions. On the other hand, it is not rare for a psychosis of defence episodically to break through the course of a hysterical or mixed neurosis.

[1894a, 314]

In conclusion I may point out that combinations of a phobia and an obsession proper may co-exist, and that indeed this is a very frequent occurrence. We may find that a phobia had developed at the beginning of the disease as a symptom of anxiety neurosis. The idea which constitutes the phobia and which is associated with the state of fear may be replaced by another idea or rather by the protective procedure that seemed to relieve the fear. Case 7 (obsessive speculating) presents a neat example of this group: a phobia along with a true substitutive obsession.

[1895c, 324]

What I call 'anxiety neurosis' may be observed in a completely developed form or in a rudimentary one, in isolation or combined with other neuroses. It is of course the cases which are in some degree complete and at the same time isolated which give particular support to the impression that anxiety neurosis is a clinical entity. In other cases, where the syndrome corresponds to a 'mixed neurosis', we are faced with the task of picking out and separating those symptoms which belong, not to neurasthenia or hysteria, and so on, but to anxiety neurosis.

[1895b, 329]

Both kinds of phobias (and also obsessions) often appear side by side; although the atypical phobias, which are based on obsessions, need not necessarily spring from the soil of anxiety neurosis. A very frequent and apparently complicated mechanism makes its appearance if, in what was originally a simple phobia belonging to an anxiety neurosis, the content of the phobia is replaced by another idea, so that the substitute is subsequent to the phobia. What are most often employed as substitutes are the 'protective measures' that were originally used to combat the phobia. Thus, for instance, 'brooding mania' arises from the subject's endeavours to disprove that he is mad, as his hypochondriacal phobia maintains; the hesitations and doubt, and still more the repetitions, of folie du doute arise from a justifiable doubt about the certainty of one's own train of thought, since one is conscious of its persistent disturbance by ideas of an obsessional sort, and so on. We can therefore assert that many syndromes, too, of obsessional neurosis, such as folie du doute and the like, are also to be reckoned, clinically if not conceptually, as belonging to anxiety neurosis.²

[1895b, 334]
(a) As virginal anxiety or anxiety in adolescents. A number of unambiguous observations have shown me that anxiety neurosis can be produced in girls who are approaching maturity by their first encounter with the problem of sex, by any more or less sudden revelation of what had till then been hidden - for instance, by witnessing the sexual act, or being told or reading about these things. Such an anxiety neurosis is combined with hysteria in an almost typical fashion. [1895b, 336]

(e) Anxiety neurosis also occurs as anxiety in widows and intentionally abstinent women, not seldom in a typical combination with obsessional ideas; and [1895b, 337]

(c) Anxiety in men who practise coitus interruptus. As has been said, coitus interruptus is injurious to the woman if it is practised without regard to her satisfaction; but it is injurious to the man if, in order to obtain satisfaction for her, he directs coitus voluntarily and postpones emission. In this way it becomes intelligible that when a married couple practise coitus interruptus, it is, as a rule, only one partner who falls ill. Moreover, in men coitus interruptus only rarely produces a pure anxiety neurosis; it usually produces a mixture of anxiety neurosis and neurasthenia. [1895b, 338]

More often, however, symptoms of anxiety occur at the same time as, and in combination with, symptoms of neurasthenia, hysteria, obsessions or melancholia. If we were to allow ourselves to be restrained by a clinical intermixture like this from acknowledging anxiety neurosis as an independent entity, we ought, logically, also to abandon once more the separation which has been so laboriously achieved between hysteria and neurasthenia. [1895b, 348]

For the purposes of analysing 'mixed neuroses' I can state this important truth: Wherever a mixed neurosis is present, it will be possible to discover an intermixture of several specific aetiologies. [1895b, 348]

In a third category of mixed neuroses the interconnection between the symptoms is still more intimate, in that the same aetiological determinant regularly and simultaneouslyprovokes both neuroses. Thus, for instance, the sudden sexual enlightenment, which we have found present in virginal anxiety, always gives rise to hysteria as well; by far the majority of cases of intentional abstinence become linked from the beginning with true obsessional ideas; coitus interruptus in men never seems to me to be able to provoke a pure anxiety neurosis, but always a mixture of it with neurasthenia. [1895b, 348]

As regards its intimate nature, anxiety neurosis presents the most interesting agreements with, and differences from, the other major neuroses, in particular neurasthenia and hysteria. It shares with neurasthenia one main characteristic - namely that the source of excitation, the precipitating cause of the disturbance, lies in the somatic field instead of the psychical one, as is the case in hysteria and obsessional neurosis. In other respects we rather find a kind of antithesis between the symptoms of anxiety neurosis and of neurasthenia, which might be brought out by such labels as 'accumulation of excitation' and 'impoverishment of excitation'. This antithesis does not prevent the two neuroses from being intermixed with each other; but it nevertheless shows itself in the fact that the most extreme forms of each are in both cases also the purest. [1895b, 349]
If anyone wants to prove to me that in these remarks I have unduly neglected the significance of the stock aetiological factors, he must confront me with observations in which my specific factor is missing - that is, with cases in which anxiety neurosis has arisen after a psychical shock although the subject has (on the whole) led a normal vita sexualis. Let us see now whether Löwenfeld's case fulfils this condition. My respected opponent has evidently not been clear about this necessity in his own mind, otherwise he would not have left us so completely in the dark about his patient's vita sexualis. I will leave on one side the fact that this case of a lady of thirty is obviously complicated by a hysteria as to the psychical origin of which I have not the least doubt; and I naturally admit without raising any objection the presence of an anxiety neurosis alongside of this hysteria. But before I turn a case to account for or against the theory of the sexual aetiology of the neuroses, I must first have studied the patient's sexual behaviour more closely than Löwenfeld has done here. I should not be content to conclude that, because the time at which the lady received her psychical shock was shortly after a confinement, coitus interruptus could not have played a part during the previous year, and that therefore sexual noxae are ruled out. I know cases of women who were made pregnant every year, and who yet had anxiety neurosis, because - incredible as it may seem - all sexual relations were stopped after the first fertilizing coition, so that in spite of having many children they suffered from sexual privation through all these years. No doctor is ignorant of the fact that women conceive from men whose potency is very slight and who are not able to give them satisfaction. Finally (and this is a consideration which should be taken into account precisely by the upholders of a hereditary aetiology), there are plenty of women who are afflicted with congenital anxiety neurosis - that is to say, who inherit, or who develop without any demonstrable disturbance from outside, a vita sexualis which is the same as the one usually acquired through coitus interruptus and similar noxae. In a number of these women we are able to discover a hysterical illness in their youth, since which their vita sexualis has been disturbed and a deflection of sexual tension from the psychical sphere has been established. Women with this kind of sexuality are incapable of obtaining real satisfaction even from normal coitus, and they develop anxiety neurosis either spontaneously or after further operative factors have supervened. Which of all these elements were present in Löwenfeld's case? I do not know. But I repeat: this case is evidence against me only if the lady who responded to a single fright with an anxiety neurosis had before then enjoyed a normal vita sexualis.

I will without delay add some factual details and some commentary to the result I have announced, in order to combat the scepticism with which I expect to meet. I have been able to carry out a complete psycho-analysis in thirteen cases of hysteria, three of that number being true combinations of hysteria and obsessional neurosis. (I do not speak of hysteria with obsessions.) In none of these cases was an event of the kind defined above missing. It was represented either by a brutal assault committed by an adult or by a seduction less rapid and less repulsive, but reaching the same conclusion. In seven out of the thirteen cases the intercourse was between children on both sides - sexual relations between a little girl and a boy a little older (most often her brother) who had himself been the victim of an earlier seduction. These relations sometimes continued for years, until the little guilty parties reached puberty; the boy would repeat the same practices with the little girl over and over again and without alteration - practices to which he himself had been subjected by some female servant or governess and which on account of their origin were often of a disgusting sort. In a few cases there was a combination of an assault and relations between children or a repetition of a brutal abuse.
The very fact of sexual aggressions of this kind taking place at such a tender age seems to reveal the influence of a previous seduction of which the precocity of sexual desire would be the consequence. In the cases analysed by me analysis confirms this suspicion. In this way an interesting fact is explained which is always found in these cases of obsessions: the regular complication of the framework of symptoms by a certain number of symptoms which are simply hysterical.

There are no doubt pure and isolated cases of hysteria or obsessions, independent of neurasthenia or anxiety neurosis; but this is not the rule. A psychoneurosis appears more often as an accessory to a neurasthenic neurosis, provoked by it and following its decline. This is because the specific causes of the latter, the contemporary disorders of sexual life, operate at the same time as auxiliary causes of the psychoneuroses, whose specific cause, the memory of the precocious sexual experience, they awaken and revive.

In all my cases of obsessional neurosis, moreover, I have found a substratum of hysterical symptoms which could be traced back to a scene of sexual passivity that preceded the pleasurable action. I suspect that this coincidence is no fortuitous one, and that precocious sexual aggressivity always implies a previous experience of being seduced. However, I can as yet give no definitive account of the aetiology of obsessional neurosis; I only have an impression that the decision as to whether hysteria or obsessional neurosis will arise on the basis of traumas in childhood depends on chronological circumstances in the development of the libido.

Lastly, the findings of my analysis are in a position to speak for themselves. In all eighteen cases (cases of pure hysteria and of hysteria combined with obsessions, and comprising six men and twelve women) I have, as I have said, come to learn of sexual experiences of this kind in childhood. I can divide my cases into three groups, according to the origin of the sexual stimulation. In the first group it is a question of assaults - of single, or at any rate isolated, instances of abuse, mostly practised on female children, by adults who were strangers, and who, incidentally, knew how to avoid inflicting gross, mechanical injury. In these assaults there was no question of the child's consent, and the first effect of the experience was preponderantly one of fright. The second group consists of cases in which some adult looking after the child - a nursery maid or governess or tutor, or, unhappily all too often, a close relative - has initiated the child into sexual intercourse and has maintained a regular love relationship with it - a love relationship, moreover, with its mental side developed - which has often lasted for years. The third group, finally, contains child-relationships proper - sexual relations between two children of different sexes, mostly a brother and sister, which are often prolonged beyond puberty and which have the most far-reaching consequences for the pair. In most of my cases I found that two or more of these aetiologies were in operation together; in a few instances the accumulation of sexual experiences coming from different quarters was truly amazing. You will easily understand this peculiar feature of my observations, however, when you consider that the patients I was treating were all cases of severe neurotic illness which threatened to make life impossible.
To this psychology, which has yet to be created to meet our needs - to this future psychology of the neuroses - I must also refer you when, in conclusion, I tell you something which will at first make you afraid that it may disturb our dawning comprehension of the aetiology of hysteria. For I must affirm that the aetiological role of infantile sexual experience is not confined to hysteria but holds good equally for the remarkable neurosis of obsessions, and perhaps also, indeed, for the various forms of chronic paranoia and other functional psychoses. I express myself on this with less definiteness, because I have as yet analysed far fewer cases of obsessional neurosis than of hysteria; and as regards paranoia, I have at my disposal only a single full analysis and a few fragmentary ones. But what I discovered in these cases seemed to be reliable and filled me with confident expectations for other cases. You will perhaps remember that already, at an earlier date, I recommended that hysteria and obsessions should be grouped together under the name of 'neuroses of defence', even before I had come to know of their common infantile aetiology. I must now add that although this need not be expected to happen in general - every one of my cases of obsessions revealed a substratum of hysterical symptoms, mostly sensations and pains, which went back precisely to the earliest childhood experiences. What, then, determines whether the infantile sexual scenes which have remained unconscious will later on, when the other pathogenic factors are super-added, give rise to hysterical or to obsessional neurosis or even to paranoia? This increase in our knowledge seems, as you see, to prejudice the aetiological value of these scenes, since it removes the specificity of the aetiological relation.

[1896c, 432]

The concurrence of a constant grouping of symptoms with a particular aetiological determinant makes it possible to pick out from the composite province of 'neurasthenia' a syndrome which deserves the name of 'anxiety neurosis', because all of its constituents arise from the symptoms of anxiety. These are either to be regarded as immediate manifestations of anxiety or as rudiments and equivalents of them (E. Hecker), and they are often in complete opposition to the symptoms which constitute neurasthenia proper. The aetiology of the two neuroses also points to an opposition of this kind. Whereas true neurasthenia arises from spontaneous emissions or is acquired through masturbation, the factors belonging to the aetiology of anxiety neurosis are such as correspond to a holding back of sexual excitation - such as abstinence when libido is present, unconsummated excitation and, above all, coitus interruptus. In actual life the neuroses here distinguished usually appear in combination, though pure cases can also be demonstrated. When a mixed neurosis of this kind is subjected to analysis, it is possible to indicate a mixture of several specific aetiologies.

[1897b, 447]
Now the important decision we have to make - and this can be done with certainty in every instance if the symptoms are carefully assessed - is whether the case bears the characteristics of neurasthenia or of a psychoneurosis (hysteria, obsessions).(Mixed cases in which signs of neurasthenia are combined with signs of a psychoneurosis are of very frequent occurrence; but we will leave consideration of them till later.) It is only in neurasthenias that questioning the patient succeeds in disclosing the aetiological factors in his sexual life. These factors are, of course, known to him and belong to the present time, or, more properly, to the period of his life since sexual maturity (though this delimitation does not cover every case). In psychoneuroses questioning of this kind has little result. It may perhaps give us a knowledge of the factors which have to be recognized as precipitating ones, and these may or may not be connected with sexual life. If they are, they show themselves to be no different in kind from the aetiological factors of neurasthenia; that is, they entirely lack any specific relation to the causation of the psychoneurosis. And yet, in every instance, the aetiology of the psychoneuroses, too, lies in the field of sexuality. By a curious circuitous path, of which I shall speak later, it is possible to arrive at a knowledge of this aetiology and to understand why the patient was unable to tell us anything about it. For the events and influences which lie at the root of every psychoneurosis, belong, not to the present day, but to an epoch of life which is long past and which is, as it were, a prehistoric one-to the time of early childhood; and that is why the patient, too, knows nothing of them. He has - though only in a particular sense - forgotten them.

Where there is a case in which symptoms of neurasthenia and of anxiety neurosis are combined - where, that is, we have a mixed case - we have only to keep to our proposition, empirically arrived at, that a mingling of neuroses implies the collaboration of several aetiological factors, and we shall find our expectation confirmed in every instance. How often these aetiological factors are linked with one another organically, through the interplay of sexual processes - for instance, coitus interruptus or insufficient potency in the man, going along with masturbation - would well deserve separate discussion.

The value of making a correct diagnostic separation of the psychoneuroses from neurasthenia is also shown by the fact that the psychoneuroses call for a different practical assessment and for special therapeutic measures. They make their appearance as a result of two kinds of determinants, either independently or in the train of the 'actual neuroses' (neurasthenia and anxiety neurosis). In the latter case we are dealing with a new type of neurosis - incidentally, a very frequent one - a mixed neurosis. The aetiology of the 'actual neuroses' has become an auxiliary aetiology of the psychoneuroses. A clinical picture arises in which, let us say, anxiety neurosis predominates but which also contains traits of genuine neurasthenia, hysteria and obsessional neurosis. When confronted with a mixture of this kind, we shall nevertheless not be wise to give up separating out the clinical pictures proper to each neurotic illness; for after all it is not difficult to explain the case to oneself in the following manner. The predominant place taken by the anxiety neurosis shows that the illness has come into being under the aetiological influence of an 'actual' sexual noxa. But the person concerned was, apart from that, disposed to one or more of the psychoneuroses owing to a special aetiology and would at some time or other have fallen ill of a psychoneurosis either spontaneously or with the advent of some other weakening factor. In this way the auxiliary aetiology for the psychoneurosis which is still lacking is supplied by the actual aetiology of the anxiety neurosis.

The value of a theoretical distinction between toxic and psychogenic neuroses is, of course, not diminished by the fact that, in most people suffering from nervous illness, disturbances arising from both sources are to be observed.
In the classificatory system of the neuroses no definite position has hitherto been assigned to 'phobias'. It seems certain that they should only be regarded as syndromes which may form part of various neuroses and that we need not rank them as an independent pathological process. For phobias of the kind to which little Hans's belongs, and which are in fact the most common, the name of 'anxiety-hysteria' seems to me not inappropriate; I suggested the term to Dr. W. Stekel when he was undertaking a description of neurotic anxiety states,¹ and I hope it will come into general use. It finds its justification in the similarity between the psychological structure of these phobias and that of hysteria - a similarity which is complete except upon a single point. That point, however, is a decisive one and well adapted for purposes of differentiation. For in anxiety-hysteria the libido which has been liberated from the pathogenic material by repression is not converted (that is, diverted from the mental sphere into a somatic innervation), but is set free. In the clinical cases that we meet with, this 'anxiety-hysteria' may be combined with 'conversion-hysteria' in any proportion. There exist cases of pure conversion-hysteria without any trace of anxiety, just as there are cases of simple anxiety-hysteria, which exhibit feelings of anxiety and phobias, but have no admixture of conversion. The case of little Hans is one of the latter sort.

Nevertheless you will rightly expect that we should devote some interest to the 'actual' neuroses as well. Their intimate clinical connection with the psychoneuroses would alone compel us to do so. I may inform you, then, that we distinguish three pure forms of 'actual' neuroses: neurasthenia, anxiety neurosis and hypochondria. Even this assertion is not contradicted. All the names are in use, it is true, but their content is indefinite and fluctuating. There are even doctors who oppose any dividing lines in the chaotic world of neurotic phenomena, any segregation of clinical entities or individual diseases, and who do not even recognize the distinction between the 'actual' neuroses and the psychoneuroses. I think they are going too far and have not chosen the path which leads to progress. The forms of neurosis which I have mentioned occur occasionally in their pure form; more often, however, they are intermixed with each other and with a psychoneurotic disorder. This need not lead us to abandon the distinction between them. Consider the difference between the study of minerals and of rocks in mineralogy. The minerals are described as individuals, no doubt on the basis of the fact that they often occur as crystals, sharply separated from their environment. Rocks consist of aggregations of minerals, which, we may be sure, have not come together by chance but as a result of what determined their origin. In the theory of the neuroses we still know too little of the course of their development to produce anything resembling petrology. But we are certainly doing the right thing if we start by isolating from the mass the individual clinical entities which we recognize and which are comparable to the minerals.
Every analyst will have treated a few cases which have had this gratifying outcome. He has succeeded in clearing up the patient's neurotic disturbance, and it has not returned and has not been replaced by any other such disturbance. Nor are we without some insight into the determinants of these successes. The patient's ego had not been noticeably altered and the aetiology of his disturbance had been essentially traumatic. The aetiology of every neurotic disturbance is, after all, a mixed one. It is a question either of the instincts being excessively strong - that is to say, recalcitrant to taming by the ego - or of the effects of early (i.e. premature) traumas which the immature ego was unable to master. As a rule there is a combination of both factors, the constitutional and the accidental. The stronger the constitutional factor, the more readily will a trauma lead to a fixation and leave behind a developmental disturbance; the stronger the trauma, the more certainly will its injurious effects become manifest even when the instinctual situation is normal. There is no doubt that an aetiology of the traumatic sort offers by far the more favourable field for analysis. Only when a case is a predominantly traumatic one will analysis succeed in doing what it is so superlatively able to do; only then will it, thanks to having strengthened the patient's ego, succeed in replacing by a correct solution the inadequate decision made in his early life. Only in such cases can one speak of an analysis having been definitively ended. In them, analysis has done all that it should and does not need to be continued. It is true that, if the patient who has been restored in this way never produces another disorder calling for analysis, we do not know how much his immunity may not be due to a kind fate which has spared him ordeals that are too severe. [1937c, 5018]
Unless we have first come to a complete agreement upon the terminology involved, it is not easy to decide whether a particular case is to be reckoned as a hysteria or some other neurosis (I am speaking here of neuroses which are not of a purely neurasthenic type; and we have still to await the directing hand which shall set up boundary-marks in the region of the commonly occurring mixed neuroses and which shall bring out the features essential for their characterization. If, accordingly, we are still accustomed to diagnosing a hysteria, in the narrower sense of the term, from its similarity to familiar typical cases, we shall scarcely be able to dispute the fact that the case of Frau Emmy von N. was one of hysteria. The mildness of her deliria and hallucinations (while her other mental activities remained intact), the change in her personality and store of memories when she was in a state of artificial somnambulism, the anaesthesia in her painful leg, certain data revealed in her anamnesis, her ovarian neuralgia, etc., admit of no doubt as to the hysterical nature of the illness, or at least of the patient. That the question can be raised at all is due only to one particular feature of the case, which also provides an opportunity for a comment that is of general validity. As we have explained in the 'Preliminary Communication' which appears at the beginning of this volume, we regard hysterical symptoms as the effects and residues of excitations which have acted upon the nervous system as traumas. Residues of this kind are not left behind if the original excitation has been discharged by abreaction or thought-activity. It is impossible any longer at this point to avoid introducing the idea of quantities (even though not measurable ones). We must regard the process as though a sum of excitation impinging on the nervous system is transformed into chronic symptoms in so far as it has not been employed for external action in proportion to its amount. Now we are accustomed to find in hysteria that a considerable part of this 'sum of excitation' of the trauma is transformed into purely somatic symptoms. It is this characteristic of hysteria which has so long stood in the way of its being recognized as a psychical disorder. [1895d, 79]
If one proceeds in this manner with one's patients, one also gains the conviction that, so far as the theory of the sexual aetiology of neurasthenia is concerned, there are no negative cases. In my mind, at least, the conviction has become so certain that where an interrogation has shown a negative result, I have turned this to account too for diagnostic purposes. I have told myself, that is, that such a case cannot be one of neurasthenia. In this way I have been led in several instances to assume the presence of progressive paralysis instead of neurasthenia, because I had not succeeded in establishing the fact - a fact that was necessary for my theory - that the patient indulged very freely in masturbation; and the further course of those cases later confirmed my view. In another instance the patient, who exhibited no clear organic changes, complained of intracranial pressure, headaches and dyspepsia, but countered my suspicions about his sexual life straightforwardly and with unshaken certainty; and the possibility occurred to me that he might have a latent suppuration in one of his nasal sinuses. A specialist colleague of mine confirmed this inference I had made from the negative sexual results of my interrogation, by removing the pus from the patient's antrum and relieving him of his ailments.

But in view of the close connections between the psychoneuroses and the simple neuroses, which go so far, indeed, that a differential diagnosis is not always easy for inexperienced observers, it could not be long before the knowledge arrived at in the one field was extended to the other. Moreover, apart from this consideration, a deeper investigation of the psychical mechanism of hysterical symptoms led to the same result. For if the psychical traumas from which the hysterical symptoms were derived were pursued further and further by means of the 'cathartic' procedure initiated by Breuer and me, experiences were eventually reached which belonged to the patient's childhood and related to his sexual life. And this was so, even in cases in which the onset of the illness had been brought about by some commonplace emotion of a non-sexual kind. Unless these sexual traumas of childhood were taken into account it was impossible either to elucidate the symptoms (to understand the way in which they were determined) or to prevent their recurrence. In this way the unique significance of sexual experiences in the aetiology of the psychoneuroses seemed to be established beyond a doubt; and this fact remains to this day one of the corner-stones of my theory.
I have turned observations of this kind to account in my therapeutic work by leading back the attention of patients with phobias and obsessions to the repressed sexual ideas in spite of all their protestations, and, wherever possible, by stopping up the sources from which those ideas sprang. I cannot, of course, assert that all phobias and obsessions arise in the manner I have shown here. In the first place, my experience of them includes only a limited number compared with the frequency of these neuroses; and in the second place, I myself am aware that such 'psychasthenic' symptoms, as Janet terms them, are not all equivalent.¹ There are, for instance, purely hysterical phobias. Nevertheless, I think that it will be possible to show the presence of the mechanism of transposition of affect in the great majority of phobias and obsessions, and I would therefore urge that these neuroses, which are found in an isolated state as often as in combination with hysteria or neurasthenia, should not be thrown into a heap along with common neurasthenia, for the basic symptoms of which there is no ground at all to assume a psychical mechanism.

[1894a, 312]

The anxiety neurosis, too, has a sexual origin as far as I can see, but it does not attach itself to ideas taken from sexual life; properly speaking, it has no psychical mechanism. Its specific cause is the accumulation of sexual tension, produced by abstinence or by un consummated sexual excitation (using the term as a general formula for the effects of, of relative impotence in the husband, of excitation without satisfaction in engaged couples, of enforced abstinence, etc.).

[1895c, 324]

(3) The anamnesis of patients often discloses that the symptoms of anxiety neurosis have at some definite time succeeded the symptoms of some other neurosis - neurasthenia, perhaps - and have taken their place. In these instances it can quite regularly be shown that, shortly before this change of the picture, a corresponding change has occurred in the form of the sexual noxa.

[1895b, 340]
Observations of this sort, which can be multiplied at will, positively thrust a sexual aetiology on the doctor for a certain category of cases. And other cases, which would otherwise remain unintelligible, can at least be understood and classified without inconsistency by employing that aetiology as a key. I have in mind those very numerous cases in which, it is true, everything is present that has been found in the previous category - on the one hand the manifestations of anxiety neurosis, and on the other the specific factor of coitus interruptus - but in which something else as well intrudes itself: namely, a long interval between the presumed aetiology and its effects, and also perhaps aetiological factors that are not of a sexual nature. Take, for instance, a man who, on receiving news of his father's death, had a heart attack and from that moment fell a victim to an anxiety neurosis. The case is not comprehensible, for, till then, the man was not neurotic. The death of his father, who was well advanced in years, did not take place under in any way special circumstances, and it will be admitted that the normal and expected decease of an aged father is not one of those experiences which usually cause a healthy adult to fall ill. Perhaps the aetiological analysis will become clearer if I add that this man had been practising coitus interruptus for eleven years, with due consideration for his wife's satisfaction. The clinical symptoms are, at least, exactly the same as those which appear in other people after only a short sexual noxa of the same kind, and without the interpolation of any other trauma. A similar assessment must be made of the case of a woman whose anxiety neurosis broke out after the loss of her child, or of the student whose preparatory studies for his final examination were interfered with by an anxiety neurosis. I think that in these instances, too, the effect is not explained by the ostensible aetiology. One is not necessarily 'overworked' by study, and a healthy mother as a rule reacts only with normal grief to the loss of a child. Above all, however, I should have expected the student, as a result of his overwork, to acquire cephalasthenia, and the mother, as a result of her bereavement, hysteria. That both should have been overtaken by anxiety neurosis leads me to attach importance to the fact that the mother had been living for eight years in conditions of marital coitus interruptus, and that the student had for three years had an ardent love affair with a 'respectable' girl whom he had to avoid making pregnant.

What we have so far said about anxiety neurosis already provides a few starting points for gaining an insight into the mechanism of this neurosis. In the first place there was our suspicion that we had to do with an accumulation of excitation; and then there was the extremely important fact that the anxiety which underlies the clinical symptoms of the neurosis can be traced to no psychical origin. Such an origin would exist, for instance, if it was found that the anxiety neurosis was based on a single or repeated justifiable fright, and that that fright had since provided the source for the subject's readiness for anxiety. But this is not so. Hysteria or a traumatic neurosis can be acquired from a single fright, but never anxiety neurosis. Since coitus interruptus takes such a prominent place among the causes of anxiety neurosis, I thought at first that the source of the continuous anxiety might lie in the fear, recurring every time the sexual act was performed, that the technique might go wrong and conception consequently take place. But I have found that this state of feeling, either in the man or the woman, during coitus interruptus has no influence on the generation of anxiety neurosis, that women who are basically indifferent about the consequence of a possible conception are just as liable to the neurosis as those who shudder at the possibility, and that everything depends simply on which partner has forfeited satisfaction in this sexual technique.
The two last aetiological conditions on our list seem to fall into place without difficulty. The tendency to anxiety in masturbators who have become neurasthenic is explained by the fact that it is very easy for them to pass into a state of ‘abstinence’ after they have been accustomed for so long to discharging even the smallest quantity of somatic excitation, faulty though that discharge is. Finally, the last case, - the generation of anxiety neurosis through severe illness, overwork, exhausting sick-nursing, etc., - finds an easy interpretation when brought into relation with the effects of coitus interruptus. Here the psyche, on account of its deflection, would seem to be no longer capable of mastering the somatic excitation, a task on which, as we know, it is continuously engaged. We are aware to what a low level libido can sink under these conditions; and we have here a good example of a neurosis which, although it exhibits no sexual aetiology, nevertheless exhibits a sexual mechanism.

From these considerations it appears that we must further distinguish the aetiological conditions for the onset of the neuroses from their specific aetiological factors. The former - for example, coitus interruptus, masturbation or abstinence - are still ambiguous, and each of them can produce different neuroses. Only the aetiological factors which can be picked out in them, such as inadequate disburdening, psychical insufficiency or defence accompanied by substitution, have an unambiguous and specific relation to the aetiology of the individual major neuroses.

In the second number of Mendel's Neurologisches Zentralblatt for 1895, I published a short paper in which I ventured an attempt to detach a number of nervous states from neurasthenia and to establish them as an independent entity under the name of 'anxiety neurosis'.¹ I was led to do so by the presence of a constant conjunction of certain clinical features with certain aetiological ones - a thing which, in general, should permit us to make a separation of this kind. I found - and in this Hecker (1893) had anticipated me - that the neurotic symptoms in question could all be classed together as constituting expressions of anxiety; and, from my study of the aetiology of the neuroses, I was able to add that these portions of the complex of the 'anxiety neurosis' exhibit special aetiological preconditions which are almost the opposite of the aetiology of neurasthenia. My observations had shown me that in the aetiology of the neuroses (at all events of acquired cases and acquirable forms) sexual factors play a predominant part and one which has been given far too little weight; so that a statement such as that 'the aetiology of the neuroses lies in sexuality', with all its unavoidable incorrectness per excessum et defectum, nevertheless comes nearer to the truth than do the other doctrines, which hold the field at the present time. A further assertion which my observations forced me to make was to the effect that the various sexual noxae are not to be found in the aetiology of every neurosis indifferently, but that unmistakable special relationships hold between particular noxae and particular neuroses. Thus I could assume that I had discovered the specific causes of the various neuroses. I then sought to formulate shortly the special character of the sexual noxae which constitute the aetiology of anxiety neurosis, and, on the basis of my view of the sexual process (p. 108), I arrived at the proposition: anxiety neurosis is created by everything which keeps somatic sexual tension away from the psychical sphere, which interferes with its being worked over psychically. If we go back to the concrete circumstances in which this factor becomes operative, we are led to assert that abstinence, whether voluntary or involuntary, sexual intercourse with incomplete satisfaction, coitus interruptus, deflection of psychical interest from sexuality, and similar things, are the specific aetiological factors of the states to which I have given the name of anxiety neurosis.

¹ [1895f, 352]
I, too, have made exactly the same observation, without, however, being misled by it. I myself have caused anxiety attacks to disappear by means of psychical treatment, improvement of the patient's general health, and so on; but I have naturally not concluded from this that what had caused the anxiety attack was a lack of treatment. Not that I should like to foist a conclusion of this sort upon Löwenfeld. My joking remark is only intended to show that the state of affairs may easily be complicated enough to render Löwenfeld's objection quite invalid. I have not found it difficult to reconcile the fact brought forward here with my assertion that anxiety neurosis has a specific aetiology. It will readily be granted that there are aetiological factors which, in order to exercise their effect, must operate with a certain intensity (or quantity) and over a certain period of time - which, that is to say, become summated. The effects of alcohol are a standard example of causation like this through summation. It follows that there must be a period of time in which the specific aetiology is at work but in which its effect is not yet manifest. During this time the subject is not ill as yet, but he is predisposed to a particular illness - in our case, to anxiety neurosis - and now the addition of a stock noxa will be able to set the neurosis off, just as would a further intensification of the operation of the specific noxa. The situation may also be expressed as follows: it is not enough for the specific noxa to be present; it must also reach a definite amount; and, in the process of reaching that limit, a quantity of specific noxa can be replaced by a quota of stock noxa. If the latter is removed once more, we find ourselves below a certain threshold and the clinical symptoms depart once more. The whole therapy of the neuroses rests upon the fact that the total load upon the nervous system, to which it has succumbed, can be brought below this threshold by influencing the aetiological mixture in a great variety of ways. From these circumstances we can draw no conclusion as to the existence or non-existence of a specific aetiology. These considerations are surely indisputable and assured. But anyone who does not think them sufficient may be influenced by the following argument. According to the views of Löwenfeld and very many others, the aetiology of anxiety states is to be found in heredity. Now heredity is certainly immune to alteration; thus if anxiety neurosis is curable by treatment, we should have to conclude according to Löwenfeld's argument that its aetiology cannot reside in heredity.

[1895f, 358]

For the rest, I might have been spared having to defend myself against these two objections of Löwenfeld's, if my respected opponent had paid greater attention to my paper itself. In it, both these objections are anticipated and answered. I have only been able to repeat here what I said there; and I have even purposely analysed the same cases over again. Moreover the aetiological formulas on which I have just laid weight are contained in the text of my paper. I will repeat them once more. I maintain that there exists a specific aetiological factor for anxiety neurosis which can be replaced in its operation by stock noxae in a quantitative sense, but not in a qualitative one; I furthermore maintain that this specific factor determines above all the form of the neurosis; whether a neurotic illness occurs at all depends on the total load upon the nervous system (in proportion to its capacity to carry the load). As a rule the neuroses are overdetermined; that is to say, several factors operate together in their aetiology.

[1895f, 359]

'But where there are grounds for regarding the neurosis as an acquired one, careful enquiry directed to that end reveals that a set of noxae and influences from sexual life . . .' Löwenfeld quotes this passage and adds the following gloss: 'From this it appears that Freud always regards a neurosis as "acquired" whenever incidental causes are to be found for it.'

[1895f, 362]
When I consult my experience on this point, I cannot find that there is any antithetic relation as regards anxiety neurosis between hereditary disposition and the specific sexual factor. On the contrary, the two aetiological factors support and supplement each other. The sexual factor is usually only operative in those who have an innate hereditary taint as well; heredity alone is usually not able to produce an anxiety neurosis, but waits for the occurrence of a sufficient amount of the specific sexual noxa. The discovery of the hereditary element does not, therefore, exempt us from searching for a specific factor. On its discovery, incidentally, all our therapeutic interest as well depends. For what can we do therapeutically about heredity as an aetiological element? It has always been there in the patient and will continue to be there until the end of his life. Taken by itself, it cannot help us to understand the episodic onset of a neurosis or the cessation of a neurosis as a result of treatment. It is nothing but a precondition of the neurosis - an inexpressibly important precondition, it is true, but nevertheless one which has been over-estimated, to the detriment of therapy and theoretical comprehension. To be convinced by the contrasting state of affairs, one has only to think of the cases of nervous diseases that run in families (such as chorea chronica, Thomsen's disease, and so on), in which heredity unites in itself all the aetiological preconditions.

[1895f, 365]

This, to tell the truth, is no new, unheard-of proposition. Sexual disorders have always been admitted among the causes of nervous illness, but they have been subordinated to heredity - and co-ordinated with the other agents provocateurs; their aetiological influence has been restricted to a limited number of observed cases. Physicians had even fallen into the habit of not investigating them unless the patient brought them up himself. What gives its distinctive character to my line of approach is that I elevate these sexual influences to the rank of specific causes, that I recognize their action in every case of neurosis, and finally that I trace a regular parallelism, a proof of a special aetiological relation between the nature of the sexual influence and the pathological species of the neurosis.

[1896a, 373]

These remarks, which perhaps contain the germ of a theoretical explanation of the functional mechanism of the neurosis in question, give rise already to a suspicion that a complete and truly scientific exposition of the subject is not possible at the present time, and that it would be necessary to start off by approaching the physiological problem of sexual life from a fresh angle.

[1896a, 375]

There are no doubt pure and isolated cases of hysteria or obsessions, independent of neurasthenia or anxiety neurosis; but this is not the rule. A psychoneurosis appears more often as an accessory to a neurasthenic neurosis, provoked by it and following its decline. This is because the specific causes of the latter, the contemporary disorders of sexual life, operate at the same time as auxiliary causes of the psychoneuroses, whose specific cause, the memory of the precocious sexual experience, they awaken and revive.

[1896a, 380]
Obsessions similarly presuppose a sexual experience in childhood (though one of a different nature from that found in hysteria). The aetiology of the two neuro-psychoses of defence is related as follows to the aetiology of the two simple neuroses, neurasthenia and anxiety neurosis. Both the latter disorders are direct effects of the sexual noxae themselves, as I have shown in my paper on anxiety neurosis (1895b); both the defence neuroses are indirect consequences of sexual noxae which have occurred before the advent of sexual maturity - are consequences, that is, of the psychical memory-traces of those noxae. The current causes which produce neurasthenia and anxiety neurosis often at the same time play the part of exciting causes of the neuroses of defence; on the other hand, the specific causes of a defence-neurosis - the traumas of childhood - can at the same time lay the foundations for a later development of neurasthenia. Finally, it not infrequently happens, too, that neurasthenia or anxiety neurosis is maintained, not by current sexual noxae, but, instead, solely by the persisting effect of a memory of childhood traumas.¹

Nor is it true that patients put insuperable obstacles in the way of an investigation into their sexual life. After some slight hesitation, adults usually adjust themselves to the situation by saying: 'After all, I'm at the doctor's; I can say anything to him.' A great many women who find it difficult enough to go through life concealing their sexual feelings, are relieved to find that with the doctor no other consideration outweighs that of their recovery, and they are grateful to him that for once they are allowed to behave quite humanly about sexual things. A dim knowledge of the overwhelming importance of sexual factors in the production of neuroses (a knowledge which I am trying to capture afresh for science) seems never to have been lost in the consciousness of laymen. How often do we witness scenes like this: A married couple, one of whom is suffering from a neurosis, comes to us for consultation. After we have made a great many introductory remarks and apologies to the effect that no conventional barriers should exist between them and the doctor who wants to be of use in such cases, and so on, we tell them that we suspect that the cause of the illness lies in the unnatural and detrimental form of sexual intercourse which they must have chosen since the wife's last confinement. We tell them that doctors do not as a rule concern themselves with such matters, but that that is reprehensible of them, even though the patients do not want to be told about things like that, etc. Thereupon one of the couple nudges the other and says: 'You see! I told you all along it would make me ill.' And the other answers: 'Well, I know, I thought so too; but what is one to do?'

¹[1896b, 388]

[1897b, 457]
Thus, in every case of neurosis there is a sexual aetiology; but in neurasthenia it is an aetiology of a present-day kind, whereas in the psychoneuroses the factors are of an infantile nature. This is the first great contrast in the aetiology of the neuroses. A second one emerges when we take account of a difference in the symptomatology of neurasthenia itself. Here, on the one hand, we find cases in which certain complaints characteristic of neurasthenia (intracranial pressure, proneness to fatigue, dyspepsia, constipation, spinal irritation, etc.) are prominent; in other cases these signs play a minor part and the clinical picture is composed of other symptoms, all of which exhibit a relation to the nuclear symptom, that of anxiety (free anxiousness, unrest, expectant anxiety, complete, rudimentary or supplementary anxiety attacks, locomotor vertigo, agoraphobia, insomnia, increased sensitivity to pain, and so on). I have left the name of neurasthenia to the first type, but have distinguished the second type as 'anxiety neurosis'; and I have given reasons for this separation in another place, where I have also taken account of the fact that as a rule both neuroses appear together. For the present purpose it is enough to emphasize that parallel to the difference in the symptoms of these two forms of illness there goes a difference in their aetiology. Neurasthenia can always be traced back to a condition of the nervous system such as is acquired by excessive masturbation or arises spontaneously from frequent emissions; anxiety neurosis regularly discloses sexual influences which have in common the factor of reservation or of incomplete satisfaction - such as coitus interruptus, abstinence together with a lively libido, so-called unconsummated excitation, and so on. In my short paper intended to introduce anxiety neurosis I put forward the formula that anxiety is always libido which has been deflected from its employment.

The sexual causes, too, are the ones which most readily offer the physician a foothold for his therapeutic influence. Heredity is no doubt an important factor, when it is present; it enables a strong pathological effect to come about where otherwise only a very slight one would have resulted. But heredity is inaccessible to the physician's influence; everyone is born with his own hereditary tendencies to illness, and we can do nothing to change them. Nor should we forget that it is precisely in regard to the aetiology of the neurasthenias that we must necessarily deny the first place to heredity. Neurasthenia (in both its forms) is one of those affections which anyone may easily acquire without having any hereditary taint. If it were otherwise, the enormous increase in neurasthenia, of which all the authorities complain, would be unthinkable. In what concerns civilization, among whose sins people so often include responsibility for neurasthenia, these authorities may indeed be right (although the way in which this comes about is probably quite different from what they imagine). Yet the state of our civilization is, once again, something that is unalterable for the individual. Moreover this factor, being common to all the members of the same society, can never explain the fact of selectivity in the incidence of the illness. The physician who is not neurasthenic is exposed to the same influence of an allegedly detrimental civilization as the neurasthenic patient whom he has to treat. Subject to these limitations, the factors of exhaustion retain their significance. But the element of 'overwork', which physicians are so fond of producing to their patients as the cause of their neurosis, is too often unduly misused. It is quite true that anyone who, owing to sexual noxae, has made himself disposed to neurasthenia, tolerates intellectual work and the psychical exigencies of life badly; but no one ever becomes neurotic through work or excitement alone. Intellectual work is rather a protection against falling ill of neurasthenia; it is precisely the most unremitting intellectual workers who remain exempt from neurasthenia, and what neurasthenics complain of as 'overwork that is making them ill' does not as a rule deserve to be called 'intellectual work' at all, either in its quality or quantity. Physicians will have to become accustomed to explaining to an office-worker who has been 'overworked' at his desk or to a housewife for whom her domestic activities have become too heavy, that they have fallen ill, not because they have tried to carry out duties which are in fact easily performed by a civilized brain, but because all the while they have been grossly neglecting and damaging their sexual life.
A perspicacious physician will therefore take it upon himself to decide under what conditions the use of measures for preventing conception are justified, and, among those measures, he will have to separate the harmful from the harmless ones. Everything is harmful that hinders the occurrence of satisfaction. But, as we know, we possess at present no method of preventing conception which fulfils every legitimate requirement - that is, which is certain and convenient, which does not diminish the sensation of pleasure during coitus and which does not wound the woman's sensibilities. This sets physicians a practical task to the solution of which they could bend their energies with rewarding results. Whoever fills in this lacuna in our medical technique will have preserved the enjoyment of life and maintained the health of numberless people; though, it is true, he will also have paved the way for a drastic change in our social conditions. [1897b, 469]

The value of making a correct diagnostic separation of the psychoneuroses from neurasthenia is also shown by the fact that the psychoneuroses call for a different practical assessment and for special therapeutic measures. They make their appearance as a result of two kinds of determinants, either independently or in the train of the 'actual neuroses' (neurasthenia and anxiety neurosis). In the latter case we are dealing with a new type of neurosis - incidentally, a very frequent one - a mixed neurosis. The aetiology of the 'actual neuroses' has become an auxiliary aetiology of the psychoneuroses. A clinical picture arises in which, let us say, anxiety neurosis predominates but which also contains traits of genuine neurasthenia, hysteria and obsessional neurosis. When confronted with a mixture of this kind, we shall nevertheless not be wise to give up separating out the clinical pictures proper to each neurotic illness; for after all it is not difficult to explain the case to oneself in the following manner. The predominant place taken by the anxiety neurosis shows that the illness has come into being under the aetiological influence of an 'actual' sexual noxa. But the person concerned was, apart from that, disposed to one or more of the psychoneuroses owing to a special aetiology and would at some time or other have fallen ill of a psychoneurosis either spontaneously or with the advent of some other weakening factor. In this way the auxiliary aetiology for the psychoneurosis which is still lacking is supplied by the actual aetiology of the anxiety neurosis. [1897b, 471]
The reproaches against her father for having made her ill, together with the self-reproach underlying them, the leucorrhoea, the playing with the reticule, the bed-wetting after her sixth year, the secret which she would not allow the doctors to tear from her - the circumstantial evidence of her having masturbated in childhood seems to me complete and without a flaw. In the present case I had begun to suspect the masturbation when she had told me of her cousin's gastric pains, and had then identified herself with her by complaining for days together of similar painful sensations. It is well known that gastric pains occur especially often in those who masturbate. According to a personal communication made to me by Wilhelm Fliess, it is precisely gastralgias of this character which can be interrupted by an application of cocaine to the 'gastric spot' discovered by him in the nose, and which can be cured by the cauterization of the same spot. In confirmation of my suspicion Dora gave me two facts from her conscious knowledge: she herself had frequently suffered from gastric pains, and she had good reasons for believing that her cousin was a masturbator. It is a very common thing for patients to recognize in other people a connection which, on account of their emotional resistances, they cannot perceive in themselves. And, indeed, Dora no longer denied my supposition, although she still remembered nothing. Even the date which she assigned to the bed-wetting, when she said that it lasted 'till a short time before the appearance of the nervous asthma', appears to me to be of clinical significance. Hysterical symptoms hardly ever appear so long as children are masturbate, but only afterwards, when a period of abstinence has set in;¹ they form a substitute for masturbatory satisfaction, the desire for which continues to persist in the unconscious until another and more normal kind of satisfaction appears - where that is still attainable. For upon whether it is still attainable or not depends the possibility of a hysteria being cured by marriage and normal sexual intercourse. But if the satisfaction afforded in marriage is again removed - as it may be owing to coitus interruptus, psychological estrangement, or other causes - then the libido flows back again into its old channel and manifests itself once more in hysterical symptoms.

[1905e, 1415]
Originally my theory related only to the clinical pictures comprised under the term 'neurasthenia', among which I was particularly struck by two, which occasionally appear as pure types and which I described as 'neurasthenia proper' and 'anxiety neurosis'. It had, to be sure, always been a matter of common knowledge that sexual factors may play a part in the causation of these forms of illness; but those factors were not regarded as invariably operative, nor was there any idea of giving them precedence over other aetiological influences. I was surprised to begin with at the frequency of gross disturbances in the vita sexualis of nervous patients; the more I set about looking for such disturbances - bearing in mind the fact that everyone hides the truth in matters of sex - and the more skilful I became at pursuing my enquiries in the face of a preliminary denial, the more regularly was I able to discover pathogenic factors in sexual life, till little seemed to stand in the way of my assuming their universal occurrence. It was necessary, however, to presuppose from the start that sexual irregularities occurred with similar frequency in our ordinary society under the pressure of social conditions; and a doubt might remain as to the degree of deviation from normal sexual functioning which should be regarded as pathogenic. I was therefore obliged to attach less importance to the invariable evidence of sexual noxae than to a second discovery which seemed to me less ambiguous. It emerged that the form taken by the illness - neurasthenia or anxiety neurosis - bore a constant relation to the nature of the sexual noxa involved. In typical cases of neurasthenia a history of regular masturbation or persistent emissions was found; in anxiety neurosis factors appeared such as coitus interruptus, 'unconsummated excitement', and other conditions - in all of which there seemed to be the common element of an insufficient discharge of the libido that had been produced. It was only after this discovery, which was easy to make and could be confirmed as often as one liked, that I had the courage to claim a preferential position for sexual influences in the aetiology of the neuroses. Furthermore, in the mixed forms of neurasthenia and anxiety neurosis which are so common it was possible to trace a combination of the aetologies which I had assumed for the two pure forms. Moreover, this twofold form assumed by the neurosis seemed to tally with the polar (i.e. the masculine and feminine) character of sexuality.

[1906a, 1575]

At the time at which I was attributing to sexuality this important part in the production of the simple neuroses,¹ I was still faithful to a purely psychological theory in regard to the psychoneuroses - a theory in which the sexual factor was regarded as no more significant than any other emotional source of feeling. On the basis of some observations made by Josef Breuer on a hysterical patient more than ten years earlier, I collaborated with him in a study of the mechanism of the generation of hysterical symptoms, using the method of awakening the patient's memories in a state of hypnosis; and we reached conclusions which enabled us to bridge the gap between Charcot's traumatic hysteria and common non-traumatic hysteria (Breuer and Freud, 1895). We were led to the assumption that hysterical symptoms are the permanent results of psychical traumas, the sum of affect attaching to which has, for particular reasons, been prevented from being worked over consciously and has therefore found an abnormal path into somatic innervation. The terms 'strangulated affect', 'conversion' and 'abreaction' cover the distinctive features of this hypothesis.

[1906a, 1576]
I will postpone until later in this paper a more thorough going discussion of the question whether we are to regard the sexual experiences of childhood as the causes of hysteria (and obsessional neurosis), and I will now return to the form taken by the theory in some of my shorter preliminary publications during the years 1895 and 1896 (Freud, 1896b and 1896c). By laying stress on the supposed aetiological factors it was possible at that time to draw a contrast between the common neuroses as disorders with a contemporary aetiology and psychoneuroses whose aetiology was chiefly to be looked for in the sexual experiences of the remote past. The theory culminated in this thesis: if the vita sexualis is normal, there can be no neurosis. [1906a, 1577]

We have been led on imperceptibly from the question of the causation of the psychoneuroses to the problem of their essential nature. If we are prepared to take into account what has been learnt from psycho-analysis, we can only say that the essence of these illnesses lies in disturbances of the sexual processes, the processes which determine in the organism the formation and utilization of sexual libido. It is scarcely possible to avoid picturing these processes as being in the last resort of a chemical nature; so that in what are termed the 'actual' neuroses we may recognize the somatic effects of disturbances of the sexual metabolism, and in the psychoneuroses the psychical effects of those disturbances as well. The similarity of the neuroses to the phenomena of intoxication and abstinence after the use of certain alkaloids, as well as to Graves' disease and Addison's disease, is forced upon our notice clinically. And just as these last two illnesses should no longer be described as 'nervous diseases', so also the 'neuroses' proper, in spite of their name, may soon have to be excluded from that category as well. [1906a, 1582]

Careful clinical observation allows us to distinguish two groups of nervous disorders: the neuroses proper and the psychoneuroses. In the former the disturbances (the symptoms), whether they show their effects in somatic or mental functioning, appear to be of a toxic nature. They behave exactly like the phenomena accompanying an excess or a deprivation of certain nerve poisons. These neuroses - which are commonly grouped together as 'neurasthenia' - can be induced by certain injurious influences in sexual life, without any hereditary taint being necessarily present; indeed, the form taken by the disease corresponds to the nature of these noxae, so that often enough the particular sexual aetiology can at once be deduced from the clinical picture. There is a total absence, on the other hand, of any such regular correspondence between the form of a nervous illness and the other injurious influences of civilization which are blamed by the authorities. We may, therefore, regard the sexual factor as the essential one in the causation of the neuroses proper. [1908d, 1950]

With the psychoneuroses, the influence of heredity is more marked and the causation less transparent. A peculiar method of investigation known as psycho-analysis has, however, enabled us to recognize that the symptoms of these disorders (hysteria, obsessional neurosis, etc.) are psychogenic and depend upon the operation of unconscious (repressed) ideational complexes. This same method has also taught us what those unconscious complexes are and has shown that, quite generally speaking, they have a sexual content. They spring from the sexual needs of people who are unsatisfied and represent for them a kind of substitutive satisfaction. We must therefore view all factors which impair sexual life, suppress its activity or distort its aims as being pathogenic factors in the psychoneuroses as well. [1908d, 1951]
This brings us to the question whether sexual intercourse in legal marriage can offer full compensation for the restrictions imposed before marriage. There is such an abundance of material supporting a reply in the negative that we can give only the briefest summary of it. It must above all be borne in mind that our cultural sexual morality restricts sexual intercourse even in marriage itself, since it imposes on married couples the necessity of contenting themselves, as a rule, with very few procreative acts. As a consequence of this consideration, satisfying sexual intercourse in marriage takes place only for a few years; and we must subtract from this, of course, the intervals of abstinence necessitated by regard for the wife's health. After these three, four or five years, the marriage becomes a failure in so far as it has promised the satisfaction of sexual needs. For all the devices hitherto invented for preventing conception impair sexual enjoyment, hurt the fine susceptibilities of both partners and even actually cause illness. Fear of the consequences of sexual intercourse first brings the married couple's physical affection to an end; and then, as a remoter result, it usually puts a stop as well to the mental sympathy between them, which should have been the successor to their original passionate love. The spiritual disillusionment and bodily deprivation to which most marriages are thus doomed puts both partners back in the state they were in before their marriage, except for being the poorer by the loss of an illusion, and they must once more have recourse to their fortitude in mastering and deflecting their sexual instinct. We need not enquire how far men, by then in their maturer years, succeed in this task. Experience shows that they very frequently avail themselves of the degree of sexual freedom which is allowed them - although only with reluctance and under a veil of silence - by even the strictest sexual code. The 'double' sexual morality which is valid for men in our society is the plainest admission that society itself does not believe in the possibility of enforcing the precepts which it itself has laid down. But experience shows as well that women, who, as being the actual vehicle of the sexual interests of mankind, are only endowed in a small measure with the gift of sublimating their instincts, and who, though they may find a sufficient substitute for the sexual object in an infant at the breast, do not find one in a growing child - experience shows, I repeat, that women, when they are subjected to the disillusionments of marriage, fall ill of severe neuroses which permanently darken their lives. (Under the cultural conditions of to-day, marriage has long ceased to be a panacea for the nervous troubles of women; and if we doctors still advise marriage in such cases, we are nevertheless aware that, on the contrary, a girl must be very healthy if she is to be able to tolerate it, and we urgently advise our male patients not to marry any girl who has had nervous trouble before marriage. On the contrary, the cure for nervous illness arising from marriage would be marital unfaithfulness. But the more strictly a woman has been brought up and the more sternly she has submitted to the demands of civilization, the more she is afraid of taking this way out; and in the conflict between her desires and her sense of duty, she once more seeks refuge in a neurosis. Nothing protects her virtue as securely as an illness. Thus the married state, which is held out as a consolation to the sexual instinct of the civilized person in his youth, proves to be inadequate even to the demands of the actual period of life covered by it. There is no question of its being able to compensate for the deprivation which precedes it. [1908d, 1957]

But even if the damage done by civilized sexual morality is admitted, it may be argued in reply to our third question that the cultural gain derived from such an extensive restriction of sexuality probably more than balances these sufferings, which, after all, only affect a minority in any severe form. I must confess that I am unable to balance gain against loss correctly on this point, but I could advance a great many more considerations on the side of the loss. Going back to the subject of abstinence, which I have already touched on, I must insist that it brings in its train other noxae besides those involved in the neuroses and that the importance of the neuroses has for the most part not been fully appreciated. [1908d, 1958]
The retardation of sexual development and sexual activity at which our education and civilization aim is certainly not injurious to begin with. It is seen to be a necessity, when one considers the late age at which young people of the educated classes reach independence and are able to earn a living. (This reminds one, incidentally, of the intimate interconnection between all our cultural institutions and of the difficulty of altering any part of them without regard to the whole.) But abstinence continued long after the age of twenty is no longer unobjectionable for a young man; and it leads to other damage even when it does not lead to neurosis. People say, to be sure, that the struggle against such a powerful instinct, and the strengthening of all the ethical and aesthetic forces which are necessary for this struggle, 'steel' the character; and this is true for a few specially favourably organized natures. It must also be admitted that the differentiation of individual character, which is so marked in our day, has only become possible with the existence of sexual restriction. But in the vast majority of cases the struggle against sexuality eats up the energy available in a character and this at the very time when a young man is in need of all his forces in order to win his share and place in society. The relationship between the amount of sublimation possible and the amount of sexual activity necessary naturally varies very much from person to person and even from one calling to another. An abstinent artist is hardly conceivable; but an abstinent young savant is certainly no rarity. The latter can, by his self-restraint, liberate forces for his studies; while the former probably finds his artistic achievements powerfully stimulated by his sexual experience. In general I have not gained the impression that sexual abstinence helps to bring about energetic and self-reliant men of action or original thinkers or bold emancipators and reformers. Far more often it goes to produce well-behaved weaklings who later become lost in the great mass of people that tends to follow, unwillingly, the leads given by strong individuals.

[1908d, 1958]

In considering the question of abstinence, the distinction is not nearly strictly enough made between two forms of it - namely abstention from any sexual activity whatever and abstention from sexual intercourse with the opposite sex. Many people who boast of succeeding in being abstinent have only been able to do so with the help of masturbation and similar satisfactions which are linked with the auto-erotic sexual activities of early childhood. But precisely because of this connection such substitutive means of sexual satisfaction are by no means harmless; they predispose to the numerous varieties of neuroses and psychoses which are conditional on an involution of sexual life to its infantile forms. Masturbation, moreover, is far from meeting the ideal demands of civilized sexual morality, and consequently drives young people into the same conflicts with the ideals of education which they hoped to escape by abstinence. Furthermore, it vitiates the character through indulgence, and this in more than one way. In the first place, it teaches people to achieve important aims without taking trouble and by easy paths instead of through an energetic exertion of force - that is, it follows the principle that sexuality lays down the pattern of behaviour; secondly, in the phantasies that accompany satisfaction the sexual object is raised to a degree of excellence which is not easily found again in reality. A witty writer (Karl Kraus in the Vienna paper Die Fackel) once expressed this truth in reverse by cynically remarking: 'Copulation is no more than an unsatisfying substitute for masturbation.'

[1908d, 1960]
Psycho-analysis is unjustly reproached, Gentlemen, for leading to purely psychological theories of pathological problems. The emphasis which it lays on the pathogenic role of sexuality, which, after all, is certainly not an exclusively psychical factor should alone protect it from this reproach. Psycho-analysts never forget that the mental is based on the organic, although their work can only carry them as far as this basis and no beyond it. Thus psycho-analysis is ready to admit, and indeed to postulate, that not all disturbances of vision need be psychogenic, like those that are evoked by the repression of erotic scopophilia. If an organ which serves the two sorts of instinct increases its erotogenic role, it is in general to be expected that this will not occur without the excitability and innervation of the organ undergoing changes which will manifest themselves as disturbances of its function in the service of the ego. Indeed, if we find that an organ normally serving the purpose of sense-perception begins to behave like an actual genital when its erotogenic role is increased, we shall not regard it as improbable that toxic changes are also occurring in it. For lack of a better name we must retain the old unsuitable term of 'neurotic' disturbances for both classes of functional disturbances - those of physiological as well as those of toxic origin - which follow from an increase in the erotogenic factor. Generally speaking, the neurotic disturbances of vision stand in the same relation to the psychogenic ones as the 'actual neuroses' do to the psychoneuroses: psychogenic visual disturbances can no doubt hardly ever appear without neurotic ones, but the latter can appear without the former. These neurotic symptoms are unfortunately little appreciated and understood even today; for they are not directly accessible to psycho-analysis, and other methods of research have left the standpoint of sexuality out of account.

All this seems very clear, and yet it must be admitted the there is one factor which often makes it difficult to form a judgement. Some nervous states which we call the 'actual neuroses', such as typical neurasthenia and pure anxiety neurosis, obviously depend on the somatic factor in sexual life, while we have no certain picture as yet of the part played in them by the psychical factor and by repression. In such cases it is natural that the physician should first consider some 'actual' therapy, some alteration in the patient's somatic sexual activity, and he does so with perfect justification if his diagnosis is correct. The lady who consulted the young doctor complained chiefly of anxiety-states, and so he probably assumed that she was suffering from an anxiety neurosis, and felt justified in recommending a somatic therapy to her. Again a convenient misapprehension! A person suffering from anxiety is not for that reason necessarily suffering from anxiety neurosis; such a diagnosis of it cannot be based on the name; one has to know what signs constitute an anxiety neurosis, and be able to distinguish it from other pathological states which are also manifested by anxiety. My impression was that the lady in question was suffering from anxiety hysteria, and the whole value of such nosographical distinctions, one which quite justifies them, lies in the fact that they indicate a different aetiology and a different treatment. No one who took into consideration the possibility of anxiety hysteria in this case would have fallen into the error of neglecting the mental factors, as this physician did with his three alternatives.

(b) as to the aetiological relation of masturbation to the 'actual neuroses'.

[1910k, 2377]

[1912f, 2568]
On the question of the relation of masturbation and emissions to the causation of so-called 'neurasthenia', I find myself like many of you, in opposition to Stekel, and, subject to a limitation which I shall mention presently, I maintain, as against him, my former views. I see nothing that could oblige us to abandon the distinction between 'actual neuroses' and psychoneuroses, and I cannot regard the genesis of the symptoms in the case of the former as anything but toxic. Here Stekel really seems to me greatly to overstretch psychogenicity. My view is still what it was in the first instance, more than fifteen years ago: namely, that the two 'actual neuroses' - neurasthenia and anxiety neurosis (and perhaps we ought to add hypochondria proper as a third 'actual neurosis') - provide the psychoneuroses with the necessary 'somatic compliance'; they provide the excitatory material, which is then psychically selected and given a 'psychical coating', so that, speaking generally, the nucleus of the psychoneurotic symptom - the grain of sand at the centre of the pearl - is formed of a somatic sexual manifestation. This is clearer, it is true, of anxiety neurosis and its relation to hysteria than it is of neurasthenia, into which no careful psycho-analytic investigations have yet been made. In anxiety neurosis, as you have often been able to convince yourselves, it is at bottom a small fragment of undischarged excitation connected with coition which emerges as an anxiety symptom or provides the nucleus for the formation of a hysterical symptom.

The essence of the theories about the 'actual neuroses' which I have put forward in the past and am defending to-day lies in my assertion, based on experiment, that their symptoms, unlike psychoneurotic ones, cannot be analysed. That is to say, the constipation, headaches and fatigue of the so-called neurasthenic do not admit of being traced back historically or symbolically to operative experiences and cannot be understood as substitutes for sexual satisfaction or as compromises between opposing instinctual impulses, as is the case with psycho-neurotic symptoms (even though the latter may perhaps have the same appearance). I do not believe it will be possible to upset this assertion by the help of psycho-analysis. On the other hand I will grant to-day what I was unable to believe formerly - that an analytic treatment can have an indirect curative effect on 'actual' symptoms. It can do so either by enabling the current noxae to be better tolerated, or by enabling the sick person to escape from the current noxae by making a change in his sexual régime. These would be desirable prospects from the point of view of our therapeutic interest.

We see that, if we follow up this line of thought, we come up against the problem not only of hypochondria, but of the other 'actual' neuroses - neurasthenia and anxiety neurosis. Let us therefore stop at this point. It is not within the scope of a purely psychological inquiry to penetrate so far behind the frontiers of physiological research. I will merely mention that from this point of view we may suspect that the relation of hypochondria to paraphrenia is similar to that of the other 'actual' neuroses to hysteria and obsessional neurosis: we may suspect, that is, that it is dependent on ego-libido just as the others are on object-libido, and that hypochondriacal anxiety is the counterpart, as coming from ego-libido, to neurotic anxiety. Further, since we are already familiar with the idea that the mechanism of falling ill and of the formation of symptoms in the transference neuroses - the path from introversion to regression - is to be linked to a damming-up of object-libido,¹ we may come to closer quarters with the idea of a damming-up of ego-libido as well and may bring this idea into relation with the phenomena of hypochondria and paraphrenia.

¹ [1914c, 2940]
But I still owe you further enlightenment, Gentlemen, on my reasons for not starting my account of the theory of the neuroses with the common neurotic state. You may perhaps suppose that it was because in that case I should have had greater difficulty in proving the sexual causation of the neuroses. But you would be wrong there. In the case of the transference neuroses one must work one's way through the interpretation of symptoms before one can arrive at that discovery. In the common forms of what are known as the 'actual neuroses' the aetiological significance of sexual life is a crude fact that springs to the observer's eyes. I came upon it more than twenty years ago when one day I asked myself the question of why in the examination of neurotics their sexual activities were so regularly excluded from consideration. At that time I sacrificed my popularity with my patients for the sake of these enquiries; but after only a brief effort I was able to declare that 'if the *vita sexualis* is normal, there can be no neurosis' - and by this I meant no 'actual neurosis'. No doubt this statement passes too lightly over people's individual differences; it suffers, too, from the indefiniteness inseparable from the judgement of what is 'normal'. But as a rough guide it retains its value to this day. I had by then reached the point of establishing specific relations between particular forms of neurosis and particular sexual noxae; and I have no doubt that I could repeat the same observations to-day if similar pathological material were still at my disposal. I found often enough that a man who indulged in a certain kind of incomplete sexual satisfaction (for instance, manual masturbation) had fallen ill of a particular form of 'actual neurosis', and that this neurosis promptly gave place to another if he replaced this sexual régime by another equally far from being irreproachable. I was then in a position to infer the change in a patient's sexual mode of life from an alteration in his condition. I also learnt then to stand obstinately by my suspicions till I had overcome the patients' disingenuousness and compelled them to confirm my views. It is true that thereafter they preferred to go to other doctors who did not make such keen enquiries about their sexual life.

[1916-1917, 3438]

Even at that time I could not fail to notice that the causation of the illness did not always point to sexual life. One person, it was true, fell ill directly from a sexual noxa; but another did so because he had lost his fortune or had been through an exhausting organic illness. The explanation of these varieties came later, when we gained an insight into the suspected interrelations between the ego and the libido, and the explanation became the more satisfactory the deeper that insight extended. A person only falls ill of a neurosis if his ego has lost the capacity to allocate his libido in some way. The stronger is his ego, the easier will it be for it to carry out that task. Any weakening of his ego from whatever cause must have the same effect as an excessive increase in the claims of the libido and will thus make it possible for him to fall ill of a neurosis. There are other and more intimate relations between the ego and the libido; but these have not yet come within our scope, so I will not bring them up as part of my present explanation. What remains essential and makes things clear to us is that, in every case and no matter how the illness is set going, the symptoms of the neurosis are sustained by the libido and are consequently evidence that it is being employed abnormally.

[1916-1917, 3438]
Now, however, I must draw your attention to the decisive difference between the symptoms of the 'actual' neuroses and those of the psychoneuroses, the first group of which, the transference neuroses, have occupied us so much hitherto. In both cases the symptoms originate from the libido, and are thus abnormal employments of it, substitutive satisfactions. But the symptoms of the 'actual' neuroses - intracranial pressure, sensations of pain, a state of irritation in an organ, weakening or inhibition of a function - have no 'sense', no psychical meaning. They are not only manifested predominantly in the body (as are hysterical symptoms, for instance, as well), but they are also themselves entirely somatic processes, in the generating of which all the complicated mental mechanisms we have come to know are absent. Thus they really are what psychoneurotic symptoms were so long believed to be. But if so, how can they correspond to employments of the libido, which we have recognized as a force operating in the mind? Well, Gentlemen, that is a very simple matter. Let me remind you of one of the very first objections that were brought up against psycho-analysis. It was said then that it was occupied in finding a purely psychological theory of neurotic phenomena and this was quite hopeless, since psychological theories could never explain an illness. People had chosen to forget that the sexual function is not a purely psychical thing any more than it is a purely somatic one. It influences bodily and mental life alike. If in the symptoms of the psychoneuroses we have become acquainted with manifestations of disturbances in the psychical operation of the sexual function, we shall not be surprised to find in the 'actual' neuroses the direct somatic consequences of sexual disturbances.

Clinical medicine has given us a valuable pointer towards an interpretation of these disturbances, and one that has been taken into account by various enquirers. The 'actual' neuroses, in the details of their symptoms and also in their characteristic of influencing every organic system and every function, exhibit an unmistakable resemblance to the pathological states which arise from the chronic influence of external toxic substances and from a sudden withdrawal of them - to intoxications and conditions of abstinence. The two groups of disorders are brought together still more closely by intermediate conditions such as Grave's disease which we have learnt to recognize as equally due to the operation of toxic substances, but of toxins which are not introduced into the body from outside but originate in the subject's own metabolism. In view of these analogies, we cannot, I think, avoid regarding the neuroses as results of disturbances in the sexual metabolism, whether because more of these sexual toxins is produced than the subject can deal with, or whether because internal and even psychical conditions restrict the proper employment of these substances. The popular mind has from time immemorial paid homage to hypotheses of this kind on the nature of sexual desire, speaking of love as an 'intoxication' and believing that falling in love is brought about by love philtres - though here the operative agent is to some extent externalized. And for us this would be an occasion for recalling the erotogenic zones and our assertion that sexual excitation can be generated in the most various organs. But for the rest the phrase 'sexual metabolism' or 'chemistry of sexuality' is a term without content; we know nothing about it and cannot even decide whether we are to assume two sexual substances, which would then be named 'male' and 'female', or whether we could be satisfied with one sexual toxin which we should have to recognize as the vehicle of all the stimulant effects of the libido. The theoretical structure of psycho-analysis that we have created is in truth a superstructure, which will one day have to be set upon its organic foundation. But we are still ignorant of this.

[1916-1917, 3439]
What characterizes psycho-analysis as a science is not the material which it handles but the technique with which it works. It can be applied to the history of civilization, to the science of religion and to mythology, no less than to the theory of the neuroses, without doing violence to its essential nature. What it aims at and achieves is nothing other than the uncovering of what is unconscious in mental life. The problems of the 'actual' neuroses, whose symptoms are probably generated by direct toxic damage, offer psycho-analysis no points of attack. It can do little towards throwing light on them and must leave the task to biologico-medical research.

Nevertheless you will rightly expect that we should devote some interest to the 'actual' neuroses as well. Their intimate clinical connection with the psychoneuroses would alone compel us to do so. I may inform you, then, that we distinguish three pure forms of 'actual' neuroses: neurasthenia, anxiety neurosis and hypochondria. Even this assertion is not contradicted. All the names are in use, it is true, but their content is indefinite and fluctuating. There are even doctors who oppose any dividing lines in the chaotic world of neurotic phenomena, any segregation of clinical entities or individual diseases, and who do not even recognize the distinction between the 'actual' neuroses and the psychoneuroses. I think they are going too far and have not chosen the path which leads to progress. The forms of neurosis which I have mentioned occur occasionally in their pure form; more often, however, they are intermixed with each other and with a psychoneurotic disorder. This need not lead us to abandon the distinction between them. Consider the difference between the study of minerals and of rocks in mineralogy. The minerals are described as individuals, no doubt on the basis of the fact that they often occur as crystals, sharply separated from their environment. Rocks consist of aggregations of minerals, which, we may be sure, have not come together by chance but as a result of what determined their origin. In the theory of the neuroses we still know too little of the course of their development to produce anything resembling petrology. But we are certainly doing the right thing if we start by isolating from the mass the individual clinical entities which we recognize and which are comparable to the minerals.

The fact of there being a connection between sexual restraint and anxiety states is, so far as I know, no longer disputed even by physicians who have no contact with psycho-analysis. But I can well believe that an attempt is made to reverse the relation and to put forward the view that the people concerned are such as are already inclined to apprehensiveness and for that reason practise restraint in sexual matters as well. This, however, is decisively contradicted by the behaviour of women, whose sexual activity is essentially of a passive nature - is determined, that is to say, by their treatment by the man. The more passionate a woman is - the more inclined, therefore, to sexual intercourse and the more capable of being satisfied - the more certain she is to react with manifestations of anxiety to a man’s impotence or to coitus interruptus, whereas in the case of anaesthetic women or those without much libido such ill-treatment plays a far smaller part.
The Aetiological Significance of Sexual Life. - The second novelty which emerged after the hypnotic technique had been replaced by free associations was of a clinical nature. It was discovered in the course of the prolonged search for the traumatic experiences from which hysterical symptoms appeared to be derived. The more carefully the search was pursued the more extensive seemed to be the network of aetiologically significant impressions involved, but the further back, too, did they reach into the patient's puberty or childhood. At the same time they assumed a uniform character and eventually it became inevitable to bow before the evidence and recognize that at the root of the formation of every symptom there were to be found traumatic experiences from early sexual life. Thus a sexual trauma stepped into the place of an ordinary trauma and the latter was seen to owe its aetiological significance to an associative or symbolic connection with the former, which had preceded it. An investigation of cases of common nervousness (falling into the two classes of neurasthenia and anxiety neurosis) which was simultaneously undertaken led to the conclusion that these disorders could be traced to contemporary abuses in the patients' sexual life and could be removed if these were brought to an end. It was thus easy to infer that neuroses in general are an expression of disturbances in sexual life, the so-called actual-neuroses being the consequences (by chemical agency) of contemporary injuries and the psycho-neuroses the consequences (by psychical modification) of bygone injuries to a biological function which had hitherto been gravely neglected by science. None of the theses of psycho-analysis has met with such tenacious scepticism or such embittered resistance as this assertion of the preponderating aetiological significance of sexual life in the neuroses. It should, however, be expressly remarked that, in its development up to the present day, psycho-analysis has found no reason to retreat from this opinion.

[1923a, 3920]

Under the influence of my surprising discovery, I now took a momentous step. I went beyond the domain of hysteria and began to investigate the sexual life of the so-called neurasthenics who used to visit me in numbers during my consultation hours. This experiment cost me, it is true, my popularity as a doctor, but it brought me convictions which to-day, almost thirty years later, have lost none of their force. There was a great deal of equivocation and mystery-making to be overcome, but, once that had been done, it turned out that in all of these patients grave abuses of the sexual function were present. Considering how extremely widespread are these abuses on the one hand and neurasthenia on the other, a frequent coincidence between the two would not have proved much; but there was more in it than that one bald fact. Closer observation suggested to me that it was possible to pick out from the confused jumble of clinical pictures covered by the name of neurasthenia two fundamentally different types, which might appear in any degree of mixture but which were nevertheless to be observed in their pure forms. In the one type the central phenomenon was the anxiety attack with its equivalents, rudimentary forms and chronic substitutive symptoms; I consequently gave it the name of anxiety neurosis, and limited the term neurasthenia to the other type. Now it was easy to establish the fact that each of these types had a different abnormality of sexual life as its corresponding aetiological factor: in the former, coitus interruptus, unconsummated excitation and sexual abstinence, and in the latter, excessive masturbation and too numerous nocturnal emissions. In a few specially instructive cases, which had shown a surprising alteration in the clinical picture from one type to the other, it could be proved that there had been a corresponding change in the underlying sexual régime. If it was possible to put an end to the abuse and allow its place to be taken by normal sexual activity, a striking improvement in the condition was the reward.

[1925d, 4202]
I was thus led into regarding the neuroses as being without exception disturbances of the sexual function, the so-called 'actual neuroses' being the direct toxic expression of such disturbances and the psychoneuroses their mental expression. My medical conscience felt pleased at my having arrived at this conclusion. I hoped that I had filled up a gap in medical science, which, in dealing with a function of such great biological importance, had failed to take into account any injuries beyond those caused by infection or by gross anatomical lesions. The medical aspect of the matter was, moreover, supported by the fact that sexuality was not something purely mental. It had a somatic side as well, and it was possible to assign special chemical processes to it and to attribute sexual excitation to the presence of some particular, though at present unknown, substances. There must also have been some good reason why the true spontaneous neuroses resembled no group of diseases more closely than the phenomena of intoxication and abstinence, which are produced by the administration or privation of certain toxic substances, or than exophthalmic goitre, which is known to depend upon the product of the thyroid gland.
[1925d, 4203]

Since that time I have had no opportunity of returning to the investigation of the 'actual neuroses'; nor has this part of my work been continued by anyone else. If I look back to-day at my early findings, they strike me as being the first rough outlines of what is probably a far more complicated subject. But on the whole they seem to me still to hold good. I should have been very glad if I had been able, later on, to make a psycho-analytic examination of some more cases of simple juvenile neurasthenia, but unluckily the occasion did not arise. To avoid misconceptions, I should like to make it clear that I am far from denying the existence of mental conflicts and of neurotic complexes in neurasthenia. All that I am asserting is that the symptoms of these patients are not mentally determined or removable by analysis, but that they must be regarded as direct toxic consequences of disturbed sexual chemical processes.
[1925d, 4203]

It may be asked how I arrived at this idea of transformation in the first instance. It was while I was studying the 'actual neuroses', at a time when analysis was still a very long way from distinguishing between processes in the ego and processes in the id. I found that outbreaks of anxiety and a general state of preparedness for anxiety were produced by certain sexual practices such as coitus interruptus, undischarged sexual excitation or enforced abstinence - that is, whenever sexual excitation was inhibited, arrested or deflected in its progress towards satisfaction. Since sexual excitation was an expression of libidinal instinctual impulses it did not seem too rash to assume that the libido was turned into anxiety through the agency of these disturbances. The observations which I made at the time still hold good. Moreover, it cannot be denied that the libido belonging to the id-processes is subjected to disturbance at the instigation of repression. It might still be true, therefore, that in repression anxiety is produced from the libidinal cathexis of the instinctual impulses. But how can we reconcile this conclusion with our other conclusion that the anxiety felt in phobias is an ego anxiety and arises in the ego, and that it does not proceed out of repression but, on the contrary, sets repression in motion? There seems to be a contradiction here which it is not at all a simple matter to solve. It will not be easy to reduce the two sources of anxiety to a single one. We might attempt to do so by supposing that, when coitus is disturbed or sexual excitation interrupted or abstinence enforced, the ego scents certain dangers to which it reacts with anxiety. But this takes us nowhere. On the other hand, our analysis of the phobias seems to admit of no correction. Non liquet.
[1926d, 4269]
Furthermore, it is only the sexual aetiology which makes it possible for us to understand all the details of the clinical history of neurasthenics, the mysterious improvements in the middle of the course of the illness and the equally incomprehensible deteriorations, both of which are usually related by doctors and patients to whatever treatment has been adopted. In my records, which include more than two hundred cases, there is, for instance, the story of a man who, when the treatment prescribed by his family physician had done him no good, went to Pastor Kneipp and for a year after being treated by him showed an extraordinary improvement in the middle of his illness. But when, a year later, his symptoms grew worse once more and he again went to Wörishofen for help, the second treatment was unsuccessful. A glance into the patient's family record solved the double riddle. Six and a half months after his first return from Wörishofen his wife bore him a child. This meant that he had left her at the beginning of a pregnancy of which he was not yet aware; after his return he was able to practise natural intercourse with her. At the close of this period, which had a curative effect on him, his neurosis was started up afresh by his once more resorting to coitus interruptus; the second treatment was bound to prove a failure, since this pregnancy of his wife's remained her last. [1897b, 464]

There was a similar case, in which, once again, the treatment had an unexpected effect which called for an explanation. This case turned out to be still more instructive, for it exhibited a puzzling alternation in the symptoms of the neurosis. A young neurotic patient had been sent by his physician to a reputable hydropathic establishment on account of a typical neurasthenia. There his condition steadily improved at first, so that there was every prospect that he would be discharged as a grateful disciple of hydrotherapy. But in the sixth week a complete change occurred; the patient 'could no longer tolerate the water', became more and more nervous, and finally left the establishment after two more weeks, uncured and dissatisfied. When he complained to me about this therapeutic fraud I asked him a few questions about the symptoms which had overtaken him in the middle of the treatment. Curiously enough, a complete change had come over them. He had entered the sanatorium with intracranial pressure, fatigue and dyspepsia; what had troubled him during the treatment were excitement, attacks of dyspnoea, vertigo in walking, and disturbances of sleep. I was now able to say to him: 'You are doing hydrotherapy an injustice. As you yourself very well knew, you fell ill as a result of long-continued masturbation. In the sanatorium you gave up this form of satisfaction, and therefore you quickly recovered. When you felt well, however, you unwisely sought to have relations with a lady - a fellow-patient, let us suppose - which could only lead to excitement without normal satisfaction. The beautiful walks in the neighbourhood of the establishment gave you ample opportunity for this. It was this relationship, not a sudden inability to tolerate hydrotherapy, which caused you to fall ill once more. Moreover, your present state of health leads me to conclude that you are continuing this relationship here in town as well.' I can assure my readers that the patient confirmed what I said, point by point. [1897b, 465]
The present treatment of neurasthenia - which is, perhaps, carried out most successfully in hydropathic establishments - has as its aim the amelioration of the nervous condition by means of two factors: shielding the patient and strengthening him. I have nothing to say against such a method of treatment, except that it takes no account of the circumstances of the patient's sexual life. According to my experience, it is highly desirable that the medical directors of such establishments should become properly aware that they are dealing, not with victims of civilization or heredity, but - *sit venia verbo* - with people who are crippled in sexuality. They would then, on the one hand, be more easily able to account for their successes as well as their failures; and, on the other, they would achieve new successes which, till now, have been at the mercy of chance or of the patient's unguided behaviour. If we take a neurasthenic woman, suffering from anxiety, away from her home and send her to a hydropathic establishment, and if there, freed from all duties, she is made to bathe and take exercise and eat plenty of food, we shall certainly be inclined to think that the improvement - often a brilliant one - which is achieved in a few weeks or months is due to the rest which she has enjoyed and to the invigorating effects of hydrotherapy. That may be so: but we are overlooking the fact that her removal from home also entails an interruption of marital intercourse, and that it is only the temporary elimination of this pathogenic cause which makes it possible for her to recover under favourable treatment. Neglect of this aetiological point of view brings its subsequent revenge, when what seemed such a gratifying cure turns out to be a very transitory one. Soon after the patient has returned to ordinary life the symptoms of the complaint appear once more and oblige him either to spend a part of his existence unproductively from time to time in establishments of this kind or to direct his hopes of recovery elsewhere. It is therefore clear that with neurasthenia the therapeutic problems must be attacked, not in hydropathic institutions but within the framework of the patient's life.

[1897b, 466]
It would be more dignified as well as more helpful to the patient - who, after all, has to come to terms with his ailments - for the doctor to tell the truth, as he knows it from his daily practice. The psychoneuroses as a genus are by no means mild illnesses. When hysteria sets in, no one can foretell when it will come to an end. We mostly comfort ourselves with the vain prophecy that 'one day it will suddenly disappear'. Recovery often enough turns out to be merely an agreement to mutual toleration between the sick part of the patient and the healthy part; or it is the result of the transformation of a symptom into a phobia. A girl's hysteria, calmed down with difficulty, revives in her as a wife after the short interruption of young married happiness. The only difference is that another person, the husband, is now driven by his own interests to keep silence about her condition. Even if an illness of this kind leads to no manifest incapacity on the patients' part to carry on their life, it nearly always prevents free unfolding of their mental powers. Obsessions recur throughout their lives; and phobias and other restrictions upon the will have hitherto been unamenable to treatment of any kind. All this is kept from the knowledge of the layman. The father of a hysterical girl is consequently horrified if, for instance, he is asked to agree to her being given a year's treatment, when she has perhaps only been ill for a few months. The layman is, as it were, deeply convinced in himself that all these psychoneuroses are unnecessary; so he has no patience with the processes of the illness and no readiness to make sacrifices for its treatment. If, in face of a case of typhus which lasts three weeks, or of a broken leg which takes six months to mend, he adopts a more understanding attitude, and if, as soon as his child shows the first signs of a curvature of the spine, he finds it reasonable that orthopaedic treatment should be carried on over several years, the difference in his behaviour is due to the better knowledge on the part of the physicians who pass on their knowledge honestly to the layman. Honesty on the part of the physician and willing acquiescence on the part of the layman will be established for the neuroses too, as soon as an insight into the nature of those affections becomes common property in the medical world. Radical treatment of these disorders will no doubt always require special training and will be incompatible with other kinds of medical activity. On the other hand, this class of physicians, which will, I believe, be a large one in the future, has the prospect of achieving noteworthy results and of obtaining a satisfying insight into the mental life of mankind. [1897b, 475]

A youngish man of university education introduced himself to me with the statement that he had suffered from obsessions ever since his childhood, but with particular intensity for the last four years. The chief features of his disorder were fears that something might happen to two people of whom he was very fond - his father and a lady whom he admired. Besides this he was aware of compulsive impulses - such as an impulse, for instance, to cut his throat with a razor; and further he produced prohibitions, sometimes in connection with quite unimportant things. He had wasted years, he told me, in fighting against these ideas of his, and in this way had lost much ground in the course of his life. He had tried various treatments, but none had been of any use to him except a course of hydrotherapy at a sanatorium near ---; and this, he thought, had probably only been because he had made an acquaintance there which had led to regular sexual intercourse. Here he had no opportunities of the sort, and he seldom had intercourse and only at irregular intervals. He felt disgust at prostitutes. Altogether, he said, his sexual life had been stunted; masturbation had played only a small part in it, in his sixteenth or seventeenth year. His potency was normal; he had first had intercourse at the age of twenty-six. [1909d, 2129]
Under the influence of my surprising discovery, I now took a momentous step. I went beyond the domain of hysteria and began to investigate the sexual life of the so-called neurasthenics who used to visit me in numbers during my consultation hours. This experiment cost me, it is true, my popularity as a doctor, but it brought me convictions which to-day, almost thirty years later, have lost none of their force. There was a great deal of equivocation and mystery-making to be overcome, but, once that had been done, it turned out that in all of these patients grave abuses of the sexual function were present. Considering how extremely widespread are these abuses on the one hand and neurasthenia on the other, a frequent coincidence between the two would not have proved much; but there was more in it than that one bald fact. Closer observation suggested to me that it was possible to pick out from the confused jumble of clinical pictures covered by the name of neurasthenia two fundamentally different types, which might appear in any degree of mixture but which were nevertheless to be observed in their pure forms. In the one type the central phenomenon was the anxiety attack with its equivalents, rudimentary forms and chronic substitutive symptoms; I consequently gave it the name of anxiety neurosis, and limited the term neurasthenia to the other type. Now it was easy to establish the fact that each of these types had a different abnormality of sexual life as its corresponding aetiological factor: in the former, coitus interruptus, unconsummated excitation and sexual abstinence, and in the latter, excessive masturbation and too numerous nocturnal emissions. In a few specially instructive cases, which had shown a surprising alteration in the clinical picture from one type to the other, it could be proved that there had been a corresponding change in the underlying sexual régime. If it was possible to put an end to the abuse and allow its place to be taken by normal sexual activity, a striking improvement in the condition was the reward.

[1925d, 4202]
It is difficult to make any statement of general validity about neurasthenia, so long as we use that name to cover all the things which Beard has included under it. In my opinion, it can be nothing but a gain to neuropathology if we make an attempt to separate from neurasthenia proper all those neurotic disturbances in which, on the one hand, the symptoms are more firmly linked to one another than to the typical symptoms of neurasthenia (such as intracranial pressure, spinal irritation, and dyspepsia with flatulence and constipation); and which, on the other hand, exhibit essential differences in their aetiology and mechanism from the typical neurasthenic neurosis. If we accept this plan, we shall soon obtain a fairly uniform picture of neurasthenia. We shall then be in a position to differentiate from genuine neurasthenia more sharply than has hitherto been possible various pseudo-neurasthenias (such as the clinical picture of the organically determined nasal reflex neurosis, the nervous disorders of the cachexias and arterio-sclerosis, the preliminary stages of general paralysis of the insane, and of some psychoses). Further, it will be possible - as Möbius has proposed - to eliminate some of the status nervosi of hereditarily degenerate individuals; and we shall also discover reasons why a number of neuroses which are to-day described as neurasthenia - in particular, neuroses of an intermittent or periodical nature - ought rather to be included under melancholia. But the most marked change of all will be introduced if we decide to detach from neurasthenia the syndrome which I propose to describe in the following pages and which satisfies especially fully the conditions set out above. The symptoms of this syndrome are clinically much more closely related to one another than to those of genuine neurasthenia (that is, they frequently appear together and they replace one another in the course of the illness); and both the aetiology and the mechanism of this neurosis are fundamentally different from the aetiology and mechanism of genuine neurasthenia as it will be left after this separation has been effected.

In such circumstances it would perhaps be more expedient not to answer critical objections until I had myself expressed my views on this complicated subject in greater detail and had made them more intelligible. Nevertheless, I cannot resist the motives which prompt me to make an immediate answer to a criticism of my theory of anxiety neurosis which has appeared in recent days. I do so because its author, L. Löwenfeld of Munich, the author of Pathologie und Therapie der Neurasthenia, is a man whose judgement undoubtedly carries great weight with the medical public; because of a mistaken view which Löwenfeld's account imputes to me; and finally because I wish to combat at the very start the impression that my theory can be refuted quite so easily by the first objections that come to hand.

(e) There is no doubt that certain nervous disorders can develop in people who are perfectly healthy and whose family is above reproach. This is a matter of daily observation in cases of Beard's neurasthenia; if neurasthenia were restricted to people who were predisposed, it would never have attained the importance and extent with which we are familiar.

As concurrent (or auxiliary) causes of neuroses may be enumerated all the stock agents met with elsewhere: emotional disturbance, physical exhaustion, acute illnesses, intoxications, traumatic accidents, intellectual overwork, etc. I maintain that none of these, not even the last, enters into the aetiology of the neuroses regularly or necessarily, and I am aware that to declare this opinion is to put oneself in direct opposition to a theory which is looked upon as universally accepted and irreproachable. Since Beard declared that neurasthenia was the fruit of our modern civilization, he has only met with believers; but I find it impossible to accept this view. A laborious study of the neuroses has taught me that the specific aetiology of the neuroses has escaped Beard's notice.
Neurasthenia proper, if we detach anxiety neurosis from it, has a very monotonous clinical appearance: fatigue, intracranial pressure, flatulent dyspepsia, constipation, spinal paraesthesias, sexual weakness, etc. The only specific aetiology it allows of is (immoderate) masturbation or spontaneous emissions.

[1896a, 374]

Now the important decision we have to make - and this can be done with certainty in every instance if the symptoms are carefully assessed - is whether the case bears the characteristics of neurasthenia or of a psychoneurosis (hysteria, obsessions). (Mixed cases in which signs of neurasthenia are combined with signs of a psychoneurosis are of very frequent occurrence; but we will leave consideration of them till later.) It is only in neurasthenias that questioning the patient succeeds in disclosing the aetiological factors in his sexual life. These factors are, of course, known to him and belong to the present time, or, more properly, to the period of his life since sexual maturity (though this delimitation does not cover every case). In psychoneuroses questioning of this kind has little result. It may perhaps give us a knowledge of the factors which have to be recognized as precipitating ones, and these may or may not be connected with sexual life. If they are, they show themselves to be no different in kind from the aetiological factors of neurasthenia; that is, they entirely lack any specific relation to the causation of the psychoneurosis. And yet, in every instance, the aetiology of the psychoneuroses, too, lies in the field of sexuality. By a curious circuitous path, of which I shall speak later, it is possible to arrive at a knowledge of this aetiology and to understand why the patient was unable to tell us anything about it. For the events and influences which lie at the root of every psychoneurosis, belong, not to the present day, but to an epoch of life which is long past and which is, as it were, a prehistoric one-to the time of early childhood; and that is why the patient, too, knows nothing of them. He has - though only in a particular sense - forgotten them.

[1897b, 459]

Thus, in every case of neurosis there is a sexual aetiology; but in neurasthenia it is an aetiology of a present-day kind, whereas in the psychoneuroses the factors are of an infantile nature. This is the first great contrast in the aetiology of the neuroses. A second one emerges when we take account of a difference in the symptomatology of neurasthenia itself. Here, on the one hand, we find cases in which certain complaints characteristic of neurasthenia (intracranial pressure, proneness to fatigue, dyspepsia, constipation, spinal irritation, etc.) are prominent; in other cases these signs play a minor part and the clinical picture is composed of other symptoms, all of which exhibit a relation to the nuclear symptom, that of anxiety (free anxiousness, unrest, expectant anxiety, complete, rudimentary or supplementary anxiety attacks, locomotor vertigo, agoraphobia, insomnia, increased sensitivity to pain, and so on). I have left the name of neurasthenia to the first type, but have distinguished the second type as 'anxiety neurosis'; and I have given reasons for this separation in another place, where I have also taken account of the fact that as a rule both neuroses appear together. For the present purpose it is enough to emphasize that parallel to the difference in the symptoms of these two forms of illness there goes a difference in their aetiology. Neurasthenia can always be traced back to a condition of the nervous system such as is acquired by excessive masturbation or arises spontaneously from frequent emissions; anxiety neurosis regularly discloses sexual influences which have in common the factor of reservation or of incomplete satisfaction - such as coitus interruptus, abstinence together with a lively libido, so-called un consummated excitation, and so on. In my short paper intended to introduce anxiety neurosis I put forward the formula that anxiety is always libido which has been deflected from its employment.

[1897b, 460]
If one proceeds in this manner with one's patients, one also gains the conviction that, so far as the theory of the sexual aetiology of neurasthenia is concerned, there are no negative cases. In my mind, at least, the conviction has become so certain that where an interrogation has shown a negative result, I have turned this to account too for diagnostic purposes. I have told myself, that is, that such a case cannot be one of neurasthenia. In this way I have been led in several instances to assume the presence of progressive paralysis instead of neurasthenia, because I had not succeeded in establishing the fact - a fact that was necessary for my theory - that the patient indulged very freely in masturbation; and the further course of those cases later confirmed my view. In another instance the patient, who exhibited no clear organic changes, complained of intracranial pressure, headaches and dyspepsia, but countered my suspicions about his sexual life straightforwardly and with unshaken certainty; and the possibility occurred to me that he might have a latent suppuration in one of his nasal sinuses. A specialist colleague of mine confirmed this inference I had made from the negative sexual results of my interrogation, by removing the pus from the patient's antrum and relieving him of his ailments.

There was a similar case, in which, once again, the treatment had an unexpected effect which called for an explanation. This case turned out to be still more instructive, for it exhibited a puzzling alternation in the symptoms of the neurosis. A young neurotic patient had been sent by his physician to a reputable hydropathic establishment on account of a typical neurasthenia. There his condition steadily improved at first, so that there was every prospect that he would be discharged as a grateful disciple of hydrotherapy. But in the sixth week a complete change occurred; the patient 'could no longer tolerate the water', became more and more nervous, and finally left the establishment after two more weeks, uncured and dissatisfied. When he complained to me about this therapeutic fraud I asked him a few questions about the symptoms which had overtaken him in the middle of the treatment. Curiously enough, a complete change had come over them. He had entered the sanatorium with intracranial pressure, fatigue and dyspepsia; what had troubled him during the treatment were excitement, attacks of dyspnoea, vertigo in walking, and disturbances of sleep. I was now able to say to him: 'You are doing hydrotherapy an injustice. As you yourself very well knew, you fell ill as a result of long-continued masturbation. In the sanatorium you gave up this form of satisfaction, and therefore you quickly recovered. When you felt well, however, you unwisely sought to have relations with a lady - a fellow-patient, let us suppose - which could only lead to excitement without normal satisfaction. The beautiful walks in the neighbourhood of the establishment gave you ample opportunity for this. It was this relationship, not a sudden inability to tolerate hydrotherapy, which caused you to fall ill once more. Moreover, your present state of health leads me to conclude that you are continuing this relationship here in town as well.' I can assure my readers that the patient confirmed what I said, point by point.

On the other hand, he (the patient) was the material which was being used for the analysis (or synthesis). What was in question was the success of the treatment. The reference to his legs in the dream reminded him of an experience of the previous evening. He had been having a dancing-lesson and had met a lady of whom he had been eager to make a conquest. He clasped her to himself so tightly that on one occasion she gave a scream. As he relaxed his pressure against her legs, he felt her strong responsive pressure against the lower part of his thighs as far down as his knees - the point mentioned in his dream. So that in this connection it was the woman who was the magnesium in the retort - things were working at last. He was feminine in relation to me, just as he was masculine in relation to the woman. If it was working with the lady it was working with him in the treatment. His feeling himself and the sensations in his knees pointed to masturbation and fitted in with his fatigue on the previous day. -His appointment with the lady had in fact been for half-past eleven. His wish to miss it by oversleeping and to stay with his sexual objects at home (that is, to keep to masturbation) corresponded to his resistance.
In other cases the motives for forgetting are less easy to discover, and when found arouse greater surprise. Thus, for instance, in former years I noticed that, out of a fairly large number of visits to patients, I only forgot those to non-paying patients or to colleagues. My shame at this discovery led me to adopt the habit of making a note beforehand in the morning of the visits I intended to make during the day. I do not know if other doctors have arrived at the same practice by the same road. But in this way we get some idea of what causes the so called neurasthenic patient to jot down, in his notorious 'notes', the various things he wants to tell the doctor. The ostensible reason is that he has no confidence in the reproductive capacity of his memory. That is perfectly correct, but the scene usually proceeds as follows. The patient has recounted his various complaints and enquiries in a very long-winded manner. After he has finished he pauses for a moment, then pulls out the jottings and adds apologetically: 'I've made some notes, as I can't remember things.' As a rule he finds that they contain nothing new. He repeats each point and answers it himself: 'Yes, I've asked about that already.' With the notes he is probably only demonstrating one of his symptoms: the frequency with which his intentions are disturbed through the interference of obscure motives.

[1901b, 1238]

**PSYCHO-ANALYSIS** An important addition to our knowledge of the sexual instinct in certain people who at least approximate to the normal can be obtained from a source which can only be reached in one particular way. There is only one means of obtaining exhaustive information that will not be misleading about the sexual life of the persons known as 'psychoneurotics' - sufferers from hysteria, from obsessional neurasthenia, from what is wrongly described as neurasthenia, and, undoubtedly, from dementia praecox and paranoia was well. They must be subjected to psycho-analytic investigation, which is employed in the therapeutic procedure introduced by Josef Breuer and myself in 1893 and known at that time as 'catharsis'.

[1905d, 1488]

Medical research has at last shown that people of this kind are not to be looked upon as suffering from a disease of the stomach or of the eyes or whatever it may be, but that it must be a question in their case of an illness of the nervous system as a whole. Examination of the brain and nerves of these patients has so far, however, revealed no perceptible changes; and, indeed, some of the features of their symptomatology prohibit any expectation that even more accurate methods of investigation could ever discover changes of a sort that would throw light upon the illness. This condition has been described as 'nervousness' (neurasthenia or hysteria) and has been characterized as a merely 'functional' disorder of the nervous system.¹ Incidentally, an exhaustive examination of the brain (after the patient's death) has been equally without results in the case of many more permanent nervous disorders, as well as in illnesses with exclusively mental symptoms, such as what are known as obsessions and delusional insanity.

[1890a, 1587]

Binswanger (1896): 'Neurasthenia in particular has been described as an essentially modern disorder, and Beard, to whom we are indebted for a first comprehensive account of it believed that he had discovered a new nervous disease which had developed specifically on American soil. This supposition was of course a mistaken one; nevertheless, the fact that it was an American physician who was first able to grasp and describe the peculiar features of this illness, as the fruit of a wide experience, indicates, no doubt, the close connections which exist between it and modern life, with its unbridled pursuit of money and possessions, and its immense advances in the field of technology which have rendered illusory every obstacle, whether temporal or spatial, to our means of intercommunication.'

[1908d, 1950]
Careful clinical observation allows us to distinguish two groups of nervous disorders: the neuroses proper and the psychoneuroses. In the former the disturbances (the symptoms), whether they show their effects in somatic or mental functioning, appear to be of a toxic nature. They behave exactly like the phenomena accompanying an excess or a deprivation of certain nerve poisons. These neuroses - which are commonly grouped together as 'neurasthenia' - can be induced by certain injurious influences in sexual life, without any hereditary taint being necessarily present; indeed, the form taken by the disease corresponds to the nature of these noxae, so that often enough the particular sexual aetiology can at once be deduced from the clinical picture. There is a total absence, on the other hand, of any such regular correspondence between the form of a nervous illness and the other injurious influences of civilization which are blamed by the authorities. We may, therefore, regard the sexual factor as the essential one in the causation of the neuroses proper.

[1908d, 1950]

Now, however, I must draw your attention to the decisive difference between the symptoms of the 'actual' neuroses and those of the psychoneuroses, the first group of which, the transference neuroses, have occupied us so much hitherto. In both cases the symptoms originate from the libido, and are thus abnormal employments of it, substitutive satisfactions. But the symptoms of the 'actual' neuroses - intracranial pressure, sensations of pain, a state of irritation in an organ, weakening or inhibition of a function - have no 'sense', no psychical meaning. They are not only manifested predominantly in the body (as are hysterical symptoms, for instance, as well), but they are also themselves entirely somatic processes, in the generating of which all the complicated mental mechanisms we have come to know are absent. Thus they really are what psychoneurotic symptoms were so long believed to be. But if so, how can they correspond to employments of the libido, which we have recognized as a force operating in the mind? Well, Gentlemen, that is a very simple matter. Let me remind you of one of the very first objections that were brought up against psycho-analysis. It was said then that it was occupied in finding a purely psychological theory of neurotic phenomena and this was quite hopeless, since psychological theories could never explain an illness. People had chosen to forget that the sexual function is not a purely psychical thing any more than it is a purely somatic one. It influences bodily and mental life alike. If in the symptoms of the psychoneuroses we have become acquainted with manifestations of disturbances in the psychical operation of the sexual function, we shall not be surprised to find in the 'actual' neuroses the direct somatic consequences of sexual disturbances.

[1916-1917, 3439]
Nevertheless you will rightly expect that we should devote some interest to the 'actual' neuroses as well. Their intimate clinical connection with the psychoneuroses would alone compel us to do so. I may inform you, then, that we distinguish three pure forms of 'actual' neuroses: neurasthenia, anxiety neurosis and hypochondria. Even this assertion is not uncontradicted. All the names are in use, it is true, but their content is indefinite and fluctuating. There are even doctors who oppose any dividing lines in the chaotic world of neurotic phenomena, any segregation of clinical entities or individual diseases, and who do not even recognize the distinction between the 'actual' neuroses and the psychoneuroses. I think they are going too far and have not chosen the path which leads to progress. The forms of neurosis which I have mentioned occur occasionally in their pure form; more often, however, they are intermixed with each other and with a psychoneurotic disorder. This need not lead us to abandon the distinction between them. Consider the difference between the study of minerals and of rocks in mineralogy. The minerals are described as individuals, no doubt on the basis of the fact that they often occur as crystals, sharply separated from their environment. Rocks consist of aggregations of minerals, which, we may be sure, have not come together by chance but as a result of what determined their origin. In the theory of the neuroses we still know too little of the course of their development to produce anything resembling petrology. But we are certainly doing the right thing if we start by isolating from the mass the individual clinical entities which we recognize and which are comparable to the minerals.

Under the influence of my surprising discovery, I now took a momentous step. I went beyond the domain of hysteria and began to investigate the sexual life of the so-called neurasthenics who used to visit me in numbers during my consultation hours. This experiment cost me, it is true, my popularity as a doctor, but it brought me convictions which to-day, almost thirty years later, have lost none of their force. There was a great deal of equivocation and mystery-making to be overcome, but, once that had been done, it turned out that in all of these patients grave abuses of the sexual function were present. Considering how extremely widespread are these abuses on the one hand and neurasthenia on the other, a frequent coincidence between the two would not have proved much; but there was more in it than that one bald fact. Closer observation suggested to me that it was possible to pick out from the confused jumble of clinical pictures covered by the name of neurasthenia two fundamentally different types, which might appear in any degree of mixture but which were nevertheless to be observed in their pure forms. In the one type the central phenomenon was the anxiety attack with its equivalents, rudimentary forms and chronic substitutive symptoms; I consequently gave it the name of anxiety neurosis, and limited the term neurasthenia to the other type. Now it was easy to establish the fact that each of these types had a different abnormality of sexual life as its corresponding aetiological factor: in the former, coitus interruptus, unconsummated excitation and sexual abstinence, and in the latter, excessive masturbation and too numerous nocturnal emissions. In a few specially instructive cases, which had shown a surprising alteration in the clinical picture from one type to the other, it could be proved that there had been a corresponding change in the underlying sexual régime. If it was possible to put an end to the abuse and allow its place to be taken by normal sexual activity, a striking improvement in the condition was the reward.
In this manner I found that neurasthenia presented a monotonous clinical picture in which, as my analyses showed, a 'psychical mechanism' played no part. There was a sharp distinction between neurasthenia and 'obsessional neurosis', the neurosis of obsessional ideas proper. In this latter one I was able to recognize a complicated psychical mechanism, an aetiology similar to that of hysteria and an extensive possibility of reducing it by psychotherapy. On the other hand, it seemed to me absolutely necessary to detach from neurasthenia a complex of neurotic symptoms which depend on a quite different and indeed at bottom a contrary aetiology. The component symptoms of this complex are united by a characteristic which has already been recognized by Hecker (1893). For they are either symptoms or equivalents and rudiments of manifestations of anxiety; and for this reason I have given to this complex which is to be detached from neurasthenia the name of 'anxiety neurosis'. I have maintained that it arises from, an accumulation of physical tension, which is itself once more of sexual origin. This neurosis, too, has no psychical mechanism, but it invariably influences mental life, so that 'anxious expectation', phobias, hyperaesthesia to pains, etc., are among its regular manifestations. This anxiety neurosis, in my sense of the term, no doubt coincides in part with the neurosis which, under the name of 'hypochondria', finds a place in not a few descriptions alongside hysteria and neurasthenia. But I cannot regard the delimitation of hypochondria in any of the works in question as being the correct one, and the applicability of its name seems to me to be prejudiced by the fixed connection of that term with the symptom of 'fear of illness'.

(a) People who, as a result of practising masturbation, have become neurasthenics, fall victims to anxiety neurosis as soon as they give up their form of sexual satisfaction. Such people have made themselves particularly incapable of tolerating abstinence.

We can include within the framework of this description of the sexual process not only the aetiology of anxiety neurosis but that of genuine neurasthenia. Neurasthenia develops whenever the adequate unloading (the adequate action) is replaced by a less adequate one - thus, when normal coition, carried out in the most favourable conditions, is replaced by masturbation or spontaneous emission. Anxiety neurosis, on the other hand, is the product of all those factors which prevent the somatic sexual excitation from being worked over psychically. The manifestations of anxiety neurosis appear when the somatic excitation which has been deflected from the psyche is expended subcortically in totally inadequate reactions.
I will now attempt to discover whether the aetiological conditions for anxiety neurosis which I set out above exhibit the common character that I have just attributed to them. The first aetiological factor I postulated for men was intentional abstinence. Abstinence consists in the withholding of the specific action which ordinarily follows upon libido. Such withholding may have two consequences. In the first place, the somatic excitation accumulates; it is then deflected into other paths, which hold out greater promise of discharge than does the path through the psyche. Thus the libido will in the end sink, and the excitation will manifest itself subcortically as anxiety. In the second place, if the libido is not diminished, or if the somatic excitation is expended, by a short cut, in emissions, or if, in consequence of being forced back, the excitation really ceases, then all kinds of things other than an anxiety neurosis will ensue. Abstinence, then, leads to anxiety neurosis in the manner described above. But it is also the operative agent in my second aetiological group, that of unconsummated excitation. My third group, that of coitus reservatus with consideration for the woman, operates by disturbing the man's psychical preparedness for the sexual process, in that it introduces alongside of the task of mastering the sexual affect another psychical task, one of a deflecting sort. In consequence of this psychical deflection, once more, libido gradually disappears, and the further course of things is then the same as in the case of abstinence. Anxiety in senescence (the male climacteric) requires another explanation. Here there is no diminution of libido; but, as in the female climacteric, so great an increase occurs in the production of somatic excitation that the psyche proves relatively insufficient to master it.

The two last aetiological conditions on our list seem to fall into place without difficulty. The tendency to anxiety in masturbators who have become neurasthenic is explained by the fact that it is very easy for them to pass into a state of 'abstinence' after they have been accustomed for so long to discharging even the smallest quantity of somatic excitation, faulty though that discharge is. Finally, the last case, - the generation of anxiety neurosis through severe illness, overwork, exhausting sick-nursing, etc., - finds an easy interpretation when brought into relation with the effects of coitus interruptus. Here the psyche, on account of its deflection, would seem to be no longer capable of mastering the somatic excitation, a task on which, as we know, it is continuously engaged. We are aware to what a low level libido can sink under these conditions; and we have here a good example of a neurosis which, although it exhibits no sexual aetiology, nevertheless exhibits a sexual mechanism.

A multiplicity of aetiological factors such as this, which determine a mixed neurosis, may occur purely fortuitously. For instance, a fresh noxa may add its effects to those of an already existing one. Thus, a woman who has always been hysterical may begin at a certain point in her marriage to experience coitus reservatus; she will then acquire an anxiety neurosis in addition to her hysteria. Or again, a man who has hitherto masturbated and has become neurasthenic, may get engaged and become sexually excited by his fiancée; his neurasthenia will now be joined by a new anxiety neurosis.
In other cases the multiplicity of aetiological factors is by no means fortuitous: one of the factors has brought the other into operation. For example, a woman with whom her husband practises coitus reservatus without regard to her satisfaction may find herself compelled to masturbate in order to put an end to the distressing excitation that follows such an act; as a result, she will produce, not an anxiety neurosis pure and simple, but an anxiety neurosis accompanied by symptoms of neurasthenia. Another woman suffering from the same noxa may have to fight against lascivious images against which she tries to defend herself; and in this way she will, through the coitus interruptus, acquire obsessions as well as an anxiety neurosis. Finally, as a result of coitus interruptus, a third woman may lose her affection for her husband and feel an attraction for another man, which she carefully keeps secret; in consequence, she will exhibit a mixture of anxiety neurosis and hysteria.
[1895b, 348]

Neurasthenia proper, if we detach anxiety neurosis from it, has a very monotonous clinical appearance: fatigue, intracranial pressure, flatulent dyspepsia, constipation, spinal paraesthesias, sexual weakness, etc. The only specific aetiology it allows of is (immoderate) masturbation or spontaneous emissions.
[1896a, 374]

The concurrence of a constant grouping of symptoms with a particular aetiological determinant makes it possible to pick out from the composite province of 'neurasthenia' a syndrome which deserves the name of 'anxiety neurosis', because all of its constituents arise from the symptoms of anxiety. These are either to be regarded as immediate manifestations of anxiety or as rudiments and equivalents of them (E. Hecker), and they are often in complete opposition to the symptoms which constitute neurasthenia proper. The aetiology of the two neuroses also points to an opposition of this kind. Whereas true neurasthenia arises from spontaneous emissions or is acquired through masturbation, the factors belonging to the aetiology of anxiety neurosis are such as correspond to a holding back of sexual excitation - such as abstinence when libido is present, unconsummated excitation and, above all, coitus interruptus. In actual life the neuroses here distinguished usually appear in combination, though pure cases can also be demonstrated. When a mixed neurosis of this kind is subjected to analysis, it is possible to indicate a mixture of several specific aetiologies.
[1897b, 447]
Thus, in every case of neurosis there is a sexual aetiology; but in neurasthenia it is an aetiology of a present-day kind, whereas in the psychoneuroses the factors are of an infantile nature. This is the first great contrast in the aetiology of the neuroses. A second one emerges when we take account of a difference in the symptomatology of neurasthenia itself. Here, on the one hand, we find cases in which certain complaints characteristic of neurasthenia (intracranial pressure, proneness to fatigue, dyspepsia, constipation, spinal irritation, etc.) are prominent; in other cases these signs play a minor part and the clinical picture is composed of other symptoms, all of which exhibit a relation to the nuclear symptom, that of anxiety (free anxiousness, unrest, expectant anxiety, complete, rudimentary or supplementary anxiety attacks, locomotor vertigo, agoraphobia, insomnia, increased sensitivity to pain, and so on). I have left the name of neurasthenia to the first type, but have distinguished the second type as 'anxiety neurosis'; and I have given reasons for this separation in another place, where I have also taken account of the fact that as a rule both neuroses appear together. For the present purpose it is enough to emphasize that parallel to the difference in the symptoms of these two forms of illness there goes a difference in their aetiology. Neurasthenia can always be traced back to a condition of the nervous system such as is acquired by excessive masturbation or arises spontaneously from frequent emissions; anxiety neurosis regularly discloses sexual influences which have in common the factor of reservation or of incomplete satisfaction - such as coitus interruptus, abstinence together with a lively libido, so-called unconsummated excitation, and so on. In my short paper intended to introduce anxiety neurosis I put forward the formula that anxiety is always libido which has been deflected from its employment.

[1897b, 460]

If one proceeds in this manner with one's patients, one also gains the conviction that, so far as the theory of the sexual aetiology of neurasthenia is concerned, there are no negative cases. In my mind, at least, the conviction has become so certain that where an interrogation has shown a negative result, I have turned this to account too for diagnostic purposes. I have told myself, that is, that such a case cannot be one of neurasthenia. In this way I have been led in several instances to assume the presence of progressive paralysis instead of neurasthenia, because I had not succeeded in establishing the fact - a fact that was necessary for my theory - that the patient indulged very freely in masturbation; and the further course of those cases later confirmed my view. In another instance the patient, who exhibited no clear organic changes, complained of intracranial pressure, headaches and dyspepsia, but countered my suspicions about his sexual life straightforwardly and with unshaken certainty; and the possibility occurred to me that he might have a latent supposition in one of his nasal sinuses. A specialist colleague of mine confirmed this inference I had made from the negative sexual results of my interrogation, by removing the pus from the patient's antrum and relieving him of his ailments.

[1897b, 461]
Furthermore, it is only the sexual aetiology which makes it possible for us to understand all the details of the clinical history of neurasthenics, the mysterious improvements in the middle of the course of the illness and the equally incomprehensible deteriorations, both of which are usually related by doctors and patients to whatever treatment has been adopted. In my records, which include more than two hundred cases, there is, for instance, the story of a man who, when the treatment prescribed by his family physician had done him no good, went to Pastor Kneipp and for a year after being treated by him showed an extraordinary improvement in the middle of his illness. But when, a year later, his symptoms grew worse once more and he again went to Wörishofen for help, the second treatment was unsuccessful. A glance into the patient's family record solved the double riddle. Six and a half months after his first return from Wörishofen his wife bore him a child. This meant that he had left her at the beginning of a pregnancy of which he was not yet aware; after his return he was able to practise natural intercourse with her. At the close of this period, which had a curative effect on him, his neurosis was started up afresh by his once more resorting to coitus interruptus; the second treatment was bound to prove a failure, since this pregnancy of his wife's remained her last.

[1897b, 464]

There was a similar case, in which, once again, the treatment had an unexpected effect which called for an explanation. This case turned out to be still more instructive, for it exhibited a puzzling alternation in the symptoms of the neurosis. A young neurotic patient had been sent by his physician to a reputable hydropathic establishment on account of a typical neurasthenia. There his condition steadily improved at first, so that there was every prospect that he would be discharged as a grateful disciple of hydrotherapy. But in the sixth week a complete change occurred; the patient 'could no longer tolerate the water', became more and more nervous, and finally left the establishment after two more weeks, uncured and dissatisfied. When he complained to me about this therapeutic fraud I asked him a few questions about the symptoms which had overtaken him in the middle of the treatment. Curiously enough, a complete change had come over them. He had entered the sanatorium with intracranial pressure, fatigue and dyspepsia; what had troubled him during the treatment were excitement, attacks of dyspnoea, vertigo in walking, and disturbances of sleep. I was now able to say to him: 'You are doing hydrotherapy an injustice. As you yourself very well knew, you fell ill as a result of long-continued masturbation. In the sanatorium you gave up this form of satisfaction, and therefore you quickly recovered. When you felt well, however, you unwisely sought to have relations with a lady - a fellow-patient, let us suppose - which could only lead to excitement without normal satisfaction. The beautiful walks in the neighbourhood of the establishment gave you ample opportunity for this. It was this relationship, not a sudden inability to tolerate hydrotherapy, which caused you to fall ill once more. Moreover, your present state of health leads me to conclude that you are continuing this relationship here in town as well.' I can assure my readers that the patient confirmed what I said, point by point.

[1897b, 465]
The present treatment of neurasthenia - which is, perhaps, carried out most successfully in hydropathic establishments - has as its aim the amelioration of the nervous condition by means of two factors: shielding the patient and strengthening him. I have nothing to say against such a method of treatment, except that it takes no account of the circumstances of the patient's sexual life. According to my experience, it is highly desirable that the medical directors of such establishments should become properly aware that they are dealing, not with victims of civilization or heredity, but - sit venia verbo - with people who are crippled in sexuality. They would then, on the one hand, be more easily able to account for their successes as well as their failures; and, on the other, they would achieve new successes which, till now, have been at the mercy of chance or of the patient's unguided behaviour. If we take a neurasthenic woman, suffering from anxiety, away from her home and send her to a hydropathic establishment, and if there, freed from all duties, she is made to bathe and take exercise and eat plenty of food, we shall certainly be inclined to think that the improvement - often a brilliant one - which is achieved in a few weeks or months is due to the rest which she has enjoyed and to the invigorating effects of hydrotherapy. That may be so: but we are overlooking the fact that her removal from home also entails an interruption of marital intercourse, and that it is only the temporary elimination of this pathogenic cause which makes it possible for her to recover under favourable treatment. Neglect of this aetiological point of view brings its subsequent revenge, when what seemed such a gratifying cure turns out to be a very transitory one. Soon after the patient has returned to ordinary life the symptoms of the complaint appear once more and oblige him either to spend a part of his existence unproductively from time to time in establishments of this kind or to direct his hopes of recovery elsewhere. It is therefore clear that with neurasthenia the therapeutic problems must be attacked, not in hydropathic institutions but within the framework of the patient's life.

[1897b, 466]

In other cases our aetiological theory can help the physician in charge of the institution by throwing light on the source of failures which occur in the institution itself, and can suggest to him means of avoiding them. Masturbation is far commoner among grown-up girls and mature men than is generally supposed, and it has a harmful effect not only by producing neurasthenic symptoms, but also because it keeps the patients under the weight of what they feel to be a disgraceful secret. Physicians who are not accustomed to translate neurasthenia into masturbation account for the patient's pathological state by referring it to some catchword like anaemia, undernourishment, overwork, etc., and then expect to cure him by applying a therapy devised against those conditions. To their astonishment, however, periods of improvement in him alternate with periods in which all his symptoms grow worse and are accompanied by severe depression. The outcome of such a treatment is, in general, doubtful. If physicians knew that all the while the patient was struggling against his sexual habit and that he was in despair because he had once more been obliged to give way to it, if they understood how to win his secret from him, to make it less serious in his eyes and to support him in his fight against the habit, then the success of their therapeutic efforts might in this way well be assured.

[1897b, 467]
This does not exhaust the possibilities which flow from a recognition of the sexual aetiology of the neuroses. The main benefit which we obtain from it for neurasthenics lies in the sphere of prophylaxis. If masturbation is the cause of neurasthenia in youth, and if, later on, it acquires aetiological significance for anxiety neurosis as well, by reason of the reduction of potency which it brings about, then the prevention of masturbation in both sexes is a task that deserves more attention than it has hitherto received. When we reflect upon all the injuries, both the grosser and the finer ones, which proceed from neurasthenia - a disorder which we are told is growing more and more prevalent - we see that it is positively a matter of public interest that men should enter upon sexual relations with full potency. In matters of prophylaxis, however, the individual is relatively helpless. The whole community must become interested in the matter and give their assent to the creation of generally acceptable regulations. At present we are still far removed from such a state of affairs which would promise relief, and it is for this reason that we may with justice regard civilization, too, as responsible for the spread of neurasthenia. Much would have to be changed. The resistance of a generation of physicians who can no longer remember their own youth must be broken down; the pride of fathers, who are unwilling to descend to the level of humanity in their children's eyes, must be overcome; and the unreasonable prudery of mothers must be combated - the mothers who at present look upon it as an incomprehensible and undeserved stroke of fate that 'their children should have been the ones to become neurotic'. But above all, a place must be created in public opinion for the discussion of the problems of sexual life. It will have to become possible to talk about these things without being stamped as a trouble-maker or as a person who makes capital out of the lower instincts. And so here, too, there is enough work left to do for the next hundred years - in which our civilization will have to learn to come to terms with the claims of our sexuality.

On the other hand, he (the patient) was the material which was being used for the analysis (or synthesis). What was in question was the success of the treatment. The reference to his legs in the dream reminded him of an experience of the previous evening. He had been having a dancing-lesson and had met a lady of whom he had been eager to make a conquest. He clasped her to himself so tightly that on one occasion she gave a scream. As he relaxed his pressure against her legs, he felt her strong responsive pressure against the lower part of his thighs as far down as his knees - the point mentioned in his dream. So that in this connection it was the woman who was the magnesium in the retort - things were working at last. He was feminine in relation to me, just as he was masculine in relation to the woman. If it was working with the lady it was working with him in the treatment. His feeling himself and the sensations in his knees pointed to masturbation and fitted in with his fatigue on the previous day. -His appointment with the lady had in fact been for half-past eleven. His wish to miss it by oversleeping and to stay with his sexual objects at home (that is, to keep to masturbation) corresponded to his resistance.
Originally my theory related only to the clinical pictures comprised under the term 'neurasthenia', among which I was particularly struck by two, which occasionally appear as pure types and which I described as 'neurasthenia proper' and 'anxiety neurosis'. It had, to be sure, always been a matter of common knowledge that sexual factors may play a part in the causation of these forms of illness; but those factors were not regarded as invariably operative, nor was there any idea of giving them precedence over other aetiological influences. I was surprised to begin with at the frequency of gross disturbances in the *vita sexualis* of nervous patients; the more I set about looking for such disturbances - bearing in mind the fact that everyone hides the truth in matters of sex - and the more skilful I became at pursuing my enquiries in the face of a preliminary denial, the more regularly was I able to discover pathogenic factors in sexual life, till little seemed to stand in the way of my assuming their universal occurrence. It was necessary, however, to presuppose from the start that sexual irregularities occurred with similar frequency in our ordinary society under the pressure of social conditions; and a doubt might remain as to the degree of deviation from normal sexual functioning which should be regarded as pathogenic. I was therefore obliged to attach less importance to the invariable evidence of sexual noxae than to a second discovery which seemed to me less ambiguous. It emerged that the form taken by the illness - neurasthenia or anxiety neurosis - bore a constant relation to the nature of the sexual noxa involved. In typical cases of neurasthenia a history of regular masturbation or persistent emissions was found; in anxiety neurosis factors appeared such as *coitus interruptus*, 'unconsummated excitation', and other conditions - in all of which there seemed to be the common element of an insufficient discharge of the libido that had been produced. It was only after this discovery, which was easy to make and could be confirmed as often as one liked, that I had the courage to claim a preferential position for sexual influences in the aetiology of the neuroses. Furthermore, in the mixed forms of neurasthenia and anxiety neurosis which are so common it was possible to trace a combination of the aetiologies which I had assumed for the two pure forms. Moreover, this twofold form assumed by the neurosis seemed to tally with the polar (i.e. the masculine and feminine) character of sexuality.

[1906a, 1575]

Careful clinical observation allows us to distinguish two groups of nervous disorders: the *neuroses* proper and the *psychoneuroses*. In the former the disturbances (the symptoms), whether they show their effects in somatic or mental functioning, appear to be of a toxic nature. They behave exactly like the phenomena accompanying an excess or a deprivation of certain nerve poisons. These neuroses - which are commonly grouped together as 'neurasthenia' - can be induced by certain injurious influences in sexual life, without any hereditary taint being necessarily present; indeed, the form taken by the disease corresponds to the nature of these noxae, so that often enough the particular sexual aetiology can at once be deduced from the clinical picture. There is a total absence, on the other hand, of any such regular correspondence between the form of a nervous illness and the other injurious influences of civilization which are blamed by the authorities. We may, therefore, regard the sexual factor as the essential one in the causation of the neuroses proper.

[1908d, 1950]
The retardation of sexual development and sexual activity at which our education and civilization aim is certainly not injurious to begin with. It is seen to be a necessity, when one considers the late age at which young people of the educated classes reach independence and are able to earn a living. (This reminds one, incidentally, of the intimate interconnection between all our cultural institutions and of the difficulty of altering any part of them without regard to the whole.) But abstinence continued long after the age of twenty is no longer unobjectionable for a young man; and it leads to other damage even when it does not lead to neurosis. People say, to be sure, that the struggle against such a powerful instinct, and the strengthening of all the ethical and aesthetic forces which are necessary for this struggle, 'steel' the character; and this is true for a few specially favourably organized natures. It must also be admitted that the differentiation of individual character, which is so marked in our day, has only become possible with the existence of sexual restriction. But in the vast majority of cases the struggle against sexuality eats up the energy available in a character and this at the very time when a young man is in need of all his forces in order to win his share and place in society. The relationship between the amount of sublimation possible and the amount of sexual activity necessary naturally varies very much from person to person and even from one calling to another. An abstinent artist is hardly conceivable; but an abstinent young savant is certainly no rarity. The latter can, by his self-restraint, liberate forces for his studies; while the former probably finds his artistic achievements powerfully stimulated by his sexual experience. In general I have not gained the impression that sexual abstinence helps to bring about energetic and self-reliant men of action or original thinkers or bold emancipators and reformers. Far more often it goes to produce well-behaved weaklings who later become lost in the great mass of people that tends to follow, unwillingly, the leads given by strong individuals.

[1908d, 1958]

All this seems very clear, and yet it must be admitted the there is one factor which often makes it difficult to form a judgement. Some nervous states which we call the 'actual neuroses', such as typical neurasthenia and pure anxiety neurosis, obviously depend on the somatic factor in sexual life, while we have no certain picture as yet of the part played in them by the psychical factor and by repression. In such cases it is natural that the physician should first consider some 'actual' therapy, some alteration in the patient's somatic sexual activity, and he does so with perfect justification if his diagnosis is correct. The lady who consulted the young doctor complained chiefly of anxiety-states, and so he probably assumed that she was suffering from an anxiety neurosis, and felt justified in recommending a somatic therapy to her. Again a convenient misapprehension! A person suffering from anxiety is not for that reason necessarily suffering from anxiety neurosis; such a diagnosis of it cannot be based on the name; one has to know what signs constitute an anxiety neurosis, and be able to distinguish it from other pathological states which are also manifested by anxiety. My impression was that the lady in question was suffering from anxiety hysteria, and the whole value of such nosographical distinctions, one which quite justifies them, lies in the fact that they indicate a different aetiology and a different treatment. No one who took into consideration the possibility of anxiety hysteria in this case would have fallen into the error of neglecting the mental factors, as this physician did with his three alternatives.

[1910k, 2377]
On the question of the relation of masturbation and emissions to the causation of so-called 'neurasthenia', I find myself like many of you, in opposition to Stekel, and, subject to a limitation which I shall mention presently, I maintain, as against him, my former views. I see nothing that could oblige us to abandon the distinction between 'actual neuroses' and psychoneuroses, and I cannot regard the genesis of the symptoms in the case of the former as anything but toxic. Here Stekel really seems to me greatly to overstretch psychogenicity. My view is still what it was in the first instance, more than fifteen years ago: namely, that the two 'actual neuroses' - neurasthenia and anxiety neurosis (and perhaps we ought to add hypochondria proper as a third 'actual neurosis') - provide the psychoneuroses with the necessary 'somatic compliance'; they provide the excitatory material, which is then psychically selected and given a 'psychical coating', so that, speaking generally, the nucleus of the psychoneurotic symptom - the grain of sand at the centre of the pearl - is formed of a somatic sexual manifestation. This is clearer, it is true, of anxiety neurosis and its relation to hysteria than it is of neurasthenia, into which no careful psycho-analytic investigations have yet been made. In anxiety neurosis, as you have often been able to convince yourselves, it is at bottom a small fragment of undischarged excitation connected with coition which emerges as an anxiety symptom or provides the nucleus for the formation of a hysterical symptom.

Let us consider again the outstanding fact that the patient protected herself against her love for a man by means of a paranoid delusion. The key to the understanding of this is to be found in the history of the development of the delusion. As we might have expected, the latter was at first aimed against the woman. But now, on this paranoid basis, the advance from a female to a male object was accomplished. Such an advance is unusual in paranoia; as a rule we find that the victim of persecution remains fixated to the same persons, and therefore to the same sex to which his love-objects belonged before the paranoid transformation took place. But neurotic disorder does not preclude an advance of this kind, and our observation may be typical of many others. There are many similar processes occurring outside paranoia which have not yet been looked at from this point of view, amongst them some which are very familiar. For instance, the so-called neurasthenic's unconscious attachment to incestuous love-objects prevents him from choosing a strange woman as his object and restricts his sexual activity to phantasy. But within the limits of phantasy he achieves the progress which is denied him, and he succeeds in replacing mother and sister by extraneous objects. Since the veto of the censorship does not come into action with these objects, he can become conscious in his phantasies of his choice of these substitute-figures.
But I still owe you further enlightenment, Gentlemen, on my reasons for not starting my account of the theory of the neuroses with the common neurotic state. You may perhaps suppose that it was because in that case I should have had greater difficulty in proving the sexual causation of the neuroses. But you would be wrong there. In the case of the transference neuroses one must work one's way through the interpretation of symptoms before one can arrive at that discovery. In the common forms of what are known as the 'actual neuroses' the aetiological significance of sexual life is a crude fact that springs to the observer's eyes. I came upon it more than twenty years ago when one day I asked myself the question of why in the examination of neurotics their sexual activities were so regularly excluded from consideration. At that time I sacrificed my popularity with my patients for the sake of these enquiries; but after only a brief effort I was able to declare that 'if the \textit{vita sexualis} is normal, there can be no \textit{neurosis} - and by this I meant no 'actual neurosis'. No doubt this statement passes too lightly over people's individual differences; it suffers, too, from the indefiniteness inseparable from the judgement of what is 'normal'. But as a rough guide it retains its value to this day. I had by then reached the point of establishing specific relations between particular forms of neurosis and particular sexual noxae; and I have no doubt that I could repeat the same observations to-day if similar pathological material were still at my disposal. I found often enough that a man who indulged in a certain kind of incomplete sexual satisfaction (for instance, manual masturbation) had fallen ill of a particular form of 'actual neurosis', and that this neurosis promptly gave place to another if he replaced this sexual \textit{régime} by another equally far from being irreproachable. I was then in a position to infer the change in a patient's sexual mode of life from an alteration in his condition. I also learnt then to stand obstinately by my suspicions till I had overcome the patients' disingenuousness and compelled them to confirm my views. It is true that thereafter they preferred to go to other doctors who did not make such keen enquiries about their sexual life.

[1916-1917, 3438]

Now, however, I must draw your attention to the decisive difference between the symptoms of the 'actual' neuroses and those of the psychoneuroses, the first group of which, the transference neuroses, have occupied us so much hitherto. In both cases the symptoms originate from the libido, and are thus abnormal employments of it, substitutive satisfactions. But the symptoms of the 'actual' neuroses - intracranial pressure, sensations of pain, a state of irritation in an organ, weakening or inhibition of a function - have no 'sense', no psychical meaning. They are not only manifested predominantly in the body (as are hysterical symptoms, for instance, as well), but they are also themselves entirely somatic processes, in the generating of which all the complicated mental mechanisms we have come to know are absent. Thus they really are what psychoneurotic symptoms were so long believed to be. But if so, how can they correspond to employments of the libido, which we have recognized as a force operating in the \textit{mind}? Well, Gentlemen, that is a very simple matter. Let me remind you of one of the very first objections that were brought up against psycho-analysis. It was said then that it was occupied in finding a purely psychological theory of neurotic phenomena and this was quite hopeless, since psychological theories could never explain an illness. People had chosen to forget that the sexual function is not a purely psychical thing any more than it is a purely somatic one. It influences bodily and mental life alike. If in the symptoms of the psychoneuroses we have become acquainted with manifestations of disturbances in the \textit{psychical} operation of the sexual function, we shall not be surprised to find in the 'actual' neuroses the direct \textit{somatic} consequences of sexual disturbances.

[1916-1917, 3439]
The Aetiological Significance of Sexual Life. - The second novelty which emerged after the hypnotic technique had been replaced by free associations was of a clinical nature. It was discovered in the course of the prolonged search for the traumatic experiences from which hysterical symptoms appeared to be derived. The more carefully the search was pursued the more extensive seemed to be the network of aetiologically significant impressions involved, but the further back, too, did they reach into the patient's puberty or childhood. At the same time they assumed a uniform character and eventually it became inevitable to bow before the evidence and recognize that at the root of the formation of every symptom there were to be found traumatic experiences from early sexual life. Thus a sexual trauma stepped into the place of an ordinary trauma and the latter was seen to owe its aetiological significance to an associative or symbolic connection with the former, which had preceded it. An investigation of cases of common nervousness (falling into the two classes of neurasthenia and anxiety neurosis) which was simultaneously undertaken led to the conclusion that these disorders could be traced to contemporary abuses in the patients' sexual life and could be removed if these were brought to an end. It was thus easy to infer that neuroses in general are an expression of disturbances in sexual life, the so-called actual-neuroses being the consequences (by chemical agency) of contemporary injuries and the psycho-neuroses the consequences (by psychical modification) of bygone injuries to a biological function which had hitherto been gravely neglected by science. None of the theses of psycho-analysis has met with such tenacious scepticism or such embittered resistance as this assertion of the preponderating aetiological significance of sexual life in the neuroses. It should, however, be expressly remarked that, in its development up to the present day, psycho-analysis has found no reason to retreat from this opinion.

[1923a, 3920]

Under the influence of my surprising discovery, I now took a momentous step. I went beyond the domain of hysteria and began to investigate the sexual life of the so-called neurasthenics who used to visit me in numbers during my consultation hours. This experiment cost me, it is true, my popularity as a doctor, but it brought me convictions which to-day, almost thirty years later, have lost none of their force. There was a great deal of equivocation and mystery-making to be overcome, but, once that had been done, it turned out that in all of these patients grave abuses of the sexual function were present. Considering how extremely widespread are these abuses on the one hand and neurasthenia on the other, a frequent coincidence between the two would not have proved much; but there was more in it than that one bald fact. Closer observation suggested to me that it was possible to pick out from the confused jumble of clinical pictures covered by the name of neurasthenia two fundamentally different types, which might appear in any degree of mixture but which were nevertheless to be observed in their pure forms. In the one type the central phenomenon was the anxiety attack with its equivalents, rudimentary forms and chronic substitutive symptoms; I consequently gave it the name of anxiety neurosis, and limited the term neurasthenia to the other type. Now it was easy to establish the fact that each of these types had a different abnormality of sexual life as its corresponding aetiological factor: in the former, coitus interruptus, unconsummated excitation and sexual abstinence, and in the latter, excessive masturbation and too numerous nocturnal emissions. In a few specially instructive cases, which had shown a surprising alteration in the clinical picture from one type to the other, it could be proved that there had been a corresponding change in the underlying sexual régime. If it was possible to put an end to the abuse and allow its place to be taken by normal sexual activity, a striking improvement in the condition was the reward.

[1925d, 4202]
Since that time I have had no opportunity of returning to the investigation of the 'actual neuroses'; nor has this part of my work been continued by anyone else. If I look back to-day at my early findings, they strike me as being the first rough outlines of what is probably a far more complicated subject. But on the whole they seem to me still to hold good. I should have been very glad if I had been able, later on, to make a psycho-analytic examination of some more cases of simple juvenile neurasthenia, but unluckily the occasion did not arise. To avoid misconceptions, I should like to make it clear that I am far from denying the existence of mental conflicts and of neurotic complexes in neurasthenia. All that I am asserting is that the symptoms of these patients are not mentally determined or removable by analysis, but that they must be regarded as direct toxic consequences of disturbed sexual chemical processes. [1925d, 4203]
People who, as a result of practising masturbation, have become neurasthenics, fall victims to anxiety neurosis as soon as they give up their form of sexual satisfaction. Such people have made themselves particularly incapable of tolerating abstinence.

I may note here, as being important for an understanding of anxiety neurosis, that any pronounced development of that affection only occurs among men who have remained potent and women who are not anaesthetic. Among neurotics whose potency has already been severely damaged by masturbation, the anxiety neurosis resulting from abstinence is very slight and is mostly restricted to hypochondria and mild chronic vertigo. The majority of women, indeed, are to be regarded as 'potent'; a really impotent - i.e. a really anaesthetic - woman is in a similar way little susceptible to anxiety neurosis, and she tolerates the noxae I have described remarkably well.

The two last aetiological conditions on our list seem to fall into place without difficulty. The tendency to anxiety in masturbators who have become neurasthenic is explained by the fact that it is very easy for them to pass into a state of 'abstinence' after they have been accustomed for so long to discharging even the smallest quantity of somatic excitation, faulty though that discharge is. Finally, the last case, - the generation of anxiety neurosis through severe illness, overwork, exhausting sick-nursing, etc., - finds an easy interpretation when brought into relation with the effects of coitus interruptus. Here the psyche, on account of its deflection, would seem to be no longer capable of mastering the somatic excitation, a task on which, as we know, it is continuously engaged. We are aware to what a low level libido can sink under these conditions; and we have here a good example of a neurosis which, although it exhibits no sexual aetiology, nevertheless exhibits a sexual mechanism.

Active masturbation must be excluded from my list of the sexual noxae in early childhood which are pathogenic for hysteria. Although it is found so very often side by side with hysteria, this is due to the circumstance that masturbation itself is a much more frequent consequence of abuse or seduction than is supposed.

In other cases our aetiological theory can help the physician in charge of the institution by throwing light on the source of failures which occur in the institution itself, and can suggest to him means of avoiding them. Masturbation is far commoner among grown-up girls and mature men than is generally supposed, and it has a harmful effect not only by producing neurasthenic symptoms, but also because it keeps the patients under the weight of what they feel to be a disgraceful secret. Physicians who are not accustomed to translate neurasthenia into masturbation account for the patient's pathological state by referring it to some catchword like anaemia, undernourishment, overwork, etc., and then expect to cure him by applying a therapy devised against those conditions. To their astonishment, however, periods of improvement in him alternate with periods in which all his symptoms grow worse and are accompanied by severe depression. The outcome of such a treatment is, in general, doubtful. If physicians knew that all the while the patient was struggling against his sexual habit and that he was in despair because he had once more been obliged to give way to it, if they understood how to win his secret from him, to make it less serious in his eyes and to support him in his fight against the habit, then the success of their therapeutic efforts might in this way well be assured.
To break the patient of the habit of masturbating is only one of the new therapeutic tasks which are imposed on the physician who takes the sexual aetiology of the neurosis into account; and it seems that precisely this task, like the cure of any other addiction, can only be carried out in an institution and under medical supervision. Left to himself, the masturbator is accustomed, whenever something happens that depresses him, to return to his convenient form of satisfaction. Medical treatment, in this instance, can have no other aim than to lead the neurasthenic, who has now recovered his strength, back to normal sexual intercourse. For sexual need, when once it has been aroused and has been satisfied for any length of time, can no longer be silenced; it can only be displaced along another path. Incidentally, the same thing applies to all treatments for breaking an addiction. Their success will only be an apparent one, so long as the physician contents himself with withdrawing the narcotic substance from his patients, without troubling about the source from which their imperative need for it springs. ‘Habit’ is a mere form of words, without any explanatory value. Not everyone who has occasion to take morphia, cocaine, chloral hydrate, and so on, for a period, acquires in this way an ‘addiction’ to them. Closer enquiry usually shows that these narcotics are meant to serve - directly or indirectly - as a substitute for a lack of sexual satisfaction; and whenever normal sexual life can no longer be re-established, we can count with certainty on the patient’s relapse. [1897b, 467]

This does not exhaust the possibilities which flow from a recognition of the sexual aetiology of the neuroses. The main benefit which we obtain from it for neurasthenics lies in the sphere of prophylaxis. If masturbation is the cause of neurasthenia in youth, and if, later on, it acquires aetiological significance for anxiety neurosis as well, by reason of the reduction of potency which it brings about, then the prevention of masturbation in both sexes is a task that deserves more attention than it has hitherto received. When we reflect upon all the injuries, both the grosser and the finer ones, which proceed from neurasthenia - a disorder which we are told is growing more and more prevalent - we see that it is positively a matter of public interest that men should enter upon sexual relations with full potency. In matters of prophylaxis, however, the individual is relatively helpless. The whole community must become interested in the matter and give their assent to the creation of generally acceptable regulations. At present we are still far removed from such a state of affairs which would promise relief, and it is for this reason that we may with justice regard civilization, too, as responsible for the spread of neurasthenia. Much would have to be changed. The resistance of a generation of physicians who can no longer remember their own youth must be broken down; the pride of fathers, who are unwilling to descend to the level of humanity in their children's eyes, must be overcome; and the unreasonable prudery of mothers must be combated - the mothers who at present look upon it as an incomprehensible and undeserved stroke of fate that 'their children should have been the ones to become neurotic'. But above all, a place must be created in public opinion for the discussion of the problems of sexual life. It will have to become possible to talk about these things without being stamped as a trouble-maker or as a person who makes capital out of the lower instincts. And so here, too, there is enough work left to do for the next hundred years - in which our civilization will have to learn to come to terms with the claims of our sexuality. [1897b, 470]

She either failed to hear or did not understand the last word and had to get her husband to give her the necessary explanation. The verse was replaced in the content of the dream by an innocent recollection of some job she had done clumsily when she was at school, and the replacement was made possible owing to the common element of closed shutters. The connection between the topics of masturbation and impotence is obvious enough. The ‘Apollo’ in the latent content of this dream linked it with an earlier one in which the virgin Pallas figured. Altogether far from innocent. [1900a, 673]
One of my patients, a man whose sexual abstinence was imposed on him by a severe neurosis, and whose phantasies were fixed upon his mother, had repeated dreams of going upstairs in her company. I once remarked to him that a moderate amount of masturbation would probably do him less harm than his compulsive self-restraint, and this provoked the following dream:
[1900a, 832]

This was dreamt by a young man who was endeavouring to give up his habit of masturbating in favour of sexual relations with women.
[1900a, 839]

On the other hand, he (the patient) was the material which was being used for the analysis (or synthesis). What was in question was the success of the treatment. The reference to his legs in the dream reminded him of an experience of the previous evening. He had been having a dancing-lesson and had met a lady of whom he had been eager to make a conquest. He clasped her to himself so tightly that on one occasion she gave a scream. As he relaxed his pressure against her legs, he felt her strong responsive pressure against the lower part of his thighs as far down as his knees - the point mentioned in his dream. So that in this connection it was the woman who was the magnesium in the retort - things were working at last. He was feminine in relation to me, just as he was masculine in relation to the woman. If it was working with the lady it was working with him in the treatment. His feeling himself and the sensations in his knees pointed to masturbation and fitted in with his fatigue on the previous day. -His appointment with the lady had in fact been for half-past eleven. His wish to miss it by oversleeping and to stay with his sexual objects at home (that is, to keep to masturbation) corresponded to his resistance.
[1900a, 840]

The meaning of dreams 'with a dental stimulus', which I often had to analyse in patients, escaped me for a long time because, to my surprise, there were invariably too strong resistances against their interpretation. Overwhelming evidence left me at last in no doubt that in males the motive force of these dreams was derived from nothing other than the masturbatory desires of the pubertal period. I will analyse two dreams of this kind, one of which is also a 'flying dream.' They were both dreamt by the same person, a young man with strong homosexual leanings, which were, however, inhibited in real life.
[1900a, 842]
Originally my theory related only to the clinical pictures comprised under the term 'neurasthenia', among which I was particularly struck by two, which occasionally appear as pure types and which I described as 'neurasthenia proper' and 'anxiety neurosis'. It had, to be sure, always been a matter of common knowledge that sexual factors may play a part in the causation of these forms of illness; but those factors were not regarded as invariably operative, nor was there any idea of giving them precedence over other aetiological influences. I was surprised to begin with at the frequency of gross disturbances in the vita sexualis of nervous patients; the more I set about looking for such disturbances - bearing in mind the fact that everyone hides the truth in matters of sex - and the more skilful I became at pursuing my enquiries in the face of a preliminary denial, the more regularly was I able to discover pathogenic factors in sexual life, till little seemed to stand in the way of my assuming their universal occurrence. It was necessary, however, to presuppose from the start that sexual irregularities occurred with similar frequency in our ordinary society under the pressure of social conditions; and a doubt might remain as to the degree of deviation from normal sexual functioning which should be regarded as pathogenic. I was therefore obliged to attach less importance to the invariable evidence of sexual noxae than to a second discovery which seemed to me less ambiguous. It emerged that the form taken by the illness - neurasthenia or anxiety neurosis - bore a constant relation to the nature of the sexual noxa involved. In typical cases of neurasthenia a history of regular masturbation or persistent emissions was found; in anxiety neurosis factors appeared such as coitus interruptus, 'unconsummated excitation', and other conditions - in all of which there seemed to be the common element of an insufficient discharge of the libido that had been produced. It was only after this discovery, which was easy to make and could be confirmed as often as one liked, that I had the courage to claim a preferential position for sexual influences in the aetiology of the neuroses. Furthermore, in the mixed forms of neurasthenia and anxiety neurosis which are so common it was possible to trace a combination of the aetiologies which I had assumed for the two pure forms. Moreover, this twofold form assumed by the neurosis seemed to tally with the polar (i.e. the masculine and feminine) character of sexuality.

Unconscious phantasies have either been unconscious all along and have been formed in the unconscious; or - as is more often the case - they were once conscious phantasies, day-dreams, and have since been purposely forgotten and have become unconscious through 'repression'. Their content may afterwards either have remained the same or have undergone alterations, so that the present unconscious phantasies are derivatives of the once conscious ones. Now an unconscious phantasy has a very important connection with the subject's sexual life; for it is identical with the phantasy which served to give him sexual satisfaction during a period of masturbation. At that time the masturbatory act (in the widest sense of the term) was compounded of two parts. One was the evocation of a phantasy and the other some active behaviour for obtaining self-gratification at the height of the phantasy. This compound, as we know, was itself merely soldered together.¹ Originally the action was a purely auto-erotic procedure for the purpose of obtaining pleasure from some particular part of the body, which could be described as erotogenic. Later, this action became merged with a wishful idea from the sphere of object-love and served as a partial realization of the situation in which the phantasy culminated. When, subsequently, the subject renounces this type of satisfaction, composed of masturbation and phantasy, the action is given up, while the phantasy, from being conscious, becomes unconscious. If no other mode of sexual satisfaction supervenes, the subject remains abstinent; and if he does not succeed in sublimating his libido - that is, in deflecting his sexual excitation to higher aims -, the condition is now fulfilled for his unconscious phantasy to be revived and to proliferate, and, at least as regards some part of its content, to put itself into effect, with the whole force of his need for love, in the form of a pathological symptom.

[1906a, 1575]

[1908a, 1934]
The bisexual nature of hysterical symptoms, which can in any event be demonstrated in numerous cases, is an interesting confirmation of my view that the postulated existence of an innate bisexual disposition in man is especially clearly visible in the analysis of psychoneurotics.² An exactly analogous state of affairs occurs in the same field when a person who is masturbating tries in his conscious phantasies to have the feelings both of the man and of the woman in the situation which he is picturing. Further counterparts are to be found in certain hysterical attacks in which the patient simultaneously plays both parts in the underlying sexual phantasy. In one case which I observed, for instance, the patient pressed her dress up against her body with one hand (as the woman), while she tried to tear it off with the other (as the man). This simultaneity of contradictory actions serves to a large extent to obscure the situation, which is otherwise so plastically portrayed in the attack, and it is thus well suited to conceal the unconscious phantasy that is at work.

[1908a, 1938]

In considering the question of abstinence, the distinction is not nearly strictly enough made between two forms of it - namely abstention from any sexual activity whatever and abstention from sexual intercourse with the opposite sex. Many people who boast of succeeding in being abstinent have only been able to do so with the help of masturbation and similar satisfactions which are linked with the auto-erotic sexual activities of early childhood. But precisely because of this connection such substitutive means of sexual satisfaction are by no means harmless; they predispose to the numerous varieties of neuroses and psychoses which are conditional on an involution of sexual life to its infantile forms. Masturbation, moreover, is far from meeting the ideal demands of civilized sexual morality, and consequently drives young people into the same conflicts with the ideals of education which they hoped to escape by abstinence. Furthermore, it vitiates the character through indulgence, and this in more than one way. In the first place, it teaches people to achieve important aims without taking trouble and by easy paths instead of through an energetic exertion of force - that is, it follows the principle that sexuality lays down the pattern of behaviour; secondly, in the phantasies that accompany satisfaction the sexual object is raised to a degree of excellence which is not easily found again in reality. A witty writer (Karl Kraus in the Vienna paper Die Fackel) once expressed this truth in reverse by cynically remarking: 'Copulation is no more than an unsatisfying substitute for masturbation.'

[1908d, 1960]

All these unavoidable and unintended consequences of the requirement for abstinence converge in the one common result of completely ruin the preparation for marriage - marriage, which civilized sexual morality thinks should be the sole heir to the sexual impulsions. Every man whose libido, as a result of masturbatory or perverse sexual practices, has become habituated to situations and conditions of satisfaction which are not normal, develops diminished potency in marriage. Women, too, who have been able to preserve their virginity with the help of similar measures, show themselves anaesthetic to normal intercourse in marriage. A marriage begun with a reduced capacity to love on both sides succumbs to the process of dissolution even more quickly than others. As a result of the man's weak potency, the woman is not satisfied, and she remains anaesthetic even in cases where her disposition to frigidity, derived from her education, could have been overcome by a powerful sexual experience. A couple like this finds more difficulties, too, in the prevention of children than a healthy one, since the husband's diminished potency tolerates the use of contraceptives badly. In this perplexity, sexual intercourse, as being the source of all their embarrassments, is soon given up, and with this the basis of married life is abandoned.

[1908d, 1961]
There is another point in regard to which we must avoid giving way to this temptation. Hans admitted that every night before going to sleep he amused himself with playing with his penis. 'Ah!' the family doctor will be inclined to say, 'now we have it. The child masturbated; hence his pathological anxiety.' But gently. That the child was getting pleasure for himself by masturbating does not by any means explain his anxiety; on the contrary, it makes it more problematical than ever. States of anxiety are not produced by masturbation or by getting satisfaction in any shape. Moreover, we may presume that Hans, who was now four and three-quarters, had been indulging in this pleasure every evening for at least a year (see p. 2003). And we shall find that at this moment he was actually engaged in a struggle to break himself of the habit - a state of things which fits in much better with repression and the generation of anxiety.

[1909b, 2020]

To this unimpeachable body of evidence we shall be able to add fresh material, if we turn to the history of the masturbatory side of our patient's sexual activities. There is a conflict between the opinions of doctors and patients on this subject which has not hitherto been properly appreciated. The patients are unanimous in their belief that masturbation, by which they mean masturbation during puberty, is the root and origin of all their troubles. The doctors are, upon the whole, unable to decide what line to take; but, influenced by the knowledge that not only neurotics but most normal people pass through a period of masturbation during their puberty, the majority of them are inclined to dismiss the patients' assertions as gross exaggerations. In my opinion the patients are once again nearer to a correct view than the doctors; for the patients have some glimmering notion of the truth, while the doctors are in danger of overlooking an essential point. The thesis propounded by the patients certainly does not correspond to the facts in the sense in which they themselves construe it, namely, that masturbation during puberty (which may almost be described as a typical occurrence) is responsible for all neurotic disturbances. Their thesis requires interpretation. The masturbation of puberty is in fact no more than a revival of the masturbation of infancy, a subject which has hitherto invariably been neglected. Infantile masturbation reaches a kind of climax, as a rule, between the ages of three and four or five; and it is the clearest expression of a child's sexual constitution, in which the aetiology of subsequent neuroses must be sought. In this disguised way, therefore, the patients are putting the blame for their illnesses upon their infantile sexuality; and they are perfectly right in doing so. On the other hand, the problem of masturbation becomes insoluble if we attempt to treat it as a clinical unit, and forget that it can represent the discharge of every variety of sexual component and of every sort of phantasy to which such components can give rise. The injurious effects of masturbation are only in a very small degree autonomous - that is to say, determined by its own nature. They are in substance merely part and parcel of the pathogenic significance of the subject's sexual life as a whole. The fact that so many people can tolerate masturbation - that is, a certain amount of it - without injury merely shows that their sexual constitution and the course of development of their sexual life have been such as to allow them to exercise the sexual function within the limits of what is culturally permissible; whereas other people, because their sexual constitution has been less favourable or their development has been disturbed, fall ill as a result of their sexuality - they cannot, that is, achieve the necessary suppression or sublimation of their sexual components without having recourse to inhibitions or substitutes.¹

[1909d, 2159]
Our present patient's behaviour in the matter of masturbation was most remarkable. He did not practise it during puberty and therefore, according to one set of views, he might have expected to be exempt from neurosis. On the other hand, an impulsion towards masturbatory activities came over him in his twenty-first year, shortly after his father's death. He felt very much ashamed of himself each time he gave way to this kind of gratification, and soon foresaw the habit. From that time onwards it reappeared only upon rare and extraordinary occasions. It was provoked, he told me, when he experienced especially fine moments, or when he read especially fine passages. It occurred once, for instance, on a lovely summer's afternoon when, in the middle of Vienna, he heard a postilion blowing his horn in the most wonderful way - until a policeman stopped him, because blowing horns is not allowed in the centre of the town. And another time it happened when he read in Dichtung und Warheit how the young Goethe had freed himself in a burst of tenderness from the effects of a curse which a jealous mistress had pronounced upon the next woman who should kiss his lips after her; he had long, almost superstitiously, suffered the curse to hold him back, but now he broke his bonds and kissed his love joyfully again and again.

It seemed to the patient not a little strange that he should be impelled to masturbate precisely upon such beautiful and uplifting occasions as these. But I could not help pointing out that these two occasions had something in common - a prohibition, and the defiance of a command.

Starting from these indications and from other data of a similar kind, I ventured to put forward a construction to the effect that when he was a child of under six he had been guilty of some sexual misdemeanour connected with masturbation and had been soundly castigated for it by his father. This punishment, according to my hypothesis, had, it was true, put an end to his masturbating, but on the other hand it had left behind it an ineradicable grudge against his father and had established him for all time in his role of an interferer with the patient's sexual enjoyment.¹ To my great astonishment the patient then informed me that his mother had repeatedly described to him an occurrence of this kind which dated from his earliest childhood and had evidently escaped being forgotten by her on account of its remarkable consequences. He himself, however, had no recollection of it whatever. The tale was as follows. When he was very small - it became possible to establish the date more exactly owing to its having coincided with the fatal illness of an elder sister - he had done something naughty, for which his father had given him a beating. The little boy had flown into a terrible rage and had hurled abuse at his father even while he was under his blows. But as he knew no bad language, he had called him all the names of common objects that he could think of, and had screamed: 'You lamp! You towel! You plate!' and so on. His father, shaken by such an outburst of elemental fury, had stopped beating him, and had declared: 'The child will be either a great man or a great criminal!'² The patient believed that the scene made a permanent impression upon himself as well as upon his father. His father, he said, never beat him again; and he also attributed to this experience a part of the change which came over his own character. From that time forward he was a coward - out of fear of the violence of his own rage. His whole life long, moreover, he was terribly afraid of blows, and used to creep away and hide, filled with terror and indignation, when one of his brothers or sisters was beaten.

[1909d, 2160]
Now that we have gained an insight into this piece of mental development we can no longer regard it as contradictory and incomprehensible that the precondition of the loved one's being like a prostitute should derive directly from the mother complex. The type of male love which we have described bears the traces of this evolution and is simple to understand as a fixation on the phantasies formed by the boy in puberty - phantasies which have later after all found a way out into real life. There is no difficulty in assuming that the masturbation assiduously practised in the years of puberty has played its part in the fixation of the phantasies.

[1910h, 2333]

It has been our purpose on this occasion to show the direction into which the study of the problem of masturbation has been forced by the emergence of the psycho-analytic method of approach. How far we have succeeded in that purpose will appear from our readers' applause, or perhaps still more clearly from their disapproval.

[1912f, 2567]

With your permission I will set before you a summary of the points on which we seem to be agreed or divided.

We are all agreed, I feel, (a) on the importance of the phantasies which accompany or represent the act of masturbation, (b) on the importance of the sense of guilt, whatever its source may be, which is attached to masturbation, and (c) on the impossibility of assigning a qualitative determinant for the injurious effects of masturbation. (On this last point agreement is not unanimous.)

Unresolved differences of opinion have appeared

(a) in respect to a denial of a somatic factor in the effects of masturbation,
(b) in respect to a general denial of the injurious effects of masturbation,
(c) with regard to the origin of the sense of guilt, which some of you wish to attribute directly to lack of satisfaction, while others adduce social factors in addition, or the attitude of the subject's personality at the moment, and
(d) with regard to the ubiquity of masturbation in children.

Lastly, significant uncertainties exist

(a) as to the mechanism of the injurious effects of masturbation, if there are any, and
(b) as to the aetiological relation of masturbation to the 'actual neuroses'.

[1912f, 2568]

I have, as you know, divided masturbation according to the subject's age into (1) masturbation in infants, which includes all auto-erotic activities serving the purpose of sexual satisfaction, (2) masturbation in children, which arises directly out of the preceding kind and has already become fixed to certain erotogenic zones, and (3) masturbation at puberty, which is either continuous with childhood masturbation or is separated from it by the period of latency. In some of the accounts which I have heard you give, full justice has not quite been done to this temporal division. The ostensible unity of masturbation, which is fostered by the customary medical terminology, has given rise to some generalizations where a differentiation according to the three periods of life would have been better justified. It has been a matter for regret, too, that we have not been able to pay as much attention to female as to male masturbation; female masturbation, I believe, is deserving of a special study and in its case it is particularly true that a special emphasis lies on the modifications in it that arise in relation to the subject's age.

[1912f, 2569]
On the question of the relation of masturbation and emissions to the causation of so-called 'neurasthenia', I find myself like many of you, in opposition to Stekel, and, subject to a limitation which I shall mention presently, I maintain, as against him, my former views. I see nothing that could oblige us to abandon the distinction between 'actual neuroses' and psychoneuroses, and I cannot regard the genesis of the symptoms in the case of the former as anything but toxic. Here Stekel really seems to me greatly to overstretch psychogenicity. My view is still what it was in the first instance, more than fifteen years ago: namely, that the two 'actual neuroses' - neurasthenia and anxiety neurosis (and perhaps we ought to add hypochondria proper as a third 'actual neurosis') - provide the psychoneuroses with the necessary 'somatic compliance'; they provide the excitatory material, which is then psychically selected and given a 'psychical coating', so that, speaking generally, the nucleus of the psychoneurotic symptom - the grain of sand at the centre of the pearl - is formed of a somatic sexual manifestation. This is clearer, it is true, of anxiety neurosis and its relation to hysteria than it is of neurasthenia, into which no careful psycho-analytic investigations have yet been made. In anxiety neurosis, as you have often been able to convince yourselves, it is at bottom a small fragment of undischarged excitation connected with coition which emerges as an anxiety symptom or provides the nucleus for the formation of a hysterical symptom.

I am loth to take up a position on the question that has been dealt with by you so extensively of the injuriousness of masturbation, for it offers no proper approach to the problems which concern us. But we must all do so, no doubt: the world seems to feel no other interest in masturbation. You will recall that at our former series of discussions on the subject we had among us as a visitor a distinguished Viennese paediatrician. What was it that he repeatedly asked us to tell him? Simply, how far masturbation is injurious and why it injures some people but not others. So we must force our researches to make a pronouncement to meet this practical demand.
I must confess that here again I am unable to share Stekel's point of view, in spite of the many courageous and correct comments that he has made to us on the question. As he sees it, the injuriousness of masturbation amounts to no more than a senseless prejudice which, purely as a result of personal limitations, we are unwilling to cast off with sufficient thoroughness. I believe, however, that if we fix our eyes on the problem *sine ira et studio*[^1] - so far, of course, as we are able to, - we shall be obliged to declare, rather, that to take up such a position contradicts our fundamental views on the aetiology of the neuroses. Masturbation corresponds essentially to infantile sexual activity and to its subsequent retention at a more mature age. We derive the neuroses from a conflict between a person's sexual urges and his other (ego) trends. Now someone might say: 'In my view the pathogenic factor in this aetiological relation lies solely in the ego's reaction to its sexuality.' By this he would be asserting that anyone could keep free of neurosis if only he were willing to allow unrestricted satisfaction to his sexual urges. But it is clearly arbitrary, and evidently pointless as well, to come to such a decision, and not to allow the sexual urges themselves to have any share in the pathogenic process. But if you admit that the sexual urges can have a pathogenic effect, you should no longer deny a similar significance to masturbation, which after all only consists in carrying out such sexual instinctual impulses. In every case which seems to show that masturbation is pathogenic, you will, no doubt, be able to trace the operation further back - to the instincts which manifest themselves in the masturbation and to the resistances which are directed against those instincts. Masturbation is not anything ultimate - whether somatically or psychologically - it is not a real 'agent', but merely the name for certain activities. Yet, however much we may trace things further back, our judgement on the causation of the illness will nevertheless rightly remain attached to this activity. And do not forget that masturbation is not to be equated with sexual activity in general: it is sexual activity subjected to certain limiting conditions. Thus it also remains possible that it is precisely these peculiarities of masturbatory activity which are the vehicles of its pathogenic effects.

[^1]: 1912f, 2572

We are therefore brought back once more from arguments to clinical observation, and we are warned by it not to strike out the heading 'Injurious Effects of Masturbation'. We are at all events confronted in the neuroses with cases in which masturbation has done damage.

[^1]: 1912f, 2573

We are therefore brought back once more from arguments to clinical observation, and we are warned by it not to strike out the heading 'Injurious Effects of Masturbation'. We are at all events confronted in the neuroses with cases in which masturbation has done damage.
This damage seems to occur in three different ways:

(a) Organic injury may occur by some unknown mechanism. Here we must take into account the considerations of excess and of inadequate satisfaction, which have often been mentioned by you.

(b) The injury may occur through the laying down of a psychical pattern according to which there is no necessity for trying to alter the external world in order to satisfy a great need. Where, however, a far-reaching reaction against this pattern develops, the most valuable character-traits may be initiated.

(c) A fixation of infantile sexual aims may be made possible, and a persistence of psychical infantilism. Here we have the disposition for the occurrence of a neurosis. As psycho-analysts we cannot fail to be greatly interested in this result of masturbation - which in this case means, of course, masturbation occurring at puberty and continued afterwards. We must keep in mind the significance which masturbation acquires as a carrying into effect of phantasy - that half-way region interpolated between life in accordance with the pleasure principle and life in accordance with the reality principle; and we must remember how masturbation makes it possible to bring about sexual developments and sublimations in phantasy, which are nevertheless not advances but injurious compromises - though it is true, as an important remark of Stekel's has pointed out, that this same compromise renders severe perverse inclinations harmless and averts the worst consequences of abstinence.

[1912f, 2573]

And now I am obliged to add a few words on the second of the two painful questions we have been asked. Assuming that masturbation can be injurious, under what conditions and in what people does it prove to be so?

[1912f, 2574]

Allow me, therefore, to proceed with my brief account of infantile sexuality. What I have already reported of two systems of organs might be confirmed in reference to the others. A child's sexual life is indeed made up entirely of the activities of a number of component instincts which seek, independently of one another, to obtain pleasure, in part from the subject's own body and in part already from an external object. Among these organs the genitals come into prominence very soon. There are people in whom obtaining pleasure from their own genitals, without the assistance of any other genitals or of an object, continues uninterruptedly from infantile masturbation to the unavoidable masturbation of puberty and persists for an indefinite length of time afterwards. Incidentally, the topic of masturbation is not one that can be so easily disposed of: it is something that calls for examination from many angles.

[1916-1917, 3386]

We may note too in passing that the analysis of the infantile perversion dealt with here is also of help in solving an old riddle - one which, it is true, has always troubled those who have not accepted psycho-analysis more than analysts themselves. Yet quite recently even Bleuler regarded it as a remarkable and inexplicable fact that neurotics make masturbation the central point of their sense of guilt. We have long assumed that this sense of guilt relates to the masturbation of early childhood and not to that of puberty, and that in the main it is to be connected not with the act of masturbation but with the phantasy which, although unconscious, lies at its root - that is to say, with the Oedipus complex.

[1919e, 3655]
There is yet another surprising effect of penis-envy, or of the discovery of the inferiority of the clitoris, which is undoubtedly the most important of all. In the past I had often formed an impression that in general women tolerate masturbation worse than men, that they more frequently fight against it and that they are unable to make use of it in circumstances in which a man would seize upon it as a way of escape without any hesitation. Experience would no doubt elicit innumerable exceptions to this statement, if we attempted to turn it into a rule. The reactions of human individuals of both sexes are of course made up of masculine and feminine traits. But it appeared to me nevertheless as though masturbation were further removed from the nature of women than of men, and the solution of the problem could be assisted by the reflection that masturbation, at all events of the clitoris, is a masculine activity and that the elimination of clitoral sexuality is a necessary precondition for the development of femininity. Analyses of the remote phallic period have now taught me that in girls, soon after the first signs of penis-envy, an intense current of feeling against masturbation makes its appearance, which cannot be attributed exclusively to the educational influence of those in charge of the child. This impulse is clearly a forerunner of the wave of repression which at puberty will do away with a large amount of the girl's masculine sexuality in order to make room for the development of her femininity. It may happen that this first opposition to auto-erotic activity fails to attain its end. And this was in fact the case in the instances which I analysed. The conflict continued, and both then and later the girl did everything she could to free herself from the compulsion to masturbate. Many of the later manifestations of sexual life in women remain unintelligible unless this powerful motive is recognized.

I cannot explain the opposition which is raised in this way by little girls to phallic masturbation except by supposing that there is some concurrent factor which turns her violently against that pleasurable activity. Such a factor lies close at hand. It cannot be anything else than her narcissistic sense of humiliation which is bound up with penis-envy, the reminder that after all this is a point on which she cannot compete with boys and that it would therefore be best for her to give up the idea of doing so. Thus the little girl's recognition of the anatomical distinction between the sexes forces her away from masculinity and masculine masturbation on to new lines which lead to the development of femininity.
The brilliantly told, faultlessly motivated story is of course complete in itself and is certain to make a deep effect upon the reader. But analysis shows us that its invention is based fundamentally upon a wishful phantasy belonging to the period of puberty, which a number of people actually remember consciously. The phantasy embodies a boy's wish that his mother should herself initiate him into sexual life in order to save him from the dreaded injuries caused by masturbation. (The numerous creative works that deal with the theme of redemption have the same origin.) The 'vice' of masturbation is replaced by the addiction to gambling; and the emphasis laid upon the passionate activity of the hands betrays this derivation. Indeed, the passion for play is an equivalent of the old compulsion to masturbate; 'playing' is the actual word used in the nursery to describe the activity of the hands upon the genitals. The irresistible nature of the temptation, the solemn resolutions, which are nevertheless invariably broken, never to do it again, the stupefying pleasure and the bad conscience which tells the subject that he is ruining himself (committing suicide) - all these elements remain unaltered in the process of substitution. It is true that Zweig's story is told by the mother, not by the son. It must flatter the son to think: 'if my mother only knew what dangers masturbation involves me in, she would certainly save me from them by allowing me to lavish all my tenderness on her own body'. The equation of the mother with a prostitute, which is made by the young man in the story, is linked up with the same phantasy. It brings the unattainable woman within easy reach. The bad conscience which accompanies the phantasy brings about the unhappy ending of the story. It is also interesting to notice how the façade given to the story by its author seeks to disguise its analytic meaning. For it is extremely questionable whether the erotic life of women is dominated by sudden and mysterious impulses. On the contrary, analysis reveals an adequate motivation for the surprising behaviour of this woman who had hitherto turned away from love. Faithful to the memory of her dead husband, she had armed herself against all similar attractions; but - and here the son's phantasy is right - she did not, as a mother, escape her quite unconscious transference of love on to her son, and Fate was able to catch her at this undefended spot.

If the addiction to gambling, with the unsuccessful struggles to break the habit and the opportunities it affords for self-punishment, is a repetition of the compulsion to masturbate, we shall not be surprised to find that it occupied such a large space in Dostoevsky's life. After all, we find no cases of severe neurosis in which the auto-erotic satisfaction of early childhood and of puberty has not played a part; and the relation between efforts to suppress it and fear of the father are too well known to need more than a mention.

. . . I have read your critical review of my Dostoevsky study with great pleasure. All your objections deserve consideration and must be recognized as in a sense apt. I can bring forward a little in my defence. But of course it will not be a question of who is right or who is wrong.

I think you are applying too high a standard to this triviality. It was written as a favour to someone and written reluctantly. I always write reluctantly nowadays. No doubt you noticed this about it. This is not meant, of course, to excuse hasty or false judgements, but merely the careless architecture of the essay as a whole. I cannot dispute the unharmonious effect produced by the addition of the Zweig analysis; but deeper examination will perhaps show some justification for it. If I had not been hampered by considerations of the place where my essay was to appear, I should certainly have written: 'We may expect that in the history of a neurosis accompanied by such a severe sense of guilt a special part will be played by the struggle against masturbation. This expectation is completely fulfilled by Dostoevsky's pathological addiction to gambling. For, as we can see from a short story of Zweig's . . . etc.' That is to say, the amount of space given to the short story corresponds not to the relation: Zweig-Dostoevsky, but to the other one: masturbation-neurosis. All the same, the outcome was clumsy.
You all know the immense aetiological importance attributed by our neurotic patients to their masturbation. They make it responsible for all their troubles and we have the greatest difficulty in persuading them that they are mistaken. In fact, however, we ought to admit to them that they are right, for masturbation is the executive agent of infantile sexuality, from the faulty development of which they are indeed suffering. But what neurotics mostly blame is the masturbation of the period of puberty; they have mostly forgotten that of early infancy, which is what is really in question. I wish I might have an opportunity some time of explaining to you at length how important all the factual details of early masturbation become for the individual’s subsequent neurosis or character: whether or not it was discovered, how the parents struggled against it or permitted it, or whether he succeeded in suppressing it himself. All of this leaves permanent traces on his development. But I am on the whole glad that I need not do this. It would be a hard and tedious task and at the end of it you would put me in an embarrassing situation by quite certainly asking me to give you some practical advice as to how a parent or educator should deal with the masturbation of small children. From the development of girls, which is what my present lecture is concerned with, I can give you the example of a child herself trying to get free from masturbating. She does not always succeed in this. If envy for the penis has provoked a powerful impulse against clitoridial masturbation but this nevertheless refuses to give way, a violent struggle for liberation ensues in which the girl, as it were, herself takes over the role of her deposed mother and gives expression to her entire dissatisfaction with her inferior clitoris in her efforts against obtaining satisfaction from it. Many years later, when her masturbatory activity has long since been suppressed, an interest still persists which we must interpret as a defence against a temptation that is still dreaded. It manifests itself in the emergence of sympathy for those to whom similar difficulties are attributed, it plays a part as a motive in contracting a marriage and, indeed, it may determine the choice of a husband or lover. Disposing of early infantile masturbation is truly no easy or indifferent business.

[1933a, 4729]
I will say finally that the pathogenesis of neurasthenia and anxiety neurosis can easily do without the co-operation of a hereditary disposition. That is the outcome of daily observation. But if heredity is present, the development of the neurosis will be affected by its powerful influence.

[1896a, 375]

The sexual causes, too, are the ones which most readily offer the physician a foothold for his therapeutic influence. Heredity is no doubt an important factor, when it is present; it enables a strong pathological effect to come about where otherwise only a very slight one would have resulted. But heredity is inaccessible to the physician's influence; everyone is born with his own hereditary tendencies to illness, and we can do nothing to change them. Nor should we forget that it is precisely in regard to the aetiology of the neurasthenias that we must necessarily deny the first place to heredity. Neurasthenia (in both its forms) is one of those affections which anyone may easily acquire without having any hereditary taint. If it were otherwise, the enormous increase in neurasthenia, of which all the authorities complain, would be unthinkable. In what concerns civilization, among whose sins people so often include responsibility for neurasthenia, these authorities may indeed be right (although the way in which this comes about is probably quite different from what they imagine). Yet the state of our civilization is, once again, something that is unalterable for the individual. Moreover this factor, being common to all the members of the same society, can never explain the fact of selectivity in the incidence of the illness. The physician who is not neurasthenic is exposed to the same influence of an allegedly detrimental civilization as the neurasthenic patient whom he has to treat. Subject to these limitations, the factors of exhaustion retain their significance. But the element of 'overwork', which physicians are so fond of producing to their patients as the cause of their neurosis, is too often unduly misused. It is quite true that anyone who, owing to sexual noxae, has made himself disposed to neurasthenia, tolerates intellectual work and the psychical exigencies of life badly; but no one ever becomes neurotic through work or excitement alone. Intellectual work is rather a protection against falling ill of neurasthenia; it is precisely the most unremitting intellectual workers who remain exempt from neurasthenia, and what neurasthenics complain of as 'overwork that is making them ill' does not as a rule deserve to be called 'intellectual work' at all, either in its quality or quantity. Physicians will have to become accustomed to explaining to an office-worker who has been 'overworked' at his desk or to a housewife for whom her domestic activities have become too heavy, that they have fallen ill, not because they have tried to carry out duties which are in fact easily performed by a civilized brain, but because all the while they have been grossly neglecting and damaging their sexual life.

[1897b, 463]

Careful clinical observation allows us to distinguish two groups of nervous disorders: the neuroses proper and the psychoneuroses. In the former the disturbances (the symptoms), whether they show their effects in somatic or mental functioning, appear to be of a toxic nature. They behave exactly like the phenomena accompanying an excess or a deprivation of certain nerve poisons. These neuroses - which are commonly grouped together as 'neurasthenia' - can be induced by certain injurious influences in sexual life, without any hereditary taint being necessarily present; indeed, the form taken by the disease corresponds to the nature of these noxae, so that often enough the particular sexual aetiology can at once be deduced from the clinical picture. There is a total absence, on the other hand, of any such regular correspondence between the form of a nervous illness and the other injurious influences of civilization which are blamed by the authorities. We may, therefore, regard the sexual factor as the essential one in the causation of the neuroses proper.

[1908d, 1950]
The behaviour of the gastro-intestinal tract in anxiety neurosis presents a sharp contrast to the influence of neurasthenia on those functions. Mixed cases often show the familiar 'alternation between diarrhoea and constipation'. Analogous to this diarrhoea is the need to urinate that occurs in anxiety neurosis.
[1895b, 335]
As an example of the technique which I have described above of carrying out investigations in non-somnambulistic states - that is, where there is no extension of consciousness - I will describe an instance which I happen to have analysed in the course of the last few days. I was treating a woman of thirty-eight, suffering from anxiety neurosis (agoraphobia, attacks of fear of death, etc.). Like so many such patients, she had a disinclination to admitting that she had acquired these troubles in her married life and would have liked to push them back into her early youth. Thus she told me that she was seventeen when she had had a first attack of dizziness, with anxiety and feelings of faintness, in the street in her small native town, and that these attacks had recurred from time to time, till a few years ago they had given place to her present disorder. I suspected that these first attacks of dizziness, in which the anxiety faded more and more into the background, were hysterical and I made up my mind to embark on an analysis of them. To begin with she only knew that this first attack came over her while the was out shopping in the principal street. 'What were you going to buy?' - 'Different things, I believe; they were for a ball I had been invited to.' - 'When was this ball to take place?' - 'Two days later, I think.' - 'Something must have happened to agitate you a few days before, something that made an impression on you.' - 'I can't think of anything. After all, it was twenty-one years ago.' - 'That makes no difference; you will remember all the same. I shall press on your head, and when I relax the pressure, you will think of something or see something, and you must tell me what that is.' I went through this procedure; but she remained silent. 'Well, has nothing occurred to you?' - 'I have thought of something, but it can't have any connection with this.' - 'Tell it to me anyway.' - 'I thought of a friend of mine, a girl, who is dead. But she died when I was eighteen - a year later, that is.' - 'We shall see. Let's stick to this point. What about this friend of yours?' - 'Her death was a great shock to me, as I used to see a lot of her. A few weeks earlier another girl had died, and that had made a great stir in the town. So after all, I must have been seventeen at the time.' - 'There, you see, I told you we could rely on the things that come into your head under the pressure of my hand. Now, can you remember what you were thinking about when you felt dizzy in the street?' - 'I wasn't thinking of anything; I only felt dizzy.' - 'That's not possible. States like that never happen without being accompanied by some idea. I shall press once more and the thought you had will come back to you.... Well, what has occurred to you?' - 'The idea that I am the third.' - 'What does that mean?' - 'When I got the attack of dizziness I must have thought: "Now I am dying, like the other two girls."' - 'That was the idea, then. As you were having the attack you thought of your friend. So her death must have made a great impression on you.' - 'Yes, it did. I can remember now that when I heard of her death I felt it was dreadful to be going to a ball, while she was dead. But I was looking forward so much to the ball and was so busy with preparations for it; I didn't want to think of what had happened at all.' (We may observe here a deliberate repression from consciousness, which rendered the patient's memory of her friend pathogenic.) [1895d, 100]

'Sit down here. What is it like when you get "out of breath"?'
[1895d, 112]

Was I to make an attempt at an analysis? I could not venture to transplant hypnosis to these altitudes, but perhaps I might succeed with a simple talk. I should have to try a lucky guess. I had found often enough that in girls anxiety was a consequence of the horror by which a virginal mind is overcome when it is faced for the first time with the world of sexuality.¹ [1895d, 113]
I will quote here the case in which I first recognized this causal connection. I was treating a young married woman who was suffering from a complicated neurosis and, once again, was unwilling to admit that her illness arose from her married life. She objected that while she was still a girl she had had attacks of anxiety, ending in fainting fits. I remained firm. When we had come to know each other better she suddenly said to me one day: 'I'll tell you now how I came by my attacks of anxiety when I was a girl. At that time I used to sleep in a room next to my parents; the door was left open and a night-light used to burn on the table. So more than once I saw my father get into bed with my mother and heard sounds that greatly excited me. It was then that my attacks came on.'

In this manner I found that neurasthenia presented a monotonous clinical picture in which, as my analyses showed, a 'psychical mechanism' played no part. There was a sharp distinction between neurasthenia and 'obsessional neurosis', the neurosis of obsessional ideas proper. In this latter one I was able to recognize a complicated psychical mechanism, an aetiology similar to that of hysteria and an extensive possibility of reducing it by psychotherapy. On the other hand, it seemed to me absolutely necessary to detach from neurasthenia a complex of neurotic symptoms which depend on a quite different and indeed at bottom a contrary aetiology. The component symptoms of this complex are united by a characteristic which has already been recognized by Hecker (1893). For they are either symptoms or equivalents and rudiments of manifestations of anxiety; and for this reason I have given to this complex which is to be detached from neurasthenia the name of 'anxiety neurosis'. I have maintained that it arises from, an accumulation of physical tension, which is itself once more of sexual origin. This neurosis, too, has no psychical mechanism, but it invariably influences mental life, so that 'anxious expectation', phobias, hyperaesthesia to pains, etc., are among its regular manifestations. This anxiety neurosis, in my sense of the term, no doubt coincides in part with the neurosis which, under the name of 'hypochondria', finds a place in not a few descriptions alongside hysteria and neurasthenia. But I cannot regard the delimitation of hypochondria in any of the works in question as being the correct one, and the applicability of its name seems to me to be prejudiced by the fixed connection of that term with the symptom of 'fear of illness'.

Breuer's patient, Anna O., seems to contradict my opinion and to be an example of a pure hysterical disorder. This case, however, which has been so fruitful for our knowledge of hysteria, was not considered at all by its observer from the point of view of a sexual neurosis, and is now quite useless for this purpose. When I began to analyse the second patient, Frau Emmy von N., the expectation of a sexual neurosis being the basis of hysteria was fairly remote from my mind. I had come fresh from the school of Charcot, and I regarded the linking of hysteria with the topic of sexuality as a sort of insult - just as the women patients themselves do. When I go through my notes on this case to-day there seems to me no doubt at all that it must be looked on as a case of severe anxiety neurosis accompanied by anxious expectation and phobias - an anxiety neurosis which originated from sexual abstinence and had become combined with hysteria. Case 3, that of Miss Lucy R., can perhaps best be described as a marginal case of pure hysteria. It was a short hysteria which ran an episodic course and had an unmistakable sexual aetiology, such as would correspond to an anxiety neurosis. The patient was an over-mature girl with a need to be loved, whose affections had been too hastily aroused through a misunderstanding. The anxiety neurosis, however, did not become visible, or it escaped me. Case 4, Katharina, was nothing less than a model of what I have described as 'virginal anxiety'. It was a combination of anxiety neurosis and hysteria. The former created the symptoms, while the latter repeated them and operated with them. Incidentally, it was a case typical of a large number of neuroses in young people that are described as 'hysteria'. Case 5, that of Fräulein Elisabeth von R., was once again not investigated as a sexual neurosis. I was only able to express, without confirming it, a suspicion that a spinal neurasthenia may have been its basis.
I hope to be able to demonstrate, on another occasion, that there is reason to distinguish a special neurosis, the 'anxiety neurosis', of which the chief symptom is this emotional state. I shall then enumerate its various symptoms and insist on the necessity for differentiating this neurosis from neurasthenia, with which it is now confused. Phobias, then, are part of the anxiety neurosis, and are almost always accompanied by other symptoms of the same group.

The anxiety neurosis, too, has a sexual origin as far as I can see, but it does not attach itself to ideas taken from sexual life; properly speaking, it has no psychical mechanism. Its specific cause is the accumulation of sexual tension, produced by abstinence or by unconsummated sexual excitation (using the term as a general formula for the effects of, of relative impotence in the husband, of excitation without satisfaction in engaged couples, of enforced abstinence, etc.).

It is under such conditions, extremely frequent in modern society, especially among women, that anxiety neurosis (of which phobias are a psychical manifestation) develops.

I call this syndrome 'anxiety neurosis', because all its components can be grouped round the chief symptom of anxiety, because each one of them has a definite relationship to anxiety. I thought that this view of the symptoms of anxiety neurosis had originated with me, until an interesting paper by E. Hecker (1893) came into my hands, in which I found the same interpretation expounded with all the clarity and completeness that could be desired. Nevertheless, although Hecker recognizes certain symptoms as equivalents or rudiments of an anxiety attack, he does not separate them from the domain of neurasthenia, as I propose to do. But this is evidently due to his not having taken into account the difference between the aetiological determinants in the two cases. When this latter difference is recognized there is no longer any necessity for designating anxiety symptoms by the same name as genuine neurasthenic ones; for the principal purpose of giving what is otherwise an arbitrary name is to make it easier to lay down general statements.

What I call 'anxiety neurosis' may be observed in a completely developed form or in a rudimentary one, in isolation or combined with other neuroses. It is of course the cases which are in some degree complete and at the same time isolated which give particular support to the impression that anxiety neurosis is a clinical entity. In other cases, where the syndrome corresponds to a 'mixed neurosis', we are faced with the task of picking out and separating those symptoms which belong, not to neurasthenia or hysteria, and so on, but to anxiety neurosis.

Anxious expectation, of course, shades off imperceptibly into normal anxiety, comprising all that is ordinarily spoken of as anxiousness - or a tendency to take a pessimistic view of things; but at every opportunity it goes beyond a plausible anxiousness of this kind, and it is frequently recognized by the patient himself as a kind of compulsion. For one form of anxious expectation - that relating to the subject's own health - we may reserve the old term hypochondria. The height reached by the hypochondria is not always parallel with the general anxious expectation; it requires as a precondition the existence of paraesthesias and distressing bodily sensations. Thus hypochondria is the form favoured by genuine neurasthenics when, as often happens, they fall victims to anxiety neurosis.
(3) But anxiousness - which, though mostly latent as regards consciousness, is constantly lurking in the background - has other means of finding expression besides this. It can suddenly break through into consciousness without being aroused by a train of ideas, and thus provoke an anxiety attack. An anxiety attack of this sort may consist of the feeling of anxiety, alone, without any associated idea, or accompanied by the interpretation that is nearest to hand, such as ideas of the extinction of life, or of a stroke, or of a threat of madness; or else some kind of paraesthesia (similar to the hysterical aura) may be combined with the feeling of anxiety, or, finally, the feeling of anxiety may have linked to it a disturbance of one or more of the bodily functions - such as respiration, heart action, vasomotor innervation or glandular activity. From this combination the patient picks out in particular now one, now another, factor. He complains of 'spasms of the heart', 'difficulty in breathing', 'outbreaks of sweating', 'ravenous hunger', and such like; and, in his description, the feeling of anxiety often recedes into the background or is referred to quite unrecognizably as 'being unwell', 'feeling uncomfortable', and so on.

(b) Anxiety attacks accompanied by disturbances of respiration, several forms of nervous dyspnoea, attacks resembling asthma, and the like. I would emphasize that even these attacks are not always accompanied by recognizable anxiety.

Attacks of vertigo are not seldom accompanied by the worst sort of anxiety, often combined with cardiac and respiratory disturbances. According to my observations, vertigo produced by heights, mountains and precipices is also often present in anxiety neurosis. Furthermore, I am not sure whether it is not also right to recognize alongside of this a vertigo a stomache laeso.

(10) Several of the symptoms I have mentioned, which accompany or take the place of an anxiety attack, also appear in a chronic form. In that case they are still less easy to recognize, since the anxious sensation which goes with them is less clear than in an anxiety attack. This is especially true of diarrhoea, vertigo and paraesthesias. Just as an attack of vertigo can be replaced by a fainting fit, so chronic vertigo can be replaced by a constant feeling of great feebleness, lassitude and so on.

In some cases of anxiety neurosis no aetiology at all is to be discovered. It is worth noting that in such cases there is seldom any difficulty in establishing evidence of a grave hereditary taint.

(a) As virginal anxiety or anxiety in adolescents. A number of unambiguous observations have shown me that anxiety neurosis can be produced in girls who are approaching maturity by their first encounter with the problem of sex, by any more or less sudden revelation of what had till then been hidden - for instance, by witnessing the sexual act, or being told or reading about these things. Such an anxiety neurosis is combined with hysteria in an almost typical fashion.

(e) Anxiety neurosis also occurs as anxiety in widows and intentionally abstinent women, not seldom in a typical combination with obsessional ideas; and

(d) Anxiety in senescent men. There are men who have a climacteric like women, and who produce an anxiety neurosis at the time of their decreasing potency and increasing libido.
To this I must reply in the first place that, considering the admittedly enormous frequency of the neuroses and especially of anxiety neurosis, it would certainly not be right to expect to find an aetiological factor for them that is of rare occurrence; in the second place, that a postulate of pathology is in fact satisfied, if in an aetiological investigation it can be shown that the presence of an aetiological factor is more frequent than its effects, since, in order for these latter to occur, other conditions may have to exist in addition (such as disposition, summation of specific aetiological elements, or reinforcement by other stock noxae); and further, that a detailed dissection of suitable cases of anxiety neurosis proves beyond question the importance of the sexual factor. I will confine myself here, however, to the single aetiological factor of coitus interruptus and to bringing out certain observations which confirm it.

Observations of this sort, which can be multiplied at will, positively thrust a sexual aetiology on the doctor for a certain category of cases. And other cases, which would otherwise remain unintelligible, can at least be understood and classified without inconsistency by employing that aetiology as a key. I have in mind those very numerous cases in which, it is true, everything is present that has been found in the previous category - on the one hand the manifestations of anxiety neurosis, and on the other the specific factor of coitus interruptus - but in which something else as well intrudes itself: namely, a long interval between the presumed aetiology and its effects, and also perhaps aetiological factors that are not of a sexual nature. Take, for instance, a man who, on receiving news of his father’s death, had a heart attack and from that moment fell a victim to an anxiety neurosis. The case is not comprehensible, for, till then, the man was not neurotic. The death of his father, who was well advanced in years, did not take place under in any way special circumstances, and it will be admitted that the normal and expected decease of an aged father is not one of those experiences which usually cause a healthy adult to fall ill. Perhaps the aetiological analysis will become clearer if I add that this man had been practising coitus interruptus for eleven years, with due consideration for his wife's satisfaction. The clinical symptoms are, at least, exactly the same as those which appear in other people after only a short sexual noxa of the same kind, and without the interpolation of any other trauma. A similar assessment must be made of the case of a woman whose anxiety neurosis broke out after the loss of her child, or of the student whose preparatory studies for his final examination were interfered with by an anxiety neurosis. I think that in these instances, too, the effect is not explained by the ostensible aetiology. One is not necessarily ‘overworked’ by study, and a healthy mother as a rule reacts only with normal grief to the loss of a child. Above all, however, I should have expected the student, as a result of his overwork, to acquire cephalasthenia, and the mother, as a result of her bereavement, hysteria. That both should have been overtaken by anxiety neurosis leads me to attach importance to the fact that the mother had been living for eight years in conditions of marital coitus interruptus, and that the student had for three years had an ardent love affair with a ‘respectable’ girl whom he had to avoid making pregnant.

The following theoretical discussion can only claim to have the value of a first, groping attempt; criticism of it ought not to affect an acceptance of the facts which have been brought forward above. Moreover, an assessment of this ‘theory of anxiety neurosis’ is made the more difficult from being only a fragment of a more comprehensive account of the neuroses.
What we have so far said about anxiety neurosis already provides a few starting points for gaining an insight into the mechanism of this neurosis. In the first place there was our suspicion that we had to do with an accumulation of excitation; and then there was the extremely important fact that the anxiety which underlies the clinical symptoms of the neurosis can be traced to no psychical origin. Such an origin would exist, for instance, if it was found that the anxiety neurosis was based on a single or repeated justifiable fright, and that that fright had since provided the source for the subject's readiness for anxiety. But this is not so. Hysteria or a traumatic neurosis can be acquired from a single fright, but never anxiety neurosis. Since coitus interruptus takes such a prominent place among the causes of anxiety neurosis, I thought at first that the source of the continuous anxiety might lie in the fear, recurring every time the sexual act was performed, that the technique might go wrong and conception consequently take place. But I have found that this state of feeling, either in the man or the woman, during coitus interruptus has no influence on the generation of anxiety neurosis, that women who are basically indifferent about the consequence of a possible conception are just as liable to the neurosis as those who shudder at the possibility, and that everything depends simply on which partner has forfeited satisfaction in this sexual technique.

We can include within the framework of this description of the sexual process not only the aetiology of anxiety neurosis but that of genuine neurasthenia. Neurasthenia develops whenever the adequate unloading (the adequate action) is replaced by a less adequate one - thus, when normal coition, carried out in the most favourable conditions, is replaced by masturbation or spontaneous emission. Anxiety neurosis, on the other hand, is the product of all those factors which prevent the somatic sexual excitation from being worked over psychically. The manifestations of anxiety neurosis appear when the somatic excitation which has been deflected from the psyche is expended subcortically in totally inadequate reactions.

I will now attempt to discover whether the aetiological conditions for anxiety neurosis which I set out above exhibit the common character that I have just attributed to them. The first aetiological factor I postulated for men was intentional abstinence. Abstinence consists in the withholding of the specific action which ordinarily follows upon libido. Such withholding may have two consequences. In the first place, the somatic excitation accumulates; it is then deflected into other paths, which hold out greater promise of discharge than does the path through the psyche. Thus the libido will in the end sink, and the excitation will manifest itself subcortically as anxiety. In the second place, if the libido is not diminished, or if the somatic excitation is expended, by a short cut, in emissions, or if, in consequence of being forced back, the excitation really ceases, then all kinds of things other than an anxiety neurosis will ensue. Abstinence, then, leads to anxiety neurosis in the manner described above. But it is also the operative agent in my second aetiological group, that of unconsummated excitation. My third group, that of coitus reservatus with consideration for the woman, operates by disturbing the man's psychical preparedness for the sexual process, in that it introduces alongside of the task of mastering the sexual affect another psychical task, one of a deflecting sort. In consequence of this psychical deflection, once more, libido gradually disappears, and the further course of things is then the same as in the case of abstinence. Anxiety in senescence (the male climacteric) requires another explanation. Here there is no diminution of libido; but, as in the female climacteric, so great an increase occurs in the production of somatic excitation that the psyche proves relatively insufficient to master it.
The aetiological conditions applying to women can be brought into the framework of my scheme with no greater difficulties than in the case of men. Virginal anxiety is a particularly clear example. For here the groups of ideas to which the somatic sexual excitation should become attached are not yet enough developed. In the newly-married woman who is anaesthetic, anxiety only appears if the first cohabitations arouse a sufficient amount of somatic excitation. When the local indications of such excitement (spontaneous sensations of stimulation, desire to micturate and so on) are lacking, anxiety is also absent. The case of ejaculatio praecox and of coitus interruptus can be explained on the same lines as in men, namely that the libidinal desire for the psychically unsatisfying act gradually disappears, while the excitation which has been aroused during the act is expended subcortically. The alienation between the somatic and the psychical sphere is established more readily and is more difficult to remove in women than in men. The cases of widowhood and of voluntary abstinence, and also that of the climacteric, are dealt with in the same way in both sexes; but where abstinence is concerned there is in the case of women no doubt the further matter of intentional repression of the sexual circle of ideas, to which an abstinent woman, in her struggle against temptation, must often make up her mind. The horror which, at the time of the menopause, an ageing woman feels at her unduly increased libido may act in a similar sense.

[1895b, 346]

The view here developed depicts the symptoms of anxiety neurosis as being in a sense surrogates of the omitted specific action following on sexual excitation. In further support of this view, I may point out that in normal copulation too the excitation expends itself, among other things, in accelerated breathing, palpitation, sweating, congestion, and so on. In the corresponding anxiety attacks of our neurosis we have before us the dyspnoea, palpitations, etc. of copulation in an isolated and exaggerated form.

[1895b, 347]

The purest cases of anxiety neurosis are usually the most marked. They are found in sexually potent youthful individuals, with an undivided aetiology, and an illness that is not of too long standing.

[1895b, 348]

A multiplicity of aetiological factors such as this, which determine a mixed neurosis, may occur purely fortuitously. For instance, a fresh noxa may add its effects to those of an already existing one. Thus, a woman who has always been hysterical may begin at a certain point in her marriage to experience coitus reservatus; she will then acquire an anxiety neurosis in addition to her hysteria. Or again, a man who has hitherto masturbated and has become neurasthenic, may get engaged and become sexually excited by his fiancée; his neurasthenia will now be joined by a new anxiety neurosis.

[1895b, 348]

In other cases the multiplicity of aetiological factors is by no means fortuitous: one of the factors has brought the other into operation. For example, a woman with whom her husband practises coitus reservatus without regard to her satisfaction may find herself compelled to masturbate in order to put an end to the distressing excitation that follows such an act; as a result, she will produce, not an anxiety neurosis pure and simple, but an anxiety neurosis accompanied by symptoms of neurasthenia. Another woman suffering from the same noxa may have to fight against lascivious images against which she tries to defend herself; and in this way she will, through the coitus interruptus, acquire obsessions as well as an anxiety neurosis. Finally, as a result of coitus interruptus, a third woman may lose her affection for her husband and feel an attraction for another man, which she carefully keeps secret; in consequence, she will exhibit a mixture of anxiety neurosis and hysteria.

[1895b, 348]
In a third category of mixed neuroses the interconnection between the symptoms is still more intimate, in that the same aetiological determinant regularly and simultaneously provokes both neuroses. Thus, for instance, the sudden sexual enlightenment, which we have found present in virginal anxiety, always gives rise to hysteria as well; by far the majority of cases of intentional abstinence become linked from the beginning with true obsessional ideas; coitus interruptus in men never seems to me to be able to provoke a pure anxiety neurosis, but always a mixture of it with neurasthenia.

The symptomatology of hysteria and anxiety neurosis show many points in common which have not yet been sufficiently considered. The appearance of symptoms either in a chronic form or in attacks, the paraesthesias, grouped like aurae, the hyperaesthesias and pressure-points which are found in certain surrogates of an anxiety attack (in dyspnoea and heart-attacks), the intensification, through conversion, of pains which perhaps have an organic justification - these and other features which the two illnesses have in common even allow of a suspicion that not a little of what is attributed to hysteria might with more justice be put to the account of anxiety neurosis. If one goes into the mechanism of the two neuroses, so far as it has been possible to discover it hitherto, aspects come to light which suggest that anxiety neurosis is actually the somatic counterpart to hysteria. In the latter just as in the former there is an accumulation of excitation (which is perhaps the basis for the similarity between their symptoms we have mentioned). In the latter just as in the former we find a psychical insufficiency, as a consequence of which abnormal somatic processes arise. In the latter just as in the former, too, instead of a psychical working-over of the excitation, a deflection of it occurs into the somatic field; the difference is merely that in anxiety neurosis the excitation, in whose displacement the neurosis expresses itself, is purely somatic (somatic sexual excitation), whereas in hysteria it is psychical (provoked by conflict). Thus it is not to be wondered at that hysteria and anxiety neurosis regularly combine with each other, as is seen in 'virginal anxiety' or in 'sexual hysteria', and that hysteria simply borrows a number of its symptoms from anxiety neurosis, and so on. These intimate relations which anxiety neurosis has with hysteria provide a fresh argument, moreover, for insisting on the detachment of anxiety neurosis from neurasthenia; for if this detachment is not granted, we shall also be unable any longer to maintain the distinction which has been acquired with so much labour and which is so indispensable for the theory of the neuroses, between neurasthenia and hysteria.
In the second number of Mendel's *Neurologisches Zentralblatt* for 1895, I published a short paper in which I ventured an attempt to detach a number of nervous states from neurasthenia and to establish them as an independent entity under the name of 'anxiety neurosis'.¹ I was led to do so by the presence of a constant conjunction of certain clinical features with certain aetiological ones - a thing which, in general, should permit us to make a separation of this kind. I found - and in this Hecker (1893) had anticipated me - that the neurotic symptoms in question could all be classed together as constituting expressions of anxiety; and, from my study of the aetiology of the neuroses, I was able to add that these portions of the complex of the 'anxiety neurosis' exhibit special aetiological preconditions which are almost the opposite of the aetiology of neurasthenia. My observations had shown me that in the aetiology of the neuroses (at all events of *acquired* cases and *acquirable* forms) sexual factors play a predominant part and one which has been given far too little weight; so that a statement such as that 'the aetiology of the neuroses lies in sexuality', with all its unavoidable incorrectness *per excessum et defectum*, nevertheless comes nearer to the truth than do the other doctrines, which hold the field at the present time. A further assertion which my observations forced me to make was to the effect that the various sexual noxae are not to be found in the aetiology of every neurosis indifferently, but that unmistakable special relationships hold between particular noxae and particular neuroses. Thus I could assume that I had discovered the specific causes of the various neuroses. I then sought to formulate shortly the special character of the sexual noxae which constitute the aetiology of anxiety neurosis, and, on the basis of my view of the sexual process (p. 108), I arrived at the proposition: anxiety neurosis is created by everything which keeps somatic sexual tension away from the psychical sphere, which interferes with its being worked over psychically. If we go back to the concrete circumstances in which this factor becomes operative, we are led to assert that abstinence, whether voluntary or involuntary, sexual intercourse with incomplete satisfaction, coitus interruptus, deflection of psychical interest from sexuality, and similar things, are the specific aetiological factors of the states to which I have given the name of anxiety neurosis.

With an unerring eye Löwenfeld (1895) detects the essential feature of my paper - namely, my assertion that anxiety-symptoms have a specific and uniform aetiology of a sexual nature. If this cannot be established as a fact, then the main reason for detaching an independent anxiety neurosis from neurasthenia disappears as well. There remains, it is true, one difficulty to which I called attention - the fact that anxiety-symptoms also have such very unmistakable connections with hysteria, so that a decision on Löwenfeld's lines would prejudice the separation between hysteria and neurasthenia. This difficulty, however, is met by a recourse to heredity as the common cause of all these neuroses (a view which I will go into later).

(1) I emphasized as a point essential to an understanding of anxiety neurosis that the anxiety appearing in it does not admit of a psychical derivation - that is to say that the preparedness for anxiety, which constitutes the nucleus of the neurosis, cannot be acquired by a single or repeated affect of psychically justified fright. Fright, I maintained, might result in hysteria or a traumatic neurosis, but not in an anxiety neurosis. This denial, it is easy to see, is nothing else than the counterpart to my contention, on the positive side, that the anxiety appearing in my neurosis corresponds to a somatic sexual tension which has been deflected from the psychical field - a tension which would otherwise have made itself felt as libido.
Against this, Löwenfeld insists on the fact that in a number of cases 'states of anxiety appear immediately or shortly after a psychical shock (fright alone, or accidents which were accompanied by fright), and in such situations there are sometimes circumstances which make the simultaneous operation of sexual noxae of the kind mentioned extremely improbable.' He gives, shortly, as a particularly pregnant example, one clinical observation (to serve instead of many). This example concerns a woman of thirty, with a hereditary taint, who had been married for four years and who had had a first, difficult, confinement a year before. A few weeks after this event her husband had an attack of illness which frightened her, and in her agitation she ran about the cold room in her chemise. From that time on she was ill. First she had states of anxiety and palpitations in the evening, then came attacks of convulsive trembling, and after that phobias, and so on. It was the picture of a fully-developed anxiety neurosis. 'Here,' concludes Löwenfeld, 'the anxiety states are obviously of psychical origin, brought about by the single fright.'

So it was with my cases of anxiety neurosis. Let us take the man who, after receiving the news of his father's death, fell ill so inexplicably. (I add 'inexplicably' because the death was not unexpected and did not occur in unusual or shattering circumstances.) This man had carried out coitus interruptus for eleven years with his wife, whom he tried for the most part to satisfy. Again, the young man who was not equal to the quarrels between his wife and his mother, had practised withdrawal with his young wife from the first, in order to spare himself the burden of children. Then we have the student who acquired an anxiety neurosis from overwork, instead of the cerebral neurasthenia that was to be expected: he had maintained a relationship for three years with a girl whom it was not permissible for him to make pregnant. Again, there was the woman who, childless herself, was overtaken by an anxiety neurosis about a niece's illness: she was married to an impotent man and had never been sexually satisfied. And so on. Not all these cases are equally clear or equally good evidence for my thesis; but when I add them to the very considerable number of cases in which the aetiology shows nothing but the specific factor, they fit without contradiction into the theory I have put forward and they allow of an extension of our aetiological understanding beyond the boundaries hitherto in force.

[1895f, 355]
If anyone wants to prove to me that in these remarks I have unduly neglected the significance of the stock aetiological factors, he must confront me with observations in which my specific factor is missing - that is, with cases in which anxiety neurosis has arisen after a psychical shock although the subject has (on the whole) led a normal vita sexualis. Let us see now whether Löwenfeld's case fulfils this condition. My respected opponent has evidently not been clear about this necessity in his own mind, otherwise he would not have left us so completely in the dark about his patient's vita sexualis. I will leave on one side the fact that this case of a lady of thirty is obviously complicated by a hysteria as to the psychical origin of which I have not the least doubt; and I naturally admit without raising any objection the presence of an anxiety neurosis alongside of this hysteria. But before I turn a case to account for or against the theory of the sexual aetiology of the neuroses, I must first have studied the patient's sexual behaviour more closely than Löwenfeld has done here. I should not be content to conclude that, because the time at which the lady received her psychical shock was shortly after a confinement, coitus interruptus could not have played a part during the previous year, and that therefore sexual noxae are ruled out. I know cases of women who were made pregnant every year, and who yet had anxiety neurosis, because - incredible as it may seem - all sexual relations were stopped after the first fertilizing coition, so that in spite of having many children they suffered from sexual privation through all these years. No doctor is ignorant of the fact that women conceive from men whose potency is very slight and who are not able to give them satisfaction. Finally (and this is a consideration which should be taken into account precisely by the upholders of a hereditary aetiology), there are plenty of women who are afflicted with congenital anxiety neurosis - that is to say, who inherit, or who develop without any demonstrable disturbance from outside, a vita sexualis which is the same as the one usually acquired through coitus interruptus and similar noxae. In a number of these women we are able to discover a hysterical illness in their youth, since which their vita sexualis has been disturbed and a deflection of sexual tension from the psychical sphere has been established. Women with this kind of sexuality are incapable of obtaining real satisfaction even from normal coitus, and they develop anxiety neurosis either spontaneously or after further operative factors have supervened. Which of all these elements were present in Löwenfeld's case? I do not know. But I repeat: this case is evidence against me only if the lady who responded to a single fright with an anxiety neurosis had before then enjoyed a normal vita sexualis.

[1895f, 357]
I, too, have made exactly the same observation, without, however, being misled by it. I myself have caused anxiety attacks to disappear by means of psychical treatment, improvement of the patient's general health, and so on; but I have naturally not concluded from this that what had caused the anxiety attack was a lack of treatment. Not that I should like to foist a conclusion of this sort upon Löwenfeld. My joking remark is only intended to show that the state of affairs may easily be complicated enough to render Löwenfeld's objection quite invalid. I have not found it difficult to reconcile the fact brought forward here with my assertion that anxiety neurosis has a specific aetiology. It will readily be granted that there are aetiological factors which, in order to exercise their effect, must operate with a certain intensity (or quantity) and over a certain period of time - which, that is to say, become summated. The effects of alcohol are a standard example of causation like this through summation. It follows that there must be a period of time in which the specific aetiology is at work but in which its effect is not yet manifest. During this time the subject is not ill as yet, but he is predisposed to a particular illness - in our case, to anxiety neurosis - and now the addition of a stock noxa will be able to set the neurosis off, just as would a further intensification of the operation of the specific noxa. The situation may also be expressed as follows: it is not enough for the specific noxa to be present; it must also reach a definite amount; and, in the process of reaching that limit, a quantity of specific noxa can be replaced by a quota of stock noxa. If the latter is removed once more, we find ourselves below a certain threshold and the clinical symptoms depart once more. The whole therapy of the neuroses rests upon the fact that the total load upon the nervous system, to which it has succumbed, can be brought below this threshold by influencing the aetiological mixture in a great variety of ways. From these circumstances we can draw no conclusion as to the existence or non-existence of a specific aetiology. These considerations are surely indisputable and assured. But anyone who does not think them sufficient may be influenced by the following argument. According to the views of Löwenfeld and very many others, the aetiology of anxiety states is to be found in heredity. Now heredity is certainly immune to alteration; thus if anxiety neurosis is curable by treatment, we should have to conclude according to Löwenfeld's argument that its aetiology cannot reside in heredity.

For the rest, I might have been spared having to defend myself against these two objections of Löwenfeld's, if my respected opponent had paid greater attention to my paper itself. In it, both these objections are anticipated and answered. I have only been able to repeat here what I said there; and I have even purposely analysed the same cases over again. Moreover the aetiological formulas on which I have just laid weight are contained in the text of my paper. I will repeat them once more. I maintain that there exists a specific aetiological factor for anxiety neurosis which can be replaced in its operation by stock noxae in a QUANTITATIVE sense, but not in a QUALITATIVE one; I furthermore maintain that this specific factor determines above all the FORM of the neurosis; whether a neurotic illness occurs at all depends on the total load upon the nervous system (in proportion to its capacity to carry the load). As a rule the neuroses are overdetermined; that is to say, several factors operate together in their aetiology.
Against Löwenfeld's further assertion - that anxiety-states only appear under certain conditions and fail to appear when those conditions are avoided, regardless of what the subject's vita sexualis may be - it must be pointed out that he clearly has in mind here only the anxiety of phobias, as, indeed, is shown by the examples attached to the passage I have quoted. He says nothing at all about the spontaneous anxiety attacks which take the form of vertigo, palpitation, dyspnoea, trembling, sweating, and so on. My theory, on the contrary, seems by no means unequal to explaining the emergence or non-emergence of these attacks of anxiety. For in a whole number of such cases of anxiety neurosis there does in fact appear to be a periodicity in the emergence of the states of anxiety, similar to what has been observed in epilepsy, except that in the latter the mechanism of the periodicity is more transparent. On closer examination we discover the presence, with great regularity, of an excitatory sexual process (that is, a process which is able to generate somatic sexual tension), and which, after the lapse of a definite and often constant interval of time, is followed by the anxiety attack. This role is played, in abstinent women, by menstrual excitation; it is played, too, by nocturnal pollutions, which also recur periodically. Above all, it is played by sexual intercourse itself (harmful from its being incomplete), which carries over its own periodicity to the effects it brings about, viz. to the anxiety attacks. If anxiety attacks occur which break through the usual periodicity, it is generally possible to trace them back to an incidental cause of rare and irregular occurrence - to a single sexual experience, something read or seen, and the like. The interval I have mentioned varies from a few hours to two days; it is the same as that which elapses in other people between the occurrence of the same causes and the onset of the well-known sexual migraine, which has well-established connections with the syndrome of anxiety neurosis.

Besides this, there are plenty of cases in which a single anxiety-state is provoked by the extra addition of a stock factor, by an excitement of some kind or other. The same holds good, therefore, for the aetiology of the individual anxiety attack as for the causation of the whole neurosis. It is not very strange that the anxiety of the phobias should obey different conditions; they have a more complicated structure than purely somatic anxiety attacks. In phobias the anxiety is linked to a definite ideational or perceptual content, and the arousal of this psychical content is the chief condition for the emergence of the anxiety. When this happens, anxiety is 'generated', just as for instance sexual tension is generated by the arousal of libidinal ideas. The connection of this process, however, with the theory of anxiety neurosis has not yet been elucidated.

I see no reason why I should try to hide the gaps and weaknesses in my theory. The main thing about the problem of the phobias seems to me to be that when the vita sexualis is normal - then the specific condition, a disturbance of sexual life in the sense of a deflection of the somatic from the psychical, is not fulfilled - phobias do not appear at all. However much else may be obscure about the mechanism of phobias, my theory can only be refuted when I have been shown phobias where sexual life is normal or even where there is a disturbance of it of a non-specific sort.

The schematic picture for the aetiology of anxiety neurosis seems to me to be on the same lines:
The anxiety neurosis exhibits a much richer clinical picture: irritability, states of anxious expectation, phobias, anxiety attacks, complete or rudimentary, attacks of fear and of vertigo, tremors, sweating, congestion, dyspnoea, tachycardia, etc., chronic diarrhoea, chronic locomotor vertigo, hyperaesthesia, insomnia, etc.¹ It is easily revealed as being the specific effect of various disorders of sexual life which possess a characteristic common to all of them. Enforced abstinence, unconsummated genital excitation (excitation which is not relieved by a sexual act), coition which is imperfect or interrupted (which does not end in gratification), sexual efforts which exceed the subject's psychical capacity, etc. - all these agents, which occur only too frequently in modern life, seem to agree in the fact that they disturb the equilibrium of the psychical and somatic functions in sexual acts, and that they prevent the psychical participation necessary in order to free the nervous economy from sexual tension.

[1896a, 374]

The concurrence of a constant grouping of symptoms with a particular aetiological determinant makes it possible to pick out from the composite province of 'neurasthenia' a syndrome which deserves the name of 'anxiety neurosis', because all of its constituents arise from the symptoms of anxiety. These are either to be regarded as immediate manifestations of anxiety or as rudiments and equivalents of them (E. Hecker), and they are often in complete opposition to the symptoms which constitute neurasthenia proper. The aetiology of the two neuroses also points to an opposition of this kind. Whereas true neurasthenia arises from spontaneous emissions or is acquired through masturbation, the factors belonging to the aetiology of anxiety neurosis are such as correspond to a holding back of sexual excitation - such as abstinence when libido is present, unconsummated excitation and, above all, coitus interruptus. In actual life the neuroses here distinguished usually appear in combination, though pure cases can also be demonstrated. When a mixed neurosis of this kind is subjected to analysis, it is possible to indicate a mixture of several specific aetiologies.

[1897b, 447]

An attempt to arrive at a theory of anxiety neurosis leads to a formula to the effect that its mechanism lies in the deflection of somatic sexual excitation from the psychical field and a consequent abnormal employment of that excitation. Neurotic anxiety is transformed sexual libido.

[1897b, 447]
Thus, in every case of neurosis there is a sexual aetiology; but in neurasthenia it is an aetiology of a present-day kind, whereas in the psychoneuroses the factors are of an infantile nature. This is the first great contrast in the aetiology of the neuroses. A second one emerges when we take account of a difference in the symptomatology of neurasthenia itself. Here, on the one hand, we find cases in which certain complaints characteristic of neurasthenia (intracranial pressure, proneness to fatigue, dyspepsia, constipation, spinal irritation, etc.) are prominent; in other cases these signs play a minor part and the clinical picture is composed of other symptoms, all of which exhibit a relation to the nuclear symptom, that of anxiety (free anxiousness, unrest, expectant anxiety, complete, rudimentary or supplementary anxiety attacks, locomotor vertigo, agoraphobia, insomnia, increased sensitivity to pain, and so on). I have left the name of neurasthenia to the first type, but have distinguished the second type as ‘anxiety neurosis’; and I have given reasons for this separation in another place, where I have also taken account of the fact that as a rule both neuroses appear together. For the present purpose it is enough to emphasize that parallel to the difference in the symptoms of these two forms of illness there goes a difference in their aetiology. Neurasthenia can always be traced back to a condition of the nervous system such as is acquired by excessive masturbation or arises spontaneously from frequent emissions; anxiety neurosis regularly discloses sexual influences which have in common the factor of reservation or of incomplete satisfaction - such as coitus interruptus, abstinence together with a lively libido, so-called unconsummated excitation, and so on. In my short paper intended to introduce anxiety neurosis I put forward the formula that anxiety is always libido which has been deflected from its employment.

There was a similar case, in which, once again, the treatment had an unexpected effect which called for an explanation. This case turned out to be still more instructive, for it exhibited a puzzling alternation in the symptoms of the neurosis. A young neurotic patient had been sent by his physician to a reputable hydropathic establishment on account of a typical neurasthenia. There his condition steadily improved at first, so that there was every prospect that he would be discharged as a grateful disciple of hydrotherapy. But in the sixth week a complete change occurred; the patient ‘could no longer tolerate the water’, became more and more nervous, and finally left the establishment after two more weeks, uncured and dissatisfied. When he complained to me about this therapeutic fraud I asked him a few questions about the symptoms which had overtaken him in the middle of the treatment. Curiously enough, a complete change had come over them. He had entered the sanatorium with intracranial pressure, fatigue and dyspepsia; what had troubled him during the treatment were excitement, attacks of dyspnoea, vertigo in walking, and disturbances of sleep. I was now able to say to him: ‘You are doing hydrotherapy an injustice. As you yourself very well knew, you fell ill as a result of long-continued masturbation. In the sanatorium you gave up this form of satisfaction, and therefore you quickly recovered. When you felt well, however, you unwisely sought to have relations with a lady - a fellow-patient, let us suppose - which could only lead to excitement without normal satisfaction. The beautiful walks in the neighbourhood of the establishment gave you ample opportunity for this. It was this relationship, not a sudden inability to tolerate hydrotherapy, which caused you to fall ill once more. Moreover, your present state of health leads me to conclude that you are continuing this relationship here in town as well.’ I can assure my readers that the patient confirmed what I said, point by point.
This does not exhaust the possibilities which flow from a recognition of the sexual aetiology of the neuroses. The main benefit which we obtain from it for neurasthenics lies in the sphere of prophylaxis. If masturbation is the cause of neurasthenia in youth, and if, later on, it acquires aetiological significance for anxiety neurosis as well, by reason of the reduction of potency which it brings about, then the prevention of masturbation in both sexes is a task that deserves more attention than it has hitherto received. When we reflect upon all the injuries, both the grosser and the finer ones, which proceed from neurasthenia - a disorder which we are told is growing more and more prevalent - we see that it is positively a matter of public interest that men should enter upon sexual relations with full potency. In matters of prophylaxis, however, the individual is relatively helpless. The whole community must become interested in the matter and give their assent to the creation of generally acceptable regulations. At present we are still far removed from such a state of affairs which would promise relief, and it is for this reason that we may with justice regard civilization, too, as responsible for the spread of neurasthenia. Much would have to be changed. The resistance of a generation of physicians who can no longer remember their own youth must be broken down; the pride of fathers, who are unwilling to descend to the level of humanity in their children's eyes, must be overcome; and the unreasonable prudery of mothers must be combated - the mothers who at present look upon it as an incomprehensible and undeserved stroke of fate that 'their children should have been the ones to become neurotic'. But above all, a place must be created in public opinion for the discussion of the problems of sexual life. It will have to become possible to talk about these things without being stamped as a trouble-maker or as a person who makes capital out of the lower instincts. And so here, too, there is enough work left to do for the next hundred years - in which our civilization will have to learn to come to terms with the claims of our sexuality.
I owe the following dream, not to a patient, but to an intelligent jurist of my acquaintance. He told it to me, once again, in order to restrain me from rash generalizing on the theory of wishful dreams. 'I dreamt', said my informant, 'that I came up to my house with a lady on my arm. A closed carriage was standing in front of it and a man came up to me, showed me his credentials as a police officer and requested me to follow him. I asked him to allow me a little time to put my affairs in order. Can you suppose that I have a wish to be arrested?' - Of course not, I could only agree. Do you happen to know the charge on which you were arrested? - 'Yes, for infanticide, I believe.' - Infanticide? But surely you're aware that that's a crime that can only be committed by a mother on a new-born child? - 'Quite true.' - And what were the circumstances in which you had the dream? What happened on the previous evening? - 'I would prefer not to tell you. It's a delicate matter.' - Nevertheless I shall have to hear it; otherwise we shall have to give up the idea of interpreting the dream. - 'Very well then, listen. I didn't spend last night at home but with a lady who means a great deal to me. When we woke up in the morning there was a further passage between us, after which I went to sleep again and had the dream I described to you.' - Is she a married woman? - 'Yes.' - And you don't want to have a child by her? - 'Oh, no; that might give us away.' - So you don't practice normal intercourse? - 'I take the precaution of withdrawing before ejaculation.' - I think I may assume that you had used this device several times during the night, and that after repeating it in the morning you felt a little uncertain whether you had carried it out successfully. - 'That's possible, no doubt.' - In that case your dream was the fulfilment of a wish. It gave you a reassurance that you had not procreated a child, or, what amounts to the same thing, that you had killed a child. The intermediate links are easily indicated. You remember that a few days ago we were talking about marriage difficulties and how inconsistent it is that there should be no objection to carrying out intercourse in such a way that no fertilization takes place, whereas any interference when once the ovum and semen have come together and a foetus has been formed is punished as a crime. We went on to recall the mediaeval controversy over the exact point of time at which the soul enters the foetus, since it is not until after that that the concept of murder becomes applicable. No doubt, too, you know Lenau's gruesome poem in which child murder and child prevention are equated. - 'Oddly enough I happened to think of Lenau this morning, quite by chance, as it seemed.' - An after-echo of your dream. And now I can show you another incidental wish-fulfilment contained in your dream. You came up to your house with the lady on your arm. Thus you were bringing her home, instead of spending the night in her house as you did in reality. There may be more than one reason why the wish-fulfilment which constitutes the core of the dream was disguised in such a disagreeable form. Perhaps you have learned from my paper on the aetiology of anxiety neurosis that I regard coitus interruptus as one of the aetiological factors in the development of neurotic anxiety? It would tally with this if, after carrying out sexual intercourse in this way several times, you were left in an uneasy mood which afterwards became an element in the construction of your dream. Moreover, you made use of this moodiness to help disguise the wish-fulfilment. Incidentally, your reference to infanticide has not been explained. How did you come to light on this specifically feminine crime? - 'I must admit that some years ago I became involved in an occurrence of that kind. I was responsible for a girl's trying to avoid the consequence of a love-affair with me by means of an abortion. I had nothing to do with her carrying out her intention, but for a long time I naturally felt very nervous in case the business came out.' - I quite understand that. This recollection provides a second reason why you must have been worried by your suspicion that your device might have gone wrong. 

[1900a, 650]
Originally my theory related only to the clinical pictures comprised under the term 'neurasthenia', among which I was particularly struck by two, which occasionally appear as pure types and which I described as 'neurasthenia proper' and 'anxiety neurosis'. It had, to be sure, always been a matter of common knowledge that sexual factors *may* play a part in the causation of these forms of illness; but those factors were not regarded as invariably operative, nor was there any idea of giving them precedence over other aetiological influences. I was surprised to begin with at the frequency of gross disturbances in the *vita sexualis* of nervous patients; the more I set about looking for such disturbances - bearing in mind the fact that everyone hides the truth in matters of sex - and the more skilful I became at pursuing my enquiries in the face of a preliminary denial, the more regularly was I able to discover pathogenic factors in sexual life, till little seemed to stand in the way of my assuming their universal occurrence. It was necessary, however, to presuppose from the start that sexual irregularities occurred with similar frequency in our ordinary society under the pressure of social conditions; and a doubt might remain as to the degree of deviation from normal sexual functioning which should be regarded as pathogenic. I was therefore obliged to attach less importance to the invariable evidence of sexual noxae than to a second discovery which seemed to me less ambiguous. It emerged that the form taken by the illness - neurasthenia or anxiety neurosis - bore a constant relation to the nature of the sexual noxa involved. In typical cases of neurasthenia a history of regular masturbation or persistent emissions was found; in anxiety neurosis factors appeared such as *coitus interruptus*, 'unconsummated excitation', and other conditions - in all of which there seemed to be the common element of an insufficient discharge of the libido that had been produced. It was only after this discovery, which was easy to make and could be confirmed as often as one liked, that I had the courage to claim a preferential position for sexual influences in the aetiology of the neuroses. Furthermore, in the mixed forms of neurasthenia and anxiety neurosis which are so common it was possible to trace a combination of the aetiologies which I had assumed for the two pure forms. Moreover, this twofold form assumed by the neurosis seemed to tally with the polar (i.e. the masculine and feminine) character of sexuality.

[1906a, 1575]
This brings us to the question whether sexual intercourse in legal marriage can offer full compensation for the restrictions imposed before marriage. There is such an abundance of material supporting a reply in the negative that we can give only the briefest summary of it. It must above all be borne in mind that our cultural sexual morality restricts sexual intercourse even in marriage itself, since it imposes on married couples the necessity of contenting themselves, as a rule, with a very few procreative acts. As a consequence of this consideration, satisfying sexual intercourse in marriage takes place only for a few years; and we must subtract from this, of course, the intervals of abstention necessitated by regard for the wife's health. After these three, four or five years, the marriage becomes a failure in so far as it has promised the satisfaction of sexual needs. For all the devices hitherto invented for preventing conception impair sexual enjoyment, hurt the fine susceptibilities of both partners and even actually cause illness. Fear of the consequences of sexual intercourse first brings the married couple's physical affection to an end; and then, as a remoter result, it usually puts a stop as well to the mental sympathy between them, which should have been the successor to their original passionate love. The spiritual disillusionment and bodily deprivation to which most marriages are thus doomed puts both partners back in the state they were in before their marriage, except for being the poorer by the loss of an illusion, and they must once more have recourse to their fortitude in mastering and deflecting their sexual instinct. We need not enquire how far men, by then in their maturer years, succeed in this task. Experience shows that they very frequently avail themselves of the degree of sexual freedom which is allowed them - although only with reluctance and under a veil of silence - by even the strictest sexual code. The 'double' sexual morality which is valid for men in our society is the plainest admission that society itself does not believe in the possibility of enforcing the precepts which it itself has laid down. But experience shows as well that women, who, as being the actual vehicle of the sexual interests of mankind, are only endowed in a small measure with the gift of sublimating their instincts, and who, though they may find a sufficient substitute for the sexual object in an infant at the breast, do not find one in a growing child - experience shows, I repeat, that women, when they are subjected to the disillusionments of marriage, fall ill of severe neuroses which permanently darken their lives. (Under the cultural conditions of to-day, marriage has long ceased to be a panacea for the nervous troubles of women; and if we doctors still advise marriage in such cases, we are nevertheless aware that, on the contrary, a girl must be very healthy if she is to be able to tolerate it, and we urgently advise our male patients not to marry any girl who has had nervous trouble before marriage. On the contrary, the cure for nervous illness arising from marriage would be marital unfaithfulness. But the more strictly a woman has been brought up and the more sternly she has submitted to the demands of civilization, the more she is afraid of taking this way out; and in the conflict between her desires and her sense of duty, she once more seeks refuge in a neurosis. Nothing protects her virtue as securely as an illness. Thus the married state, which is held out as a consolation to the sexual instinct of the civilized person in his youth, proves to be inadequate even to the demands of the actual period of life covered by it. There is no question of its being able to compensate for the deprivation which precedes it.
[1908d, 1957]
There is a second explanation, also unconcerned with sexuality, which has, however, a much more general scope than the first. It suggests that primitive man is prey to a perpetual lurking apprehensiveness, just as in the psycho-analytic theory of the neuroses we claim to be the case with people suffering from anxiety neurosis. This apprehensiveness will appear most strongly on all occasions which differ in any way from the usual, which involve something new or unexpected, something not understood or uncanny. This is also the origin of the ceremonial practices, widely adopted in later religions, which are connected with the beginning of every new undertaking, the start of every new period of time, the first-fruits of human, animal and plant life. The dangers which the anxious man believes to be threatening him never appear more vivid in his expectation than on the threshold of a dangerous situation, and then, too, is the only time when protecting himself against them is of any use. The first act of intercourse in marriage can certainly claim, on grounds of importance, to be preceded by such precautionary measures. These two attempts at explanation, based on horror of blood and on fear of first occurrences, do not contradict but rather reinforce each other. The first occasion of sexual intercourse is certainly a critical action, all the more so if it is to involve a flow of blood.

[1918a, 2353]

On the question of the relation of masturbation and emissions to the causation of so-called 'neurasthenia', I find myself like many of you, in opposition to Stekel, and, subject to a limitation which I shall mention presently, I maintain, as against him, my former views. I see nothing that could obliges us to abandon the distinction between 'actual neuroses' and psychoneuroses, and I cannot regard the genesis of the symptoms in the case of the former as anything but toxic. Here Stekel really seems to me greatly to overstretch psychogenicity. My view is still what it was in the first instance, more than fifteen years ago: namely, that the two 'actual neuroses' - neurasthenia and anxiety neurosis (and perhaps we ought to add hypochondria proper as a third 'actual neurosis') - provide the psychoneuroses with the necessary 'somatic compliance'; they provide the excitatory material, which is then psychically selected and given a 'psychical coating', so that, speaking generally, the nucleus of the psychoneurotic symptom - the grain of sand at the centre of the pearl - is formed of a somatic sexual manifestation. This is clearer, it is true, of anxiety neurosis and its relation to hysteria than it is of neurasthenia, into which no careful psycho-analytic investigations have yet been made. In anxiety neurosis, as you have often been able to convince yourselves, it is at bottom a small fragment of undischarged excitation connected with coition which emerges as an anxiety symptom or provides the nucleus for the formation of a hysterical symptom.

[1912f, 2570]
Nevertheless you will rightly expect that we should devote some interest to the 'actual' neuroses as well. Their intimate clinical connection with the psychoneuroses would alone compel us to do so. I may inform you, then, that we distinguish three pure forms of 'actual' neuroses: neurasthenia, anxiety neurosis and hypochondria. Even this assertion is not uncontradicted. All the names are in use, it is true, but their content is indefinite and fluctuating. There are even doctors who oppose any dividing lines in the chaotic world of neurotic phenomena, any segregation of clinical entities or individual diseases, and who do not even recognize the distinction between the 'actual' neuroses and the psychoneuroses. I think they are going too far and have not chosen the path which leads to progress. The forms of neurosis which I have mentioned occur occasionally in their pure form; more often, however, they are intermixed with each other and with a psychoneurotic disorder. This need not lead us to abandon the distinction between them. Consider the difference between the study of minerals and of rocks in mineralogy. The minerals are described as individuals, no doubt on the basis of the fact that they often occur as crystals, sharply separated from their environment. Rocks consist of aggregations of minerals, which, we may be sure, have not come together by chance but as a result of what determined their origin. In the theory of the neuroses we still know too little of the course of their development to produce anything resembling petrology. But we are certainly doing the right thing if we start by isolating from the mass the individual clinical entities which we recognize and which are comparable to the minerals.

1916-1917, 3440

If we now pass over to consider neurotic anxiety, what fresh forms and situations are manifested by anxiety? There is much to be described here. In the first place we find a general apprehensiveness, a kind of freely floating anxiety which is ready to attach itself to any idea that is in any way suitable, which influences judgement, selects what is to be expected, and lies in wait for any opportunity that will allow it to justify itself. We call this state 'expectant anxiety' or 'anxious expectation'. People who are tormented by this kind of anxiety always foresee the most frightful of all possibilities, interpret every chance event as a premonition of evil and exploit every uncertainty in a bad sense. A tendency to an expectation of evil of this sort is to be found as a character trait in many people whom one cannot otherwise regard as sick; one calls them over-anxious or pessimistic. A striking amount of expectant anxiety, however, forms a regular feature of a nervous disorder to which I have given the name of 'anxiety neurosis' and which I include among the 'actual' neuroses.

1916-1917, 3446
Under the influence of my surprising discovery, I now took a momentous step. I went beyond the domain of hysteria and began to investigate the sexual life of the so-called neurasthenics who used to visit me in numbers during my consultation hours. This experiment cost me, it is true, my popularity as a doctor, but it brought me convictions which to-day, almost thirty years later, have lost none of their force. There was a great deal of equivocation and mystery-making to be overcome, but, once that had been done, it turned out that in all of these patients grave abuses of the sexual function were present. Considering how extremely widespread are these abuses on the one hand and neurasthenia on the other, a frequent coincidence between the two would not have proved much; but there was more in it than that one bald fact. Closer observation suggested to me that it was possible to pick out from the confused jumble of clinical pictures covered by the name of neurasthenia two fundamentally different types, which might appear in any degree of mixture but which were nevertheless to be observed in their pure forms. In the one type the central phenomenon was the anxiety attack with its equivalents, rudimentary forms and chronic substitutive symptoms; I consequently gave it the name of anxiety neurosis, and limited the term neurasthenia to the other type. Now it was easy to establish the fact that each of these types had a different abnormality of sexual life as its corresponding aetiological factor: in the former, coitus interruptus, unconsummated excitation and sexual abstinence, and in the latter, excessive masturbation and too numerous nocturnal emissions. In a few specially instructive cases, which had shown a surprising alteration in the clinical picture from one type to the other, it could be proved that there had been a corresponding change in the underlying sexual régime. If it was possible to put an end to the abuse and allow its place to be taken by normal sexual activity, a striking improvement in the condition was the reward.

[1925d, 4202]
In this manner I found that neurasthenia presented a monotonous clinical picture in which, as my analyses showed, a 'psychical mechanism' played no part. There was a sharp distinction between neurasthenia and 'obsessional neurosis', the neurosis of obsessional ideas proper. In this latter one I was able to recognize a complicated psychical mechanism, an aetiology similar to that of hysteria and an extensive possibility of reducing it by psychotherapy. On the other hand, it seemed to me absolutely necessary to detach from neurasthenia a complex of neurotic symptoms which depend on a quite different and indeed at bottom a contrary aetiology. The component symptoms of this complex are united by a characteristic which has already been recognized by Hecker (1893). For they are either symptoms or equivalents and rudiments of manifestations of anxiety; and for this reason I have given to this complex which is to be detached from neurasthenia the name of 'anxiety neurosis'. I have maintained that it arises from, an accumulation of physical tension, which is itself once more of sexual origin. This neurosis, too, has no psychical mechanism, but it invariably influences mental life, so that 'anxious expectation', phobias, hyperaesthesia to pains, etc., are among its regular manifestations. This anxiety neurosis, in my sense of the term, no doubt coincides in part with the neurosis which, under the name of 'hypochondria', finds a place in not a few descriptions alongside hysteria and neurasthenia. But I cannot regard the delimitation of hypochondria in any of the works in question as being the correct one, and the applicability of its name seems to me to be prejudiced by the fixed connection of that term with the symptom of 'fear of illness'.

I hope to be able to demonstrate, on another occasion, that there is reason to distinguish a special neurosis, the 'anxiety neurosis', of which the chief symptom is this emotional state. I shall then enumerate its various symptoms and insist on the necessity for differentiating this neurosis from neurasthenia, with which it is now confused. Phobias, then, are part of the anxiety neurosis, and are almost always accompanied by other symptoms of the same group.

It is difficult to make any statement of general validity about neurasthenia, so long as we use that name to cover all the things which Beard has included under it. In my opinion, it can be nothing but a gain to neuropathology if we make an attempt to separate from neurasthenia proper all those neurotic disturbances in which, on the one hand, the symptoms are more firmly linked to one another than to the typical symptoms of neurasthenia (such as intracranial pressure, spinal irritation, and dyspepsia with flatulence and constipation); and which, on the other hand, exhibit essential differences in their aetiology and mechanism from the typical neurasthenic neurosis. If we accept this plan, we shall soon obtain a fairly uniform picture of neurasthenia. We shall then be in a position to differentiate from genuine neurasthenia more sharply than has hitherto been possible various pseudo-neurasthenias (such as the clinical picture of the organically determined nasal reflex neurosis, the nervous disorders of the cachexias and arterio-sclerosis, the preliminary stages of general paralysis of the insane, and of some psychoses). Further, it will be possible - as Möbius has proposed - to eliminate some of the status nervosi of hereditarily degenerate individuals; and we shall also discover reasons why a number of neuroses which are to-day described as neurasthenia - in particular, neuroses of an intermittent or periodical nature - ought rather to be included under melancholia. But the most marked change of all will be introduced if we decide to detach from neurasthenia the syndrome which I propose to describe in the following pages and which satisfies especially fully the conditions set out above. The symptoms of this syndrome are clinically much more closely related to one another than to those of genuine neurasthenia (that is, they frequently appear together and they replace one another in the course of the illness); and both the aetiology and the mechanism of this neurosis are fundamentally different from the aetiology and mechanism of genuine neurasthenia as it will be left after this separation has been effected.
More often, however, symptoms of anxiety occur at the same time as, and in combination with, symptoms of neurasthenia, hysteria, obsessions or melancholia. If we were to allow ourselves to be restrained by a clinical intermixture like this from acknowledging anxiety neurosis as an independent entity, we ought, logically, also to abandon once more the separation which has been so laboriously achieved between hysteria and neurasthenia.

[1895b, 348]

The symptomatology of hysteria and anxiety neurosis show many points in common which have not yet been sufficiently considered. The appearance of symptoms either in a chronic form or in attacks, the paraesthesias, grouped like aurae, the hyperaesthesias and pressure-points which are found in certain surrogates of an anxiety attack (in dyspnoea and heart-attacks), the intensification, through conversion, of pains which perhaps have an organic justification - these and other features which the two illnesses have in common even allow of a suspicion that not a little of what is attributed to hysteria might with more justice be put to the account of anxiety neurosis. If one goes into the mechanism of the two neuroses, so far as it has been possible to discover it hitherto, aspects come to light which suggest that anxiety neurosis is actually the somatic counterpart to hysteria. In the latter just as in the former there is an accumulation of excitation (which is perhaps the basis for the similarity between their symptoms we have mentioned). In the latter just as in the former we find a psychical insufficiency, as a consequence of which abnormal somatic processes arise. In the latter just as in the former, too, instead of a psychical working-over of the excitation, a deflection of it occurs into the somatic field; the difference is merely that in anxiety neurosis the excitation, in whose displacement the neurosis expresses itself, is purely somatic (somatic sexual excitation), whereas in hysteria it is psychical (provoked by conflict). Thus it is not to be wondered at that hysteria and anxiety neurosis regularly combine with each other, as is seen in 'virginal anxiety' or 'sexual hysteria', and that hysteria simply borrows a number of its symptoms from anxiety neurosis, and so on. These intimate relations which anxiety neurosis has with hysteria provide a fresh argument, moreover, for insisting on the detachment of anxiety neurosis from neurasthenia; for if this detachment is not granted, we shall also be unable any longer to maintain the distinction which has been acquired with so much labour and which is so indispensable for the theory of the neuroses, between neurasthenia and hysteria.

[1895b, 349]
In the second number of Mendel's *Neurologisches Zentralblatt* for 1895, I published a short paper in which I ventured an attempt to detach a number of nervous states from neurasthenia and to establish them as an independent entity under the name of 'anxiety neurosis'.¹ I was led to do so by the presence of a constant conjunction of certain clinical features with certain aetiological ones - a thing which, in general, should permit us to make a separation of this kind. I found - and in this Hecker (1893) had anticipated me - that the neurotic symptoms in question could all be classed together as constituting expressions of anxiety; and, from my study of the aetiology of the neuroses, I was able to add that these portions of the complex of the 'anxiety neurosis' exhibit special aetiological preconditions which are almost the opposite of the aetiology of neurasthenia. My observations had shown me that in the aetiology of the neuroses (at all events of acquired cases and acquirable forms) sexual factors play a predominant part and one which has been given far too little weight; so that a statement such as that 'the aetiology of the neuroses lies in sexuality', with all its unavoidable incorrectness *per excessum et defectum*, nevertheless comes nearer to the truth than do the other doctrines, which hold the field at the present time. A further assertion which my observations forced me to make was to the effect that the various sexual noxae are not to be found in the aetiology of every neurosis indifferently, but that unmistakable special relationships hold between particular noxae and particular neuroses. Thus I could assume that I had discovered the specific causes of the various neuroses. I then sought to formulate shortly the special character of the sexual noxae which constitute the aetiology of anxiety neurosis, and, on the basis of my view of the sexual process (p. 108), I arrived at the proposition: anxiety neurosis is created by everything which keeps somatic sexual tension away from the psychical sphere, which interferes with its being worked over psychically. If we go back to the concrete circumstances in which this factor becomes operative, we are led to assert that abstinence, whether voluntary or involuntary, sexual intercourse with incomplete satisfaction, coitus interruptus, deflection of psychical interest from sexuality, and similar things, are the specific aetiological factors of the states to which I have given the name of anxiety neurosis.

[1895f, 352]

With an unerring eye Löwenfeld (1895) detects the essential feature of my paper - namely, my assertion that anxiety-symptoms have a specific and uniform aetiology of a sexual nature. If this cannot be established as a fact, then the main reason for detaching an independent anxiety neurosis from neurasthenia disappears as well. There remains, it is true, one difficulty to which I called attention - the fact that anxiety-symptoms also have such very unmistakable connections with hysteria, so that a decision on Löwenfeld's lines would prejudice the separation between hysteria and neurasthenia. This difficulty, however, is met by a recourse to heredity as the common cause of all these neuroses (a view which I will go into later).

[1895f, 354]
'On the grounds for detaching a particular syndrome from neurasthenia under the description "anxiety neurosis"."
[1897b, 447]

Under the influence of my surprising discovery, I now took a momentous step. I went beyond the domain of hysteria and began to investigate the sexual life of the so-called neurasthenics who used to visit me in numbers during my consultation hours. This experiment cost me, it is true, my popularity as a doctor, but it brought me convictions which to-day, almost thirty years later, have lost none of their force. There was a great deal of equivocation and mystery-making to be overcome, but, once that had been done, it turned out that in all of these patients grave abuses of the sexual function were present. Considering how extremely widespread are these abuses on the one hand and neurasthenia on the other, a frequent coincidence between the two would not have proved much; but there was more in it than that one bald fact. Closer observation suggested to me that it was possible to pick out from the confused jumble of clinical pictures covered by the name of neurasthenia two fundamentally different types, which might appear in any degree of mixture but which were nevertheless to be observed in their pure forms. In the one type the central phenomenon was the anxiety attack with its equivalents, rudimentary forms and chronic substitutive symptoms; I consequently gave it the name of anxiety neurosis, and limited the term neurasthenia to the other type. Now it was easy to establish the fact that each of these types had a different abnormality of sexual life as its corresponding aetiological factor: in the former, coitus interruptus, unconsummated excitation and sexual abstinence, and in the latter, excessive masturbation and too numerous nocturnal emissions. In a few specially instructive cases, which had shown a surprising alteration in the clinical picture from one type to the other, it could be proved that there had been a corresponding change in the underlying sexual régime. If it was possible to put an end to the abuse and allow its place to be taken by normal sexual activity, a striking improvement in the condition was the reward.
[1925d, 4202]
Anxious expectation is the nuclear symptom of the neurosis. It openly reveals, too, a portion of the theory of the neurosis. We may perhaps say that here a quantum of anxiety in a freely floating state, which, where there is expectation, controls the choice of ideas and is always ready to link itself with any suitable ideational content.

What we have so far said about anxiety neurosis already provides a few starting points for gaining an insight into the mechanism of this neurosis. In the first place there was our suspicion that we had to do with an accumulation of excitation; and then there was the extremely important fact that the anxiety which underlies the clinical symptoms of the neurosis can be traced to no psychical origin. Such an origin would exist, for instance, if it was found that the anxiety neurosis was based on a single or repeated justifiable fright, and that that fright had since provided the source for the subject's readiness for anxiety. But this is not so. Hysteria or a traumatic neurosis can be acquired from a single fright, but never anxiety neurosis. Since coitus interruptus takes such a prominent place among the causes of anxiety neurosis, I thought at first that the source of the continuous anxiety might lie in the fear, recurring every time the sexual act was performed, that the technique might go wrong and conception consequently take place. But I have found that this state of feeling, either in the man or the woman, during coitus interruptus has no influence on the generation of anxiety neurosis, that women who are basically indifferent about the consequence of a possible conception are just as liable to the neurosis as those who shudder at the possibility, and that everything depends simply on which partner has forfeited satisfaction in this sexual technique.

A further point of departure is furnished by the observation, not so far mentioned, that in whole sets of cases anxiety neurosis is accompanied by a most noticeable decrease of sexual libido or psychical desire, so that on being told that their complaint results from 'insufficient satisfaction', patients regularly reply that that is impossible, for precisely now all sexual need has become extinguished in them. From all these indications - that we have to do with an accumulation of excitation; that the anxiety which probably corresponds to this accumulated excitation is of somatic origin, so that what is being accumulated is a somatic excitation; and, further, that this somatic excitation is of a sexual nature and that a decrease of psychical participation in the sexual processes goes along with it - all these indications, I say, incline us to expect that the mechanism of anxiety is to be looked for in a deflection of somatic excitation from the psychical sphere, and in a consequent abnormal employment of that excitation.

(a) It is not difficult to establish the fact that expectant anxiety or general apprehensiveness is closely dependent on certain happenings in sexual life, or, let us say, certain employments of the libido. The simplest and most instructive case of this sort occurs in people who expose themselves to what is known as unconsummated excitation - that is, people in whom violent sexual excitations meet with no sufficient discharge, cannot be brought to a satisfying conclusion - men for instance, while they are engaged to be married, and women whose husbands are insufficiently potent or, as a precaution, perform the sexual act in an incomplete or curtailed fashion. In such circumstances the libidinal excitation vanishes and anxiety appears in its place whether in the form of expectant anxiety or in attacks and anxiety-equivalents. Interruption of the sexual act as a precaution, if it is practised as a sexual régime, is such a regular cause of anxiety neurosis in men, but more particularly in women, that in medical practice it is advisable in such cases to begin by investigating this aetiology. It will then be found on countless occasions that the anxiety neurosis disappears when the sexual abuse is discontinued.

[1895b, 330]

[1895b, 343]

[1916-1917, 3448]
More often, however, symptoms of anxiety occur at the same time as, and in combination with, symptoms of neurasthenia, hysteria, obsessions or melancholia. If we were to allow ourselves to be restrained by a clinical intermixture like this from acknowledging anxiety neurosis as an independent entity, we ought, logically, also to abandon once more the separation which has been so laboriously achieved between hysteria and neurasthenia. [1895b, 348]

But I still owe you further enlightenment, Gentlemen, on my reasons for not starting my account of the theory of the neuroses with the common neurotic state. You may perhaps suppose that it was because in that case I should have had greater difficulty in proving the sexual causation of the neuroses. But you would be wrong there. In the case of the transference neuroses one must work one's way through the interpretation of symptoms before one can arrive at that discovery. In the common forms of what are known as the 'actual neuroses' the aetiological significance of sexual life is a crude fact that springs to the observer's eyes. I came upon it more than twenty years ago when one day I asked myself the question of why in the examination of neurotics their sexual activities were so regularly excluded from consideration. At that time I sacrificed my popularity with my patients for the sake of these enquiries; but after only a brief effort I was able to declare that 'if the vita sexualis is normal, there can be no neurosis' - and by this I meant no 'actual neurosis'. No doubt this statement passes too lightly over people's individual differences; it suffers, too, from the indefiniteness inseparable from the judgement of what is 'normal'. But as a rough guide it retains its value to this day. I had by then reached the point of establishing specific relations between particular forms of neurosis and particular sexual noxae; and I have no doubt that I could repeat the same observations to-day if similar pathological material were still at my disposal. I found often enough that a man who indulged in a certain kind of incomplete sexual satisfaction (for instance, manual masturbation) had fallen ill of a particular form of 'actual neurosis', and that this neurosis promptly gave place to another if he replaced this sexual régime by another equally far from being irreproachable. I was then in a position to infer the change in a patient's sexual mode of life from an alteration in his condition. I also learnt then to stand obstinately by my suspicions till I had overcome the patients' disingenuousness and compelled them to confirm my views. It is true that thereafter they preferred to go to other doctors who did not make such keen enquiries about their sexual life. [1916-1917, 3438]

(a) It is not difficult to establish the fact that expectant anxiety or general apprehensiveness is closely dependent on certain happenings in sexual life, or, let us say, certain employments of the libido. The simplest and most instructive case of this sort occurs in people who expose themselves to what is known as unconsummated excitation - that is, people in whom violent sexual excitations meet with no sufficient discharge, cannot be brought to a satisfying conclusion - men for instance, while they are engaged to be married, and women whose husbands are insufficiently potent or, as a precaution, perform the sexual act in an incomplete or curtailed fashion. It will then be found on countless occasions that the anxiety neurosis disappears when the sexual abuse is discontinued. [1916-1917, 3448]
The fact of there being a connection between sexual restraint and anxiety states is, so far as I know, no longer disputed even by physicians who have no contact with psycho-analysis. But I can well believe that an attempt is made to reverse the relation and to put forward the view that the people concerned are such as are already inclined to apprehensiveness and for that reason practise restraint in sexual matters as well. This, however, is decisively contradicted by the behaviour of women, whose sexual activity is essentially of a passive nature - is determined, that is to say, by their treatment by the man. The more passionate a woman is - the more inclined, therefore, to sexual intercourse and the more capable of being satisfied - the more certain she is to react with manifestations of anxiety to a man's impotence or to coitus interruptus, whereas in the case of anaesthetic women or those without much libido such ill-treatment plays a far smaller part.

[1916-1917, 3449]

The Aetiological Significance of Sexual Life. - The second novelty which emerged after the hypnotic technique had been replaced by free associations was of a clinical nature. It was discovered in the course of the prolonged search for the traumatic experiences from which hysterical symptoms appeared to be derived. The more carefully the search was pursued the more extensive seemed to be the network of aetiologically significant impressions involved, but the further back, too, did they reach into the patient's puberty or childhood. At the same time they assumed a uniform character and eventually it became inevitable to bow before the evidence and recognize that at the root of the formation of every symptom there were to be found traumatic experiences from early sexual life. Thus a sexual trauma stepped into the place of an ordinary trauma and the latter was seen to owe its aetiological significance to an associative or symbolic connection with the former, which had preceded it. An investigation of cases of common nervousness (falling into the two classes of neuasthenia and anxiety neurosis) which was simultaneously undertaken led to the conclusion that these disorders could be traced to contemporary abuses in the patients' sexual life and could be removed if these were brought to an end. It was thus easy to infer that neuroses in general are an expression of disturbances in sexual life, the so-called actual-neuroses being the consequences (by chemical agency) of contemporary injuries and the psycho-neuroses the consequences (by psychical modification) of bygone injuries to a biological function which had hitherto been gravely neglected by science. None of the theses of psycho-analysis has met with such tenacious scepticism or such embittered resistance as this assertion of the preponderating aetiological significance of sexual life in the neuroses. It should, however, be expressly remarked that, in its development up to the present day, psycho-analysis has found no reason to retreat from this opinion.

[1923a, 3920]
Under the influence of my surprising discovery, I now took a momentous step. I went beyond the domain of hysteria and began to investigate the sexual life of the so-called neurasthenics who used to visit me in numbers during my consultation hours. This experiment cost me, it is true, my popularity as a doctor, but it brought me convictions which to-day, almost thirty years later, have lost none of their force. There was a great deal of equivocation and mystery-making to be overcome, but, once that had been done, it turned out that in all of these patients grave abuses of the sexual function were present. Considering how extremely widespread are these abuses on the one hand and neurasthenia on the other, a frequent coincidence between the two would not have proved much; but there was more in it than that one bald fact. Closer observation suggested to me that it was possible to pick out from the confused jumble of clinical pictures covered by the name of neurasthenia two fundamentally different types, which might appear in any degree of mixture but which were nevertheless to be observed in their pure forms. In the one type the central phenomenon was the anxiety attack with its equivalents, rudimentary forms and chronic substitutive symptoms; I consequently gave it the name of anxiety neurosis, and limited the term neurasthenia to the other type. Now it was easy to establish the fact that each of these types had a different abnormality of sexual life as its corresponding aetiological factor: in the former, coitus interruptus, unconsummated excitation and sexual abstinence, and in the latter, excessive masturbation and too numerous nocturnal emissions. In a few specially instructive cases, which had shown a surprising alteration in the clinical picture from one type to the other, it could be proved that there had been a corresponding change in the underlying sexual régime. If it was possible to put an end to the abuse and allow its place to be taken by normal sexual activity, a striking improvement in the condition was the reward.

It may be asked how I arrived at this idea of transformation in the first instance. It was while I was studying the 'actual neuroses', at a time when analysis was still a very long way from distinguishing between processes in the ego and processes in the id. I found that outbreaks of anxiety and a general state of preparedness for anxiety were produced by certain sexual practices such as coitus interruptus, undischarged sexual excitation or enforced abstinence - that is, whenever sexual excitation was inhibited, arrested or deflected in its progress towards satisfaction. Since sexual excitation was an expression of libidinal instinctual impulses it did not seem too rash to assume that the libido was turned into anxiety through the agency of these disturbances. The observations which I made at the time still hold good. Moreover, it cannot be denied that the libido belonging to the id-processes is subjected to disturbance at the instigation of repression. It might still be true, therefore, that in repression anxiety is produced from the libidinal cathexis of the instinctual impulses. But how can we reconcile this conclusion with our other conclusion that the anxiety felt in phobias is an ego anxiety and arises in the ego, and that it does not proceed out of repression but, on the contrary, sets repression in motion? There seems to be a contradiction here which it is not at all a simple matter to solve. It will not be easy to reduce the two sources of anxiety to a single one. We might attempt to do so by supposing that, when coitus is disturbed or sexual excitation interrupted or abstinence enforced, the ego scents certain dangers to which it reacts with anxiety. But this takes us nowhere. On the other hand, our analysis of the phobias seems to admit of no correction. Non liquet.
We see, then, that it is not so much a question of taking back our earlier findings as of bringing them into line with more recent discoveries. It is still an undeniable fact that in sexual abstinence, in improper interference with the course of sexual excitation or if the latter is diverted from being worked over psychically, anxiety arises directly out of libido; in other words, that the ego is reduced to a state of helplessness in the face of an excessive tension due to need, as it was in the situation of birth, and that anxiety is then generated. Here once more, though the matter is of little importance, it is very possible that what finds discharge in the generating of anxiety is precisely the surplus of unutilized libido. As we know, a psychoneurosis is especially liable to develop on the basis of an 'actual' neurosis. This looks as though the ego were attempting to save itself from anxiety, which it has learned to keep in suspension for a while, and to bind it by the formation of symptoms. Analysis of the traumatic war neuroses - a term which, incidentally, covers a great variety of disorders - would probably have shown that a number of them possess some characteristics of the 'actual' neuroses.

Our investigations were far from remaining unsuccessful: we reached a few important conclusions. In regard to anxious expectation clinical experience revealed that it had a regular connection with the libidinal economics of sexual life. The commonest cause of anxiety neurosis is unconsummated excitation. Libidinal excitation is aroused but not satisfied, not employed; apprehensiveness then appears instead of this libido that has been diverted from its employment. I even thought I was justified in saying that this unsatisfied libido was directly changed into anxiety. This view found support in some quite regularly occurring phobias of small children. Many of these phobias are very puzzling to us, but others, such as the fear of being alone and the fear of strangers, can be explained with certainty. Loneliness as well as a strange face arouse the child's longing for his familiar mother; he is unable to control this libidinal excitation, he cannot hold it in suspense but changes it into anxiety. This infantile anxiety must therefore be regarded not as of the realistic but as of the neurotic kind. Infantile phobias and the expectation of anxiety in anxiety neurosis offer us two examples of one way in which neurotic anxiety originates: by a direct transformation of libido. We shall at once come to know of a second mechanism, but it will turn out not to be very different from the first.

For we consider that what is responsible for the anxiety in hysteria and other neuroses is the process of repression. We believe it is possible to give a more complete account of this than before, if we separate what happens to the idea that has to be repressed from what happens to the quota of libido attaching to it. It is the idea which is subjected to repression and which may be distorted to the point of being unrecognizable; but its quota of affect is regularly transformed into anxiety - and this is so whatever the nature of the affect may be, whether it is aggressiveness or love. It makes no essential difference, then, for what reason a quota of libido has become unemployable: whether it is on account of the infantile weakness of the ego, as in children's phobias, or on account of somatic processes in sexual life, as in anxiety neurosis, or owing to repression, as in hysteria. Thus in reality the two mechanisms that bring about neurotic anxiety coincide.
And now, only one more remark on the problem of anxiety. Neurotic anxiety has changed in our hands into realistic anxiety, into fear of particular external situations of danger. But we cannot stop there, we must take another step - though it will be a step backward. We ask ourselves what it is that is actually dangerous and actually feared in a situation of danger of this kind. It is plainly not the injury to the subject as judged objectively, for this need be of no significance psychologically, but something brought about by it in the mind. Birth, for instance, our model for an anxiety state, can after all scarcely be regarded on its own account as an injury, although it may involve a danger of injuries. The essential thing about birth, as about every situation of danger, is that it calls up in mental experience a state of highly tense excitation, which is felt as unpleasure and which one is not able to master by discharging it. Let us call a state of this kind, before which the efforts of the pleasure principle break down, a 'traumatic' moment. Then, if we take in succession neurotic anxiety, realistic anxiety and the situation of danger, we arrive at this simple proposition: what is feared, what is the object of the anxiety, is invariably the emergence of a traumatic moment, which cannot be dealt with by the normal rules of the pleasure principle. We understand at once that our endowment with the pleasure principle does not guarantee us against objective injuries but only against a particular injury to our psychical economics. It is a long step from the pleasure principle to the self-preservation instinct; the intentions of the two of them are very far from coinciding from the start. But we see something else besides; perhaps it is the solution we are in search of. Namely, that in all this it is a question of relative quantities. It is only the magnitude of the sum of excitation that turns an impression into a traumatic moment, paralyses the function of the pleasure principle and gives the situation of danger its significance. And if that is how things are, if these puzzles can be solved so prosaically, why should it not be possible for similar traumatic moments to arise in mental life without reference to hypothetical situations of danger - traumatic moments, then, in which anxiety is not aroused as a signal but is generated anew for a fresh reason. Clinical experience declares decidedly that such is in fact the case. It is only the later repressions that exhibit the mechanism we have described, in which anxiety is awakened as a signal of an earlier situation of danger. The first and original repressions arise directly from traumatic moments, when the ego meets with an excessively great libidinal demand; they construct their anxiety afresh, although, it is true, on the model of birth. The same may apply to the generation of anxiety in anxiety neurosis owing to somatic damage to the sexual function. We shall no longer maintain that it is the libido itself that is turned into anxiety in such cases. But I can see no objection to there being a twofold origin of anxiety - one as a direct consequence of the traumatic moment and the other as a signal threatening a repetition of such a moment. [1933a, 4700]
The main objection to my postulate of a sexual aetiology for anxiety neurosis will probably be
to the following effect. Abnormal conditions in sexual life of the kind I have described are found
so extremely frequently that they are bound to be forthcoming wherever one looks for them.
Their presence in the cases of anxiety neurosis which I have enumerated does not, therefore,
prove that we have unearthed in them the aetiology of the neurosis. Moreover, the number of
people who practise coitus interruptus and the like is incomparably larger than the number who
are afflicted with anxiety neurosis, and the great majority of the former tolerate this noxa very
well.
[1895b, 340]

(1) So long as an anxiety neurosis in young married women is not yet established, but only
appears in bouts and disappears again spontaneously, it is possible to demonstrate that each
such bout of the neurosis is traceable to a coitus which was deficient in satisfaction. Two days
after this experience - or, in the case of people with little resistance, the day after - the attack of
anxiety or vertigo regularly appears, bringing in its train other symptoms of the neurosis. All this
vanishes once more, provided that marital intercourse is comparatively rare. A chance absence
of the husband from home, or a holiday in the mountains which necessitates a separation of the
couple, has a good effect. The gynaecological treatment which is usually resorted to in the first
instance is beneficial because, while it lasts, marital intercourse is stopped. Curiously enough
the success of local treatment is only transitory: the neurosis sets in again in the mountains, as
soon as the husband begins his holiday too; and so on. If, as a physician who understands this
aetiology, one arranges, in a case in which the neurosis has not yet been established, for coitus
interruptus to be replaced by normal intercourse, one obtains a therapeutic proof of the
assertion I have made. The anxiety is removed, and - unless there is fresh cause for it of the
same sort - it does not return.
[1895b, 340]
Observations of this sort, which can be multiplied at will, positively thrust a sexual aetiology on the doctor for a certain category of cases. And other cases, which would otherwise remain unintelligible, can at least be understood and classified without inconsistency by employing that aetiology as a key. I have in mind those very numerous cases in which, it is true, everything is present that has been found in the previous category - on the one hand the manifestations of anxiety neurosis, and on the other the specific factor of coitus interruptus - but in which something else as well intrudes itself: namely, a long interval between the presumed aetiology and its effects, and also perhaps aetiological factors that are not of a sexual nature. Take, for instance, a man who, on receiving news of his father's death, had a heart attack and from that moment fell a victim to an anxiety neurosis. The case is not comprehensible, for, till then, the man was not neurotic. The death of his father, who was well advanced in years, did not take place under in any way special circumstances, and it will be admitted that the normal and expected decease of an aged father is not one of those experiences which usually cause a healthy adult to fall ill. Perhaps the aetiological analysis will become clearer if I add that this man had been practising coitus interruptus for eleven years, with due consideration for his wife's satisfaction. The clinical symptoms are, at least, exactly the same as those which appear in other people after only a short sexual noxa of the same kind, and without the interpolation of any other trauma. A similar assessment must be made of the case of a woman whose anxiety neurosis broke out after the loss of her child, or of the student whose preparatory studies for his final examination were interfered with by an anxiety neurosis. I think that in these instances, too, the effect is not explained by the ostensible aetiology. One is not necessarily 'overworked' by study, and a healthy mother as a rule reacts only with normal grief to the loss of a child. Above all, however, I should have expected the student, as a result of his overwork, to acquire cephalasthenia, and the mother, as a result of her bereavement, hysteria. That both should have been overtaken by anxiety neurosis leads me to attach importance to the fact that the mother had been living for eight years in conditions of marital coitus interruptus, and that the student had for three years had an ardent love affair with a 'respectable' girl whom he had to avoid making pregnant.

(1) I emphasized as a point essential to an understanding of anxiety neurosis that the anxiety appearing in it does not admit of a psychical derivation - that is to say that the preparedness for anxiety, which constitutes the nucleus of the neurosis, cannot be acquired by a single or repeated affect of psychically justified fright. Fright, I maintained, might result in hysteria or a traumatic neurosis, but not in an anxiety neurosis. This denial, it is easy to see, is nothing else than the counterpart to my contention, on the positive side, that the anxiety appearing in my neurosis corresponds to a somatic sexual tension which has been deflected from the psychical field - a tension which would otherwise have made itself felt as libido.

Against this, Löwenfeld insists on the fact that in a number of cases 'states of anxiety appear immediately or shortly after a psychical shock (fright alone, or accidents which were accompanied by fright), and in such situations there are sometimes circumstances which make the simultaneous operation of sexual noxae of the kind mentioned extremely improbable.' He gives, shortly, as a particularly pregnant example, one clinical observation (to serve instead of many). This example concerns a woman of thirty, with a hereditary taint, who had been married for four years and who had had a first, difficult, confinement a year before. A few weeks after this event her husband had an attack of illness which frightened her, and in her agitation she ran about the cold room in her chemise. From that time on she was ill. First she had states of anxiety and palpitations in the evening, then came attacks of convulsive trembling, and after that phobias, and so on. It was the picture of a fully-developed anxiety neurosis. 'Here,' concludes Löwenfeld, 'the anxiety states are obviously of psychical origin, brought about by the single fright.'
I do not doubt that my respected critic can produce many similar cases. I myself can supply a long list of analogous examples. Anyone who has not seen such cases - and they are extremely common - of an outbreak of anxiety neurosis after a psychical shock, ought not to regard himself as qualified to take part in discussions about anxiety neurosis. I will only remark in this connection that neither fright nor anxious expectation need always be found in the aetiology of such cases; any other emotion will do as well. If I hastily recall a few cases from my memory, I think of a man of forty-five who had his first attack of anxiety (with cardiac collapse) at the news of the death of his father, who was an old man; from that time on he developed a complete and typical anxiety neurosis with agoraphobia. Again, I think of a young man who was overtaken by the same neurosis on account of his agitation about the disagreements between his young wife and his mother and who had a fresh onset of agoraphobia after every domestic quarrel. Then, there was a student, something of an idler, who produced his first anxiety attacks during a period in which, under the spur of his father's displeasure, he was working hard for an examination. I recall, too, a woman, herself childless, who fell ill as a result of anxiety about the health of a small niece. And other similar instances. About the facts themselves, which Löwenfeld uses against me, there is not the slightest doubt.

So it was with my cases of anxiety neurosis. Let us take the man who, after receiving the news of his father's death, fell ill so inexplicably. (I add 'inexplicably' because the death was not unexpected and did not occur in unusual or shattering circumstances.) This man had carried out coitus interruptus for eleven years with his wife, whom he tried for the most part to satisfy. Again, the young man who was not equal to the quarrels between his wife and his mother, had practised withdrawal with his young wife from the first, in order to spare himself the burden of children. Then we have the student who acquired an anxiety neurosis from overwork, instead of the cerebral neurasthenia that was to be expected: he had maintained a relationship for three years with a girl whom it was not permissible for him to make pregnant. Again, there was the woman who, childless herself, was overtaken by an anxiety neurosis about a niece's illness: she was married to an impotent man and had never been sexually satisfied. And so on. Not all these cases are equally clear or equally good evidence for my thesis; but when I add them to the very considerable number of cases in which the aetiology shows nothing but the specific factor, they fit without contradiction into the theory I have put forward and they allow of an extension of our aetiological understanding beyond the boundaries hitherto in force.
If anyone wants to prove to me that in these remarks I have unduly neglected the significance of the stock aetiological factors, he must confront me with observations in which my specific factor is missing - that is, with cases in which anxiety neurosis has arisen after a psychical shock although the subject has (on the whole) led a normal vita sexualis. Let us see now whether Löwenfeld's case fulfils this condition. My respected opponent has evidently not been clear about this necessity in his own mind, otherwise he would not have left us so completely in the dark about his patient's vita sexualis. I will leave on one side the fact that this case of a lady of thirty is obviously complicated by a hysteria as to the psychical origin of which I have not the least doubt; and I naturally admit without raising any objection the presence of an anxiety neurosis alongside of this hysteria. But before I turn a case to account for or against the theory of the sexual aetiology of the neuroses, I must first have studied the patient's sexual behaviour more closely than Löwenfeld has done here. I should not be content to conclude that, because the time at which the lady received her psychical shock was shortly after a confinement, coitus interruptus could not have played a part during the previous year, and that therefore sexual noxae are ruled out. I know cases of women who were made pregnant every year, and who yet had anxiety neurosis, because - incredible as it may seem - all sexual relations were stopped after the first fertilizing coition, so that in spite of having many children they suffered from sexual privation through all these years. No doctor is ignorant of the fact that women conceive from men whose potency is very slight and who are not able to give them satisfaction. Finally (and this is a consideration which should be taken into account precisely by the upholders of a hereditary aetiology), there are plenty of women who are afflicted with congenital anxiety neurosis - that is to say, who inherit, or who develop without any demonstrable disturbance from outside, a vita sexualis which is the same as the one usually acquired through coitus interruptus and similar noxae. In a number of these women we are able to discover a hysterical illness in their youth, since which their vita sexualis has been disturbed and a deflection of sexual tension from the psychical sphere has been established. Women with this kind of sexuality are incapable of obtaining real satisfaction even from normal coitus, and they develop anxiety neurosis either spontaneously or after further operative factors have supervened. Which of all these elements were present in Löwenfeld's case? I do not know. But I repeat: this case is evidence against me only if the lady who responded to a single fright with an anxiety neurosis had before then enjoyed a normal vita sexualis.

(2) Löwenfeld says further that he has repeatedly seen anxiety states appear and disappear where a change in the subject's sexual life had certainly not taken place but where other factors were in play.
I, too, have made exactly the same observation, without, however, being misled by it. I myself have caused anxiety attacks to disappear by means of psychical treatment, improvement of the patient's general health, and so on; but I have naturally not concluded from this that what had caused the anxiety attack was a lack of treatment. Not that I should like to foist a conclusion of this sort upon Löwenfeld. My joking remark is only intended to show that the state of affairs may easily be complicated enough to render Löwenfeld's objection quite invalid. I have not found it difficult to reconcile the fact brought forward here with my assertion that anxiety neurosis has a specific aetiology. It will readily be granted that there are aetiological factors which, in order to exercise their effect, must operate with a certain intensity (or quantity) and over a certain period of time - which, that is to say, become summed. The effects of alcohol are a standard example of causation like this through summation. It follows that there must be a period of time in which the specific aetiology is at work but in which its effect is not yet manifest. During this time the subject is not ill as yet, but he is predisposed to a particular illness - in our case, to anxiety neurosis - and now the addition of a stock noxa will be able to set the neurosis off, just as would a further intensification of the operation of the specific noxa. The situation may also be expressed as follows: it is not enough for the specific noxa to be present; it must also reach a definite amount; and, in the process of reaching that limit, a quantity of specific noxa can be replaced by a quota of stock noxa. If the latter is removed once more, we find ourselves below a certain threshold and the clinical symptoms depart once more. The whole therapy of the neuroses rests upon the fact that the total load upon the nervous system, to which it has succumbed, can be brought below this threshold by influencing the aetiological mixture in a great variety of ways. From these circumstances we can draw no conclusion as to the existence or non-existence of a specific aetiology. These considerations are surely indisputable and assured. But anyone who does not think them sufficient may be influenced by the following argument. According to the views of Löwenfeld and very many others, the aetiology of anxiety states is to be found in heredity. Now heredity is certainly immune to alteration; thus if anxiety neurosis is curable by treatment, we should have to conclude according to Löwenfeld's argument that its aetiology cannot reside in heredity.

Against Löwenfeld's further assertion - that anxiety-states only appear under certain conditions and fail to appear when those conditions are avoided, regardless of what the subject's vita sexualis may be - it must be pointed out that he clearly has in mind here only the anxiety of phobias, as, indeed, is shown by the examples attached to the passage I have quoted. He says nothing at all about the spontaneous anxiety attacks which take the form of vertigo, palpitation, dyspnoea, trembling, sweating, and so on. My theory, on the contrary, seems by no means unequal to explaining the emergence or non-emergence of these attacks of anxiety. For in a whole number of such cases of anxiety neurosis there does in fact appear to be a periodicity in the emergence of the states of anxiety, similar to what has been observed in epilepsy, except that in the latter the mechanism of the periodicity is more transparent. On closer examination we discover the presence, with great regularity, of an excitatory sexual process (that is, a process which is able to generate somatic sexual tension), and which, after the lapse of a definite and often constant interval of time, is followed by the anxiety attack. This role is played, in abstinent women, by menstrual excitation; it is played, too, by nocturnal pollutions, which also recur periodically. Above all, it is played by sexual intercourse itself (harmful from its being incomplete), which carries over its own periodicity to the effects it brings about, viz. to the anxiety attacks. If anxiety attacks occur which break through the usual periodicity, it is generally possible to trace them back to an incidental cause of rare and irregular occurrence - to a single sexual experience, something read or seen, and the like. The interval I have mentioned varies from a few hours to two days; it is the same as that which elapses in other people between the occurrence of the same causes and the onset of the well-known sexual migraine, which has well-established connections with the syndrome of anxiety neurosis.
The fact of there being a connection between sexual restraint and anxiety states is, so far as I know, no longer disputed even by physicians who have no contact with psycho-analysis. But I can well believe that an attempt is made to reverse the relation and to put forward the view that the people concerned are such as are already inclined to apprehensiveness and for that reason practise restraint in sexual matters as well. This, however, is decisively contradicted by the behaviour of women, whose sexual activity is essentially of a passive nature - is determined, that is to say, by their treatment by the man. The more passionate a woman is - the more inclined, therefore, to sexual intercourse and the more capable of being satisfied - the more certain she is to react with manifestations of anxiety to a man's impotence or to coitus interruptus, whereas in the case of anaesthetic women or those without much libido such ill-treatment plays a far smaller part.
[1916-1917, 3449]
A further point of departure is furnished by the observation, not so far mentioned, that in whole sets of cases anxiety neurosis is accompanied by a most noticeable decrease of sexual libido or *psychical desire*, so that on being told that their complaint results from 'insufficient satisfaction', patients regularly reply that that is impossible, for precisely now all sexual need has become extinguished in them. From all these indications - that we have to do with an accumulation of excitation; that the anxiety which probably corresponds to this accumulated excitation is of somatic origin, so that what is being accumulated is a *somatic* excitation; and, further, that this somatic excitation is of a sexual nature and that a decrease of *psychical* participation in the sexual processes goes along with it - all these indications, I say, incline us to expect that *the mechanism of anxiety is to be looked for in a deflection of somatic excitation from the psychical sphere, and in a consequent abnormal employment of that excitation.*

We can include within the framework of this description of the sexual process not only the aetiology of anxiety neurosis but that of genuine neurasthenia. Neurasthenia develops whenever the adequate unloading (the adequate action) is replaced by a less adequate one - thus, when normal coition, carried out in the most favourable conditions, is replaced by masturbation or spontaneous emission. Anxiety neurosis, on the other hand, is the product of all those factors which prevent the somatic sexual excitation from being worked over psychically. The manifestations of anxiety neurosis appear when the somatic excitation which has been deflected from the psyche is expended subcortically in totally inadequate reactions.

I will now attempt to discover whether the aetiological conditions for anxiety neurosis which I set out above exhibit the common character that I have just attributed to them. The first aetiological factor I postulated for men was intentional abstinence. Abstinence consists in the withholding of the specific action which ordinarily follows upon libido. Such withholding may have two consequences. In the first place, the somatic excitation accumulates; it is then deflected into other paths, which hold out greater promise of discharge than does the path through the psyche. Thus the libido will in the end sink, and the excitation will manifest itself subcortically as anxiety. In the second place, if the libido is not diminished, or if the somatic excitation is expended, by a short cut, in emissions, or if, in consequence of being forced back, the excitation really ceases, then all kinds of things other than an anxiety neurosis will ensue. Abstinence, then, leads to anxiety neurosis in the manner described above. But it is also the operative agent in my second aetiological group, that of unconsummated excitation. My third group, that of coitus reservatus with consideration for the woman, operates by disturbing the man's psychical preparedness for the sexual process, in that it introduces alongside of the task of mastering the sexual affect another psychical task, one of a deflecting sort. In consequence of this psychical deflection, once more, libido gradually disappears, and the further course of things is then the same as in the case of abstinence. Anxiety in senescence (the male climacteric) requires another explanation. Here there is no diminution of libido; but, as in the female climacteric, so great an increase occurs in the production of somatic excitation that the psyche proves relatively insufficient to master it.

The view here developed depicts the symptoms of anxiety neurosis as being in a sense *surrogates* of the omitted specific action following on sexual excitation. In further support of this view, I may point out that in normal copulation too the excitation expends itself, among other things, in accelerated breathing, palpitation, sweating, congestion, and so on. In the corresponding anxiety attacks of our neurosis we have before us the dyspnoea, palpitations, etc. of copulation in an isolated and exaggerated form.
(1) I emphasized as a point essential to an understanding of anxiety neurosis that the anxiety appearing in it does not admit of a psychical derivation - that is to say that the preparedness for anxiety, which constitutes the nucleus of the neurosis, cannot be acquired by a single or repeated affect of psychically justified fright. Fright, I maintained, might result in hysteria or a traumatic neurosis, but not in an anxiety neurosis. This denial, it is easy to see, is nothing else than the counterpart to my contention, on the positive side, that the anxiety appearing in my neurosis corresponds to a somatic sexual tension which has been deflected from the psychical field - a tension which would otherwise have made itself felt as libido.

I see no reason why I should try to hide the gaps and weaknesses in my theory. The main thing about the problem of the phobias seems to me to be that when the vita sexualis is normal - then the specific condition, a disturbance of sexual life in the sense of a deflection of the somatic from the psychical, is not fulfilled - phobias do not appear at all. However much else may be obscure about the mechanism of phobias, my theory can only be refuted when I have been shown phobias where sexual life is normal or even where there is a disturbance of it of a non-specific sort.

This new view of things calls for an examination of another assertion of mine - namely, that the ego is the actual seat of anxiety. I think this proposition still holds good. There is no reason to assign any manifestation of anxiety to the super-ego; while the expression 'anxiety of the id' would stand in need of correction, though rather as to its form than its substance. Anxiety is an affective state and as such can, of course, only be felt by the ego. The id cannot have anxiety as the ego can; for it is not an organization and cannot make a judgement about situations of danger. On the other hand it very often happens that processes take place or begin to take place in the id which cause the ego to produce anxiety. Indeed, it is probable that the earliest repressions as well as most of the later ones are motivated by an ego-anxiety of this sort in regard to particular processes in the id. Here again we are rightly distinguishing between two cases: the case in which something occurs in the id which activates one of the danger-situations for the ego and induces the latter to give the anxiety-signal for inhibition to take place, and the case in which a situation analogous to the trauma of birth is established in the id and an automatic reaction of anxiety ensues. The two cases may be brought closer together if it is pointed out that the second case corresponds to the earliest and original danger-situation, while the first case corresponds to any one of the later determinants of anxiety that have been derived from it; or, as applied to the disorders which we in fact come across, that the second case is operative in the aetiology of the 'actual' neuroses, while the first remains typical for that of the psychoneuroses.

(b) Anxiety from Transformation of Libido

The view of anxiety which I have put forward in these pages diverges somewhat from the one I have hitherto thought correct. Formerly I regarded anxiety as a general reaction of the ego under conditions of unpleasure. I always sought to justify its appearance on economic grounds and I assumed, on the strength of my investigations into the 'actual' neuroses, that libido (sexual excitation) which was rejected or not utilized by the ego found direct discharge in the form of anxiety. It cannot be denied that these various assertions did not go very well together, or at any rate did not necessarily follow from one another. Moreover, they gave the impression of there being a specially intimate connection between anxiety and libido and this did not accord with the general character of anxiety as a reaction to unpleasure.
For we consider that what is responsible for the anxiety in hysteria and other neuroses is the process of repression. We believe it is possible to give a more complete account of this than before, if we separate what happens to the idea that has to be repressed from what happens to the quota of libido attaching to it. It is the idea which is subjected to repression and which may be distorted to the point of being unrecognizable; but its quota of affect is regularly transformed into anxiety - and this is so whatever the nature of the affect may be, whether it is aggressiveness or love. It makes no essential difference, then, for what reason a quota of libido has become unemployable: whether it is on account of the infantile weakness of the ego, as in children's phobias, or on account of somatic processes in sexual life, as in anxiety neurosis, or owing to repression, as in hysteria. Thus in reality the two mechanisms that bring about neurotic anxiety coincide.

[1933a, 4690]
In some cases of anxiety neurosis no aetiology at all is to be discovered. It is worth noting that in such cases there is seldom any difficulty in establishing evidence of a grave hereditary taint. [1895b, 336]

With an unerring eye Löwenfeld (1895) detects the essential feature of my paper - namely, my assertion that anxiety-symptoms have a specific and uniform aetiology of a sexual nature. If this cannot be established as a fact, then the main reason for detaching an independent anxiety neurosis from neurasthenia disappears as well. There remains, it is true, one difficulty to which I called attention - the fact that anxiety-symptoms also have such very unmistakable connections with hysteria, so that a decision on Löwenfeld's lines would prejudice the separation between hysteria and neurasthenia. This difficulty, however, is met by a recourse to heredity as the common cause of all these neuroses (a view which I will go into later). [1895f, 354]

If I consider this aetiological formula for anxiety neurosis in detail, I am able to add the following remarks. Whether a special personal constitution (which need not be produced by heredity) is absolutely necessary for the production of an anxiety neurosis, or whether any normal person can be made to have an anxiety neurosis by some given quantitative increase of the specific factor - this I am not able to decide with certainty; but I incline strongly to the latter view. -Hereditary disposition is the most important precondition for anxiety neurosis; but it is not an indispensable one, since it is absent in a class of borderline cases. -The presence of the specific sexual factor can, in the majority of cases, be demonstrated with certainty. In one series of cases (congenital ones) this factor is not separated from the precondition of heredity, but is fulfilled with the help of it. That is to say, in some patients this peculiarity of the \textit{vita sexualis} - psychical inadequacy in mastering somatic sexual tension - is innate in the form of a stigma whereas ordinarily it is \textit{via} that peculiarity that they acquire the neurosis. In another class of borderline cases the specific cause is contained in a contributory one. This is when the psychical inadequacy which I have just mentioned is brought about by exhaustion and such causes. All these cases fall into classes which melt into one another and do not form separate categories. In all of them, moreover, we find that the sexual tension undergoes the same vicissitudes; and for most of them the distinction between precondition, specific and auxiliary cause holds good, in conformity with the solution of the aetiological equation which I have given above. [1895f, 364]

When I consult my experience on this point, I cannot find that there is any antithetic relation as regards anxiety neurosis between hereditary disposition and the specific sexual factor. On the contrary, the two aetiological factors support and supplement each other. The sexual factor is usually only operative in those who have an innate hereditary taint as well; heredity alone is usually not able to produce an anxiety neurosis, but waits for the occurrence of a sufficient amount of the specific sexual noxa. The discovery of the hereditary element does not, therefore, exempt us from searching for a specific factor. On its discovery, incidentally, all our therapeutic interest as well depends. For what can we do therapeutically about heredity as an aetiological element? It has always been there in the patient and will continue to be there until the end of his life. Taken by itself, it cannot help us to understand the episodic onset of a neurosis or the cessation of a neurosis as a result of treatment. It is nothing but a \textit{precondition} of the neurosis - an inexpressibly important precondition, it is true, but nevertheless one which has been overestimated, to the detriment of therapy and theoretical comprehension. To be convinced by the contrasting state of affairs, one has only to think of the cases of nervous diseases that run in families (such as chorea chronica, Thomsen's disease, and so on), in which heredity unites in itself all the aetiological preconditions. [1895f, 365]
I will say finally that the pathogenesis of neurasthenia and anxiety neurosis can easily do without the co-operation of a hereditary disposition. That is the outcome of daily observation. But if heredity is present, the development of the neurosis will be affected by its powerful influence.

[1896a, 375]
(3) But anxiousness - which, though mostly latent as regards consciousness, is constantly lurking in the background - has other means of finding expression besides this. It can suddenly break through into consciousness without being aroused by a train of ideas, and thus provoke an anxiety attack. An anxiety attack of this sort may consist of the feeling of anxiety, alone, without any associated idea, or accompanied by the interpretation that is nearest to hand, such as ideas of the extinction of life, or of a stroke, or of a threat of madness; or else some kind of paraesthesia (similar to the hysterical aura) may be combined with the feeling of anxiety, or, finally, the feeling of anxiety may have linked to it a disturbance of one or more of the bodily functions - such as respiration, heart action, vasomotor innervation or glandular activity. From this combination the patient picks out in particular now one, now another, factor. He complains of 'spasms of the heart', 'difficulty in breathing', 'outbreaks of sweating', 'ravenous hunger', and such like; and, in his description, the feeling of anxiety often recedes into the background or is referred to quite unrecognizably as 'being unwell', 'feeling uncomfortable', and so on.

(b) Anxiety attacks accompanied by disturbances of respiration, several forms of nervous dyspnoea, attacks resembling asthma, and the like. I would emphasize that even these attacks are not always accompanied by recognizable anxiety.

[1895b, 330]
So there I was with the neuroses once again - for nothing else could very well be the matter with this strong, well-built girl with her unhappy look. I was interested to find that neuroses could flourish in this way at a height of over 6,000 feet; I questioned her further therefore. I report the conversation that followed between us just as it is impressed on my memory and I have not altered the patient's dialect.
[1895d, 111]

This did not, at first sight, sound like a nervous symptom. But soon it occurred to me that probably it was only a description that stood for an anxiety attack: she was choosing shortness of breath out of the complex of sensations arising from anxiety and laying undue stress on that single factor.
[1895d, 112]

(3) But anxiousness - which, though mostly latent as regards consciousness, is constantly lurking in the background - has other means of finding expression besides this. It can suddenly break through into consciousness without being aroused by a train of ideas, and thus provoke an anxiety attack. An anxiety attack of this sort may consist of the feeling of anxiety, alone, without any associated idea, or accompanied by the interpretation that is nearest to hand, such as ideas of the extinction of life, or of a stroke, or of a threat of madness; or else some kind of paraesthesia (similar to the hysterical aura) may be combined with the feeling of anxiety, or, finally, the feeling of anxiety may have linked to it a disturbance of one or more of the bodily functions - such as respiration, heart action, vasomotor innervation or glandular activity. From this combination the patient picks out in particular now one, now another, factor. He complains of 'spasms of the heart', 'difficulty in breathing', 'outbreaks of sweating', 'ravenous hunger', and such like; and, in his description, the feeling of anxiety often recedes into the background or is referred to quite unrecognizably as 'being unwell', 'feeling uncomfortable', and so on.
[1895b, 330]

(b) Anxiety attacks accompanied by disturbances of respiration, several forms of nervous dyspnoea, attacks resembling asthma, and the like. I would emphasize that even these attacks are not always accompanied by recognizable anxiety.
[1895b, 331]

(5) Waking up at night in a fright (the pavor nocturnus of adults), which is usually combined with anxiety, dyspnoea, sweating and so on, is very often nothing else than a variant of the anxiety attack. This disturbance is the determinant of a second form of sleeplessness within the field of anxiety neurosis. I have become convinced, moreover, that the pavor nocturnus of children, too, exhibits a form which belongs to anxiety neurosis. The streak of hysteria about it, the linking of the anxiety with the reproduction of an appropriate experience or a dream, causes the pavor nocturnus of children to appear as something special. But the pavor can also emerge in a pure form, without any dream or recurring hallucination.
[1895b, 332]

Attacks of vertigo are not seldom accompanied by the worst sort of anxiety, often combined with cardiac and respiratory disturbances. According to my observations, vertigo produced by heights, mountains and precipices is also often present in anxiety neurosis. Furthermore, I am not sure whether it is not also right to recognize alongside of this a vertigo a stomacho laeso.
[1895b, 332]
(3) But anxiousness - which, though mostly latent as regards consciousness, is constantly lurking in the background - has other means of finding expression besides this. It can suddenly break through into consciousness without being aroused by a train of ideas, and thus provoke an anxiety attack. An anxiety attack of this sort may consist of the feeling of anxiety, alone, without any associated idea, or accompanied by the interpretation that is nearest to hand, such as ideas of the extinction of life, or of a stroke, or of a threat of madness; or else some kind of paraesthesia (similar to the hysterical aura) may be combined with the feeling of anxiety, or, finally, the feeling of anxiety may have linked to it a disturbance of one or more of the bodily functions - such as respiration, heart action, vasomotor innervation or glandular activity. From this combination the patient picks out in particular now one, now another, factor. He complains of 'spasms of the heart', 'difficulty in breathing', 'outbreaks of sweating', 'ravenous hunger', and such like; and, in his description, the feeling of anxiety often recedes into the background or is referred to quite unrecognizably as 'being unwell', 'feeling uncomfortable', and so on.

[1895b, 330]

(a) Anxiety attacks accompanied by disturbances of the heart action, such as palpitation, either with transitory arrhythmia or with tachycardia of longer duration which may end in serious weakness of the heart and which is not always easily differentiated from organic heart affection; and, again, pseudo-angina pectoris - diagnostically a delicate subject!

[1895b, 331]

(6) 'Vertigo' occupies a prominent place in the group of symptoms of anxiety neurosis. In its mildest form it is best described as 'giddiness'; in its severer manifestations, as 'attacks of vertigo' (with or without anxiety), it must be classed among the gravest symptoms of the neurosis. The vertigo of anxiety neurosis is not rotatory nor does it especially affect certain planes or directions, like Meniere's vertigo. It belongs to the class of locomotor or co-ordinatory vertigo, as does the vertigo in oculomotor paralysis. It consists in a specific state of discomfort, accompanied by sensations of the ground rocking, of the legs giving way and of its being impossible to stand up any more; while the legs feel as heavy as lead and tremble or the knees bend. This vertigo never leads to a fall. On the other hand, I should like to state that an attack of vertigo of this kind may have its place taken by a profound fainting fit. Other conditions in the nature of fainting occurring in anxiety neurosis appear to depend upon cardiac collapse.

[1895b, 332]

Attacks of vertigo are not seldom accompanied by the worst sort of anxiety, often combined with cardiac and respiratory disturbances. According to my observations, vertigo produced by heights, mountains and precipices is also often present in anxiety neurosis. Furthermore, I am not sure whether it is not also right to recognize alongside of this a vertigo a stomacho laeso.

[1895b, 332]
(3) But anxiousness - which, though mostly latent as regards consciousness, is constantly lurking in the background - has other means of finding expression besides this. It can suddenly break through into consciousness without being aroused by a train of ideas, and thus provoke an anxiety attack. An anxiety attack of this sort may consist of the feeling of anxiety, alone, without any associated idea, or accompanied by the interpretation that is nearest to hand, such as ideas of the extinction of life, or of a stroke, or of a threat of madness; or else some kind of paraesthesia (similar to the hysterical aura) may be combined with the feeling of anxiety, or, finally, the feeling of anxiety may have linked to it a disturbance of one or more of the bodily functions - such as respiration, heart action, vasomotor innervation or glandular activity. From this combination the patient picks out in particular now one, now another, factor. He complains of 'spasms of the heart', 'difficulty in breathing', 'outbreaks of sweating', 'ravenous hunger', and such like; and, in his description, the feeling of anxiety often recedes into the background or is referred to quite unrecognizably as 'being unwell', 'feeling uncomfortable', and so on.

(e) Attacks of ravenous hunger, often accompanied by vertigo.

(8) The digestive activities undergo only a few disturbances in anxiety neurosis; but these are characteristic ones. Sensations such as an inclination to vomit and nausea are not rare, and the symptom of ravenous hunger may, by itself or in conjunction with other symptoms (such as congestions), give rise to a rudimentary anxiety attack. As a chronic change, analogous to anxious expectation, we find an inclination to diarrhoea, and this has been the occasion of the strangest diagnostic errors. Unless I am mistaken, it is this diarrhoea to which Möbius (1894) has drawn attention recently in a short paper. I suspect, further, that Peyer's reflex diarrhoea, which he derives from disorders of the prostate (Peyer, 1893), is nothing else than this diarrhoea of anxiety neurosis. The illusion of a reflex relationship is created because the same factors come into play in the aetiology of anxiety neurosis as are at work in the setting up of such affections of the prostate and similar disorders.
(3) But anxiousness - which, though mostly latent as regards consciousness, is constantly lurking in the background - has other means of finding expression besides this. It can suddenly break through into consciousness without being aroused by a train of ideas, and thus provoke an anxiety attack. An anxiety attack of this sort may consist of the feeling of anxiety, alone, without any associated idea, or accompanied by the interpretation that is nearest to hand, such as ideas of the extinction of life, or of a stroke, or of a threat of madness; or else some kind of paraesthesia (similar to the hysterical aura) may be combined with the feeling of anxiety, or, finally, the feeling of anxiety may have linked to it a disturbance of one or more of the bodily functions - such as respiration, heart action, vasomotor innervation or glandular activity. From this combination the patient picks out in particular now one, now another, factor. He complains of 'spasms of the heart', 'difficulty in breathing', 'outbreaks of sweating', 'ravenous hunger', and such like; and, in his description, the feeling of anxiety often recedes into the background or is referred to quite unrecognizably as 'being unwell', 'feeling uncomfortable', and so on.

[1895b, 330]

(c) Attacks of sweating, often at night.
[1895b, 331]

(5) Waking up at night in a fright (the pavor nocturnus of adults), which is usually combined with anxiety, dyspnoea, sweating and so on, is very often nothing else than a variant of the anxiety attack. This disturbance is the determinant of a second form of sleeplessness within the field of anxiety neurosis. I have become convinced, moreover, that the pavor nocturnus of children, too, exhibits a form which belongs to anxiety neurosis. The streak of hysteria about it, the linking of the anxiety with the reproduction of an appropriate experience or a dream, causes the pavor nocturnus of children to appear as something special. But the pavor can also emerge in a pure form, without any dream or recurring hallucination.
[1895b, 332]
(h) Attacks of what are known as *congestions*, including practically everything that has been termed vasomotor neurasthenia.
[1895b, 331]
(i) Attacks of paraesthesias. (But these seldom occur without anxiety or a similar feeling of discomfort.) [1895b, 331]

(9) The paraesthesias which may accompany attacks of vertigo or anxiety are interesting because they, like the sensations of the hysterical aura, become associated in a definite sequence; although I find that these associations, in contrast to the hysterical ones, are atypical and changing. A further similarity to hysteria is provided by the fact that in anxiety neurosis a kind of conversion* takes place on to bodily sensations, which may easily be overlooked - for instance, on to rheumatic muscles. A whole number of what are known as rheumatic individuals who, moreover, can be shown to be rheumatic - are in reality suffering from anxiety neurosis. Along with this increase of sensitivity to pain, I have also observed in a number of cases of anxiety neurosis a tendency to hallucinations; and these could not be interpreted as hysterical. [1895b, 335]
(e) Attacks of *ravenous hunger*, often accompanied by vertigo.
[1895b, 331]

(g) Attacks of locomotor *vertigo*.
[1895b, 331]

(6) *Vertigo* occupies a prominent place in the group of symptoms of anxiety neurosis. In its mildest form it is best described as 'giddiness'; in its severer manifestations, as 'attacks of vertigo' (with or without anxiety), it must be classed among the gravest symptoms of the neurosis. The vertigo of anxiety neurosis is not rotatory nor does it especially affect certain planes or directions, like Meniere's vertigo. It belongs to the class of locomotor or co-ordinatory vertigo, as does the vertigo in oculomotor paralysis. It consists in a specific state of discomfort, accompanied by sensations of the ground rocking, of the legs giving way and of its being impossible to stand up any more; while the legs feel as heavy as lead and tremble or the knees bend. This vertigo never leads to a fall. On the other hand, I should like to state that an attack of vertigo of this kind may have its place taken by a profound fainting fit. Other conditions in the nature of fainting occurring in anxiety neurosis appear to depend upon cardiac collapse.
[1895b, 332]

Attacks of vertigo are not seldom accompanied by the worst sort of anxiety, often combined with cardiac and respiratory disturbances. According to my observations, vertigo produced by heights, mountains and precipices is also often present in anxiety neurosis. Furthermore, I am not sure whether it is not also right to recognize alongside of this a *vertigo a stomacho laeso*.
[1895b, 332]

(c) In some neurotic conditions locomotion is inhibited by a disinclination to walk or a weakness in walking. In hysteria there will be a paralysis of the motor apparatus, or this one special function of the apparatus will be abolished (abasia). Especially characteristic are the increased difficulties that appear in locomotion owing to the introduction of certain stipulations whose non-observance results in anxiety (phobia).
[1926d, 4250]
(5) *Waking up at night in a fright* (the *pavor nocturnus* of adults), which is usually combined with anxiety, dyspnoea, sweating and so on, is very often nothing else than a variant of the anxiety attack. This disturbance is the determinant of a second form of sleeplessness within the field of anxiety neurosis. I have become convinced, moreover, that the *pavor nocturnus* of children, too, exhibits a form which belongs to anxiety neurosis. The streak of hysteria about it, the linking of the anxiety with the reproduction of an appropriate experience or a dream, causes the *pavor nocturnus* of children to appear as something special. But the *pavor* can also emerge in a pure form, without any dream or recurring hallucination. [1895, 332]
(10) Several of the symptoms I have mentioned, which accompany or take the place of an anxiety attack, also appear in a chronic form. In that case they are still less easy to recognize, since the anxious sensation which goes with them is less clear than in an anxiety attack. This is especially true of diarrhoea, vertigo and paraesthesias. Just as an attack of vertigo can be replaced by a fainting fit, so chronic vertigo can be replaced by a constant feeling of great feebleness, lassitude and so on.
[1895b, 335]
(d) Attacks of tremor and shivering which are only too easily confused with hysterical attacks. [1895b, 331]

The behaviour of the gastro-intestinal tract in anxiety neurosis presents a sharp contrast to the influence of neurasthenia on those functions. Mixed cases often show the familiar 'alternation between diarrhoea and constipation'. Analogous to this diarrhoea is the need to urinate that occurs in anxiety neurosis. [1895b, 335]

(9) The paraesthesias which may accompany attacks of vertigo or anxiety are interesting because they, like the sensations of the hysterical aura, become associated in a definite sequence; although I find that these associations, in contrast to the hysterical ones, are atypical and changing. A further similarity to hysteria is provided by the fact that in anxiety neurosis a kind of conversion¹ takes place on to bodily sensations, which may easily be overlooked - for instance, on to rheumatic muscles. A whole number of what are known as rheumatic individuals who, moreover, can be shown to be rheumatic - are in reality suffering from anxiety neurosis. Along with this increase of sensitivity to pain, I have also observed in a number of cases of anxiety neurosis a tendency to hallucinations; and these could not be interpreted as hysterical. [1895b, 335]

(10) Several of the symptoms I have mentioned, which accompany or take the place of an anxiety attack, also appear in a chronic form. In that case they are still less easy to recognize, since the anxious sensation which goes with them is less clear than in an anxiety attack. This is especially true of diarrhoea, vertigo and paraesthesias. Just as an attack of vertigo can be replaced by a fainting fit, so chronic vertigo can be replaced by a constant feeling of great feebleness, lassitude and so on. [1895b, 335]

A further point of departure is furnished by the observation, not so far mentioned, that in whole sets of cases anxiety neurosis is accompanied by a most noticeable decrease of sexual libido or psychical desire, so that on being told that their complaint results from 'insufficient satisfaction', patients regularly reply that that is impossible, for precisely now all sexual need has become extinguished in them. From all these indications - that we have to do with an accumulation of excitation; that the anxiety which probably corresponds to this accumulated excitation is of somatic origin, so that what is being accumulated is a somatic excitation; and, further, that this somatic excitation is of a sexual nature and that a decrease of psychical participation in the sexual processes goes along with it - all these indications, I say, incline us to expect that the mechanism of anxiety is to be looked for in a deflection of somatic excitation from the psychical sphere, and in a consequent abnormal employment of that excitation. [1895b, 343]
There are still a few words to be said about the relations of anxiety neurosis to the other neuroses as regards their onset and their internal connections. [1895b, 348]

A noteworthy relation between the symptoms of the 'actual' neuroses and of the psychoneuroses makes a further important contribution to our knowledge of the formation of symptoms in the latter. For a symptom of an 'actual' neurosis is often the nucleus and first stage of a psychoneurotic symptom. A relation of this kind can be most clearly observed between neurasthenia and the transference neurosis known as 'conversion hysteria', between anxiety neurosis and anxiety hysteria, but also between hypochondria and the forms of disorder which will be mentioned later under the name of paraphrenia (dementia praecox and paranoia). Let us take as an example a case of hysterical headache or lumbar pain. Analysis shows us that, by condensation and displacement, it has become a substitutive satisfaction for a whole number of libidinal phantasies or memories. But this pain was also at one time a real one and it was then a direct sexual-toxic symptom, the somatic expression of a libidinal excitation. We are far from asserting that all hysterical symptoms contain a nucleus of this kind. But it remains a fact that this is especially often the case and that whatever somatic influences (whether normal or pathological) are brought about by libidinal excitation are preferred for the construction of hysterical symptoms. In such cases they play the part of the grain of sand which a mollusc coats with layers of mother-of-pearl. In the same way, the passing indications of sexual excitement which accompany the sexual act are employed by the psychoneurosis as the most convenient and appropriate material for the construction of symptoms. [1916-1917, 3441]
As regards its intimate nature, anxiety neurosis presents the most interesting agreements with, and differences from, the other major neuroses, in particular neurasthenia and hysteria. It shares with neurasthenia one main characteristic - namely that the source of excitation, the precipitating cause of the disturbance, lies in the somatic field instead of the psychical one, as is the case in hysteria and obsessional neurosis. In other respects we rather find a kind of antithesis between the symptoms of anxiety neurosis and of neurasthenia, which might be brought out by such labels as 'accumulation of excitation' and 'impoverishment of excitation'. This antithesis does not prevent the two neuroses from being intermixed with each other; but it nevertheless shows itself in the fact that the most extreme forms of each are in both cases also the purest.

[1895b, 349]
I hope to be able to demonstrate, on another occasion, that there is reason to distinguish a special neurosis, the 'anxiety neurosis', of which the chief symptom is this emotional state. I shall then enumerate its various symptoms and insist on the necessity for differentiating this neurosis from neurasthenia, with which it is now confused. Phobias, then, are part of the anxiety neurosis, and are almost always accompanied by other symptoms of the same group.

[1895c, 324]

We can include within the framework of this description of the sexual process not only the aetiology of anxiety neurosis but that of genuine neurasthenia. Neurasthenia develops whenever the adequate unloading (the adequate action) is replaced by a less adequate one - thus, when normal coition, carried out in the most favourable conditions, is replaced by masturbation or spontaneous emission. Anxiety neurosis, on the other hand, is the product of all those factors which prevent the somatic sexual excitation from being worked over psychically. The manifestations of anxiety neurosis appear when the somatic excitation which has been deflected from the psyche is expended subcortically in totally inadequate reactions.

[1895b, 345]

As regards its intimate nature, anxiety neurosis presents the most interesting agreements with, and differences from, the other major neuroses, in particular neurasthenia and hysteria. It shares with neurasthenia one main characteristic - namely that the source of excitation, the precipitating cause of the disturbance, lies in the somatic field instead of the psychical one, as is the case in hysteria and obsessional neurosis. In other respects we rather find a kind of antithesis between the symptoms of anxiety neurosis and of neurasthenia, which might be brought out by such labels as 'accumulation of excitation' and 'impoverishment of excitation'. This antithesis does not prevent the two neuroses from being intermixed with each other; but it nevertheless shows itself in the fact that the most extreme forms of each are in both cases also the purest.

[1895b, 349]
In the second number of Mendel's *Neurologisches Zentralblatt* for 1895, I published a short paper in which I ventured an attempt to detach a number of nervous states from neurasthenia and to establish them as an independent entity under the name of 'anxiety neurosis'.¹ I was led to do so by the presence of a constant conjunction of certain clinical features with certain aetiological ones - a thing which, in general, should permit us to make a separation of this kind. I found - and in this Hecker (1893) had anticipated me - that the neurotic symptoms in question could all be classed together as constituting expressions of anxiety; and, from my study of the aetiology of the neuroses, I was able to add that these portions of the complex of the 'anxiety neurosis' exhibit special aetiological preconditions which are almost the opposite of the aetiology of neurasthenia. My observations had shown me that in the aetiology of the neuroses (at all events of acquired cases and acquirable forms) sexual factors play a predominant part and one which has been given far too little weight; so that a statement such as that 'the aetiology of the neuroses lies in sexuality', with all its unavoidable incorrectness *per excessum et defectum*, nevertheless comes nearer to the truth than do the other doctrines, which hold the field at the present time. A further assertion which my observations forced me to make was to the effect that the various sexual noxae are not to be found in the aetiology of every neurosis indifferently, but that unmistakable special relationships hold between particular noxae and particular neuroses. Thus I could assume that I had discovered the specific causes of the various neuroses. I then sought to formulate shortly the special character of the sexual noxae which constitute the aetiology of anxiety neurosis, and, on the basis of my view of the sexual process (p. 108), I arrived at the proposition: anxiety neurosis is created by everything which keeps somatic sexual tension away from the psychical sphere, which interferes with its being worked over psychically. If we go back to the concrete circumstances in which this factor becomes operative, we are led to assert that abstinence, whether voluntary or involuntary, sexual intercourse with incomplete satisfaction, coitus interruptus, deflection of psychical interest from sexuality, and similar things, are the specific aetiological factors of the states to which I have given the name of anxiety neurosis.

[1895f, 352]
In other cases the multiplicity of aetiological factors is by no means fortuitous: one of the factors has brought the other into operation. For example, a woman with whom her husband practises coitus reservatus without regard to her satisfaction may find herself compelled to masturbate in order to put an end to the distressing excitation that follows such an act; as a result, she will produce, not an anxiety neurosis pure and simple, but an anxiety neurosis accompanied by symptoms of neurasthenia. Another woman suffering from the same noxa may have to fight against lascivious images against which she tries to defend herself; and in this way she will, through the coitus interruptus, acquire obsessions as well as an anxiety neurosis. Finally, as a result of coitus interruptus, a third woman may lose her affection for her husband and feel an attraction for another man, which she carefully keeps secret; in consequence, she will exhibit a mixture of anxiety neurosis and hysteria.

In a third category of mixed neuroses the interconnection between the symptoms is still more intimate, in that the same aetiological determinant regularly and simultaneously provokes both neuroses. Thus, for instance, the sudden sexual enlightenment, which we have found present in virginal anxiety, always gives rise to hysteria as well; by far the majority of cases of intentional abstinence become linked from the beginning with true obsessional ideas; coitus interruptus in men never seems to me to be able to provoke a pure anxiety neurosis, but always a mixture of it with neurasthenia.

Originally my theory related only to the clinical pictures comprised under the term 'neurasthenia', among which I was particularly struck by two, which occasionally appear as pure types and which I described as 'neurasthenia proper' and 'anxiety neurosis'. It had, to be sure, always been a matter of common knowledge that sexual factors may play a part in the causation of these forms of illness; but those factors were not regarded as invariably operative, nor was there any idea of giving them precedence over other aetiological influences. I was surprised to begin with at the frequency of gross disturbances in the vita sexualis of nervous patients; the more I set about looking for such disturbances - bearing in mind the fact that everyone hides the truth in matters of sex - and the more skilful I became at pursuing my enquiries in the face of a preliminary denial, the more regularly was I able to discover pathogenic factors in sexual life, till little seemed to stand in the way of my assuming their universal occurrence. It was necessary, however, to presuppose from the start that sexual irregularities occurred with similar frequency in our ordinary society under the pressure of social conditions; and a doubt might remain as to the degree of deviation from normal sexual functioning which should be regarded as pathogenic. I was therefore obliged to attach less importance to the invariable evidence of sexual noxae than to a second discovery which seemed to me less ambiguous. It emerged that the form taken by the illness - neurasthenia or anxiety neurosis - bore a constant relation to the nature of the sexual noxa involved. In typical cases of neurasthenia a history of regular masturbation or persistent emissions was found; in anxiety neurosis factors appeared such as coitus interruptus, 'unconsummated excitation', and other conditions - in all of which there seemed to be the common element of an insufficient discharge of the libido that had been produced. It was only after this discovery, which was easy to make and could be confirmed as often as one liked, that I had the courage to claim a preferential position for sexual influences in the aetiology of the neuroses. Furthermore, in the mixed forms of neurasthenia and anxiety neurosis which are so common it was possible to trace a combination of the aetiologies which I had assumed for the two pure forms. Moreover, this twofold form assumed by the neurosis seemed to tally with the polar (i.e. the masculine and feminine) character of sexuality.
Nevertheless you will rightly expect that we should devote some interest to the 'actual' neuroses as well. Their intimate clinical connection with the psychoneuroses would alone compel us to do so. I may inform you, then, that we distinguish three pure forms of 'actual' neuroses: neurasthenia, anxiety neurosis and hypochondria. Even this assertion is not uncontradicted. All the names are in use, it is true, but their content is indefinite and fluctuating. There are even doctors who oppose any dividing lines in the chaotic world of neurotic phenomena, any segregation of clinical entities or individual diseases, and who do not even recognize the distinction between the 'actual' neuroses and the psychoneuroses. I think they are going too far and have not chosen the path which leads to progress. The forms of neurosis which I have mentioned occur occasionally in their pure form; more often, however, they are intermixed with each other and with a psychoneurotic disorder. This need not lead us to abandon the distinction between them. Consider the difference between the study of minerals and of rocks in mineralogy. The minerals are described as individuals, no doubt on the basis of the fact that they often occur as crystals, sharply separated from their environment. Rocks consist of aggregations of minerals, which, we may be sure, have not come together by chance but as a result of what determined their origin. In the theory of the neuroses we still know too little of the course of their development to produce anything resembling petrology. But we are certainly doing the right thing if we start by isolating from the mass the individual clinical entities which we recognize and which are comparable to the minerals.

[1916-1917, 3440]
But in view of the close connections between the psychoneuroses and the simple neuroses, which go so far, indeed, that a differential diagnosis is not always easy for inexperienced observers, it could not be long before the knowledge arrived at in one field was extended to the other. Moreover, apart from this consideration, a deeper investigation of the psychical mechanism of hysterical symptoms led to the same result. For if the psychical traumas from which the hysterical symptoms were derived were pursued further and further by means of the 'cathartic' procedure initiated by Breuer and me, experiences were eventually reached which belonged to the patient's childhood and related to his sexual life. And this was so, even in cases in which the onset of the illness had been brought about by some commonplace emotion of a non-sexual kind. Unless these sexual traumas of childhood were taken into account it was impossible either to elucidate the symptoms (to understand the way in which they were determined) or to prevent their recurrence. In this way the unique significance of sexual experiences in the aetiology of the psychoneuroses seemed to be established beyond a doubt; and this fact remains to this day one of the corner-stones of my theory.

[1906a, 1576]

Psycho-analysis is unjustly reproached, Gentlemen, for leading to purely psychological theories of pathological problems. The emphasis which it lays on the pathogenic role of sexuality, which, after all, is certainly not an exclusively psychical factor should alone protect it from this reproach. Psycho-analysts never forget that the mental is based on the organic, although their work can only carry them as far as this basis and no beyond it. Thus psycho-analysis is ready to admit, and indeed to postulate, that not all disturbances of vision need be psychogenic, like those that are evoked by the repression of erotic scopophilia. If an organ which serves the two sorts of instinct increases its erotogenic role, it is in general to be expected that this will not occur without the excitability and innervation of the organ undergoing changes which will manifest themselves as disturbances of its function in the service of the ego. Indeed, if we find that an organ normally serving the purpose of sense-perception begins to behave like an actual genital when its erotogenic role is increased, we shall not regard it as improbable that toxic changes are also occurring in it. For lack of a better name we must retain the old unsuitable term of 'neurotic' disturbances for both classes of functional disturbances - those of physiological as well as those of toxic origin - which follow from an increase in the erotogenic factor. Generally speaking, the neurotic disturbances of vision stand in the same relation to the psychogenic ones as the 'actual neuroses' do to the psychoneuroses: psychogenic visual disturbances can no doubt hardly ever appear without neurotic ones, but the latter can appear without the former. These neurotic symptoms are unfortunately little appreciated and understood even today; for they are not directly accessible to psycho-analysis, and other methods of research have left the standpoint of sexuality out of account.

[1910i, 2370]
A noteworthy relation between the symptoms of the 'actual' neuroses and of the psychoneuroses makes a further important contribution to our knowledge of the formation of symptoms in the latter. For a symptom of an 'actual' neurosis is often the nucleus and first stage of a psychoneurotic symptom. A relation of this kind can be most clearly observed between neurasthenia and the transference neurosis known as 'conversion hysteria', between anxiety neurosis and anxiety hysteria, but also between hypochondria and the forms of disorder which will be mentioned later under the name of paraphrenia (dementia praecox and paranoia). Let us take as an example a case of hysterical headache or lumbar pain. Analysis shows us that, by condensation and displacement, it has become a substitutive satisfaction for a whole number of libidinal phantasies or memories. But this pain was also at one time a real one and it was then a direct sexual-toxic symptom, the somatic expression of a libidinal excitation. We are far from asserting that all hysterical symptoms contain a nucleus of this kind. But it remains a fact that this is especially often the case and that whatever somatic influences (whether normal or pathological) are brought about by libidinal excitation are preferred for the construction of hysterical symptoms. In such cases they play the part of the grain of sand which a mollusc coats with layers of mother-of-pearl. In the same way, the passing indications of sexual excitement which accompany the sexual act are employed by the psychoneurosis as the most convenient and appropriate material for the construction of symptoms.
[1916-1917, 3441]
With an unerring eye Löwenfeld (1895) detects the essential feature of my paper - namely, my assertion that anxiety-symptoms have a specific and uniform aetiology of a sexual nature. If this cannot be established as a fact, then the main reason for detaching an independent anxiety neurosis from neurasthenia disappears as well. There remains, it is true, one difficulty to which I called attention - the fact that anxiety-symptoms also have such very unmistakable connections with hysteria, so that a decision on Löwenfeld's lines would prejudice the separation between hysteria and neurasthenia. This difficulty, however, is met by a recourse to heredity as the common cause of all these neuroses (a view which I will go into later).

[1895f, 354]

5 I must not omit to remark at this point that I shall not consider any theory of paranoia trustworthy unless it also covers the hypochondriacal symptoms by which that disorder is almost invariably accompanied. It seems to me that hypochondria stands in the same relation to paranoia as anxiety neurosis does to hysteria.

[1911c, 2427]

A noteworthy relation between the symptoms of the 'actual' neuroses and of the psychoneuroses makes a further important contribution to our knowledge of the formation of symptoms in the latter. For a symptom of an 'actual' neurosis is often the nucleus and first stage of a psychoneurotic symptom. A relation of this kind can be most clearly observed between neurasthenia and the transference neurosis known as 'conversion hysteria', between anxiety neurosis and anxiety hysteria, but also between hypochondria and the forms of disorder which will be mentioned later under the name of paraphrenia (dementia praecox and paranoia). Let us take as an example a case of hysterical headache or lumbar pain. Analysis shows us that, by condensation and displacement, it has become a substitutive satisfaction for a whole number of libidinal phantasies or memories. But this pain was also at one time a real one and it was then a direct sexual-toxic symptom, the somatic expression of a libidinal excitation. We are far from asserting that all hysterical symptoms contain a nucleus of this kind. But it remains a fact that this is especially often the case and that whatever somatic influences (whether normal or pathological) are brought about by libidinal excitation are preferred for the construction of hysterical symptoms. In such cases they play the part of the grain of sand which a mollusc coats with layers of mother-of-pearl. In the same way, the passing indications of sexual excitement which accompany the sexual act are employed by the psychoneurosis as the most convenient and appropriate material for the construction of symptoms.

[1916-1917, 3441]
For we consider that what is responsible for the anxiety in hysteria and other neuroses is the process of repression. We believe it is possible to give a more complete account of this than before, if we separate what happens to the idea that has to be repressed from what happens to the quota of libido attaching to it. It is the idea which is subjected to repression and which may be distorted to the point of being unrecognizable; but its quota of affect is regularly transformed into anxiety - and this is so whatever the nature of the affect may be, whether it is aggressiveness or love. It makes no essential difference, then, for what reason a quota of libido has become unemployable: whether it is on account of the infantile weakness of the ego, as in children's phobias, or on account of somatic processes in sexual life, as in anxiety neurosis, or owing to repression, as in hysteria. Thus in reality the two mechanisms that bring about neurotic anxiety coincide.
[1933a, 4690]
In this manner I found that neurasthenia presented a monotonous clinical picture in which, as my analyses showed, a 'psychical mechanism' played no part. There was a sharp distinction between neurasthenia and 'obsessional neurosis', the neurosis of obsessional ideas proper. In this latter one I was able to recognize a complicated psychical mechanism, an aetiology similar to that of hysteria and an extensive possibility of reducing it by psychotherapy. On the other hand, it seemed to me absolutely necessary to detach from neurasthenia a complex of neurotic symptoms which depend on a quite different and indeed at bottom a contrary aetiology. The component symptoms of this complex are united by a characteristic which has already been recognized by Hecker (1893). For they are either symptoms or equivalents and rudiments of manifestations of anxiety; and for this reason I have given to this complex which is to be detached from neurasthenia the name of 'anxiety neurosis'. I have maintained that it arises from, an accumulation of physical tension, which is itself once more of sexual origin. This neurosis, too, has no psychical mechanism, but it invariably influences mental life, so that 'anxious expectation', phobias, hyperaesthesia to pains, etc., are among its regular manifestations. This anxiety neurosis, in my sense of the term, no doubt coincides in part with the neurosis which, under the name of 'hypochondria', finds a place in not a few descriptions alongside hysteria and neurasthenia. But I cannot regard the delimitation of hypochondria in any of the works in question as being the correct one, and the applicability of its name seems to me to be prejudiced by the fixed connection of that term with the symptom of 'fear of illness'.

[1895d, 229]

A noteworthy relation between the symptoms of the 'actual' neuroses and of the psychoneuroses makes a further important contribution to our knowledge of the formation of symptoms in the latter. For a symptom of an 'actual' neurosis is often the nucleus and first stage of a psychoneurotic symptom. A relation of this kind can be most clearly observed between neurasthenia and the transference neurosis known as 'conversion hysteria', between anxiety neurosis and anxiety hysteria, but also between hypochondria and the forms of disorder which will be mentioned later under the name of paraphrenia (dementia praecox and paranoia). Let us take as an example a case of hysterical headache or lumbar pain. Analysis shows us that, by condensation and displacement, it has become a substitutive satisfaction for a whole number of libidinal phantasies or memories. But this pain was also at one time a real one and it was then a direct sexual-toxic symptom, the somatic expression of a libidinal excitation. We are far from asserting that all hysterical symptoms contain a nucleus of this kind. But it remains a fact that this is especially often the case and that whatever somatic influences (whether normal or pathological) are brought about by libidinal excitation are preferred for the construction of hysterical symptoms. In such cases they play the part of the grain of sand which a mollusc coats with layers of mother-of-pearl. In the same way, the passing indications of sexual excitement which accompany the sexual act are employed by the psychoneurosis as the most convenient and appropriate material for the construction of symptoms.

[1916-1917, 3441]
In other cases our aetiological theory can help the physician in charge of the institution by throwing light on the source of failures which occur in the institution itself, and can suggest to him means of avoiding them. Masturbation is far commoner among grown-up girls and mature men than is generally supposed, and it has a harmful effect not only by producing neurasthenic symptoms, but also because it keeps the patients under the weight of what they feel to be a disgraceful secret. Physicians who are not accustomed to translate neurasthenia into masturbation account for the patient's pathological state by referring it to some catchword like anaemia, undernourishment, overwork, etc., and then expect to cure him by applying a therapy devised against those conditions. To their astonishment, however, periods of improvement in him alternate with periods in which all his symptoms grow worse and are accompanied by severe depression. The outcome of such a treatment is, in general, doubtful. If physicians knew that all the while the patient was struggling against his sexual habit and that he was in despair because he had once more been obliged to give way to it, if they understood how to win his secret from him, to make it less serious in his eyes and to support him in his fight against the habit, then the success of their therapeutic efforts might in this way well be assured.

[1897b, 467]

This does not exhaust the possibilities which flow from a recognition of the sexual aetiology of the neuroses. The main benefit which we obtain from it for neurasthenics lies in the sphere of prophylaxis. If masturbation is the cause of neurasthenia in youth, and if, later on, it acquires aetiological significance for anxiety neurosis as well, by reason of the reduction of potency which it brings about, then the prevention of masturbation in both sexes is a task that deserves more attention than it has hitherto received. When we reflect upon all the injuries, both the grosser and the finer ones, which proceed from neurasthenia - a disorder which we are told is growing more and more prevalent - we see that it is positively a matter of public interest that men should enter upon sexual relations with full potency. In matters of prophylaxis, however, the individual is relatively helpless. The whole community must become interested in the matter and give their assent to the creation of generally acceptable regulations. At present we are still far removed from such a state of affairs which would promise relief, and it is for this reason that we may with justice regard civilization, too, as responsible for the spread of neurasthenia. Much would have to be changed. The resistance of a generation of physicians who can no longer remember their own youth must be broken down; the pride of fathers, who are unwilling to descend to the level of humanity in their children's eyes, must be overcome; and the unreasonable prudery of mothers must be combated - the mothers who at present look upon it as an incomprehensible and undeserved stroke of fate that 'their children should have been the ones to become neurotic'. But above all, a place must be created in public opinion for the discussion of the problems of sexual life. It will have to become possible to talk about these things without being stamped as a trouble-maker or as a person who makes capital out of the lower instincts. And so here, too, there is enough work left to do for the next hundred years - in which our civilization will have to learn to come to terms with the claims of our sexuality.

[1897b, 470]
All this seems very clear, and yet it must be admitted that there is one factor which often makes it difficult to form a judgement. Some nervous states which we call the 'actual neuroses', such as typical neurasthenia and pure anxiety neurosis, obviously depend on the somatic factor in sexual life, while we have no certain picture as yet of the part played in them by the psychical factor and by repression. In such cases it is natural that the physician should first consider some 'actual' therapy, some alteration in the patient's somatic sexual activity, and he does so with perfect justification if his diagnosis is correct. The lady who consulted the young doctor complained chiefly of anxiety-states, and so he probably assumed that she was suffering from an anxiety neurosis, and felt justified in recommending a somatic therapy to her. Again a convenient misapprehension! A person suffering from anxiety is not for that reason necessarily suffering from anxiety neurosis; such a diagnosis of it cannot be based on the name; one has to know what signs constitute an anxiety neurosis, and be able to distinguish it from other pathological states which are also manifested by anxiety. My impression was that the lady in question was suffering from anxiety hysteria, and the whole value of such nosographical distinctions, one which quite justifies them, lies in the fact that they indicate a different aetiology and a different treatment. No one who took into consideration the possibility of anxiety hysteria in this case would have fallen into the error of neglecting the mental factors, as this physician did with his three alternatives.

[1910k, 2377]

The essence of the theories about the 'actual neuroses' which I have put forward in the past and am defending to-day lies in my assertion, based on experiment, that their symptoms, unlike psychoneurotic ones, cannot be analysed. That is to say, the constipation, headaches and fatigue of the so-called neurasthenic do not admit of being traced back historically or symbolically to operative experiences and cannot be understood as substitutes for sexual satisfaction or as compromises between opposing instinctual impulses, as is the case with psycho-neurotic symptoms (even though the latter may perhaps have the same appearance). I do not believe it will be possible to upset this assertion by the help of psycho-analysis. On the other hand I will grant to-day what I was unable to believe formerly - that an analytic treatment can have an indirect curative effect on 'actual' symptoms. It can do so either by enabling the current noxae to be better tolerated, or by enabling the sick person to escape from the current noxae by making a change in his sexual régime. These would be desirable prospects from the point of view of our therapeutic interest.

[1912f, 2571]
Under the influence of my surprising discovery, I now took a momentous step. I went beyond the domain of hysteria and began to investigate the sexual life of the so-called neurasthenics who used to visit me in numbers during my consultation hours. This experiment cost me, it is true, my popularity as a doctor, but it brought me convictions which to-day, almost thirty years later, have lost none of their force. There was a great deal of equivocation and mystery-making to be overcome, but, once that had been done, it turned out that in all of these patients grave abuses of the sexual function were present. Considering how extremely widespread are these abuses on the one hand and neurasthenia on the other, a frequent coincidence between the two would not have proved much; but there was more in it than that one bald fact. Closer observation suggested to me that it was possible to pick out from the confused jumble of clinical pictures covered by the name of neurasthenia two fundamentally different types, which might appear in any degree of mixture but which were nevertheless to be observed in their pure forms. In the one type the central phenomenon was the anxiety attack with its equivalents, rudimentary forms and chronic substitutive symptoms; I consequently gave it the name of anxiety neurosis, and limited the term neurasthenia to the other type. Now it was easy to establish the fact that each of these types had a different abnormality of sexual life as its corresponding aetiological factor: in the former, coitus interruptus, unconsummated excitation and sexual abstinence, and in the latter, excessive masturbation and too numerous nocturnal emissions. In a few specially instructive cases, which had shown a surprising alteration in the clinical picture from one type to the other, it could be proved that there had been a corresponding change in the underlying sexual régime. If it was possible to put an end to the abuse and allow its place to be taken by normal sexual activity, a striking improvement in the condition was the reward.

[1925d, 4202]
The present treatment of neurasthenia - which is, perhaps, carried out most successfully in hydropathic establishments - has as its aim the amelioration of the nervous condition by means of two factors: shielding the patient and strengthening him. I have nothing to say against such a method of treatment, except that it takes no account of the circumstances of the patient's sexual life. According to my experience, it is highly desirable that the medical directors of such establishments should become properly aware that they are dealing, not with victims of civilization or heredity, but - sit venia verbo - with people who are crippled in sexuality. They would then, on the one hand, be more easily able to account for their successes as well as their failures; and, on the other, they would achieve new successes which, till now, have been at the mercy of chance or of the patient's unguided behaviour. If we take a neurasthenic woman, suffering from anxiety, away from her home and send her to a hydropathic establishment, and if there, freed from all duties, she is made to bathe and take exercise and eat plenty of food, we shall certainly be inclined to think that the improvement - often a brilliant one - which is achieved in a few weeks or months is due to the rest which she has enjoyed and to the invigorating effects of hydrotherapy. That may be so: but we are overlooking the fact that her removal from home also entails an interruption of marital intercourse, and that it is only the temporary elimination of this pathogenic cause which makes it possible for her to recover under favourable treatment. Neglect of this aetiological point of view brings its subsequent revenge, when what seemed such a gratifying cure turns out to be a very transitory one. Soon after the patient has returned to ordinary life the symptoms of the complaint appear once more and oblige him either to spend a part of his existence unproductively from time to time in establishments of this kind or to direct his hopes of recovery elsewhere. It is therefore clear that with neurasthenia the therapeutic problems must be attacked, not in hydropathic institutions but within the framework of the patient's life.

This does not exhaust the possibilities which flow from a recognition of the sexual aetiology of the neuroses. The main benefit which we obtain from it for neurasthenics lies in the sphere of prophylaxis. If masturbation is the cause of neurasthenia in youth, and if, later on, it acquires aetiological significance for anxiety neurosis as well, by reason of the reduction of potency which it brings about, then the prevention of masturbation in both sexes is a task that deserves more attention than it has hitherto received. When we reflect upon all the injuries, both the grosser and the finer ones, which proceed from neurasthenia - a disorder which we are told is growing more and more prevalent - we see that it is positively a matter of public interest that men should enter upon sexual relations with full potency. In matters of prophylaxis, however, the individual is relatively helpless. The whole community must become interested in the matter and give their assent to the creation of generally acceptable regulations. At present we are still far removed from such a state of affairs which would promise relief, and it is for this reason that we may with justice regard civilization, too, as responsible for the spread of neurasthenia. Much would have to be changed. The resistance of a generation of physicians who can no longer remember their own youth must be broken down; the pride of fathers, who are unwilling to descend to the level of humanity in their children's eyes, must be overcome; and the unreasonable prudery of mothers must be combated - the mothers who at present look upon it as an incomprehensible and undeserved stroke of fate that 'their' children should have been the ones to become neurotic'. But above all, a place must be created in public opinion for the discussion of the problems of sexual life. It will have to become possible to talk about these things without being stamped as a trouble-maker or as a person who makes capital out of the lower instincts. And so here, too, there is enough work left to do for the next hundred years - in which our civilization will have to learn to come to terms with the claims of our sexuality.
Since that time I have had no opportunity of returning to the investigation of the 'actual neuroses'; nor has this part of my work been continued by anyone else. If I look back to-day at my early findings, they strike me as being the first rough outlines of what is probably a far more complicated subject. But on the whole they seem to me still to hold good. I should have been very glad if I had been able, later on, to make a psycho-analytic examination of some more cases of simple juvenile neurasthenia, but unluckily the occasion did not arise. To avoid misconceptions, I should like to make it clear that I am far from denying the existence of mental conflicts and of neurotic complexes in neurasthenia. All that I am asserting is that the symptoms of these patients are not mentally determined or removable by analysis, but that they must be regarded as direct toxic consequences of disturbed sexual chemical processes.

[1925d, 4203]
Another task is set to the physician by the aetiology of anxiety neurosis. It consists in inducing the patient to give up all detrimental forms of sexual intercourse and to adopt normal sexual relations. This duty, it will be understood, falls primarily on the patient's trusted physician - his family doctor; and he will do his patient a serious injury if he regards himself as too respectable to intervene in this field.

[1897b, 468]
Obsessions similarly presuppose a sexual experience in childhood (though one of a different nature from that found in hysteria). The aetiology of the two neuro-psychoses of defence is related as follows to the aetiology of the two simple neuroses, neurasthenia and anxiety neurosis. Both the latter disorders are direct effects of the sexual noxae themselves, as I have shown in my paper on anxiety neurosis (1895b); both the defence neuroses are indirect consequences of sexual noxae which have occurred before the advent of sexual maturity - are consequences, that is, of the psychical memory-traces of those noxae. The current causes which produce neurasthenia and anxiety neurosis often at the same time play the part of exciting causes of the neuroses of defence; on the other hand, the specific causes of a defence-neurosis - the traumas of childhood - can at the same time lay the foundations for a later development of neurasthenia. Finally, it not infrequently happens, too, that neurasthenia or anxiety neurosis is maintained, not by current sexual noxae, but, instead, solely by the persisting effect of a memory of childhood traumas.¹

[1896b, 388]

The value of making a correct diagnostic separation of the psychoneuroses from neurasthenia is also shown by the fact that the psychoneuroses call for a different practical assessment and for special therapeutic measures. They make their appearance as a result of two kinds of determinants, either independently or in the train of the 'actual neuroses' (neurasthenia and anxiety neurosis). In the latter case we are dealing with a new type of neurosis - incidentally, a very frequent one - a mixed neurosis. The aetiology of the 'actual neuroses' has become an auxiliary aetiology of the psychoneuroses. A clinical picture arises in which, let us say, anxiety neurosis predominates but which also contains traits of genuine neurasthenia, hysteria and obsessional neurosis. When confronted with a mixture of this kind, we shall nevertheless not be wise to give up separating out the clinical pictures proper to each neurotic illness; for after all it is not difficult to explain the case to oneself in the following manner. The predominant place taken by the anxiety neurosis shows that the illness has come into being under the aetiological influence of an 'actual' sexual noxa. But the person concerned was, apart from that, disposed to one or more of the psychoneuroses owing to a special aetiology and would at some time or other have fallen ill of a psychoneurosis either spontaneously or with the advent of some other weakening factor. In this way the auxiliary aetiology for the psychoneurosis which is still lacking is supplied by the actual aetiology of the anxiety neurosis.

[1897b, 471]

All this seems very clear, and yet it must be admitted the there is one factor which often makes it difficult to form a judgement. Some nervous states which we call the 'actual neuroses', such as typical neurasthenia and pure anxiety neurosis, obviously depend on the somatic factor in sexual life, while we have no certain picture as yet of the part played in them by the psychical factor and by repression. In such cases it is natural that the physician should first consider some 'actual' therapy, some alteration in the patient's somatic sexual activity, and he does so with perfect justification if his diagnosis is correct. The lady who consulted the young doctor complained chiefly of anxiety-states, and so he probably assumed that she was suffering from an anxiety neurosis, and felt justified in recommending a somatic therapy to her. Again a convenient misapprehension! A person suffering from anxiety is not for that reason necessarily suffering from anxiety neurosis; such a diagnosis of it cannot be based on the name; one has to know what signs constitute an anxiety neurosis, and be able to distinguish it from other pathological states which are also manifested by anxiety. My impression was that the lady in question was suffering from anxiety hysteria, and the whole value of such nosographical distinctions, one which quite justifies them, lies in the fact that they indicate a different aetiology and a different treatment. No one who took into consideration the possibility of anxiety hysteria in this case would have fallen into the error of neglecting the mental factors, as this physician did with his three alternatives.

[1910k, 2377]
Now, however, I must draw your attention to the decisive difference between the symptoms of the 'actual' neuroses and those of the psychoneuroses, the first group of which, the transference neuroses, have occupied us so much hitherto. In both cases the symptoms originate from the libido, and are thus abnormal employments of it, substitutive satisfactions. But the symptoms of the 'actual' neuroses - intracranial pressure, sensations of pain, a state of irritation in an organ, weakening or inhibition of a function - have no 'sense', no psychical meaning. They are not only manifested predominantly in the body (as are hysterical symptoms, for instance, as well), but they are also themselves entirely somatic processes, in the generating of which all the complicated mental mechanisms we have come to know are absent. Thus they really are what psychoneurotic symptoms were so long believed to be. But if so, how can they correspond to employments of the libido, which we have recognized as a force operating in the mind? Well, Gentlemen, that is a very simple matter. Let me remind you of one of the very first objections that were brought up against psycho-analysis. It was said then that it was occupied in finding a purely psychological theory of neurotic phenomena and this was quite hopeless, since psychological theories could never explain an illness. People had chosen to forget that the sexual function is not a purely psychical thing any more than it is a purely somatic one. It influences bodily and mental life alike. If in the symptoms of the psychoneuroses we have become acquainted with manifestations of disturbances in the psychical operation of the sexual function, we shall not be surprised to find in the 'actual' neuroses the direct somatic consequences of sexual disturbances.

[1916-1917, 3439]

And now perhaps you understand better why I did not choose to arrange my material differently. If I had promised you an 'Introduction to the Theory of the Neuroses' the correct path would certainly have led from the simple forms of the 'actual' neuroses to the more complicated psychical illnesses due to disturbance of the libido. As regards the former I should have had to collect from various sources what we have learnt or believe we know, and in connection with the psychoneuroses psycho-analysis would have come up for discussion as the most important technical aid in throwing light on those conditions. But what I intended to give and what I announced was an 'Introduction to Psycho-Analysis'. It was more important for me that you should gain an idea of psycho-analysis than that you should obtain some pieces of knowledge about the neuroses; and for that reason the 'actual' neuroses, unproductive so far as psycho-analysis is concerned, could no longer have a place in the foreground. I believe, too, that I have made the better choice for you. For, on account of the profundity of its hypotheses and the comprehensiveness of its connections, psycho-analysis deserves a place in the interest of every educated person, while the theory of the neuroses is a chapter in medicine like any other.

[1916-1917, 3440]
Nevertheless you will rightly expect that we should devote some interest to the 'actual' neuroses as well. Their intimate clinical connection with the psychoneuroses would alone compel us to do so. I may inform you, then, that we distinguish three pure forms of 'actual' neuroses: neurasthenia, anxiety neurosis and hypochondria. Even this assertion is not uncontradicted. All the names are in use, it is true, but their content is indefinite and fluctuating. There are even doctors who oppose any dividing lines in the chaotic world of neurotic phenomena, any segregation of clinical entities or individual diseases, and who do not even recognize the distinction between the 'actual' neuroses and the psychoneuroses. I think they are going too far and have not chosen the path which leads to progress. The forms of neurosis which I have mentioned occur occasionally in their pure form; more often, however, they are intermixed with each other and with a psychoneurotic disorder. This need not lead us to abandon the distinction between them. Consider the difference between the study of minerals and of rocks in mineralogy. The minerals are described as individuals, no doubt on the basis of the fact that they often occur as crystals, sharply separated from their environment. Rocks consist of aggregations of minerals, which, we may be sure, have not come together by chance but as a result of what determined their origin. In the theory of the neuroses we still know too little of the course of their development to produce anything resembling petrology. But we are certainly doing the right thing if we start by isolating from the mass the individual clinical entities which we recognize and which are comparable to the minerals.

A noteworthy relation between the symptoms of the 'actual' neuroses and of the psychoneuroses makes a further important contribution to our knowledge of the formation of symptoms in the latter. For a symptom of an 'actual' neurosis is often the nucleus and first stage of a psychoneurotic symptom. A relation of this kind can be most clearly observed between neurasthenia and the transference neurosis known as 'conversion hysteria', between anxiety neurosis and anxiety hysteria, but also between hypochondria and the forms of disorder which will be mentioned later under the name of paraphrenia (dementia praecox and paranoia). Let us take as an example a case of hysterical headache or lumbar pain. Analysis shows us that, by condensation and displacement, it has become a substitutive satisfaction for a whole number of libidinal phantasies or memories. But this pain was also at one time a real one and it was then a direct sexual-toxic symptom, the somatic expression of a libidinal excitation. We are far from asserting that all hysterical symptoms contain a nucleus of this kind. But it remains a fact that this is especially often the case and that whatever somatic influences (whether normal or pathological) are brought about by libidinal excitation are preferred for the construction of hysterical symptoms. In such cases they play the part of the grain of sand which a mollusc coats with layers of mother-of-pearl. In the same way, the passing indications of sexual excitement which accompany the sexual act are employed by the psychoneurosis as the most convenient and appropriate material for the construction of symptoms.

[1916-1917, 3440]
The Aetiological Significance of Sexual Life. - The second novelty which emerged after the hypnotic technique had been replaced by free associations was of a clinical nature. It was discovered in the course of the prolonged search for the traumatic experiences from which hysterical symptoms appeared to be derived. The more carefully the search was pursued the more extensive seemed to be the network of aetiologically significant impressions involved, but the further back, too, did they reach into the patient's puberty or childhood. At the same time they assumed a uniform character and eventually it became inevitable to bow before the evidence and recognize that at the root of the formation of every symptom there were to be found traumatic experiences from early sexual life. Thus a sexual trauma stepped into the place of an ordinary trauma and the latter was seen to owe its aetiological significance to an associative or symbolic connection with the former, which had preceded it. An investigation of cases of common nervousness (falling into the two classes of neurasthenia and anxiety neurosis) which was simultaneously undertaken led to the conclusion that these disorders could be traced to contemporary abuses in the patients' sexual life and could be removed if these were brought to an end. It was thus easy to infer that neuroses in general are an expression of disturbances in sexual life, the so-called actual-neuroses being the consequences (by chemical agency) of contemporary injuries and the psycho-neuroses the consequences (by psychical modification) of bygone injuries to a biological function which had hitherto been gravely neglected by science. None of the theses of psycho-analysis has met with such tenacious scepticism or such embittered resistance as this assertion of the preponderating aetiological significance of sexual life in the neuroses. It should, however, be expressly remarked that, in its development up to the present day, psycho-analysis has found no reason to retreat from this opinion.

[1923a, 3920]

Since that time I have had no opportunity of returning to the investigation of the 'actual neuroses'; nor has this part of my work been continued by anyone else. If I look back to-day at my early findings, they strike me as being the first rough outlines of what is probably a far more complicated subject. But on the whole they seem to me still to hold good. I should have been very glad if I had been able, later on, to make a psycho-analytic examination of some more cases of simple juvenile neurasthenia, but unluckily the occasion did not arise. To avoid misconceptions, I should like to make it clear that I am far from denying the existence of mental conflicts and of neurotic complexes in neurasthenia. All that I am asserting is that the symptoms of these patients are not mentally determined or removable by analysis, but that they must be regarded as direct toxic consequences of disturbed sexual chemical processes.

[1925d, 4203]
Now the important decision we have to make - and this can be done with certainty in every instance if the symptoms are carefully assessed - is whether the case bears the characteristics of neurasthenia or of a psychoneurosis (hysteria, obsessions). (Mixed cases in which signs of neurasthenia are combined with signs of a psychoneurosis are of very frequent occurrence; but we will leave consideration of them till later.) It is only in neurasthenias that questioning the patient succeeds in disclosing the aetiological factors in his sexual life. These factors are, of course, known to him and belong to the present time, or, more properly, to the period of his life since sexual maturity (though this delimitation does not cover every case). In psychoneuroses questioning of this kind has little result. It may perhaps give us a knowledge of the factors which have to be recognized as precipitating ones, and these may or may not be connected with sexual life. If they are, they show themselves to be no different in kind from the aetiological factors of neurasthenia; that is, they entirely lack any specific relation to the causation of the psychoneurosis. And yet, in every instance, the aetiology of the psychoneuroses, too, lies in the field of sexuality. By a curious circuitous path, of which I shall speak later, it is possible to arrive at a knowledge of this aetiology and to understand why the patient was unable to tell us anything about it. For the events and influences which lie at the root of every psychoneurosis, belong, not to the present day, but to an epoch of life which is long past and which is, as it were, a prehistoric one-to the time of early childhood; and that is why the patient, too, knows nothing of them. He has - though only in a particular sense - forgotten them.

The Aetiological Significance of Sexual Life. - The second novelty which emerged after the hypnotic technique had been replaced by free associations was of a clinical nature. It was discovered in the course of the prolonged search for the traumatic experiences from which hysterical symptoms appeared to be derived. The more carefully the search was pursued the more extensive seemed to be the network of aetiologically significant impressions involved, but the further back, too, did they reach into the patient's puberty or childhood. At the same time they assumed a uniform character and eventually it became inevitable to bow before the evidence and recognize that at the root of the formation of every symptom there were to be found traumatic experiences from early sexual life. Thus a sexual trauma stepped into the place of an ordinary trauma and the latter was seen to owe its aetiological significance to an associative or symbolic connection with the former, which had preceded it. An investigation of cases of common nervousness (falling into the two classes of neurasthenia and anxiety neurosis) which was simultaneously undertaken led to the conclusion that these disorders could be traced to contemporary abuses in the patients' sexual life and could be removed if these were brought to an end. It was thus easy to infer that neuroses in general are an expression of disturbances in sexual life, the so-called actual-neuroses being the consequences (by chemical agency) of contemporary injuries and the psycho-neuroses the consequences (by psychical modification) of bygone injuries to a biological function which had hitherto been gravely neglected by science. None of the theses of psycho-analysis has met with such tenacious scepticism or such embittered resistance as this assertion of the preponderating aetiological significance of sexual life in the neuroses. It should, however, be expressly remarked that, in its development up to the present day, psycho-analysis has found no reason to retreat from this opinion.

[1897b, 459]

[1923a, 3920]
As regards the second class of major neuroses, hysteria and obsessional neurosis, the solution of the aetiological problem is of surprising simplicity and uniformity. I owe my results to a new method of psycho-analysis, Josef Breuer's exploratory procedure; it is a little intricate, but it is irreplaceable, so fertile has it shown itself to be in throwing light upon the obscure paths of unconscious ideation. By means of that procedure - this is not the place in which to describe it - hysterical symptoms are traced back to their origin, which is always found in some event of the subject's sexual life appropriate for the production of a distressing emotion. Travelling backwards into the patient's past, step by step, and always guided by the organic train of symptoms and of memories and thoughts aroused, I finally reached the starting-point of the pathological process; and I was obliged to see that at bottom the same thing was present in all the cases submitted to analysis - the action of an agent which must be accepted as the specific cause of hysteria.

[1896a, 375]

Now the important decision we have to make - and this can be done with certainty in every instance if the symptoms are carefully assessed - is whether the case bears the characteristics of neurasthenia or of a psychoneurosis (hysteria, obsessions). (Mixed cases in which signs of neurasthenia are combined with signs of a psychoneurosis are of very frequent occurrence; but we will leave consideration of them till later.) It is only in neurasthenias that questioning the patient succeeds in disclosing the aetiological factors in his sexual life. These factors are, of course, known to him and belong to the present time, or, more properly, to the period of his life since sexual maturity (though this delimitation does not cover every case). In psychoneuroses questioning of this kind has little result. It may perhaps give us a knowledge of the factors which have to be recognized as precipitating ones, and these may or may not be connected with sexual life. If they are, they show themselves to be no different in kind from the aetiological factors of neurasthenia; that is, they entirely lack any specific relation to the causation of the psychoneurosis. And yet, in every instance, the aetiology of the psychoneuroses, too, lies in the field of sexuality. By a curious circuitous path, of which I shall speak later, it is possible to arrive at a knowledge of this aetiology and to understand why the patient was unable to tell us anything about it. For the events and influences which lie at the root of every psychoneurosis, belong, not to the present day, but to an epoch of life which is long past and which is, as it were, a prehistoric one-to the time of early childhood; and that is why the patient, too, knows nothing of them. He has - though only in a particular sense - forgotten them.

[1897b, 459]
Thus, in every case of neurosis there is a sexual aetiology; but in neurasthenia it is an aetiology of a present-day kind, whereas in the psychoneuroses the factors are of an infantile nature. This is the first great contrast in the aetiology of the neuroses. A second one emerges when we take account of a difference in the symptomatology of neurasthenia itself. Here, on the one hand, we find cases in which certain complaints characteristic of neurasthenia (intracranial pressure, proneness to fatigue, dyspepsia, constipation, spinal irritation, etc.) are prominent; in other cases these signs play a minor part and the clinical picture is composed of other symptoms, all of which exhibit a relation to the nuclear symptom, that of anxiety (free anxiousness, unrest, expectant anxiety, complete, rudimentary or supplementary anxiety attacks, locomotor vertigo, agoraphobia, insomnia, increased sensitivity to pain, and so on). I have left the name of neurasthenia to the first type, but have distinguished the second type as 'anxiety neurosis'; and I have given reasons for this separation in another place, where I have also taken account of the fact that as a rule both neuroses appear together. For the present purpose it is enough to emphasize that parallel to the difference in the symptoms of these two forms of illness there goes a difference in their aetiology. Neurasthenia can always be traced back to a condition of the nervous system such as is acquired by excessive masturbation or arises spontaneously from frequent emissions; anxiety neurosis regularly discloses sexual influences which have in common the factor of reservation or of incomplete satisfaction - such as coitus interruptus, abstention together with a lively libido, so-called unconsummated excitation, and so on. In my short paper intended to introduce anxiety neurosis I put forward the formula that anxiety is always libido which has been deflected from its employment.

[1897b, 460]

The value of making a correct diagnostic separation of the psychoneuroses from neurasthenia is also shown by the fact that the psychoneuroses call for a different practical assessment and for special therapeutic measures. They make their appearance as a result of two kinds of determinants, either independently or in the train of the 'actual neuroses' (neurasthenia and anxiety neurosis). In the latter case we are dealing with a new type of neurosis - incidentally, a very frequent one - a mixed neurosis. The aetiology of the 'actual neuroses' has become an auxiliary aetiology of the psychoneuroses. A clinical picture arises in which, let us say, anxiety neurosis predominates but which also contains traits of genuine neurasthenia, hysteria and obsessional neurosis. When confronted with a mixture of this kind, we shall nevertheless not be wise to give up separating out the clinical pictures proper to each neurotic illness; for after all it is not difficult to explain the case to oneself in the following manner. The predominant place taken by the anxiety neurosis shows that the illness has come into being under the aetiological influence of an 'actual' sexual noxa. But the person concerned was, apart from that, disposed to one or more of the psychoneuroses owing to a special aetiology and would at some time or other have fallen ill of a psychoneurosis either spontaneously or with the advent of some other weakening factor. In this way the auxiliary aetiology for the psychoneurosis which is still lacking is supplied by the actual aetiology of the anxiety neurosis.

[1897b, 471]

This ego-libido is, however, only conveniently accessible to analytic study when it has been put to the use of cathecting sexual objects, that is, when it has become object-libido. We can then perceive it concentrating upon objects, becoming fixed upon them or abandoning them, moving from one object to another and, from these situations, directing the subject's sexual activity, which leads to the satisfaction, that is, to the partial and temporary extinction, of the libido. The psycho-analysis of what are termed transference neuroses (hysteria and obsessional neurosis) affords us a clear insight at this point.

[1905d, 1531]
I will postpone until later in this paper a more thorough going discussion of the question whether we are to regard the sexual experiences of childhood as the causes of hysteria (and obsessional neurosis), and I will now return to the form taken by the theory in some of my shorter preliminary publications during the years 1895 and 1896 (Freud, 1896b and 1896c). By laying stress on the supposed aetiological factors it was possible at that time to draw a contrast between the common neuroses as disorders with a contemporary aetiology and psychoneuroses whose aetiology was chiefly to be looked for in the sexual experiences of the remote past. The theory culminated in this thesis: if the vita sexualis is normal, there can be no neurosis.

[1906a, 1577]

We have been led on imperceptibly from the question of the causation of the psychoneuroses to the problem of their essential nature. If we are prepared to take into account what has been learnt from psycho-analysis, we can only say that the essence of these illnesses lies in disturbances of the sexual processes, the processes which determine in the organism the formation and utilization of sexual libido. It is scarcely possible to avoid picturing these processes as being in the last resort of a chemical nature; so that in what are termed the 'actual' neuroses we may recognize the somatic effects of disturbances of the sexual metabolism, and in the psychoneuroses the psychical effects of those disturbances as well. The similarity of the neuroses to the phenomena of intoxication and abstinence after the use of certain alkaloids, as well as to Graves' disease and Addison's disease, is forced upon our notice clinically. And just as these last two illnesses should no longer be described as 'nervous diseases', so also the 'neuroses' proper, in spite of their name, may soon have to be excluded from that category as well.

[1906a, 1582]

Psycho-analysis is unjustly reproached, Gentlemen, for leading to purely psychological theories of pathological problems. The emphasis which it lays on the pathogenic role of sexuality, which, after all, is certainly not an exclusively psychical factor should alone protect it from this reproach. Psycho-analysts never forget that the mental is based on the organic, although their work can only carry them as far as this basis and no beyond it. Thus psycho-analysis is ready to admit, and indeed to postulate, that not all disturbances of vision need be psychogenic, like those that are evoked by the repression of erotic scopophilia. If an organ which serves the two sorts of instinct increases its erotogenic role, it is in general to be expected that this will not occur without the excitability and innervation of the organ undergoing changes which will manifest themselves as disturbances of its function in the service of the ego. Indeed, if we find that an organ normally serving the purpose of sense-perception begins to behave like an actual genital when its erotogenic role is increased, we shall not regard it as improbable that toxic changes are also occurring in it. For lack of a better name we must retain the old unsuitable term of 'neurotic' disturbances for both classes of functional disturbances - those of physiological as well as those of toxic origin - which follow from an increase in the erotogenic factor. Generally speaking, the neurotic disturbances of vision stand in the same relation to the psychogenic ones as the 'actual neuroses' do to the psychoneuroses: psychogenic visual disturbances can no doubt hardly ever appear without neurotic ones, but the latter can appear without the former. These neurotic symptoms are unfortunately little appreciated and understood even today; for they are not directly accessible to psycho-analysis, and other methods of research have left the standpoint of sexuality out of account.

[1910i, 2370]
The value of the concepts 'ego-libido' and 'object-libido' lies in the fact that they are derived from the study of the intimate characteristics of neurotic and psychotic processes. A differentiation of libido into a kind which is proper to the ego and one which is attached to objects is an unavoidable corollary to an original hypothesis which distinguished between sexual instincts and ego-instincts. At any rate, analysis of the pure transference neuroses (hysteria and obsessional neurosis) compelled me to make this distinction and I only know that all attempts to account for these phenomena by other means have been completely unsuccessful.

[1914c, 2934]

I should like to anticipate, Gentlemen, the qualifications which I shall have to make later in the universal validity of these statements. I will therefore point out to you that all I have said here about repression and the formation and meaning of symptoms was derived from three forms of neurosis - anxiety hysteria, conversion hysteria and obsessional neurosis - and that in the first instance it is also valid only for these forms. These three disorders, which we are accustomed to group together as 'transference neuroses', also circumscribe the region in which psychoanalytic therapy can function. The other neuroses have been far less thoroughly studied by psycho-analysis; in one group of them the impossibility of therapeutic influence has been a reason for this neglect. Nor should you forget that psycho-analysis is still a very young science, that preparing for it costs much trouble and time, and that not at all long ago it was being practised single-handed. Nevertheless, we are everywhere on the point of penetrating to an understanding of these other disorders which are not transference neuroses. I hope later to be able to introduce you to the extensions of our hypotheses and findings which result from adaptation to this new material, and to show you that these further studies have not led to contradictions but to the establishment of higher unities. If, then, everything I am saying here applies to the transference neuroses, let me first increase the value of symptoms by a new piece of information. For a comparative study of the determining causes of falling ill leads to a result which can be expressed in a formula: these people fall ill in one way or another of frustration, when reality prevents them from satisfying their sexual wishes. You see how excellently these two findings tally with each other. It is only thus that symptoms can be properly viewed as substitutive satisfactions for what is missed in life.

[1916-1917, 3372]

Discussions like this, Gentlemen, are bound to become some what arid. So let us turn to clinical material in order to find applications of it that will be a little more impressive. Hysteria and obsessional neurosis are, as you know, the two chief representatives of the group of transference neuroses. Now it is true that in hysteria there is a regression of the libido to the primary incestuous sexual objects and that this occurs quite regularly; but there is as good as no regression to an earlier stage of the sexual organization. To offset this, the chief part in the mechanism of hysteria is played by repression. If I might venture to complete what we already know for certain about this neurosis by making a construction, I might explain the position thus. The unification of the component instincts under the primacy of the genitals has been accomplished; but its results come up against the resistance of the preconscious system which is linked with consciousness. Thus the genital organization holds good for the unconscious, but not in the same way for the preconscious; and this rejection on the part of the preconscious brings about a picture which has certain resemblances to the state of things before genital primacy. But it is nevertheless something quite different.

[1916-1917, 3406]
One reason is probably that the title 'Introduction to Psycho-Analysis' is no longer applicable to the present section, which is supposed to deal with the neuroses. An introduction to psycho-analysis is provided by the study of parapraxes and dreams; the theory of the neuroses is psycho-analysis itself. It would not, I believe have been possible to give you a knowledge of the subject-matter of the theory of the neuroses in so short a time except in this concentrated form. It was a question of presenting you with a connected account of the sense and significance of symptoms and of the external and internal determinants and mechanism of their formation. That is what I have tried to do; it is more or less the nucleus of what psycho-analysis has to teach today. It involved saying a great deal about the libido and its development and a little, too, about that of the ego. Our introduction had already prepared you in advance for the premisses of our technique and for the major considerations of the unconscious and of repression (of resistance). You will discover from one of the next lectures the points from which the work of psycho-analysis makes its further organic advance. For the time being I have made no secret of the fact that everything I have said is derived from the study of a single group of nervous disorders what are termed the 'transference neuroses'. Indeed, I have traced the mechanism of symptom-formation in the case only of the hysterical neurosis. Even if you have acquired no thorough knowledge and have not retained every detail, yet I hope that you have formed some picture of the methods by which psycho-analysis works, of the problems which it attacks and of the results at which it has arrived.

[1916-1917, 3432]

But I still owe you further enlightenment, Gentlemen, on my reasons for not starting my account of the theory of the neuroses with the common neurotic state. You may perhaps suppose that it was because in that case I should have had greater difficulty in proving the sexual causation of the neuroses. But you would be wrong there. In the case of the transference neuroses one must work one's way through the interpretation of symptoms before one can arrive at that discovery. In the common forms of what are known as the 'actual neuroses' the aetiological significance of sexual life is a crude fact that springs to the observer's eyes. I came upon it more than twenty years ago when one day I asked myself the question of why in the examination of neurotics their sexual activities were so regularly excluded from consideration. At that time I sacrificed my popularity with my patients for the sake of these enquiries; but after only a brief effort I was able to declare that 'if the \textit{vita sexualis} is normal, there can be no neurosis' - and by this I meant no 'actual neurosis'. No doubt this statement passes too lightly over people's individual differences; it suffers, too, from the indefiniteness inseparable from the judgement of what is 'normal'. But as a rough guide it retains its value to this day. I had by then reached the point of establishing specific relations between particular forms of neurosis and particular sexual noxae; and I have no doubt that I could repeat the same observations to-day if similar pathological material were still at my disposal. I found often enough that a man who indulged in a certain kind of incomplete sexual satisfaction (for instance, manual masturbation) had fallen ill of a particular form of 'actual neurosis', and that this neurosis promptly gave place to another if he replaced this sexual \textit{régime} by another equally far from being irreproachable. I was then in a position to infer the change in a patient's sexual mode of life from an alteration in his condition. I also learnt then to stand obstinately by my suspicions till I had overcome the patients' disingenuousness and compelled them to confirm my views. It is true that thereafter they preferred to go to other doctors who did not make such keen enquiries about their sexual life.

[1916-1917, 3438]
The transference possesses this extraordinary, and for the treatment, positively central, importance in hysteria, anxiety hysteria and obsessional neurosis, which are for that reason rightly classed together as 'transference neuroses'. No one who has taken in a full impression of the fact of transference from his analytic work will any longer doubt the nature of the suppressed impulses that obtain expression in the symptoms of these neuroses, and will call for no more powerful evidence of their libidinal character. It may be said that our conviction of the significance of symptoms as substitutive satisfactions of the libido only received its final confirmation after the enlistment of the transference.

[1916-1917, 3487]

Narcissism. - The most important theoretical advance has certainly been the application of the libido theory to the repressing ego. The ego itself came to be regarded as a reservoir of what was described as narcissistic libido, from which the libidinal cathexes of objects flowed out and into which they could be once more withdrawn. By the help of this conception it became possible to embark upon the analysis of the ego and to make a clinical distinction of the psychoneuroses into transference neuroses and narcissistic disorders. In the former (hysteria and obsessional neurosis) the subject has at his disposal a quantity of libido striving to be transferred on to extraneous objects, and use is made of this in carrying out analytic treatment; on the other hand, the narcissistic disorders (dementia praecox, paranoia, melancholia) are characterized by a withdrawal of the libido from objects and they are therefore scarcely accessible to analytic therapy. But their therapeutic inaccessibility has not prevented analysis from making the most fruitful beginnings in the deeper study of these illnesses, which are counted among the psychoses.

[1923a, 3925]

Contrast between Sexual and Ego Instincts. - Psycho-analysis early became aware that all mental occurrences must be regarded as built on the basis of an interplay of the forces of the elementary instincts. This, however, led to a difficult predicament, since psychology included no theory of the instincts. No one could say what an instinct really was, the question was left entirely to individual caprice, and every psychologist was in the habit of postulating any instincts in any number that he chose. The first sphere of phenomena to be studied by psycho-analysis comprised what are known as the transference neuroses (hysteria and obsessional neurosis). It was found that their symptoms came about by sexual instinctual impulses being rejected (repressed) by the subject's personality (his ego) and then finding expression by circuitous paths through the unconscious. These facts could be met by drawing a contrast between the sexual instincts and ego instincts (instincts of self-preservation), which was in line with the popular saying that hunger and love are what make the world go round: libido was the manifestation of the force of love in the same sense as was hunger of the self-preservation instinct. The nature of the ego instincts remained for the time being undefined and, like all the other characteristics of the ego, inaccessible to analysis. There was no means of deciding whether, and if so what, qualitative differences were to be assumed to exist between the two classes of instincts.

[1923a, 3931]
A decisive advance was made when the analysis of dementia praecox and other psychotic disorders was ventured upon and thus the examination was begun of the ego itself, which had so far been known only as the agency of repression and opposition. It was found that the pathogenic process in dementia praecox is the withdrawal of the libido from objects and its introduction into the ego, while the clamorous symptoms of the disease arise from the vain struggles of the libido to find a pathway back to objects. It thus turned out to be possible for object-libido to change into cathexis of the ego and vice versa. Further reflection showed that this process must be presumed to occur on the largest scale and that the ego is to be regarded as a great reservoir of libido from which libido is sent out to objects and which is always ready to absorb libido flowing back from objects. Thus the instincts of self-preservation were also of a libidinal nature: they were sexual instincts which, instead of external objects, had taken the subject's own ego as an object. Clinical experience had made us familiar with people who behaved in a striking fashion as though they were in love with themselves and this perversion had been given the name of narcissism. The libido of the self-preservative instincts was now described as narcissistic libido and it was recognized that a high degree of this self-love constituted the primary and normal state of things. The earlier formula laid down for the transference neuroses consequently required to be modified, though not corrected. It was better, instead of speaking of a conflict between sexual instincts and ego instincts, to speak of a conflict between object-libido and ego-libido, or, since the nature of these instincts was the same, between the object-cathexes and the ego.

Among the hypothetical concepts which enable the doctor to deal with the analytic material, the first to be mentioned is that of 'libido'. Libido means in psycho-analysis in the first instance the force (thought of as quantitatively variable and measurable) of the sexual instincts directed towards an object - 'sexual' in the extended sense required by analytic theory. Further study showed that it was necessary to set alongside this 'object-libido' a 'narcissistic' or 'ego-libido', directed to the subject's own ego; and the interaction of these two forces has enabled us to account for a great number of normal and abnormal processes in mental life. A rough distinction was soon made between what are known as the 'transference neuroses' and the narcissistic disorders. The former (hysteria and obsessional neurosis) are the objects proper of psycho-analytic treatment, while the others, the narcissistic neuroses, though they can, it is true, be examined by the help of analysis, offer fundamental difficulties to therapeutic influence. It is true that the libido theory of psycho-analysis is by no means complete and that its relation to a general theory of the instincts is not yet clear, for psycho-analysis is a young science, quite unfinished and in a stage of rapid development. Here, however, it should be emphatically pointed out how erroneous the charge of pan-sexualism is which is so often levelled at psycho-analysis. It seeks to show that psycho-analytic theory knows of no mental motive forces other than purely sexual ones and in doing so exploits popular prejudices by using the word 'sexual' not in its analytic but in its vulgar sense.

[1923a, 3933]

[1924f, 4113]
With the psychoneuroses, the influence of heredity is more marked and the causation less transparent. A peculiar method of investigation known as psycho-analysis has, however, enabled us to recognize that the symptoms of these disorders (hysteria, obsessional neurosis, etc.) are psychogenic and depend upon the operation of unconscious (repressed) ideational complexes. This same method has also taught us what those unconscious complexes are and has shown that, quite generally speaking, they have a sexual content. They spring from the sexual needs of people who are unsatisfied and represent for them a kind of substitutive satisfaction. We must therefore view all factors which impair sexual life, suppress its activity or distort its aims as being pathogenic factors in the psychoneuroses as well.

[1908d, 1951]

There are a large number of phenomena related to facial and other expressive movements and to speech, as well as many processes of thought (both in normal and sick people), which have hitherto escaped the notice of psychology because they have been regarded as no more than the results of organic disorder or of some abnormal failure in function of the mental apparatus. What I have in mind are 'parapraxes' (slips of the tongue or pen, forgetfulness, etc.), haphazard actions and dreams in normal people, and convulsive attacks, deliria, visions, and obsessive ideas or acts in neurotic subjects. These phenomena (in so far as they were not entirely neglected, as was the case with the parapraxes) were relegated to pathology and an attempt was made to find 'physiological' explanations of them, though these were invariably unsatisfactory. Psycho-analysis, on the contrary, has been able to show that all these things can be explained by means of hypotheses of a purely psychological nature and can be fitted into the chain of psychical events already known to us. Thus on the one hand psycho-analysis has narrowed the region subject to the physiological point of view and on the other hand has brought a large section of pathology into the sphere of psychology. In this instance the normal phenomena provide the more convincing evidence. Psycho-analysis cannot be accused of having applied to normal cases findings arrived at from pathological material. The evidence in the latter and in the former was reached independently and shows that normal processes and what are described as pathological ones follow the same rules.

[1913j, 2803]

Starting from dreams, the investigations of psycho-analysis have enabled it to construct a psychology of the neuroses which is being continuously built up piece by piece. But what we are here concerned with - the psychological interest of psycho-analysis - obliges us to enter more fully into only two sides of this far reaching subject: the evidence that many pathological phenomena which had hitherto been believed to require physiological explanations are in fact psychical acts, and the evidence that the processes which lead to abnormal consequences can be traced back to psychical motive forces.

[1913j, 2809]
Some of the phobias, it is true, corresponded to the primary phobias of human beings, and especially of neuropaths - in particular, for instance, her fear of animals (snakes and toads, as well as all the vermin of which Mephistopheles boasted himself master), and of thunderstorms and so on. But these phobias too were established more firmly by traumatic events. Thus her fear of toads was strengthened by her experience in early childhood of having a dead toad thrown at her by one of her brothers, which led to her first attack of hysterical spasms; and similarly, her fear of thunderstorms was brought out by the shock which gave rise to her clacking, and her fear of fogs by her walk on the Island of Rügen. Nevertheless, in this group the primary - or, one might say, the instinctive - fear (regarded as a psychical stigma) plays the preponderant part.

[1895d, 80]

Two constituents are found in every obsession: (1) an idea that forces itself upon the patient (2) an associated emotional state. Now in the group of phobias this emotional state is always one of 'anxiety', while in true obsessions other emotional states, such as doubt, remorse, or anger, may occur just as well as anxiety. I will first attempt to explain the really remarkable psychological mechanism of true obsessions, a mechanism quite different from that of the phobias.

[1895c, 317]

Among the phobias, also, two groups may be differentiated, according to the nature of the object feared: (1) common phobias, an exaggerated fear of things that everyone detests or fears to some extent: such as night, solitude, death, illnesses, dangers in general, snakes, etc. (2) contingent phobias, the fear of special conditions that inspire no fear in the normal man; for example, agoraphobia and the other phobias of locomotion. It is interesting to note that these phobias have not the obsessive feature that characterizes true obsessions and the common phobias. The emotional state appears in their instance only under special conditions which the patient carefully avoids.

[1895c, 323]

The mechanism of phobias is entirely different from that of obsessions. Substitution is no longer the predominant feature in the former; psychological analysis reveals no incompatible, replaced idea in them. Nothing is ever found but the emotional state of anxiety which, by a kind of selective process, brings up all the ideas adapted to become the subject of a phobia. In the case of agoraphobia, etc., we often find the recollection of an anxiety attack; and what the patient actually fears is the occurrence of such an attack under the special conditions in which he believes he cannot escape it.

[1895c, 323]
Indeed, when we look into the matter more closely, we must recognize the fact that the dream-work is doing nothing original in making substitutions of this kind. In order to gain its ends - in this case the possibility of a representation hampered by censorship - it merely follows the paths which it finds already laid down in the unconscious; and it gives preference to those transformations of the repressed material which can also become conscious in the form of jokes or allusions and of which the phantasies of neurotic patients are so full. At this point we suddenly reach an understanding of Scherner's dream interpretations, whose essential correctness I have defended elsewhere. The imagination's pre-occupation with the subject's own body is by no means peculiar to dreams or characteristic only of them. My analyses have shown me that it is habitually present in the unconscious thoughts of neurotics, and that it is derived from sexual curiosity, which, in growing youths or girls, is directed to the genitals of the other sex, and to those of their own as well. Nor, as Scherner and Volkelt have rightly insisted, is a house the only circle of ideas employed for symbolizing the body; and this is equally true of dreams and of the unconscious phantasies of neurosis. It is true that I know patients who have retained an architectural symbolism for the body and the genitals. (Sexual interest ranges far beyond the sphere of the external genitalia.) For these patients pillars and columns represent the legs (as they do in the Song of Solomon), every gateway stands for one of the bodily orifices (a 'hole'), every water-pipe is a reminder of the urinary apparatus, and so on. But the circle of ideas centring round plant-life or the kitchen may just as readily be chosen to conceal sexual images.¹ In the former case the way has been well prepared by linguistic usage, itself the precipitate of imaginative similes reaching back to remote antiquity: e.g. the Lord's vineyard, the seed, and the maiden's garden in the Song of Solomon. The ugliest as well as the most intimate details of sexual life may be thought and dreamt of in seemingly innocent allusions to activities in the kitchen; and the symptoms of hysteria could never be interpreted if we forgot that sexual symbolism can find its best hiding-place behind what is commonplace and inconspicuous. There is a valid sexual meaning behind the neurotic child's intolerance of blood or raw meat, or his nausea at the sight of eggs or macaroni, and behind the enormous exaggeration in neurotics of the natural human dread of snakes. Wherever neuroses make use of such disguises they are following paths along which all humanity passed in the earliest periods of civilization - paths of whose continued existence today, under the thinnest of veils, evidence is to be found in linguistic usages, superstitions and customs.

[1900a, 815]

One day I discovered to my great astonishment that the view of dreams which came nearest to the truth was not the medical but the popular one, half-involved though it still was in superstition. For I had been led to fresh conclusions on the subject of dreams by applying to them a new method of psychological investigation which had done excellent service in the solution of phobias, obsessions and delusions, etc. Since then, under the name of 'psycho-analysis', it has found acceptance by a whole school of research workers. The numerous analogies that exist between dream-life and a great variety of conditions of psychical illness in waking life have indeed been correctly observed by many medical investigators. There seemed, therefore, good ground for hoping that a method of investigation which had given satisfactory results in the case of psychopathic structures would also be of use in throwing light upon dreams. Phobias and obsessions are as alien to normal consciousness as dreams are to waking consciousness; their origin is as unknown to consciousness as that of dreams. In the case of these psychopathic structures practical considerations led to an investigation of their origin and mode of development; for experience had shown that the discovery of the trains of thought which, concealed from consciousness, connect the pathological ideas with the remaining contents of the mind is equivalent to a resolution of the symptoms and has as its consequence the mastering of ideas which till then could not be inhibited. Thus psychotherapy was the starting-point of the procedure of which I made use for the explanation of dreams.

[1901a, 1053]
Childhood opinions about the nature of marriage, which are not seldom retained by conscious memory, have great significance for the symptomatology of later neurotic illness. At first they find expression in children's games in which each child does with another whatever it is that in his view constitutes being married; and then, later on, the wish to be married may choose the infantile form of expression and so make its appearance in a phobia which is at first sight unrecognizable, or in some corresponding symptom.¹

His father's investigations may have been without success at some points; but it does no harm to make acquaintance at close quarters with a phobia of this sort - which we may feel inclined to name after its new objects. For in this way we get to see how diffuse it really is. It extends on to horses and on to carts, on to the fact that horses fall down and that they bite, on to horses of a particular character, on to carts that are heavily loaded. I will reveal at once that all these characteristics were derived from the circumstance that the anxiety originally had no reference at all to horses but was transposed on to them secondarily and had now become fixed upon those elements of the horse-complex which showed themselves well adapted for certain transferences. We must specially acknowledge one most important result of the boy's examination by his father. We have learned the immediate precipitating cause after which the phobia broke out. This was when the boy saw a big heavy horse fall down; and one at least of the interpretations of this impression seems to be that emphasized by his father, namely, that Hans at that moment perceived a wish that his father might fall down in the same way - and be dead. His serious expression as he was telling the story no doubt referred to this unconscious meaning. May there not have been yet another meaning concealed behind all this? And what can have been the significance of the making a row with its legs?

It has been noticeable for some time that Hans's imagination was being coloured by images derived from traffic, and was advancing systematically from horses, which draw vehicles, to railways. In the same way a railway-phobia eventually becomes associated with every street-phobia.

I shall now proceed to examine this observation of the development and resolution of a phobia in a boy under five years of age, and I shall have to do so from three points of view. In the first place I shall consider how far it supports the assertions which I put forward in my *Three Essays on the Theory of Sexuality* (1905d). Secondly, I shall consider to what extent it can contribute towards our understanding of this very frequent form of disorder. And thirdly, I shall consider whether it can be made to shed any light upon the mental life of children or to afford any criticism of our educational aims.

Disorders of this kind are called 'phobias', and we might classify Hans's case as an agoraphobia if it were not for the fact that it is a characteristic of that complaint that the locomotion of which the patient is otherwise incapable can always be easily performed when he is accompanied by some specially selected person - in the last resort, by the physician. Hans's phobia did not fulfil this condition; it soon ceased having any relation to the question of locomotion and became more and more clearly concentrated upon horses. In the early days of his illness, when the anxiety was at its highest pitch, he expressed a fear that 'the horse'll come into the room', and it was this that helped me so much towards understanding his condition.
Anxiety-hysterias are the most common of all psychoneurotic disorders. But, above all, they are those which make their appearance earliest in life; they are *par excellence* the neuroses of childhood. When a mother uses such phrases as that her child's 'nerves' are in a bad state, we can be certain that in nine cases out of ten the child is suffering from some kind of anxiety or from many kinds at once. Unfortunately the finer mechanism of these highly significant disorders has not yet been sufficiently studied. It has not yet been established whether anxiety-hysteria is determined, in contradistinction to conversion-hysteria and other neuroses, solely by constitutional factors or solely by accidental experiences, or by what combination of the two.¹ It seems to me that of all neurotic disorders it is the least dependent upon a special constitutional predisposition and that it is consequently the most easily acquired at any time of life. [1909b, 2100]

One essential characteristic of anxiety-hysterias is very easily pointed out. An anxiety-hysteria tends to develop more and more into a 'phobia'. In the end the patient may have got rid of all his anxiety, but only at the price of subjecting himself to all kinds of inhibitions and restrictions. From the outset in anxiety-hysteria the mind is constantly at work in the direction of once more psychically binding the anxiety which has become liberated; but this work can neither bring about a retransformation of the anxiety into libido, nor can it establish any contact with the complexes which were the source of the libido. Nothing is left for it but to cut off access to every possible occasion that might lead to the development of anxiety, by erecting mental barriers in the nature of precautions, inhibitions, or prohibitions; and it is these defensive structures that appear to us in the form of phobias and that constitute to our eyes the essence of the disease. [1909b, 2100]
Furthermore, let me say in Hans's favour (and I frankly admit my partisan attitude) that he is not the only child who has been overtaken by a phobia at some time or other in his childhood. Troubles of that kind are well known to be quite extraordinarily frequent, even in children the strictness of whose upbringing has left nothing to be desired. In later life these children either become neurotic or remain healthy. Their phobias are shouted down in the nursery because they are inaccessible to treatment and are decidedly inconvenient. In the course of months or years they diminish, and the child seems to recover; but no one can tell what psychological changes are necessitated by such a recovery, or what alterations in character are involved in it. When, however, an adult neurotic patient comes to us for psycho-analytic treatment (and let us assume that his illness has only become manifest after he has reached maturity), we find regularly that his neurosis has as its point of departure an infantile anxiety such as we have been discussing, and is in fact a continuation of it; so that, as it were, a continuous and undisturbed thread of psychical activity, taking its start from the conflicts of his childhood, has been spun through his life - irrespective of whether the first symptom of those conflicts has persisted or has retreated under the pressure of circumstances. I think, therefore, that Hans's illness may perhaps have been no more serious than that of many other children who are not branded as 'degenerates'; but since he was brought up without being intimidated, and with as much consideration and as little coercion as possible, his anxiety dared to show itself more boldly. With him there was no place for such motives as a bad conscience or a fear of punishment, which with other children must no doubt contribute to making the anxiety less. It seems to me that we concentrate too much upon symptoms and concern ourselves too little with their causes. In bringing up children we aim only at being left in peace and having no difficulties, in short, at training up a model child, and we pay very little attention to whether such a course of development is for the child's good as well. I can therefore quite imagine that it may have been to Hans's advantage to have produced this phobia. For it directed his parents' attention to the unavoidable difficulties by which a child is confronted when in the course of his cultural training he is called upon to overcome the innate instinctual components of his mind; and his trouble brought his father to his assistance. It may be that Hans now enjoys an advantage over other children, in that he no longer carries within him that seed in the shape of repressed complexes which must always be of some significance for a child's later life, and which undoubtedly brings with it a certain degree of deformity of character if not a predisposition to a subsequent neurosis. I am inclined to think that this is so, but I do not know if many others will share my opinion; nor do I know whether experience will prove me right.

[1909b, 2120]

We are also now coming to the opinion that analytic technique must be modified in certain ways according to the nature of the disease and the dominant instinctual trends in the patient. We started out from the treatment of conversion hysteria; in anxiety hysteria (phobias) we must to some extent alter our procedure. For these patient cannot bring out the material necessary for resolving their phobia so long as they feel protected by obeying the condition which it lays down. One cannot, of course, succeed in getting them to give up their protective measures and work under the influence of anxiety from the beginning of the treatment. One must therefore help them by interpreting their unconscious to them until they can make up their minds to do without the protection of their phobia and expose themselves to a now greatly mitigated anxiety. Only after they have done so does the material become accessible, which, when it has been mastered, leads to a solution of the phobia. Other modifications of technique, which seem to me not yet ripe for discussion, will be required in the treatment of obsessional neurosis. In this connection very important questions arise, which have not hitherto been elucidated: how far the instincts which the patient is combating are to be allowed some satisfaction during the treatment, and what difference it makes whether these impulses are active (sadistic) or passive (masochistic) in their nature.

[1910d, 2310]
To-day we find taboos among primitive peoples already elaborated into an intricate system of just the sort that neurotics among ourselves develop in their phobias, and we find old motifs replaced by new ones that fit together harmoniously. Leaving aside these genetic problems, then, we will go back to the idea that primitive man institutes a taboo where he fears some danger. Taking it generally this danger is a psychical one, for primitive man is not impelled at this point to make two distinctions, which to us it seems cannot be disregarded. He does not separate material from psychical danger, nor real from imaginary. In his consistently applied animistic view of the universe, every danger springs from the hostile intention of some being with a soul like himself, and this is as much the case with dangers which threaten him from some natural force as it is with those from other human beings or animals. But on the other hand he is accustomed to project his own internal impulses of hostility on to the external world, to ascribe them, that is, to the objects which he feels to be disagreeable or even merely strange. In this way women also are regarded as being a source of such dangers, and the first act of sexual intercourse with a woman stands out as a danger of particular intensity.

[1918a, 2356]

The representation of the penis as a weapon, cutting knife, ¹ dagger, etc., is familiar to us from the anxiety dreams of abstinent women in particular and also lies at the root of numerous phobias in neurotic people. The complicated disguise of this present dream, however, demands that we should make an attempt to clarify our understanding of it by a psycho-analytic interpretation based on interpretations already carried out. In doing so we are not overlooking the fact that we shall be going beyond the material presented in the folk tale itself and that consequently our conclusions will lose in certainty.

[1957a [1911], 2527]

² In the course of psycho-analyses of neurotics who suffer (or who suffered in their childhood) from fear of ghosts, it is often possible to show without much difficulty that the ghosts are disguises for the patient's parents. Cf. in this connection a paper upon 'Sexual Ghosts' by Haeberlin (1912). Here the person concerned was not the subject's parent (who was dead) but someone else of erotic significance to him.

[1912-1913, 2709]

The secondary revision of the product of the dream-work is an admirable example of the nature and pretensions of a system. There is an intellectual function in us which demands unity, connection and intelligibility from any material, whether of perception or thought, that comes within its grasp; and if, as a result of special circumstances, it is unable to establish a true connection, it does not hesitate to fabricate a false one. Systems constructed in this way are known to us not only from dreams, but also from phobias, from obsessive thinking and from delusions. The construction of systems is seen most strikingly in delusional disorders (in paranoia), where it dominates the symptomatic picture; but its occurrence in other forms of neuro-psychosis must not be overlooked. In all these cases it can be shown that a rearrangement of the psychical material has been made with a fresh aim in view; and the rearrangement may often have to be a drastic one if the outcome is to be made to appear intelligible from the point of view of the system. Thus a system is best characterized by the fact that at least two reasons can be discovered for each of its products: a reason based upon the premises of the system (a reason, then, which may be delusional) and a concealed reason, which we must judge to be the truly operative and the real one.

[1912-1913, 2737]
A second form of anxiety, in contrast to the ones I have just described, is bound psychically and attached particular objects or situations. This is the anxiety of the extremely multifarious and often very strange 'phobias'. Stanley Hall, the respected American psychologist, has recently taken the trouble to present us with a whole series of these phobias in all the magnificence of Greek names. This sounds like a list of the ten Plagues of Egypt, though their number goes far beyond ten. Listen to all the things that can become the object or content of a phobia: darkness, open air, open spaces, cats, spiders, caterpillars, snakes, mice, thunderstorms, sharp points, blood, enclosed spaces, crowds, solitude, crossing bridges, sea voyages and railway journeys, etc., etc. A first attempt at finding one's way about in this confusion suggests a division into three groups. Some of the dreaded objects and situations have something uncanny about them for normal people as well, some relation to danger; and such phobias, therefore, do not strike us as unintelligible, though their strength is greatly exaggerated. Thus most of us have a sense of repulsion if we meet with a snake. Snake phobia, we might say, is a universal human characteristic; and Darwin has described most impressively how he could not avoid feeling fear of a snake that struck at him, even though he knew that he was protected from it by a thick sheet of glass. We may refer to a second group the cases in which a relation to a danger is still present, though we are accustomed to minimize the danger and not to anticipate it. The majority of situation phobias belong to this group. We know that there is more chance of an accident when we are on a railway-journey than when we stay at home - the chance of a collision; we know, too, that a ship may go down, in which case there is a probability of being drowned; but we do not think about these dangers, and travel by rail and ship without anxiety. It cannot be disputed that we should fall into the river if the bridge collapsed at the moment we were crossing it; but that happens so exceedingly seldom that it does not arise as a danger. Solitude, too, has its dangers and in certain circumstances we avoid it; but there is no question of our not being able to tolerate it under any condition even for a moment. Much the same is true of crowds, of enclosed spaces, of thunderstorms and so on. What in general appears to us strange in these phobias of neurotics is not so much their content as their intensity. The anxiety of phobias is positively overwhelming. And sometimes we get an impression that what neurotics are afraid of are not at all the same things and situations which may in certain circumstances cause anxiety in us too and which they describe by the same names.

We are left with a third group of phobias, which is quite beyond our comprehension. When a strong, grown-up man is unable owing to anxiety to walk along a street or cross a square in his own familiar home-town, when a healthy, well-developed woman is thrown into insensate anxiety because a cat has brushed against the edge of her dress or because a mouse has run across the room, how are we to relate these things to the danger which they obviously constitute for the phobic subject? In the case of such animal phobias there can be no question of an exaggeration of universal human antipathies, since, as though to demonstrate the contrary, there are numerous people who cannot pass by a cat without coaxing it and stroking it. The mouse that these women are so much afraid of is also [in German] one of the chief terms of affection; a girl who is delighted when her lover calls her one will often scream with terror when she sees the pretty creature which bears that name. In the case of the man with agoraphobia the only explanation that we can reach is that he is behaving like a small child. A child is actually taught as part of his education to avoid such situations as dangerous; and our agoraphobic will in fact be saved from his anxiety if we accompany him across the square.
The two forms of anxiety that I have just described - the freely floating expectant anxiety and the sort which is bound to phobias - are independent of each other. One is not a higher stage, as it were, of the other; and they only appear simultaneously in exceptional cases and, so to speak, accidentally. The most powerful general apprehensiveness need not be expressed in phobias; people whose whole existence is restricted by agoraphobia may be entirely free from pessimistic expectant anxiety. Some phobias - for instance, agoraphobia and railway phobia - are demonstrably acquired at a fairly mature age, while others - such as fear of darkness, thunderstorms and animals - seem to have been present from the first. Those of the former kind have the significance of severe illnesses; the latter make their appearance rather as eccentricities or whims. I must add that we class all these phobias as anxiety hysteria; that is to say, we regard them as a disorder closely related to the familiar conversion hysteria. [1916-1917, 3447]

In children the first phobias relating to situations are those of darkness and solitude. The former of these often persists throughout life; both are involved when a child feels the absence of some loved person who looks after it - its mother, that is to say. While I was in the next room, I heard a child who was afraid of the dark call out: 'Do speak to me, Auntie! I'm frightened!' 'Why, what good would that do? You can't see me.' To this the child replied: 'If someone speaks, it gets lighter.' Thus a longing felt in the dark is transformed into a fear of the dark. Far from its being the case that neurotic anxiety is only secondary and a special case of realistic anxiety, we see on the contrary that in a small child something that behaves like realistic anxiety shares its essential feature - origin from unemployable libido - with neurotic anxiety. Innately, children seem to have little true realistic anxiety. In all the situations which can later become determinants of phobias (on heights, on narrow bridges over water, on railway journeys, on ships) children exhibit no anxiety; and, to be sure, the greater their ignorance the less their anxiety. It would have been a very good thing if they had inherited more of such life-preserving instincts, for that would have greatly facilitated the task of watching over them to prevent their running into one danger after another. The fact is that children, to begin with, over-estimate their strength and behave fearlessly because they are ignorant of dangers. They will run along the brink of the water, climb on to the window-sill, play with sharp objects and with fire - in short, do everything that is bound to damage them and to worry those in charge of them. When in the end realistic anxiety is awakened in them, that is wholly the result of education; for they cannot be allowed to make the instructive experiences themselves. [1916-1917, 3454]

You will be glad to hear that the analysis of phobias has not much more that is new to teach us. For the same thing happens with them as with children's anxiety: unemployable libido is being constantly transformed into an apparently realistic anxiety and thus a tiny external danger is introduced to represent the claims of the libido. There is nothing to be wondered at in this agreement, for the infantile phobias are not only the prototype of the later ones which we class as 'anxiety hysteria' but are actually their precondition and the prelude to them. Every hysterical phobia goes back to an infantile anxiety and is a continuation of it, even if it has a different content and must thus be given another name. The difference between the two disorders lies in their mechanism. In order that libido shall be changed into anxiety, it no longer suffices in the case of adults for the libido to have become momentarily unemployable in the form of a longing. Adults have long since learnt how to hold such libido in suspense or to employ it in some other way. If, however, the libido belongs to a psychical impulse which has been subjected to repression, then circumstances are re-established similar to those in the case of a child in whom there is still no distinction between conscious and unconscious; and by mean of regression to the infantile phobia a passage is opened, as it were, through which the transformation of libido into anxiety can be comfortably accomplished. [1916-1917, 3455]
Why this should be so calls for a rather long reply. First of all, we must sift the facts. In a great number of cases the old determinants of anxiety do really lapse, after having produced neurotic reactions. The phobias of very young children, fears of being alone or in the dark or with strangers - phobias which can almost be called normal - usually pass off later on; the child 'grows out of them', as we say about some other disturbances of childhood. Animal phobias, which are of such frequent occurrence, undergo the same fate and many conversion hysterias of early years find no continuation in later life. Ceremonial actions appear extremely often in the latency period, but only a very small percentage of them develop later into a full obsessional neurosis. In general, so far as we can tell from our observations of town children belonging to the white races and living according to fairly high cultural standards, the neuroses of childhood are in the nature of regular episodes in a child's development, although too little attention is still being paid to them. Signs of childhood neuroses can be detected in all adult neurotics without exception; but by no means all children who show those signs become neurotic in later life. It must be, therefore, that certain determinants of anxiety are relinquished and certain danger-situations lose their significance as the individual becomes more mature. Moreover, some of these danger-situations manage to survive into later times by modifying their determinants of anxiety so as to bring them up to date. Thus, for instance, a man may retain his fear of castration in the guise of a syphilidophobia, after he has come to know that it is no longer customary to castrate people for indulging their sexual lusts, but that, on the other hand, severe diseases may overtake anyone who thus gives way to his instincts. Other determinants of anxiety, such as fear of the super-ego, are destined not to disappear at all but to accompany people throughout their lives. In that case the neurotic will differ from the normal person in that his reactions to the dangers in question will be unduly strong. Finally, being grown-up affords no absolute protection against a return of the original traumatic anxiety-situation. Each individual has in all probability a limit beyond which his mental apparatus fails in its function of mastering the quantities of excitation which require to be disposed of.

[1926d, 4302]
To provide this secondary connection for the liberated affect, any idea can be made use of which is either able, from its nature, to be united with an affect of the quality in question, or which has certain relations to the incompatible idea which make it seem as though it could serve as a surrogate for it. Thus, for example, liberated anxiety, whose sexual origin must not be remembered by the patient, will seize upon the common primary phobias of mankind about animals, thunderstorms, darkness and so on, or upon things which are unmistakably associated in one way or another with what is sexual-such as micturition, defaecation, or dirtying and contagion generally.

[1894a, 309]

¹ The group of typical phobias, of which agoraphobia is a typical model, cannot be traced back to the psychical mechanism described above; on the contrary, the mechanism of agoraphobia differs from that of obsessions proper, and of the phobias that are reducible to them, in one decisive point. There is no repressed idea from which the anxiety affect might have been separated off. The anxiety of these phobias has another origin.
[1894a, 312]

The mechanism of phobias is entirely different from that of obsessions. Substitution is no longer the predominant feature in the former; psychological analysis reveals no incompatible, replaced idea in them. Nothing is ever found but the emotional state of anxiety which, by a kind of selective process, brings up all the ideas adapted to become the subject of a phobia. In the case of agoraphobia, etc., we often find the recollection of an anxiety attack; and what the patient actually fears is the occurrence of such an attack under the special conditions in which he believes he cannot escape it.
[1895c, 323]

(7) On the basis of chronic anxiousness (anxious expectation) on the one hand, and a tendency to anxiety attacks accompanied by vertigo on the other, two groups of typical phobias develop, the first relating to general physiological dangers, the second relating to locomotion. To the first group belong fear of snakes, thunderstorms, darkness, vermin, and so on, as well as the typical moral over-scrupulousness and forms of doubting mania. Here the available anxiety is simply employed to reinforce aversions which are instinctively implanted in everyone. But as a rule a phobia which acts in an obsessional manner is only formed if there is added to this the recollection of an experience in which the anxiety was able to find expression as, for instance, after the patient has experienced a thunderstorm in the open. It is a mistake to try to explain such cases as being simply a persistence of strong impressions; what makes these experiences significant and the memory of them lasting is, after all, only the anxiety which was able to emerge at the time and which can similarly emerge now. In other words, such impressions remain powerful only in people with ‘anxious expectation’.
[1895b, 333]

The relation of these phobias to the phobias of obsessional neurosis, whose mechanism I made clear in an earlier paper¹ in this periodical, is of the following kind. What they have in common is that in both an idea becomes obsessional as a result of being attached to an available affect. The mechanism of transposition of affect thus holds good for both kinds of phobia. But in the phobias of anxiety neurosis (1) this affect always has the same colour, which is that of anxiety; and (2) the affect does not originate in a repressed idea, but turns out to be not further reducible by psychological analysis, nor amenable to psychotherapy. The mechanism of substitution, therefore, does not hold good for the phobias of anxiety neurosis.
[1895b, 334]
Besides this, there are plenty of cases in which a single anxiety-state is provoked by the extra addition of a stock factor, by an excitement of some kind or other. The same holds good, therefore, for the aetiology of the individual anxiety attack as for the causation of the whole neurosis. It is not very strange that the anxiety of the phobias should obey different conditions; they have a more complicated structure than purely somatic anxiety attacks. In phobias the anxiety is linked to a definite ideational or perceptual content, and the arousal of this psychical content is the chief condition for the emergence of the anxiety. When this happens, anxiety is 'generated', just as for instance sexual tension is generated by the arousal of libidinal ideas. The connection of this process, however, with the theory of anxiety neurosis has not yet been elucidated.

This is just the situation in our dream. It is hardly rash to assume that the unintelligibility of the dream's content, as it exists in the memory has led to its being recast in a form designed to make sense of the situation. That situation, however, is in the process deprived of its original meaning and put to extraneous uses. But, as we shall see later, it is a common thing for the conscious thought-activity of a second psychical system to misunderstand the content of a dream in this way, and this misunderstanding must be regarded as one of the factors in determining the final form assumed by dreams. Moreover we shall learn that similar misunderstandings (taking place, once again, within one and the same psychical personality) play a major part in the construction of obsessions and phobias.

It is worth remarking that we have here three symptoms - the disgust, the sensation of pressure on the upper part of the body, and the avoidance of men engaged in affectionate conversation - all of them derived from a single experience, and that it is only by taking into account the interrelation of these three phenomena that we can understand the way in which the formation of the symptoms came about. The disgust is the symptom of repression in the erotogenic oral zone, which, as we shall hear, had been over-indulged in Dora's infancy by the habit of sensual sucking. The pressure of the erect member probably led to an analogous change in the corresponding female organ, the clitoris; and the excitation of this second erotogenic zone was referred by a process of displacement to the simultaneous pressure against the thorax and became fixed there. Her avoidance of men who might possibly be in a state of sexual excitement follows the mechanism of a phobia, its purpose being to safeguard her against any revival of the repressed perception.
MECHANICAL EXCITATIONS At this point we must also mention the production of sexual excitation by rhythmic mechanical agitation of the body. Stimuli of this kind operate in three different ways: on the sensory apparatus of the vestibular nerves, on the skin, and on the deeper parts (e.g. the muscles and articular structures). The existence of these pleasurable sensations - and it is worth emphasizing the fact that in this connection the concepts of 'sexual excitation' and 'satisfaction' can to a great extent be used without distinction, a circumstance which we must later endeavour to explain - the existence, then, of these pleasurable sensations, caused by forms of mechanical agitation of the body, is confirmed by the fact that children are so fond of games of passive movement, such as swinging and being thrown up into the air, and insist on such games being incessantly repeated.¹ It is well known that rocking is habitually used to induce sleep in restless children. The shaking produced by driving in carriages and later by railway-travel exercises such a fascinating effect upon older children that every boy, at any rate, has at one time or other in his life wanted to be an engine driver or a coachman. It is a puzzling fact that boys take such an extraordinarily intense interest in things connected with railways, and, at the age at which the production of phantasies is most active (shortly before puberty), use those things as the nucleus of a symbolism that is peculiarly sexual. A compulsive link of this kind between railway-travel and sexuality is clearly derived from the pleasurable character of the sensations of movement. In the event of repression, which turns so many childish preferences into their opposite, these same individuals, when they are adolescents or adults, will react to rocking or swinging with a feeling of nausea, will be terribly exhausted by a railway journey, or will be subject to attacks of anxiety on the journey and will protect themselves against a repetition of the painful experience by a dread of railway-travel. [1905d, 1520]

Childhood opinions about the nature of marriage, which are not seldom retained by conscious memory, have great significance for the symptomatology of later neurotic illness. At first they find expression in children's games in which each child does with another whatever it is that in his view constitutes being married; and then, later on, the wish to be married may choose the infantile form of expression and so make its appearance in a phobia which is at first sight unrecognizable, or in some corresponding symptom.¹ [1908c, 1976]

Then again, there were the states into which he fell on two consecutive evenings before going to sleep, and which were characterized by anxiety mingled with clear traces of tenderness. These states show that at the beginning of his illness there was as yet no phobia whatever present, whether of streets or of walking or even of horses. If there had been, his evening states would be inexplicable; for who bothers at bed time about streets and walking? On the other hand it becomes quite clear why he was so fearful in the evening, if we suppose that at bedtime he was overwhelmed by an intensification of his libido - for its object was his mother, and its aim may perhaps have been to sleep with her. He had besides learnt from his experience that at Gmunden his mother could be prevailed upon, when he got into such moods, to take him into her bed, and he wanted to gain the same ends here in Vienna. Nor must we forget that for part of the time at Gmunden he had been alone with his mother, as his father had not been able to spend the whole of the holidays there, and further, that in the country his affections had been divided among a number of playmates and friends of both sexes, while in Vienna he had none, so that his libido was in a position to return undivided to his mother. [1909b, 1818]
His anxiety, then, corresponded to repressed longing. But it was not the same thing as the longing: the repression must be taken into account too. Longing can be completely transformed into satisfaction if it is presented with the object longed for. Therapy of that kind is no longer effective in dealing with anxiety. The anxiety remains even when the longing can be satisfied. It can no longer be completely retransformed into libido; there is something that keeps the libido back under repression.¹ This was shown to be so in the case of Hans on the occasion of his next walk, when his mother went with him. He was with his mother, and yet he still suffered from anxiety - that is to say, from an unsatisfied longing for her. It is true that the anxiety was less; for he did allow himself to be induced to go for the walk, whereas he had obliged the nursemaid to turn back. Nor is a street quite the right place for 'coaxing', or whatever else this young lover may have wanted. But his anxiety had stood the test; and the next thing for it to do was to find an object. It was on this walk that he first expressed a fear that a horse would bite him. Where did the material for this phobia come from? Probably from the complexes, as yet unknown to us, which had contributed to the repression and were keeping under repression his libidinal feelings towards his mother. That is an unsolved problem, and we shall now have to follow the development of the case in order to arrive at its solution. Hans's father has already given us certain clues, probably trustworthy ones, such as that Hans had always observed horses with interest on account of their large widdlers, that he had supposed that his mother must have a widdler like a horse, and so on. We might thus be led to think that the horse was merely a substitute for his mother. But if so, what would be the meaning of his being afraid in the evening that a horse would come into the room? A small boy's foolish fears, it will be said. But a neurosis never says foolish things, any more than a dream. When we cannot understand something, we always fall back on abuse. An excellent way of making a task lighter.

¹ [1909b, 2019]

His father's investigations may have been without success at some points; but it does no harm to make acquaintance at close quarters with a phobia of this sort - which we may feel inclined to name after its new objects. For in this way we get to see how diffuse it really is. It extends on to horses and on to carts, on to the fact that horses fall down and that they bite, on to horses of a particular character, on to carts that are heavily loaded. I will reveal at once that all these characteristics were derived from the circumstance that the anxiety originally had no reference at all to horses but was transposed on to them secondarily and had now become fixed upon those elements of the horse-complex which showed themselves well adapted for certain transferences. We must specially acknowledge one most important result of the boy's examination by his father. We have learned the immediate precipitating cause after which the phobia broke out. This was when the boy saw a big heavy horse fall down; and one at least of the interpretations of this impression seems to be that emphasized by his father, namely, that Hans at that moment perceived a wish that his father might fall down in the same way - and be dead. His serious expression as he was telling the story no doubt referred to this unconscious meaning. May there not have been yet another meaning concealed behind all this? And what can have been the significance of the making a row with its legs?

[1909b, 2040]

² ['**Wegen dem Pferd**'] I may explain that Hans was not maintaining that he had got the nonsense at **that time** but in **that connection**. Indeed, it must have been so, for theoretical considerations require that what is to-day the object of a phobia must at one time in the past have been the source of a high degree of pleasure. I may at the same time complete what the child was unable to express, and add that the little word 'wegen' ['because of', 'cos of'] was the means of enabling the phobia to extend from horses on to 'Wagen' ['vehicles'] or, as Hans was accustomed to pronounce the word and hear it pronounced, 'Wägen' [pronounced exactly like 'wegen']. It must never be forgotten how much more concretely children treat words than grown-up people do, and consequently how much more significant for them are similarities of sound in words.

[1909b, 2047]
Disorders of this kind are called 'phobias', and we might classify Hans's case as an agoraphobia if it were not for the fact that it is a characteristic of that complaint that the locomotion of which the patient is otherwise incapable can always be easily performed when he is accompanied by some specially selected person - in the last resort, by the physician. Hans's phobia did not fulfil this condition; it soon ceased having any relation to the question of locomotion and became more and more clearly concentrated upon horses. In the early days of his illness, when the anxiety was at its highest pitch, he expressed a fear that 'the horse'll come into the room', and it was this that helped me so much towards understanding his condition.

In the classificatory system of the neuroses no definite position has hitherto been assigned to 'phobias'. It seems certain that they should only be regarded as syndromes which may form part of various neuroses and that we need not rank them as an independent pathological process. For phobias of the kind to which little Hans's belongs, and which are in fact the most common, the name of 'anxiety-hysteria' seems to me not inappropriate; I suggested the term to Dr. W. Stekel when he was undertaking a description of neurotic anxiety states,¹ and I hope it will come into general use. It finds its justification in the similarity between the psychological structure of these phobias and that of hysteria - a similarity which is complete except upon a single point. That point, however, is a decisive one and well adapted for purposes of differentiation. For in anxiety-hysteria the libido which has been liberated from the pathogenic material by repression is not converted (that is, diverted from the mental sphere into a somatic innervation), but is set free In the clinical cases that we meet with, this 'anxiety-hysteria' may be combined with 'conversion-hysteria' in any proportion. There exist cases of pure conversion-hysteria without any trace of anxiety, just as there are cases of simple anxiety-hysteria, which exhibit feelings of anxiety and phobias, but have no admixture of conversion. The case of little Hans is one of the latter sort.

One essential characteristic of anxiety-hysterias is very easily pointed out. An anxiety-hysteria tends to develop more and more into a 'phobia'. In the end the patient may have got rid of all his anxiety, but only at the price of subjecting himself to all kinds of inhibitions and restrictions. From the outset in anxiety-hysteria the mind is constantly at work in the direction of once more psychically binding the anxiety which has become liberated; but this work can neither bring about a retransformation of the anxiety into libido, nor can it establish any contact with the complexes which were the source of the libido. Nothing is left for it but to cut off access to every possible occasion that might lead to the development of anxiety, by erecting mental barriers in the nature of precautions, inhibitions, or prohibitions; and it is these defensive structures that appear to us in the form of phobias and that constitute to our eyes the essence of the disease.

I have already remarked in the course of my running commentary on the case history that it is most instructive to plunge in this way into the details of a phobia, and thus arrive at a conviction of the secondary nature of the relation between the anxiety and its objects. It is this that accounts for phobias being at once so curiously diffuse and so strictly conditioned. It is evident that the material for the particular disguises which Hans's fear adopted was collected from the impressions to which he was all day long exposed owing to the Head Customs House being situated on the opposite side of the street. In this connection, too, he showed signs of an impulse - though it was now inhibited by his anxiety - to play with the loads on the carts, with the packages, casks and boxes, like the street-boys.
Quite unexpectedly, and certainly without any prompting from his father, Hans now began to be occupied with the 'lumf' complex, and to show disgust at things that reminded him of evacuating his bowels. His father, who was reluctant to go with him along that line, pushed on with the analysis through thick and thin in the direction in which he wanted to go. He elicited from Hans the recollection of an event at Gmunden, the impression of which lay concealed behind that of the falling bus-horse. While they were playing at horses, Fritzl, the playmate of whom he was so fond, but at the same time, perhaps, his rival with his many girl friends, had hit his foot against a stone and had fallen down, and his foot had bled. Seeing the bus-horse fall had reminded him of this accident. It deserves to be noticed that Hans, who was at the moment concerned with other things, began by denying that Fritzl had fallen down (though this, was the event which formed the connection between the two scenes) and only admitted it at a later stage of the analysis. It is especially interesting, however, to observe the way in which the transformation of Hans's libido into anxiety was projected on to the principal object of his phobia, on to horses. Horses interested him the most of all the large animals; playing at horses was his favourite game with the other children. I had a suspicion - and this was confirmed by Hans's father when I asked him - that the first person who had served Hans as a horse must have been his father; and it was this that had enabled him to regard Fritzl as a substitute for his father when the accident happened at Gmunden. When repression had set in and brought a revulsion of feeling along with it, horses, which had till then been associated with so much pleasure, were necessarily turned into objects of fear.

This is how, basing my conclusions upon the findings of the analysis, I am obliged to reconstruct the unconscious complexes and wishes, the repression and reawakening of which produced little Hans's phobia. I am aware that in so doing I am attributing a great deal to the mental capacity of a child between four and five years of age; but I have let myself be guided by what we have recently learned, and I do not consider myself bound by the prejudices of our ignorance. It might perhaps have been possible to make use of Hans's fear of the 'making a row with the legs' for filling up a few more gaps in our adjudication upon the evidence. Hans, it is true, declared that it reminded him of his kicking about with his legs when he was compelled to leave off playing so as to do lumf; so that this element of the neurosis becomes connected with the problem whether his mother liked having children or was compelled to have them. But I have an impression that this is not the whole explanation of the 'making a row with the legs'. Hans's father was unable to confirm my suspicion that there was some recollection stirring in the child's mind of having observed a scene of sexual intercourse between his parents in their bedroom. So let us be content with what we have discovered.
This allows us, therefore, to make a radical distinction. We shall probably come to understand the case more deeply if we turn to those other components which do fulfil the two conditions that have just been mentioned. These other components were tendencies in Hans which had already been suppressed and which, so far as we can tell, had never been able to find uninhibited expression: hostile and jealous feelings towards his father, and sadistic impulses (premonitions, as it were, of copulation) towards his mother. These early suppressions may perhaps have gone to form the predisposition for his subsequent illness. These aggressive propensities of Hans's found no outlet, and as soon as there came a time of privation and of intensified sexual excitement, they tried to break their way out with reinforced strength. It was then that the battle which we call his 'phobia' burst out. During the course of it a part of the repressed ideas, in a distorted form and transposed on to another complex, forced their way into consciousness as the content of the phobia. But it was a decidedly paltry success. Victory lay with the forces of repression; and they made use of the opportunity to extend their domain over components other than those that had rebelled. This last circumstance, however, does not in the least alter the fact that the essence of Hans's illness was entirely dependent upon the nature of the instinctual components that had to be repulsed. The content of his phobia was such as to impose a very great measure of restriction upon his freedom of movement, and that was its purpose. It was therefore a powerful reaction against the obscure impulses to movement which were especially directed against his mother. For Hans horses had always typified pleasure in movement ('I'm a young horse', he had said as he jumped about); but since this pleasure in movement included the impulse to copulate, the neurosis imposed a restriction on it and exalted the horse into an emblem of terror. Thus it would seem as though all that the repressed instincts got from the neurosis was the honour of providing pretexts for the appearance of the anxiety in consciousness. But however clear may have been the victory in Hans's phobia of the forces that were opposed to sexuality, nevertheless, since such an illness is in its very nature a compromise, this cannot have been all that the repressed instincts obtained. After all, Hans's phobia of horses was an obstacle to his going into the street, and could serve as a means of allowing him to stay at home with his beloved mother. In this way, therefore, his affection for his mother triumphantly achieved its aim. In consequence of his phobia, the lover clung to the object of his love - though, to be sure, steps had been taken to make him innocuous. The true character of a neurotic disorder is exhibited in this twofold result. [1909b, 2117]

We are also now coming to the opinion that analytic technique must be modified in certain ways according to the nature of the disease and the dominant instinctual trends in the patient. We started out from the treatment of conversion hysteria; in anxiety hysteria (phobias) we must to some extent alter our procedure. For these patient cannot bring out the material necessary for resolving their phobia so long as they feel protected by obeying the condition which it lays down. One cannot, of course, succeed in getting them to give up their protective measures and work under the influence of anxiety from the beginning of the treatment. One must therefore help them by interpreting their unconscious to them until they can make up their minds to do without the protection of their phobia and expose themselves to a now greatly mitigated anxiety. Only after they have done so does the material become accessible, which, when it has been mastered, leads to a solution of the phobia. Other modifications of technique, which seem to me not yet ripe for discussion, will be required in the treatment of obsessional neurosis. In this connection very important questions arise, which have not hitherto been elucidated: how far the instincts which the patient is combating are to be allowed some satisfaction during the treatment, and what difference it makes whether these impulses are active (sadistic) or passive (masochistic) in their nature. [1910d, 2310]
I shall try here to penetrate a little further into the mechanism of paraphrenia and shall bring together those views which already seem to me to deserve consideration. The difference between paraphrenic affections and the transference neuroses appears to me to lie in the circumstance that, in the former, the libido that is liberated by frustration does not remain attached to objects in phantasy, but withdraws on to the ego. Megalomania would accordingly correspond to the psychical mastering of this latter amount of libido, and would thus be the counterpart of the introversion on to phantasies that is found in the transference neuroses; a failure of this psychical function gives rise to the hypochondria of paraphrenia and this is homologous to the anxiety of the transference neuroses. We know that this anxiety can be resolved by further psychical working over, i.e. by conversion, reaction-formation or the construction of protections (phobias). The corresponding process in paraphrenics is an attempt at restoration, to which the striking manifestations of the disease are due. Since paraphrenia frequently, if not usually, brings about only a partial detachment of the libido from objects, we can distinguish three groups of phenomena in the clinical picture: (1) those representing what remains of a normal state or of neurosis (residual phenomena); (2) those representing the morbid process (detachment of libido from its objects and, further, megalomania, hypochondria, affective disturbance and every kind of regression); (3) those representing restoration, in which the libido is once more attached to objects, after the manner of a hysteria (in dementia praecox or paraphrenia proper), or of an obsessional neurosis (in paranoia). This fresh libidinal cathexis differs from the primary one in that it starts from another level and under other conditions. The difference between the transference neuroses brought about in the case of this fresh kind of libidinal cathexis and the corresponding formations where the ego is normal should be able to afford us the deepest insight into the structure of our mental apparatus.

[1914c, 2941]

From the field of anxiety hysteria I will choose a well-analysed example of an animal phobia. The instinctual impulse subjected to repression here is a libidinal attitude towards the father, coupled with fear of him. After repression, this impulse vanishes out of consciousness: the father does not appear in it as an object of libido. As a substitute for him we find in a corresponding place some animal which is more or less fitted to be an object of anxiety. The formation of the substitute for the ideational portion has come about by displacement along a chain of connections which is determined in a particular way. The quantitative portion has not vanished, but has been transformed into anxiety. The result is fear of a wolf, instead of a demand for love from the father. The categories here employed are of course not enough to supply an adequate explanation of even the simplest case of psychoneurosis: there are always other considerations to be taken into account. A repression such as occurs in an animal phobia must be described as radically unsuccessful. All that it has done is to remove and replace the idea; it has failed altogether in sparing unpleasure. And for this reason, too, the work of the neurosis does not cease. It proceeds to a second phase, in order to attain its immediate and more important purpose. What follows is an attempt at flight - the formation of the phobia proper, of a number of avoidances which are intended to prevent a release of the anxiety. More specialized investigation enables us to understand the mechanism by which the phobia achieves its aim.

[1915d, 2985]
We are obliged to take quite another view of the process of repression when we consider the picture of a true conversion hysteria. Here the salient point is that it is possible to bring about a total disappearance of the quota of affect. When this is so, the patient displays towards his symptoms what Charcot called 'la belle indifférence hystériques'. In other cases this suppression is not so completely successful: some distressing sensations may attach to the symptoms themselves, or it may prove impossible to prevent some release of anxiety, which in turn sets to work the mechanism of forming a phobia. The ideational content of the instinctual representative is completely withdrawn from consciousness; as a substitute - and at the same time as a symptom - we have an over-strong innervation (in typical cases, a somatic one), sometimes of a sensory, sometimes of a motor character, either as an excitation or an inhibition. The over-innervated area proves on a closer view to be a part of the repressed instinctual representative itself - a part which, as though by a process of condensation, has drawn the whole cathexis on to itself. These remarks do not of course bring to light the whole mechanism of a conversion hysteria; in especial the factor of regression, which will be considered in another connection, has also to be taken into account. In so far as repression in hysteria is made possible only by the extensive formation of substitutes, it may be judged to be entirely unsuccessful; as regards dealing with the quota of affect, however, which is the true task of repression, it generally signifies a total success. In conversion hysteria the process of repression is completed with the formation of the symptom and does not, as in anxiety hysteria, need to continue to a second phase - or rather, strictly speaking, to continue endlessly.

[1915d, 2986]

On the occasion of a repetition (if there should be one) of this process, a first step is taken in the direction of mastering the unwelcome development of anxiety. The cathexis that has taken flight attaches itself to a substitutive idea which, on the one hand, is connected by association with the rejected idea, and, on the other, has escaped repression by reason of its remoteness from that idea. This substitutive idea - a 'substitute by displacement' - permits the still uninhibitable development of anxiety to be rationalized. It now plays the part of an anticathexis for the system Cs. (Pcs.), by securing it against an emergence in the Cs. of the repressed idea. On the other hand it is, or acts as if it were, the point of departure for the release of the anxiety-affect, which has now really become quite uninhibitable. Clinical observation shows, for instance, that a child suffering from an animal phobia experiences anxiety under two kinds of conditions: in the first place, when his repressed love-impulse becomes intensified, and, in the second, when he perceives the animal he is afraid of. The substitutive idea acts in the one instance as a point at which there is a passage across from the system Ucs. to the system Cs., and, in the other instance, as a self-sufficing source for the release of anxiety. The extending dominance of the system Cs. usually manifests itself in the fact that the first of these two modes of excitation of the substitutive idea gives place more and more to the second. The child may perhaps end by behaving as though he had no predilection whatever towards his father but had become quite free from him, and as though his fear of the animal was a real fear - except that this fear of the animal, fed as such a fear is from an unconscious instinctual source, proves obdurate and exaggerated in the face of all influences brought to bear from the system Cs., and thereby betrays its derivation from the system Ucs. - In the second phase of anxiety hysteria, therefore, the anticathexis from the system Cs. has led to substitute-formation.

[1915e, 3005]
Soon the same mechanism finds a fresh application. The process of repression, as we know, is not yet completed, and it finds a further aim in the task of inhibiting the development of the anxiety which arises from the substitute. This is achieved by the whole of the associated environment of the substitutive idea being cathected with special intensity, so that it can display a high degree of sensibility to excitation. Excitation of any point in this outer structure must inevitably, on account of its connection with the substitutive idea, give rise to a slight development of anxiety; and this is now used as a signal to inhibit, by means of a fresh flight on the part of the cathexis, the further progress of the development of anxiety. The further away the sensitive and vigilant anticathexes are situated from the feared substitute, the more precisely can the mechanism function which is designed to isolate the substitutive idea and to protect it from fresh excitations. These precautions naturally only guard against excitations which approach the substitutive idea from outside, through perception; they never guard against instinctual excitation, which reaches the substitutive idea from the direction of its link with the repressed idea. Thus the precautions do not begin to operate till the substitute has satisfactorily taken over representation of the repressed, and they can never operate with complete reliability. With each increase of instinctual excitation the protecting rampart round the substitutive idea must be shifted a little further outwards. The whole construction, which is set up in an analogous way in the other neuroses, is termed a phobia. The flight from a conscious cathexis of the substitutive idea is manifested in the avoidances, renunciations and prohibitions by which we recognize anxiety hysteria.

Surveying the whole process, we may say that the third phase repeats the work of the second on an ampler scale. The system Cs. now protects itself against the activation of the substitutive idea by an anticathexis of its environment, just as previously it had secured itself against the emergence of the repressed idea by a cathexis of the substitutive idea. In this way the formation of substitutes by displacement has been further continued. We must also add that the system Cs. had earlier only one small area at which the repressed instinctual impulse could break through, namely, the substitutive idea; but that ultimately this enclave of unconscious influence extends to the whole phobic outer structure. Further, we may lay stress on the interesting consideration that by means of the whole defensive mechanism thus set in action a projection outward of the instinctual danger has been achieved. The ego behaves as if the danger of a development of anxiety threatened it not from the direction of an instinctual impulse but from the direction of a perception, and it is thus enabled to react against this external danger with the attempts at flight represented by phobic avoidances. In this process repression is successful in one particular: the release of anxiety can to some extent be dammed up, but only at a heavy sacrifice of personal freedom. Attempts at flight from the demands of instinct are, however, in general useless, and, in spite of everything, the result of phobic flight remains unsatisfactory.
A great deal of what we have found in anxiety hysteria also holds good for the other two neuroses, so that we can confine our discussion to their points of difference and to the part played by anticathexis. In conversion hysteria the instinctual cathexis of the repressed idea is changed into the innervation of the symptom. How far and in what circumstances the unconscious idea is drained empty by this discharge into innervation, so that it can relinquish its pressure upon the system Cs. - these and similar questions had better be reserved for a special investigation of hysteria. In conversion hysteria the part played by the anticathexis proceeding from the system Cs. (Pcs.) is clear and becomes manifest in the formation of the symptom. It is the anticathexis that decides upon what portion of the instinctual representative the whole cathexis of the latter is able to be concentrated. The portion thus selected to be a symptom fulfils the condition of expressing the wishful aim of the instinctual impulse no less than the defensive or punitive efforts of the system Cs.; thus it becomes hypercathected, and it is maintained from both directions like the substitutive idea in anxiety hysteria. From this circumstance we may conclude without hesitation that the amount of energy expended by the system Cs. on repression need not be so great as the cathectic energy of the symptom; for the strength of the repression is measured by the amount of anticathexis expended, whereas the symptom is supported not only by this anticathexis but also by the instinctual cathexis from the system Ucs. which is condensed in the symptom.

[1915e, 3007]

As regards obsessional neurosis, we need only add to the observations brought forward in the preceding paper that it is here that the anticathexis from the system Cs. comes most noticeably into the foreground. It is this which, organized as a reaction-formation, brings about the first repression, and which is later the point at which the repressed idea breaks through. We may venture the supposition that it is because of the predominance of the anticathexis and the absence of discharge that the work of repression seems far less successful in anxiety hysteria and in obsessional neurosis than in conversion hysteria.

[1915e, 3008]

A dream tells us that something was going on which tended to interrupt sleep, and it enables us to understand in what way it has been possible to fend off this interruption. The final outcome is that the sleeper has dreamt and is able to go on sleeping; the internal demand which was striving to occupy him has been replaced by an external experience, whose demand has been disposed of. A dream is, therefore, among other things, a projection: an externalization of an internal process. We may recall that we have already met with projection elsewhere among the means adopted for defence. The mechanism of a hysterical phobia, too, culminates in the fact that the subject is able to protect himself by attempts at flight against an external danger which has taken the place of an internal instinctual claim. We will, however, defer the full treatment of projection till we come to analyse the narcissistic disorder in which this mechanism plays the most striking part.

[1917d, 3028]
You will be glad to hear that the analysis of phobias has not much more that is new to teach us. For the same thing happens with them as with children's anxiety: unemployable libido is being constantly transformed into an apparently realistic anxiety and thus a tiny external danger is introduced to represent the claims of the libido. There is nothing to be wondered at in this agreement, for the infantile phobias are not only the prototype of the later ones which we class as 'anxiety hysteria' but are actually their precondition and the prelude to them. Every hysterical phobia goes back to an infantile anxiety and is a continuation of it, even if it has a different content and must thus be given another name. The difference between the two disorders lies in their mechanism. In order that libido shall be changed into anxiety, it no longer suffices in the case of adults for the libido to have become momentarily unemployable in the form of a longing. Adults have long since learnt how to hold such libido in suspense or to employ it in some other way. If, however, the libido belongs to a psychical impulse which has been subjected to repression, then circumstances are re-established similar to those in the case of a child in whom there is still no distinction between conscious and unconscious; and by mean of regression to the infantile phobia a passage is opened, as it were, through which the transformation of libido into anxiety can be comfortably accomplished.

[1916-1917, 3455]

I have said that transformation into anxiety - it would be better to say discharge in the form of anxiety - is the immediate vicissitude of libido which is subjected to repression. I must add that that vicissitude is not the only or the definitive one. In the neuroses processes are in action which endeavour to bind this generating of anxiety and which even succeed in doing so in various ways. In phobias, for instance, two phases of the neurotic process can be clearly distinguished. The first is concerned with repression and the changing of libido into anxiety, which is then bound to an external danger. The second consists in the erection of all the precautions and guarantees by means of which any contact can be avoided with this danger, treated as it is like an external thing. Repression corresponds to an attempt at flight by the ego from libido which is felt as a danger. A phobia may be compared to an entrenchment against an external danger which now represents the dreaded libido. The weakness of the defensive system in phobias lies, of course, in the fact that the fortress which has been so greatly strengthened towards the outside remains assailable from within. A projection outwards of the danger of libido can never succeed thoroughly. For that reason, in other neuroses other systems of defence are in use against the possible generation of anxiety. That is a most interesting part of the psychology of the neuroses; but unluckily it would lead us too far and it presupposes a deeper specialized knowledge. I will only add one thing more. I have already spoken to you of the 'anticathexis' which is employed by the ego in the process of repression and which must be permanently maintained in order that the repression may have stability. This ant cathexis has the task of carrying through the various forms of defence against the generating of anxiety after repression.

[1916-1917, 3456]

Let us return to the phobias. I can safely say that you now see how inadequate it is merely to seek to explain their content, to take no interest in anything but how it comes about that this or that object or some particular situation or other has been made into the object of the phobia. The content of a phobia has just about as much importance in relation to it as the manifest façade of a dream has in relation to the dream. It must be admitted, subject to the necessary qualifications, that among the contents of phobias there are a number which, as Stanley Hall insists, are adapted to serve as objects of anxiety owing to phylogenetic inheritance. It tallies with this, indeed, that many of these anxiety-objects can only establish their connection with danger by a symbolic tie.

[1916-1917, 3457]

¹ Just as vermin often stands for babies in dreams and phobias.

[1918b, 3564]
Let us now consider the phobia. It came into existence on the level of the genital organization, and shows us the relatively simple mechanism of an anxiety-hysteria. The ego, by developing anxiety, was protecting itself against what it regarded as an overwhelming danger, namely, homosexual satisfaction. But the process of repression left behind it a trace which cannot be overlooked. The object to which the dangerous sexual aim had been attached had to have its place taken in consciousness by another one. What became conscious was fear not of the father but of the wolf. Nor did the process stop at the formation of a phobia with a single content. A considerable time afterwards the wolf was replaced by the lion. Simultaneously with sadistic impulses against small animals there was a phobia directed towards them, in their capacity of representatives of the boy's rivals, the possible small children. The origin of the butterfly phobia is of especial interest. It was like a repetition of the mechanism that produced the wolf phobia in the dream. Owing to a chance stimulus an old experience, the scene with Grusha, was activated; her threat of castration thus produced deferred effects, though at the time it was uttered it had made no impression.¹

[1918b, 3588]

It may truly be said that the anxiety that was concerned in the formation of these phobias was a fear of castration. This statement involves no contradiction of the view that the anxiety originated from the repression of homosexual libido. Both modes of expression refer to the same process: namely, the withdrawal of libido by the ego from the homosexual wishful impulse, the libido having then become converted into free anxiety and subsequently bound in phobias. The first method of statement merely mentions in addition the motive by which the ego was actuated.

[1918b, 3589]

It may be difficult, too, for many of us, to abandon the belief that there is an instinct towards perfection at work in human beings, which has brought them to their present high level of intellectual achievement and ethical sublimation and which may be expected to watch over their development into supermen. I have no faith, however, in the existence of any such internal instinct and I cannot see how this benevolent illusion is to be preserved. The present development of human beings requires, as it seems to me, no different explanation from that of animals. What appears in a minority of human individuals as an untiring impulsion towards further perfection can easily be understood as a result of the instinctual repression upon which is based all that is most precious in human civilization. The repressed instinct never ceases to strive for complete satisfaction, which would consist in the repetition of a primary experience of satisfaction. No substitutive or reactive formations and no sublimations will suffice to remove the repressed instinct's persisting tension; and it is the difference in amount between the pleasure of satisfaction which is demanded and that which is actually achieved that provides the driving factor which will permit of no halting at any position attained, but, in the poet's words, 'ungebändigt immer vorwärts dringt'.¹ The backward path that leads to complete satisfaction is as a rule obstructed by the resistances which maintain the repressions. So there is no alternative but to advance in the direction in which growth is still free - though with no prospect of bringing the process to a conclusion or of being able to reach the goal. The processes involved in the formation of a neurotic phobia, which is nothing else than an attempt at flight from the satisfaction of an instinct, present us with a model of the manner of origin of this supposititious 'instinct towards perfection' - an instinct which cannot possibly be attributed to every human being. The dynamic conditions for its development are, indeed, universally present; but it is only in rare cases that the economic situation appears to favour the production of the phenomenon.

[1920g, 3744]
Narcissism. - A decisive advance was made when the analysis of dementia praecox and other psychotic disorders was ventured upon and thus the examination was begun of the ego itself, which had so far been known only as the agency of repression and opposition. It was found that the pathogenic process in dementia praecox is the withdrawal of the libido from objects and its introduction into the ego, while the clamorous symptoms of the disease arise from the vain struggles of the libido to find a pathway back to objects. It thus turned out to be possible for object-libido to change into cathexis of the ego and vice versa. Further reflection showed that this process must be presumed to occur on the largest scale and that the ego is to be regarded as a great reservoir of libido from which libido is sent out to objects and which is always ready to absorb libido flowing back from objects. Thus the instincts of self-preservation were also of a libidinal nature: they were sexual instincts which, instead of external objects, had taken the subject's own ego as an object. Clinical experience had made us familiar with people who behaved in a striking fashion as though they were in love with themselves and this perversion had been given the name of narcissism. The libido of the self-preservation instincts was now described as narcissistic libido and it was recognized that a high degree of this self-love constituted the primary and normal state of things. The earlier formula laid down for the transference neuroses consequently required to be modified, though not corrected. It was better, instead of speaking of a conflict between sexual instincts and ego instincts, to speak of a conflict between object-libido and ego-libido, or, since the nature of these instincts was the same, between the object-cathexes and the ego.

[1923a, 3933]

This time we will not lose sight of the part played by anxiety. We have said that as soon as the ego recognizes the danger of castration it gives the signal of anxiety and inhibits through the pleasure-unpleasure agency (in a way which we cannot as yet understand) the impending cathetic process in the id. At the same time the phobia is formed. And now the castration anxiety is directed to a different object and expressed in a distorted form, so that the patient is afraid, not of being castrated by his father, but of being bitten by a horse or devoured by a wolf. This substitutive formation has two obvious advantages. In the first place it avoids a conflict due to ambivalence (for the father was a loved object, too), and in the second place it enables the ego to cease generating anxiety. For the anxiety belonging to a phobia is conditional; it only emerges when the object of it is perceived - and rightly so, since it is only then that the danger-situation is present. There is no need to be afraid of being castrated by a father who is not there. On the other hand one cannot get rid of a father; he can appear whenever he chooses. But if he is replaced by an animal, all one has to do is to avoid the sight of it - that is, its presence - in order to be free from danger and anxiety. 'Little Hans', therefore, imposed a restriction upon his ego. He produced the inhibition of not leaving the house, so as not to come across any horses. The young Russian had an even easier time of it, for it was hardly a privation for him not to look at a particular picture-book any more. If his naughty sister had not kept on showing him the book with the picture of the wolf standing upright in it, he would have been able to feel safe from his fear.

[1926d, 4282]
On a previous occasion I have stated that phobias have the character of a projection in that they replace an internal, instinctual danger by an external, perceptual one. The advantage of this is that the subject can protect himself against an external danger by fleeing from it and avoiding the perception of it, whereas it is useless to flee from dangers that arise from within. This statement of mine was not incorrect, but it did not go below the surface of things. For an instinctual demand is, after all, not dangerous in itself; it only becomes so inasmuch as it entails a real external danger, the danger of castration. Thus what happens in a phobia in the last resort is merely that one external danger is replaced by another. The view that in a phobia the ego is able to escape anxiety by means of avoidance or of inhibitory symptoms fits in very well with the theory that that anxiety is only an affective signal and that no alteration has taken place in the economic situation.

The anxiety felt in animal phobias is, therefore, an affective reaction on the part of the ego to danger; and the danger which is being signalled in this way is the danger of castration. This anxiety differs in no respect from the realistic anxiety which the ego normally feels in situations of danger, except that its content remains unconscious and only becomes conscious in the form of a distortion.

The same will prove true, I think, of the phobias of adults, although the material which their neuroses work over is much more abundant and there are some additional factors in the formation of the symptoms. Fundamentally the position is identical. The agoraphobic patient imposes a restriction on his ego so as to escape a certain instinctual danger - namely, the danger of giving way to his erotic desires. For if he did so the danger of being castrated, or some similar danger, would once more be conjured up as it was in his childhood. I may cite as an instance the case of a young man who became agoraphobic because he was afraid of yielding to the solicitations of prostitutes and of contracting a syphilitic infection from them as a punishment.

I am well aware that a number of cases exhibit a more complicated structure and that many other repressed instinctual impulses can enter into a phobia. But they are only tributary streams which have for the most part joined the main current of the neurosis at a later stage. The symptomatology of agoraphobia is complicated by the fact that the ego does not confine itself to making a renunciation. In order to rob the situation of danger it does more: it usually effects a temporal regression to infancy (in extreme cases, to a time when the subject was in his mother's womb and protected against the dangers which threaten him in the present). Such a regression now becomes a condition whose fulfilment exempts the ego from making its renunciation. For instance, an agoraphobic patient may be able to walk in the street provided he is accompanied, like a small child, by someone he knows and trusts; or, for the same reason, he may be able to go out alone provided he remains within a certain distance of his own house and does not go to places which are not familiar to him or where people do not know him. What these stipulations are will depend in each case on the infantile factors which dominate him through his neurosis. The phobia of being alone is unambiguous in its meaning, irrespective of any infantile regression: it is, ultimately, an endeavour to avoid the temptation to indulge in solitary masturbation. Infantile regression can, of course, only take place when the subject is no longer a child.
A phobia generally sets in after a first anxiety attack has been experienced in specific circumstances, such as in the street or in a train or in solitude. Thereafter the anxiety is held in ban by the phobia, but it re-emerges whenever the protective condition cannot be fulfilled. The mechanism of phobia does good service as a means of defence and tends to be very stable. A continuation of the defensive struggle, in the shape of a struggle against the symptom, occurs frequently but not invariably.
[1926d, 4285]

One objection to it is that loss of an object (or loss of love on the part of the object) and the threat of castration are just as much dangers coming from outside as, let us say, a ferocious animal would be; they are not instinctual dangers. Nevertheless, the two cases are not the same. A wolf would probably attack us irrespectively of our behaviour towards it; but the loved person would not cease to love us nor should we be threatened with castration if we did not entertain certain feelings and intentions within us. Thus such instinctual impulses are determinants of external dangers and so become dangerous in themselves; and we can now proceed against the external danger by taking measures against the internal ones. In phobias of animals the danger seems to be still felt entirely as an external one, just as it has undergone an external displacement in the symptom. In obsessional neuroses the danger is much more internalized. That portion of anxiety in regard to the super-ego which constitutes social anxiety still represents an internal substitute for an external danger, while the other portion - moral anxiety - is already completely endopsychic.
[1926d, 4300]

There is another kind of anticathexis, however, which seems more suited to the peculiar character of hysteria. A repressed instinctual impulse can be activated (newly cathected) from two directions: from within, through reinforcement from its internal sources of excitation, and from without, through the perception of an object that it desires. The hysterical anticathexis is mainly directed outwards, against dangerous perceptions. It takes the form of a special kind of vigilance which, by means of restrictions of the ego, causes situations to be avoided that would entail such perceptions, or, if they do occur, manages to withdraw the subject's attention from them. Some French analysts, in particular Laforgue, have recently given this action of hysteria the special name of 'scotomization'. This technique of anticathexis is still more noticeable in the phobias, whose interest is concentrated on removing the subject ever further from the possibility of the occurrence of the feared perception. The fact that anticathexis has an opposite direction in hysteria and the phobias from what it has in obsessional neurosis - though the distinction is not an absolute one - seems to be significant. It suggests that there is an intimate connection between repression and external anticathexis on the one hand and between regression and internal anticathexis (i.e. alteration in the ego through reaction-formation) on the other. The task of defence against a dangerous perception is, incidentally, common to all neuroses. Various commands and prohibitions in obsessional neurosis have the same end in view.
[1926d, 4311]

In this connection the puzzling phobias of early childhood deserve to be mentioned once again. We have been able to explain some of them, such as the fear of being alone or in the dark or with strangers, as reactions to the danger of losing the object. Others, like the fear of small animals, thunder storms, etc., might perhaps be accounted for as vestigial traces of the congenital preparedness to meet real dangers which is so strongly developed in other animals. In man, only that part of this archaic heritage is appropriate which has reference to the loss of the object. If childhood phobias become fixated and grow stronger and persist into later years, analysis shows that their content has become associated with instinctual demands and has come to stand for internal dangers as well.
[1926d, 4320]
For we have recently been examining the way in which anxiety is generated in certain phobias which we class as anxiety hysteria, and have chosen cases in which we were dealing with the typical repression of wishful impulses arising from the Oedipus complex. We should have expected to find that it was a libidinal cathexis of the boy's mother as object which, as a result of repression, had been changed into anxiety and which now emerged, expressed in symptomatic terms, attached to a substitute for his father. I cannot present you with the detailed steps of an investigation such as this; it will be enough to say that the surprising result was the opposite of what we expected. It was not the repression that created the anxiety; the anxiety was there earlier; it was the anxiety that made the repression. But what sort of anxiety can it have been? Only anxiety in the face of a threatening external danger - that is to say, a realistic anxiety. It is true that the boy felt anxiety in the face of a demand by his libido - in this instance, anxiety at being in love with his mother; so the case was in fact one of neurotic anxiety. But this being in love only appeared to him as an internal danger, which he must avoid by renouncing that object, because it conjured up an external situation of danger. And in every case we examine we obtain the same result. It must be confessed that we were not prepared to find that internal instinctual danger would turn out to be a determinant and preparation for an external, real, situation of danger.

But we have not made any mention at all so far of what the real danger is that the child is afraid of as a result of being in love with his mother. The danger is the punishment of being castrated, of losing his genital organ. You will of course object that after all that is not a real danger. Our boys are not castrated because they are in love with their mothers during the phase of the Oedipus complex. But the matter cannot be dismissed so simply. Above all, it is not a question of whether castration is really carried out; what is decisive is that the danger is one that threatens from outside and that the child believes in it. He has some ground for this, for people threaten him often enough with cutting off his penis during the phallic phase, at the time of his early masturbation, and hints at that punishment must regularly find a phylogenetic reinforcement in him. It is our suspicion that during the human family's primaeval period castration used actually to be carried out by a jealous and cruel father upon growing boys, and that circumcision, which so frequently plays a part in puberty rites among primitive peoples, is a clearly recognizable relic of it. We are aware that here we are diverging widely from the general opinion; but we must hold fast to the view that fear of castration is one of the commonest and strongest motives for repression and thus for the formation of neuroses. The analysis of cases in which circumcision, though not, it is true, castration, has been carried out on boys as a cure or punishment for masturbation (a far from rare occurrence in Anglo-American society) has given our conviction a last degree of certainty. It is very tempting at this point to go more deeply into the castration complex, but I will stick to our subject.

The negative reactions follow the opposite aim: that nothing of the forgotten traumas shall be remembered and nothing repeated. We can summarize them as 'defensive reactions'. Their principal expression are what are called 'avoidances', which may be intensified into 'inhibitions' and 'phobias'. These negative reactions too make the most powerful contributions to the stamping of character. Fundamentally they are just as much fixations to the trauma as their opposites, except that they are fixations with a contrary purpose. The symptoms of neurosis in the narrower sense are compromises in which both the trends proceeding from traumas come together, so that the share, now of one and now of the other tendency, finds preponderant expression in them. This opposition between the reactions sets up conflicts which in the ordinary course of events can reach no conclusion.
The anxiety belonging to this emotional state, which underlies all phobias, is not derived from any memory; we may well wonder what the source of this powerful condition of the nervous system can be.

I hope to be able to demonstrate, on another occasion, that there is reason to distinguish a special neurosis, the ‘anxiety neurosis’, of which the chief symptom is this emotional state. I shall then enumerate its various symptoms and insist on the necessity for differentiating this neurosis from neurasthenia, with which it is now confused. Phobias, then, are part of the anxiety neurosis, and are almost always accompanied by other symptoms of the same group.

It is under such conditions, extremely frequent in modern society, especially among women, that anxiety neurosis (of which phobias are a psychical manifestation) develops.

In conclusion I may point out that combinations of a phobia and an obsession proper may co-exist, and that indeed this is a very frequent occurrence. We may find that a phobia had developed at the beginning of the disease as a symptom of anxiety neurosis. The idea which constitutes the phobia and which is associated with the state of fear may be replaced by another idea or rather by the protective procedure that seemed to relieve the fear. Case 7 (obsessive speculating) presents a neat example of this group: a phobia along with a true substitutive obsession.

On the basis of chronic anxiousness (anxious expectation) on the one hand, and a tendency to anxiety attacks accompanied by vertigo on the other, two groups of typical phobias develop, the first relating to general physiological dangers, the second relating to locomotion. To the first group belong fear of snakes, thunderstorms, darkness, vermin, and so on, as well as the typical moral over-scrupulousness and forms of doubting mania. Here the available anxiety is simply employed to reinforce aversions which are instinctively implanted in everyone. But as a rule a phobia which acts in an obsessional manner is only formed if there is added to this the recollection of an experience in which the anxiety was able to find expression as, for instance, after the patient has experienced a thunderstorm in the open. It is a mistake to try to explain such cases as being simply a persistence of strong impressions; what makes these experiences significant and the memory of them lasting is, after all, only the anxiety which was able to emerge at the time and which can similarly emerge now. In other words, such impressions remain powerful only in people with ‘anxious expectation’.
Against Löwenfeld's further assertion - that anxiety-states only appear under certain conditions and fail to appear when those conditions are avoided, regardless of what the subject's *vita sexualis* may be - it must be pointed out that he clearly has in mind here only the anxiety of *phobias*, as, indeed, is shown by the examples attached to the passage I have quoted. He says nothing at all about the spontaneous anxiety attacks which take the form of vertigo, palpitation, dyspnœa, trembling, sweating, and so on. My theory, on the contrary, seems by no means unequal to explaining the emergence or non-emergence of these attacks of anxiety. For in a whole number of such cases of anxiety neurosis there does in fact appear to be a periodicity in the emergence of the states of anxiety, similar to what has been observed in epilepsy, except that in the latter the mechanism of the periodicity is more transparent. On closer examination we discover the presence, with great regularity, of an excitatory sexual process (that is, a process which is able to generate somatic sexual tension), and which, after the lapse of a definite and often constant interval of time, is followed by the anxiety attack. This role is played, in abstinent women, by menstrual excitation; it is played, too, by nocturnal pollutions, which also recur periodically. Above all, it is played by sexual intercourse itself (harmful from its being incomplete), which carries over its own periodicity to the effects it brings about, viz. to the anxiety attacks. If anxiety attacks occur which break through the usual periodicity, it is generally possible to trace them back to an incidental cause of rare and irregular occurrence - to a single sexual experience, something read or seen, and the like. The interval I have mentioned varies from a few hours to two days; it is the same as that which elapses in other people between the occurrence of the same causes and the onset of the well-known sexual migraine, which has well-established connections with the syndrome of anxiety neurosis. [1895f, 361]

Besides this, there are plenty of cases in which a single anxiety-state is provoked by the extra addition of a stock factor, by an excitement of some kind or other. The same holds good, therefore, for the aetiology of the individual anxiety attack as for the causation of the whole neurosis. It is not very strange that the anxiety of the phobias should obey different conditions; they have a more complicated structure than purely somatic anxiety attacks. In phobias the anxiety is linked to a definite ideational or perceptual content, and the arousal of this psychical content is the chief condition for the emergence of the anxiety. When this happens, anxiety is "generated", just as for instance sexual tension is generated by the arousal of libidinal ideas. The connection of this process, however, with the theory of anxiety neurosis has not yet been elucidated. [1895f, 361]

The anxiety neurosis exhibits a much richer clinical picture: irritability, states of anxious expectation, phobias, anxiety attacks, complete or rudimentary, attacks of fear and of vertigo, tremors, sweating, congestion, dyspnœa, tachycardia, etc., chronic diarrhoea, chronic locomotor vertigo, hyperaesthesia, insomnia, etc.¹ It is easily revealed as being the specific effect of various disorders of sexual life which possess a characteristic common to all of them. Enforced abstinence, unconsummated genital excitation (excitation which is not relieved by a sexual act), coition which is imperfect or interrupted (which does not end in gratification), sexual efforts which exceed the subject's psychical capacity, etc. - all these agents, which occur only too frequently in modern life, seem to agree in the fact that they disturb the equilibrium of the psychical and somatic functions in sexual acts, and that they prevent the psychical participation necessary in order to free the nervous economy from sexual tension. [1896a, 374]
There remain to be discussed anxiety-dreams as a special sub-species of dreams with a distressing content. The notion of regarding these as wishful dreams will meet with very little sympathy from the unenlightened. Nevertheless I can deal with anxiety-dreams very briefly at this point. They do not present us with a new aspect of the dream-problem; what they face us with is the whole question of neurotic anxiety. The anxiety that we feel in a dream is only apparently explained by the dream's content. If we submit the content of the dream to analysis, we find that the anxiety in the dream is no better justified by the dream's content than, let us say, the anxiety in a phobia is justified by the idea to which the phobia relates. No doubt it is true, for instance, that it is possible to fall out of a window and that there is therefore reason for exercising a certain degree of caution in the neighbourhood of a window; but we cannot see why the anxiety felt in a phobia on this subject is so great and pursues the patient far beyond its occasion. We find then that the same thing may be validly asserted both of phobias and of anxiety-dreams: in both cases the anxiety is only superficially attached to the idea that accompanies it; it originates from another source.

There is no longer anything contradictory to us in the notion that a psychical process which develops anxiety can nevertheless be the fulfilment of a wish. We know that it can be explained by the fact that the wish belongs to one system, the Ucs., while it has been repudiated and suppressed by the other system, the Pcs. Even where psychical health is perfect, the subjugation of the Ucs. by the Pcs. is not complete; the measure of suppression indicates the degree of our psychical normality. Neurotic symptoms show that the two systems are in conflict with each other; they are the products of a compromise which brings the conflict to an end for the time being. On the one hand, they allow the Ucs. an outlet for the discharge of its excitation, and provide it with a kind of sally-port, while, on the other hand they make it possible for the Pcs. to control the Ucs. to some extent. It is instructive to consider, for instance, the significance of a hysterical phobia or an agoraphobia. Let us suppose that a neurotic patient is unable to cross the street alone - a condition which we rightly regard as a 'symptom.' If we remove this symptom by compelling him to carry out the act of which he believes himself incapable, the consequence will be an attack of anxiety; and indeed the occurrence of an anxiety-attack in the street is often the precipitating cause of the onset of an agoraphobia. We see, therefore, that the symptom has been constructed in order to avoid an outbreak of anxiety; the phobia is erected like a frontier fortification against the anxiety.
MECHANICAL EXCITATIONS  At this point we must also mention the production of sexual
excitation by rhythmic mechanical agitation of the body. Stimuli of
this kind operate in three different ways: on the sensory apparatus of the vestibular nerves, on
the skin, and on the deeper parts (e.g. the muscles and articular structures). The existence of
these pleasurable sensations - and it is worth emphasizing the fact that in this connection the
concepts of 'sexual excitation' and 'satisfaction' can to a great extent be used without distinction,
a circumstance which we must later endeavour to explain - the existence, then, of these
pleasurable sensations, caused by forms of mechanical agitation of the body, is confirmed by
the fact that children are so fond of games of passive movement, such as swinging and being
thrown up into the air, and insist on such games being incessantly repeated.¹ It is well known
that rocking is habitually used to induce sleep in restless children. The shaking produced by
driving in carriages and later by railway-travel exercises such a fascinating effect upon older
children that every boy, at any rate, has at one time or other in his life wanted to be an engine
driver or a coachman. It is a puzzling fact that boys take such an extraordinary intense interest
in things connected with railways, and, at the age at which the production of phantasies is most
active (shortly before puberty), use those things as the nucleus of a symbolism that is peculiarly
sexual. A compulsive link of this kind between railway-travel and sexuality is clearly derived
from the pleasurable character of the sensations of movement. In the event of repression, which
turns so many childish preferences into their opposite, these same individuals, when they are
adolescents or adults, will react to rocking or swinging with a feeling of nausea, will be terribly
exhausted by a railway journey, or will be subject to attacks of anxiety on the journey and will
protect themselves against a repetition of the painful experience by a dread of railway-travel.
[1905d, 1520]

Here, then, we have the beginning of Hans's anxiety as well as of his phobia. As we see,
there is good reason for keeping the two separate. Moreover, the material seems to be amply
sufficient for giving us our bearings; and no moment of time is so favourable for the
understanding of a case as its initial stage, such as we have here, though unluckily that stage is
as a rule neglected or passed over in silence. The disorder set in with thoughts that were at the
same time fearful and tender, and then followed an anxiety dream on the subject of losing his
mother and so not being able to coax with her any more. His affection for his mother must
therefore have become enormously intensified. This was the fundamental phenomenon in his
condition. In support of this, we may, recall his two attempts at seducing his mother, the first of
which dated back to the summer, while the second (a simple commendation of his penis)
ocurred immediately before the outbreak of his street-anxiety. It was this increased affection
for his mother which turned suddenly into anxiety - which, as we should say, succumbed to
repression. We do not yet know from what quarter the impetus towards repression may have
come. Perhaps it was merely the result of the intensity of the child's emotions, which had
become greater than he could control; or perhaps other forces which we have not yet
recognized were also at work. This we shall learn as we go on. Hans's anxiety, which thus
corresponded to a repressed erotic longing, was, like every infantile anxiety, without an object to
begin with: it was still anxiety and not yet fear. The child cannot tell what he is afraid of; and
when Hans, on the first walk with the nursemaid, would not say what he was afraid of, it was
simply that he himself did not yet know. He said all that he knew, which was that in the street he
missed his mother, whom he could coax with, and that he did not want to be away from her. In
saying this he quite straightforwardly confessed the primary meaning of his dislike of streets.
[1909b, 2017]
His father's investigations may have been without success at some points; but it does no harm to make acquaintance at close quarters with a phobia of this sort - which we may feel inclined to name after its new objects. For in this way we get to see how diffuse it really is. It extends on to horses and on to carts, on to the fact that horses fall down and that they bite, on to horses of a particular character, on to carts that are heavily loaded. I will reveal at once that all these characteristics were derived from the circumstance that the anxiety originally had no reference at all to horses but was transposed on to them secondarily and had now become fixed upon those elements of the horse-complex which showed themselves well adapted for certain transferences. We must specially acknowledge one most important result of the boy's examination by his father. We have learned the immediate precipitating cause after which the phobia broke out. This was when the boy saw a big heavy horse fall down; and one at least of the interpretations of this impression seems to be that emphasized by his father, namely, that Hans at that moment perceived a wish that his father might fall down in the same way - and be dead. His serious expression as he was telling the story no doubt referred to this unconscious meaning. May there not have been yet another meaning concealed behind all this? And what can have been the significance of the making a row with its legs? [1909b, 2040]

Disorders of this kind are called 'phobias', and we might classify Hans's case as an agoraphobia if it were not for the fact that it is a characteristic of that complaint that the locomotion of which the patient is otherwise incapable can always be easily performed when he is accompanied by some specially selected person - in the last resort, by the physician. Hans's phobia did not fulfil this condition; it soon ceased having any relation to the question of locomotion and became more and more clearly concentrated upon horses. In the early days of his illness, when the anxiety was at its highest pitch, he expressed a fear that 'the horse'll come into the room', and it was this that helped me so much towards understanding his condition. [1909b, 2099]

In the classificatory system of the neuroses no definite position has hitherto been assigned to 'phobias'. It seems certain that they should only be regarded as syndromes which may form part of various neuroses and that we need not rank them as an independent pathological process. For phobias of the kind to which little Hans's belongs, and which are in fact the most common, the name of 'anxiety-hysteria' seems to me not inappropriate; I suggested the term to Dr. W. Stekel when he was undertaking a description of neurotic anxiety states,' and I hope it will come into general use. It finds its justification in the similarity between the psychological structure of these phobias and that of hysteria - a similarity which is complete except upon a single point. That point, however, is a decisive one and well adapted for purposes of differentiation. For in anxiety-hysteria the libido which has been liberated from the pathogenic material by repression is not converted (that is, diverted from the mental sphere into a somatic innervation), but is set free In the clinical cases that we meet with, this 'anxiety-hysteria' may be combined with 'conversion-hysteria' in any proportion. There exist cases of pure conversion-hysteria without any trace of anxiety, just as there are cases of simple anxiety-hysteria, which exhibit feelings of anxiety and phobias, but have no admixture of conversion. The case of little Hans is one of the latter sort. [1909b, 2099]
One essential characteristic of anxiety-hysterias is very easily pointed out. An anxiety-hysteria tends to develop more and more into a 'phobia'. In the end the patient may have got rid of all his anxiety, but only at the price of subjecting himself to all kinds of inhibitions and restrictions. From the outset in anxiety-hysteria the mind is constantly at work in the direction of once more psychically binding the anxiety which has become liberated; but this work can neither bring about a retransformation of the anxiety into libido, nor can it establish any contact with the complexes which were the source of the libido. Nothing is left for it but to cut off access to every possible occasion that might lead to the development of anxiety, by erecting mental barriers in the nature of precautions, inhibitions, or prohibitions; and it is these defensive structures that appear to us in the form of phobias and that constitute to our eyes the essence of the disease.

I have already remarked in the course of my running commentary on the case history that it is most instructive to plunge in this way into the details of a phobia, and thus arrive at a conviction of the secondary nature of the relation between the anxiety and its objects. It is this that accounts for phobias being at once so curiously diffuse and so strictly conditioned. It is evident that the material for the particular disguises which Hans's fear adopted was collected from the impressions to which he was all day long exposed owing to the Head Customs House being situated on the opposite side of the street. In this connection, too, he showed signs of an impulse - though it was now inhibited by his anxiety - to play with the loads on the carts, with the packages, casks and boxes, like the street-boys.

Quite unexpectedly, and certainly without any prompting from his father, Hans now began to be occupied with the 'lumf' complex, and to show disgust at things that reminded him of evacuating his bowels. His father, who was reluctant to go with him along that line, pushed on with the analysis through thick and thin in the direction in which he wanted to go. He elicited from Hans the recollection of an event at Gmunden, the impression of which lay concealed behind that of the falling bus-horse. While they were playing at horses, Fritzl, the playmate of whom he was so fond, but at the same time, perhaps, his rival with his many girl friends, had hit his foot against a stone and had fallen down, and his foot had bled. Seeing the bus-horse fall had reminded him of this accident. It deserves to be noticed that Hans, who was at the moment concerned with other things, began by denying that Fritzl had fallen down (though this, was the event which formed the connection between the two scenes) and only admitted it at a later stage of the analysis. It is especially interesting, however, to observe the way in which the transformation of Hans's libido into anxiety was projected on to the principal object of his phobia, on to horses. Horses interested him the most of all the large animals; playing at horses was his favourite game with the other children. I had a suspicion - and this was confirmed by Hans's father when I asked him - that the first person who had served Hans as a horse must have been his father; and it was this that had enabled him to regard Fritzl as a substitute for his father when the accident happened at Gmunden. When repression had set in and brought a revulsion of feeling along with it, horses, which had till then been associated with so much pleasure, were necessarily turned into objects of fear.
This allows us, therefore, to make a radical distinction. We shall probably come to understand the case more deeply if we turn to those other components which do fulfill the two conditions that have just been mentioned. These other components were tendencies in Hans which had already been suppressed and which, so far as we can tell, had never been able to find uninhibited expression: hostile and jealous feelings towards his father, and sadistic impulses (premonitions, as it were, of copulation) towards his mother. These early suppressions may perhaps have gone to form the predisposition for his subsequent illness. These aggressive propensities of Hans's found no outlet, and as soon as there came a time of privation and of intensified sexual excitement, they tried to break their way out with reinforced strength. It was then that the battle which we call his 'phobia' burst out. During the course of it a part of the repressed ideas, in a distorted form and transposed on to another complex, forced their way into consciousness as the content of the phobia. But it was a decidedly paltry success. Victory lay with the forces of repression; and they made use of the opportunity to extend their domain over components other than those that had rebelled. This last circumstance, however, does not in the least alter the fact that the essence of Hans's illness was entirely dependent upon the nature of the instinctual components that had to be repulsed. The content of his phobia was such as to impose a very great measure of restriction upon his freedom of movement, and that was its purpose. It was therefore a powerful reaction against the obscure impulses to movement which were especially directed against his mother. For Hans horses had always typified pleasure in movement ('I'm a young horse', he had said as he jumped about); but since this pleasure in movement included the impulse to copulate, the neurosis imposed a restriction on it and exalted the horse into an emblem of terror. Thus it would seem as though all that the repressed instincts got from the neurosis was the honour of providing pretexts for the appearance of the anxiety in consciousness. But however clear may have been the victory in Hans's phobia of the forces that were opposed to sexuality, nevertheless, since such an illness is in its very nature a compromise, this cannot have been all that the repressed instincts obtained. After all, Hans's phobia of horses was an obstacle to his going into the street, and could serve as a means of allowing him to stay at home with his beloved mother. In this way, therefore, his affection for his mother triumphantly achieved its aim. In consequence of his phobia, the lover clung to the object of his love - though, to be sure, steps had been taken to make him innocuous. The true character of a neurotic disorder is exhibited in this twofold result.

We are also now coming to the opinion that analytic technique must be modified in certain ways according to the nature of the disease and the dominant instinctual trends in the patient. We started out from the treatment of conversion hysteria; in anxiety hysteria (phobias) we must to some extent alter our procedure. For these patient cannot bring out the material necessary for resolving their phobia so long as they feel protected by obeying the condition which it lays down. One cannot, of course, succeed in getting them to give up their protective measures and work under the influence of anxiety from the beginning of the treatment. One must therefore help them by interpreting their unconscious to them until they can make up their minds to do without the protection of their phobia and expose themselves to a now greatly mitigated anxiety. Only after they have done so does the material become accessible, which, when it has been mastered, leads to a solution of the phobia. Other modifications of technique, which seem to me not yet ripe for discussion, will be required in the treatment of obsessional neurosis. In this connection very important questions arise, which have not hitherto been elucidated: how far the instincts which the patient is combating are to be allowed some satisfaction during the treatment, and what difference it makes whether these impulses are active (sadistic) or passive (masochistic) in their nature.
Analysis is able to trace the associative paths along which this displacement passes - both the fortuitous paths and those with a significant content. Analysis also enables us to discover the motives for the displacement. The hatred of his father that arises in a boy from rivalry for his mother is not able to achieve uninhibited sway over his mind; it has to contend against his old-established affection and admiration for the very same person. The child finds relief from the conflict arising out of this double-sided, this ambivalent emotional attitude towards his father by displacing his hostile and fearful feelings on to a substitute for his father. The displacement cannot, however, bring the conflict to an end, it cannot effect a clear-cut severance between the affectionate and the hostile feelings. On the contrary, the conflict is resumed in relation to the object on to which the displacement has been made: the ambivalence is extended to it. There could be no doubt that little Hans was not only frightened of horses; he also approached them with admiration and interest. As soon as his anxiety began to diminish, he identified himself with the dreaded creature: he began to jump about like a horse and in his turn bit his father.¹ At another stage in the resolution of his phobia he did not hesitate to identify his parents with some other large animals.²

We are obliged to take quite another view of the process of repression when we consider the picture of a true conversion hysteria. Here the salient point is that it is possible to bring about a total disappearance of the quota of affect. When this is so, the patient displays towards his symptoms what Charcot called 'la belle indifférence hystériques'. In other cases this suppression is not so completely successful: some distressing sensations may attach to the symptoms themselves, or it may prove impossible to prevent some release of anxiety, which in turn sets to work the mechanism of forming a phobia. The ideational content of the instinctual representative is completely withdrawn from consciousness; as a substitute - and at the same time as a symptom - we have an over-strong innervation (in typical cases, a somatic one), sometimes of a sensory, sometimes of a motor character, either as an excitation or an inhibition. The over-innervated area proves on a closer view to be a part of the repressed instinctual representative itself - a part which, as though by a process of condensation, has drawn the whole cathexis on to itself. These remarks do not of course bring to light the whole mechanism of a conversion hysteria; in especial the factor of regression, which will be considered in another connection, has also to be taken into account. In so far as repression in hysteria is made possible only by the extensive formation of substitutes, it may be judged to be entirely unsuccessful; as regards dealing with the quota of affect, however, which is the true task of repression, it generally signifies a total success. In conversion hysteria the process of repression is completed with the formation of the symptom and does not, as in anxiety hysteria, need to continue to a second phase - or rather, strictly speaking, to continue endlessly.

¹[1912-1913, 2769]
²[1915d, 2986]
A second form of anxiety, in contrast to the ones I have just described, is bound psychically and attached particular objects or situations. This is the anxiety of the extremely multifarious and often very strange 'phobias'. Stanley Hall, the respected American psychologist, has recently taken the trouble to present us with a whole series of these phobias in all the magnificence of Greek names. This sounds like a list of the ten Plagues of Egypt, though their number goes far beyond ten. Listen to all the things that can become the object or content of a phobia: darkness, open air, open spaces, cats, spiders, caterpillars, snakes, mice, thunderstorms, sharp points, blood, enclosed spaces, crowds, solitude, crossing bridges, sea voyages and railway journeys, etc., etc. A first attempt at finding one's way about in this confusion suggests a division into three groups. Some of the dreaded objects and situations have something uncanny about them for normal people as well, some relation to danger; and such phobias, therefore, do not strike us as unintelligible, though their strength is greatly exaggerated. Thus most of us have a sense of repulsion if we meet with a snake. Snake phobia, we might say, is a universal human characteristic; and Darwin has described most impressively how he could not avoid feeling fear of a snake that struck at him, even though he knew that he was protected from it by a thick sheet of glass. We may refer to a second group the cases in which a relation to a danger is still present, though we are accustomed to minimize the danger and not to anticipate it. The majority of situation phobias belong to this group. We know that there is more chance of an accident when we are on a railway-journey than when we stay at home - the chance of a collision; we know, too, that a ship may go down, in which case there is a probability of being drowned; but we do not think about these dangers, and travel by rail and ship without anxiety. It cannot be disputed that we should fall into the river if the bridge collapsed at the moment we were crossing it; but that happens so exceedingly seldom that it does not arise as a danger. Solitude, too, has its dangers and in certain circumstances we avoid it; but there is no question of our not being able to tolerate it under any condition even for a moment. Much the same is true of crowds, of enclosed spaces, of thunderstorms and so on. What in general appears to us strange in these phobias of neurotics is not so much their content as their intensity. The anxiety of phobias is positively overwhelming. And sometimes we get an impression that what neurotics are afraid of are not at all the same things and situations which may in certain circumstances cause anxiety in us too and which they describe by the same names.

We are left with a third group of phobias, which is quite beyond our comprehension. When a strong, grown-up man is unable owing to anxiety to walk along a street or cross a square in his own familiar home-town, when a healthy, well-developed woman is thrown into insensate anxiety because a cat has brushed against the edge of her dress or because a mouse has run across the room, how are we to relate these things to the danger which they obviously constitute for the phobic subject? In the case of such animal phobias there can be no question of an exaggeration of universal human antipathies, since, as though to demonstrate the contrary, there are numerous people who cannot pass by a cat without coaxing it and stroking it. The mouse that these women are so much afraid of is also [in German] one of the chief terms of affection; a girl who is delighted when her lover calls her one will often scream with terror when she sees the pretty creature which bears that name. In the case of the man with agoraphobia the only explanation that we can reach is that he is behaving like a small child. A child is actually taught as part of his education to avoid such situations as dangerous; and our agoraphobic will in fact be saved from his anxiety if we accompany him across the square.
The two forms of anxiety that I have just described - the freely floating expectant anxiety and the sort which is bound to phobias - are independent of each other. One is not a higher stage, as it were, of the other; and they only appear simultaneously in exceptional cases and, so to speak, accidentally. The most powerful general apprehensiveness need not be expressed in phobias; people whose whole existence is restricted by agoraphobia may be entirely free from pessimistic expectant anxiety. Some phobias - for instance, agoraphobia and railway phobia - are demonstrably acquired at a fairly mature age, while others - such as fear of darkness, thunderstorms and animals - seem to have been present from the first. Those of the former kind have the significance of severe illnesses; the latter make their appearance rather as eccentricities or whims. If a person exhibits one of these latter, one may suspect as a rule that he will have other similar ones. I must add that we class all these phobias as anxiety hysteria; that is to say, we regard them as a disorder closely related to the familiar conversion hysteria. 

[1916-1917, 3447]

The difficulty in understanding now lies else here. The anxiety which signifies a flight of the ego from its libido is after all supposed to be derived from that libido itself. This is obscure and it reminds us not to forget that after all a person's libido is fundamentally something of his and cannot be contrasted with him as something external. It is the topographical dynamics of the generation of anxiety which are still obscure to us - the question of what mental energies are produced in what process and from what mental systems they derive. This is once more a question which I cannot promise to answer: but there are two other tracks which we must not fail to follow and in doing so we shall once more be making use of direct observation and analytic enquiry as a help to our speculations. We will turn to the genesis of anxiety in children and to the source of the neurotic anxiety which is attached to phobias.

[1916-1917, 3452]

You will be glad to hear that the analysis of phobias has not much more that is new to teach us. For the same thing happens with them as with children's anxiety: unemployable libido is being constantly transformed into an apparently realistic anxiety and thus a tiny external danger is introduced to represent the claims of the libido. There is nothing to be wondered at in this agreement, for the infantile phobias are not only the prototype of the later ones which we class as 'anxiety hysteria' but are actually their precondition and the prelude to them. Every hysterical phobia goes back to an infantile anxiety and is a continuation of it, even if it has a different content and must thus be given another name. The difference between the two disorders lies in their mechanism. In order that libido shall be changed into anxiety, it no longer suffices in the case of adults for the libido to have become momentarily unemployable in the form of a longing. Adults have long since learnt how to hold such libido in suspense or to employ it in some other way. If, however, the libido belongs to a psychical impulse which has been subjected to repression, then circumstances are re-established similar to those in the case of a child in whom there is still no distinction between conscious and unconscious; and by mean of regression to the infantile phobia a passage is opened, as it were, through which the transformation of libido into anxiety can be comfortably accomplished.

[1916-1917, 3455]
I have said that transformation into anxiety - it would be better to say discharge in the form of anxiety - is the immediate vicissitude of libido which is subjected to repression. I must add that that vicissitude is not the only or the definitive one. In the neuroses processes are in action which endeavour to bind this generating of anxiety and which even succeed in doing so in various ways. In phobias, for instance, two phases of the neurotic process can be clearly distinguished. The first is concerned with repression and the changing of libido into anxiety, which is then bound to an external danger. The second consists in the erection of all the precautions and guarantees by means of which any contact can be avoided with this danger, treated as it is like an external thing. Repression corresponds to an attempt at flight by the ego from libido which is felt as a danger. A phobia may be compared to an entrenchment against an external danger which now represents the dreaded libido. The weakness of the defensive system in phobias lies, of course, in the fact that the fortress which has been so greatly strengthened towards the outside remains assailable from within. A projection outwards of the danger of libido can never succeed thoroughly. For that reason, in other neuroses other systems of defence are in use against the possible generation of anxiety. That is a most interesting part of the psychology of the neuroses; but unluckily it would lead us too far and it presupposes a deeper specialized knowledge. I will only add one thing more. I have already spoken to you of the 'anticathexis' which is employed by the ego in the process of repression and which must be permanently maintained in order that the repression may have stability. This anticathexis has the task of carrying through the various forms of defence against the generating of anxiety after repression.

Let us now consider the phobia. It came into existence on the level of the genital organization, and shows us the relatively simple mechanism of an anxiety-hysteria. The ego, by developing anxiety, was protecting itself against what it regarded as an overwhelming danger, namely, homosexual satisfaction. But the process of repression left behind it a trace which cannot be overlooked. The object to which the dangerous sexual aim had been attached had to have its place taken in consciousness by another one. What became conscious was fear not of the father but of the wolf. Nor did the process stop at the formation of a phobia with a single content. A considerable time afterwards the wolf was replaced by the lion. Simultaneously with sadistic impulses against small animals there was a phobia directed towards them, in their capacity of representatives of the boy's rivals, the possible small children. The origin of the butterfly phobia is of especial interest. It was like a repetition of the mechanism that produced the wolf phobia in the dream. Owing to a chance stimulus an old experience, the scene with Grusha, was activated; her threat of castration thus produced deferred effects, though at the time it was uttered it had made no impression.¹

It may truly be said that the anxiety that was concerned in the formation of these phobias was a fear of castration. This statement involves no contradiction of the view that the anxiety originated from the repression of homosexual libido. Both modes of expression refer to the same process: namely, the withdrawal of libido by the ego from the homosexual wishful impulse, the libido having then become converted into free anxiety and subsequently bound in phobias. The first method of statement merely mentions in addition the motive by which the ego was actuated.

¹[1918b, 3588]
The ego is the actual seat of anxiety. Threatened by dangers from three directions, it develops the flight-reflex by withdrawing its own cathexis from the menacing perception or from the similarly regarded process in the id, and emitting it as anxiety. This primitive reaction is later replaced by the carrying-out of protective cathexes (the mechanism of the phobias). What it is that the ego fears from the external and from the libidinal danger cannot be specified; we know that the fear is of being overwhelmed or annihilated, but it cannot be grasped analytically. The ego is simply obeying the warning of the pleasure principle. On the other hand, we can tell what is hidden behind the ego's dread of the super-ego, the fear of conscience. The superior being, which turned into the ego ideal, once threatened castration, and this dread of castration is probably the nucleus round which the subsequent fear of conscience has gathered; it is this dread that persists as the fear of conscience.

Here, then, is our unexpected finding: in both patients the motive force of the repression was fear of castration. The ideas contained in their anxiety - being bitten by a horse and being devoured by a wolf - were substitutes by distortion for the idea of being castrated by their father. This was the idea which had undergone repression. In the Russian boy the idea was an expression of a wish which was not able to subsist in the face of his masculine revolt; in 'Little Hans' it was the expression of a reaction in him which had turned his aggressiveness into its opposite. But the affect of anxiety, which was the essence of the phobia, came, not from the process of repression, not from the libidinal cathexes of the repressed impulses, but from the repressing agency itself. The anxiety belonging to the animal phobias was an untransformed fear of castration. It was therefore a realistic fear, a fear of a danger which was actually impending or was judged to be a real one. It was anxiety which produced repression and not, as I formerly believed, repression which produced anxiety.

It is no use denying the fact, though it is not pleasant to recall it, that I have on many occasions asserted that in repression the instinctual representative is distorted, displaced and so on, while the libido belonging to the instinctual impulse is transformed into anxiety. But now an examination of phobias, which should be best able to provide confirmatory evidence, fails to bear out my assertion; it seems, rather, to contradict it directly. The anxiety felt in animal phobias is the ego's fear of castration; while the anxiety felt in agoraphobia (a subject that has been less thoroughly studied) seems to be its fear of sexual temptation - a fear which, after all, must be connected in its origins with the fear of castration. As far as can be seen at present, the majority of phobias go back to an anxiety of this kind felt by the ego in regard to the demands of the libido. It is always the ego's attitude of anxiety which is the primary thing and which sets repression going. Anxiety never arises from repressed libido. If I had contented myself earlier with saying that after the occurrence of repression a certain amount of anxiety appeared in place of the manifestation of libido that was to be expected, I should have nothing to retract today. The description would be correct; and there does undoubtedly exist a correspondence of the kind asserted between the strength of the impulse that has to be repressed and the intensity of the resultant anxiety. But I must admit that I thought I was giving more than a mere description. I believed I had put my finger on a metapsychological process of direct transformation of libido into anxiety. I can now no longer maintain this view. And, indeed, I found it impossible at the time to explain how a transformation of that kind was carried out.
It may be asked how I arrived at this idea of transformation in the first instance. It was while I was studying the 'actual neuroses', at a time when analysis was still a very long way from distinguishing between processes in the ego and processes in the id. I found that outbreaks of anxiety and a general state of preparedness for anxiety were produced by certain sexual practices such as *coitus interruptus*, undischarged sexual excitation or enforced abstinence - that is, whenever sexual excitation was inhibited, arrested or deflected in its progress towards satisfaction. Since sexual excitation was an expression of libidinal instinctual impulses it did not seem too rash to assume that the libido was turned into anxiety through the agency of these disturbances. The observations which I made at the time still hold good. Moreover, it cannot be denied that the libido belonging to the id-processes is subjected to disturbance at the instigation of repression. It might still be true, therefore, that in repression anxiety is produced from the libidinal cathexis of the instinctual impulses. But how can we reconcile this conclusion with our other conclusion that the anxiety felt in phobias is an ego anxiety and arises in the ego, and that it does not proceed out of repression but, on the contrary, sets repression in motion? There seems to be a contradiction here which it is not at all a simple matter to solve. It will not be easy to reduce the two sources of anxiety to a single one. We might attempt to do so by supposing that, when coitus is disturbed or sexual excitation interrupted or abstinence enforced, the ego scents certain dangers to which it reacts with anxiety. But this takes us nowhere. On the other hand, our analysis of the phobias seems to admit of no correction. *Non liquet.*

We set out to study the formation of symptoms and the secondary struggle waged by the ego against symptoms. But in picking on the phobias for this purpose we have clearly made an unlucky choice. The anxiety which predominates in the picture of these disorders is now seen as a complication which obscures the situation. There are plenty of neuroses which exhibit no anxiety whatever. True conversion hysteria is one of these. Even in its most severe symptoms no admixture of anxiety is found. This fact alone ought to warn us against making too close a connection between anxiety and symptom-formation. The phobias are so closely akin to conversion hysteria in every other respect that I have felt justified in classing them alongside of it under the name of 'anxiety hysteria'. But no one has as yet been able to say what it is that determines whether any given case shall take the form of a conversion hysteria or a phobia - has been able, that is to say, to establish what determines the generating of anxiety in hysteria.

This time we will not lose sight of the part played by anxiety. We have said that as soon as the ego recognizes the danger of castration it gives the signal of anxiety and inhibits through the pleasure-unpleasure agency (in a way which we cannot as yet understand) the impending cathetic process in the id. At the same time the phobia is formed. And now the castration anxiety is directed to a different object and expressed in a distorted form, so that the patient is afraid, not of being castrated by his father, but of being bitten by a horse or devoured by a wolf. This substitutive formation has two obvious advantages. In the first place it avoids a conflict due to ambivalence (for the father was a loved object, too), and in the second place it enables the ego to cease generating anxiety. For the anxiety belonging to a phobia is conditional; it only emerges when the object of it is perceived - and rightly so, since it is only then that the danger-situation is present. There is no need to be afraid of being castrated by a father who is not there. On the other hand one cannot get rid of a father; he can appear whenever he chooses. But if he is replaced by an animal, all one has to do is to avoid the sight of it - that is, its presence - in order to be free from danger and anxiety. 'Little Hans', therefore, imposed a restriction upon his ego. He produced the inhibition of not leaving the house, so as not to come across any horses. The young Russian had an even easier time of it, for it was hardly a privation for him not to look at a particular picture-book any more. If his naughty sister had not kept on showing him the book with the picture of the wolf standing upright in it, he would have been able to feel safe from his fear.
That this latter opinion is at least in part true is shown by some striking examples. If an agoraphobic patient who has been accompanied into the street is left alone there, he will produce an anxiety attack. Or if an obsessional neurotic is prevented from washing his hands after having touched something, he will become a prey to almost unbearable anxiety. It is plain, then, that the purpose and the result of the imposed condition of being accompanied in the street and the obsessional act of washing the hands were to obviate outbreaks of anxiety of this kind. In this sense every inhibition which the ego imposes on itself can be called a symptom.

¹ It may quite often happen that although a danger-situation is correctly estimated in itself, a certain amount of instinctual anxiety is added to the realistic anxiety. In that case the instincual demand before whose satisfaction the ego recoils is a masochistic one: the instinct of destruction directed against the subject himself. Perhaps an addition of this kind explains cases in which reactions of anxiety are exaggerated, inexpedient or paralysing. Phobias of heights (windows, towers, precipices and so on) may have some such origin. Their hidden feminine significance is closely connected with masochism.

We then turned to neurotic anxiety and pointed out that we observe it under three conditions. We find it first as a freely floating, general apprehensiveness, ready to attach itself temporarily, in the form of what is known as 'expectant anxiety', to any possibility that may freshly arise - as happens, for instance, in a typical anxiety neurosis. Secondly, we find it firmly attached to certain ideas in the so-called 'phobias', in which it is still possible to recognize a relation to external danger but in which we must judge the fear exaggerated out of all proportion. Thirdly and lastly, we find anxiety in hysteria and other forms of severe neurosis, where it either accompanies symptoms or emerges independently as an attack or more persistent state, but always without any visible basis in an external danger. We then asked ourselves two questions: 'What are people afraid of in neurotic anxiety?' and 'How are we to bring it into relation with realistic anxiety felt in the face of external dangers?'

Our investigations were far from remaining unsuccessful: we reached a few important conclusions. In regard to anxious expectation clinical experience revealed that it had a regular connection with the libidinal economics of sexual life. The commonest cause of anxiety neurosis is unconsummated excitation. Libidinal excitation is aroused but not satisfied, not employed; apprehensiveness then appears instead of this libido that has been diverted from its employment. I even thought I was justified in saying that this unsatisfied libido was directly changed into anxiety. This view found support in some quite regularly occurring phobias of small children. Many of these phobias are very puzzling to us, but others, such as the fear of being alone and the fear of strangers, can be explained with certainty. Loneliness as well as a strange face arouse the child's longing for his familiar mother; he is unable to control this libidinal excitation, he cannot hold it in suspense but changes it into anxiety. This infantile anxiety must therefore be regarded not as of the realistic but as of the neurotic kind. Infantine phobias and the expectation of anxiety in anxiety neurosis offer us two examples of one way in which neurotic anxiety originates: by a direct transformation of libido. We shall at once come to know of a second mechanism, but it will turn out not to be very different from the first.
For we consider that what is responsible for the anxiety in hysteria and other neuroses is the process of repression. We believe it is possible to give a more complete account of this than before, if we separate what happens to the idea that has to be repressed from what happens to the quota of libido attaching to it. It is the idea which is subjected to repression and which may be distorted to the point of being unrecognizable; but its quota of affect is regularly transformed into anxiety - and this is so whatever the nature of the affect may be, whether it is aggressiveness or love. It makes no essential difference, then, for what reason a quota of libido has become unemployable: whether it is on account of the infantile weakness of the ego, as in children's phobias, or on account of somatic processes in sexual life, as in anxiety neurosis, or owing to repression, as in hysteria. Thus in reality the two mechanisms that bring about neurotic anxiety coincide.

[1933a, 4690]

In the course of these investigations our attention was drawn to a highly significant relation between the generation of anxiety and the formation of symptoms - namely, that these two represent and replace each other. For instance, an agoraphobic patient may start his illness with an attack of anxiety in the street. This would be repeated every time he went into the street again. He will now develop the symptom of agoraphobia; this may also be described as an inhibition, a restriction of the ego's functioning, and by means of it he spares himself anxiety attacks. We can witness the converse of this if we interfere in the formation of symptoms, as is possible, for instance, with obsessions. If we prevent a patient from carrying out a washing ceremonial, he falls into a state of anxiety which he finds hard to tolerate and from which he had evidently been protected by his symptom. And it seems, indeed, that the generation of anxiety is the earlier and the formation of symptoms the later of the two, as though the symptoms are created in order to avoid the outbreak of the anxiety state. This is confirmed too by the fact that the first neuroses of childhood are phobias - states in which we see so clearly how an initial generation of anxiety is replaced by the later formation of a symptom; we get an impression that it is from these interrelations that we shall best obtain access to an understanding of neurotic anxiety. And at the same time we have also succeeded in answering the question of what it is that a person is afraid of in neurotic anxiety and so in establishing the connection between neurotic and realistic anxiety. What he is afraid of is evidently his own libido. The difference between this situation and that of realistic anxiety lies in two points: that the danger is an internal instead of an external one and that it is not consciously recognized.

[1933a, 4690]

In phobias it is very easy to observe the way in which this internal danger is transformed into an external one - that is to say, how a neurotic anxiety is changed into an apparently realistic one. In order to simplify what is often a very complicated business, let us suppose that the agoraphobic patient is invariably afraid of feelings of temptation that are aroused in him by meeting people in the street. In his phobia he brings about a displacement and henceforward is afraid of an external situation. What he gains by this is obviously that he thinks he will be able to protect himself better in that way. One can save oneself from an external danger by flight; fleeing from an internal danger is a difficult enterprise.

[1933a, 4691]
For we have recently been examining the way in which anxiety is generated in certain phobias which we class as anxiety hysteria, and have chosen cases in which we were dealing with the typical repression of wishful impulses arising from the Oedipus complex. We should have expected to find that it was a libidinal cathexis of the boy's mother as object which, as a result of repression, had been changed into anxiety and which now emerged, expressed in symptomatic terms, attached to a substitute for his father. I cannot present you with the detailed steps of an investigation such as this; it will be enough to say that the surprising result was the opposite of what we expected. It was not the repression that created the anxiety; the anxiety was there earlier; it was the anxiety that made the repression. But what sort of anxiety can it have been? Only anxiety in the face of a threatening external danger - that is to say, a realistic anxiety. It is true that the boy felt anxiety in the face of a demand by his libido - in this instance, anxiety at being in love with his mother; so the case was in fact one of neurotic anxiety. But this being in love only appeared to him as an internal danger, which he must avoid by renouncing that object, because it conjured up an external situation of danger. And in every case we examine we obtain the same result. It must be confessed that we were not prepared to find that internal instinctual danger would turn out to be a determinant and preparation for an external, real, situation of danger.

[1933a, 4692]

But we have not made any mention at all so far of what the real danger is that the child is afraid of as a result of being in love with his mother. The danger is the punishment of being castrated, of losing his genital organ. You will of course object that after all that is not a real danger. Our boys are not castrated because they are in love with their mothers during the phase of the Oedipus complex. But the matter cannot be dismissed so simply. Above all, it is not a question of whether castration is really carried out; what is decisive is that the danger is one that threatens from outside and that the child believes in it. He has some ground for this, for people threaten him often enough with cutting off his penis during the phallic phase, at the time of his early masturbation, and hints at that punishment must regularly find a phylogenetic reinforcement in him. It is our suspicion that during the human family's primaeval period castration used actually to be carried out by a jealous and cruel father upon growing boys, and that circumcision, which so frequently plays a part in puberty rites among primitive peoples, is a clearly recognizable relic of it. We are aware that here we are diverging widely from the general opinion; but we must hold fast to the view that fear of castration is one of the commonest and strongest motives for repression and thus for the formation of neuroses. The analysis of cases in which circumcision, though not, it is true, castration, has been carried out on boys as a cure or punishment for masturbation (a far from rare occurrence in Anglo-American society) has given our conviction a last degree of certainty. It is very tempting at this point to go more deeply into the castration complex, but I will stick to our subject.

[1933a, 4693]
Indeed, when we look into the matter more closely, we must recognize the fact that the
dream-work is doing nothing original in making substitutions of this kind. In order to gain its
ends - in this case the possibility of a representation hampered by censorship - it merely follows
the paths which it finds already laid down in the unconscious; and it gives preference to those
transformations of the repressed material which can also become conscious in the form of jokes
or allusions and of which the phantasies of neurotic patients are so full. At this point we
suddenly reach an understanding of Scherner's dream interpretations, whose essential
correctness I have defended elsewhere. The imagination's pre-occupation with the subject's
own body is by no means peculiar to dreams or characteristic only of them. My analyses have
shown me that it is habitually present in the unconscious thoughts of neurotics, and that it is
derived from sexual curiosity, which, in growing youths or girls, is directed to the genitals of the
other sex, and to those of their own as well. Nor, as Scherner and Volkelt have rightly insisted,
is a house the only circle of ideas employed for symbolizing the body; and this is equally true of
dreams and of the unconscious phantasies of neurosis. It is true that I know patients who have
retained an architectural symbolism for the body and the genitals. (Sexual interest ranges far
beyond the sphere of the external genitalia.) For these patients pillars and columns represent
the legs (as they do in the Song of Solomon), every gateway stands for one of the bodily orifices
(a 'hole'), every water-pipe is a reminder of the urinary apparatus, and so on. But the circle of
ideas centring round plant-life or the kitchen may just as readily be chosen to conceal sexual
images.¹ In the former case the way has been well prepared by linguistic usage, itself the
precipitate of imaginative similes reaching back to remote antiquity: e.g. the Lord's vineyard, the
seed, and the maiden's garden in the Song of Solomon. The ugliest as well as the most intimate
details of sexual life may be thought and dreamt of in seemingly innocent allusions to activities
in the kitchen; and the symptoms of hysteria could never be interpreted if we forgot that sexual
symbolism can find its best hiding-place behind what is commonplace and inconspicuous.
There is a valid sexual meaning behind the neurotic child's intolerance of blood or raw meat, or
his nausea at the sight of eggs or macaroni, and behind the enormous exaggeration in neurotics
of the natural human dread of snakes. Wherever neuroses make use of such disguises they are
following paths along which all humanity passed in the earliest periods of civilization - paths of
whose continued existence today, under the thinnest of veils, evidence is to be found in
linguistic usages, superstitions and customs.
[1900a, 815]
A second form of anxiety, in contrast to the ones I have just described, is bound psychically and attached particular objects or situations. This is the anxiety of the extremely multifarious and often very strange 'phobias'. Stanley Hall, the respected American psychologist, has recently taken the trouble to present us with a whole series of these phobias in all the magnificence of Greek names. This sounds like a list of the ten Plagues of Egypt, though their number goes far beyond ten. Listen to all the things that can become the object or content of a phobia: darkness, open air, open spaces, cats, spiders, caterpillars, snakes, mice, thunderstorms, sharp points, blood, enclosed spaces, crowds, solitude, crossing bridges, sea voyages and railway journeys, etc., etc. A first attempt at finding one's way about in this confusion suggests a division into three groups. Some of the dreaded objects and situations have something uncanny about them for normal people as well, some relation to danger; and such phobias, therefore, do not strike us as unintelligible, though their strength is greatly exaggerated. Thus most of us have a sense of repulsion if we meet with a snake. Snake phobia, we might say, is a universal human characteristic; and Darwin has described most impressively how he could not avoid feeling fear of a snake that struck at him, even though he knew that he was protected from it by a thick sheet of glass. We may refer to a second group the cases in which a relation to a danger is still present, though we are accustomed to minimize the danger and not to anticipate it. The majority of situation phobias belong to this group. We know that there is more chance of an accident when we are on a railway-journey than when we stay at home - the chance of a collision; we know, too, that a ship may go down, in which case there is a probability of being drowned; but we do not think about these dangers, and travel by rail and ship without anxiety. It cannot be disputed that we should fall into the river if the bridge collapsed at the moment we were crossing it; but that happens so exceedingly seldom that it does not arise as a danger. Solitude, too, has its dangers and in certain circumstances we avoid it; but there is no question of our not being able to tolerate it under any condition even for a moment. Much the same is true of crowds, of enclosed spaces, of thunderstorms and so on. What in general appears to us strange in these phobias of neurotics is not so much their content as their intensity. The anxiety of phobias is positively overwhelming. And sometimes we get an impression that what neurotics are afraid of are not at all the same things and situations which may in certain circumstances cause anxiety in us too and which they describe by the same names.

[1916-1917, 3446]
Why this should be so calls for a rather long reply. First of all, we must sift the facts. In a great number of cases the old determinants of anxiety do really lapse, after having produced neurotic reactions. The phobias of very young children, fears of being alone or in the dark or with strangers - phobias which can almost be called normal - usually pass off later on; the child 'grows out of them', as we say about some other disturbances of childhood. Animal phobias, which are of such frequent occurrence, undergo the same fate and many conversion hysterias of early years find no continuation in later life. Ceremonial actions appear extremely often in the latency period, but only a very small percentage of them develop later into a full obsessional neurosis. In general, so far as we can tell from our observations of town children belonging to the white races and living according to fairly high cultural standards, the neuroses of childhood are in the nature of regular episodes in a child's development, although too little attention is still being paid to them. Signs of childhood neuroses can be detected in all adult neurotics without exception; but by no means all children who show those signs become neurotic in later life. It must be, therefore, that certain determinants of anxiety are relinquished and certain danger-situations lose their significance as the individual becomes more mature. Moreover, some of these danger-situations manage to survive into later times by modifying their determinants of anxiety so as to bring them up to date. Thus, for instance, a man may retain his fear of castration in the guise of a syphilidophobia, after he has come to know that it is no longer customary to castrate people for indulging their sexual lusts, but that, on the other hand, severe diseases may overtake anyone who thus gives way to his instincts. Other determinants of anxiety, such as fear of the super-ego, are destined not to disappear at all but to accompany people throughout their lives. In that case the neurotic will differ from the normal person in that his reactions to the dangers in question will be unduly strong. Finally, being grown-up affords no absolute protection against a return of the original traumatic anxiety-situation. Each individual has in all probability a limit beyond which his mental apparatus fails in its function of mastering the quantities of excitation which require to be disposed of.

[1926d, 4302]

We then turned to neurotic anxiety and pointed out that we observe it under three conditions. We find it first as a freely floating, general apprehensiveness, ready to attach itself temporarily, in the form of what is known as 'expectant anxiety', to any possibility that may freshly arise - as happens, for instance, in a typical anxiety neurosis. Secondly, we find it firmly attached to certain ideas in the so-called 'phobias', in which it is still possible to recognize a relation to external danger but in which we must judge the fear exaggerated out of all proportion. Thirdly and lastly, we find anxiety in hysteria and other forms of severe neurosis, where it either accompanies symptoms or emerges independently as an attack or more persistent state, but always without any visible basis in an external danger. We then asked ourselves two questions: "What are people afraid of in neurotic anxiety?" and "How are we to bring it into relation with realistic anxiety felt in the face of external dangers?"

[1933a, 4689]
The relation of these phobias to the phobias of obsessional neurosis, whose mechanism I made clear in an earlier paper¹ in this periodical, is of the following kind. What they have in common is that in both an idea becomes obsessional as a result of being attached to an available affect. The mechanism of \textit{transposition of affect} thus holds good for both kinds of phobia. But in the phobias of anxiety neurosis (1) this affect always has the same colour, which is that of anxiety; and (2) the affect does not originate in a repressed idea, but turns out to be \textit{not further reducible by psychological analysis, nor amenable to psychotherapy}. The mechanism of \textit{substitution}, therefore, does not hold good for the phobias of anxiety neurosis.

[1895b, 334]

I have already remarked in the course of my running commentary on the case history that it is most instructive to plunge in this way into the details of a phobia, and thus arrive at a conviction of the secondary nature of the relation between the anxiety and its objects. It is this that accounts for phobias being at once so curiously diffuse and so strictly conditioned. It is evident that the material for the particular disguises which Hans's fear adopted was collected from the impressions to which he was all day long exposed owing to the Head Customs House being situated on the opposite side of the street. In this connection, too, he showed signs of an impulse - though it was now inhibited by his anxiety - to play with the loads on the carts, with the packages, casks and boxes, like the street-boys.

[1909b, 2107]

No detailed analytic examination has yet been made of children's animal phobias, though they would greatly repay study. This neglect has no doubt been due to the difficulty of analysing children of such a tender age. It cannot therefore be claimed that we know the general meaning of these disorders and I myself am of the opinion that this may not turn out to be of a uniform nature. But a few cases of phobias of this kind directed towards the larger animals have proved accessible to analysis and have thus yielded their secret to the investigator. It was the same in every case: where the children concerned were boys, their fear related at bottom to their father and had merely been displaced on to the animal.

[1912-1913, 2767]

I recently published (1909b) an 'Analysis of a Phobia in a Five-Year-Old Boy', the material of which was supplied to me by the little patient's father. The boy had a phobia of horses, and as a result he refused to go out in the street. He expressed a fear that the horse would come into the room and bite him; and it turned out that this must be the punishment for a wish that the horse might fall down (that is, die). After the boy's fear of his father had been removed by reassurances, it became evident that he was struggling against wishes which had as their subject the idea of his father being absent (going away on a journey, dying). He regarded his father (as he made all too clear) as a competitor for the favours of his mother, towards whom the obscure foreshadowings of his budding sexual wishes were aimed. Thus he was situated in the typical attitude of a male child towards his parents to which we have given the name of the 'Oedipus complex' and which we regard in general as the nuclear complex of the neuroses. The new fact that we have learnt from the analysis of 'little Hans' - a fact with an important bearing upon totemism - is that in such circumstances children displace some of their feelings from their father on to an animal.

[1912-1913, 2768]
Analysis is able to trace the associative paths along which this displacement passes - both the fortuitous paths and those with a significant content. Analysis also enables us to discover the motives for the displacement. The hatred of his father that arises in a boy from rivalry for his mother is not able to achieve uninhibited sway over his mind; it has to contend against his old-established affection and admiration for the very same person. The child finds relief from the conflict arising out of this double-sided, this ambivalent emotional attitude towards his father by displacing his hostile and fearful feelings on to a substitute for his father. The displacement cannot, however, bring the conflict to an end, it cannot effect a clear-cut severance between the affectionate and the hostile feelings. On the contrary, the conflict is resumed in relation to the object on to which the displacement has been made: the ambivalence is extended to it. There could be no doubt that little Hans was not only frightened of horses; he also approached them with admiration and interest. As soon as his anxiety began to diminish, he identified himself with the dreaded creature: he began to jump about like a horse and in his turn bit his father.¹ At another stage in the resolution of his phobia he did not hesitate to identify his parents with some other large animals.²

I have said that transformation into anxiety - it would be better to say discharge in the form of anxiety - is the immediate vicissitude of libido which is subjected to repression. I must add that that vicissitude is not the only or the definitive one. In the neuroses processes are in action which endeavour to bind this generating of anxiety and which even succeed in doing so in various ways. In phobias, for instance, two phases of the neurotic process can be clearly distinguished. The first is concerned with repression and the changing of libido into anxiety, which is then bound to an external danger. The second consists in the erection of all the precautions and guarantees by means of which any contact can be avoided with this danger, treated as it is like an external thing. Repression corresponds to an attempt at flight by the ego from libido which is felt as a danger. A phobia may be compared to an entrenchment against an external danger which now represents the dreaded libido. The weakness of the defensive system in phobias lies, of course, in the fact that the fortress which has been so greatly strengthened towards the outside remains assailable from within. A projection outwards of the danger of libido can never succeed thoroughly. For that reason, in other neuroses other systems of defence are in use against the possible generation of anxiety. That is a most interesting part of the psychology of the neuroses; but unluckily it would lead us too far and it presupposes a deeper specialized knowledge. I will only add one thing more. I have already spoken to you of the 'anticathexis' which is employed by the ego in the process of repression and which must be permanently maintained in order that the repression may have stability. This anticathexis has the task of carrying through the various forms of defence against the generating of anxiety after repression.

[1912-1913, 2769]

[1916-1917, 3456]
Let us now consider the phobia. It came into existence on the level of the genital organization, and shows us the relatively simple mechanism of an anxiety-hysteria. The ego, by developing anxiety, was protecting itself against what it regarded as an overwhelming danger, namely, homosexual satisfaction. But the process of repression left behind it a trace which cannot be overlooked. The object to which the dangerous sexual aim had been attached had to have its place taken in consciousness by another one. What became conscious was fear not of the father but of the wolf. Nor did the process stop at the formation of a phobia with a single content. A considerable time afterwards the wolf was replaced by the lion. Simultaneously with sadistic impulses against small animals there was a phobia directed towards them, in their capacity of representatives of the boy’s rivals, the possible small children. The origin of the butterfly phobia is of especial interest. It was like a repetition of the mechanism that produced the wolf phobia in the dream. Owing to a chance stimulus an old experience, the scene with Grusha, was activated; her threat of castration thus produced deferred effects, though at the time it was uttered it had made no impression.¹

[1918b, 3588]

So far there seem to be no connecting links between 'Little Hans’s' repressed instinctual impulse and the substitute for it which we suspect is to be seen in his phobia of horses. Let us simplify his psychical situation by setting on one side the infantile factor and the ambivalence. Let us imagine that he is a young servant who is in love with the mistress of the house and has received some tokens of her favour. He hates his master, who is more powerful than he is, and he would like to have him out of the way. It would then be eminently natural for him to dread his master’s vengeance and to develop a fear of him - just as 'Little Hans' developed a phobia of horses. We cannot, therefore, describe the fear belonging to this phobia as a symptom. If 'Little Hans', being in love with his mother, had shown fear of his father, we should have no right to say that he had a neurosis or a phobia. His emotional reaction would have been entirely comprehensible. What made it a neurosis was one thing alone: the replacement of his father by a horse. It is this displacement, then, which has a claim to be called a symptom, and which, incidentally, constitutes the alternative mechanism which enables a conflict due to ambivalence to be resolved without the aid of a reaction-formation. Such a displacement is made possible or facilitated at 'Little Hans's' early age because the inborn traces of totemic thought can still be easily revived. Children do not as yet recognize or, at any rate, lay such exaggerated stress upon the gulf that separates human beings from the animal world. In their eyes the grown man, the object of their fear and admiration, still belongs to the same category as the big animal who has so many enviable attributes but against whom they have been warned because he may become dangerous. As we see, the conflict due to ambivalence is not dealt with in relation to one and the same person: it is circumvented, as it were, by one of the pair of conflicting impulses being directed to another person as a substitutive object.

[1926d, 4263]

One objection to it is that loss of an object (or loss of love on the part of the object) and the threat of castration are just as much dangers coming from outside as, let us say, a ferocious animal would be; they are not instinctual dangers. Nevertheless, the two cases are not the same. A wolf would probably attack us irrespectively of our behaviour towards it; but the loved person would not cease to love us nor should we be threatened with castration if we did not entertain certain feelings and intentions within us. Thus such instinctual impulses are determinants of external dangers and so become dangerous in themselves; and we can now proceed against the external danger by taking measures against the internal ones. In phobias of animals the danger seems to be still felt entirely as an external one, just as it has undergone an external displacement in the symptom. In obsessional neuroses the danger is much more internalized. That portion of anxiety in regard to the super-ego which constitutes social anxiety still represents an internal substitute for an external danger, while the other portion- moral anxiety - is already completely endopsychic.

[1926d, 4300]
Speaking with the air of superiority which is so easily acquired after the event, we may correct Hans's father, and explain that the boy's wish to 'tease' the horse had two constituents; it was compounded of an obscure sadistic desire for his mother and of a clear impulse for revenge against his father. The latter could not be reproduced until the former's turn had come to emerge in connection with the pregnancy complex. In the process of the formation of a phobia from the unconscious thoughts underlying it, condensation takes place; and for that reason the course of the analysis can never follow that of the development of the neurosis.
[1909b, 2069]
(7) On the basis of chronic anxiousness (anxious expectation) on the one hand, and a tendency to anxiety attacks accompanied by vertigo on the other, two groups of typical phobias develop, the first relating to general physiological dangers, the second relating to locomotion. To the first group belong fear of snakes, thunderstorms, darkness, vermin, and so on, as well as the typical moral over-scrupulousness and forms of doubting mania. Here the available anxiety is simply employed to reinforce aversions which are instinctively implanted in everyone. But as a rule a phobia which acts in an obsessional manner is only formed if there is added to this the recollection of an experience in which the anxiety was able to find expression as, for instance, after the patient has experienced a thunderstorm in the open. It is a mistake to try to explain such cases as being simply a persistence of strong impressions; what makes these experiences significant and the memory of them lasting is, after all, only the anxiety which was able to emerge at the time and which can similarly emerge now. In other words, such impressions remain powerful only in people with 'anxious expectation'.

[1895b, 333]

The negative reactions follow the opposite aim: that nothing of the forgotten traumas shall be remembered and nothing repeated. We can summarize them as 'defensive reactions'. Their principal expression are what are called 'avoidances', which may be intensified into 'inhibitions' and 'phobias'. These negative reactions too make the most powerful contributions to the stamping of character. Fundamentally they are just as much fixations to the trauma as their opposites, except that they are fixations with a contrary purpose. The symptoms of neurosis in the narrower sense are compromises in which both the trends proceeding from traumas come together, so that the share, now of one and now of the other tendency, finds preponderant expression in them. This opposition between the reactions sets up conflicts which in the ordinary course of events can reach no conclusion.

[1939a, 4901]
I see no reason why I should try to hide the gaps and weaknesses in my theory. The main thing about the problem of the phobias seems to me to be that *when the vita sexualis is normal* - then the specific condition, a disturbance of sexual life in the sense of a deflection of the somatic from the psychical, is not fulfilled - *phobias do not appear at all*. However much else may be obscure about the mechanism of phobias, my theory can only be refuted when I have been shown phobias where sexual life is normal or even where there is a disturbance of it of a non-specific sort.

[1895f, 362]

This allows us, therefore, to make a radical distinction. We shall probably come to understand the case more deeply if we turn to those other components which *do* fulfil the two conditions that have just been mentioned. These other components were tendencies in Hans which had already been suppressed and which, so far as we can tell, had never been able to find uninhibited expression: hostile and jealous feelings towards his father, and sadistic impulses (premonitions, as it were, of copulation) towards his mother. These early suppressions may perhaps have gone to form the predisposition for his subsequent illness. These aggressive propensities of Hans's found no outlet, and as soon as there came a time of privation and of intensified sexual excitement, they tried to break their way out with reinforced strength. It was then that the battle which we call his 'phobia' burst out. During the course of it a part of the repressed ideas, in a distorted form and transposed on to another complex, forced their way into consciousness as the content of the phobia. But it was a decidedly paltry success. Victory lay with the forces of repression; and *they made use of the opportunity to extend their domain over components other than those that had rebelled*. This last circumstance, however, does not in the least alter the fact that the essence of Hans's illness was entirely dependent upon the nature of the instinctual components that had to be repulsed. The content of his phobia was such as to impose a very great measure of restriction upon his freedom of movement, and that was its purpose. It was therefore a powerful reaction against the obscure impulses to movement which were especially directed against his mother. For Hans horses had always typified pleasure in movement ('I'm a young horse', he had said as he jumped about); but since this pleasure in movement included the impulse to copulate, the neurosis imposed a restriction on it and exalted the horse into an emblem of terror. Thus it would seem as though all that the repressed instincts got from the neurosis was the honour of providing pretexts for the appearance of the anxiety in consciousness. But however clear may have been the victory in Hans's phobia of the forces that were opposed to sexuality, nevertheless, since such an illness is in its very nature a compromise, this cannot have been all that the repressed instincts obtained. After all, Hans's phobia of horses was an obstacle to his going into the street, and could serve as a means of allowing him to stay at home with his beloved mother. In this way, therefore, his affection for his mother triumphantly achieved its aim. In consequence of his phobia, the lover clung to the object of his love - though, to be sure, steps had been taken to make him innocuous. The true character of a neurotic disorder is exhibited in this twofold result.

[1909b, 2117]
You will be glad to hear that the analysis of phobias has not much more that is new to teach us. For the same thing happens with them as with children's anxiety: unemployable libido is being constantly transformed into an apparently realistic anxiety and thus a tiny external danger is introduced to represent the claims of the libido. There is nothing to be wondered at in this agreement, for the infantile phobias are not only the prototype of the later ones which we class as 'anxiety hysteria' but are actually their precondition and the prelude to them. Every hysterical phobia goes back to an infantile anxiety and is a continuation of it, even if it has a different content and must thus be given another name. The difference between the two disorders lies in their mechanism. In order that libido shall be changed into anxiety, it no longer suffices in the case of adults for the libido to have become momentarily unemployable in the form of a longing. Adults have long since learnt how to hold such libido in suspense or to employ it in some other way. If, however, the libido belongs to a psychical impulse which has been subjected to repression, then circumstances are re-established similar to those in the case of a child in whom there is still no distinction between conscious and unconscious; and by mean of regression to the infantile phobia a passage is opened, as it were, through which the transformation of libido into anxiety can be comfortably accomplished.

[1916-1917, 3455]

It is no use denying the fact, though it is not pleasant to recall it, that I have on many occasions asserted that in repression the instinctual representative is distorted, displaced and so on, while the libido belonging to the instinctual impulse is transformed into anxiety. But now an examination of phobias, which should be best able to provide confirmatory evidence, fails to bear out my assertion; it seems, rather, to contradict it directly. The anxiety felt in animal phobias is the ego's fear of castration; while the anxiety felt in agoraphobia (a subject that has been less thoroughly studied) seems to be its fear of sexual temptation - a fear which, after all, must be connected in its origins with the fear of castration. As far as can be seen at present, the majority of phobias go back to an anxiety of this kind felt by the ego in regard to the demands of the libido. It is always the ego's attitude of anxiety which is the primary thing and which sets repression going. Anxiety never arises from repressed libido. If I had contented myself earlier with saying that after the occurrence of repression a certain amount of anxiety appeared in place of the manifestation of libido that was to be expected, I should have nothing to retract today. The description would be correct; and there does undoubtedly exist a correspondence of the kind asserted between the strength of the impulse that has to be repressed and the intensity of the resultant anxiety. But I must admit that I thought I was giving more than a mere description. I believed I had put my finger on a metapsychological process of direct transformation of libido into anxiety. I can now no longer maintain this view. And, indeed, I found it impossible at the time to explain how a transformation of that kind was carried out.

[1926d, 4268]

In this connection the puzzling phobias of early childhood deserve to be mentioned once again. We have been able to explain some of them, such as the fear of being alone or in the dark or with strangers, as reactions to the danger of losing the object. Others, like the fear of small animals, thunder storms, etc., might perhaps be accounted for as vestigial traces of the congenital preparedness to meet real dangers which is so strongly developed in other animals. In man, only that part of this archaic heritage is appropriate which has reference to the loss of the object. If childhood phobias become fixated and grow stronger and persist into later years, analysis shows that their content has become associated with instinctual demands and has come to stand for internal dangers as well.

[1926d, 4320]
For we have recently been examining the way in which anxiety is generated in certain phobias which we class as anxiety hysteria, and have chosen cases in which we were dealing with the typical repression of wishful impulses arising from the Oedipus complex. We should have expected to find that it was a libidinal cathexis of the boy's mother as object which, as a result of repression, had been changed into anxiety and which now emerged, expressed in symptomatic terms, attached to a substitute for his father. I cannot present you with the detailed steps of an investigation such as this; it will be enough to say that the surprising result was the opposite of what we expected. It was not the repression that created the anxiety; the anxiety was there earlier; it was the anxiety that made the repression. But what sort of anxiety can it have been? Only anxiety in the face of a threatening external danger - that is to say, a realistic anxiety. It is true that the boy felt anxiety in the face of a demand by his libido - in this instance, anxiety at being in love with his mother; so the case was in fact one of neurotic anxiety. But this being in love only appeared to him as an internal danger, which he must avoid by renouncing that object, because it conjured up an external situation of danger. And in every case we examine we obtain the same result. It must be confessed that we were not prepared to find that internal instinctual danger would turn out to be a determinant and preparation for an external, real, situation of danger.

[1933a, 4692]

But we have not made any mention at all so far of what the real danger is that the child is afraid of as a result of being in love with his mother. The danger is the punishment of being castrated, of losing his genital organ. You will of course object that after all that is not a real danger. Our boys are not castrated because they are in love with their mothers during the phase of the Oedipus complex. But the matter cannot be dismissed so simply. Above all, it is not a question of whether castration is really carried out; what is decisive is that the danger is one that threatens from outside and that the child believes in it. He has some ground for this, for people threaten him often enough with cutting off his penis during the phallic phase, at the time of his early masturbation, and hints at that punishment must regularly find a phylogenetic reinforcement in him. It is our suspicion that during the human family's primaeval period castration used actually to be carried out by a jealous and cruel father upon growing boys, and that circumcision, which so frequently plays a part in puberty rites among primitive peoples, is a clearly recognizable relic of it. We are aware that here we are diverging widely from the general opinion; but we must hold fast to the view that fear of castration is one of the commonest and strongest motives for repression and thus for the formation of neuroses. The analysis of cases in which circumcision, though not, it is true, castration, has been carried out on boys as a cure or punishment for masturbation (a far from rare occurrence in Anglo-American society) has given our conviction a last degree of certainty. It is very tempting at this point to go more deeply into the castration complex, but I will stick to our subject.

[1933a, 4693]
The group of typical phobias, of which agoraphobia is a typical model, cannot be traced back to the psychical mechanism described above; on the contrary, the mechanism of agoraphobia differs from that of obsessions proper, and of the phobias that are reducible to them, in one decisive point. There is no repressed idea from which the anxiety affect might have been separated off. The anxiety of these phobias has another origin.

[1894a, 312]

'I had already noticed something similar at Gmunden in the summer. When he was in bed in the evening he was usually in a very sentimental state. Once he made a remark to this effect: "Suppose I was to have no Mummy", or "Suppose you were to go away", or something of the sort; I cannot remember the exact words. Unfortunately, when he got into an elegiac mood of that kind, his mother used always to take him into bed with her.

[1909b, 2016]

His anxiety, then, corresponded to repressed longing. But it was not the same thing as the longing: the repression must be taken into account too. Longing can be completely transformed into satisfaction if it is presented with the object longed for. Therapy of that kind is no longer effective in dealing with anxiety. The anxiety remains even when the longing can be satisfied. It can no longer be completely retransformed into libido; there is something that keeps the libido back under repression.¹ This was shown to be so in the case of Hans on the occasion of his next walk, when his mother went with him. He was with his mother, and yet he still suffered from anxiety - that is to say, from an unsatisfied longing for her. It is true that the anxiety was less; for he did allow himself to be induced to go for the walk, whereas he had obliged the nursemaid to turn back. Nor is a street quite the right place for 'coaxing', or whatever else this young lover may have wanted. But his anxiety had stood the test; and the next thing for it to do was to find an object. It was on this walk that he first expressed a fear that a horse would bite him. Where did the material for this phobia come from? Probably from the complexes, as yet unknown to us, which had contributed to the repression and were keeping under repression his libidinal feelings towards his mother. That is an unsolved problem, and we shall now have to follow the development of the case in order to arrive at its solution. Hans's father has already given us certain clues, probably trustworthy ones, such as that Hans had always observed horses with interest on account of their large widdlers, that he had supposed that his mother must have a widdler like a horse, and so on. We might thus be led to think that the horse was merely a substitute for his mother. But if so, what would be the meaning of his being afraid in the evening that a horse would come into the room? A small boy's foolish fears, it will be said. But a neurosis never says foolish things, any more than a dream. When we cannot understand something, we always fall back on abuse. An excellent way of making a task lighter.

[1909b, 2019]
His father's investigations may have been without success at some points; but it does no harm to make acquaintance at close quarters with a phobia of this sort - which we may feel inclined to name after its new objects. For in this way we get to see how diffuse it really is. It extends on to horses and on to carts, on to the fact that horses fall down and that they bite, on to horses of a particular character, on to carts that are heavily loaded. I will reveal at once that all these characteristics were derived from the circumstance that the anxiety originally had no reference at all to horses but was transposed on to them secondarily and had now become fixed upon those elements of the horse-complex which showed themselves well adapted for certain transferences. We must specially acknowledge one most important result of the boy's examination by his father. We have learned the immediate precipitating cause after which the phobia broke out. This was when the boy saw a big heavy horse fall down; and one at least of the interpretations of this impression seems to be that emphasized by his father, namely, that Hans at that moment perceived a wish that his father might fall down in the same way - and be dead. His serious expression as he was telling the story no doubt referred to this unconscious meaning. May there not have been yet another meaning concealed behind all this? And what can have been the significance of the making a row with its legs?

In conclusion let me add these words. With Hans's last phantasy the anxiety which arose from his castration complex was also overcome, and his painful expectations were given a happier turn. Yes, the Doctor (the plumber) did come, he did take away his penis, - but only to give him a bigger one in exchange for it. For the rest, our young investigator has merely come somewhat early upon the discovery that all knowledge is patchwork, and that each step forward leaves an unsolved residue behind.

Not infrequently, however, a strange rift occurs in the excellent relations between children and animals. A child will suddenly begin to be frightened of some particular species of animal and to avoid touching or seeing any individual of that species. The clinical picture of an animal phobia emerges - a very common, and perhaps the earliest, form of psychoneurotic illness occurring in childhood. As a rule the phobia is attached to animals in which the child has hitherto shown a specially lively interest and it has nothing to do with any particular individual animal. There is no large choice of animals that may become objects of a phobia in the case of children living in towns: horses, dogs, cats, less often birds, and with striking frequency very small creatures such as beetles and butterflies. The senseless and immoderate fear shown in these phobias is sometimes attached to animals only known to the child from picture books and fairy tales. On a few rare occasions it is possible to discover what has led to an unusual choice of this kind; and I have to thank Karl Abraham for telling me of a case in which the child himself explained that his fear of wasps was due to their colour and stripes reminding him of tigers, which from all accounts were beasts to be feared.

No detailed analytic examination has yet been made of children's animal phobias, though they would greatly repay study. This neglect has no doubt been due to the difficulty of analysing children of such a tender age. It cannot therefore be claimed that we know the general meaning of these disorders and I myself am of the opinion that this may not turn out to be of a uniform nature. But a few cases of phobias of this kind directed towards the larger animals have proved accessible to analysis and have thus yielded their secret to the investigator. It was the same in every case: where the children concerned were boys, their fear related at bottom to their father and had merely been displaced on to the animal.

[1909b, 2040]

[1909b, 2086]

[1912-1913, 2767]

[1912-1913, 2767]
Everyone with psycho-analytic experience will no doubt have come across cases of the sort and have derived the same impression from them. Yet I can quote only a few detailed publications on the subject. This paucity of literature is an accidental circumstance and it must not be supposed that our conclusions are based on a few scattered observations. I may mention, for instance, a writer who has studied the neuroses of childhood with great understanding - Dr. M. Wulff, of Odessa. In the course of a case history of a nine-year-old boy he reports that at the age of four the patient had suffered from a dog-phobia. 'When he saw a dog running past in the street, he would weep and call out: “Dear doggie, don't bite me! I'll be good!” By "being good" he meant "not playing on the fiddle" - not masturbating. (Wulff, 1912, 15.)' The boy's dog-phobia', the author explains, 'was in reality his fear of his father displaced on to dogs; for his curious exclamation "Doggie, I'll be good!" - that is, "I won't masturbate" - was directed to his father, who had forbidden him to masturbate.' Wulff adds a footnote which is in complete agreement with my views and at the same time bears witness to the frequent occurrence of such experiences: "Phobias of this type (phobias of horses, dogs, cats, fowls and other domestic animals) are, in my opinion, at least as common in childhood as pavor nocturnus; and in analysis they almost invariably turn out to be a displacement on to the animals of the child's fear of one of his parents. I should not be prepared to maintain that the same mechanism applies to the widespread phobias of rats and mice."

I recently published (1909b) an 'Analysis of a Phobia in a Five-Year-Old Boy', the material of which was supplied to me by the little patient's father. The boy had a phobia of horses, and as a result he refused to go out in the street. He expressed a fear that the horse would come into the room and bite him; and it turned out that this must be the punishment for a wish that the horse might fall down (that is, die). After the boy's fear of his father had been removed by reassurances, it became evident that he was struggling against wishes which had as their subject the idea of his father being absent (going away on a journey, dying). He regarded his father (as he made all too clear) as a competitor for the favours of his mother, towards whom the obscure foreshadowings of his budding sexual wishes were aimed. Thus he was situated in the typical attitude of a male child towards his parents to which we have given the name of the 'Oedipus complex' and which we regard in general as the nuclear complex of the neuroses. The new fact that we have learnt from the analysis of 'little Hans' - a fact with an important bearing upon totemism - is that in such circumstances children displace some of their feelings from their father on to an animal.

Analysis is able to trace the associative paths along which this displacement passes - both the fortuitous paths and those with a significant content. Analysis also enables us to discover the motives for the displacement. The hatred of his father that arises in a boy from rivalry for his mother is not able to achieve uninhibited sway over his mind; it has to contend against his old-established affection and admiration for the very same person. The child finds relief from the conflict arising out of this double-sided, this ambivalent emotional attitude towards his father by displacing his hostile and fearful feelings on to a substitute for his father. The displacement cannot, however, bring the conflict to an end, it cannot effect a clear-cut severance between the affectionate and the hostile feelings. On the contrary, the conflict is resumed in relation to the object on to which the displacement has been made: the ambivalence is extended to it. There could be no doubt that little Hans was not only frightened of horses; he also approached them with admiration and interest. As soon as his anxiety began to diminish, he identified himself with the dreaded creature: he began to jump about like a horse and in his turn bit his father.¹ At another stage in the resolution of his phobia he did not hesitate to identify his parents with some other large animals.²

¹ [1912-1913, 2769]
² [1912-1913, 2769]
It may fairly be said that in these children’s phobias some of the features of totemism reappear, but reversed into their negative. We are, however, indebted to Ferenczi (1913a) for an interesting history of a single case which can only be described as an instance of positive totemism in a child. It is true that in the case of little Árpád (the subject of Ferenczi’s report) his totemic interests did not arise in direct relation with his Oedipus complex but on the basis of its narcissistic precondition, the fear of castration. But any attentive reader of the story of little Hans will find abundant evidence that he, too, admired his father as possessing a big penis and feared him as threatening his own. The same part is played by the father alike in the Oedipus and the castration complexes - the part of a dreaded enemy to the sexual interests of childhood. The punishment which he threatens is castration, or its substitute, blinding.¹

Later on we shall be able to assess the worth of this observation more completely. At the moment I will only emphasize two features in it which offer valuable points of agreement with totemism: the boy’s complete identification with his totem animal¹ and his ambivalent emotional attitude to it. These observations justify us, in my opinion, in substituting the father for the totem animal in the formula for totemism (in the case of males). It will be observed that there is nothing new or particularly daring in this step forward. Indeed, primitive men say the very same thing themselves, and, where the totemic system is still in force to-day, they describe the totem as their common ancestor and primal father. All we have done is to take at its literal value an expression used by these people, of which the anthropologists have been able to make very little and which they have therefore been glad to keep in the background. Psycho-analysis, on the contrary, leads us to put special stress upon this same point and to take it as the starting-point of our attempt at explaining totemism.²

¹ Fear of castration plays an extremely large part, in the case of the youthful neurotics whom we come across, as an interference in their relations with their father. The illuminating instance reported by Ferenczi (1913a) has shown us how a little boy took as his totem the beast that had pecked at his little penis. When our children come to hear of ritual circumcision, they equate it with castration. The parallel in social psychology to this reaction by children has not yet been worked out, so far as I am aware. In primaeval times and in primitive races, where circumcision is so frequent, it is performed at the age of initiation into manhood and it is at that age that its significance is to be found; it was only as a secondary development that it was shifted back to the early years of life. It is of very great interest to find that among primitive peoples circumcision is combined with cutting the hair and knocking out teeth or is replaced by them, and that our children, who cannot possibly have any knowledge of this, in fact treat these two operations, in the anxiety with which they react to them, as equivalents of castration. ³

² [1912-1913, 2770]

³ [1912-1913, 2792]
Though I am anxious to cut short this discussion still further, I must nevertheless tell you a little about the sexual researches of children: they are too characteristic of infantile sexuality and of too great significance for the symptomatology of the neuroses to be passed over. Infantile sexual researches begin very early, sometimes before the third year of life. They do not relate to the distinction between the sexes, for this means nothing to children, since they (or at any rate boys) attribute the same male genital to both sexes. If, afterwards, a boy makes the discovery of the vagina from seeing his little sister or a girl playmate, he tries, to begin with, to disavow the evidence of his senses, for he cannot imagine a human creature like himself who is without such a precious portion. Later on, he takes fright at the possibility thus presented to him; and any threats that may have been made to him earlier, because he took too intense an interest in his little organ, now produce a deferred effect. He comes under the sway of the castration complex, the form taken by which plays a great part in the construction of his character if he remains normal, in his neurosis if he falls ill, and in his resistances if he comes into analytic treatment. As regards little girls, we can say of them that they feel greatly at a disadvantage owing to their lack of a big, visible penis, that they envy boys for possessing one and that, in the main for this reason, they develop a wish to be a man - a wish that re-emerges later on, in any neurosis that may arise if they meet with a mishap in playing a feminine part. In her childhood, moreover, a girl's clitoris takes on the role of a penis entirely: it is characterized by special excitability and is the area in which auto-erotic satisfaction is obtained. The process of a girl's becoming a woman depends very much on the clitoris passing on this sensitivity to the vaginal orifice in good time and completely. In cases of what is known as sexual anaesthesia in women the clitoris has obstinately retained its sensitivity.

[1916-1917, 3387]

By the latter I mean the postures which he saw his parents adopt - the man upright, and the woman bent down like an animal. We have already heard that during his anxiety period his sister used to terrify him with a picture from the fairy-book, in which the wolf was shown standing upright, with one foot forward, with its claws stretched out and its ears pricked. He devoted himself with tireless perseverance during the treatment to the task of hunting in the second-hand book shops till he had found the illustrated fairy-book of his childhood, and had recognized his bogy in an illustration to the story of 'The Wolf and the Seven Little Goats'. He thought that the posture of the wolf in this picture might have reminded him of that of his father during the constructed primal scene. At all events the picture became the point of departure for further manifestations of anxiety. Once when he was in his seventh or eighth year he was informed that next day a new tutor was coming for him. That night he dreamt of this tutor in the shape of a lion that came towards his bed roaring loudly and in the posture of the wolf in the picture; and once again he awoke in a state of anxiety. The wolf phobia had been overcome by that time, so he was free to choose himself a new anxiety-animal, and in this late dream he was recognizing the tutor as a father-surrogate. In the later years of his childhood each of his tutors and masters played the part of his father, and was endowed with his father's influence both for good and for evil.

[1918b, 3529]

The dream ended in a state of anxiety, from which he did not recover until he had his Nanya with him. He fled, therefore, from his father to her. His anxiety was a repudiation of the wish for sexual satisfaction from his father - the trend which had put the dream into his head. The form taken by the anxiety, the fear of 'being eaten by the wolf', was only the (as we shall hear, regressive) transposition of the wish to be copulated with by his father, that is, to be given sexual satisfaction in the same way as his mother. His last sexual aim, the passive attitude towards his father, succumbed to repression, and fear of his father appeared in its place in the shape of the wolf phobia.

[1918b, 3534]
We now observe that at this point in our narrative we must make an alteration in our terminology. During the dream he had reached a new phase in his sexual organization. Up to then the sexual opposites had been for him active and passive. Since his seduction his sexual aim had been a passive one, of being touched on the genitals; it was then transformed, by regression to the earlier stage of the sadistic-anal organization, into the masochistic aim of being beaten or punished. It was a matter of indifference to him whether he reached this aim with a man or with a woman. He had travelled, without considering the difference of sex, from his Nanya to his father; he had longed to have his penis touched by his Nanya, and had tried to provoke a beating from his father. Here his genitals were left out of account; though the connection with them which had been concealed by the regression was still expressed in his phantasy of being beaten on the penis. The activation of the primal scene in the dream now brought him back to the genital organization. He discovered the vagina and the biological significance of masculine and feminine. He understood now that active was the same as masculine, while passive was the same as feminine. His passive sexual aim should now have been transformed into a feminine one, and have expressed itself as 'being copulated with by his father' instead of 'being beaten by him on the genitals or on the bottom'. This feminine aim, however, underwent repression and was obliged to let itself be replaced by fear of the wolf.

We must here break off the discussion of his sexual development until new light is thrown from the later stages of his history upon these earlier ones. For the proper appreciation of the wolf phobia we will only add that both his father and mother became wolves. His mother took the part of the castrated wolf, which let the others climb upon it; his father took the part of the wolf that climbed. But his fear, as we have heard him assure us, related only to the standing wolf, that is, to his father. It must further strike us that the fear with which the dream ended had a model in his grandfather's story. For in this the castrated wolf, which had let the others climb upon it, was seized with fear as soon as it was reminded of the fact of its taillessness. It seems, therefore, as though he had identified himself with his castrated mother during the dream, and was now fighting against that fact. 'If you want to be sexually satisfied by Father', we may perhaps represent him as saying to himself, 'you must allow yourself to be castrated like Mother; but I won't have that.' In short, a clear protest on the part of his masculinity! Let us, however, plainly understand that the sexual development of the case that we are now examining has a great disadvantage from the point of view of research, for it was by no means undisturbed. It was first decisively influenced by the seduction, and was then diverted by the scene of observation of the coitus, which in its deferred action operated like a second seduction.

Let us now consider the phobia. It came into existence on the level of the genital organization, and shows us the relatively simple mechanism of an anxiety-hysteria. The ego, by developing anxiety, was protecting itself against what it regarded as an overwhelming danger, namely, homosexual satisfaction. But the process of repression left behind it a trace which cannot be overlooked. The object to which the dangerous sexual aim had been attached had to have its place taken in consciousness by another one. What became conscious was fear of the wolf. It must further strike us that the process stop at the formation of a phobia with a single content. A considerable time afterwards the wolf was replaced by the lion. Simultaneously with sadistic impulses against small animals there was a phobia directed towards them, in their capacity of representatives of the boy's rivals, the possible small children. The origin of the butterfly phobia is of especial interest. It was like a repetition of the mechanism that produced the wolf phobia in the dream. Owing to a chance stimulus an old experience, the scene with Grusha, was activated; her threat of castration thus produced deferred effects, though at the time it was uttered it had made no impression.
It may truly be said that the anxiety that was concerned in the formation of these phobias was a fear of castration. This statement involves no contradiction of the view that the anxiety originated from the repression of homosexual libido. Both modes of expression refer to the same process: namely, the withdrawal of libido by the ego from the homosexual wishful impulse, the libido having then become converted into free anxiety and subsequently bound in phobias. The first method of statement merely mentions in addition the motive by which the ego was actuated. [1918b, 3589]

The transformation did not occur spontaneously, through internal development, but through an outside influence. Its visible effect was that the patient's relation to his father, which stood in the foreground, and which had so far found expression in the wolf phobia, was now manifested in obsessional piety. I cannot refrain from pointing out that the course of events in this part of the patient's history affords an unmistakable confirmation of an assertion which I made in Totem and Taboo upon the relation of the totem animal to the deity.¹ I there decided in favour of the view that the idea of God was not a development from the totem, but replaced it after arising independently from a root common to both ideas. The totem, I maintained, was the first father-surrogate, and the god was a later one, in which the father had regained his human shape. And we find the same thing with our patient. In his wolf phobia he had gone through the stage of the totemic father-surrogate; but that stage was now broken off, and, as a result of new relations between him and his father, was replaced by a phase of religious piety. [1918b, 3590]
These are unwelcome complications, considering that we only set out to study simple cases of symptom-formation due to repression, and with that intention selected the earliest and to all appearances, most transparent neuroses of childhood. Instead of a single repression we have found a collection of them and have become involved with regression into the bargain. Perhaps we have added to the confusion by treating the two cases of animal phobia at our disposal - 'Little Hans' and the 'Wolf Man' - as though they were cast in the same mould. As a matter of fact, certain differences between them stand out. It is only with regard to 'Little Hans' that we can say with certainty that what his phobia disposed of were the two main impulses of the Oedipus complex - his aggressiveness towards his father and his over-fondness for his mother. A tender feeling for his father was undoubtedly there too and played a part in repressing the opposite feeling; but we can prove neither that it was strong enough to draw repression upon itself nor that it disappeared afterwards. 'Hans' seems, in fact, to have been a normal boy with what is called a 'positive' Oedipus complex. It is possible that the factors which we do not find were actually at work in him, but we cannot demonstrate their existence. Even the most exhaustive analysis has gaps in its data and is insufficiently documented. In the case of the Russian the deficiency lies elsewhere. His attitude to female objects had been disturbed by an early seduction and his passive, feminine side was strongly developed. The analysis of his wolf-dream revealed very little intentional aggressiveness towards his father, but it brought forward unmistakable proof that what repression overtook was his passive tender attitude to his father. In his case, too, the other factors may have been operative as well; but they were not in evidence. How is it that, in spite of these differences in the two cases, almost amounting to an antithesis, the final outcome - a phobia - was approximately the same? The answer must be sought in another quarter. I think it will be found in the second fact which emerges from our brief comparative examination. It seems to me that in both cases we can detect what the motive force of the repression was and can substantiate our view of its nature from the line of development which the two children subsequently pursued. This motive force was the same in both of them. It was the fear of impending castration. 'Little Hans' gave up his aggressiveness towards his father from fear of being castrated. His fear that a horse would bite him can, without any forcing, be given the full sense of a fear that a horse would bite off his genitals, would castrate him. But it was from fear of being castrated, too, that the little Russian relinquished his wish to be loved by his father, for he thought that a relation of that sort presupposed a sacrifice of his genitals - of the organ which distinguished him from a female. As we see, both forms of the Oedipus complex, the normal, active form and the inverted one, came to grief through the castration complex. The Russian boy's anxiety-idea of being devoured by a wolf contained, it is true, no suggestion of castration, for the oral regression it had undergone had removed it too far from the phallic stage. But the analysis of his dream rendered further proof superfluous. It was a triumph of repression that the form in which his phobia was expressed should no longer have contained any allusion to castration.

Here, then, is our unexpected finding: in both patients the motive force of the repression was fear of castration. The ideas contained in their anxiety - being bitten by a horse and being devoured by a wolf - were substitutes by distortion for the idea of being castrated by their father. This was the idea which had undergone repression. In the Russian boy the idea was an expression of a wish which was not able to subsist in the face of his masculine revolt; in 'Little Hans' it was the expression of a reaction in him which had turned his aggressiveness into its opposite. But the affect of anxiety, which was the essence of the phobia, came, not from the process of repression, not from the libidinal cathexes of the repressed impulses, but from the repressing agency itself. The anxiety belonging to the animal phobias was an untransformed fear of castration. It was therefore a realistic fear, a fear of a danger which was actually impending or was judged to be a real one. It was anxiety which produced repression and not, as I formerly believed, repression which produced anxiety.
It is no use denying the fact, though it is not pleasant to recall it, that I have on many occasions asserted that in repression the instinctual representative is distorted, displaced and so on, while the libido belonging to the instinctual impulse is transformed into anxiety. But now an examination of phobias, which should be best able to provide confirmatory evidence, fails to bear out my assertion; it seems, rather, to contradict it directly. The anxiety felt in animal phobias is the ego's fear of castration; while the anxiety felt in agoraphobia (a subject that has been less thoroughly studied) seems to be its fear of sexual temptation - a fear which, after all, must be connected in its origins with the fear of castration. As far as can be seen at present, the majority of phobias go back to an anxiety of this kind felt by the ego in regard to the demands of the libido. It is always the ego's attitude of anxiety which is the primary thing and which sets repression going. Anxiety never arises from repressed libido. If I had contented myself earlier with saying that after the occurrence of repression a certain amount of anxiety appeared in place of the manifestation of libido that was to be expected, I should have nothing to retract to-day. The description would be correct; and there does undoubtedly exist a correspondence of the kind asserted between the strength of the impulse that has to be repressed and the intensity of the resultant anxiety. But I must admit that I thought I was giving more than a mere description. I believed I had put my finger on a metapsychological process of direct transformation of libido into anxiety. I can now no longer maintain this view. And, indeed, I found it impossible at the time to explain how a transformation of that kind was carried out.

[1926d, 4268]

This is as far as our investigations into the formation of symptoms take us. It is hardly worth while summing them up, for the results they have yielded are scanty and incomplete and tell us scarcely anything that we do not already know. It would be fruitless to turn our attention to symptom-formation in other disorders besides phobias, conversion hysteria and obsessional neurosis, for too little is known about them. But in reviewing those three neuroses together we are brought up against a very serious problem the consideration of which can no longer be put off. All three have as their outcome the destruction of the Oedipus complex; and in all three the motive force of the ego's opposition is, we believe, the fear of castration. Yet it is only in the phobias that this fear comes to the surface and is acknowledged. What has become of it in the other two neuroses? How has the ego spared itself this fear? The problem becomes accentuated when we recall the possibility, already referred to, that anxiety arises directly, by a kind of fermentation, from a libidinal cathexis whose processes have been disturbed. Furthermore, is it absolutely certain that fear of castration is the only motive force of repression (or defence)? If we think of neuroses in women we are bound to doubt it. For though we can with certainty establish in them the presence of a castration complex, we can hardly speak with propriety of castration anxiety where castration has already taken place.

[1926d, 4281]
Let us go back again to infantile phobias of animals; for, when all is said and done, we understand them better than any other cases. In animal phobias, then, the ego has to oppose a libidinal object-cathexis coming from the id - a cathexis that belongs either to the positive or the negative Oedipus complex - because it believes that to give way to it would entail the danger of castration. This question has already been discussed, but there still remains a doubtful point to clear up. In 'Little Hans's' case - that is, in the case of a positive Oedipus complex - was it his fondness for his mother or was it his aggressiveness towards his father which called out the defence by the ego? In practice it seems to make no difference, especially as each set of feelings implies the other; but the question has a theoretical interest, since it is only the feeling of affection for the mother which can count as a purely erotic one. The aggressive impulse flows mainly from the destructive instinct; and we have always believed that in a neurosis it is against the demands of the libido and not against those of any other instinct that the ego is defending itself. In point of fact we know that after 'Hans's' phobia had been formed, his tender attachment to his mother seemed to disappear, having been completely disposed of by repression, while the formation of the symptom (the substitutive formation) took place in relation to his aggressive impulses. In the 'Wolf Man' the situation was simpler. The impulse that was repressed - his feminine attitude towards his father - was a genuinely erotic one; and it was in relation to that impulse that the formation of his symptoms took place.

This time we will not lose sight of the part played by anxiety. We have said that as soon as the ego recognizes the danger of castration it gives the signal of anxiety and inhibits through the pleasure-unpleasure agency (in a way which we cannot as yet understand) the impending cathetic process in the id. At the same time the phobia is formed. And now the castration anxiety is directed to a different object and expressed in a distorted form, so that the patient is afraid, not of being castrated by his father, but of being bitten by a horse or devoured by a wolf. This substitutive formation has two obvious advantages. In the first place it avoids a conflict due to ambivalence (for the father was a loved object, too), and in the second place it enables the ego to cease generating anxiety. For the anxiety belonging to a phobia is conditional; it only emerges when the object of it is perceived - and rightly so, since it is only then that the danger-situation is present. There is no need to be afraid of being castrated by a father who is not there. On the other hand one cannot get rid of a father; he can appear whenever he chooses. But if he is replaced by an animal, all one has to do is to avoid the sight of it - that is, its presence - in order to be free from danger and anxiety. 'Little Hans', therefore, imposed a restriction upon his ego. He produced the inhibition of not leaving the house, so as not to come across any horses. The young Russian had an even easier time of it, for it was hardly a privation for him not to look at a particular picture-book any more. If his naughty sister had not kept on showing him the book with the picture of the wolf standing upright in it, he would have been able to feel safe from his fear.

On a previous occasion I have stated that phobias have the character of a projection in that they replace an internal, instinctual danger by an external, perceptual one. The advantage of this is that the subject can protect himself against an external danger by fleeing from it and avoiding the perception of it, whereas it is useless to flee from dangers that arise from within. This statement of mine was not incorrect, but it did not go below the surface of things. For an instinctual demand is, after all, not dangerous in itself; it only becomes so inasmuch as it entails a real external danger, the danger of castration. Thus what happens in a phobia in the last resort is merely that one external danger is replaced by another. The view that in a phobia the ego is able to escape anxiety by means of avoidance or of inhibitory symptoms fits in very well with the theory that that anxiety is only an affective signal and that no alteration has taken place in the economic situation.
The anxiety felt in animal phobias is, therefore, an affective reaction on the part of the ego to danger; and the danger which is being signalled in this way is the danger of castration. This anxiety differs in no respect from the realistic anxiety which the ego normally feels in situations of danger, except that its content remains unconscious and only becomes conscious in the form of a distortion. [1926d, 4283]

The same will prove true, I think, of the phobias of adults, although the material which their neuroses work over is much more abundant and there are some additional factors in the formation of the symptoms. Fundamentally the position is identical. The agoraphobic patient imposes a restriction on his ego so as to escape a certain instinctual danger - namely, the danger of giving way to his erotic desires. For if he did so the danger of being castrated, or some similar danger, would once more be conjured up as it was in his childhood. I may cite as an instance the case of a young man who became agoraphobic because he was afraid of yielding to the solicitations of prostitutes and of contracting a syphilitic infection from them as a punishment. [1926d, 4283]

The conclusion we have come to, then, is this. Anxiety is a reaction to a situation of danger. It is obviated by the ego's doing something to avoid that situation or to withdraw from it. It might be said that symptoms are created so as to avoid the generating of anxiety. But this does not go deep enough. It would be truer to say that symptoms are created so as to avoid a danger-situation whose presence has been signalled by the generation of anxiety. In the cases that we have discussed, the danger concerned was the danger of castration or of something traceable back to castration. [1926d, 4285]

When, in an earlier part of this discussion, we found that the danger of castration was of importance in more than one neurotic illness, we put ourselves on guard against overestimating that factor, since it could not be a decisive one for the female sex, who are undoubtedly more subject to neuroses than men. We now see that there is no danger of our regarding castration anxiety as the sole motive force of the defensive processes which lead to neurosis. I have shown elsewhere how little girls, in the course of their development, are led into making a tender object-cathexis by their castration complex. It is precisely in women that the danger situation of loss of object seems to have remained the most effective. All we need to do is to make a slight modification in our description of their determinant of anxiety, in the sense that it is no longer a matter of feeling the want of, or actually losing the object itself, but of losing the object's love. Since there is no doubt that hysteria has a strong affinity with femininity, just as obsessional neurosis has with masculinity, it appears probable that, as a determinant of anxiety, loss of love plays much the same part in hysteria as the threat of castration does in phobias and fear of the super-ego in obsessional neurosis. [1926d, 4298]
But we have not made any mention at all so far of what the real danger is that the child is afraid of as a result of being in love with his mother. The danger is the punishment of being castrated, of losing his genital organ. You will of course object that after all that is not a real danger. Our boys are not castrated because they are in love with their mothers during the phase of the Oedipus complex. But the matter cannot be dismissed so simply. Above all, it is not a question of whether castration is really carried out; what is decisive is that the danger is one that threatens from outside and that the child believes in it. He has some ground for this, for people threaten him often enough with cutting off his penis during the phallic phase, at the time of his early masturbation, and hints at that punishment must regularly find a phylogenetic reinforcement in him. It is our suspicion that during the human family's primaeval period castration used actually to be carried out by a jealous and cruel father upon growing boys, and that circumcision, which so frequently plays a part in puberty rites among primitive peoples, is a clearly recognizable relic of it. We are aware that here we are diverging widely from the general opinion; but we must hold fast to the view that fear of castration is one of the commonest and strongest motives for repression and thus for the formation of neuroses. The analysis of cases in which circumcision, though not, it is true, castration, has been carried out on boys as a cure or punishment for masturbation (a far from rare occurrence in Anglo-American society) has given our conviction a last degree of certainty. It is very tempting at this point to go more deeply into the castration complex, but I will stick to our subject.

Otto Rank, to whom psycho-analysis is indebted for many excellent contributions, also has the merit of having expressly emphasized the significance of the act of birth and of separation from the mother. Nevertheless we have all found it impossible to accept the extreme inferences which he has drawn from this factor as bearing on the theory of the neuroses and even on analytic therapy. The core of his theory - that the experience of anxiety at birth is the model of all later situations of danger - he found already there. If we dwell on these situations of danger for a moment, we can say that in fact a particular determinant of anxiety (that is, situation of danger) is allotted to every age of development as being appropriate to it. The danger of psychical helplessness fits the stage of the ego's early immaturity; the danger of loss of an object (or loss of love) fits the lack of self-sufficiency in the first years of childhood; the danger of being castrated fits the phallic phase; and finally fear of the super-ego, which assumes a special position, fits the period of latency. In the course of development the old determinants of anxiety should be dropped, since the situations of danger corresponding to them have lost their importance owing to the strengthening of the ego. But this only occurs most incompletely. Many people are unable to surmount the fear of loss of love; they never become sufficiently independent of other people's love and in this respect carry on their behaviour as infants. Fear of the super-ego should normally never cease, since, in the form of moral anxiety, it is indispensable in social relations, and only in the rarest cases can an individual become independent of human society. A few of the old situations of danger, too, succeed in surviving into later periods by making contemporary modifications in their determinants of anxiety. Thus, for instance, the danger of castration persists under the mark of syphilidophobia. It is true that as an adult one knows that castration is no longer customary as a punishment for the indulgence of sexual desires, but on the other hand one has learnt that instinctual liberty of that kind is threatened by serious diseases. There is no doubt that the people we describe as neurotics remain infantile in their attitude to danger and have not surmounted obsolete determinants of anxiety. We may take this as a factual contribution to the characterization of neurotics; it is not so easy to say why it should be so.

[1933a, 4693]
In a few instances a change of expression of this kind assists dream-condensation even more directly, by finding a form of words which owing to its ambiguity is able to give expression to more than one of the dream-thoughts. In this way the whole domain of verbal wit is put at the disposal of the dream-work. There is no need to be astonished at the part played by words in dream-formation. Words, since they are the nodal point of numerous ideas, may be regarded as predestined to ambiguity; and the neuroses (e.g. in framing obsessions and phobias), no less than dreams, make unashamed use of the advantages thus offered by words for purposes of condensation and disguise.¹ It is easy to show that dream-distortion too profits from displacement of expression. If one ambiguous word is used instead of two unambiguous ones the result is misleading; and if our everyday, sober method of expression is replaced by a pictorial one, our understanding is brought to a halt, particularly since a dream never tells us whether its elements are to be interpreted literally or in a figurative sense or whether they are to be connected with the material of the dream-thoughts directly or through the intermediary of some interpolated phraseology. In interpreting any dream-element it is in general doubtful [1900a, 810]

² ["Wegen dem Pferd"] I may explain that Hans was not maintaining that he had got the nonsense at that time but in that connection. Indeed, it must have been so, for theoretical considerations require that what is to-day the object of a phobia must at one time in the past have been the source of a high degree of pleasure. I may at the same time complete what the child was unable to express, and add that the little word 'wegen' ['because of', 'cos of'] was the means of enabling the phobia to extend from horses on to 'Wagen' ['vehicles'] or, as Hans was accustomed to pronounce the word and hear it pronounced, 'Wägen' [pronounced exactly like 'wegen']. It must never be forgotten how much more concretely children treat words than grown-up people do, and consequently how much more significant for them are similarities of sound in words. [1909b, 2047]
A dream tells us that something was going on which tended to interrupt sleep, and it enables us to understand in what way it has been possible to fend off this interruption. The final outcome is that the sleeper has dreamt and is able to go on sleeping; the internal demand which was striving to occupy him has been replaced by an external experience, whose demand has been disposed of. A dream is, therefore, among other things, a projection: an externalization of an internal process. We may recall that we have already met with projection elsewhere among the means adopted for defence. The mechanism of a hysterical phobia, too, culminates in the fact that the subject is able to protect himself by attempts at flight against an external danger which has taken the place of an internal instinctual claim. We will, however, defer the full treatment of projection till we come to analyse the narcissistic disorder in which this mechanism plays the most striking part.

[1917d, 3028]

We have pointed out how the living vesicle is provided with a shield against stimuli from the external world; and we had previously shown that the cortical layer next to that shield must be differentiated as an organ for receiving stimuli from without. This sensitive cortex, however, which is later to become the system Cs., also receives excitations from within. The situation of the system between the outside and the inside and the difference between the conditions governing the reception of excitation in the two cases have a decisive effect on the functioning of the system and of the whole mental apparatus. Towards the outside it is shielded against stimuli, and the amounts of excitation impinging on it have only a reduced effect. Towards the inside there can be no such shield; the excitations in the deeper layers extend into the system directly and in undiminished amount, in so far as certain of their characteristics give rise to feelings in the pleasure-unpleasure series. The excitations coming from within are, however, in their intensity and in other, qualitative, respects - in their amplitude, perhaps - more commensurate with the system's method of working than the stimuli which stream in from the external world. This state of things produces two definite results. First, the feelings of pleasure and unpleasure (which are an index to what is happening in the interior of the apparatus) predominate over all external stimuli. And secondly, a particular way is adopted of dealing with any internal excitations which produce too great an increase of unpleasure: there is a tendency to treat them as though they were acting, not from the inside, but from the outside, so that it may be possible to bring the shield against stimuli into operation as a means of defence against them. This is the origin of projection, which is destined to play such a large part in the causation of pathological processes.

[1920g, 3732]

On a previous occasion I have stated that phobias have the character of a projection in that they replace an internal, instinctual danger by an external, perceptual one. The advantage of this is that the subject can protect himself against an external danger by fleeing from it and avoiding the perception of it, whereas it is useless to flee from dangers that arise from within. This statement of mine was not incorrect, but it did not go below the surface of things. For an instinctual demand is, after all, not dangerous in itself; it only becomes so inasmuch as it entails a real external danger, the danger of castration. Thus what happens in a phobia in the last resort is merely that one external danger is replaced by another. The view that in a phobia the ego is able to escape anxiety by means of avoidance or of inhibitory symptoms fits in very well with the theory that that anxiety is only an affective signal and that no alteration has taken place in the economic situation.

[1926d, 4283]
What we have learnt about anxiety in phobias is applicable to obsessional neuroses as well. In this respect it is not difficult for us to put obsessional neuroses on all fours with phobias. In the former, the mainspring of all later symptom-formation is clearly the ego's fear of its super-ego. The danger-situation from which the ego must get away is the hostility of the super-ego. There is no trace of projection here; the danger is completely internalized. But if we ask ourselves what it is that the ego fears from the super-ego, we cannot but think that the punishment threatened by the latter must be an extension of the punishment of castration. Just as the father has become depersonalized in the shape of the super-ego, so has the fear of castration at his hands become transformed into an undefined social or moral anxiety. But this anxiety is concealed. The ego escapes it by obediently carrying out the commands, precautions and penances that have been enjoined on it. If it is impeded in doing so, it is at once overtaken by an extremely distressing feeling of discomfort which may be regarded as an equivalent of anxiety and which the patients themselves liken to anxiety.

In phobias it is very easy to observe the way in which this internal danger is transformed into an external one - that is to say, how a neurotic anxiety is changed into an apparently realistic one. In order to simplify what is often a very complicated business, let us suppose that the agoraphobic patient is invariably afraid of feelings of temptation that are aroused in him by meeting people in the street. In his phobia he brings about a displacement and henceforward is afraid of an external situation. What he gains by this is obviously that he thinks he will be able to protect himself better in that way. One can save oneself from an external danger by flight; fleeing from an internal danger is a difficult enterprise.
Both kinds of phobias (and also obsessions) often appear side by side; although the *atypical* phobias, which are based on obsessions, need not necessarily spring from the soil of anxiety neurosis. A very frequent and apparently complicated mechanism makes its appearance if, in what was originally a simple phobia belonging to an anxiety neurosis, the content of the phobia is replaced by another idea, so that the substitute is *subsequent* to the phobia. What are most often employed as substitutes are the *protective measures* that were originally used to combat the phobia. Thus, for instance, 'brooding mania' arises from the subject's endeavours to disprove that he is mad, as his hypochondriacal phobia maintains; the hesitations and doubt, and still more the repetitions, of *folie du doute* arise from a justifiable doubt about the certainty of one's own train of thought, since one is conscious of its persistent disturbance by ideas of an obsessional sort, and so on. We can therefore assert that many syndromes, too, of obsessional neurosis, such as *folie du doute* and the like, are also to be reckoned, clinically if not conceptually, as belonging to anxiety neurosis.

[1895b, 334]

**MECHANICAL EXCITATIONS** At this point we must also mention the production of sexual excitation by rhythmic mechanical agitation of the body. Stimuli of this kind operate in three different ways: on the sensory apparatus of the vestibular nerves, on the skin, and on the deeper parts (e.g. the muscles and articular structures). The existence of these pleasurable sensations - and it is worth emphasizing the fact that in this connection the concepts of 'sexual excitation' and 'satisfaction' can to a great extent be used without distinction, a circumstance which we must later endeavour to explain - the existence, then, of these pleasurable sensations, caused by forms of mechanical agitation of the body, is confirmed by the fact that children are so fond of games of passive movement, such as swinging and being thrown up into the air, and insist on such games being incessantly repeated.¹ It is well known that rocking is habitually used to induce sleep in restless children. The shaking produced by driving in carriages and later by railway-travel exercises such a fascinating effect upon older children that every boy, at any rate, has at one time or other in his life wanted to be an engine driver or a coachman. It is a puzzling fact that boys take such an extraordinarily intense interest in things connected with railways, and, at the age at which the production of phantasies is most active (shortly before puberty), use those things as the nucleus of a symbolism that is peculiarly sexual. A compulsive link of this kind between railway-travel and sexuality is clearly derived from the pleasurable character of the sensations of movement. In the event of repression, which turns so many childish preferences into their opposite, these same individuals, when they are adolescents or adults, will react to rocking or swinging with a feeling of nausea, will be terribly exhausted by a railway journey, or will be subject to attacks of anxiety on the journey and will protect themselves against a repetition of the painful experience by a dread of railway-travel. [1905d, 1520]
We are also now coming to the opinion that analytic technique must be modified in certain ways according to the nature of the disease and the dominant instinctual trends in the patient. We started out from the treatment of conversion hysteria; in anxiety hysteria (phobias) we must to some extent alter our procedure. For these patient cannot bring out the material necessary for resolving their phobia so long as they feel protected by obeying the condition which it lays down. One cannot, of course, succeed in getting them to give up their protective measures and work under the influence of anxiety from the beginning of the treatment. One must therefore help them by interpreting their unconscious to them until they can make up their minds to do without the protection of their phobia and expose themselves to a now greatly mitigated anxiety. Only after they have done so does the material become accessible, which, when it has been mastered, leads to a solution of the phobia. Other modifications of technique, which seem to me not yet ripe for discussion, will be required in the treatment of obsessional neurosis. In this connection very important questions arise, which have not hitherto been elucidated: how far the instincts which the patient is combating are to be allowed some satisfaction during the treatment, and what difference it makes whether these impulses are active (sadistic) or passive (masochistic) in their nature.

I have said that transformation into anxiety - it would be better to say discharge in the form of anxiety - is the immediate vicissitude of libido which is subjected to repression. I must add that that vicissitude is not the only or the definitive one. In the neuroses processes are in action which endeavour to bind this generating of anxiety and which even succeed in doing so in various ways. In phobias, for instance, two phases of the neurotic process can be clearly distinguished. The first is concerned with repression and the changing of libido into anxiety, which is then bound to an external danger. The second consists in the erection of all the precautions and guarantees by means of which any contact can be avoided with this danger, treated as it is like an external thing. Repression corresponds to an attempt at flight by the ego from libido which is felt as a danger. A phobia may be compared to an entrenchment against an external danger which now represents the dreaded libido. The weakness of the defensive system in phobias lies, of course, in the fact that the fortress which has been so greatly strengthened towards the outside remains assailable from within. A projection outwards of the danger of libido can never succeed thoroughly. For that reason, in other neuroses other systems of defence are in use against the possible generation of anxiety. That is a most interesting part of the psychology of the neuroses; but unluckily it would lead us too far and it presupposes a deeper specialized knowledge. I will only add one thing more. I have already spoken to you of the 'anticathexis' which is employed by the ego in the process of repression and which must be permanently maintained in order that the repression may have stability. This anticathexis has the task of carrying through the various forms of defence against the generating of anxiety after repression.

The ego is the actual seat of anxiety. Threatened by dangers from three directions, it develops the flight-reflex by withdrawing its own cathexis from the menacing perception or from the similarly regarded process in the id, and emitting it as anxiety. This primitive reaction is later replaced by the carrying-out of protective cathexes (the mechanism of the phobias). What it is that the ego fears from the external and from the libidinal danger cannot be specified; we know that the fear is of being overwhelmed or annihilated, but it cannot be grasped analytically. The ego is simply obeying the warning of the pleasure principle. On the other hand, we can tell what is hidden behind the ego's dread of the super-ego, the fear of conscience. The superior being, which turned into the ego ideal, once threatened castration, and this dread of castration is probably the nucleus round which the subsequent fear of conscience has gathered; it is this dread that persists as the fear of conscience.
A phobia generally sets in after a first anxiety attack has been experienced in specific circumstances, such as in the street or in a train or in solitude. Thereafter the anxiety is held in ban by the phobia, but it re-emerges whenever the protective condition cannot be fulfilled. The mechanism of phobia does good service as a means of defence and tends to be very stable. A continuation of the defensive struggle, in the shape of a struggle against the symptom, occurs frequently but not invariably.

[1926d, 4285]
Both kinds of phobias (and also obsessions) often appear side by side; although the atypical phobias, which are based on obsessions, need not necessarily spring from the soil of anxiety neurosis. A very frequent and apparently complicated mechanism makes its appearance if, in what was originally a simple phobia belonging to an anxiety neurosis, the content of the phobia is replaced by another idea, so that the substitute is subsequent to the phobia. What are most often employed as substitutes are the 'protective measures' that were originally used to combat the phobia. Thus, for instance, 'brooding mania' arises from the subject's endeavours to disprove that he is mad, as his hypochondriacal phobia maintains; the hesitations and doubt, and still more the repetitions, of folie du doute arise from a justifiable doubt about the certainty of one's own train of thought, since one is conscious of its persistent disturbance by ideas of an obsessional sort, and so on. We can therefore assert that many syndromes, too, of obsessional neurosis, such as folie du doute and the like, are also to be reckoned, clinically if not conceptually, as belonging to anxiety neurosis.²

[1895b, 334]
(7) On the basis of chronic anxiousness (anxious expectation) on the one hand, and a tendency to anxiety attacks accompanied by vertigo on the other, two groups of typical phobias develop, the first relating to general physiological dangers, the second relating to locomotion. To the first group belong fear of snakes, thunderstorms, darkness, vermin, and so on, as well as the typical moral over-scrupulousness and forms of doubting mania. Here the available anxiety is simply employed to reinforce aversions which are instinctively implanted in everyone. But as a rule a phobia which acts in an obsessional manner is only formed if there is added to this the recollection of an experience in which the anxiety was able to find expression as, for instance, after the patient has experienced a thunderstorm in the open. It is a mistake to try to explain such cases as being simply a persistence of strong impressions; what makes these experiences significant and the memory of them lasting is, after all, only the anxiety which was able to emerge at the time and which can similarly emerge now. In other words, such impressions remain powerful only in people with 'anxious expectation'.

[1895b, 333]

[1895b, 333]

At the end of this dream, which is clearly charged with anxiety, the dreamer falls out of bed.
This is a fresh representation of childbirth. Analytic investigation of the fear of heights, of the
dread of an impulse to throw oneself out of the window, has doubtless led you all to the same
conclusion.
[1922a, 3892]

¹ It may quite often happen that although a danger-situation is correctly estimated in itself, a certain
amount of instinctual anxiety is added to the realistic anxiety. In that case the instinctual demand before
whose satisfaction the ego recoils is a masochistic one: the instinct of destruction directed against the
subject himself. Perhaps an addition of this kind explains cases in which reactions of anxiety are
exaggerated, inexpedient or paralysing. Phobias of heights (windows, towers, precipices and so on) may
have some such origin. Their hidden feminine significance is closely connected with masochism.
[1926d, 4320]
(c) In some neurotic conditions locomotion is inhibited by a disinclination to walk or a weakness in walking. In hysteria there will be a paralysis of the motor apparatus, or this one special function of the apparatus will be abolished (abasia). Especially characteristic are the increased difficulties that appear in locomotion owing to the introduction of certain stipulations whose non-observance results in anxiety (phobia).
[1926d, 4250]
Moreover, a 'station' is used for purposes of 'Verkehr' ['traffic', 'intercourse', 'sexual intercourse']: this fact determines the psychical coating in a number of cases of railway phobia.
[1905e, 1435]

MECHANICAL EXCITATIONS   At this point we must also mention the production of sexual excitation by rhythmic mechanical agitation of the body. Stimuli of this kind operate in three different ways: on the sensory apparatus of the vestibular nerves, on the skin, and on the deeper parts (e.g. the muscles and articular structures). The existence of these pleasurable sensations - and it is worth emphasizing the fact that in this connection the concepts of 'sexual excitation' and 'satisfaction' can to a great extent be used without distinction, a circumstance which we must later endeavour to explain - the existence, then, of these pleasurable sensations, caused by forms of mechanical agitation of the body, is confirmed by the fact that children are so fond of games of passive movement, such as swinging and being thrown up into the air, and insist on such games being incessantly repeated.¹ It is well known that rocking is habitually used to induce sleep in restless children. A compulsive link of this kind between railway-travel and sexuality is clearly derived from the pleasurable character of the sensations of movement. In the event of repression, which turns so many childish preferences into their opposite, these same individuals, when they are adolescents or adults, will react to rocking or swinging with a feeling of nausea, will be terribly exhausted by a railway journey, or will be subject to attacks of anxiety on the journey and will protect themselves against a repetition of the painful experience by a dread of railway-travel.
[1905d, 1520]

The two forms of anxiety that I have just described - the freely floating expectant anxiety and the sort which is bound to phobias - are independent of each other. One is not a higher stage, as it were, of the other; and they only appear simultaneously in exceptional cases and, so to speak, accidentally. The most powerful general apprehensiveness need not be expressed in phobias; people whose whole existence is restricted by agoraphobia may be entirely free from pessimistic expectant anxiety. Some phobias - for instance, agoraphobia and railway phobia - are demonstrably acquired at a fairly mature age, while others - such as fear of darkness, thunderstorms and animals - seem to have been present from the first. Those of the former kind have the significance of severe illnesses; the latter make their appearance rather as eccentricities or whims. If a person exhibits one of these latter, one may suspect as a rule that he will have other similar ones. I must add that we class all these phobias as anxiety hysteria; that is to say, we regard them as a disorder closely related to the familiar conversion hysteria.
[1916-1917, 3447]
A patient, then, may be suffering from fluctuations in his moods which he cannot control, or from a sense of despondency by which his energy feels paralysed because he thinks he is incapable of doing anything properly, or from a nervous embarrassment among strangers. He may perceive, without understanding the reason for it, that he has difficulties in carrying out his professional work, or indeed any comparatively important decision or any undertaking. He may one day have suffered from a distressing attack - unknown in its origin - of feelings of anxiety, and since then have been unable, without a struggle, to walk along the street alone, or to travel by train; he may perhaps have had to give up both entirely. Or, a very remarkable thing, his thoughts may go their own way and refuse to be directed by his will. They pursue problems that are quite indifferent to him, but from which he cannot get free. Quite ludicrous tasks, too, are imposed on him, such as counting up the windows on the fronts of houses. And when he has performed simple actions such as posting a letter or turning off a gas-jet, he finds himself a moment later doubting whether he has really done so. This may be no more than an annoyance and a nuisance. But his state becomes intolerable if he suddenly finds he is unable to fend off the idea that he has pushed a child under the wheels of a car or has thrown a stranger off the bridge into the water, or if he has to ask himself whether he is not the murderer whom the police are looking for in connection with a crime that was discovered that day. It is obvious nonsense, as he himself knows; he has never done any harm to anyone; but if he were really the murderer who is being looked for, his feeling - his sense of guilt - could not be stronger.
The other group includes agoraphobia with all its accessory forms, the whole of them characterized by their relation to locomotion. We frequently find that this phobia is based on an attack of vertigo that has preceded it; but I do not think that one can postulate such an attack in every case. Occasionally we see that after a first attack of vertigo without anxiety, locomotion, although henceforward constantly accompanied by a sensation of vertigo, still continues to be possible without restriction; but that, under certain conditions - such as being alone or in a narrow street - when once anxiety is added to the attack of vertigo, locomotion breaks down. [1895b, 333]

On another occasion I had an opportunity of obtaining a deep insight into the unconscious mind of a young man whose life was made almost impossible by an obsessional neurosis. He was unable to go out into the street because he was tortured by the fear that he would kill everyone he met. He spent his days in preparing his alibi in case he might be charged with one of the murders committed in the town. It is unnecessary to add that he was a man of equally high morals and education. The analysis (which, incidentally, led to his recovery) showed that the basis of this distressing obsession was an impulse to murder his somewhat over-severe father. This impulse, to his astonishment, had been consciously expressed when he was seven years old, but it had, of course, originated much earlier in his childhood. After his father's painful illness and death, the patient's obsessional self-reproaches appeared - he was in his thirty-first year at the time - taking the shape of a phobia transferred on to strangers. A person, he felt, who was capable of wanting to push his own father over a precipice from the top of a mountain was not to be trusted to respect the lives of those less closely related to him; he was quite right to shut himself up in his room.
[1900a, 739]

(Extract from the dream of a young woman suffering from agoraphobia as a result of fears of seduction.)
[1900a, 824]

There is no longer anything contradictory to us in the notion that a psychical process which develops anxiety can nevertheless be the fulfilment of a wish. We know that it can be explained by the fact that the wish belongs to one system, the Ucs., while it has been repudiated and suppressed by the other system, the Pcs.¹ Even where psychical health is perfect, the subjugation of the Ucs. by the Pcs. is not complete; the measure of suppression indicates the degree of our psychical normality. Neurotic symptoms show that the two systems are in conflict with each other; they are the products of a compromise which brings the conflict to an end for the time being. On the one hand, they allow the Ucs. an outlet for the discharge of its excitation, and provide it with a kind of sally-port, while, on the other hand they make it possible for the Pcs. to control the Ucs. to some extent. It is instructive to consider, for instance, the significance of a hysterical phobia or an agoraphobia. Let us suppose that a neurotic patient is unable to cross the street alone - a condition which we rightly regard as a 'symptom.' If we remove this symptom by compelling him to carry out the act of which he believes himself incapable, the consequence will be an attack of anxiety; and indeed the occurrence of an anxiety-attack in the street is often the precipitating cause of the onset of an agoraphobia. We see, therefore, that the symptom has been constructed in order to avoid an outbreak of anxiety; the phobia is erected like a frontier fortification against the anxiety.
[1900a, 1009]

² [Footnote added 1910:] The analysis of cases of neurotic abasia and agoraphobia removes all doubt as to the sexual nature of pleasure in movement. Modern education, as we know, makes great use of games in order to divert young people from sexual activity. It would be more correct to say that in these young people it replaces sexual enjoyment by pleasure in movement - and forces sexual activity back to one of its auto-erotic components.
[1905d, 1521]
Disorders of this kind are called 'phobias', and we might classify Hans's case as an agoraphobia if it were not for the fact that it is a characteristic of that complaint that the locomotion of which the patient is otherwise incapable can always be easily performed when he is accompanied by some specially selected person - in the last resort, by the physician. Hans's phobia did not fulfil this condition; it soon ceased having any relation to the question of locomotion and became more and more clearly concentrated upon horses. In the early days of his illness, when the anxiety was at its highest pitch, he expressed a fear that 'the horse'll come into the room', and it was this that helped me so much towards understanding his condition. [1909b, 2099]

In place of a single sick person let us put society - suffering as a whole from neuroses, though composed of sick and healthy members; and in place of individual acceptance in the one case let us put general recognition in the other. A little reflection will then show you that this substitution cannot in any way alter the outcome. The success which the treatment can have with the individual must occur equally with the community. Sick people will not be able to let their various neuroses become known - their anxious over-tenderness which is meant to conceal their hatred, their agoraphobia which tells of disappointed ambition, their obsessive actions which represent self-reproaches for evil intentions and precautions against them - if all their relatives and every stranger from whom they wish to conceal their mental processes know the general meaning of such symptoms, and if they themselves know that in the manifestations of their illness they are producing nothing that other people cannot instantly interpret. The effect, however, will not be limited to the concealment of the symptoms which, incidentally, it is often impossible to carry out; for this necessity for concealment destroys the use of being ill. Disclosure of the secret will have attacked, at its most sensitive point, the 'aetiological equation' from which neuroses arise - it will have made the gain from the illness illusory; and consequently the final outcome of the changed situation brought about by the physician's indiscretion can only be that the production of the illness will be brought to a stop. [1910d, 2312]

In just the same way, an inhibition upon movement (an abasia or an agoraphobia) will gradually become more complete and more detailed, when once that system has succeeded in installing itself as a representative of an unconscious wish and of the defence against the wish. Whatever other unconscious phantasies and operative reminiscences may be present in the patient force their way to expression as symptoms along this same path, once it has been opened, and group themselves into an appropriate new arrangement within the framework of the inhibition upon movement. Thus it would be a vain and indeed a foolish task to attempt to understand the complexities and details of the symptoms of (for example) an agoraphobia on the basis of its underlying premises; for the whole consistency and strictness of the combination are merely apparent. Just as with the façades of dreams, if we look more attentively we find the most blatant inconsistency and arbitrariness in the structure of symptoms. The real reason for the details of a systematic phobia of this kind lies in concealed determinants, which need have nothing to do with an inhibition upon movement; and that, too, is why these phobias take such various and contradictory shapes in different people. [1912-1913, 2738]
A nineteen-year-old girl, well developed and gifted, was the only child of parents to whom she was superior in education and intellectual liveliness. As a child she had been wild and high spirited, and in the course of the last few years had changed, without any visible cause, into a neurotic. She was very irritable, particularly towards her mother, always dissatisfied and depressed, and inclined to indecisiveness and doubt; finally she admitted that she was no longer able to walk by herself across squares or along comparatively wide streets. We will not concern ourselves much with her complicated illness, which called for at least two diagnoses - agoraphobia and obsessional neurosis - but will dwell only on the fact that she also developed a sleep-ceremonial, with which she tormented her parents. In a certain sense it may be said that every normal person has his sleep-ceremonial or that he has established certain necessary conditions the non-fulfilment of which interferes with his going to sleep; he has imposed certain forms on the transition from the waking to the sleeping state and repeats them in the same manner every evening. But everything that a healthy person requires as a necessary condition for sleep can be understood rationally, and if external circumstances call for a change he will comply easily and without waste of time. A pathological ceremonial, however, is unyielding and insists on being carried through, even at the cost of great sacrifices; it too is screened by having a rational basis and at a superficial glance seems to diverge from the normal only by a certain exaggerated meticulousness. On closer examination, nevertheless, we can see that the screen is insufficient, that the ceremonial comprises some stipulations which go far beyond its rational basis and others which positively run counter to it. Our present patient put forward as a pretext for her nightly precautions that she needed quiet in order to sleep and must exclude every source of noise. With that end in view she did two kinds of things. The big clock in her room was stopped, all the other clocks or watches in the room were removed, and her tiny wrist-watch was not allowed even to be inside her bedside table. Flower-pots and vases were collected on the writing-table so that they might not fall over in the night and break, and disturb her in her sleep. She was aware that these measures could find only an ostensible justification in the rule in favour of quiet: the ticking of the little watch would not have been audible even if it had been left lying on the top of the bedside table, and we have all had experience of the fact that the regular ticking of a pendulum-clock never disturbs sleep but acts, rather, as a soporific. She admitted too that her fear that flower-pots and vases, if they were left in their places, might fall over and break of their own accord lacked all plausibility. In the case of other stipulations made by the ceremonial the need for quiet was dropped as a basis. Indeed, the requirement that the door between her room and her parents' bedroom should stay half-open - the fulfilment of which she ensured by placing various objects in the open doorway - seemed on the contrary to act as a source of disturbing noises. But the most important stipulations related to the bed itself. The pillow at the top end of the bed must not touch the wooden back of the bedstead. The small top pillow must lie on this large pillow in one specific way only - namely, so as to form a diamond shape. Her head had then to lie exactly along the long diameter of the diamond. The eiderdown (or 'Duchent' as we call it in Austria) had to be shaken before being laid on the bed so that its bottom end became very thick; afterwards, however, she never failed to even out this accumulation of feathers by pressing them apart.
[1916-1917, 3345]
If any of you undertakes exertions of this kind, he will certainly gain a powerful impression of the wealth of evidential material. But he will also come up against a difficulty. The sense of a symptom lies, as we have found, in some connection with the patient's experience. The more individual is the form of the symptom the more reason we shall have for expecting to be able to establish this connection. The task is then simply to discover, in respect to a senseless idea and a pointless action, the past situation in which the idea was justified and the action served a purpose. The obsessional action of our patient who ran to the table and rang for the housemaid is a perfect model of this kind of symptom. But there are - and they are very frequent symptoms of quite another character. They must be described as 'typical' symptoms of an illness; they are approximately the same in all cases, individual distinctions disappear in them or at least shrink up to such an extent that it is difficult to bring them into connection with the patients' individual experience and to relate them to particular situations they have experienced. Let us look once more at obsessional neurosis. The sleep-ceremonial of our second patient already has much that is typical about it, though at the same time it has enough individual traits to make what I might call a 'historical' interpretation possible. But all these obsessional patients have a tendency to repeat, to make their performances rhythmical and to keep them isolated from other actions. The majority of them wash too much. Patients who suffer from agoraphobia (topophobia or fear of spaces), which we no longer regard as obsessional neurosis but describe as 'anxiety hysteria', often repeat the same features in their symptoms with wearisome monotony: they are afraid of enclosed spaces, of large open squares, of lengthy roads and streets. They feel protected if they are accompanied by an acquaintance or followed by a vehicle, and so on. On this similar background, however, different patients nevertheless display their individual requirements - whims, one is inclined to say - which in some cases contradict one another directly. One patient avoids only narrow streets and another only wide ones; one can go out only if there are few people in the street, another only if there are many. In the same way, hysteria, in spite of its wealth of individual traits, has a superfluity of common, typical symptoms, which seem to resist any easy historical derivation. And we must not forget that it is these typical symptoms, indeed, which give us our bearings when we make our diagnosis. Suppose, in a case of hysteria, we have really traced a typical symptom back to an experience or a chain of similar experiences - a case of hysterical vomiting, for instance, to a series of disgusting impressions - then we are at a loss when the analysis in a similar case of vomiting reveals a series of a quite different kind of ostensibly effective experiences. It looks, then, as though for unknown reasons hysterical patients are bound to produce vomiting and as though the historical precipitating causes revealed by analysis were only pretexts which, if they happen to be there, are exploited by this internal necessity.

We are left with a third group of phobias, which is quite beyond our comprehension. When a strong, grown-up man is unable owing to anxiety to walk along a street or cross a square in his own familiar home-town, when a healthy, well-developed woman is thrown into insensate anxiety because a cat has brushed against the edge of her dress or because a mouse has run across the room, how are we to relate these things to the danger which they obviously constitute for the phobic subject? In the case of such animal phobias there can be no question of an exaggeration of universal human antipathies, since, as though to demonstrate the contrary, there are numerous people who cannot pass by a cat without coaxing it and stroking it. The mouse that these women are so much afraid of is also [in German] one of the chief terms of affection; a girl who is delighted when her lover calls her one will often scream with terror when she sees the pretty creature which bears that name. In the case of the man with agoraphobia the only explanation that we can reach is that he is behaving like a small child. A child is actually taught as part of his education to avoid such situations as dangerous; and our agoraphobic will in fact be saved from his anxiety if we accompany him across the square.
The two forms of anxiety that I have just described - the freely floating expectant anxiety and the sort which is bound to phobias - are independent of each other. One is not a higher stage, as it were, of the other; and they only appear simultaneously in exceptional cases and, so to speak, accidentally. The most powerful general apprehensiveness need not be expressed in phobias; people whose whole existence is restricted by agoraphobia may be entirely free from pessimistic expectant anxiety. Some phobias - for instance, agoraphobia and railway phobia - are demonstrably acquired at a fairly mature age, while others - such as fear of darkness, thunderstorms and animals - seem to have been present from the first. Those of the former kind have the significance of severe illnesses; the latter make their appearance rather as eccentricities or whims. If a person exhibits one of these latter, one may suspect as a rule that he will have other similar ones. I must add that we class all these phobias as anxiety hysteria; that is to say, we regard them as a disorder closely related to the familiar conversion hysteria. [1916-1917, 3447]

Instead of reporting a number of cases, I will tell you the story of a single one, in which, from considerations of medical discretion, I was condemned to play a long-suffering part. I undertook the analytic treatment - it was many years ago - of a girl who had for some time been unable, owing to anxiety, to go out in the street or to stay at home by herself. The patient slowly brought out an admission that her imagination had been seized by chance observations of the affectionate relations between her mother and a well-to-do friend of the family. But she was so clumsy - or so subtle - that she gave her mother a hint of what was being talked about in the analytic sessions. She brought this about by changing her behaviour towards her mother, by insisting on being protected by no one but her mother from her anxiety at being alone and by barring the door to her in her anxiety if she tried to leave the house. Her mother had herself been very neurotic in the past, but had been cured years before in a hydropathic establishment. Or rather, she had there made the acquaintance of the man with whom she was able to enter into a relation that was in every way satisfying to her. The girl's passionate demands took her aback, and she suddenly understood the meaning of her daughter's anxiety: the girl had made herself ill in order to keep her mother prisoner and to rob her of the freedom of movement that her relations with her lover required. The mother quickly made up her mind and brought the obnoxious treatment to an end. The girl was taken to a sanatorium for nervous diseases and was demonstrated for many years as 'a poor victim of psycho-analysis'. All this time, too, I was pursued by the calumny of responsibility for the unhappy end of the treatment. I kept silence, for I thought I was bound by the duty of medical discretion. Long afterwards I learnt from one of my colleagues, who visited the sanatorium and had seen the agoraphobic girl there, that the liaison between her mother and the well-to-do friend of the family was common knowledge in the city and that it was probably connived at by the husband and father. Thus it was to this 'secret' that the treatment had been sacrificed. [1916-1917, 3499]
Lastly, another quite different kind of activity is necessitated by the gradually growing appreciation that the various forms of disease treated by us cannot all be dealt with by the same technique. It would be premature to discuss this in detail, but I can give two examples of the way in which a new kind of activity comes into question. Our technique grew up in the treatment of hysteria and is still directed principally to the cure of that affection. But the phobias have already made it necessary for us to go beyond our former limits. One can hardly master a phobia if one waits till the patient lets the analysis influence him to give it up. He will never in that case bring into the analysis the material indispensable for a convincing resolution of the phobia. One must proceed differently. Take the example of agoraphobia; there are two classes of it, one mild, the other severe. Patients belonging to the first class suffer from anxiety when they go into the street by themselves, but they have not yet given up going out alone on that account; the others protect themselves from the anxiety by altogether ceasing to go about alone. With these last one succeeds only when one can induce them by the influence of the analysis to behave like phobic patients of the first class - that is, to go into the street and to struggle with their anxiety while they make the attempt. One starts, therefore, by moderating the phobia so far; and it is only when that has been achieved at the physician's demand that the associations and memories come into the patient's mind which enable the phobia to be resolved.

[1919a, 3634]

It is no use denying the fact, though it is not pleasant to recall it, that I have on many occasions asserted that in repression the instinctual representative is distorted, displaced and so on, while the libido belonging to the instinctual impulse is transformed into anxiety. But now an examination of phobias, which should be best able to provide confirmatory evidence, fails to bear out my assertion; it seems, rather, to contradict it directly. The anxiety felt in animal phobias is the ego's fear of castration; while the anxiety felt in agoraphobia (a subject that has been less thoroughly studied) seems to be its fear of sexual temptation - a fear which, after all, must be connected in its origins with the fear of castration. As far as can be seen at present, the majority of phobias go back to an anxiety of this kind felt by the ego in regard to the demands of the libido. It is always the ego's attitude of anxiety which is the primary thing and which sets repression going. Anxiety never arises from repressed libido. If I had contented myself earlier with saying that after the occurrence of repression a certain amount of anxiety appeared in place of the manifestation of libido that was to be expected, I should have nothing to retract today. The description would be correct; and there does undoubtedly exist a correspondence of the kind asserted between the strength of the impulse that has to be repressed and the intensity of the resultant anxiety. But I must admit that I thought I was giving more than a mere description. I believed I had put my finger on a metapsychological process of direct transformation of libido into anxiety. I can now no longer maintain this view. And, indeed, I found it impossible at the time to explain how a transformation of that kind was carried out.

[1926d, 4268]

The same will prove true, I think, of the phobias of adults, although the material which their neuroses work over is much more abundant and there are some additional factors in the formation of the symptoms. Fundamentally the position is identical. The agoraphobic patient imposes a restriction on his ego so as to escape a certain instinctual danger - namely, the danger of giving way to his erotic desires. For if he did so the danger of being castrated, or some similar danger, would once more be conjured up as it was in his childhood. I may cite as an instance the case of a young man who became agoraphobic because he was afraid of yielding to the solicitations of prostitutes and of contracting a syphilitic infection from them as a punishment.

[1926d, 4283]
I am well aware that a number of cases exhibit a more complicated structure and that many other repressed instinctual impulses can enter into a phobia. But they are only tributary streams which have for the most part joined the main current of the neurosis at a later stage. The symptomatology of agoraphobia is complicated by the fact that the ego does not confine itself to making a renunciation. In order to rob the situation of danger it does more: it usually effects a temporal regression to infancy (in extreme cases, to a time when the subject was in his mother's womb and protected against the dangers which threaten him in the present). Such a regression now becomes a condition whose fulfilment exempts the ego from making its renunciation. For instance, an agoraphobic patient may be able to walk in the street provided he is accompanied, like a small child, by someone he knows and trusts; or, for the same reason, he may be able to go out alone provided he remains within a certain distance of his own house and does not go to places which are not familiar to him or where people do not know him. What these stipulations are will depend in each case on the infantile factors which dominate him through his neurosis. The phobia of being alone is unambiguous in its meaning, irrespective of any infantile regression: it is, ultimately, an endeavour to avoid the temptation to indulge in solitary masturbation. Infantile regression can, of course, only take place when the subject is no longer a child.

That this latter opinion is at least in part true is shown by some striking examples. If an agoraphobic patient who has been accompanied into the street is left alone there, he will produce an anxiety attack. Or if an obsessional neurotic is prevented from washing his hands after having touched something, he will become a prey to almost unbearable anxiety. It is plain, then, that the purpose and the result of the imposed condition of being accompanied in the street and the obsessional act of washing the hands were to obviate outbreaks of anxiety of this kind. In this sense every inhibition which the ego imposes on itself can be called a symptom.

In the course of these investigations our attention was drawn to a highly significant relation between the generation of anxiety and the formation of symptoms - namely, that these two represent and replace each other. For instance, an agoraphobic patient may start his illness with an attack of anxiety in the street. This would be repeated every time he went into the street again. He will now develop the symptom of agoraphobia; this may also be described as an inhibition, a restriction of the ego's functioning, and by means of it he spares himself anxiety attacks. We can witness the converse of this if we interfere in the formation of symptoms, as is possible, for instance, with obsessions. If we prevent a patient from carrying out a washing ceremonial, he falls into a state of anxiety which he finds hard to tolerate and from which he had evidently been protected by his symptom. And it seems, indeed, that the generation of anxiety is the earlier and the formation of symptoms the later of the two, as though the symptoms are created in order to avoid the outbreak of the anxiety state. This is confirmed too by the fact that the first neuroses of childhood are phobias - states in which we see so clearly how an initial generation of anxiety is replaced by the later formation of a symptom; we get an impression that it is from these interrelations that we shall best obtain access to an understanding of neurotic anxiety. And at the same time we have also succeeded in answering the question of what it is that a person is afraid of in neurotic anxiety and so in establishing the connection between neurotic and realistic anxiety. What he is afraid of is evidently his own libido. The difference between this situation and that of realistic anxiety lies in two points: that the danger is an internal instead of an external one and that it is not consciously recognized.
In phobias it is very easy to observe the way in which this internal danger is transformed into an external one - that is to say, how a neurotic anxiety is changed into an apparently realistic one. In order to simplify what is often a very complicated business, let us suppose that the agoraphobic patient is invariably afraid of feelings of temptation that are aroused in him by meeting people in the street. In his phobia he brings about a displacement and henceforward is afraid of an external situation. What he gains by this is obviously that he thinks he will be able to protect himself better in that way. One can save oneself from an external danger by flight; fleeing from an internal danger is a difficult enterprise.

[1933a, 4691]
I shall have, for a special reason, to deal with this dream again elsewhere, and interpret it and consider its significance in greater detail. For it is the earliest anxiety-dream that the dreamer remembered from his childhood, and its content, taken in connection with other dreams that followed it soon afterwards and with certain events in his earliest years, is of quite peculiar interest. We must confine ourselves here to the relation of the dream to the two fairy tales which have so much in common with each other, 'Little Red Riding-Hood' and 'The Wolf and the Seven Little Goats'. The effect produced by these stories was shown in the little dreamer by a regular animal phobia. This phobia was only distinguished from other similar cases by the fact that the anxiety-animal was not an object easily accessible to observation (such as a horse or a dog), but was known to him only from stories and picture-books.
[1913d, 2601]

I shall discuss on another occasion the explanation of these animal phobias and the significance attaching to them. I will only remark in anticipation that this explanation is in complete harmony with the principal characteristic shown by the neurosis from which the present dreamer suffered later in his life. His fear of his father was the strongest motive for his falling ill, and his ambivalent attitude towards every father-surrogate was the dominating feature of his life as well as of his behaviour during the treatment.
[1913d, 2601]

If in my patient's case the wolf was merely a first father-surrogate, the question arises whether the hidden content in the fairy tales of the wolf that ate up the little goats and of 'Little Red Riding-Hood' may not simply be infantile fear of the father. Moreover, my patient's father had the characteristic, shown by so many people in relation to their children, of indulging in 'affectionate abuse'; and it is possible that during the patient's earlier years his father (though he grew severe later on) may more than once, as he caressed the little boy or played with him, have threatened in fun to 'gobble him up'. One of my patients told me that her two children could never get to be fond of their grandfather, because in the course of his affectionate romping with them he used to frighten them by saying he would cut open their tummies.
[1913d, 2601]

Not infrequently, however, a strange rift occurs in the excellent relations between children and animals. A child will suddenly begin to be frightened of some particular species of animal and to avoid touching or seeing any individual of that species. The clinical picture of an animal phobia emerges - a very common, and perhaps the earliest, form of psychoneurotic illness occurring in childhood. As a rule the phobia is attached to animals in which the child has hitherto shown a specially lively interest and it has nothing to do with any particular individual animal. There is no large choice of animals that may become objects of a phobia in the case of children living in towns: horses, dogs, cats, less often birds, and with striking frequency very small creatures such as beetles and butterflies. The senseless and immoderate fear shown in these phobias is sometimes attached to animals only known to the child from picture books and fairy tales. On a few rare occasions it is possible to discover what has led to an unusual choice of this kind; and I have to thank Karl Abraham for telling me of a case in which the child himself explained that his fear of wasps was due to their colour and stripes reminding him of tigers, which from all accounts were beasts to be feared.
[1912-1913, 2767]
No detailed analytic examination has yet been made of children's animal phobias, though they would greatly repay study. This neglect has no doubt been due to the difficulty of analysing children of such a tender age. It cannot therefore be claimed that we know the general meaning of these disorders and I myself am of the opinion that this may not turn out to be of a uniform nature. But a few cases of phobias of this kind directed towards the larger animals have proved accessible to analysis and have thus yielded their secret to the investigator. It was the same in every case: where the children concerned were boys, their fear related at bottom to their father and had merely been displaced on to the animal.

Everyone with psycho-analytic experience will no doubt have come across cases of the sort and have derived the same impression from them. Yet I can quote only a few detailed publications on the subject. This paucity of literature is an accidental circumstance and it must not be supposed that our conclusions are based on a few scattered observations. I may mention, for instance, a writer who has studied the neuroses of childhood with great understanding - Dr. M. Wulff, of Odessa. In the course of a case history of a nine-year-old boy he reports that at the age of four the patient had suffered from a dog-phobia. 'When he saw a dog running past in the street, he would weep and call out: "Dear doggie, don't bite me! I'll be good!" By "being good" he meant "not playing on the fiddle" - not masturbating. (Wulff, 1912, 15.) 'The boy's dog-phobia', the author explains, 'was in reality his fear of his father displaced on to dogs; for his curious exclamation "Doggie, I'll be good!" - that is, "I won't masturbate" - was directed to his father, who had forbidden him to masturbate.' Wulff adds a footnote which is in complete agreement with my views and at the same time bears witness to the frequent occurrence of such experiences: 'Phobias of this type (phobias of horses, dogs, cats, fowls and other domestic animals) are, in my opinion, at least as common in childhood as pavor nocturnus; and in analysis they almost invariably turn out to be a displacement on to the animals of the child's fear of one of his parents. I should not be prepared to maintain that the same mechanism applies to the widespread phobias of rats and mice.'

I recently published (1909b) an 'Analysis of a Phobia in a Five-Year-Old Boy', the material of which was supplied to me by the little patient's father. The boy had a phobia of horses, and as a result he refused to go out in the street. He expressed a fear that the horse would come into the room and bite him; and it turned out that this must be the punishment for a wish that the horse might fall down (that is, die). After the boy's fear of his father had been removed by reassurances, it became evident that he was struggling against wishes which had as their subject the idea of his father being absent (going away on a journey, dying). He regarded his father (as he made all too clear) as a competitor for the favours of his mother, towards whom the obscure foreshadowings of his budding sexual wishes were aimed. Thus he was situated in the typical attitude of a male child towards his parents to which we have given the name of the 'Oedipus complex' and which we regard in general as the nuclear complex of the neuroses. The new fact that we have learnt from the analysis of 'little Hans' - a fact with an important bearing upon totemism - is that in such circumstances children displace some of their feelings from their father on to an animal.
Analysis is able to trace the associative paths along which this displacement passes - both the fortuitous paths and those with a significant content. Analysis also enables us to discover the motives for the displacement. The hatred of his father that arises in a boy from rivalry for his mother is not able to achieve uninhibited sway over his mind; it has to contend against his old-established affection and admiration for the very same person. The child finds relief from the conflict arising out of this double-sided, this ambivalent emotional attitude towards his father by displacing his hostile and fearful feelings on to a substitute for his father. The displacement cannot, however, bring the conflict to an end, it cannot effect a clear-cut severance between the affectionate and the hostile feelings. On the contrary, the conflict is resumed in relation to the object on to which the displacement has been made: the ambivalence is extended to it. There could be no doubt that little Hans was not only frightened of horses; he also approached them with admiration and interest. As soon as his anxiety began to diminish, he identified himself with the dreaded creature: he began to jump about like a horse and in his turn bit his father.¹ At another stage in the resolution of his phobia he did not hesitate to identify his parents with some other large animals.²

It may fairly be said that in these children's phobias some of the features of totemism reappear, but reversed into their negative. We are, however, indebted to Ferenczi (1913a) for an interesting history of a single case which can only be described as an instance of positive totemism in a child. It is true that in the case of little Árpád (the subject of Ferenczi's report) his totemic interests did not arise in direct relation with his Oedipus complex but on the basis of its narcissistic precondition, the fear of castration. But any attentive reader of the story of little Hans will find abundant evidence that he, too, admired his father as possessing a big penis and feared him as threatening his own. The same part is played by the father alike in the Oedipus and the castration complexes - the part of a dreaded enemy to the sexual interests of childhood. The punishment which he threatens is castration, or its substitute, blinding.¹

Later on we shall be able to assess the worth of this observation more completely. At the moment I will only emphasize two features in it which offer valuable points of agreement with totemism: the boy's complete identification with his totem animal¹ and his ambivalent emotional attitude to it. These observations justify us, in my opinion, in substituting the father for the totem animal in the formula for totemism (in the case of males). It will be observed that there is nothing new or particularly daring in this step forward. Indeed, primitive men say the very same thing themselves, and, where the totemic system is still in force to-day, they describe the totem as their common ancestor and primal father. All we have done is to take at its literal value an expression used by these people, of which the anthropologists have been able to make very little and which they have therefore been glad to keep in the background. Psycho-analysis, on the contrary, leads us to put special stress upon this same point and to take it as the starting-point of our attempt at explaining totemism.²

[1912-1913, 2769]

[1912-1913, 2770]

[1912-1913, 2771]
The first consequence of our substitution is most remarkable. If the totem animal is the father, then the two principal ordinances of totemism, the two taboo prohibitions which constitute its core - not to kill the totem and not to have sexual relations with a woman of the same totem - coincide in their content with the two crimes of Oedipus, who killed his father and married his mother, as well as with the two primal wishes of children, the insufficient repression or the re-awakening of which forms the nucleus of perhaps every psychoneurosis. If this equation is anything more than a misleading trick of chance, it must enable us to throw a light upon the origin of totemism in the inconceivably remote past. In other words, it would enable us to make it probable that the totemic system - like little Hans's animal phobia and little Árpád's poultry perversion - was a product of the conditions involved in the Oedipus complex. In order to pursue this possibility, we shall have, in the following pages, to study a feature of the totemic system (or, as we might say, of the totemic religion) which I have hitherto scarcely found an opportunity of mentioning.

[1912-1913, 2772]

From the field of anxiety hysteria I will choose a well-analysed example of an animal phobia. The instinctual impulse subjected to repression here is a libidinal attitude towards the father, coupled with fear of him. After repression, this impulse vanishes out of consciousness: the father does not appear in it as an object of libido. As a substitute for him we find in a corresponding place some animal which is more or less fitted to be an object of anxiety. The formation of the substitute for the ideational portion has come about by displacement along a chain of connections which is determined in a particular way. The quantitative portion has not vanished, but has been transformed into anxiety. The result is fear of a wolf, instead of a demand for love from the father. The categories here employed are of course not enough to supply an adequate explanation of even the simplest case of psychoneurosis: there are always other considerations to be taken into account. A repression such as occurs in an animal phobia must be described as radically unsuccessful. All that it has done is to remove and replace the idea; it has failed altogether in sparing unpleasure. And for this reason, too, the work of the neurosis does not cease. It proceeds to a second phase, in order to attain its immediate and more important purpose. What follows is an attempt at flight - the formation of the phobia proper, of a number of avoidances which are intended to prevent a release of the anxiety. More specialized investigation enables us to understand the mechanism by which the phobia achieves its aim.

[1915d, 2985]
On the occasion of a repetition (if there should be one) of this process, a first step is taken in the direction of mastering the unwelcome development of anxiety. The cathexis that has taken flight attaches itself to a substitutive idea which, on the one hand, is connected by association with the rejected idea, and, on the other, has escaped repression by reason of its remoteness from that idea. This substitutive idea - a 'substitute by displacement' - permits the still uninhibitable development of anxiety to be rationalized. It now plays the part of an anticathexis for the system Cs. (Pcs.), by securing it against an emergence in the Cs. of the repressed idea. On the other hand it is, or acts as if it were, the point of departure for the release of the anxiety-affect, which has now really become quite uninhibitable. Clinical observation shows, for instance, that a child suffering from an animal phobia experiences anxiety under two kinds of conditions: in the first place, when his repressed love-impulse becomes intensified, and, in the second, when he perceives the animal he is afraid of. The substitutive idea acts in the one instance as a point at which there is a passage across from the system Ucs. to the system Cs., and, in the other instance, as a self-sufficing source for the release of anxiety. The extending dominance of the system Cs. usually manifests itself in the fact that the first of these two modes of excitation of the substitutive idea gives place more and more to the second. The child may perhaps end by behaving as though he had no predilection whatever towards his father but had become quite free from him, and as though his fear of the animal was a real fear - except that this fear of the animal, fed as such a fear is from an unconscious instinctual source, proves obdurate and exaggerated in the face of all influences brought to bear from the system Cs., and thereby betrays its derivation from the system Ucs. - In the second phase of anxiety hysteria, therefore, the anticathexis from the system Cs. has led to substitute-formation.

We are left with a third group of phobias, which is quite beyond our comprehension. When a strong, grown-up man is unable owing to anxiety to walk along a street or cross a square in his own familiar home-town, when a healthy, well-developed woman is thrown into insensate anxiety because a cat has brushed against the edge of her dress or because a mouse has run across the room, how are we to relate these things to the danger which they obviously constitute for the phobic subject? In the case of such animal phobias there can be no question of an exaggeration of universal human antipathies, since, as though to demonstrate the contrary, there are numerous people who cannot pass by a cat without coaxing it and stroking it. The mouse that these women are so much afraid of is also [in German] one of the chief terms of affection; a girl who is delighted when her lover calls her one will often scream with terror when she sees the pretty creature which bears that name. In the case of the man with agoraphobia the only explanation that we can reach is that he is behaving like a small child. A child is actually taught as part of his education to avoid such situations as dangerous; and our agoraphobic will in fact be saved from his anxiety if we accompany him across the square.

The two forms of anxiety that I have just described - the freely floating expectant anxiety and the sort which is bound to phobias - are independent of each other. One is not a higher stage, as it were, of the other; and they only appear simultaneously in exceptional cases and, so to speak, accidentally. The most powerful general apprehensiveness need not be expressed in phobias; people whose whole existence is restricted by agoraphobia may be entirely free from pessimistic expectant anxiety. Some phobias - for instance, agoraphobia and railway phobia - are demonstrably acquired at a fairly mature age, while others - such as fear of darkness, thunderstorms and animals - seem to have been present from the first. Those of the former kind have the significance of severe illnesses; the latter make their appearance rather as eccentricities or whims. If a person exhibits one of these latter, one may suspect as a rule that he will have other similar ones. I must add that we class all these phobias as anxiety hysteria; that is to say, we regard them as a disorder closely related to the familiar conversion hysteria.
'I shall have, for a special reason, to deal with this dream again elsewhere, and interpret it and consider its significance in greater detail. For it is the earliest anxiety-dream that the dreamer remembered from his childhood, and its content, taken in connection with other dreams that followed it soon afterwards and with certain events in his earliest years, is of quite peculiar interest. We must confine ourselves here to the relation of the dream to the two fairy tales which have so much in common with each other, "Little Red Riding-Hood" and "The Wolf and the Seven Little Goats". The effect produced by these stories was shown in the little dreamer by a regular animal phobia. This phobia was only distinguished from other similar cases by the fact that the anxiety-animal was not an object easily accessible to observation (such as a horse or a dog), but was known to him only from stories and picture-books.

[1918b, 3523]

'I shall discuss on another occasion the explanation of these animal phobias and the significance attaching to them. I will only remark in anticipation that this explanation is in complete harmony with the principal characteristic shown by the neurosis from which the present dreamer suffered later in his life. His fear of his father was the strongest motive for his falling ill, and his ambivalent attitude towards every father-surrogate was the dominating feature of his life as well as of his behaviour during the treatment.

[1918b, 3523]

'If in my patient's case the wolf was merely a first father surrogate, the question arises whether the hidden content in the fairy tales of the wolf that ate up the little goats and of "Little Red Riding-Hood" may not simply be infantile fear of the father.' Moreover, my patient's father had the characteristic, shown by so many people in relation to their children, of indulging in "affectionate abuse"; and it is possible that during the patient's earlier years his father (though he grew severe later on) may more than once, as he caressed the little boy or played with him, have threatened in fun to "gobble him up". One of my patients told me that her two children could never get to be fond of their grandfather, because in the course of his affectionate romping with them he used to frighten them by saying he would cut open their tummies.'

[1918b, 3523]

By the latter I mean the postures which he saw his parents adopt - the man upright, and the woman bent down like an animal. We have already heard that during his anxiety period his sister used to terrify him with a picture from the fairy-book, in which the wolf was shown standing upright, with one foot forward, with its claws stretched out and its ears pricked. He devoted himself with tireless perseverance during the treatment to the task of hunting in the second-hand book shops till he had found the illustrated fairy-book of his childhood, and had recognized his bogy in an illustration to the story of 'The Wolf and the Seven Little Goats'. He thought that the posture of the wolf in this picture might have reminded him of that of his father during the constructed primal scene. At all events the picture became the point of departure for further manifestations of anxiety. Once when he was in his seventh or eighth year he was informed that next day a new tutor was coming for him. That night he dreamt of this tutor in the shape of a lion that came towards his bed roaring loudly and in the posture of the wolf in the picture; and once again he awoke in a state of anxiety. The wolf phobia had been overcome by that time, so he was free to choose himself a new anxiety-animal, and in this late dream he was recognizing the tutor as a father-surrogate. In the later years of his childhood each of his tutors and masters played the part of his father, and was endowed with his father's influence both for good and for evil.

[1918b, 3529]
While he was at his secondary school the Fates provided him with a remarkable opportunity of
reviving his wolf phobia, and of using the relation which lay behind it as an occasion for severe
inhibitions. The master who taught his form Latin was called Wolf. From the very first he felt
cowed by him, and he was once taken severely to task by him for having made a stupid mistake
in a piece of Latin translation. From that time on he could not get free from a paralysing fear of
this master, and it was soon extended to other masters besides. But the occasion on which he
made his blunder in the translation was also to the purpose. He had to translate the Latin word
'filius', and he did it with the French word 'fils' instead of with the corresponding word from his
own language. The wolf, in fact, was still his father.¹
[1918b, 3530]

The wolf that he was afraid of was undoubtedly his father; but his fear of the wolf was
conditional upon the creature being in an upright posture. His recollection asserted most
definitely that he had not been terrified by pictures of wolves going on all fours or, as in the story
of 'Little Red Riding-Hood', lying in bed. The posture which, according to our construction of the
primal scene, he had seen the woman assume, was of no less significance; though in this case
the significance was limited to the sexual sphere. The most striking phenomenon of his erotic
life after maturity was his liability to compulsive attacks of falling physically in love which came
on and disappeared again in the most puzzling succession. These attacks released a
tremendous energy in him even at times when he was otherwise inhibited, and they were quite
beyond his control. I must, for a specially important reason, postpone a full consideration of this
compulsive love; but I may mention here that it was subject to a definite condition, which was
concealed from his consciousness and was discovered only during the treatment. It was
necessary that the woman should have assumed the posture which we have ascribed to his
mother in the primal scene. From his puberty he had felt large and conspicuous buttocks as the
most powerful attraction in a woman; to copulate except from behind gave him scarcely any
enjoyment. At this point a criticism may justly be raised: it may be objected that a sexual
preference of this kind for the hind parts of the body is a general characteristic of people who
are inclined to an obsessional neurosis, and that its presence does not justify us in referring it
back to a special impression in childhood. It is part of the fabric of the anal-erotic disposition and
is one of the archaic traits which distinguish that constitution. Indeed, copulation from behind -
*more ferasum* [in the fashion of animals] - may, after all, be regarded as phylogenetically the
older form. We shall return to this point too in a later discussion, when we have brought forward
the supplementary material which showed the basis of the unconscious condition upon which
his falling in love depended.
[1918b, 3531]

The dream ended in a state of anxiety, from which he did not recover until he had his Nanya
with him. He fled, therefore, from his father to her. His anxiety was a repudiation of the wish for
sexual satisfaction from his father - the trend which had put the dream into his head. The form
taken by the anxiety, the fear of 'being eaten by the wolf', was only the (as we shall hear,
regressive) transposition of the wish to be copulated with by his father, that is, to be given
sexual satisfaction in the same way as his mother. His last sexual aim, the passive attitude
towards his father, succumbed to repression, and fear of his father appeared in its place in the
shape of the wolf phobia.
[1918b, 3534]
We now observe that at this point in our narrative we must make an alteration in our terminology. During the dream he had reached a new phase in his sexual organization. Up to then the sexual opposites had been for him active and passive. Since his seduction his sexual aim had been a passive one, of being touched on the genitals; it was then transformed, by regression to the earlier stage of the sadistic-anal organization, into the masochistic aim of being beaten or punished. It was a matter of indifference to him whether he reached this aim with a man or with a woman. He had travelled, without considering the difference of sex, from his Nanya to his father; he had longed to have his penis touched by his Nanya, and had tried to provoke a beating from his father. Here his genitals were left out of account; though the connection with them which had been concealed by the regression was still expressed in his phantasy of being beaten on the penis. The activation of the primal scene in the dream now brought him back to the genital organization. He discovered the vagina and the biological significance of masculine and feminine. He understood now that active was the same as masculine, while passive was the same as feminine. His passive sexual aim should now have been transformed into a feminine one, and have expressed itself as ‘being copulated with by his father’ instead of ‘being beaten by him on the genitals or on the bottom’. This feminine aim, however, underwent repression and was obliged to let itself be replaced by fear of the wolf.

We must here break off the discussion of his sexual development until new light is thrown from the later stages of his history upon these earlier ones. For the proper appreciation of the wolf phobia we will only add that both his father and mother became wolves. His mother took the part of the castrated wolf, which let the others climb upon it; his father took the part of the wolf that climbed. But his fear, as we have heard him assure us, related only to the standing wolf, that is, to his father. It must further strike us that the fear with which the dream ended had a model in his grandfather's story. For in this the castrated wolf, which had let the others climb upon it, was seized with fear as soon as it was reminded of the fact of its taillessness. It seems, therefore, as though he had identified himself with his castrated mother during the dream, and was now fighting against that fact. 'If you want to be sexually satisfied by Father', we may perhaps represent him as saying to himself, 'you must allow yourself to be castrated like Mother; but I won't have that.' In short, a clear protest on the part of his masculinity! Let us, however, plainly understand that the sexual development of the case that we are now examining has a great disadvantage from the point of view of research, for it was by no means undisturbed. It was first decisively influenced by the seduction, and was then diverted by the scene of observation of the coitus, which in its deferred action operated like a second seduction.

Let us now consider the phobia. It came into existence on the level of the genital organization, and shows us the relatively simple mechanism of an anxiety-hysteria. The ego, by developing anxiety, was protecting itself against what it regarded as an overwhelming danger, namely, homosexual satisfaction. But the process of repression left behind it a trace which cannot be overlooked. The object to which the dangerous sexual aim had been attached had to have its place taken in consciousness by another one. What became conscious was fear not of the father but of the wolf. Nor did the process stop at the formation of a phobia with a single content. A considerable time afterwards the wolf was replaced by the lion. Simultaneously with sadistic impulses against small animals there was a phobia directed towards them, in their capacity of representatives of the boy's rivals, the possible small children. The origin of the butterfly phobia is of especial interest. It was like a repetition of the mechanism that produced the wolf phobia in the dream. Owing to a chance stimulus an old experience, the scene with Grusha, was activated; her threat of castration thus produced deferred effects, though at the time it was uttered it had made no impression.¹
It is true that it is by no means easy to demonstrate the traces of this satanic view of the father in the mental life of the individual. When a boy draws grotesque faces and caricatures, we may no doubt be able to show that he is jeering at his father in them; and when a person of either sex is afraid of robbers and burglars at night, it is not hard to recognize these as split off portions of the father.¹ The animals, too, which appear in children’s animal phobias are most often father-substitutes, as were the totem animals of primaeval times. But that the Devil is a duplicate of the father and can act as a substitute for him has not been shown so clearly elsewhere as in the demonological neurosis of this seventeenth-century painter. That is why, at the beginning of this paper, I foretold that a demonological case history of this kind would yield in the form of pure metal material which, in the neuroses of a later epoch (no longer superstitious but hypochondriacal instead) has to be laboriously extracted by analytic work from the ore of free associations and symptoms.² A deeper penetration into the analysis of our painter’s illness will probably bring stronger conviction. It is no unusual thing for a man to acquire a melancholic depression and an inhibition in his work as a result of his father’s death. When this happens, we conclude that the man had been attached to his father with an especially strong love, and we remember how often a severe melancholia appears as a neurotic form of mourning.

[1923d, 4011]

The chief literary sources of my studies in this field were the well-known works of J. G. Frazer (Totemism and Exogamy and The Golden Bough), a mine of valuable facts and opinions. But Frazer effected little towards elucidating the problems of totemism; he had several times fundamentally altered his views on the subject, and the other ethnologists and prehistorians seemed in equal uncertainty and disagreement. My starting-point was the striking correspondence between the two taboo-ordinances of totemism (not to kill the totem and not to have sexual relations with any woman of the same totem-clan) and the two elements of the Oedipus complex (getting rid of the father and taking the mother to wife). I was therefore tempted to equate the totem-animal with the father; and in fact primitive peoples themselves do this explicitly, by honouring it as the forefather of the clan. There next came to my help two facts from psycho-analysis, a lucky observation of a child made by Ferenczi, which enabled me to speak of an ‘infantile return of totemism’, and the analysis of early animal-phobias in children, which so often showed that the animal was a substitute for the father, a substitute on to which the fear of the father derived from the Oedipus complex had been displaced. Not much was lacking to enable me to recognize the killing of the father as the nucleus of totemism and the starting-point in the formation of religion.

[1925d, 4240]

Let us start with an infantile hysterical phobia of animals - for instance, the case of ‘Little Hans’, whose phobia of horses was undoubtedly typical in all its main features. The first thing that becomes apparent is that in a concrete case of neurotic illness the state of affairs is much more complex than one would suppose so long as one was dealing with abstractions. It takes a little time to find one’s bearings and to decide which the repressed impulse is, what substitutive symptom it has found and where the motive for repression lies.

[1926d, 4261]

‘Little Hans’ refused to go out into the street because he was afraid of horses. This was the raw material of the case. Which part of it constituted the symptom? Was it his having the fear? Was it his choice of an object for his fear? Was it his giving up of his freedom of movement? Or was it more than one of these combined? What was the satisfaction which he renounced? And why did he have to renounce it?

[1926d, 4261]
At a first glance one is tempted to reply that the case is not so very obscure. 'Little Hans's' unaccountable fear of horses was the symptom and his inability to go out into the streets was an inhibition, a restriction which his ego had imposed on itself so as not to arouse the anxiety-symptom. The second point is clearly correct; and in the discussion which follows I shall not concern myself any further with this inhibition. But as regards the alleged symptom, a superficial acquaintance with the case does not even disclose its true formulation. For further investigation shows that what he was suffering from was not a vague fear of horses but a quite definite apprehension that a horse was going to bite him. This idea, indeed, was endeavouring to withdraw from consciousness and get itself replaced by an undefined phobia in which only the anxiety and its object still appeared. Was it perhaps this idea that was the nucleus of his symptom?

[1926d, 4261]

We shall not make any headway until we have reviewed the little boy's psychical situation as a whole as it came to light in the course of the analytic treatment. He was at the time in the jealous and hostile Oedipus attitude towards his father, whom nevertheless - except in so far as his mother was the cause of estrangement - he dearly loved. Here, then, we have a conflict due to ambivalence: a well-grounded love and a no less justifiable hatred directed towards one and the same person. 'Little Hans's' phobia must have been an attempt to solve this conflict. Conflicts of this kind due to ambivalence are very frequent and they can have another typical outcome, in which one of the two conflicting feelings (usually that of affection) becomes enormously intensified and the other vanishes. The exaggerated degree and compulsive character of the affection alone betray the fact that it is not the only one present but is continually on the alert to keep the opposite feeling under suppression, and enable us to postulate the operation of a process which we call repression by means of reaction-formation (in the ego). Cases like 'Little Hans's' show no traces of a reaction-formation of this kind. There are clearly different ways of egress from a conflict due to ambivalence.

[1926d, 4262]

Meanwhile we have been able to establish another point with certainty. The instinctual impulse which underwent repression in 'Little Hans' was a hostile one against his father. Proof of this was obtained in his analysis while the idea of the biting horse was being followed up. He had seen a horse fall down and he had also seen a playmate, with whom he was playing at horses, fall down and hurt himself. Analysis justified the inference that he had a wishful impulse that his father should fall down and hurt himself as his playmate and the horse had done. Moreover, his attitude towards someone's departure on a certain occasion makes it probable that his wish that his father should be out of the way also found less hesitating expression. But a wish of this sort is tantamount to an intention of putting one's father out of the way oneself - is tantamount, that is, to the murderous impulse of the Oedipus complex.

[1926d, 4262]
So far there seem to be no connecting links between 'Little Hans's' repressed instinctual impulse and the substitute for it which we suspect is to be seen in his phobia of horses. Let us simplify his psychical situation by setting on one side the infantile factor and the ambivalence. Let us imagine that he is a young servant who is in love with the mistress of the house and has received some tokens of her favour. He hates his master, who is more powerful than he is, and he would like to have him out of the way. It would then be eminently natural for him to dread his master's vengeance and to develop a fear of him - just as 'Little Hans' developed a phobia of horses. We cannot, therefore, describe the fear belonging to this phobia as a symptom. If 'Little Hans', being in love with his mother, had shown fear of his father, we should have no right to say that he had a neurosis or a phobia. His emotional reaction would have been entirely comprehensible. What made it a neurosis was one thing alone: the replacement of his father by a horse. It is this displacement, then, which has a claim to be called a symptom, and which, incidentally, constitutes the alternative mechanism which enables a conflict due to ambivalence to be resolved without the aid of a reaction-formation. Such a displacement is made possible or facilitated at 'Little Hans's' early age because the inborn traces of totemic thought can still be easily revived. Children do not as yet recognize or, at any rate, lay such exaggerated stress upon the gulf that separates human beings from the animal world. In their eyes the grown man, the object of their fear and admiration, still belongs to the same category as the big animal who has so many enviable attributes but against whom they have been warned because he may become dangerous. As we see, the conflict due to ambivalence is not dealt with in relation to one and the same person: it is circumvented, as it were, by one of the pair of conflicting impulses being directed to another person as a substitutive object.

[1926d, 4263]

So far everything is clear. But the analysis of 'Hans's' phobia has been a complete disappointment in one respect. The distortion which constituted the symptom-formation was not applied to the representative (the ideational content) of the instinctual impulse that was to be repressed; it was applied to a quite different representative and one which only corresponded to a reaction to the disagreeable instinct. It would be more in accordance with our expectations if 'Little Hans' had developed, instead of a fear of horses, an inclination to ill-treat them and to beat them or if he had expressed in plain terms a wish to see them fall down or be hurt or even die in convulsions ('make a row with their feet'). Something of the sort did in fact emerge in his analysis, but it was not by any means in the forefront of his neurosis. And, curiously enough, if he really had produced a hostility of this sort not against his father but against horses as his main symptom, we should not have said that he was suffering from a neurosis. There must be something wrong either with our view of repression or with our definition of a symptom. One thing, of course, strikes us at once: if 'Little Hans' had really behaved like that to horses, it would mean that repression had in no way altered the character of his objectionable and aggressive instinctual impulse itself but only the object towards which it was directed.

[1926d, 4263]
As we know, 'Little Hans' alleged that what he was afraid of was that a horse would bite him. Now some time later I was able to learn something about the origin of another animal phobia. In this instance the dreaded animal was a wolf; it, too, had the significance of a father-substitute. As a boy the patient in question - a Russian whom I did not analyse till he was in his twenties - had had a dream (whose meaning was revealed in analysis) and, immediately after it, had developed a fear of being devoured by a wolf, like the seven little goats in the fairy tale.¹ In the case of 'Little Hans' the ascertained fact that his father used to play at horses with him doubtless determined his choice of a horse as his anxiety-animal. In the same way it appeared at least highly probable that the father of my Russian patient used, when playing with him, to pretend to be a wolf and jokingly threaten to gobble him up. Since then I have come across a third instance. The patient was a young American who came to me for analysis. He did not, it is true, develop an animal phobia, but it is precisely because of this omission that his case helps to throw light upon the other two. As a child he had been sexually excited by a fantastic children's story which had been read aloud to him about an Arab chief who pursued a 'gingerbread man' so as to eat him up. He identified himself with this edible person, and the Arab chief was easily recognizable as a father-substitute. This phantasy formed the earliest substratum of his auto-erotic phantasies.

[1926d, 4264]

The idea of being devoured by the father is typical age-old childhood material. It has familiar parallels in mythology (e.g. the myth of Kronos) and in the animal kingdom. Yet in spite of this confirmation the idea is so strange to us that we can hardly credit its existence in a child. Nor do we know whether it really means what it seems to say, and we cannot understand how it can have become the subject of a phobia. Analytic observation supplies the requisite information. It shows that the idea of being devoured by the father gives expression, in a form that has undergone regressive degradation, to a passive, tender impulse to be loved by him in a genital-erotic sense. Further investigation of the case history leaves no doubt of the correctness of this explanation. The genital impulse, it is true, betrays no sign of its tender purpose when it is expressed in the language belonging to the superseded transitional phase between the oral and sadistic organizations of the libido. Is it, moreover, a question merely of the replacement of the representative by a regressive form of expression or is it a question of a genuine regressive degradation of the genitally-directed impulse in the id? It is not at all easy to make certain. The case history of the Russian 'Wolf Man' gives very definite support to the second, more serious, view; for, from the time of the decisive dream onward, the boy became naughty, tormenting and sadistic, and soon afterwards developed a regular obsessional neurosis. At any rate, we can see that repression is not the only means which the ego can employ for the purpose of defence against an unwelcome instinctual impulse. If it succeeds in making an instinct regress, it will actually have done it more injury than it could have by repressing it. Sometimes, indeed, after forcing an instinct to regress in this way, it goes on to repress it.

[1926d, 4265]
The case of the 'Wolf Man' and the somewhat less complicated one of 'Little Hans' raise a number of further considerations. But we have already made two unexpected discoveries. There can be no doubt that the instinctual impulse which was repressed in both phobias was a hostile one against the father. One might say that that impulse had been repressed by the process of being transformed into its opposite. Instead of aggressiveness on the part of the subject towards his father, there appeared aggressiveness (in the shape of revenge) on the part of his father towards the subject. Since this aggressiveness is in any case rooted in the sadistic phase of the libido, only a certain amount of degradation is needed to reduce it to the oral stage. This stage, while only hinted at in 'Little Hans's' fear of being bitten, was blatantly exhibited in the 'Wolf Man's' terror of being devoured. But, besides this, the analysis has demonstrated, beyond a shadow of doubt, the presence of another instinctual impulse of an opposite nature which had succumbed to repression. This was a tender, passive impulse directed towards the father, which had already reached the genital (phallic) level of libidinal organization. As regards the final outcome of the process of repression, this impulse seems, indeed, to have been the more important of the two; it underwent a more far-reaching regression and had a decisive influence upon the content of the phobia. In following up a single instinctual repression we have thus had to recognize a convergence of two such processes. The two instinctual impulses that have been overtaken by repression - sadistic aggressiveness towards the father and a tender passive attitude to him - form a pair of opposites. Furthermore, a full appreciation of 'Little Hans's' case shows that the formation of his phobia had had the effect of abolishing his affectionate object-cathexis of his mother as well, though the actual content of his phobia betrayed no sign of this. The process of repression had attacked almost all the components of his Oedipus complex - both his hostile and his tender impulses towards his father and his tender impulses towards his mother. In my Russian patient this state of affairs was much less obvious. [1926d, 4266]
These are unwelcome complications, considering that we only set out to study simple cases of symptom-formation due to repression, and with that intention selected the earliest and to all appearances, most transparent neuroses of childhood. Instead of a single repression we have found a collection of them and have become involved with regression into the bargain. Perhaps we have added to the confusion by treating the two cases of animal phobia at our disposal - 'Little Hans' and the 'Wolf Man' - as though they were cast in the same mould. As a matter of fact, certain differences between them stand out. It is only with regard to 'Little Hans' that we can say with certainty that what his phobia disposed of were the two main impulses of the Oedipus complex - his aggressiveness towards his father and his over-fondness for his mother. A tender feeling for his father was undoubtedly there too and played a part in repressing the opposite feeling; but we can prove neither that it was strong enough to draw repression upon itself nor that it disappeared afterwards. 'Hans' seems, in fact, to have been a normal boy with what is called a 'positive' Oedipus complex. It is possible that the factors which we do not find were actually at work in him, but we cannot demonstrate their existence. Even the most exhaustive analysis has gaps in its data and is insufficiently documented. In the case of the Russian the deficiency lies elsewhere. His attitude to female objects had been disturbed by an early seduction and his passive, feminine side was strongly developed. The analysis of his wolf-dream revealed very little intentional aggressiveness towards his father, but it brought forward unmistakable proof that what repression overtook was his passive tender attitude to his father. In his case, too, the other factors may have been operative as well; but they were not in evidence. How is it that, in spite of these differences in the two cases, almost amounting to an antithesis, the final outcome - a phobia - was approximately the same? The answer must be sought in another quarter. I think it will be found in the second fact which emerges from our brief comparative examination. It seems to me that in both cases we can detect what the motive force of the repression was and can substantiate our view of its nature from the line of development which the two children subsequently pursued. This motive force was the same in both of them. It was the fear of impending castration. 'Little Hans' gave up his aggressiveness towards his father from fear of being castrated. His fear that a horse would bite him can, without any forcing, be given the full sense of a fear that a horse would bite off his genitals, would castrate him. But it was from fear of being castrated, too, that the little Russian relinquished his wish to be loved by his father, for he thought that a relation of that sort presupposed a sacrifice of his genitals - of the organ which distinguished him from a female. As we see, both forms of the Oedipus complex, the normal, active form and the inverted one, came to grief through the castration complex. The Russian boy's anxiety-idea of being devoured by a wolf contained, it is true, no suggestion of castration, for the oral regression it had undergone had removed it too far from the phallic stage. But the analysis of his dream rendered further proof superfluous. It was a triumph of repression that the form in which his phobia was expressed should no longer have contained any allusion to castration.

Here, then, is our unexpected finding: in both patients the motive force of the repression was fear of castration. The ideas contained in their anxiety - being bitten by a horse and being devoured by a wolf - were substitutes by distortion for the idea of being castrated by their father. This was the idea which had undergone repression. In the Russian boy the idea was an expression of a wish which was not able to subsist in the face of his masculine revolt; in 'Little Hans' it was the expression of a reaction in him which had turned his aggressiveness into its opposite. But the AFFECT of anxiety, which was the essence of the phobia, came, not from the process of repression, not from the libidinal cathexes of the repressed impulses, but from the repressing agency itself. The anxiety belonging to the animal phobias was an untransformed fear of castration. It was therefore a realistic fear, a fear of a danger which was actually impending or was judged to be a real one. It was anxiety which produced repression and not, as I formerly believed, repression which produced anxiety.
It is no use denying the fact, though it is not pleasant to recall it, that I have on many occasions asserted that in repression the instinctual representative is distorted, displaced and so on, while the libido belonging to the instinctual impulse is transformed into anxiety. But now an examination of phobias, which should be best able to provide confirmatory evidence, fails to bear out my assertion; it seems, rather, to contradict it directly. The anxiety felt in animal phobias is the ego's fear of castration; while the anxiety felt in agoraphobia (a subject that has been less thoroughly studied) seems to be its fear of sexual temptation - a fear which, after all, must be connected in its origins with the fear of castration. As far as can be seen at present, the majority of phobias go back to an anxiety of this kind felt by the ego in regard to the demands of the libido. It is always the ego's attitude of anxiety which is the primary thing and which sets repression going. Anxiety never arises from repressed libido. If I had contented myself earlier with saying that after the occurrence of repression a certain amount of anxiety appeared in place of the manifestation of libido that was to be expected, I should have nothing to retract today. The description would be correct; and there does undoubtedly exist a correspondence of the kind asserted between the strength of the impulse that has to be repressed and the intensity of the resultant anxiety. But I must admit that I was giving more than a mere description. I believed I had put my finger on a metapsychological process of direct transformation of libido into anxiety. I can now no longer maintain this view. And, indeed, I found it impossible at the time to explain how a transformation of that kind was carried out.
[1926d, 4268]

Let us go back again to infantile phobias of animals; for, when all is said and done, we understand them better than any other cases. In animal phobias, then, the ego has to oppose a libidinal object-cathexis coming from the id - a cathexis that belongs either to the positive or the negative Oedipus complex - because it believes that to give way to it would entail the danger of castration. This question has already been discussed, but there still remains a doubtful point to clear up. In 'Little Hans's' case - that is, in the case of a positive Oedipus complex - was it his fondness for his mother or was it his aggressiveness towards his father which called out the defence by the ego? In practice it seems to make no difference, especially as each set of feelings implies the other; but the question has a theoretical interest, since it is only the feeling of affection for the mother which can count as a purely erotic one. The aggressive impulse flows mainly from the destructive instinct; and we have always believed that in a neurosis it is against the demands of the libido and not against those of any other instinct that the ego is defending itself. In point of fact we know that after 'Hans's' phobia had been formed, his tender attachment to his mother seemed to disappear, having been completely disposed of by repression, while the formation of the symptom (the substitutive formation) took place in relation to his aggressive impulses. In the 'Wolf Man' the situation was simpler. The impulse that was repressed - his feminine attitude towards his father - was a genuinely erotic one; and it was in relation to that impulse that the formation of his symptoms took place.
[1926d, 4282]
This time we will not lose sight of the part played by anxiety. We have said that as soon as the ego recognizes the danger of castration it gives the signal of anxiety and inhibits through the pleasure-unpleasure agency (in a way which we cannot as yet understand) the impending cathetic process in the id. At the same time the phobia is formed. And now the castration anxiety is directed to a different object and expressed in a distorted form, so that the patient is afraid, not of being castrated by his father, but of being bitten by a horse or devoured by a wolf. This substitutive formation has two obvious advantages. In the first place it avoids a conflict due to ambivalence (for the father was a loved object, too), and in the second place it enables the ego to cease generating anxiety. For the anxiety belonging to a phobia is conditional; it only emerges when the object of it is perceived - and rightly so, since it is only then that the danger-situation is present. There is no need to be afraid of being castrated by a father who is not there. On the other hand one cannot get rid of a father; he can appear whenever he chooses. But if he is replaced by an animal, all one has to do is to avoid the sight of it - that is, its presence - in order to be free from danger and anxiety. 'Little Hans', therefore, imposed a restriction upon his ego. He produced the inhibition of not leaving the house, so as not to come across any horses. The young Russian had an even easier time of it, for it was hardly a privation for him not to look at a particular picture-book any more. If his naughty sister had not kept on showing him the book with the picture of the wolf standing upright in it, he would have been able to feel safe from his fear.

[1926d, 4282]

The anxiety felt in animal phobias is, therefore, an affective reaction on the part of the ego to danger; and the danger which is being signalled in this way is the danger of castration. This anxiety differs in no respect from the realistic anxiety which the ego normally feels in situations of danger, except that its content remains unconscious and only becomes conscious in the form of a distortion.

[1926d, 4283]

One objection to it is that loss of an object (or loss of love on the part of the object) and the threat of castration are just as much dangers coming from outside as, let us say, a ferocious animal would be; they are not instinctual dangers. Nevertheless, the two cases are not the same. A wolf would probably attack us irrespectively of our behaviour towards it; but the loved person would not cease to love us nor should we be threatened with castration if we did not entertain certain feelings and intentions within us. Thus such instinctual impulses are determinants of external dangers and so become dangerous in themselves; and we can now proceed against the external danger by taking measures against the internal ones. In phobias of animals the danger seems to be still felt entirely as an external one, just as it has undergone an external displacement in the symptom. In obsessional neuroses the danger is much more internalized. That portion of anxiety in regard to the super-ego which constitutes social anxiety still represents an internal substitute for an external danger, while the other portion - moral anxiety - is already completely endopsychic.

[1926d, 4300]
Why this should be so calls for a rather long reply. First of all, we must sift the facts. In a great number of cases the old determinants of anxiety do really lapse, after having produced neurotic reactions. The phobias of very young children, fears of being alone or in the dark or with strangers - phobias which can almost be called normal - usually pass off later on; the child 'grows out of them', as we say about some other disturbances of childhood. Animal phobias, which are of such frequent occurrence, undergo the same fate and many conversion hysterias of early years find no continuation in later life. Ceremonial actions appear extremely often in the latency period, but only a very small percentage of them develop later into a full obsessional neurosis. In general, so far as we can tell from our observations of town children belonging to the white races and living according to fairly high cultural standards, the neuroses of childhood are in the nature of regular episodes in a child's development, although too little attention is still being paid to them. Signs of childhood neuroses can be detected in all adult neurotics without exception; but by no means all children who show those signs become neurotic in later life. It must be, therefore, that certain determinants of anxiety are relinquished and certain danger-situations lose their significance as the individual becomes more mature. Moreover, some of these danger-situations manage to survive into later times by modifying their determinants of anxiety so as to bring them up to date. Thus, for instance, a man may retain his fear of castration in the guise of a syphilidophobia, after he has come to know that it is no longer customary to castrate people for indulging their sexual lusts, but that, on the other hand, severe diseases may overtake anyone who thus gives way to his instincts. Other determinants of anxiety, such as fear of the super-ego, are destined not to disappear at all but to accompany people throughout their lives. In that case the neurotic will differ from the normal person in that his reactions to the dangers in question will be unduly strong. Finally, being grown-up affords no absolute protection against a return of the original traumatic anxiety-situation. Each individual has in all probability a limit beyond which his mental apparatus fails in its function of mastering the quantities of excitation which require to be disposed of.

In this connection the puzzling phobias of early childhood deserve to be mentioned once again. We have been able to explain some of them, such as the fear of being alone or in the dark or with strangers, as reactions to the danger of losing the object. Others, like the fear of small animals, thunder storms, etc., might perhaps be accounted for as vestigial traces of the congenital preparedness to meet real dangers which is so strongly developed in other animals. In man, only that part of this archaic heritage is appropriate which has reference to the loss of the object. If childhood phobias become fixated and grow stronger and persist into later years, analysis shows that their content has become associated with instinctual demands and has come to stand for internal dangers as well.
It must be supposed that after the parricide a considerable time elapsed during which the brothers disputed with one another for their father's heritage, which each of them wanted for himself alone. A realization of the dangers and uselessness of these struggles, a recollection of the act of liberation which they had accomplished together, and the emotional ties with one another which had arisen during the period of their expulsion, led at last to an agreement among them, a sort of social contract. The first form of a social organization came about with a renunciation of instinct, a recognition of mutual obligations, the introduction of definite institutions, pronounced inviolable (holy) - that is to say, the beginnings of morality and justice. Each individual renounced his ideal of acquiring his father's position for himself and of possessing his mother and sisters. Thus the taboo on incest and the injunction to exogamy came about. A fair amount of the absolute power liberated by the removal of the father passed over to the women; there came a period of matriarchy. Recollection of their father persisted at this period of the 'fraternal alliance'. A powerful animal - at first, perhaps, always one that was feared as well - was chosen as a substitute for the father. A choice of this kind may seem strange, but the gulf which men established later between themselves and animals did not exist for primitive peoples; nor does it exist for our children, whose animal phobias we have been able to understand as fear of their father. In relation to the totem animal the original dichotomy in the emotional relation to the father (ambivalence) was wholly retained. On the one hand the totem was regarded as the clan's blood ancestor and protective spirit, who must be worshipped and protected, and on the other hand a festival was appointed at which the same fate was prepared for him that the primal father had met with. He was killed and devoured by all the tribesmen in common. (The totem meal, according to Robertson Smith.) This great festival was in fact a triumphant celebration of the combined sons' victory over their father. [1939a, 4906]

It must be admitted that this historical survey has gaps in it and is uncertain at some points. But anyone who is inclined to pronounce our construction of primaeval history purely imaginary would be gravely under-estimating the wealth and evidential value of the material contained in it. Large portions of the past, which have been linked together here into a whole, are historically attested: totemism and the male confederacies, for instance. Other portions have survived in excellent replicas. Thus authorities have often been struck by the faithful way in which the sense and content of the old totem meal is repeated in the rite of the Christian Communion, in which the believer incorporates the blood and flesh of his god in symbolic form. Numerous relics of the forgotten primaeval age have survived in popular legends and fairy tales, and the analytic study of the mental life of children has provided an unexpected wealth of material for filling the gaps in our knowledge of the earliest times. As contributions to our understanding of the son's relation to the father which is of such great importance, I need only bring forward animal phobias, the fear, which strikes us as so strange, of being eaten by the father, and the enormous intensity of the dread of being castrated. There is nothing wholly fabricated in our construction, nothing which could not be supported on solid foundations. [1939a, 4908]
Why this should be so calls for a rather long reply. First of all, we must sift the facts. In a great number of cases the old determinants of anxiety do really lapse, after having produced neurotic reactions. The phobias of very young children, fears of being alone or in the dark or with strangers - phobias which can almost be called normal - usually pass off later on; the child 'grows out of them', as we say about some other disturbances of childhood. Animal phobias, which are of such frequent occurrence, undergo the same fate and many conversion hysterias of early years find no continuation in later life. Ceremonial actions appear extremely often in the latency period, but only a very small percentage of them develop later into a full obsessional neurosis. In general, so far as we can tell from our observations of town children belonging to the white races and living according to fairly high cultural standards, the neuroses of childhood are in the nature of regular episodes in a child's development, although too little attention is still being paid to them. Signs of childhood neuroses can be detected in all adult neurotics without exception; but by no means all children who show those signs become neurotic in later life. It must be, therefore, that certain determinants of anxiety are relinquished and certain danger-situations lose their significance as the individual becomes more mature. Moreover, some of these danger-situations manage to survive into later times by modifying their determinants of anxiety so as to bring them up to date. Thus, for instance, a man may retain his fear of castration in the guise of a syphilidophobia, after he has come to know that it is no longer customary to castrate people for indulging their sexual lusts, but that, on the other hand, severe diseases may overtake anyone who thus gives way to his instincts. Other determinants of anxiety, such as fear of the super-ego, are destined not to disappear at all but to accompany people throughout their lives. In that case the neurotic will differ from the normal person in that his reactions to the dangers in question will be unduly strong. Finally, being grown-up affords no absolute protection against a return of the original traumatic anxiety-situation. Each individual has in all probability a limit beyond which his mental apparatus fails in its function of mastering the quantities of excitation which require to be disposed of.

[1926d, 4302]

In this connection the puzzling phobias of early childhood deserve to be mentioned once again. We have been able to explain some of them, such as the fear of being alone or in the dark or with strangers, as reactions to the danger of losing the object. Others, like the fear of small animals, thunder storms, etc., might perhaps be accounted for as vestigial traces of the congenital preparedness to meet real dangers which is so strongly developed in other animals. In man, only that part of this archaic heritage is appropriate which has reference to the loss of the object. If childhood phobias become fixated and grow stronger and persist into later years, analysis shows that their content has become associated with instinctual demands and has come to stand for internal dangers as well.

[1926d, 4320]
A patient, then, may be suffering from fluctuations in his moods which he cannot control, or from a sense of despondency by which his energy feels paralysed because he thinks he is incapable of doing anything properly, or from a nervous embarrassment among strangers. He may perceive, without understanding the reason for it, that he has difficulties in carrying out his professional work, or indeed any comparatively important decision or any undertaking. He may one day have suffered from a distressing attack - unknown in its origin - of feelings of anxiety, and since then have been unable, without a struggle, to walk along the street alone, or to travel by train; he may perhaps have had to give up both entirely. Or, a very remarkable thing, his thoughts may go their own way and refuse to be directed by his will. They pursue problems that are quite indifferent to him, but from which he cannot get free. Quite ludicrous tasks, too, are imposed on him, such as counting up the windows on the fronts of houses. And when he has performed simple actions such as posting a letter or turning off a gas-jet, he finds himself a moment later doubting whether he has really done so. This may be no more than an annoyance and a nuisance. But his state becomes intolerable if he suddenly finds he is unable to fend off the idea that he has pushed a child under the wheels of a car or has thrown a stranger off the bridge into the water, or if he has to ask himself whether he is not the murderer whom the police are looking for in connection with a crime that was discovered that day. It is obvious nonsense, as he himself knows; he has never done any harm to anyone; but if he were really the murderer who is being looked for, his feeling - his sense of guilt - could not be stronger.

Otto Rank, to whom psycho-analysis is indebted for many excellent contributions, also has the merit of having expressly emphasized the significance of the act of birth and of separation from the mother. Nevertheless we have all found it impossible to accept the extreme inferences which he has drawn from this factor as bearing on the theory of the neuroses and even on analytic therapy. The core of his theory - that the experience of anxiety at birth is the model of all later situations of danger - he found already there. If we dwell on these situations of danger for a moment, we can say that in fact a particular determinant of anxiety (that is, situation of danger) is allotted to every age of development as being appropriate to it. The danger of psychical helplessness fits the stage of the ego's early immaturity; the danger of loss of an object (or loss of love) fits the lack of self-sufficiency in the first years of childhood; the danger of being castrated fits the phallic phase; and finally fear of the super-ego, which assumes a special position, fits the period of latency. In the course of development the old determinants of anxiety should be dropped, since the situations of danger corresponding to them have lost their importance owing to the strengthening of the ego. But this only occurs most incompletely. Many people are unable to surmount the fear of loss of love; they never become sufficiently independent of other people's love and in this respect carry on their behaviour as infants. Fear of the super-ego should normally never cease, since, in the form of moral anxiety, it is indispensable in social relations, and only in the rarest cases can an individual become independent of human society. A few of the old situations of danger, too, succeed in surviving into later periods by making contemporary modifications in their determinants of anxiety. Thus, for instance, the danger of castration persists under the mark of syphilidophobia. It is true that as an adult one knows that castration is no longer customary as a punishment for the indulgence of sexual desires, but on the other hand one has learnt that instinctual liberty of that kind is threatened by serious diseases. There is no doubt that the people we describe as neurotics remain infantile in their attitude to danger and have not surmounted obsolete determinants of anxiety. We may take this as a factual contribution to the characterization of neurotics; it is not so easy to say why it should be so.
Disorders of this kind are called ‘phobias’, and we might classify Hans's case as an agoraphobia if it were not for the fact that it is a characteristic of that complaint that the locomotion of which the patient is otherwise incapable can always be easily performed when he is accompanied by some specially selected person - in the last resort, by the physician. Hans's phobia did not fulfil this condition; it soon ceased having any relation to the question of locomotion and became more and more clearly concentrated upon horses. In the early days of his illness, when the anxiety was at its highest pitch, he expressed a fear that 'the horse'll come into the room', and it was this that helped me so much towards understanding his condition.

[1909b, 2099]

In the classificatory system of the neuroses no definite position has hitherto been assigned to 'phobias'. It seems certain that they should only be regarded as syndromes which may form part of various neuroses and that we need not rank them as an independent pathological process. For phobias of the kind to which little Hans's belongs, and which are in fact the most common, the name of 'anxiety-hysteria' seems to me not inappropriate; I suggested the term to Dr. W. Stekel when he was undertaking a description of neurotic anxiety states," and I hope it will come into general use. It finds its justification in the similarity between the psychological structure of these phobias and that of hysteria - a similarity which is complete except upon a single point. That point, however, is a decisive one and well adapted for purposes of differentiation. For in anxiety-hysteria the libido which has been liberated from the pathogenic material by repression is not converted (that is, diverted from the mental sphere into a somatic innervation), but is set free. In the clinical cases that we meet with, this 'anxiety-hysteria' may be combined with 'conversion-hysteria' in any proportion. There exist cases of pure conversion-hysteria without any trace of anxiety, just as there are cases of simple anxiety-hysteria, which exhibit feelings of anxiety and phobias, but have no admixture of conversion. The case of little Hans is one of the latter sort.

[1909b, 2099]
What we have learnt about anxiety in phobias is applicable to obsessional neuroses as well. In this respect it is not difficult for us to put obsessional neuroses on all fours with phobias. In the former, the mainspring of all later symptom-formation is clearly the ego's fear of its super-ego. The danger-situation from which the ego must get away is the hostility of the super-ego. There is no trace of projection here; the danger is completely internalized. But if we ask ourselves what it is that the ego fears from the super-ego, we cannot but think that the punishment threatened by the latter must be an extension of the punishment of castration. Just as the father has become depersonalized in the shape of the super-ego, so has the fear of castration at his hands become transformed into an undefined social or moral anxiety. But this anxiety is concealed. The ego escapes it by obediently carrying out the commands, precautions and penances that have been enjoined on it. If it is impeded in doing so, it is at once overtaken by an extremely distressing feeling of discomfort which may be regarded as an equivalent of anxiety and which the patients themselves liken to anxiety.

[1926d, 4285]
In the classificatory system of the neuroses no definite position has hitherto been assigned to 'phobias'. It seems certain that they should only be regarded as syndromes which may form part of various neuroses and that we need not rank them as an independent pathological process. For phobias of the kind to which little Hans's belongs, and which are in fact the most common, the name of ‘anxiety-hysteria’ seems to me not inappropriate; I suggested the term to Dr. W. Stekel when he was undertaking a description of neurotic anxiety states,¹ and I hope it will come into general use. It finds its justification in the similarity between the psychological structure of these phobias and that of hysteria - a similarity which is complete except upon a single point. That point, however, is a decisive one and well adapted for purposes of differentiation. For in anxiety-hysteria the libido which has been liberated from the pathogenic material by repression is not converted (that is, diverted from the mental sphere into a somatic innervation), but is set free. In the clinical cases that we meet with, this ‘anxiety-hysteria’ may be combined with ‘conversion-hysteria’ in any proportion. There exist cases of pure conversion-hysteria without any trace of anxiety, just as there are cases of simple anxiety-hysteria, which exhibit feelings of anxiety and phobias, but have no admixture of conversion. The case of little Hans is one of the latter sort.
[1909b, 2099]

The two forms of anxiety that I have just described - the freely floating expectant anxiety and the sort which is bound to phobias - are independent of each other. One is not a higher stage, as it were, of the other; and they only appear simultaneously in exceptional cases and, so to speak, accidentally. The most powerful general apprehensiveness need not be expressed in phobias; people whose whole existence is restricted by agoraphobia may be entirely free from pessimistic expectant anxiety. Some phobias - for instance, agoraphobia and railway phobia - are demonstrably acquired at a fairly mature age, while others - such as fear of darkness, thunderstorms and animals - seem to have been present from the first. Those of the former kind have the significance of severe illnesses; the latter make their appearance rather as eccentricities or whims. If a person exhibits one of these latter, one may suspect as a rule that he will have other similar ones. I must add that we class all these phobias as anxiety hysteria; that is to say, we regard them as a disorder closely related to the familiar conversion hysteria.
[1916-1917, 3447]

We set out to study the formation of symptoms and the secondary struggle waged by the ego against symptoms. But in picking on the phobias for this purpose we have clearly made an unlucky choice. The anxiety which predominates in the picture of these disorders is now seen as a complication which obscures the situation. There are plenty of neuroses which exhibit no anxiety whatever. True conversion hysteria is one of these. Even in its most severe symptoms no admixture of anxiety is found. This fact alone ought to warn us against making too close a connection between anxiety and symptom-formation. The phobias are so closely akin to conversion hysteria in every other respect that I have felt justified in classing them alongside of it under the name of ‘anxiety hysteria’. But no one has as yet been able to say what it is that determines whether any given case shall take the form of a conversion hysteria or a phobia - has been able, that is to say, to establish what determines the generating of anxiety in hysteria.
[1926d, 4270]
A deeper insight into the mechanism of obsessional neurosis is gained if we take into account the primary fact which lies at the bottom of it. This is always the repression of an instinctual impulse (a component of the sexual instinct) which was present in the subject's constitution and which was allowed to find expression for a while during his childhood but later succumbed to suppression. In the course of the repression of this instinct a special conscientiousness is created which is directed against the instinct's aims; but this psychical reaction-formation feels insecure and constantly threatened by the instinct which is lurking in the unconscious. The influence of the repressed instinct is felt as a temptation, and during the process of repression itself anxiety is generated, which gains control over the future in the form of expectant anxiety. The process of repression which leads to obsessional neurosis must be considered as one which is only partly successful and which increasingly threatens to fail. It may thus be compared to an unending conflict; fresh psychical efforts are continually required to counterbalance the forward pressure of the instinct. Thus the ceremonial and obsessive actions arise partly as a defence against the temptation and partly as a protection against the ill which is expected. Against the temptation the protective measures seem soon to become inadequate; then the prohibitions come into play, with the purpose of keeping at a distance situations that give rise to temptation. Prohibitions take the place of obsessive actions, it will be seen, just as a phobia is designed to avert a hysterical attack. Again, a ceremonial represents the sum of the conditions subject to which something that is not yet absolutely forbidden is permitted, just as the Church's marriage ceremony signifies for the believer a sanctioning of sexual enjoyment which would otherwise be sinful. A further characteristic of obsessional neurosis, as of all similar affections, is that its manifestations (its symptoms, including the obsessive actions) fulfil the condition of being a compromise between the warring forces of the mind. They thus always reproduce something of the pleasure which they are designed to prevent; they serve the repressed instinct no less than the agencies which are repressing it. As the illness progresses, indeed, actions which were originally mostly concerned with maintaining the defence come to approximate more and more to the proscribed actions through which the instinct was able to find expression in childhood.

[1907b, 1907]
His anxiety, then, corresponded to repressed longing. But it was not the same thing as the longing: the repression must be taken into account too. Longing can be completely transformed into satisfaction if it is presented with the object longed for. Therapy of that kind is no longer effective in dealing with anxiety. The anxiety remains even when the longing can be satisfied. It can no longer be completely retransformed into libido; there is something that keeps the libido back under repression.¹ This was shown to be so in the case of Hans on the occasion of his next walk, when his mother went with him. He was with his mother, and yet he still suffered from anxiety - that is to say, from an unsatisfied longing for her. It is true that the anxiety was less; for he did allow himself to be induced to go for the walk, whereas he had obliged the nursemaid to turn back. Nor is a street quite the right place for 'coaxing', or whatever else this young lover may have wanted. But his anxiety had stood the test; and the next thing for it to do was to find an object. It was on this walk that he first expressed a fear that a horse would bite him. Where did the material for this phobia come from? Probably from the complexes, as yet unknown to us, which had contributed to the repression and were keeping under repression his libidinal feelings towards his mother. That is an unsolved problem, and we shall now have to follow the development of the case in order to arrive at its solution. Hans's father has already given us certain clues, probably trustworthy ones, such as that Hans had always observed horses with interest on account of their large widdlers, that he had supposed that his mother must have a widdler like a horse, and so on. We might thus be led to think that the horse was merely a substitute for his mother. But if so, what would be the meaning of his being afraid in the evening that a horse would come into the room? A small boy's foolish fears, it will be said. But a neurosis never says foolish things, any more than a dream. When we cannot understand something, we always fall back on abuse. An excellent way of making a task lighter.

¹ To speak quite frankly, this is actually the criterion according to which we decide whether such feelings of mingled apprehension and longing are normal or not: we begin to call them 'pathological anxiety' from the moment at which they can no longer be relieved by the attainment of the object longed for.

The treatment of anxiety-hysteria may be said hitherto to have been a purely negative one. Experience has shown that it is impossible to effect the cure of a phobia (and even in certain circumstances dangerous to attempt to do so) by violent means, that is, by first depriving the patient of his defences and then putting him in a situation in which he cannot escape the liberation of his anxiety. Consequently, nothing can be done but to leave the patient to look for protection wherever he thinks he may find it; and he is merely regarded with a not very helpful contempt for his 'incomprehensible cowardice'.

It not at all infrequently happens that it is only after doing a certain amount of psycho-analytic work with a patient that an analyst can succeed in learning the actual content of a phobia, the precise form of words of an obsessional impulse, and so on. Repression has not only descended upon the unconscious complexes, but it is continually attacking their derivatives as well, and even prevents the patient from becoming aware of the products of the disease itself. The analyst thus finds himself in the position, curious for a doctor, of coming to the help of a disease, and of procuring it its due of attention. But only those who entirely misunderstand the nature of psycho-analysis will lay stress upon this phase of the work and suppose that on its account harm is likely to be done by analysis. The fact is that you must catch your thief before you can hang him, and that it requires some expenditure of labour to get securely hold of the pathological structures - at the destruction of which the treatment is aimed.
We are also now coming to the opinion that analytic technique must be modified in certain ways according to the nature of the disease and the dominant instinctual trends in the patient. We started out from the treatment of conversion hysteria; in anxiety hysteria (phobias) we must to some extent alter our procedure. For these patient cannot bring out the material necessary for resolving their phobia so long as they feel protected by obeying the condition which it lays down. One cannot, of course, succeed in getting them to give up their protective measures and work under the influence of anxiety from the beginning of the treatment. One must therefore help them by interpreting their unconscious to them until they can make up their minds to do without the protection of their phobia and expose themselves to a now greatly mitigated anxiety. Only after they have done so does the material become accessible, which, when it has been mastered, leads to a solution of the phobia. Other modifications of technique, which seem to me not yet ripe for discussion, will be required in the treatment of obsessional neurosis. In this connection very important questions arise, which have not hitherto been elucidated: how far the instincts which the patient is combating are to be allowed some satisfaction during the treatment, and what difference it makes whether these impulses are active (sadistic) or passive (masochistic) in their nature.

[1910d, 2310]

Let us return to the phobias. I can safely say that you now see how inadequate it is merely to seek to explain their content, to take no interest in anything but how it comes about that this or that object or some particular situation or other has been made into the object of the phobia. The content of a phobia has just about as much importance in relation to it as the manifest façade of a dream has in relation to the dream. It must be admitted, subject to the necessary qualifications, that among the contents of phobias there are a number which, as Stanley Hall insists, are adapted to serve as objects of anxiety owing to phylogenetic inheritance. It tallies with this, indeed, that many of these anxiety-objects can only establish their connection with danger by a symbolic tie.

[1916-1917, 3457]

Lastly, another quite different kind of activity is necessitated by the gradually growing appreciation that the various forms of disease treated by us cannot all be dealt with by the same technique. It would be premature to discuss this in detail, but I can give two examples of the way in which a new kind of activity comes into question. Our technique grew up in the treatment of hysteria and is still directed principally to the cure of that affection. But the phobias have already made it necessary for us to go beyond our former limits. One can hardly master a phobia if one waits till the patient lets the analysis influence him to give it up. He will never in that case bring into the analysis the material indispensable for a convincing resolution of the phobia. One must proceed differently. Take the example of agoraphobia; there are two classes of it, one mild, the other severe. Patients belonging to the first class suffer from anxiety when they go into the street by themselves, but they have not yet given up going out alone on that account; the others protect themselves from the anxiety by altogether ceasing to go about alone. With these last one succeeds only when one can induce them by the influence of the analysis to behave like phobic patients of the first class - that is, to go into the street and to struggle with their anxiety while they make the attempt. One starts, therefore, by moderating the phobia so far; and it is only when that has been achieved at the physician's demand that the associations and memories come into the patient's mind which enable the phobia to be resolved.

[1919a, 3634]
Psycho-analysis finds a constantly increasing amount of support as a therapeutic procedure, owing to the fact that it can do more for its patients than any other method of treatment. The principle field of its application is in the milder neuroses - hysteria, phobias and obsessional states; and in malformations of character and sexual inhibitions or abnormalities it can also bring about marked improvements or even recoveries. Its influence upon dementia praecox and paranoia is doubtful; on the other hand, in favourable circumstances it can cope with depressive states, even if they are of a severe type.

[1926f, 4402]
My investigations into the aetiology and psychical mechanism of neurotic illnesses, which I have pursued since 1893, attracted little notice to begin with among my fellow specialists. At length, however, those investigations have met with recognition from a number of medical research workers and have also drawn attention to the psycho-analytic methods of examination and treatment to which I owe my findings. Dr. Wilhelm Stekel, who was one of the first of the colleagues to whom I was able to impart a knowledge of psycho-analysis, and who has himself become familiar with its technique through many years of practice in it, has now undertaken the task of working over one topic in the clinical aspect of these neuroses on the basis of my views and of presenting medical readers with the experiences he has obtained through the psycho-analytic method. If I am glad to take the responsibility for his work in the sense which I have just indicated, I think it is only right to declare explicitly that my direct influence upon the volume on nervous states of anxiety which lies before us has been a very slight one. The observations and all the detailed opinions and interpretations are the author's own. My share has been limited to proposing the use of the term 'anxiety hysteria'.

In the classificatory system of the neuroses no definite position has hitherto been assigned to 'phobias'. It seems certain that they should only be regarded as syndromes which may form part of various neuroses and that we need not rank them as an independent pathological process. For phobias of the kind to which little Hans's belongs, and which are in fact the most common, the name of 'anxiety-hystera' seems to me not inappropriate; I suggested the term to Dr. W. Stekel when he was undertaking a description of neurotic anxiety states,¹ and I hope it will come into general use. It finds its justification in the similarity between the psychological structure of these phobias and that of hysteria - a similarity which is complete except upon a single point. That point, however, is a decisive one and well adapted for purposes of differentiation. For in anxiety-hysteria the libido which has been liberated from the pathogenic material by repression is not converted (that is, diverted from the mental sphere into a somatic innervation), but is set free in the clinical cases that we meet with, this 'anxiety-hystera' may be combined with 'conversion-hysteria' in any proportion. There exist cases of pure conversion-hysteria without any trace of anxiety, just as there are cases of simple anxiety-hystera, which exhibit feelings of anxiety and phobias, but have no admixture of conversion. The case of little Hans is one of the latter sort.

Anxiety-hysterias are the most common of all psychoneurotic disorders. But, above all, they are those which make their appearance earliest in life; they are par excellence the neuroses of childhood. When a mother uses such phrases as that her child's 'nerves' are in a bad state, we can be certain that in nine cases out of ten the child is suffering from some kind of anxiety or from many kinds at once. Unfortunately the finer mechanism of these highly significant disorders has not yet been sufficiently studied. It has not yet been established whether anxiety-hystera is determined, in contradistinction to conversion-hysteria and other neuroses, solely by constitutional factors or solely by accidental experiences, or by what combination of the two.¹ It seems to me that of all neurotic disorders it is the least dependent upon a special constitutional predisposition and that it is consequently the most easily acquired at any time of life.
One essential characteristic of anxiety-hysteries is very easily pointed out. An anxiety-hystera tends to develop more and more into a 'phobia'. In the end the patient may have got rid of all his anxiety, but only at the price of subjecting himself to all kinds of inhibitions and restrictions. From the outset in anxiety-hystera the mind is constantly at work in the direction of once more psychically binding the anxiety which has become liberated; but this work can neither bring about a retransformation of the anxiety into libido, nor can it establish any contact with the complexes which were the source of the libido. Nothing is left for it but to cut off access to every possible occasion that might lead to the development of anxiety, by erecting mental barriers in the nature of precautions, inhibitions, or prohibitions; and it is these defensive structures that appear to us in the form of phobias and that constitute to our eyes the essence of the disease.

[1909b, 2100]

We are also now coming to the opinion that analytic technique must be modified in certain ways according to the nature of the disease and the dominant instinctual trends in the patient. We started out from the treatment of conversion hysteria; in anxiety hysteria (phobias) we must to some extent alter our procedure. For these patient cannot bring out the material necessary for resolving their phobia so long as they feel protected by obeying the condition which it lays down. One cannot, of course, succeed in getting them to give up their protective measures and work under the influence of anxiety from the beginning of the treatment. One must therefore help them by interpreting their unconscious to them until they can make up their minds to do without the protection of their phobia and expose themselves to a now greatly mitigated anxiety. Only after they have done so does the material become accessible, which, when it has been mastered, leads to a solution of the phobia. Other modifications of technique, which seem to me not yet ripe for discussion, will be required in the treatment of obsessional neurosis. In this connection very important questions arise, which have not hitherto been elucidated: how far the instincts which the patient is combating are to be allowed some satisfaction during the treatment, and what difference it makes whether these impulses are active (sadistic) or passive (masochistic) in their nature.

[1910d, 2310]

All this seems very clear, and yet it must be admitted the there is one factor which often makes it difficult to form a judgement. Some nervous states which we call the 'actual neuroses', such as typical neurasthenia and pure anxiety neurosis, obviously depend on the somatic factor in sexual life, while we have no certain picture as yet of the part played in them by the psychical factor and by repression. In such cases it is natural that the physician should first consider some 'actual' therapy, some alteration in the patient's somatic sexual activity, and he does so with perfect justification if his diagnosis is correct. The lady who consulted the young doctor complained chiefly of anxiety-states, and so he probably assumed that she was suffering from an anxiety neurosis, and felt justified in recommending a somatic therapy to her. Again a convenient misapprehension! A person suffering from anxiety is not for that reason necessarily suffering from anxiety neurosis; such a diagnosis of it cannot be based on the name; one has to know what signs constitute an anxiety neurosis, and be able to distinguish it from other pathological states which are also manifested by anxiety. My impression was that the lady in question was suffering from anxiety *hysteria*, and the whole value of such nosographical distinctions, one which quite justifies them, lies in the fact that they indicate a different aetiology and a different treatment. No one who took into consideration the possibility of anxiety hysteria in this case would have fallen into the error of neglecting the mental factors, as this physician did with his three alternatives.

[1910k, 2377]
(1) Our first reflection will tell us that it cannot be the case that this detachment of the libido occurs exclusively in paranoia; nor can it be that, where it occurs elsewhere, it has such disastrous consequences. It is quite possible that a detachment of the libido is the essential and regular mechanism of every repression. We can have no positive knowledge on that point until the other disorders that are based upon repression have been similarly examined. But it is certain that in normal mental life (and not only in periods of mourning) we are constantly detaching our libido in this way from people or from other objects without falling ill. When Faust freed himself from the world by uttering his curses, the result was not a paranoia or any other neurosis but simply a certain general frame of mind. The detachment of the libido, therefore, cannot in itself be the pathogenic factor in paranoia; there must be some special characteristic which distinguishes a paranoic detachment of the libido from other kinds. It is not difficult to suggest what that characteristic may be. What use is made of the libido after it has been set free by the process of detachment? A normal person will at once begin looking about for a substitute for the lost attachment; and until that substitute has been found the liberated libido will be kept in suspension within his mind, and will there give rise to tensions and colour his mood. In hysteria the liberated libido becomes transformed into somatic innervations or into anxiety. But in paranoia the clinical evidence goes to show that the libido, after it has been withdrawn from the object, is put to a special use. It will be remembered that the majority of cases of paranoia exhibit traces of megalomania, and that megalomania can by itself constitute a paranoia. From this it may be concluded that in paranoia the liberated libido becomes attached to the ego, and is used for the aggrandizement of the ego. A return is thus made to the stage of narcissism (known to us from the development of the libido), in which a person's only sexual object is his own ego. On the basis of this clinical evidence we can suppose that paranoics have brought along with them a fixation at the stage of narcissism, and we can assert that the length of the step back from sublimated homosexuality to narcissism is a measure of the amount of regression characteristic of paranoia.

[1911c, 2438]

I shall now take my footing once more on the clinical observation of an individual case. Over a long period I studied a woman patient whose neurosis underwent an unusual change. It began, after a traumatic experience, as a straightforward anxiety hysteria and retained that character for a few years. One day, however, it suddenly changed into an obsessional neurosis of the severest type. A case of this kind could not fail to become significant in more than one direction. On the one hand, it might perhaps claim to be looked upon like a bilingual document and to show how an identical content could be expressed by the two neuroses in different languages. On the other hand, it threatened to contradict completely our theory that disposition arises from developmental inhibition, unless we were prepared to accept the supposition that a person could innately possess more than one weak spot in his libidinal development. I told myself that we had no right to dismiss this latter possibility; but I was greatly interested to arrive at an understanding of the case.

[1913i, 2625]
Unfortunately I am unable, for familiar reasons, to enter into the history of the case as far as I should like, and I must restrict myself to the account which follows. Up to the time of her falling ill the patient had been a happy and almost completely satisfied wife. She wanted to have children, from motives based on an infantile fixation of her wishes, and she fell ill when she learned that it was impossible for her to have any by the husband who was the only object of her love. The anxiety hysteria with which she reacted to this frustration corresponded, as she herself soon learned to understand, to the repudiation of phantasies of seduction in which her firmly implanted wish for a child found expression. She now did all she could to prevent her husband from guessing that she had fallen ill owing to the frustration of which he was the cause. But I have had good reason for asserting that everyone possesses in his own unconscious an instrument with which he can interpret the utterances of the unconscious in other people. Her husband understood, without any admission or explanation on her part, what his wife’s anxiety meant; he felt hurt, without showing it, and in his turn reacted neurotically by - for the first time - failing in sexual intercourse with her. Immediately afterwards he started on a journey. His wife believed that he had become permanently impotent, and produced her first obsessional symptoms on the day before his expected return.

[1913i, 2626]

In the first place observation shows, in a manner that excludes all doubt, that the infantile experiences have an importance of their own and give evidence of it already in childhood. Children too have their neuroses, in which the factor of displacement backwards in time is necessarily very much reduced or is even completely absent, since the onset of the illness follows the traumatic experiences immediately. The study of these infantile neuroses protects us from more than one dangerous misunderstanding of the neuroses of adults, just as the dreams of children gave the key to an understanding of adult dreams. Children's neuroses are very common, much commoner than is supposed. They are often overlooked, regarded as signs of a bad or naughty child, often, too, kept under by the nursery authorities; but they can always be easily recognized in retrospect. They usually appear in the form of anxiety hysteria. We shall learn on a later occasion what that means. If a neurosis breaks out in later life, analysis regularly reveals it as a direct continuation of the infantile illness which may have emerged as no more than a veiled hint. As I have said, however, there are cases in which these signs of neurosis in childhood proceed uninterruptedly into a lifelong illness. We have been able to analyse a few examples of these children's neuroses in childhood itself - when they were actually present; but far more often we have had to be content with someone who has fallen ill in adult life enabling us to obtain a deferred insight into his childhood neurosis. In such cases we must not fail to make certain corrections and take certain precautions.

[1916-1917, 3421]
(b) A second pointer is to be found in the analysis of the psychoneuroses, and especially of hysteria. We have seen that in this illness anxiety often appears in company with the symptoms, but that unbound anxiety appears, too, manifested as an attack or as a chronic condition. The patients cannot say what it is they are afraid of, and, by the help of an unmistakable secondary revision, link it to the first phobias that come to hand - such as dying, going mad, or having a stroke. If the situation out of which the anxiety (or the symptoms accompanied by anxiety) arose is subjected to analysis, we can as a rule discover what normal course of psychical events has failed to occur and has been replaced by phenomena of anxiety. To express it in another way: we construct the unconscious process as it would have been if it had not experienced any repression and had proceeded unhindered into consciousness. This process would have been accompanied by a particular affect, and we now learn to our surprise that this affect accompanying the normal course of events is invariably replaced by anxiety after repression has occurred, no matter what its own quality may be. Thus, when we have a hysterical anxiety-state before us, its unconscious correlate may be an impulse of a similar character - anxiety, shame, embarrassment - or, just as easily, a positive libidinal excitation or a hostile aggressive one, such as rage or anger. Anxiety is therefore the universally current coinage for which any affective impulse is or can be exchanged if the ideational content attached to it is subjected to repression.
[1916-1917, 3450]

That there is a relationship between inhibition and anxiety is pretty evident. Some inhibitions obviously represent a relinquishment of a function because its exercise would produce anxiety. Many women are openly afraid of the sexual function. We class this anxiety under hysteria, just as we do the defensive symptom of disgust which, arising originally as a deferred reaction to the experiencing of a passive sexual act, appears later whenever the idea of such an act is presented. Furthermore, many obsessional acts turn out to be measures of precaution and security against sexual experiences and are thus of a phobic character.
[1926d, 4249]

We set out to study the formation of symptoms and the secondary struggle waged by the ego against symptoms. But in picking on the phobias for this purpose we have clearly made an unlucky choice. The anxiety which predominates in the picture of these disorders is now seen as a complication which obscures the situation. There are plenty of neuroses which exhibit no anxiety whatever. True conversion hysteria is one of these. Even in its most severe symptoms no admixture of anxiety is found. This fact alone ought to warn us against making too close a connection between anxiety and symptom-formation. The phobias are so closely akin to conversion hysteria in every other respect that I have felt justified in classing them alongside of it under the name of 'anxiety hysteria'. But no one has as yet been able to say what it is that determines whether any given case shall take the form of a conversion hysteria or a phobia - has been able, that is to say, to establish what determines the generating of anxiety in hysteria.
[1926d, 4270]
For we have recently been examining the way in which anxiety is generated in certain phobias which we class as anxiety hysteria, and have chosen cases in which we were dealing with the typical repression of wishful impulses arising from the Oedipus complex. We should have expected to find that it was a libidinal cathexis of the boy's mother as object which, as a result of repression, had been changed into anxiety and which now emerged, expressed in symptomatic terms, attached to a substitute for his father. I cannot present you with the detailed steps of an investigation such as this; it will be enough to say that the surprising result was the opposite of what we expected. It was not the repression that created the anxiety; the anxiety was there earlier; it was the anxiety that made the repression. But what sort of anxiety can it have been? Only anxiety in the face of a threatening external danger - that is to say, a realistic anxiety. It is true that the boy felt anxiety in the face of a demand by his libido - in this instance, anxiety at being in love with his mother; so the case was in fact one of neurotic anxiety. But this being in love only appeared to him as an internal danger, which he must avoid by renouncing that object, because it conjured up an external situation of danger. And in every case we examine we obtain the same result. It must be confessed that we were not prepared to find that internal instinctual danger would turn out to be a determinant and preparation for an external, real, situation of danger.

[1933a, 4692]
From the field of *anxiety hysteria* I will choose a well-analysed example of an animal phobia. The instinctual impulse subjected to repression here is a libidinal attitude towards the father, coupled with fear of him. After repression, this impulse vanishes out of consciousness: the father does not appear in it as an object of libido. As a substitute for him we find in a corresponding place some animal which is more or less fitted to be an object of anxiety. The formation of the substitute for the ideational portion has come about by *displacement* along a chain of connections which is determined in a particular way. The quantitative portion has not vanished, but has been transformed into anxiety. The result is fear of a wolf, instead of a demand for love from the father. The categories here employed are of course not enough to supply an adequate explanation of even the simplest case of psychoneurosis: there are always other considerations to be taken into account. A repression such as occurs in an animal phobia must be described as radically unsuccessful. All that it has done is to remove and replace the idea; it has failed altogether in sparing unpleasure. And for this reason, too, the work of the neurosis does not cease. It proceeds to a second phase, in order to attain its immediate and more important purpose. What follows is an attempt at flight - the formation of the *phobia proper*, of a number of avoidances which are intended to prevent a release of the anxiety. More specialized investigation enables us to understand the mechanism by which the phobia achieves its aim.

[1915d, 2985]

In anxiety hysteria a first phase of the process is frequently overlooked, and may perhaps be in fact missed out; on careful observation, however, it can be clearly discerned. It consists in anxiety appearing without the subject knowing what he is afraid of. We must suppose that there was present in the *Ucs.* some love-impulse demanding to be transposed into the system *Pcs.*; but the cathexis directed to it from the latter system has drawn back from the impulse (as though in an attempt at flight) and the unconscious libidinal cathexis of the rejected idea has been discharged in the form of anxiety.

[1915e, 3005]

On the occasion of a repetition (if there should be one) of this process, a first step is taken in the direction of mastering the unwelcome development of anxiety. The cathexis that has taken flight attaches itself to a substitutive idea which, on the one hand, is connected by association with the rejected idea, and, on the other, has escaped repression by reason of its remoteness from that idea. This substitutive idea - a 'substitute by displacement' - permits the still uninhibitable development of anxiety to be rationalized. It now plays the part of an anticathexis for the system *Cs.* (*Pcs.*), by securing it against an emergence in the *Cs.* of the repressed idea. On the other hand it is, or acts as if it were, the point of departure for the release of the anxiety-affect, which has now really become quite uninhibitable. Clinical observation shows, for instance, that a child suffering from an animal phobia experiences anxiety under two kinds of conditions: in the first place, when his repressed love-impulse becomes intensified, and, in the second, when he perceives the animal he is afraid of. The substitutive idea acts in the one instance as a point at which there is a passage across from the system *Ucs.* to the system *Cs.*, and, in the other instance, as a self-sufficing source for the release of anxiety. The extending dominance of the system *Cs.* usually manifests itself in the fact that the first of these two modes of excitation of the substitutive idea gives place more and more to the second. The child may perhaps end by behaving as though he had no predilection whatever towards his father but had become quite free from him, and as though his fear of the animal was a real fear - except that this fear of the animal, fed as such a fear is from an unconscious instinctual source, proves obdurate and exaggerated in the face of all influences brought to bear from the system *Cs.*, and thereby betrays its derivation from the system *Ucs.* - in the second phase of anxiety hysteria, therefore, the anticathexis from the system *Cs.* has led to substitute-formation.

[1915e, 3005]
Soon the same mechanism finds a fresh application. The process of repression, as we know, is not yet completed, and it finds a further aim in the task of inhibiting the development of the anxiety which arises from the substitute. This is achieved by the whole of the associated environment of the substitutive idea being cathected with special intensity, so that it can display a high degree of sensibility to excitation. Excitation of any point in this outer structure must inevitably, on account of its connection with the substitutive idea, give rise to a slight development of anxiety; and this is now used as a signal to inhibit, by means of a fresh flight on the part of the cathexis, the further progress of the development of anxiety. The further away the sensitive and vigilant anticathexes are situated from the feared substitute, the more precisely can the mechanism function which is designed to isolate the substitutive idea and to protect it from fresh excitations. These precautions naturally only guard against excitations which approach the substitutive idea from outside, through perception; they never guard against instinctual excitation, which reaches the substitutive idea from the direction of its link with the repressed idea. Thus the precautions do not begin to operate till the substitute has satisfactorily taken over representation of the repressed, and they can never operate with complete reliability. With each increase of instinctual excitation the protecting rampart round the substitutive idea must be shifted a little further outwards. The whole construction, which is set up in an analogous way in the other neuroses, is termed a phobia. The flight from a conscious cathexis of the substitutive idea is manifested in the avoidances, renunciations and prohibitions by which we recognize anxiety hysteria.

Surveying the whole process, we may say that the third phase repeats the work of the second on an ampler scale. The system Cs. now protects itself against the activation of the substitutive idea by an anticathexis of its environment, just as previously it had secured itself against the emergence of the repressed idea by a cathexis of the substitutive idea. In this way the formation of substitutes by displacement has been further continued. We must also add that the system Cs. had earlier only one small area at which the repressed instinctual impulse could break through, namely, the substitutive idea; but that ultimately this enclave of unconscious influence extends to the whole phobic outer structure. Further, we may lay stress on the interesting consideration that by means of the whole defensive mechanism thus set in action a projection outward of the instinctual danger has been achieved. The ego behaves as if the danger of a development of anxiety threatened it not from the direction of an instinctual impulse but from the direction of a perception, and it is thus enabled to react against this external danger with the attempts at flight represented by phobic avoidances. In this process repression is successful in one particular: the release of anxiety can to some extent be dammed up, but only at a heavy sacrifice of personal freedom. Attempts at flight from the demands of instinct are, however, in general useless, and, in spite of everything, the result of phobic flight remains unsatisfactory.
A great deal of what we have found in anxiety hysteria also holds good for the other two neuroses, so that we can confine our discussion to their points of difference and to the part played by anticathexis. In conversion hysteria the instinctual cathexis of the repressed idea is changed into the innervation of the symptom. How far and in what circumstances the unconscious idea is drained empty by this discharge into innervation, so that it can relinquish its pressure upon the system Cs. - these and similar questions had better be reserved for a special investigation of hysteria. In conversion hysteria the part played by the anticathexis proceeding from the system Cs. (Pcs.) is clear and becomes manifest in the formation of the symptom. It is the anticathexis that decides upon what portion of the instinctual representative the whole cathexis of the latter is able to be concentrated. The portion thus selected to be a symptom fulfils the condition of expressing the wishful aim of the instinctual impulse no less than the defensive or punitive efforts of the system Cs.; thus it becomes hypercathected, and it is maintained from both directions like the substitutive idea in anxiety hysteria. From this circumstance we may conclude without hesitation that the amount of energy expended by the system Cs. on repression need not be so great as the cathectic energy of the symptom; for the strength of the repression is measured by the amount of anticathexis expended, whereas the symptom is supported not only by this anticathexis but also by the instinctual cathexis from the system Ucs. which is condensed in the symptom.

As regards obsessional neurosis, we need only add to the observations brought forward in the preceding paper that it is here that the anticathexis from the system Cs. comes most noticeably into the foreground. It is this which, organized as a reaction-formation, brings about the first repression, and which is later the point at which the repressed idea breaks through. We may venture the supposition that it is because of the predominance of the anticathexis and the absence of discharge that the work of repression seems far less successful in anxiety hysteria and in obsessional neurosis than in conversion hysteria.
Anxiety-hysterias are the most common of all psychoneurotic disorders. But, above all, they are those which make their appearance earliest in life; they are *par excellence* the neuroses of childhood. When a mother uses such phrases as that her child's 'nerves' are in a bad state, we can be certain that in nine cases out of ten the child is suffering from some kind of anxiety or from many kinds at once. Unfortunately the finer mechanism of these highly significant disorders has not yet been sufficiently studied. It has not yet been established whether anxiety-hysteria is determined, in contradistinction to conversion-hysteria and other neuroses, solely by constitutional factors or solely by accidental experiences, or by what combination of the two.¹ It seems to me that of all neurotic disorders it is the least dependent upon a special constitutional predisposition and that it is consequently the most easily acquired at any time of life.

¹ [Footnote added 1923:] The question which is raised here has not been pursued further. But there is no reason to suppose that anxiety-hysteria is an exception to the rule that both predisposition and experience must co-operate in the aetiology of a neurosis. Rank's view of the effects of the trauma of birth seems to throw special light upon the predisposition to anxiety-hysteria which is so strong in childhood.

[1909b, 2100]
All this seems very clear, and yet it must be admitted that there is one factor which often makes it difficult to form a judgement. Some nervous states which we call the 'actual neuroses', such as typical neurasthenia and pure anxiety neurosis, obviously depend on the somatic factor in sexual life, while we have no certain picture as yet of the part played in them by the psychical factor and by repression. In such cases it is natural that the physician should first consider some 'actual' therapy, some alteration in the patient's somatic sexual activity, and he does so with perfect justification if his diagnosis is correct. The lady who consulted the young doctor complained chiefly of anxiety-states, and so he probably assumed that she was suffering from an anxiety neurosis, and felt justified in recommending a somatic therapy to her. Again a convenient misapprehension! A person suffering from anxiety is not for that reason necessarily suffering from anxiety neurosis; such a diagnosis of it cannot be based on the name; one has to know what signs constitute an anxiety neurosis, and be able to distinguish it from other pathological states which are also manifested by anxiety. My impression was that the lady in question was suffering from anxiety **hysteria**, and the whole value of such nosographical distinctions, one which quite justifies them, lies in the fact that they indicate a different aetiology and a different treatment. No one who took into consideration the possibility of anxiety hysteria in this case would have fallen into the error of neglecting the mental factors, as this physician did with his three alternatives. [1910k, 2377]
One essential characteristic of anxiety-hysterias is very easily pointed out. An anxiety-hysteria tends to develop more and more into a 'phobia'. In the end the patient may have got rid of all his anxiety, but only at the price of subjecting himself to all kinds of inhibitions and restrictions. From the outset in anxiety-hysteria the mind is constantly at work in the direction of once more psychically binding the anxiety which has become liberated; but this work can neither bring about a retransformation of the anxiety into libido, nor can it establish any contact with the complexes which were the source of the libido. Nothing is left for it but to cut off access to every possible occasion that might lead to the development of anxiety, by erecting mental barriers in the nature of precautions, inhibitions, or prohibitions; and it is these defensive structures that appear to us in the form of phobias and that constitute to our eyes the essence of the disease. [1909b, 2100]

We are also now coming to the opinion that analytic technique must be modified in certain ways according to the nature of the disease and the dominant instinctual trends in the patient. We started out from the treatment of conversion hysteria; in anxiety hysteria (phobias) we must to some extent alter our procedure. For these patient cannot bring out the material necessary for resolving their phobia so long as they feel protected by obeying the condition which it lays down. One cannot, of course, succeed in getting them to give up their protective measures and work under the influence of anxiety from the beginning of the treatment. One must therefore help them by interpreting their unconscious to them until they can make up their minds to do without the protection of their phobia and expose themselves to a now greatly mitigated anxiety. Only after they have done so does the material become accessible, which, when it has been mastered, leads to a solution of the phobia. Other modifications of technique, which seem to me not yet ripe for discussion, will be required in the treatment of obsessional neurosis. In this connection very important questions arise, which have not hitherto been elucidated: how far the instincts which the patient is combating are to be allowed some satisfaction during the treatment, and what difference it makes whether these impulses are active (sadistic) or passive (masochistic) in their nature. [1910d, 2310]

The two forms of anxiety that I have just described - the freely floating expectant anxiety and the sort which is bound to phobias - are independent of each other. One is not a higher stage, as it were, of the other; and they only appear simultaneously in exceptional cases and, so to speak, accidentally. The most powerful general apprehensiveness need not be expressed in phobias; people whose whole existence is restricted by agoraphobia may be entirely free from pessimistic expectant anxiety. Some phobias - for instance, agoraphobia and railway phobia - are demonstrably acquired at a fairly mature age, while others - such as fear of darkness, thunderstorms and animals - seem to have been present from the first. Those of the former kind have the significance of severe illnesses; the latter make their appearance rather as eccentricities or whims. If a person exhibits one of these latter, one may suspect as a rule that he will have other similar ones. I must add that we class all these phobias as anxiety hysteria; that is to say, we regard them as a disorder closely related to the familiar conversion hysteria. [1916-1917, 3447]
For we have recently been examining the way in which anxiety is generated in certain phobias which we class as anxiety hysteria, and have chosen cases in which we were dealing with the typical repression of wishful impulses arising from the Oedipus complex. We should have expected to find that it was a libidinal cathexis of the boy's mother as object which, as a result of repression, had been changed into anxiety and which now emerged, expressed in symptomatic terms, attached to a substitute for his father. I cannot present you with the detailed steps of an investigation such as this; it will be enough to say that the surprising result was the opposite of what we expected. It was not the repression that created the anxiety; the anxiety was there earlier; it was the anxiety that made the repression. But what sort of anxiety can it have been? Only anxiety in the face of a threatening external danger - that is to say, a realistic anxiety. It is true that the boy felt anxiety in the face of a demand by his libido - in this instance, anxiety at being in love with his mother; so the case was in fact one of neurotic anxiety. But this being in love only appeared to him as an internal danger, which he must avoid by renouncing that object, because it conjured up an external situation of danger. And in every case we examine we obtain the same result. It must be confessed that we were not prepared to find that internal instinctual danger would turn out to be a determinant and preparation for an external, real, situation of danger.
[1933a, 4692]
The treatment of anxiety-hysteria may be said hitherto to have been a purely negative one. Experience has shown that it is impossible to effect the cure of a phobia (and even in certain circumstances dangerous to attempt to do so) by violent means, that is, by first depriving the patient of his defences and then putting him in a situation in which he cannot escape the liberation of his anxiety. Consequently, nothing can be done but to leave the patient to look for protection wherever he thinks he may find it; and he is merely regarded with a not very helpful contempt for his 'incomprehensible cowardice'.

We are also now coming to the opinion that analytic technique must be modified in certain ways according to the nature of the disease and the dominant instinctual trends in the patient. We started out from the treatment of conversion hysteria; in anxiety hysteria (phobias) we must to some extent alter our procedure. For these patient cannot bring out the material necessary for resolving their phobia so long as they feel protected by obeying the condition which it lays down. One cannot, of course, succeed in getting them to give up their protective measures and work under the influence of anxiety from the beginning of the treatment. One must therefore help them by interpreting their unconscious to them until they can make up their minds to do without the protection of their phobia and expose themselves to a now greatly mitigated anxiety. Only after they have done so does the material become accessible, which, when it has been mastered, leads to a solution of the phobia. Other modifications of technique, which seem to me not yet ripe for discussion, will be required in the treatment of obsessional neurosis. In this connection very important questions arise, which have not hitherto been elucidated: how far the instincts which the patient is combating are to be allowed some satisfaction during the treatment, and what difference it makes whether these impulses are active (sadistic) or passive (masochistic) in their nature.

Oddly enough, the three therapeutic alternatives of this so-called psycho-analyst leave no room for psycho-analysis! This woman could apparently only be cured of her anxiety by returning to her husband, or by satisfying her needs by masturbation or with a lover. And where does analytic treatment come in, the treatment which we regard as the main remedy in anxiety-states?
We have nothing new to say on the question of the origin of these dispositional hypnoid states. They often, it would seem, grow out of the day-dreams which are so common even in healthy people and to which needlework and similar occupations render women especially prone. Why it is that the 'pathological associations' brought about in these states are so stable and why they have so much more influence on somatic processes than ideas are usually found to do - these questions coincide with the general problem of the effectiveness of hypnotic suggestions. Our observations contribute nothing fresh on this subject. But they throw a light on the contradiction between the dictum 'hysteria is a psychosis' and the fact that among hysterics may be found people of the clearest intellect, strongest will, greatest character and highest critical power. This characterization holds good of their waking thoughts; but in their hypnoid states they are insane, as we all are in dreams. Whereas, however, our dream-psychoses have no effect upon our waking state, the products of hypnoid states intrude into waking life in the form of hysterical symptoms.

[1895d, 15]
At about the time at which the clinic was established and at which he gave up the Chair of Pathological Anatomy, a change occurred in the direction of Charcot's scientific pursuits, and to this we owe the finest of his work. He now pronounced that the theory of organic nervous illnesses was for the time being fairly complete, and he began to turn his attention almost exclusively to hysteria, which thus all at once became the focus of general interest. This, the most enigmatic of all nervous diseases, for the evaluation of which medicine had not yet found a serviceable angle of approach, had just then fallen into thorough discredit; and this discredit extended not only to the patients but to the physicians who concerned themselves with the neurosis. It was held that in hysteria anything was possible, and no credence was given to a hysterical about anything. The first thing that Charcot's work did was to restore its dignity to the topic. Little by little, people gave up the scornful smile with which the patient could at that time feel certain of being met. She was no longer necessarily a malingerer, for Charcot had thrown the whole weight of his authority on the side of the genuineness and objectivity of hysterical phenomena. Charcot had repeated on a small scale the act of liberation in memory of which Pinel's portrait hung in the lecture hall of the Salpêtrière. Once the blind fear of being made a fool of by the unfortunate patient had been given up - a fear which till then had stood in the way of a serious study of the neurosis - the question could arise as to what method of approach would lead most quickly to a solution of the problem. A quite unbiased observer might have arrived at this conclusion: if I find someone in a state which bears all the signs of a painful affect - weeping, screaming and raging - the conclusion seems probable that a mental process is going on in him of which those physical phenomena are the appropriate expression. A healthy person, if he were asked, would be in a position to say what impression it was that was tormenting him; but the hysterical would answer that he did not know. The problem would at once arise of how it is that a hysterical patient is overcome by an affect about whose cause he asserts that he knows nothing. If we keep to our conclusion that a corresponding psychical process must be present, and if nevertheless we believe the patient when he denies it; if we bring together the many indications that the patient is behaving as though he does know about it; and if we enter into the history of the patient's life and find some occasion, some trauma, which would appropriately evoke precisely those expressions of feeling - then everything points to one solution: the patient is in a special state of mind in which all his impressions or his recollections of them are no longer held together by an associative chain, a state of mind in which it is possible for a recollection to express its affect by means of somatic phenomena without the group of the other mental processes, the ego, knowing about it or being able to intervene to prevent it. If we had called to mind the familiar psychological difference between sleep and waking, the strangeness of our hypothesis might have seemed less. No one should object that the theory of a splitting of consciousness as a solution to the riddle of hysteria is much too remote to impress an unbiased and untrained observer. For, by pronouncing possession by a demon to be the cause of hysterical phenomena, the Middle Ages in fact chose this solution; it would only have been a matter of exchanging the religious terminology of that dark and superstitious age for the scientific language of to-day.

[1893f, 281]
Charcot, however, did not follow this path towards an explanation of hysteria, although he drew copiously upon the surviving reports of witch trials and of possession, in order to show that the manifestations of the neurosis were the same in those days as they are now. He treated hysteria as just another topic in neuropathology; he gave a complete description of its phenomena, demonstrated that these had their own laws and uniformities, and showed how to recognize the symptoms which enable a diagnosis of hysteria to be made. The most painstaking investigations, initiated by himself and his pupils, extended over hysterical disturbances of sensibility in the skin and deeper tissues, over the behaviour of the sense organs, and over the peculiarities of hysterical contractures and paralyses, and of trophic disturbances and changes in metabolism. The many different forms of hysterical attack were described, and a schematic plan was drawn up by depicting the typical configuration of the major hysterical attack as occurring in four stages, which made it possible to trace the commonly observed 'minor' attacks back to this same typical configuration. The localization and frequency of occurrence of the so-called 'hysterogenic zones' and their relationship to the attacks were also studied, and so on. Once all this information about the manifestations of hysteria had been arrived at, a number of surprising discoveries were made. Hysteria in males, and especially in men of the working class was found far more often than had been expected; it was convincingly shown that certain conditions which had been put down to alcoholic intoxication or lead-poisoning were of a hysterical nature; it was possible to subsume under hysteria a whole number of affections which had hitherto not been understood and which had remained unclassified; and where the neurosis had become joined with other disorders to form complex pictures, it was possible to separate out the part played by hysteria. Most far-reaching of all were the investigations into nervous illnesses which followed upon severe traumas - the 'traumatic neuroses' - views about which are still under discussion and in connection with which Charcot has successfully put forward the arguments in favour of hysteria. [1893f, 282]

Let us first consider the relation of children to their brothers and sisters. I do not know why we presuppose that that relation must be a loving one; for instances of hostility between adult brothers and sisters force themselves upon everyone's experience and we can often establish the fact that the disunity originated in childhood or has always existed. But it is further true that a great many adults, who are on affectionate terms with their brothers and sisters and are ready to stand by them to-day, passed their childhood on almost unbroken terms of enmity with them. The elder child ill-treats the younger, maligns him and robs him of his toys; while the younger is consumed with impotent rage against the elder, envies and fears him, or meets his oppressor with the first stirrings of a love of liberty and a sense of justice. Their parents complain that the children do not get on with one another, but cannot discover why. It is easy to see that the character of even a good child is not what we should wish to find it in an adult. Children are completely egoistic; they feel their needs intensely and strive ruthlessly to satisfy them - especially as against the rivals, other children, and first and foremost as against their brothers and sisters. But we do not on that account call a child 'bad', we call him 'naughty'; he is no more answerable for his evil deeds in our judgement than in the eyes of the law. And it is right that this should be so; for we may expect that, before the end of the period which we count as childhood, altruistic impulses and morality will awaken in the little egoist and (to use Meynert's terms) a secondary ego will overlay and inhibit the primary one. It is true, no doubt, that morality does not set in simultaneously all along the line and that the length of non-moral childhood varies in different individuals. If this morality fails to develop, we like to talk of 'degeneracy', though what in fact faces us is an inhibition in development. After the primary character has already been overlaid by later development, it can still be laid bare again, at all events in part, in cases of hysterical illness. There is a really striking resemblance between what is known as the hysterical character and that of a naughty child. Obsessional neurosis, on the contrary, corresponds to a super-morality imposed as a reinforcing weight upon fresh stirrings of the primary character. [1900a, 729]
For a third kind of incompleteness in this report neither the patient nor the author is responsible. It is, on the contrary, obvious that a single case history, even if it were complete and open to no doubt, cannot provide an answer to all the questions arising out of the problem of hysteria. It cannot give an insight into all the types of this disorder, into all the forms of internal structure of the neurosis, into all the possible kinds of relation between the mental and the somatic which are to be found in hysteria. It is not fair to expect from a single case more than it can offer. And any one who has hitherto been unwilling to believe that a psychosexual aetiology holds good generally and without exception for hysteria is scarcely likely to be convinced of the fact by taking stock of a single case history. He would do better to suspend his judgement until his own work has earned him the right to a conviction.¹

No doubt this case history, as I have so far outlined it, does not upon the whole seem worth recording. It is merely a case of 'petite hystérie' with the commonest of all somatic and mental symptoms: dyspnoea, tussis nervosa, aphonia, and possibly migraines, together with depression, hysterical unsociability, and a taedium vitae which was probably not entirely genuine. More interesting cases of hysteria have no doubt been published, and they have very often been more carefully described; for nothing will be found in the following pages on the subject of stigmata of cutaneous sensibility, limitation of the visual field, or similar matters. I may venture to remark, however, that all such collections of the strange and wonderful phenomena of hysteria have but slightly advanced our knowledge of a disease which still remains as great a puzzle as ever. What is wanted is precisely an elucidation of the commonest cases and of their most frequent and typical symptoms. I should have been very well satisfied if the circumstances had allowed me to give a complete elucidation of this case of petite hystérie. And my experiences with other patients leave me in no doubt that my analytic method would have enabled me to do so.

When you hear such an enumeration of symptoms, you will be inclined to think it safe to assume, even though you are not doctors, that what we have before us is a severe illness, probably affecting the brain, that it offers small prospect of recovery and will probably lead to the patient's early decease. You must be prepared to learn from the doctors, however, that, in a number of cases which display severe symptoms such as these, it is justifiable to take a different and a far more favourable view. If a picture of this kind is presented by a young patient of the female sex, whose vital internal organs (heart, kidneys, etc.) are shown on objective examination to be normal, but who has been subjected to violent emotional shocks - if, moreover, her various symptoms differ in certain matters of detail from what would have been expected - then doctors are not inclined to take the case too seriously. They decide that what they have before them is not an organic disease of the brain, but the enigmatic condition which, from the time of ancient Greek medicine, has been known as 'hysteria' and which has the power of producing illusory pictures of a whole number of serious diseases. They consider that there is then no risk to life but that a return to health - even a complete one - is probable. It is not always quite easy to distinguish a hysteria like this from a severe organic illness. There is no need for us to know, however, how a differential diagnosis of that kind is made; it will suffice to have an assurance that the case of Breuer's patient was precisely of a kind in which no competent physician could fail to make a diagnosis of hysteria. And here we may quote from the report of the patient's illness the further fact that it made its appearance at a time when she was nursing her father, of whom she was devotedly fond, through the grave illness which led to his death, and that, as a result of her own illness, she was obliged to give up nursing him.

¹[1905e, 1356]

[1905e, 1364]

[1910a, 2200]
So far it has been an advantage to us to accompany the doctors; but the moment of parting is at hand. For you must not suppose that a patient's prospects of medical assistance are improved in essentials by the fact that a diagnosis of hysteria has been substituted for one of severe organic disease of the brain. Medical skill is in most cases powerless against severe diseases of the brain; but neither can the doctor do anything against hysterical disorders. He must leave it to kindly Nature to decide when and how his optimistic prognosis shall be fulfilled.¹

To put the matter more directly. The investigation of hysterical patients and of other neurotics leads us to the conclusion that their repression of the idea to which the intolerable wish is attached has been a failure. It is true that they have driven it out of consciousness and out of memory and have apparently saved themselves a large amount of displeasure. But the repressed wishful impulse continues to exist in the unconscious. It is on the look-out for an opportunity of being activated, and when that happens it succeeds in sending into consciousness a disguised and unrecognizable substitute for what had been repressed, and to this there soon become attached the same feelings of displeasure which it was hoped had been saved by the repression. This substitute for the repressed idea - the symptom - is proof against further attacks from the defensive ego; and in place of the short conflict an ailment now appears which is not brought to an end by the passage of time. Alongside the indication of distortion in the symptom, we can trace in it the remains of some kind of indirect resemblance to the idea that was originally repressed. The paths along which the substitution was effected can be traced in the course of the patient's psycho-analytic treatment; and in order to bring about recovery, the symptom must be led back along the same paths and once more turned into the repressed idea. If what was repressed is brought back again into conscious mental activity - a process which presupposes the overcoming of considerable resistances - the resulting psychical conflict, which the patient had tried to avoid, can, under the physician's guidance, reach a better outcome than was offered by repression. There are a number of such opportune solutions, which may bring the conflict and the neurosis to a happy end, and which may in certain instances be combined. The patient's personality may be convinced that it has been wrong in rejecting the pathogenic wish and may be led into accepting it wholly or in part; or the wish itself may be directed to a higher and consequently unobjectionable aim (this is what we call its 'sublimation'); or the rejection of the wish may be recognized as a justifiable one, but the automatic and therefore inefficient mechanism of repression may be replaced by a condemning judgement with the help of the highest human mental functions - conscious control of the wish is attained.

The first and most serious objection is that the content of adults' dreams is as a rule unintelligible and could not look more unlike the fulfilment of a wish. And here is the answer. Such dreams have been subjected to distortion; the psychical process underlying them might originally have been expressed in words quite differently. You must distinguish the manifest content of the dream, as you vaguely recollect it in the morning and laboriously (and, as it seems, arbitrarily) clothe it in words, and the latent dream-thoughts, which you must suppose were present in the unconscious. This distortion in dreams is the same process that you have already come to know in investigating the formation of hysterical symptoms. It indicates, too, that the same interplay of mental forces is at work in the formation of dreams as in that of symptoms. The manifest content of the dream is the distorted substitute for the unconscious dream-thoughts and this distortion is the work of the ego's forces of defence - of resistances. In waking life these resistances altogether prevent the repressed wishes of the unconscious from entering consciousness; and during the lowered state of sleep they are at least strong enough to oblige them to adopt a veil of disguise. Thereafter, the dreamer can no more understand the meaning of his dreams than the hysterical can understand the connection and significance of his symptoms.
Adler is right in maintaining that when a person with an active mental life recognizes an inferiority in one of his organs, it acts as a spur and calls out a higher level of performance in him through overcompensation. But it would be altogether an exaggeration if, following Adler's example, we sought to attribute every successful achievement to this factor of an original inferiority of an organ. Not all artists are handicapped with bad eyesight, nor were all orators originally stammerers. And there are plenty of instances of excellent achievements springing from superior organic endowment. In the aetiology of neuroses organic inferiority and imperfect development play an insignificant part - much the same as that played by currently active perceptual material in the formation of dreams. Neuroses make use of such inferiorities as a pretext, just as they do of every other suitable factor. We may be tempted to believe a neurotic woman patient when she tells us that it was inevitable she should fall ill, since she is ugly, deformed or lacking in charm, so that no one could love her; but the very next neurotic will teach us better - for she persists in her neurosis and in her aversion to sexuality, although she seems more desirable, and is more desired, than the average woman. The majority of hysterical women are among the attractive and even beautiful representatives of their sex, while, on the other hand, the frequency of ugliness, organic defects and infirmities in the lower classes of society does not increase the incidence of neurotic illness among them. [1914c, 2952]

A little reflection was bound to show that it would be impossible to restrict to the provinces of dreams and nervous disorders a view such as this of the life of the human mind. If that view has hit upon a truth, it must apply equally to normal mental events, and even the highest achievements of the human spirit must bear a demonstrable relation to the factors found in pathlogy - to repression, to the efforts at mastering the unconscious and to the possibilities of satisfying the primitive instincts. There was thus an irresistible temptation and, indeed, a scientific duty, to apply the research methods of psycho-analysis, in regions far remote from its native soil, to the various mental sciences. And indeed psycho-analytic work upon patients itself pointed persistently in the direction of this new task, for it was obvious that the forms assumed by the different neuroses echoed the most highly admired productions of our culture. Thus hysterics are undoubtedly imaginative artists, even if they express their phantasies mimetically in the main and without considering their intelligibility to other people; the ceremonials and prohibitions of obsessional neurotics drive us to suppose that they have created a private religion of their own; and the delusions of paranoics have an unpalatable external similarity and internal kinship to the systems of our philosophers. It is impossible to escape the conclusion that these patients are, in an asocial fashion, making the very attempts at solving their conflicts and appeasing their pressing needs which, when those attempts are carried out in a fashion that is acceptable to the majority, are known as poetry, religion and philosophy. [1919g, 3704]

The study of dreams may be considered the most trustworthy method of investigating deep mental processes. Now dreams occurring in traumatic neuroses have the characteristic of repeatedly bringing the patient back into the situation of his accident, a situation from which he wakes up in another fright. This astonishes people far too little. They think the fact that the traumatic experience is constantly forcing itself upon the patient even in his sleep is a proof of the strength of that experience: the patient is, as one might say, fixated to his trauma. Fixations to the experience which started the illness have long been familiar to us in hysteria. Breuer and Freud declared in 1893 that 'hysterics suffer mainly from reminiscences'. In the war neuroses, too, observers like Ferenczi and Simmel have been able to explain certain motor symptoms by fixation to the moment at which the trauma occurred. [1920g, 3719]
Breuer was a physician, a pupil of the clinician Oppolzer. In his youth he had worked at the physiology of respiration under Ewald Hering, and later, in the scanty hours of leisure allowed by an extensive medical practice, he occupied himself successfully with experiments on the function of the vestibular apparatus in animals. Nothing in his education could lead one to expect that he would gain the first decisive insight into the age-old riddle of the hysterical neurosis and would make a contribution of imperishable value to our knowledge of the human mind. But he was a man of rich and universal gifts, and his interests extended in many directions far beyond his professional activities. [1925g, 4171]

No doubt not the whole of what Charcot taught us at that time holds good to-day; some of it has become doubtful, some has definitely failed to withstand the test of time. But enough is left over that has found a permanent place in the storehouse of science. Before leaving Paris I discussed with the great man a plan for a comparative study of hysterical and organic paralyses. I wished to establish the thesis that in hysteria paralyses and anaesthesias of the various parts of the body are demarcated according to the popular idea of their limits and not according to anatomical facts. He agreed with this view, but it was easy to see that in reality he took no special interest in penetrating more deeply into the psychology of the neuroses. When all is said and done, it was from pathological anatomy that his work had started. [1925d, 4191]

I will now return to the year 1886, the time of my settling down in Vienna as a specialist in nervous diseases. The duty devolved upon me of giving a report before the 'Gesellschaft der Aerzte' upon what I had seen and learnt with Charcot. But I met with a bad reception. Persons of authority, such as the chairman (Bamberger, the physician), declared that what I said was incredible. Meynert challenged me to find some cases in Vienna similar to those which I had described and to present them before the Society. I tried to do so; but the senior physicians in whose departments I found any such cases refused to allow me to observe them or to work at them. One of them, an old surgeon, actually broke out with the exclamation: 'But, my dear sir, how can you talk such nonsense? Hysteron (sic) means the uterus. So how can a man be hysterical?' I objected in vain that what I wanted was not to have my diagnosis approved, but to have the case put at my disposal. At length, outside the hospital, I came upon a case of classical hysterical hemi-anaesthesia in a man, and demonstrated it before the 'Gesellschaft der Aerzte'. This time I was applauded, but no further interest was taken in me. The impression that the high authorities had rejected my innovations remained unshaken; and, with my hysteria in men and my production of hysterical paralyses by suggestion, I found myself forced into the Opposition. As I was soon afterwards excluded from the laboratory of cerebral anatomy and for terms on end had nowhere to deliver my lectures, I withdrew from academic life and ceased to attend the learned societies. It is a whole generation since I have visited the 'Gesellschaft der Aerzte'. [1925d, 4193]

The reaction-formations in the ego of the obsessional neurotic, which we recognize as exaggerations of normal character-formation, should be regarded, I think, as yet another mechanism of defence and placed alongside of regression and repression. They seem to be absent or very much weaker in hysteria. Looking back, we can now get an idea of what is peculiar to the defensive process in hysteria. It seems that in it the process is limited to repression alone. The ego turns away from the disagreeable instinctual impulse, leaves it to pursue its course in the unconscious, and takes no further part in its fortunes. This view cannot be absolutely correct, for we are acquainted with the case in which a hysterical symptom is at the same time a fulfilment of a penalty imposed by the super-ego; but it may describe a general characteristic of the behaviour of the ego in hysteria. [1926d, 4274]
When, in an earlier part of this discussion, we found that the danger of castration was of importance in more than one neurotic illness, we put ourselves on guard against overestimating that factor, since it could not be a decisive one for the female sex, who are undoubtedly more subject to neuroses than men. We now see that there is no danger of our regarding castration anxiety as the sole motive force of the defensive processes which lead to neurosis. I have shown elsewhere how little girls, in the course of their development, are led into making a tender object-cathexis by their castration complex. It is precisely in women that the danger situation of loss of object seems to have remained the most effective. All we need to do is to make a slight modification in our description of their determinant of anxiety, in the sense that it is no longer a matter of feeling the want of, or actually losing the object itself, but of losing the object's love. Since there is no doubt that hysteria has a strong affinity with femininity, just as obsessional neurosis has with masculinity, it appears probable that, as a determinant of anxiety, loss of love plays much the same part in hysteria as the threat of castration does in phobias and fear of the super-ego in obsessional neurosis.

[1926d, 4298]

Why this should be so calls for a rather long reply. First of all, we must sift the facts. In a great number of cases the old determinants of anxiety do really lapse, after having produced neurotic reactions. The phobias of very young children, fears of being alone or in the dark or with strangers - phobias which can almost be called normal - usually pass off later on; the child 'grows out of them', as we say about some other disturbances of childhood. Animal phobias, which are of such frequent occurrence, undergo the same fate and many conversion hysterias of early years find no continuation in later life. Ceremonial actions appear extremely often in the latency period, but only a very small percentage of them develop later into a full obsessional neurosis. In general, so far as we can tell from our observations of town children belonging to the white races and living according to fairly high cultural standards, the neuroses of childhood are in the nature of regular episodes in a child's development, although too little attention is still being paid to them. Signs of childhood neuroses can be detected in all adult neurotics without exception; but by no means all children who show those signs become neurotic in later life. It must be, therefore, that certain determinants of anxiety are relinquished and certain danger-situations lose their significance as the individual becomes more mature. Moreover, some of these danger-situations manage to survive into later times by modifying their determinants of anxiety so as to bring them up to date. Thus, for instance, a man may retain his fear of castration in the guise of a syphilidophobia, after he has come to know that it is no longer customary to castrate people for indulging their sexual lusts, but that, on the other hand, severe diseases may overtake anyone who thus gives way to his instincts. Other determinants of anxiety, such as fear of the super-ego, are destined not to disappear at all but to accompany people throughout their lives. In that case the neurotic will differ from the normal person in that his reactions to the dangers in question will be unduly strong. Finally, being grown-up affords no absolute protection against a return of the original traumatic anxiety-situation. Each individual has in all probability a limit beyond which his mental apparatus fails in its function of mastering the quantities of excitation which require to be disposed of.

[1926d, 4302]
Everything in the sphere of this first attachment to the mother seemed to me so difficult to grasp in analysis - so grey with age and shadowy and almost impossible to revivify - that it was as if it had succumbed to an especially inexorable repression. But perhaps I gained this impression because the women who were in analysis with me were able to cling to the very attachment to the father in which they had taken refuge from the early phase that was in question. It does indeed appear that women analysts - as, for instance, Jeanne Lampl-de Groot and Helene Deutsch - have been able to perceive these facts more easily and clearly because they were helped in dealing with those under their treatment by the transference to a suitable mother-substitute. Nor have I succeeded in seeing my way through any case completely, and I shall therefore confine myself to reporting the most general findings and shall give only a few examples of the new ideas which I have arrived at. Among these is a suspicion that this phase of attachment to the mother is especially intimately related to the aetiology of hysteria, which is not surprising when we reflect that both the phase and the neurosis are characteristically feminine, and further, that in this dependence on the mother we have the germ of later paranoia in women.¹ For this germ appears to be the surprising, yet regular, fear of being killed (?) devoured) by the mother. It is plausible to assume that this fear corresponds to a hostility which develops in the child towards her mother in consequence of the manifold restrictions imposed by the latter in the course of training and bodily care and that the mechanism of projection is favoured by the early age of the child's psychical organization.

[1931b, 4591]
These two psychical characteristics, which I regard as generally present in hysterical paroxysms, opened the way to a number of important considerations. I will, however, put off discussing them till I have given some attention to the mechanism of the somatic symptoms.

[1895d, 82]

Luckily for our explanation, some of these sexual experiences at puberty exhibit a further inadequacy, which is calculated to stimulate us into continuing our analytic work. For it sometimes happens that they, too, lack suitability as determinants although this is much more rarely so than with the traumatic scenes belonging to later life. Thus, for instance, let us take the two women patients whom I have just spoken of as cases in which the experiences at puberty were actually innocent ones. As a result of those experiences the patients had become subject to peculiar painful sensations in the genitals which had established themselves as the main symptoms of the neurosis. I was unable to find indications that they had been determined either by the scenes at puberty or by later scenes; but they were certainly not normal organic sensations nor signs of sexual excitement. It seemed an obvious thing, then, to say to ourselves that we must look for the determinants of these symptoms in yet other experiences, in experiences which went still further back - and that we must, for the second time, follow the saving notion which had earlier led us from the first traumatic scenes to the chains of memories behind them. In doing so, to be sure, we arrive at the period of earliest childhood, a period before the development of sexual life; and this would seem to involve the abandonment of a sexual aetiology. But have we not a right to assume that even the age of childhood is not wanting in slight sexual excitations, that later sexual development may perhaps be decisively influenced by childhood experiences? Injuries sustained by an organ which is as yet immature, or by a function which is in process of developing, often cause more severe and lasting effects than they could do in maturer years. Perhaps the abnormal reaction to sexual impressions which surprises us in hysterical subjects at the age of puberty is quite generally based on sexual experiences of this sort in childhood, in which case those experiences must be of a similar nature to one another, and must be of an important kind. If this is so, the prospect is opened up that what has hitherto had to be laid at the door of a still unexplained hereditary predisposition may be accounted for as having been acquired at an early age. And since infantile experiences with a sexual content could after all only exert a psychical effect through their memory-traces, would not this view be a welcome amplification of the finding of psycho-analysis which tells us that hysterical symptoms can only arise with the co-operation of memories?

[1896c, 416]
The orthopaedic institute referred back to a remark I had made in which I had compared the treatment, alike in its length and in its nature, to an orthopaedic one. When I started her treatment I had been obliged to tell her that for the time being I had not much time for her, though later I should be able to give her a whole hour daily. This had stirred up her old sensitiveness, which is a principal trait in the character of children inclined to hysteria: they are insatiable for love. My patient had been the youngest of a family of six children (hence: at the same time as five others) and had therefore been her father's favourite; but even so she seems to have felt that her adored father devoted too little of his time and attention to her. -Her waiting for me to say it wasn't true had the following origin. A young tailor's apprentice had brought her a dress and she had given him the money for it. Afterwards she had asked her husband whether if the boy lost the money she would have to pay it over again. Her husband, to tease her, had said that so. (The teasing in the dream.) She kept on asking over and over again and waited for him to say after all it wasn't true. It was then possible to infer that in the latent content of the dream she had had a thought of whether she would have to pay me twice as much if I gave her twice as much time - a thought which she felt was avaricious or filthy. (Uncleanliness in childhood is often replaced in dreams by avariciousness for money; the link between the two is the word 'filthy'.) If the whole passage about waiting for me to say, etc., was intended in the dream as a circumlocution for the word 'filthy', then her standing in the corner and not lying down in the bed would fit in with it as constituents of a scene from her childhood: a scene in which she had dirtied her bed and been punished by being made to stand in the corner, with a threat that her father would not love her any more and her brothers and sisters would laugh at her, and so on. -The small squares related to her little niece, who had shown her the arithmetical trick of arranging the digits in nine squares (I believe this is correct) so that they add up in all directions to fifteen.

In this scene - second in order of mention, but first in order of time - the behaviour of this child of fourteen was already entirely and completely hysterical. I should without question consider a person hysterical in whom an occasion for sexual excitement elicited feelings that were preponderantly or exclusively unpleasurable; and I should do so whether or no the person were capable of producing somatic symptoms. The elucidation of the mechanism of this reversal of affect is one of the most important and at the same time one of the most difficult problems in the psychology of the neuroses. In my own judgement I am still some way from having achieved this end; and I may add that within the limits of the present paper I shall be able to bring forward only a part of such knowledge on the subject as I do possess.
Am I now going on to assert that in every instance in which there are periodical attacks of aphonia we are to diagnose the existence of a loved person who is at times away from the patient? Nothing could be further from my intention. The determination of Dora's symptoms is far too specific for it to be possible to expect a frequent recurrence of the same accidental aetiology. But, if so, what is the value of our elucidation of the aphonia in the present case? Have we not merely allowed ourselves to become the victims of a jeu d'esprit? I think not. In this connection we must recall the question which has so often been raised, whether the symptoms of hysteria are of psychical or of somatic origin, or whether, if the former is granted, they are necessarily all of them psychically determined. Like so many other questions to which we find investigators returning again and again without success, this question is not adequately framed. The alternatives stated in it do not cover the real essence of the matter. As far as I can see, every hysterical symptom involves the participation of both sides. It cannot occur without the presence of a certain degree of somatic compliance offered by some normal or pathological process in or connected with one of the bodily organs. And it cannot occur more than once - and the capacity for repeating itself is one of the characteristics of a hysterical symptom - unless it has a psychical significance, a meaning. The hysterical symptom does not carry this meaning with it, but the meaning is lent to it, soldered to it, as it were; and in every instance the meaning can be a different one, according to the nature of the suppressed thoughts which are struggling for expression. However, there are a number of factors at work which tend to make less arbitrary the relations between the unconscious thoughts and the somatic processes that are at their disposal as a means of expression, and which tend to make those relations approximate to a few typical forms. For therapeutic purposes the most important determinants are those given by the fortuitous psychical material; the clearing-up of the symptoms is achieved by looking for their psychical significance. When everything that can be got rid of by psycho-analysis has been cleared away, we are in a position to form all kinds of conjectures, which probably meet the facts, as regards the somatic basis of the symptoms - a basis which is as a rule constitutional and organic. Thus in Dora's case we shall not content ourselves with a psycho-analytic interpretation of her attacks of coughing and aphonia; but we shall also indicate the organic factor which was the source of the 'somatic compliance' that enabled her to express her love for a man who was periodically absent. And if the connection between the symptomatic expression and the unconscious mental content should strike us as being in this case a clever tour de force, we shall be relieved to hear that it succeeds in creating the same impression in every other case and in every other instance.

[1905e, 1378]
Nevertheless, in publishing this paper, incomplete though it is, I had two objects in view. In the first place, I wished to supplement my book on the interpretation of dreams by showing how an art, which would otherwise be useless, can be turned to account for the discovery of the hidden and repressed parts of mental life. (Incidentally, in the process of analysing the two dreams dealt with in the paper, the technique of dream-interpretation, which is similar to that of psycho-analysis, has come under consideration.) In the second place, I wished to stimulate interest in a whole group of phenomena of which science is still in complete ignorance to-day because they can only be brought to light by the use of this particular method. No one, I believe, can have had any true conception of the complexity of the psychological events in a case of hysteria - the juxtaposition of the most dissimilar tendencies, the mutual dependence of contrary ideas, the repressions and displacements, and so on. The emphasis laid by Janet upon the ‘idée fixe’ which becomes transformed into a symptom amounts to no more than an extremely meagre attempt at schematization. Moreover, it is impossible to avoid the suspicion that, when the ideas attaching to certain excitations are incapable of becoming conscious, those excitations must act upon one another differently, run a different course, and manifest themselves differently from those other excitations which we describe as ‘normal’ and which have ideas attaching to them of which we become conscious. When once things have been made clear up to this point, no obstacle can remain in the way of an understanding of a therapeutic method which removes neurotic symptoms by transforming ideas of the former kind into normal ones.

SEXUAL USE OF THE MUCOUS MEMBRANE OF THE LIPS AND MOUTH   The use of the mouth as a sexual organ is regarded as a perversion if the lips (or tongue) of one person are brought into contact with the genitals of another, but not if the mucous membranes of the lips of both of them come together. This exception is the point of contact with what is normal. Those who condemn the other practices (which have no doubt been common among mankind from primaeval times) as being perversions, are giving way to an unmistakable feeling of disgust, which protects them from accepting sexual aims of the kind. The limits of such disgust are, however, often purely conventional: a man who will kiss a pretty girl's lips passionately, may perhaps be disgusted at the idea of using her tooth-brush, though there are no grounds for supposing that his own oral cavity, for which he feels no disgust, is any cleaner than the girl's. Here, then, our attention is drawn to the factor of disgust, which interferes with the libidinal overvaluation of the sexual object but can in turn be overridden by libido. Disgust seems to be one of the forces which have led to a restriction of the sexual aim. These forces do not as a rule extend to the genitals themselves. But there is no doubt that the genitals of the opposite sex can in themselves be an object of disgust and that such an attitude is one of the characteristics of all hysterics, and especially of hysterical women. The sexual instinct in its strength enjoys overriding this disgust. (See below.)

FINDINGS OF PSYCHO-ANALYSIS   In this manner the fact has emerged that symptoms represent a substitute for impulses the source of whose strength is derived from the sexual instinct. What we know about the nature of hysterics before they fall ill - and they may be regarded as typical of all psychoneurotics - and about the occasions which precipitate their falling ill, is in complete harmony with this view. The character of hysterics shows a degree of sexual repression in excess of the normal quantity, an intensification of resistance against the sexual instinct (which we have already met with in the form of shame, disgust and morality), and what seems like an instinctive aversion on their part to any intellectual consideration of sexual problems. As a result of this, in especially marked cases, the patients remain in complete ignorance of sexual matters right into the period of sexual maturity.¹
On a cursory view, this trait, which is so characteristic of hysteria, is not uncommonly screened by the existence of a second constitutional character present in hysteria, namely the predominant development of the sexual instinct. Psycho-analysis, however, can invariably bring the first of these factors to light and clear up the enigmatic contradiction which hysteria presents, by revealing the pair of opposites by which it is characterized - exaggerated sexual craving and excessive aversion to sexuality.

[1905d, 1489]

PREVENTION OF INVERSION One of the tasks implicit in object-choice is that it should find its way to the opposite sex. This, as we know, is not accomplished without a certain amount of fumbling. Often enough the first impulses after puberty go astray, though without any permanent harm resulting. Dessoir has justly remarked upon the regularity with which adolescent boys and girls form sentimental friendships with others of their own sex. No doubt the strongest force working against a permanent inversion of the sexual object is the attraction which the opposing sexual characters exercise upon one another. Nothing can be said within the framework of the present discussion to throw light upon it.¹ This factor is not in itself, however, sufficient to exclude inversion; there are to doubt a variety of other contributory factors. Chief among these is its authoritative prohibition by society. Where inversion is not regarded as a crime it will be found that it answers fully to the sexual inclinations of no small number of people. It may be presumed, in the next place, that in the case of men a childhood recollection of the affection shown them by their mother and others of the female sex who looked after them when they were children contributes powerfully to directing their choice towards women; on the other hand their early experience of being deterred by their father from sexual activity and their competitive relation with him deflect them from their own sex. Both of these two factors apply equally to girls, whose sexual activity is particularly subject to the watchful guardianship of their mother. They thus acquire a hostile relation to their own sex which influences their object-choice decisively in what is regarded as the normal direction. The education of boys by male persons (by slaves, in antiquity) seems to encourage homosexuality.

The frequency of inversion among the present-day aristocracy is made somewhat more intelligible by their employment of menservants, as well as by the fact that their mothers give less personal care to their children. In the case of some hysterics it is found that the early loss of one of their parents, whether by death, divorce or separation, with the result that the remaining parent absorbs the whole of the child's love, determines the sex of the person who is later to be chosen as a sexual object, and may thus open the way to permanent inversion.

[1905d, 1541]

Medical research has at last shown that people of this kind are not to be looked upon as suffering from a disease of the stomach or of the eyes or whatever it may be, but that it must be a question in their case of an illness of the nervous system as a whole. Examination of the brain and nerves of these patients has so far, however, revealed no perceptible changes; and, indeed, some of the features of their symptomatology prohibit any expectation that even more accurate methods of investigation could ever discover changes of a sort that would throw light upon the illness. This condition has been described as 'nervousness' (neurasthenia or hysteria) and has been characterized as a merely 'functional' disorder of the nervous system.¹ Incidentally, an exhaustive examination of the brain (after the patient's death) has been equally without results in the case of many more permanent nervous disorders, as well as in illnesses with exclusively mental symptoms, such as what are known as obsessions and delusional insanity.

[1890a, 1587]
Physicians were thus faced by the problem of investigating the nature and origin of the symptoms shown by these nervous or neurotic patients. In the course of this investigation it was found that in some at least of these patients the signs of their illness originate from nothing other than a change in the action of their minds upon their bodies and that the immediate cause of their disorder is to be looked for in their minds. What may be the remoter causes of the disturbance which affects their minds is another question, with which we need not now concern ourselves. But medical science was here provided with an opportunity for directing its full attention to what had previously been the neglected side of the mutual relation between body and mind.

[1890a, 1588]

The field I have in mind is indeed very different from yours. I am referring to the therapy employed for certain 'nervous diseases' - what are known as the psychoneuroses - of which hysteria and obsessional ideas may be taken as samples. The method is called 'psychoanalysis'; it was evolved by me from the 'cathartic' method of therapy first practised by Josef Breuer in Vienna.¹ To combat your surprise, I must draw an analogy between the criminal and the hysteric. In both we are concerned with a secret, with something hidden. But in order not to be paradoxical I must at once point out the difference. In the case of the criminal it is a secret which he knows and hides from you, whereas in the case of the hysteric it is a secret which he himself does not know either, which is hidden even from himself. How is this possible? Now we know, through laborious research, that all these illnesses are the result of the patient’s having succeeded in repressing certain ideas and memories that are strongly cathexed with affect, together with the wishes that arise from them, in such a way that they play no part in his thinking - do not enter into his consciousness - and thus remain unknown to him. But from this repressed psychical material (these ‘complexes’) are generated the somatic and psychical symptoms which plague the patient in just the same way as a guilty conscience does. In this one respect, therefore, the difference between the criminal and the hysteric is fundamental.

[1906c, 1892]

The neuroses exhibit on the one hand striking and far-reaching points of agreement with those great social institutions, art, religion and philosophy. But on the other hand they seem like distortions of them. It might be maintained that a case of hysteria is a caricature of a work of art, that an obsessional neurosis is a caricature of a religion and that a paranoic delusion is a caricature of a philosophical system. The divergence resolves itself ultimately into the fact that the neuroses are asocial structures; they endeavour to achieve by private means what is effected in society by collective effort. If we analyse the instincts at work in the neuroses, we find that the determining influence in them is exercised by instinctual forces of sexual origin; the corresponding cultural formations, on the other hand, are based upon social instincts, originating from the combination of egoistic and erotic elements. Sexual needs are not capable of uniting men in the same way as are the demands of self-preservation. Sexual satisfaction is essentially the private affair of each individual.

[1912-1913, 2717]
A disturbance of memory of this kind is enough for obsessional neurosis; but the case is different with hysteria. As a rule the latter neurosis is marked by amnesias on a really large scale. In analysing each separate hysterical symptom one is usually led to a whole chain of impressions of events, which, when they recur, are expressly described by the patient as having been till then forgotten. On the one hand, this chain reaches back to the earliest years of life, so that the hysterical amnesia can be recognized as an immediate continuation of the infantile amnesia which, for us normal people, conceals the beginnings of our mental life. On the other hand, we learn with astonishment that even the patient's most recent experiences can be subject to forgetting, and that the occasions which precipitated the outbreak of the illness or led to its intensification are in particular encroached upon, if not completely swallowed up, by amnesia. It regularly happens that important details have disappeared from the total picture of a recent recollection of this sort or that they have been replaced by falsifications of memory. Indeed it happens with almost equal regularity that certain memories of recent experiences only emerge shortly before the end of an analysis - memories which had been held back till that late moment and had left perceptible gaps in the continuity of the case.

[1916-1917, 3360]
Our experiences have shown us, however, that the most various symptoms, which are ostensibly spontaneous and, as one might say, idopathic products of hysteria, are just as strictly related to the precipitating trauma as the phenomena to which we have just alluded and which exhibit the connection quite clearly. The symptoms which we have been able to trace back to precipitating factors of this sort include neuralgias and anaesthesias of very various kinds, many of which had persisted for years, contractures and paralyses, hysterical attacks and epileptiform convulsions, which every observer regarded as true epilepsy, petit mal and disorders in the nature of tic, chronic vomiting and anorexia, carried to the pitch of rejection of all nourishment, various forms of disturbance of vision, constantly recurrent visual hallucinations, etc. The disproportion between the many years' duration of the hysterical symptom and the single occurrence which provoked it is what we are accustomed invariably to find in traumatic neuroses. Quite frequently it is some event in childhood that sets up a more or less severe symptom which persists during the years that follow.

[1895d, 7]

In other cases the connection is not so simple. It consists only in what might be called a 'symbolic' relation between the precipitating cause and the pathological phenomenon - a relation such as healthy people form in dreams. For instance, a neuralgia may follow upon mental pain or vomiting upon a feeling of moral disgust. We have studied patients who used to make the most copious use of this sort of symbolization. In still other cases it is not possible to understand at first sight how they can be determined in the manner we have suggested. It is precisely the typical hysterical symptoms which fall into this class, such as hemi-anaesthesia, contraction of the field of vision, epileptiform convulsions, and so on. An explanation of our views on this group must be reserved for a fuller discussion of the subject.

[1895d, 8]

For we found, to our great surprise at first, that each individual hysterical symptom immediately and permanently disappeared when we had succeeded in bringing clearly to light the memory of the event by which it was provoked and in arousing its accompanying affect, and when the patient had described that event in the greatest possible detail and had put the affect into words. Recollection without affect almost invariably produces no result. The psychical process which originally took place must be repeated as vividly as possible; it must be brought back to its status nascendi and then given verbal utterance. Where what we are dealing with are phenomena involving stimuli (spasms, neuralgias and hallucinations) these re-appear once again with the fullest intensity and then vanish for ever. Failures of function, such as paralyses and anaesthesias, vanish in the same way, though, of course, without the temporary intensification being discernible.¹

[1895d, 9]

What we have asserted of chronic hysterical symptoms can be applied almost completely to hysterical attacks. Charcot, as is well known, has given us a schematic description of the 'major' hysterical attack, according to which four phases can be distinguished in a complete attack: (1) the epileptoid phase, (2) the phase of large movements, (3) the phase of 'attitudes passionelles' (the hallucinatory phase), and (4) the phase of terminal delirium. Charcot derives all those forms of hysterical attack which are in practice met with more often than the complete 'grande attaque', from the abbreviation, absence or isolation of these four distinct phases.

[1895d, 15]
Evening. - She was in very good spirits and showed a great sense of humour. She told me incidentally that the affair of the lift was not as she had reported it. The proprietor had only said what he did in order to give an excuse for the lift not being used for downward journeys. She asked me a great many questions which had nothing pathological about them. She has had distressingly severe pains in her face, in her hand on the thumb side and in her leg. She gets stiff and has pains in her face if she sits without moving or stares at some fixed point for any considerable time. If she lifts anything heavy it brings on pains in her arm. - An examination of her right leg showed fairly good sensibility in her thigh, a high degree of anaesthesia in the lower part of the leg and in the foot and less in the region of the buttock and hip.

It is not possible to assign the same origin to all the somatic symptoms of these patients. On the contrary, even from this case, which was not rich in them, we find that the somatic symptoms of a hysteria can arise in a variety of ways. I will venture, in the first place, to include pains among somatic symptoms. So far as I can see, one set of Frau von N.'s pains were certainly determined organically by the slight mortifications (of a rheumatic kind) in the muscles, tendons or fascia which cause so much more pain to neurotics than to normal people. Another set of pains were in all probability memories of pains - were mnemic symbols of the times of agitation and sick-nursing which played such a large part in the patient's life. These pains, too, may well have been originally justified on organic grounds but had since then been adapted for the purposes of the neurosis. I base these assertions about Frau von N.'s pains mainly on observations made elsewhere which I shall report on a later page. On this particular point little information could be gathered from the patient herself.

[1895d, 67]
¹ I have been deeply impressed in another of my patients by this interesting contrast during somnambulism between a most far-reaching obedience in everything unconnected with the symptoms and the obstinacy with which those symptoms persist because they are deeply rooted and inaccessible to analysis. A lively and gifted girl, who had suffered for eighteen months from severe disturbances of her power of walking, was under my treatment for more than five months without my being able to help her. She was analgesic and had painful areas in both legs and a rapid tremor in her hands. She walked bent forward, dragging her legs and with short steps; she staggered as though she was a cerebellar case and, indeed, often fell down. Her temperament was strikingly cheerful. One of the leading authorities in Vienna at the time was misled by this syndrome into diagnosing her case as one of multiple sclerosis. Another specialist recognized her as a hysterical - a diagnosis which was supported by the complicated picture presented by the disease in its beginnings (pains, fainting-fits, amaurosis) - and handed her on to me for treatment. I tried to improve her gait by suggestion, manipulation of her legs under hypnosis, etc., but I had no success in spite of her being an excellent subject for somnambulism. One day, after she once more came tottering into the room, one arm supported on her father's, the other on an umbrella whose tip was already much worn down, I lost patience and shouted at her in her hypnosis: 'This has gone on too long. To-morrow morning that umbrella of yours will break in your hands and you'll have to walk without it, and from that time on you will never need an umbrella again.' I cannot imagine how I came to be so foolish as to give a suggestion to an umbrella. Afterwards I fell ashamed of myself, and did not suspect that my clever patient would save my reputation in the eyes of her father, who was a physician and was present during her hypnoses. Next day her father said to me: 'What do you think she did yesterday? We were walking along the Ringstrasse when she suddenly got into the highest spirits. She began singing - in the very middle of the street - "Ein freies Leben führen wir" ["We live a free life"] and beat time on the pavement with her umbrella and broke it.' Of course she herself had no notion that she had wittily transformed a nonsensical suggestion into a brilliantly successful one. Since her condition was not improved by assurances, commands and treatment under hypnosis, I turned to psychical analysis and requested her to tell me what emotion had preceded the onset of her illness. She answered (under hypnosis but without any signs of feeling) that a short time previously a young relative of hers had died to whom she had for many years considered herself engaged. This piece of information, however, produced no alteration whatever in her condition. Accordingly, during her next hypnosis, I told her I was quite convinced that her cousin's death had had nothing at all to do with her state, but that something else had happened which she had not mentioned. At this she gave way to the extent of letting fall a single significant phrase; but she had hardly said a word before she stopped, and her old father, who was sitting behind her, began to sob bitterly. Naturally I pressed my investigation no further; but I never saw the patient again.

[1895d, 90]

At the end of the year 1892 a colleague of my acquaintance referred a young lady to me who was being treated by him for chronically recurrent suppurative rhinitis. It subsequently turned out that the obstinate persistence of her trouble was due to caries of the ethmoid bone. Latterly she had complained of some new symptoms which the well-informed physician was no longer able to attribute to a local affection. She had entirely lost her sense of smell and was almost continuously pursued by one or two subjective olfactory sensations. She found these most distressing. She was, moreover, in low spirits and fatigued, and she complained of heaviness in the head, diminished appetite and loss of efficiency.

[1895d, 95]

The young lady, who was living as a governess in the house of the managing director of a factory in Outer Vienna, came to visit me from time to time in my consulting hours. She was an Englishwoman. She had a delicate constitution, with a poor pigmentation, but was in good health apart from her nasal affection. Her first statements confirmed what the physician had told me. She was suffering from depression and fatigue and was tormented by subjective sensations of smell. As regards hysterical symptoms, she showed a fairly definite general analgesia, with no loss of tactile sensibility, and a rough examination (with the hand) revealed no restriction of the visual field. The interior of her nose was completely analgesic and without reflexes; she was sensitive to tactile pressure there, but the perception proper to it as a sense-organ was absent, alike for specific stimuli and for others (e.g. ammonia or acetic acid). The purulent nasal catarrh was just then in a phase of improvement.

[1895d, 95]
In the autumn of 1892 I was asked by a doctor I knew to examine a young lady who had been suffering for more than two years from pains in her legs and who had difficulties in walking. When making this request he added that he thought the case was one of hysteria, though there was no trace of the usual indications of that neurosis. He told me that he knew the family slightly and that during the last few years it had met with many misfortunes and not much happiness. First the patient's father had died, then her mother had had to undergo a serious eye-operation and soon afterwards a married sister had succumbed to a heart-affection of long standing after a confinement. In all these troubles and in all the sick-nursing involved, the largest share had fallen to our patient.

My first interview with this young woman of twenty-four years of age did not help me to make much further progress in understanding the case. She seemed intelligent and mentally normal and bore her troubles, which interfered with her social life and pleasures, with a cheerful air - the belle indifférence of a hysteric, I could not help thinking. She walked with the upper part of her body bent forward, but without making use of any support. Her gait was not of any recognized pathological type, and moreover was by no means strikingly bad. All that was apparent was that she complained of great pain in walking and of being quickly overcome by fatigue both in walking and in standing, and that after a short time she had to rest, which lessened the pains but did not do away with them altogether. The pain was of an indefinite character; I gathered that it was something in the nature of a painful fatigue. A fairly large, ill-defined area of the anterior surface of the right thigh was indicated as the focus of the pains, from which they most often radiated and where they reached their greatest intensity. In this area the skin and muscles were also particularly sensitive to pressure and pinching (though the prick of a needle was, if anything, met with a certain amount of unconcern). This hyperalgesia of the skin and muscles was not restricted to this area but could be observed more or less over the whole of both legs. The muscles were perhaps even more sensitive to pain than the skin; but there could be no question that the thighs were the parts most sensitive to both these kinds of pain. The motor power of the legs could not be described as small, and the reflexes were of medium strength. There were no other symptoms, so that there was no ground for suspecting the presence of any serious organic affection. The disorder had developed gradually during the previous two years and varied greatly in intensity.

If we put greater misfortunes on one side and enter into a girl's feelings, we cannot refrain from deep human sympathy with Fräulein Elisabeth. But what shall we say of the purely medical interest of this tale of suffering, of its relations to her painful locomotor weakness, and of the chances of an explanation and cure afforded by our knowledge of these psychical traumas?
About a year after this successful hypnotic treatment Frau Cäcilie's illness took a new and surprising turn. She suddenly developed new pathological states, different from those that had characterized the last few years. But after some reflection the patient declared that she had had all of them before at various times during the course of her long illness, which had lasted for thirty years. There now developed a really surprising wealth of hysterical attacks which the patient was able to assign to their right place in her past. And soon, too, it was possible to follow the often highly involved trains of thought that determined the order in which these attacks occurred. They were like a series of pictures with explanatory texts. Pitres must have had something of the sort in mind in putting forward his description of what he termed 'délire émnésique'. It was most remarkable to see the way in which a hysterical state of this kind belonging to the past was reproduced. There first came on, while the patient was in the best of health, a pathological mood with a particular colouring which she regularly misunderstood and attributed to some commonplace event of the last few hours. Then, to the accompaniment of an increasing clouding of consciousness, there followed hysterical symptoms: hallucinations, pains, spasms and long declamatory speeches. Finally, these were succeeded by the emergence in a hallucinatory form of an experience from the past which made it possible to explain her initial mood and what had determined the symptoms of her present attack. With this last piece of the attack her clarity of mind returned. Her troubles disappeared as though by magic and she felt well once again - till the next attack, half a day later. As a rule I was sent for at the climax of the attack, induced a state of hypnosis, called up the reproduction of the traumatic experience and hastened the end of the attack by artificial means. Since I assisted at several hundreds of such cycles with the patient, I gained the most instructive information on the way in which hysterical symptoms are determined. Indeed, it was the study of this remarkable case, jointly with Breuer, that led directly to the publication of our 'Preliminary Communication'.

[1895d, 160]

An example makes plain what is intended by the first of these two sentences. We were frequently able to observe the following course of events with one of our patients (Frau Cäcilie M.). While she was feeling comparatively well a hysterical symptom would appear - a tormenting, obsessive hallucination, a neuralgia, or something of the kind - and would for some time increase in intensity. Simultaneously the patient's mental capacity would continuously decrease, and after a few days any uninitiated observer would have been bound to call her weak-minded. She would then be relieved of the unconscious idea (the memory of a psychical trauma, often belonging to the remote past), either by the physician under hypnosis or by her suddenly describing the event in a state of agitation and to the accompaniment of a lively emotion. When this had happened she did not merely become quiet and cheerful and free from the tormenting symptom; it was always astonishing to observe the width and clarity of her intellect and the acuteness of her understanding and judgement. Chess, which she played excellently, was a favourite occupation of hers, and she enjoyed playing two games at a time, which can scarcely be regarded as indicating a lack of mental synthesis. It was impossible to escape the impression that during a course of events such as we have just described the unconscious idea drew to itself an ever-increasing portion of her psychical activity and that the more this happened the smaller became the part played by conscious thought, till it was reduced to total imbecility; but that when, to use the remarkably apt Viennese expression, she was 'beisammen' [literally 'together', meaning 'in one's right mind'], she possessed quite remarkable mental powers.

[1895d [Breuer], 208]
After I had in this way fixed the simple pictures of neurasthenia, anxiety neurosis and obsessional ideas, I went on to consider the cases of neurosis which are commonly included under the diagnosis of hysteria. I reflected that it was not right to stamp a neurosis as a whole as hysterical because a few hysterical signs were prominent in its complex of symptoms. I could well understand this practice, since after all hysteria is the oldest, best-known and most striking of the neuroses under consideration; but it was an abuse, for it put down to the account of hysteria so many traits of perversion and degeneracy. Whenever a hysterical sign, such as an anaesthesia or a characteristic attack, was found in a complicated case of psychical degeneracy, the whole condition was described as one of 'hysteria', so that it is not surprising that the worst and the most contradictory things were found together under this label. But just as it was certain that this diagnosis was incorrect, it was equally certain that we ought also to separate out the various neuroses; and since we were acquainted with neurasthenia, anxiety neurosis, etc., in a pure form, there was no longer any need to overlook them in the combined picture.

[1895d, 229]

Among the tasks presented by analysis is that of getting rid of symptoms which are capable of increasing in intensity or of returning: pains, symptoms (such as vomiting) which are due to stimuli, sensations or contractures. While we are working at one of these symptoms we come across the interesting and not undesired phenomenon of 'joining in the conversation'. The problematical symptom re-appears, or appears with greater intensity, as soon as we reach the region of the pathogenic organization which contains the symptom's aetiology, and thenceforward it accompanies the work with characteristic oscillations which are instructive to the physician. The intensity of the symptom (let us take for instance a desire to vomit) increases the deeper we penetrate into one of the relevant pathogenic memories; it reaches its climax shortly before the patient gives utterance to that memory; and when he has finished doing so it suddenly diminishes or even vanishes completely for a time. If, owing to resistance, the patient delays his telling for a long time, the tension of the sensation - of the desire to vomit - becomes unbearable, and if we cannot force him to speak he actually begins to vomit. In this way we obtain a plastic impression of the fact that 'vomiting' takes the place of a psychical act (in this instance, the act of utterance), exactly as the conversion theory of hysteria maintains.

[1895d, 261]

(1) If there is a personal estrangement - if, for instance, the patient feels she has been neglected, has been too little appreciated or has been insulted, or if she has heard unfavourable comments on the physician or the method of treatment. This is the least serious case. The obstacle can easily be overcome by discussion and explanation, even though the sensitiveness and suspiciousness of hysterical patients may occasionally attain surprising dimensions.

[1895d, 266]
Charcot, however, did not follow this path towards an explanation of hysteria, although he drew copiously upon the surviving reports of witch trials and of possession, in order to show that the manifestations of the neurosis were the same in those days as they are now. He treated hysteria as just another topic in neuropathology; he gave a complete description of its phenomena, demonstrated that these had their own laws and uniformities, and showed how to recognize the symptoms which enable a diagnosis of hysteria to be made. The most painstaking investigations, initiated by himself and his pupils, extended over hysterical disturbances of sensibility in the skin and deeper tissues, over the behaviour of the sense organs, and over the peculiarities of hysterical contractures and paralyses, and of trophic disturbances and changes in metabolism. The many different forms of hysterical attack were described, and a schematic plan was drawn up by depicting the typical configuration of the major hysterical attack as occurring in four stages, which made it possible to trace the commonly observed 'minor' attacks back to this same typical configuration. The localization and frequency of occurrence of the so-called 'hysterogenic zones' and their relationship to the attacks were also studied, and so on. Once all this information about the manifestations of hysteria had been arrived at, a number of surprising discoveries were made. Hysteria in males, and especially in men of the working class was found far more often than had been expected; it was convincingly shown that certain conditions which had been put down to alcoholic intoxication or lead-poisoning were of a hysterical nature; it was possible to subsume under hysteria a whole number of affections which had hitherto not been understood and which had remained unclassified; and where the neurosis had become joined with other disorders to form complex pictures, it was possible to separate out the part played by hysteria. Most far-reaching of all were the investigations into nervous illnesses which followed upon severe traumas - the 'traumatic neuroses' - views about which are still under discussion and in connection with which Charcot has successfully put forward the arguments in favour of hysteria.

I will now give you a few instances of this. First, here is an example of the occurrence of contractures. Throughout the whole period of her illness, Breuer's patient, whom I have already mentioned, exhibited a contracture of the right arm. It emerged under hypnosis that at a time before she had fallen ill she was subjected to the following trauma. She was sitting half-dozing at the bedside of her sick father; her right arm was hanging over the back of her chair and went to sleep. At this moment she had a terrifying hallucination; she tried to fend it off with her arm but was unable to do so. This gave her a violent fright, and for the time being the matter ended there. It was not until the outbreak of her hysteria that the contracture of the arm set in. In another woman patient, I observed that her speech was interrupted by a peculiar 'clacking' with her tongue, which resembled the cry of a capercaillie. I had been familiar with this symptom for months and regarded it as a tic. It was only after I once happened to question her under hypnosis about its origin that I discovered that the noise had first appeared on two occasions. On each of these she had made a firm decision to keep absolutely quiet. This happened once when she was nursing a child of hers who was seriously ill. (Nursing sick people often plays a part in the aetiology of hysteria.) The child had fallen asleep and she was determined not to make any noise that might wake it. But fear that she might make a noise turned into actually making one - an instance of 'hysterical counter-will'; she pressed her lips together and made the clacking noise with her tongue. Many years later the same symptom had arisen a second time, once again when she had made a decision to be absolutely quiet, and it had persisted ever afterwards. A single precipitating cause is often not enough to fixate a symptom; but if this same symptom appears several times accompanied by a particular affect, it becomes fixated and chronic.
The determination of the symptom by the psychical trauma is not so transparent in every instance. There is often only what may be described as a 'symbolic' relation between the determining cause and the hysterical symptom. This is especially true of pains. Thus one patient suffered from piercing pains between her eyebrows. The reason was that once when she was a child her grandmother had given her an enquiring, 'piercing' look. The same patient suffered for a time from violent pains in her right heel, for which there was no explanation. These pains, it turned out, were connected with an idea that occurred to the patient when she made her first appearance in society. She was overcome with fear that she might not 'find herself on a right footing'. Symbolizations of this kind were employed by many patients for a whole number of so-called neuralgias and pains. It is as though there were an intention to express the mental state by means of a physical one; and linguistic usage affords a bridge by which this can be effected. In the case, however, of what are after all the typical symptoms of hysteria - such as hemi-anaesthesia, restriction of the visual field, epileptiform convulsions, etc. - a psychical mechanism of this sort cannot be demonstrated. On the other hand this can often be done in respect to the hysterogenic zones.

[1893a, 294]

The conversion may be either total or partial. It proceeds along the line of the motor or sensory innervation which is related - whether intimately or more loosely - to the traumatic experience. By this means the ego succeeds in freeing itself from the contradiction; but instead, it has burdened itself with a mnemonic symbol which finds a lodgement in consciousness, like a sort of parasite, either in the form of an unresolvable motor innervation or as a constantly recurring hallucinatory sensation, and which persists until a conversion in the opposite direction takes place. Consequently the memory-trace of the repressed idea has, after all, not been dissolved; from now on, it forms the nucleus of a second psychical group.

[1894a, 305]

Not everyone who suffers from obsessions is as clear as this about their origin. As a rule, when one draws a patient's attention to the original idea of a sexual kind, the answer is: 'It can't come from that. I didn't think at all much about that. For a moment I was frightened, but I turned my mind away from it and I haven't been troubled by it since.' In this frequent objection we have evidence that the obsession represents a substitute or surrogate for the incompatible sexual idea and has taken its place in consciousness.

[1894a, 308]

So long as the patients are aware of the sexual origin of their obsessions, they often keep them secret. If they do complain about them, they usually express their astonishment that they should be subject to the affect in question - that they should feel anxiety, or have certain impulses, and so on. To the experienced physician, on the contrary, the affect seems justified and comprehensible; what he finds noticeable is only that an affect of that kind should be linked with an idea which does not merit it. The affect of the obsession appears to him, in other words, as being dislodged or transposed; and if he has accepted what has been said in these pages, he will be able, in a number of cases of obsessions, to attempt to re-translate them into sexual terms.

[1894a, 309]
The symptomatology of hysteria and anxiety neurosis show many points in common which have not yet been sufficiently considered. The appearance of symptoms either in a chronic form or in attacks, the paraesthesias, grouped like auras, the hyperaesthesias and pressure-points which are found in certain surrogates of an anxiety attack (in dyspnœa and heart-attacks), the intensification, through conversion, of pains which perhaps have an organic justification - these and other features which the two illnesses have in common even allow of a suspicion that not a little of what is attributed to hysteria might with more justice be put to the account of anxiety neurosis. If one goes into the mechanism of the two neuroses, so far as it has been possible to discover it hitherto, aspects come to light which suggest that anxiety neurosis is actually the somatic counterpart to hysteria. In the latter just as in the former there is an accumulation of excitation (which is perhaps the basis for the similarity between their symptoms we have mentioned). In the latter just as in the former we find a psychological insufficiency, as a consequence of which abnormal somatic processes arise. In the latter just as in the former, instead of a psychical working-over of the excitation, a deflection of it occurs into the somatic field; the difference is merely that in anxiety neurosis the excitation, in whose displacement the neurosis expresses itself, is purely somatic (somatic sexual excitation), whereas in hysteria it is psychical (provoked by conflict). Thus it is not to be wondered at that hysteria and anxiety neurosis regularly combine with each other, as is seen in 'virginal anxiety' or in 'sexual hysteria', and that hysteria simply borrows a number of its symptoms from anxiety neurosis, and so on. These intimate relations which anxiety neurosis has with hysteria provide a fresh argument, moreover, for insisting on the detachment of anxiety neurosis from neurasthenia; for if this detachment is not granted, we shall also be unable any longer to maintain the distinction which has been acquired with so much labour and which is so indispensable for the theory of the neuroses, between neurasthenia and hysteria.

Besides these compromise symptoms, which signify the return of the repressed and consequently a collapse of the defence that had been originally achieved, the obsessional neurosis constructs a set of further symptoms, whose origin is quite different. For the ego seeks to fend off the derivatives of the initially repressed memory, and in this defensive struggle it creates symptoms which might be classed together as 'secondary defence'. These are all of them 'protective measures', which have already done good service in the fight against obsessional ideas and obsessional affects. If these aids in the defensive struggle genuinely succeed in once more repressing the symptoms of the return which have forced themselves on the ego, then the obsession is transferred to the protective measures themselves and creates a third form of 'obsessional neurosis'- obsessional actions. These actions are never primary; they never contain anything but a defence - never an aggression. A psychical analysis of them shows that, in spite of their peculiarity, they can always be fully explained by being traced back to the obsessional memories which they are fighting against.¹

[1895b, 349]

[1896b, 392]
Secondary defence against the obsessional ideas may be effected by a forcible diversion on to other thoughts with a content as contrary as possible. This is why *obsessional brooding*, if it succeeds, regularly deals with abstract and *suprasensual* things; because the ideas that have been repressed are always concerned with *sensuality*. Or else the patient tries to make himself master of each of his obsessional ideas singly by logical work and by having recourse to his conscious memories. This leads to *obsessional thinking*, to a *compulsion to test things* and to *doubting mania*. The advantage which perception has over memory in such tests at first causes the patient, and later compels him, to collect and store up all the objects with which he has come into contact. Secondary defence against obsessional effects leads to a still wider set of protective measures which are capable of being transformed into obsessional acts. These may be grouped according to their purpose: *penitential* measures (burdensome ceremonials, the observation of numbers), *precautionary* measures (all sorts of phobias, superstition, pedantry, increase of the primary symptom of conscientiousness); measures to do with *fear of betrayal* (collecting scraps of paper, seclusiveness), or to ensure *numbing* (dipsomania). Among these obsessional acts and obsessional impulses, phobias, since they circumscribe the patient's existence, play the greatest part.

[1896b, 393]

It only remains for me now to employ what has been learned from this case of paranoia for making a comparison between paranoia and obsessional neurosis. In each of them, repression has been shown to be the nucleus of the psychical mechanism, and in each what has been repressed is a sexual experience in childhood. In this case of paranoia, too, every obsession sprang from repression; the symptoms of paranoia allow of a classification similar to the one which has proved justified for obsessional neurosis. Part of the symptoms, once again, arise from primary defence - namely, all the delusional ideas which are characterized by distrust and suspicion and which are concerned with ideas of being persecuted by others. In obsessional neurosis the initial self-reproach has been repressed by the formation of the primary symptom of defence: *self-distrust*. With this, the self-reproach is acknowledged as justified; and, to weigh against this, the conscientiousness which the subject has acquired during his healthy interval now protects him from giving credence to the self-reproaches which return in the form of obsessional ideas. In paranoia, the self-reproach is repressed in a manner which may be described as *projection*. It is repressed by erecting the defensive symptom of *distrust of other people*. In this way the subject withdraws his acknowledgement of the self-reproach; and, as if to make up for this, he is deprived of a protection against the self-reproaches which return in his delusional ideas.

[1896b, 403]

Gentlemen, the problem, the approaches to which I have just formulated, concerns the *mechanism* of the formation of hysterical symptoms. We find ourselves obliged, however, to describe the *causation* of those symptoms without taking that mechanism into account, and this involves an inevitable loss of completeness and clarity in our discussion. Let us go back to the part played by the infantile sexual scenes. I am afraid that I may have misled you into over-estimating their power to form symptoms. Let me, therefore, once more stress the fact that every case of hysteria exhibits symptoms which are determined, not by infantile but by later, often by recent, experiences. Other symptoms, it is true, go back to the very earliest experiences and belong, so to speak, to the most ancient nobility. Among these latter are all to be found the numerous and diverse sensations and paraesthesias of the genital organs and other parts of the body, these sensations and paraesthesias being phenomena which simply correspond to the sensory content of the infantile scenes, reproduced in a hallucinatory fashion, often painfully intensified.

[1896c, 428]
One thing more, Gentlemen. It is true that earlier I put the relation between recent and infantile aetiology aside as a separate theme. Nevertheless, I cannot leave the subject without overstepping this resolution at least with one remark. You will agree with me that there is one fact above all which leads us astray in the psychological understanding of hysterical phenomena, and which seems to warn us against measuring psychical acts in hysterics and in normal people with the same yardstick. That fact is the discrepancy between psychically exciting stimuli and psychical reactions which we come upon in hysterical subjects. We try to account for it by assuming the presence in them of a general abnormal sensitivity to stimuli, and we often endeavour to explain it on a physiological basis, as if in such patients certain organs of the brain which serve to transmit stimuli were in a peculiar chemical state (like the spinal centres of a frog, perhaps, which has been injected with strychnine) or as if these cerebral organs had withdrawn from the influence of higher inhibiting centres (as in animals being experimented on under vivisection). Occasionally one or other of these concepts may be perfectly valid as an explanation of hysterical phenomena; I do not dispute this. But the main part of the phenomenon - of the abnormal, exaggerated, hysterical reaction to psychical stimuli - admits of another explanation, an explanation which is supported by countless examples from the analyses of patients. And this is as follows: The reaction of hysterics is only apparently exaggerated; it is bound to appear exaggerated to us because we only know a small part of the motives from which it arises.

To this psychology, which has yet to be created to meet our needs - to this future psychology of the neuroses - I must also refer you when, in conclusion, I tell you something which will at first make you afraid that it may disturb our dawning comprehension of the aetiology of hysteria. For I must affirm that the aetiological role of infantile sexual experience is not confined to hysteria but holds good equally for the remarkable neurosis of obsessions, and perhaps also, indeed, for the various forms of chronic paranoia and other functional psychoses. I express myself on this with less definiteness, because I have as yet analysed far fewer cases of obsessional neurosis than of hysteria; and as regards paranoia, I have at my disposal only a single full analysis and a few fragmentary ones. But what I discovered in these cases seemed to be reliable and filled me with confident expectations for other cases. You will perhaps remember that already, at an earlier date, I recommended that hysteria and obsessions should be grouped together under the name of 'neuroses of defence', even before I had come to know of their common infantile aetiology. I must now add that although this need not be expected to happen in general - every one of my cases of obsessions revealed a substratum of hysterical symptoms, mostly sensations and pains, which went back precisely to the earliest childhood experiences. What, then, determines whether the infantile sexual scenes which have remained unconscious will later on, when the other pathogenic factors are super-added, give rise to hysterical or to obsessional neurosis or even to paranoia? This increase in our knowledge seems, as you see, to prejudice the aetiological value of these scenes, since it removes the specificity of the aetiological relation.

A young woman after the birth of her first child was compelled to give up breast-feeding it owing to a complex of hysterical symptoms (loss of appetite, sleeplessness, pains in her breasts, failure of milk-secretion, agitation). When, after the birth of a second child, these obstacles recurred, deep hypnosis on two occasions, accompanied by counter-suggestions, succeeded in removing the obstacles, so that the patient became an excellent nursing mother. The same result was brought about a year later in similar circumstances after two more hypnoses. Some remarks are appended on the fact that it is possible in hysterical patients for distressing antithetic or anxious ideas to be realized which normal people are able to inhibit; several observations of tic are traced back to this mechanism of 'counter-will'.

[1896c, 429]

[1897b, 443]
If anyone is curious to know, I may add that the dream concealed a phantasy of my behaving in an improper and sexually provocative manner, and of the patient putting up a defence against my conduct. If this interpretation seems incredible, I need only point to the numerous instances in which doctors have charges of the same kind brought against them by hysterical women. But in such cases the phantasy emerges into consciousness undisguised and in the form of a delusion, instead of being distorted and appearing only as a dream. - [Added 1909:] This dream occurred at the beginning of the patient's psychoanalytic treatment. It was not until later that I learnt that she had been repeating in it the initial trauma from which her neurosis had arisen. I have since then come across the same behaviour in other patients; having been exposed to a sexual assault in their childhood, they seek, as it were, to bring about a repetition of it in their dreams. [1900a, 671]

I once had an opportunity of making a detailed study of a young woman who passed through a variety of psychical conditions. Her illness began with a state of confusional excitement during which she displayed a quite special aversion to her mother, hitting and abusing her whenever she came near her bed, while at the same period she was docile and affectionate towards a sister who was many years her senior. This was followed by a state in which she was lucid but somewhat apathetic and suffered from badly disturbed sleep. It was during this phase that I began treating her and analysing her dreams. An immense number of these dreams were concerned, with a greater or less degree of disguise, with the death of her mother: at one time she would be attending an old woman's funeral, at another she and her sister would be sitting at table dressed in mourning. There could be no question as to the meaning of these dreams. As her condition improved still further, hysterical phobias developed. The most tormenting of these was a fear that something might have happened to her mother. She was obliged to hurry home, wherever she might be, to convince herself that her mother was still alive. This case, taken in conjunction with what I had learnt from other sources, was highly instructive: it exhibited, translated as it were into different languages, the various ways in which the psychical apparatus reacted to one and the same exciting idea. In the confusional state, in which, as I believe, the second psychical agency was overwhelmed by the normally suppressed first one, her unconscious hostility to her mother found a powerful motor expression. When the calmer condition set in, when the rebellion was suppressed and the domination of the censorship re-established, the only region left open in which her hostility could realize the wish for her mother's death was that of dreaming. When a normal state was still more firmly established, it led to the production of her exaggerated worry about her mother as a hysterical counter-reaction and defensive phenomenon. In view of this it is no longer hard to understand why hysterical girls are so often attached to their mothers with such exaggerated affection. [1900a, 738]

In the case of a psychical complex which has come under the influence of the censorship imposed by resistance, the affects are the constituent which is least influenced and which alone can give us a pointer as to how we should fill in the missing thoughts. This is seen even more clearly in the psychoneuroses than in dreams. Their affects are always appropriate, at least in their quality though we must allow for their intensity being increased owing to displacements of neurotic attention. If a hysterical is surprised at having to be so frightened of something trivial or if a man suffering from obsessions is surprised at such distressing self-reproaches arising out of a mere nothing, they have both gone astray, because they regard the ideational content - the triviality or the mere nothing - as what is essential; and they put up an unsuccessful fight because they take this ideational content as the starting-point of their thought-activity. Psychoanalysis can put them upon the right path by recognizing the affect as being, on the contrary, justified and by seeking out the idea which belongs to it but has been repressed and replaced by a substitute. A necessary premise to all this is that the release of affect and the ideational content do not constitute the indissoluble organic unity as which we are in the habit of treating them, but that these two separate entities may be merely soldered together and can thus be detached from each other by analysis. Dream-interpretation shows that this is in fact the case. [1900a, 905]
Here is another example. A fourteen-year-old boy came to me for psycho-analytic treatment suffering from tic convulsif, hysterical vomiting, headaches, etc. I began the treatment by assuring him that if he shut his eyes he would see pictures or have ideas, which he was then to communicate to me. He replied in pictures. His last impression before coming to me was revived visually in his memory. He had been playing at draughts with his uncle and saw the board in front of him. He thought of various positions, favourable or unfavourable, and of moves that one must not make. He then saw a dagger lying on the board - an object that belonged to his father but which his imagination placed on the board. Then there was a sickle lying on the board and next a scythe. And there now appeared a picture of an old peasant mowing the grass in front of the patient's distant home with a scythe. After a few days I discovered the meaning of this series of pictures. The boy had been upset by an unhappy family situation. He had a father who was a hard man, liable to fits of rage, who had been unhappily married to the patient's mother, and whose educational methods had consisted of threats. His father had been divorced from his mother, a tender and affectionate woman, had married again and had one day brought a young woman home with him who was to be the boy's new mother. It was during the first few days after this that the fourteen-year-old boy's illness had come on. His suppressed rage against his father was what had constructed this series of pictures with their understandable allusions. The material for them was provided by a recollection from mythology. The sickle was the one with which Zeus castrated his father; the scythe and the picture of the old peasant represented Kronos, the violent old man who devoured his children and on whom Zeus took such unfilial vengeance. His father's marriage gave the boy an opportunity of repaying the reproaches and threats which he had heard from his father long before because he had played with his genitals. (Cf. the playing at draughts; the forbidden moves; the dagger which could be used to kill.) In this case long-repressed memories and derivatives from them which had remained unconscious slipped into consciousness by a roundabout path in the form of apparently meaningless pictures.

² In the days while I was engaged in writing these pages the following almost incredible instance of forgetting happened to me. On the first of January I was going through my medical engagement book so that I could send out my accounts. Under the month of June I came across the name 'M---l' but could not recall who it belonged to. My bewilderment grew when I turned the pages and discovered that I treated the case in a sanatorium and made daily visits over a period of weeks. A patient treated under such conditions cannot be forgotten by a doctor after scarcely six months. Could it have been a man, I asked myself, a case of general paralysis, an uninteresting case? Finally the record of the fees I had received brought back to me all the facts that had striven to escape my memory. M---l was a fourteen-year-old girl, the most remarkable case I had had in recent years, one which taught me a lesson I am not likely ever to forget and whose outcome cost me moments of the greatest distress. The child fell ill of an unmistakable hysteria, which did in fact clear up quickly and radically under my care. After this improvement the child was taken away from me by her parents. She still complained of abdominal pains which had played the chief part in the clinical picture of her hysteria. Two months later she died of sarcoma of the abdominal glands. The hysteria, to which she was at the same time predisposed, used the tumour as a provoking cause, and I, with my attention held by the noisy but harmless manifestations of the hysteria, had perhaps overlooked the first signs of the insidious and incurable disease.

It is in fact my belief that we must accept this judgement for a whole series of seemingly accidental clumsy movements. It is true that they make a show of something violent and sweeping, like a spastic-atactic movement, but they prove to be governed by an intention and achieve their aim with a certainty which cannot in general be credited to our conscious voluntary movements. Moreover they have both features - their violence and their unerring aim - in common with the motor manifestations of the hysterical neurosis, and partly, too, with the motor performances of somnambulism. This fact indicates that both in these cases and in the movements under consideration the same unknown modification of the innervatory process is present.
Similarly, falling, stumbling and slipping need not always be interpreted as purely accidental miscarriages of motor actions. The double meanings that language attaches to these expressions are enough to indicate the kind of phantasies involved, which can be represented by such losses of bodily equilibrium. I can recall a number of fairly mild nervous illnesses in women and girls which set in after a fall not accompanied by any injury, and which were taken to be traumatic hysterias resulting from the shock of the fall. Even at that time I had an impression that these events were differently connected and that the fall was already a product of the neurosis and expressed the same unconscious phantasies with a sexual content, which could be assumed to be the forces operating behind the symptoms. Is not the same thing meant by a proverb which runs: 'When a girl falls she falls on her back'?

² For example, the phantasies of hysterics concerning sexual and cruel maltreatment correspond, at times even down to details, with the complaints of persecuted paranoics. It is curious, but not unintelligible, that we meet the identical content in the form of reality in the contrivances of perverts for the satisfaction of their desires.

³ For a third kind of incompleteness in this report neither the patient nor the author is responsible. It is, on the contrary, obvious that a single case history, even if it were complete and open to no doubt, cannot provide an answer to all the questions arising out of the problem of hysteria. It cannot give an insight into all the types of this disorder, into all the forms of internal structure of the neurosis, into all the possible kinds of relation between the mental and the somatic which are to be found in hysteria. It is not fair to expect from a single case more than it can offer. And any one who has hitherto been unwilling to believe that a psychosexual aetiology holds good generally and without exception for hysteria is scarcely likely to be convinced of the fact by taking stock of a single case history. He would do better to suspend his judgement until his own work has earned him the right to a conviction.

The patient, to whom I shall in future give the name of 'Dora', had even at the age of eight begun to develop neurotic symptoms. She became subject at that time to chronic dyspnoea with occasional accesses in which the symptom was very much aggravated. The first onset occurred after a short expedition in the mountains and was accordingly put down to over-exertion. In the course of six months, during which she was made to rest and was carefully looked after, this condition gradually passed off. The family doctor seems to have had not a moment's hesitation in diagnosing the disorder as purely nervous and in excluding any organic cause for the dyspnoea; but he evidently considered this diagnosis compatible with the aetiology of over-exertion.

¹ [1901b, 1254]

² [1901b, 1325]

³ [1905e, 1356]

¹ [1905e, 1362]
The little girl went through the usual infectious diseases of childhood without suffering any lasting damage. As she herself told me - and her words were intended to convey a deeper meaning - her brother was as a rule the first to start the illness and used to have it very slightly, and she would then follow suit with a severe form of it. When she was about twelve she began to suffer from unilateral headaches in the nature of a migraine, and from attacks of nervous coughing. At first these two symptoms always appeared together, but they became separated later on and ran different courses. The migraine grew rarer, and by the time she was sixteen she had quite got over it. But attacks of \textit{tussis nervosa}, which had no doubt been started by a common catarrh, continued to occur over the whole period. When, at the age of eighteen, she came to me for treatment, she was again coughing in a characteristic manner. The number of these attacks could not be determined; but they lasted from three to five weeks, and on one occasion for several months. The most troublesome symptom during the first half of an attack of this kind, at all events in the last few years, used to be a complete loss of voice. The diagnosis that this was once more a nervous complaint had been established long since; but the various methods of treatment which are usual, including hydrotherapy and the local application of electricity, had produced no result. It was in such circumstances as these that the child had developed into a mature young woman of very independent judgement, who had grown accustomed to laugh at the efforts of doctors, and in the end to renounce their help entirely. Moreover, she had always been against calling in medical advice, though she had no personal objection to her family doctor. Every proposal to consult a new physician aroused her resistance, and it was only her father's authority which induced her to come to me at all.

I first saw her when she was sixteen, in the early summer. She was suffering from a cough and from hoarseness, and even at that time I proposed giving her psychological treatment. My proposal was not adopted, since the attack in question, like the others, passed off spontaneously, though it had lasted unusually long. During the next winter she came and stayed in Vienna with her uncle and his daughters after the death of the aunt of whom she had been so fond. There she fell ill of a feverish disorder which was diagnosed at the time as appendicitis.² In the following autumn, since her father's health seemed to justify the step, the family left the health-resort of B--- for good and all. They first moved to the town where her father's factory was situated, and then, scarcely a year later, settled permanently in Vienna.

Dora was by that time in the first bloom of youth - a girl of intelligent and engaging looks. But she was a source of heavy trials for her parents. Low spirits and an alteration in her character had now become the main features of her illness. She was clearly satisfied neither with herself nor with her family; her attitude towards her father was unfriendly, and she was on very bad terms with her mother, who was bent upon drawing her into taking a share in the work of the house. She tried to avoid social intercourse, and employed herself - so far as she was allowed to by the fatigue and lack of concentration of which she complained - with attending lectures for women and with carrying on more or less serious studies. One day her parents were thrown into a state of great alarm by finding on the girl's writing-desk, or inside it, a letter in which she took leave of them because, as she said, she could no longer endure her life.¹ Her father, indeed, being a man of some perspicacity, guessed that the girl had no serious suicidal intentions. But he was none the less very much shaken; and when one day, after a slight passage of words between him and his daughter, she had a first attack of loss of consciousness² - an event which was subsequently covered by an amnesia - it was determined, in spite of her reluctance, that she should come to me for treatment.
No doubt this case history, as I have so far outlined it, does not upon the whole seem worth recording. It is merely a case of 'petite hystérie' with the commonest of all somatic and mental symptoms: dyspnoea, tussis nervosa, aphonía, and possibly migraines, together with depression, hysterical unsociability, and a taedium vitae which was probably not entirely genuine. More interesting cases of hysteria have no doubt been published, and they have very often been more carefully described; for nothing will be found in the following pages on the subject of stigmata of cutaneous sensibility, limitation of the visual field, or similar matters. I may venture to remark, however, that all such collections of the strange and wonderful phenomena of hysteria have but slightly advanced our knowledge of a disease which still remains as great a puzzle as ever. What is wanted is precisely an elucidation of the commonest cases and of their most frequent and typical symptoms. I should have been very well satisfied if the circumstances had allowed me to give a complete elucidation of this case of petite hystérie. And my experiences with other patients leave me in no doubt that my analytic method would have enabled me to do so.

¹ Here is an instance of this. Another physician in Vienna, whose conviction of the unimportance of sexual factors in hysteria has probably been very much strengthened by such experiences as this, was consulted in the case of a fourteen-year-old girl who suffered from dangerous hysterical vomiting. He made up his mind to ask her the painful question whether by any chance she had ever had a love-affair with a man. 'No!' answered the child, no doubt with well-affected astonishment; and then repeated to her mother in her irreverent way: 'Only fancy! the old stupid asked me if I was in love!' She afterwards came to me for treatment, and proved - though not during our very first conversation, to be sure - to have been a masturbator for many years, with a considerable leucorrhoeal discharge (which had a close bearing on her vomiting). She had finally broken herself of the habit, but was tormented in her abstinence by the most acute sense of guilt, so that she looked upon every misfortune that befell her family as a divine punishment for her transgression. Besides this, she was under the influence of the romance of an unmarried aunt, whose pregnancy (a second determinant for her vomiting) was supposed to have been happily hidden from her. The girl was looked upon as a 'mere child,' but she turned out to be initiated into all the essentials of sexual relations.

² The experience with Herr K. - his making love to her and the insult to her honour which was involved - seems to provide in Dora's case the psychical trauma which Breuer and I declared long ago to be the indispensable prerequisite for the production of a hysterical disorder. But this new case also presents all the difficulties which have since led me to go beyond that theory,¹ besides an additional difficulty of a special kind. For, as so often happens in histories of cases of hysteria, the trauma that we know of as having occurred in the patient's past life is insufficient to explain or to determine the particular character of the symptoms; we should understand just as much or just as little of the whole business if the result of the trauma had been symptoms quite other than tussis nervosa, aphonía, depression, and taedium vitae. But there is the further consideration that some of these symptoms (the cough and the loss of voice) had been produced by the patient years before the time of the trauma, and that their earliest appearances belong to her childhood, since they occurred in her eighth year. If, therefore, the trauma theory is not to be abandoned, we must go back to her childhood and look about there for any influences or impressions which might have had an effect analogous to that of a trauma. Moreover, it deserves to be remarked that in the investigation even of cases in which the first symptoms had not already set in childhood I have been driven to trace back the patients' life history to their earliest years.²
In order to particularize Dora's case it is not enough merely to draw attention to the reversal of affect; there has also been a displacement of sensation. Instead of the genital sensation which would certainly have been felt by a healthy girl in such circumstances,¹ Dora was overcome by the unpleasurable feeling which is proper to the tract of mucous membrane at the entrance to the alimentary canal - that is by disgust. The stimulation of her lips by the kiss was no doubt of importance in localizing the feeling at that particular place; but I think I can also recognize another factor in operation.²

The disgust which Dora felt on that occasion did not become a permanent symptom, and even at the time of the treatment it was only, as it were, potentially present. She was a poor eater and confessed to some disinclination for food. On the other hand, the scene had left another consequence behind it in the shape of a sensory hallucination which occurred from time to time and even made its appearance while she was telling me her story. She declared that she could still feel upon the upper part of her body the pressure of Herr K.'s embrace. In accordance with certain rules of symptom-formation which I have come to know, and at the same time taking into account certain other of the patient's peculiarities, which were otherwise inexplicable, - such as her unwillingness to walk past any man whom she saw engaged in eager or affectionate conversation with a lady, - I have formed in my own mind the following reconstruction of the scene. I believe that during the man's passionate embrace she felt not merely his kiss upon her lips but also the pressure of his erect member against her body. This perception was revolting to her; it was dismissed from her memory, repressed, and replaced by the innocent sensation of pressure upon her thorax, which in turn derived an excessive intensity from its repressed source. Once more, therefore, we find a displacement from the lower part of the body to the upper.³ On the other hand, the compulsive piece of behaviour which I have mentioned was formed as though it were derived from the undistorted recollection of the scene: she did not like walking past any man who she thought was in a state of sexual excitement, because she wanted to avoid seeing for a second time the somatic sign which accompanies it.

³ All these discussions contain much that is typical and valid for hysteria in general. The subject of erection solves some of the most interesting hysterical symptoms. The attention that women pay to the outlines of men's genitals as seen through their clothing becomes, when it has been repressed, a source of the very frequent cases of avoiding company and of dreading society. - It is scarcely possible to exaggerate the pathogenic significance of the comprehensive tie uniting the sexual and the excremental, a tie which is at the basis of a very large number of hysterical phobias.
Her other reproach against her father was that his ill-health was only a pretext and that he
exploited it for his own purposes. This reproach, too, concealed a whole section of her own
secret history. One day she complained of a professedly new symptom, which consisted of
piercing gastric pains. 'Whom are you copying now?' I asked her, and found I had hit the mark.
The day before she had visited her cousins, the daughters of the aunt who had died. The
younger one had become engaged, and this had given occasion to the elder one for falling ill
with gastric pains, and she was to be sent off to Semmering. Dora thought it was all just envy on
the part of the elder sister; she always got ill when she wanted something, and what she wanted
now was to be away from home so as not to have to look on at her sister's happiness.¹ But
Dora's own gastric pains proclaimed the fact that she identified herself with her cousin, who,
according to her, was a malingerer. Her grounds for this identification were either that she too
envied the luckier girl her love, or that she saw her own story reflected in that of the elder sister,
who had recently had a love-affair which had ended unhappily.² But she had also learned from
observing Frau K. what useful things illnesses could become. Herr K. spent part of the year in
travelling. Whenever he came back, he used to find his wife in bad health, although, as Dora
knew, she had been quite well only the day before. Dora realized that the presence of the
husband had the effect of making his wife ill, and that she was glad to be ill so as to be able to
escape the conjugal duties which she so much detested. At this point in the discussion Dora
suddenly brought in an allusion to her own alternations between poor and bad health during the
first years of her girlhood at B--; and I was thus driven to suspect that her states of health were
to be regarded as depending upon something else, in the same way as Frau K.'s. (It is a rule of
psycho-analytic technique that an internal connection which is still undisclosed will announce its
presence by means of a contiguity - a temporal proximity of associations; just as in writing, if 'a'
and 'b' are put side by side, it means that the syllable 'ab' is to be formed out of them.) Dora had
had a very large number of attacks of coughing accompanied by loss of voice. Could it be that
the presence or absence of the man she loved had had an influence upon the appearance and
disappearance of the symptoms of her illness? If this were so, it must be possible to discover
some coincidence or other which would betray the fact. I asked her what the average length of
these attacks had been. 'From three to six weeks, perhaps.' How long had Herr K.'s absences
lasted? 'Three to six weeks, too', she was obliged to admit. Her illness was therefore a
demonstration of her love for K., just as his wife's was a demonstration of her dislik. It was only
necessary to suppose that her behaviour had been the opposite of Frau K.'s and that she had
been ill when he was absent and well when he had come back. And this really seemed to have
been so, at least during the first period of the attacks. Later on it no doubt became necessary to
obscure the coincidence between her attacks of illness and the absence of the man she secretly
loved, lest its regularity should betray her secret. The length of the attacks would then remain as
a trace of their original significance.

[1905e, 1376]
I remembered that long before, while I was working at Charcot's clinic, I had seen and heard how in cases of hysterical mutism writing operated vicariously in the place of speech. Such patients were able to write more fluently, quicker, and better than others did or than they themselves had done previously. The same thing had happened with Dora. In the first days of her attacks of aphonia 'writing had always come specially easy to her'. No psychological elucidation was really required for this peculiarity, which was the expression of a physiological substitutive function enforced by necessity; it was noticeable, however, that such an elucidation was easily to be found. Herr K. used to write to her at length while he was travelling and to send her picture post-cards. It used to happen that she alone was informed as to the date of his return, and that his arrival took his wife by surprise. Moreover, that a person will correspond with an absent friend whom he cannot talk to is scarcely less obvious than that if he has lost his voice he will try to make himself understood in writing. Dora's aphonia, then, allowed of the following symbolic interpretation. When the man she loved was away she gave up speaking; speech had lost its value since she could not speak to him. On the other hand, writing gained in importance, as being the only means of communication with him in his absence.

I was on the point of remarking to her how much easier it is to remember things of that kind about one's brother than about oneself, when she continued the train of recollections which had been revived: 'Yes. I used to do it too, for some time, but not until my seventh or eighth year. It must have been serious, because I remember now that the doctor was called in. It lasted till a short time before my nervous asthma.'

¹ This word played the same part with the fourteen-year old girl whose case history I have compressed into a few lines on p. 1365 n. I had established the child in a pension with an intelligent lady, who took charge of her for me. The lady reported that the little girl could not bear her to be in the room while she was going to bed, and that when she was in bed she had a marked cough, of which there was no trace in the daytime. When the girl was questioned about these symptoms, the only thing that occurred to her was that her grandmother coughed in the same way, and that she was said to have a catarrh. It was clear from this that the child herself had a catarrh, and that she did not want to be observed while she performed her evening ablutions. This catarrh which, thanks to its name, had been displaced from the lower to the upper part of her body, exhibited a quite unusual degree of intensity.

I must now proceed to touch upon some further relations existing between Dora's genital catarrh and her hysterical symptoms. At a time when any psychological elucidation of hysteria was still very remote, I used to hear experienced fellow-doctors who were my seniors maintain that in the case of hysterical patients suffering from leucorrhoea any increase in the catarrh was regularly followed by an intensification of the hysterical troubles, and especially of loss of appetite and vomiting. No one was very clear about the nature of the connection but I fancy the general inclination was towards the opinion held by gynaecologists. According to their hypothesis, as is well known, disorders of the genitals exercise upon the nervous functions a direct and far-reaching influence in the nature of an organic disturbance - though a therapeutic test of this theory is apt to leave one in the lurch. In the light of our present knowledge we cannot exclude the possibility of the existence of a direct organic influence of this sort; but it is at all events easier to indicate its psychical coating. The pride taken by women in the appearance of their genitals is quite a special feature of their vanity; and disorders of the genitals which they think calculated to inspire feelings of repugnance or even disgust have an incredible power of humiliating them, of lowering their self-esteem, and of making them irritable, sensitive, and distrustful. An abnormal secretion of the mucous membrane of the vagina is looked upon as a source of disgust.
I then remembered that shortly after her aunt's death Dora had had an attack of what had been alleged to be appendicitis. Up till then I had not ventured to count that illness among her hysterical productions. She told me that during the first few days she had had high fever and had felt the pain in her abdomen that she had read about in the encyclopaedia. She had been given cold fomentations but had not been able to bear them. On the second day her period had set in, accompanied by violent pains. (Since her health had been bad, the periods had been very irregular.) At that time she used to suffer continually from constipation.

[1905e, 1437]

It was not really possible to regard this state as a purely hysterical one. Although hysterical fever does undoubtedly occur, yet it seemed too arbitrary to put down the fever accompanying this questionable illness to hysteria instead of to some organic cause operative at the time. I was on the point of abandoning the track, when she herself helped me along it by producing her last addendum to the dream: she saw herself particularly distinctly going up the stairs.

[1905e, 1437]

What, then, was the meaning of this condition, of this attempted simulation of a perityphlitis? The remainder of the disorder, the dragging of one leg, was entirely out of keeping with perityphlitis. It must, no doubt, fit in better with the secret and possibly sexual meaning of the clinical picture; and if it were elucidated might in its turn throw light on the meaning which we were in search of. I looked about for a method of approaching the puzzle. Periods of time had been mentioned in the dream; and time is assuredly never a matter of indifference in any biological event. I therefore asked Dora when this attack of appendicitis had taken place; whether it had been before or after the scene by the lake. Every difficulty was resolved at a single blow by her prompt reply: 'Nine months later.' The period of time is sufficiently characteristic. Her supposed attack of appendicitis had thus enabled the patient with the modest means at her disposal (the pains and the menstrual flow) to realize a phantasy of childbirth.² Dora was naturally aware of the significance of this period of time, and could not dispute the probability of her having, on the occasion under discussion, read up in the encyclopaedia about pregnancy and childbirth. But what was all this about her dragging her leg? I could now hazard a guess. That is how people walk when they have twisted a foot. So she had made a 'false step': which was true indeed if she could give birth to a child nine months after the scene by the lake. But there was still another requirement upon the fulfilment of which I had to insist. I am convinced that a symptom of this kind can only arise where it has an infantile prototype. All my experience hitherto has led me to hold firmly to the view that recollections derived from the impressions of later years do not possess sufficient force to enable them to establish themselves as symptoms. I scarcely dared hope that Dora would provide me with the material that I wanted from her childhood, for the fact is that I am not yet in a position to assert the general validity of this rule, much as I should like to be able to do so. But in this case there came an immediate confirmation of it. Yes, said Dora, once when she was a child she had twisted the same foot; she had slipped on one of the steps as she was going downstairs. The foot - and it was actually the same one that she afterwards dragged - had swelled up and had to be bandaged and she had had to lie up for some weeks. This had been a short time before the attack of nervous asthma in her eighth year.

[1905e, 1438]
After this she had gone on quite well till the middle of October, when she had had another attack of aphonia which had lasted for six weeks. I was surprised at this news, and, on my asking her whether there had been any exciting cause, she told me that the attack had followed upon a violent fright. She had seen some one run over by a carriage. Finally she came out with the fact that the accident had occurred to no less a person than Herr K. himself. She had come across him in the street one day; they had met in a place where there was a great deal of traffic; he had stopped in front of her as though in bewilderment, and in his abstraction he had allowed himself to be knocked down by a carriage.¹ She had been able to convince herself, however, that he escaped without serious injury. She still felt some slight emotion if she heard any one speak of her father's affair with Frau K., but otherwise she had no further concern with the matter. She was absorbed in her work, and had no thoughts of marrying.

[1905e, 1455]

She went on to tell me that she had come for help on account of a right-sided facial neuralgia, from which she was now suffering day and night. 'How long has it been going on?' "Exactly a fortnight."² I could not help smiling; for I was able to show her that exactly a fortnight earlier she had read a piece of news that concerned me in the newspaper. (This was in 1902.) And this she confirmed.

[1905e, 1455]

The removal of the symptoms of hysterical patients by psycho-analysis proceeds on the supposition that those symptoms are substitutes - transcriptions as it were - for a number of emotionally cathected mental processes, wishes and desires, which, by the operation of a special psychical procedure (repression), have been prevented from obtaining discharge in psychical activity that is admissible to consciousness. These mental processes, therefore, being held back in a state of unconsciousness, strive to obtain an expression that shall be appropriate to their emotional importance - to obtain discharge; and in the case of hysteria they find such an expression (by means of the process of 'conversion') in somatic phenomena, that is, in hysterical symptoms. By systematically turning these symptoms back (with the help of a special technique ) into emotionally cathected ideas - ideas that will now have become conscious - it is possible to obtain the most accurate knowledge of the nature and origin of these formerly unconscious psychical structures.

[1905d, 1489]

The significance of the erotogenic zones as apparatuses subordinate to the genitals and as substitutes for them is, among all the psychoneuroses, most clearly to be seen in hysteria; but this does not imply that that significance is any the less in the other forms of illness. It is only that in them it is less recognizable, because in their case (obsessional neurosis and paranoia) the formation of the symptoms takes place in regions of the mental apparatus which are more remote from the particular centres concerned with somatic control. In obsessional neurosis what is more striking is the significance of those impulses which create new sexual aims and seem independent of erotogenic zones. Nevertheless, in scopophilia and exhibitionism the eye corresponds to an erotogenic zone; while in the case of those components of the sexual instinct which involve pain and cruelty the same role is assumed by the skin - the skin, which in particular parts of the body has become differentiated into sense organs or modified into mucous membrane, and is thus the erotogenic zone par excellence.¹

[1905d, 1493]
This one-sided attitude of medicine towards the body has undergone a gradual change in the course of the last decade and a half, a change brought about directly by clinical experience. There are a large number of patients, suffering from affections of greater or less severity, whose disorders and complaints make great demands on the skill of their physicians, but in whom no visible or observable signs of a pathological process can be discovered either during their life or after their death, in spite of all the advances in the methods of investigation made by scientific medicine. One group of these patients are distinguished by the copiousness and variety of their symptoms: they are incapable of intellectual work because of headaches or inability to concentrate their attention, their eyes ache when they read, their legs become fatigued when they walk, develop dull pains or go to sleep, their digestion is disturbed by distressing sensations, by eructations or gastric spasms, they cannot defaecate without aperients, they are subject to sleeplessness, and so on. They may suffer from all these disorders simultaneously or in succession, or from only a selection of them; but in every case the illness is evidently the same. Moreover, its signs are often variable and replace one another. A patient who has hitherto been incapacitated by headaches but has had a fairly good digestion may next day enjoy a clear head but may thenceforward be unable to manage most kinds of food. Again, his sufferings may suddenly cease if there is a marked change in the circumstances of his existence. If he is travelling he may feel perfectly well and be able to enjoy the most varied diet without any ill effects, but when he gets home he may once more have to restrict himself to sour milk. In a few cases the disorder - whether it is a pain or a weakness resembling a paralysis - may suddenly pass from one side of the body to the other: it may jump from his right side to the corresponding part of the body on his left side. But in every instance it is to be observed that the symptoms are very clearly influenced by excitement, emotion, worry, etc., and also that they can disappear and give place to perfect health without leaving any traces, even if they have persisted over a long period.

Medical research has at last shown that people of this kind are not to be looked upon as suffering from a disease of the stomach or of the eyes or whatever it may be, but that it must be a question in their case of an illness of the nervous system as a whole. Examination of the brain and nerves of these patients has so far, however, revealed no perceptible changes; and, indeed, some of the features of their symptomatology prohibit any expectation that even more accurate methods of investigation could ever discover changes of a sort that would throw light upon the illness. This condition has been described as ‘nervousness’ (neurasthenia or hysteria) and has been characterized as a merely ‘functional’ disorder of the nervous system.¹ Incidentally, an exhaustive examination of the brain (after the patient's death) has been equally without results in the case of many more permanent nervous disorders, as well as in illnesses with exclusively mental symptoms, such as what are known as obsessions and delusional insanity.

Physicians were thus faced by the problem of investigating the nature and origin of the symptoms shown by these nervous or neurotic patients. In the course of this investigation it was found that in some at least of these patients the signs of their illness originate from nothing other than a change in the action of their minds upon their bodies and that the immediate cause of their disorder is to be looked for in their minds. What may be the remoter causes of the disturbance which affects their minds is another question, with which we need not now concern ourselves. But medical science was here provided with an opportunity for directing its full attention to what had previously been the neglected side of the mutual relation between body and mind.

¹ [1890a, 1587]

[1890a, 1588]
The field I have in mind is indeed very different from yours. I am referring to the therapy employed for certain 'nervous diseases' - what are known as the psychoneuroses - of which hysteria and obsessional ideas may be taken as samples. The method is called 'psycho-analysis'; it was evolved by me from the 'cathartic' method of therapy first practised by Josef Breuer in Vienna.¹ To combat your surprise, I must draw an analogy between the criminal and the hysteric. In both we are concerned with a secret, with something hidden. But in order not to be paradoxical I must at once point out the difference. In the case of the criminal it is a secret which he knows and hides from you, whereas in the case of the hysteric it is a secret which he himself does not know either, which is hidden even from himself. How is this possible? Now we know, through laborious research, that all these illnesses are the result of the patient's having succeeded in repressing certain ideas and memories that are strongly cathected with affect, together with the wishes that arise from them, in such a way that they play no part in his thinking - do not enter into his consciousness - and thus remain unknown to him. But from this repressed psychical material (these 'complexes') are generated the somatic and psychical symptoms which plague the patient in just the same way as a guilty conscience does. In this one respect, therefore, the difference between the criminal and the hysteric is fundamental.

[1906c, 1892]

In this way, unconscious phantasies are the immediate psychical precursors of a whole number of hysterical symptoms. Hysterical symptoms are nothing other than unconscious phantasies brought into view through 'conversion'; and in so far as the symptoms are somatic ones, they are often enough taken from the circle of the same sexual sensations and motor innervations as those which had originally accompanied the phantasy when it was still conscious. In this way the giving up of the habit of masturbation is in fact undone, and the purpose of the whole pathological process, which is a restoration of the original, primary sexual satisfaction, is achieved - though never completely, it is true, but always in a sort of approximation.

[1908a, 1935]

Anyone who studies hysteria, therefore, soon finds his interest turned away from its symptoms to the phantasies from which they proceed. The technique of psycho-analysis enables us in the first place to infer from the symptoms what those unconscious phantasies are and then to make them conscious to the patient. By this means it has been found that the content of the hysteric's unconscious phantasies corresponds completely to the situations in which satisfaction is consciously obtained by perverts; and if anyone is at a loss for examples of such situations he has only to recall the world-famous performances of the Roman Emperors, the wild excesses of which were, of course, determined only by the enormous and unrestrained power possessed by the authors of the phantasies. The delusions of paranoics are phantasies of the same nature, though they are phantasies which have become directly conscious. They rest on the sadomasochistic components of the sexual instinct, and they, too, may find their complete counterpart in certain unconscious phantasies of hysterical subjects. We also know of cases - cases which have their practical importance as well - in which hysterics do not give expression to their phantasies in the form of symptoms but as conscious realizations, and in that way devise and stage assaults, attacks or acts of sexual aggression.

[1908a, 1935]
Investigation of the childhood history of hysterical patients shows that the hysterical attack is designed to take the place of an auto-erotic satisfaction previously practised and since given up. In a great number of cases this satisfaction (masturbation by contact or by pressure of the thighs, or, again, by movements of the tongue, and so on) recurs during the attack itself, while the subject's consciousness is deflected. Moreover, the onset of an attack that is due to an increase of libido and is in the service of the primary purpose - as a consolation - exactly repeats the conditions under which, at the earlier time, the patient had intentionally sought this auto-erotic satisfaction. The anamnesis of the patient shows the following stages: (a) auto-erotic satisfaction, without ideational content; (b) the same satisfaction, connected with a phantasy which leads to the act of satisfaction; (c) renunciation of the act, with retention of the phantasy; (d) repression of the phantasy, which then comes into effect as a hysterical attack, either in an unchanged form, or in a modified one and adapted to new environmental impressions. Furthermore, (e) the phantasy may even reinstate the act of satisfaction belonging to it which had ostensibly been given up. This is a typical cycle of infantile sexual activity: repression, failure of repression, and return of the repressed.

[1909a, 1983]

The loss of consciousness, the 'absence', in a hysterical attack is derived from the fleeting but unmistakable lapse of consciousness which is observable at the climax of every intense sexual satisfaction, including auto-erotic ones. This course of development can be traced with most certainty where hysterical absences arise from the onset of pollutions in young people of the female sex. The so-called 'hypnoid states' - absences during day-dreaming -, which are so common in hysterical subjects, show the same origin. The mechanism of these absences is comparatively simple. All the subject's attention is concentrated to begin with on the course of the process of satisfaction; with the occurrence of the satisfaction, the whole of this cathexis of attention is suddenly removed, so that there ensues a momentary void in her consciousness. This gap in consciousness, which might be termed a physiological one, is then widened in the service of repression, till it can swallow up everything that the repressing agency rejects.

[1909a, 1984]

In the classificatory system of the neuroses no definite position has hitherto been assigned to 'phobias'. It seems certain that they should only be regarded as syndromes which may form part of various neuroses and that we need not rank them as an independent pathological process. For phobias of the kind to which little Hans's belongs, and which are in fact the most common, the name of 'anxiety-hysteria' seems to me not inappropriate; I suggested the term to Dr. W. Stekel when he was undertaking a description of neurotic anxiety states,' and I hope it will come into general use. It finds its justification in the similarity between the psychological structure of these phobias and that of hysteria - a similarity which is complete except upon a single point. That point, however, is a decisive one and well adapted for purposes of differentiation. For in anxiety-hysteria the libido which has been liberated from the pathogenic material by repression is not converted (that is, diverted from the mental sphere into a somatic innervation), but is set free In the clinical cases that we meet with, this 'anxiety-hysteria' may be combined with 'conversion-hysteria' in any proportion. There exist cases of pure conversion-hysteria without any trace of anxiety, just as there are cases of simple anxiety-hysteria, which exhibit feelings of anxiety and phobias, but have no admixture of conversion. The case of little Hans is one of the latter sort.

[1909b, 2099]
Such is my excuse for having curtailed so drastically the history of this case and its treatment. And I can offer still more cogent reasons for having confined myself to the statement only of some disconnected results of the psycho-analytic investigation of obsessional neuroses. I must confess that I have not yet succeeded in completely penetrating the complicated texture of a severe case of obsessional neurosis, and that, if I were to reproduce the analysis, it would be impossible for me to make the structure, such as by the help of analysis we know or suspect it to be, visible to others through the mass of therapeutic work superimposed upon it. What add so greatly to the difficulty of doing this are the resistances of the patients and the forms in which they are expressed. But even apart from this it must be admitted that an obsessional neurosis is in itself not an easy thing to understand - much less so than a case of hysteria. Actually, indeed, we should have expected to find the contrary. The language of an obsessional neurosis - the means by which it expresses its secret thoughts - is, as it were, only a dialect of the language of hysteria; but it is a dialect in which we ought to be able to find our way about more easily, since it is more nearly related to the forms of expression adopted by our conscious thought than is the language of hysteria. Above all, it does not involve the leap from a mental process to a somatic innervation - hysterical conversion - which can never be fully comprehensible to us.

[1909d, 2128]

Dr. Breuer's patient was a girl of twenty-one, of high intellectual gifts. Her illness lasted for over two years, and in the course of it she developed a series of physical and psychological disturbances which decidedly deserved to be taken seriously. She suffered from a rigid paralysis, accompanied by loss of sensation, of both extremities on the right side of her body; and the same trouble from time to time affected her on her left side. Her eye movements were disturbed and her power of vision was subject to numerous restrictions. She had difficulties over the posture of her head; she had a severe nervous cough. She had an aversion to taking nourishment, and on one occasion she was for several weeks unable to drink in spite of a tormenting thirst. Her powers of speech were reduced, even to the point of her being unable to speak or understand her native language. Finally, she was subject to conditions of 'absence', of confusion, of delirium, and of alteration of her whole personality, to which we shall have presently to turn our attention.

[1910a, 2200]

This relation of an organ with a double claim on it - its relation to the conscious ego and to repressed sexuality - is to be seen even more clearly in motor organs than in the eye: as when, for instance, a hand which has tried to carry out an act of sexual aggression, and has become paralysed hysterically, is unable, after that act has been inhibited, to do anything else as though it were obstinately insisting on carrying out a repressed innervation; or as when the fingers of people who have given up masturbation refuse to learn the delicate movements required for playing the piano or the violin. As regards the eye, we are in the habit of translating the obscure psychical processes concerned in the repression of sexual scopophilia and in the development of the psychogenic disturbance of vision as though a punishing voice was speaking from within the subject, and saying: 'Because you sought to misuse your organ of sight for evil sensual pleasures, it is fitting that you should not see anything at all any more', and as though it was in this way approving the outcome of the process. The idea of talion punishment is involved in this, and in fact our explanation of psychogenic visual disturbance coincides with what is suggested by myths and legends. The beautiful legend of Lady Godiva tells how all the town's inhabitants hid behind their shuttered windows, so as to make easier the lady's task of riding naked through the streets in broad daylight, and how the only man who peeped through the shutters at her revealed loveliness was punished by going blind. Nor is this the only example which suggests that neurotic illness holds the hidden key to mythology as well.

[1910i, 2370]
(1) Our first reflection will tell us that it cannot be the case that this detachment of the libido occurs exclusively in paranoia; nor can it be that, where it occurs elsewhere, it has such disastrous consequences. It is quite possible that a detachment of the libido is the essential and regular mechanism of every repression. We can have no positive knowledge on that point until the other disorders that are based upon repression have been similarly examined. But it is certain that in normal mental life (and not only in periods of mourning) we are constantly detaching our libido in this way from people or from other objects without falling ill. When Faust freed himself from the world by uttering his curses, the result was not a paranoia or any other neurosis but simply a certain general frame of mind. The detachment of the libido, therefore, cannot in itself be the pathogenic factor in paranoia; there must be some special characteristic which distinguishes a paranoic detachment of the libido from other kinds. It is not difficult to suggest what that characteristic may be. What use is made of the libido after it has been set free by the process of detachment? A normal person will at once begin looking about for a substitute for the lost attachment; and until that substitute has been found the liberated libido will be kept in suspension within his mind, and will there give rise to tensions and colour his mood. In hysteria the liberated libido becomes transformed into somatic innervations or into anxiety. But in paranoia the clinical evidence goes to show that the libido, after it has been withdrawn from the object, is put to a special use. It will be remembered that the majority of cases of paranoia exhibit traces of megalomania, and that megalomania can by itself constitute a paranoia. From this it may be concluded that in paranoia the liberated libido becomes attached to the ego, and is used for the aggrandizement of the ego. A return is thus made to the stage of narcissism (known to us from the development of the libido), in which a person's only sexual object is his own ego. On the basis of this clinical evidence we can suppose that paranoics have brought along with them a fixation at the stage of narcissism, and we can assert that the length of the step back from sublimated homosexuality to narcissism is a measure of the amount of regression characteristic of paranoia.

[1911c, 2438]

We are obliged to take quite another view of the process of repression when we consider the picture of a true conversion hysteria. Here the salient point is that it is possible to bring about a total disappearance of the quota of affect. When this is so, the patient displays towards his symptoms what Charcot called 'la belle indifférence hystériques'. In other cases this suppression is not so completely successful: some distressing sensations may attach to the symptoms themselves, or it may prove impossible to prevent some release of anxiety, which in turn sets to work the mechanism of forming a phobia. The ideational content of the instinctual representative is completely withdrawn from consciousness; as a substitute - and at the same time as a symptom - we have an over-strong innervation (in typical cases, a somatic one), sometimes of a sensory, sometimes of a motor character, either as an excitation or an inhibition. The over-innervated area proves on a closer view to be a part of the repressed instinctual representative itself - a part which, as though by a process of condensation, has drawn the whole cathexis on to itself. These remarks do not of course bring to light the whole mechanism of a conversion hysteria; in especial the factor of regression, which will be considered in another connection, has also to be taken into account. In so far as repression in hysteria is made possible only by the extensive formation of substitutes, it may be judged to be entirely unsuccessful; as regards dealing with the quota of affect, however, which is the true task of repression, it generally signifies a total success. In conversion hysteria the process of repression is completed with the formation of the symptom and does not, as in anxiety hysteria, need to continue to a second phase - or rather, strictly speaking, to continue endlessly.

[1915d, 2986]
The physical movement of 'changing her position', Tausk remarks, depicted the words 'putting her in a false position' and her identification with her lover. I would call attention once more to the fact that the whole train of thought is dominated by the element which has for its content a bodily innervation (or, rather, the sensation of it). Furthermore, a hysterical woman would, in the first example, have in fact convulsively twisted her eyes, and, in the second, have given actual jerks, instead of having the impulse to do so or the sensation of doing so: and in neither example would she have any accompanying conscious thoughts, nor would she have been able to express any such thoughts afterwards.
[1915e, 3020]

Before we draw any conclusion from impressions such as these, let us consider further the distinctions between the formation of substitutes in schizophrenia on the one hand, and in hysteria and obsessional neurosis on the other - subtle distinctions which nevertheless make a strange impression. A patient whom I have at present under observation has allowed himself to be withdrawn from all the interests of life on account of a bad condition of the skin of his face. He declares that he has black heads and deep holes in his face which everyone notices. Analysis shows that he is playing out his castration complex upon his skin. At first he worked at these blackheads remorselessly; and it gave him great satisfaction to squeeze them out, because, as he said, something spurted out when he did so. Then he began to think that a deep cavity appeared wherever he had got rid of a blackhead, and he reproached himself most vehemently with having ruined his skin for ever by 'constantly fiddling about with his hand'. Pressing out the content of the blackheads is clearly to him a substitute for masturbation. The cavity which then appears owing to his fault is the female genital, i.e. the fulfilment of the threat of castration (or the phantasy representing that threat) provoked by his masturbating. This substitutive formation has, in spite of its hypochondriacal character, considerable resemblance to a hysterical conversion; and yet we have a feeling that something different must be going on here, that a substitutive formation such as this cannot be attributed to hysteria, even before we can say in what the difference consists. A tiny little cavity such as a pore of the skin would hardly be used by a hysterical as a symbol for the vagina, which he is otherwise ready to compare with every imaginable object that encloses a hollow space. Besides, we should expect the multiplicity of these little cavities to prevent him from using them as a substitute for the female genital. The same applies to the case of a young patient reported by Tausk some years ago to the Vienna Psycho-Analytical Society. This patient behaved in other respects exactly as though he were suffering from an obsessional neurosis; he took hours to wash and dress, and so on. It was noticeable, however, that he was able to give the meaning of his inhibitions without any resistance. In putting on his stockings, for instance, he was disturbed by the idea that he must pull apart the stitches in the knitting, i.e. the holes, and to him every hole was a symbol of the female genital aperture. This again is a thing which we cannot attribute to an obsessional neurotic. Reitler observed a patient of the latter sort, who also suffered from having to take a long time over putting on his stockings; this man, after overcoming his resistances, found as the explanation that his foot symbolized a penis, that putting on the stocking stood for a masturbatory act, and that he had to keep on pulling the stocking on and off, partly in order to complete the picture of masturbation, and partly in order to undo that act.
[1915e, 3021]
This neurosis, known as 'obsessional neurosis', is not so popular as the universally familiar hysteria. It is not, if I may express myself thus, so obtrusively noisy, it behaves more like a private affair of the patient's, it dispenses almost entirely with somatic phenomena, and creates all its symptoms in the mental sphere. Obsessional neurosis and hysteria are the forms of neurotic illness upon the study of which psycho-analysis was first built, and in the treatment of which, too, our therapy celebrates its triumphs. But obsessional neurosis, in which the puzzling leap from the mental to the physical plays no part, has actually, through the efforts of psycho-analysis, become more perspicuous and familiar to us than hysteria, and we have learnt that it displays certain extreme characteristics of the nature of neurosis far more glaringly.

[1916-1917, 3339]

We shall not be able to dismiss a second objection so easily. If you survey a fairly long series of interpretations of symptoms, you will probably start by judging that the concept of a substitutive sexual satisfaction has been stretched to its extreme limits in them. You will not fail to emphasize the fact that these symptoms offer nothing real in the way of satisfaction, that often enough they are restricted to the revival of a sensation or the representation of a phantasy derived from a sexual complex. And you will further point out that these supposed sexual satisfactions often take on a childish and discreditable form, approximate to an act of masturbation perhaps, or recall dirty kinds of naughtiness which are forbidden even to children - habits of which they have been broken. And, going on from this, you will also express surprise that we are representing as a sexual satisfaction what would rather have to be described as the satisfaction of lusts that are cruel or horrible or would even have to be called unnatural. We shall come to no agreement, Gentlemen, on this latter point till we have made a thorough investigation of the sexual life of human beings and till, in doing so, we have decided what it is that we are justified in calling 'sexual'.

[1916-1917, 3374]

As you probably know, the hysterical neurosis can produce its symptoms in any system of organs and so disturb any function. Analysis shows that in this way all the so-called perverse impulses which seek to replace the genital by some other organ manifest themselves: these organs are then behaving like substitutive genitals. The symptoms of hysteria have actually led us to the view that the bodily organs, besides the functional part they play, must be recognized as having a sexual (erotogenic) significance, and that the execution of the first of these tasks is disturbed if the second of them makes too many claims. Countless sensations and innervations which we come across as symptoms of hysteria in organs that have no apparent connection with sexuality are in this way revealed to us as being in the nature of fulfilments of perverse sexual impulses in relation to which other organs have acquired the significance of the sexual parts. We learn too to what a large extent the organs for the intake of nourishment and for excretion can in particular become the vehicles of sexual excitation. Here, then, we have the same thing that we were shown by the perversions; only in their case it was visible easily and unmistakably, whereas in hysteria we have to take a circuitous path by way of the interpretation of symptoms, and do not then ascribe the perverse sexual impulses concerned to the subject's consciousness but locate them in his unconscious.

[1916-1917, 3380]
Thus forearmed we can proceed to the consideration of a suggestion which we shall certainly not be spared. 'Why', we shall be asked, 'are you so obstinate in describing as being already sexuality what on your own evidence are indefinable manifestations in childhood out of which sexual life will later develop? Why should you not be content instead with giving them a physiological description and simply say that in an infant at the breast we already observe activities, such as sensual sucking or holding back the excreta, which show us that he is striving for "organ-pleasure"? In that way you would have avoided the hypothesis, so repugnant to every feeling, of the smallest babies having a sexual life.' - Indeed, Gentlemen, I have no objection at all to organ-pleasure. I know that even the supreme pleasure of sexual union is only an organ-pleasure attached to the activity of the genitals. But can you tell me when this originally indifferent organ-pleasure acquires the sexual character which it undoubtedly possesses in the later phases of development? Do we know any more about 'organ-pleasure' than about sexuality? You will reply that it gains its sexual character precisely when the genitals begin to play their part; 'sexual' coincides with 'genital'. You will even reject the objection raised by the perversions by pointing out to me that in the majority of perversions a genital orgasm is after all aimed at, even if it is arrived at by a method other than the union of the genitals. You are certainly taking up a much stronger position in determining the characteristics of what is sexual if you knock out of it the relation to reproduction which is made untenable by the perversions and put genital activity in its place. But, if so, we are no longer far apart: it is only a question of the genital organs versus the other organs. What are you going to do, however, about the numerous experiences which show you that the genitals can be represented as regards their yield of pleasure by other organs, as in the case of kissing or of the perverse practices of voluptuaries or of the symptoms of hysteria? In that neurosis it is quite usual for signs of stimulation, sensations and innervations, and even the processes of erection, which belong properly to the genitals, to be displaced on to other, remote regions of the body - as, for instance, by transposition upwards, to the head and face. Being thus convinced that you have nothing to catch hold of for your characterization of what is sexual, you will no doubt have to make up your minds to follow my example and extend the description of being 'sexual' to the activities of early childhood, too, which strive for organ-pleasure.

A noteworthy relation between the symptoms of the 'actual' neuroses and of the psychoneuroses makes a further important contribution to our knowledge of the formation of symptoms in the latter. For a symptom of an 'actual' neurosis is often the nucleus and first stage of a psychoneurotic symptom. A relation of this kind can be most clearly observed between neurasthenia and the transference neurosis known as 'conversion hysteria', between anxiety neurosis and anxiety hysteria, but also between hypochondria and the forms of disorder which will be mentioned later under the name of paraphrenia (dementia praecox and paranoia). Let us take as an example a case of hysterical headache or lumbar pain. Analysis shows us that, by condensation and displacement, it has become a substitutive satisfaction for a whole number of libidinal phantasies or memories. But this pain was also at one time a real one and it was then a direct sexual-toxic symptom, the somatic expression of a libidinal excitation. We are far from asserting that all hysterical symptoms contain a nucleus of this kind. But it remains a fact that this is especially often the case and that whatever somatic influences (whether normal or pathological) are brought about by libidinal excitation are preferred for the construction of hysterical symptoms. In such cases they play the part of the grain of sand which a mollusc coats with layers of mother-of-pearl. In the same way, the passing indications of sexual excitement which accompany the sexual act are employed by the psychoneurosis as the most convenient and appropriate material for the construction of symptoms.
The third of the forms of neurotic anxiety faces us with the puzzling fact that here the connection between anxiety and a threatening danger is completely lost to view. For instance, anxiety may appear in hysteria as an accompaniment to hysterical symptoms, or in some chance condition of excitement in which, it is true, we should expect some manifestation of affect but least of all one of anxiety; or it may make its appearance, divorced from any determinants and equally incomprehensible to us and to the patient, as an unrelated attack of anxiety. Here there is no sign whatever of any danger or of any cause that could be exaggerated into one. We next learn from these spontaneous attacks that the complex which we describe as a state of anxiety is capable of fragmentation. The total attack can be represented by a single, intensely developed symptom, by a tremor, a vertigo, by palpitation of the heart, or by dyspnoea; and the general feeling by which we recognize anxiety may be absent or have become indistinct. Yet these conditions, which we describe as 'anxiety-equivalents', have to be equated with anxiety in all clinical and aetiological respects.

(b) A second pointer is to be found in the analysis of the psychoneuroses, and especially of hysteria. We have seen that in this illness anxiety often appears in company with the symptoms, but that unbound anxiety appears, too, manifested as an attack or as a chronic condition. The patients cannot say what it is they are afraid of, and, by the help of an unmistakable secondary revision, link it to the first phobias that come to hand - such as dying, going mad, or having a stroke. If the situation out of which the anxiety (or the symptoms accompanied by anxiety) arose is subjected to analysis, we can as a rule discover what normal course of psychical events has failed to occur and has been replaced by phenomena of anxiety. To express it in another way: we construct the unconscious process as it would have been if it had not experienced any repression and had proceeded unhindered into consciousness. This process would have been accompanied by a particular affect, and we now learn to our surprise that this affect accompanying the normal course of events is invariably replaced by anxiety after repression has occurred, no matter what its own quality may be. Thus, when we have a hysterical anxiety-state before us, its unconscious correlate may be an impulse of a similar character - anxiety, shame, embarrassment - or, just as easily, a positive libidinal excitation or a hostile aggressive one, such as rage or anger. Anxiety is therefore the universally current coinage for which any affective impulse is or can be exchanged if the ideational content attached to it is subjected to repression.

History - The best way of understanding psycho-analysis is still by tracing its origin and development. In 1880 and 1881 Dr. Josef Breuer of Vienna, a well-known physician and experimental physiologist, was occupied in the treatment of a girl who had fallen ill of a severe hysteria while she was nursing her sick father. The clinical picture was made up of motor paralyses, inhibitions, and disturbances of consciousness. Following a hint given him by the patient herself, who was a person of great intelligence, he put her into a state of hypnosis and contrived that, by describing to him the moods and thoughts that were uppermost in her mind, she returned on each particular occasion to a normal mental condition. By consistently repeating the same laborious process, he succeeded in freeing her from all her inhibitions and paralyses, so that in the end he found his trouble rewarded by a great therapeutic success as well as by an unexpected insight into the nature of the puzzling neurosis. Nevertheless, Breuer refrained from following up his discovery or from publishing anything about the case until some ten years later, when the personal influence of the present writer (Freud, who had returned to Vienna in 1886 after studying in the school of Charcot) prevailed on him to take up the subject afresh and embark upon a joint study of it. These two, Breuer and Freud, published a preliminary paper 'On the Psychical Mechanism of Hysterical Phenomena' in 1893, and in 1895 a volume entitled Studies on Hysteria (which reached its fourth edition in 1922), in which they described their therapeutic procedure as 'cathartic'.

[1923a, 3912]
From a clinical standpoint the neuroses must necessarily be put alongside the intoxications and such disorders as Graves' disease. These are conditions arising from an excess or a relative lack of certain highly active substances, whether produced inside the body or introduced into it from outside - in short, they are disturbances of the chemistry of the body, toxic conditions. If someone succeeded in isolating and demonstrating the hypothetical substance or substances concerned in neuroses, he would have no need to worry about opposition from the medical profession. For the present, however, no such avenue of approach to the problem is open. At the moment we can only start from the symptoms presented by a neurosis - symptoms which in the case of hysteria, for instance, consist of a combination of somatic and mental disturbances. Now Charcot's experiments as well as Breuer's clinical observations taught us that the somatic symptoms of hysteria are psychogenic too - that is, that they are precipitates of mental processes that have run their course. By putting a subject into a state of hypnosis it was possible at will to produce the somatic symptoms of hysteria artificially.

[1925e, 4123]

No doubt not the whole of what Charcot taught us at that time holds good to-day: some of it has become doubtful, some has definitely failed to withstand the test of time. But enough is left over that has found a permanent place in the storehouse of science. Before leaving Paris I discussed with the great man a plan for a comparative study of hysterical and organic paralyses. I wished to establish the thesis that in hysteria paralyses and anaesthesias of the various parts of the body are demarcated according to the popular idea of their limits and not according to anatomical facts. He agreed with this view, but it was easy to see that in reality he took no special interest in penetrating more deeply into the psychology of the neuroses. When all is said and done, it was from pathological anatomy that his work had started.

[1925d, 4191]

When I was back in Vienna I turned once more to Breuer's observation and made him tell me more about it. The patient had been a young girl of unusual education and gifts, who had fallen ill while she was nursing her father, of whom she was devotedly fond. When Breuer took over her case it presented a variegated picture of paralyses with contractures, inhibitions and states of mental confusion. A chance observation showed her physician that she could be relieved of these clouded states of consciousness if she was induced to express in words the affective phantasy by which she was at the moment dominated. From this discovery, Breuer arrived at a new method of treatment. He put her into deep hypnosis and made her tell him each time what it was that was oppressing her mind. After the attacks of depressive confusion had been overcome in this way, he employed the same procedure for removing her inhibitions and physical disorders. In her waking state the girl could no more describe than other patients how her symptoms had arisen, and she could discover no link between them and any experiences of her life. In hypnosis she immediately discovered the missing connection. It turned out that all her symptoms went back to moving events which she had experienced while nursing her father; that is to say, her symptoms had a meaning and were residues or reminiscences of those emotional situations. It was found in most instances that there had been some thought or impulse which she had had to suppress while she was by her father's sick-bed, and that, in place of it, as a substitute for it, the symptom had afterwards appeared. But as a rule the symptom was not the precipitate of a single such 'traumatic' scene, but the result of a summation of a number of similar situations. When the patient recalled a situation of this kind in a hallucinatory way under hypnosis and carried through to its conclusion, with a free expression of emotion, the mental act which she had originally suppressed, the symptom was abolished and did not return. By this procedure Breuer succeeded, after long and painful efforts, in relieving his patient of all her symptoms.

[1925d, 4198]
We set out to study the formation of symptoms and the secondary struggle waged by the ego against symptoms. But in picking on the phobias for this purpose we have clearly made an unlucky choice. The anxiety which predominates in the picture of these disorders is now seen as a complication which obscures the situation. There are plenty of neuroses which exhibit no anxiety whatever. True conversion hysteria is one of these. Even in its most severe symptoms no admixture of anxiety is found. This fact alone ought to warn us against making too close a connection between anxiety and symptom-formation. The phobias are so closely akin to conversion hysteria in every other respect that I have felt justified in classing them alongside of it under the name of ‘anxiety hysteria’. But no one has as yet been able to say what it is that determines whether any given case shall take the form of a conversion hysteria or a phobia - has been able, that is to say, to establish what determines the generating of anxiety in hysteria.

The commonest symptoms of conversion hysteria - motor paralyses, contractures, involuntary actions or discharges, pains and hallucinations - are cathetic processes which are either permanently maintained or intermittent. But this puts fresh difficulties in the way. Not much is actually known about these symptoms. Analysis can show what the disturbed excitatory process is which the symptoms replace. It usually turns out that they themselves have a share in that process. It is as though the whole energy of the process had been concentrated in this one part of it. For instance, it will be found that the pains from which a patient suffer was present in the situation in which the repression occurred; or that his hallucination was, at that time, a perception; or that his motor paralysis is a defence against an action which should have been performed in that situation but was inhibited; or that his contracture is usually a displacement of an intended innervation of the muscles in some other part of his body; or that his convulsions are the expression of an outburst of affect which has been withdrawn from the normal control of the ego. The sensation of unpleasure which accompanies the appearance of the symptoms varies in a striking degree. In chronic symptoms which have been displaced on to motility, like paralyses and contractures, it is almost always entirely absent; the ego behaves towards the symptoms as though it had nothing to do with them. In intermittent symptoms and in those concerned with the sensory sphere, sensations of unpleasure are as a rule distinctly felt; and in some of them may reach an extreme degree. The picture presented is so manifold that it is difficult to discover the factor which permits of all these variations and yet allows a uniform explanation of them. There is, moreover, little to be seen in conversion hysteria of the ego's struggle against the symptom after it has been formed. It is only when sensitivity to pain in some part of the body constitutes the symptom that that symptom is in a position to play a dual role. The symptom of pain will appear no less regularly whenever the part of the body concerned is touched from outside than when the pathogenic situation which it represents is associatively activated from within; and the ego will take precautions to prevent the symptom from being aroused through external perceptions. Why the formation of symptoms in conversion hysteria should be such a peculiarly obscure thing I cannot tell; but the fact affords us a good reason for quitting such an unproductive field of enquiry without delay.
An important element in the theory of repression is the view that repression is not an event that occurs once but that it requires a permanent expenditure. If this expenditure were to cease, the repressed impulse, which is being fed all the time from its sources, would on the next occasion flow along the channels from which it had been forced away, and the repression would either fail in its purpose or would have to be repeated an indefinite number of times. Thus it is because instincts are continuous in their nature that the ego has to make its defensive action secure by a permanent expenditure. This action undertaken to protect repression is observable in analytic treatment as resistance. Resistance presupposes the existence of what I have called anticathexis. An anticathexis of this kind is clearly seen in obsessional neurosis. It appears there in the form of an alteration of the ego, as a reaction-formation in the ego, and is effected by the reinforcement of the attitude which is the opposite of the instinctual trend that has to be repressed - as, for instance, in pity, conscientiousness and cleanliness. These reaction-formations of obsessional neurosis are essentially exaggerations of the normal traits of character which develop during the latency period. The presence of an anticathexis in hysteria is much more difficult to detect, though theoretically it is equally indispensable. In hysteria, too, a certain amount of alteration of the ego through reaction-formation is unmistakable and in some circumstances becomes so marked that it forces itself on our attention as the principal symptom. The conflict due to ambivalence, for instance, is resolved in hysteria by this means. The subject's hatred of a person whom he loves is kept down by an exaggerated amount of tenderness for him and apprehensiveness about him. But the difference between reaction-formations in obsessional neurosis and in hysteria is that in the latter they do not have the universality of a character-trait but are confined to particular relationships. A hysterical woman, for instance, may be specially affectionate with her own children whom at bottom she hates; but she will not on that account be more loving in general than other women or even more affectionate to other children. The reaction-formation of hysteria clings tenaciously to a particular object and never spreads over into a general disposition of the ego, whereas what is characteristic of obsessional neurosis is precisely a spreading-over of this kind - a loosening of relations to the object and a facilitation of displacement in the choice of object.

[1926d, 4310]

Or again our patient - and this time let us make her a woman - may suffer in another way and in a different field. She is a pianist, but her fingers are overcome by cramp and refuse to serve her. Or when she thinks of going to a party she promptly becomes aware of a call of nature the satisfaction of which would be incompatible with a social gathering. She has therefore given up going to parties, dances, theatres or concerts. She is overcome by violent headaches or other painful sensations at times when they are most inconvenient. She may even be unable to keep down any meal she eats which can become dangerous in the long run. And, finally, it is a lamentable fact that she cannot tolerate any agitations, which after all are inevitable in life. On such occasions she falls in a faint, often accompanied by muscular spasms that recall sinister pathological states.  
[1926e, 4329]
I now pass on to my second example, which raises the same problem. An unmarried woman, no longer young, had been cut off from life since puberty by an inability to walk, owing to severe pains in the legs. Her condition was obviously of a hysterical nature, and it had defied many kinds of treatment. An analysis lasting three-quarters of a year removed the trouble and restored to the patient, an excellent and worthy person, her right to a share in life. In the years following her recovery she was consistently unfortunate. There were disasters in her family, and financial losses, and, as she grew older, she saw every hope of happiness in love and marriage vanish. But the one-time invalid stood up to all this valiantly and was a support to her family in difficult times. I cannot remember whether it was twelve or fourteen years after the end of her analysis that, owing to profuse haemorrhages, she was obliged to undergo a gynaecological examination. A myoma was found, which made a complete hysterectomy advisable. From the time of this operation, the woman became ill once more. She fell in love with her surgeon, wallowed in masochistic phantasies about the fearful changes in her inside - phantasies with which she concealed her romance - and proved inaccessible to a further attempt at analysis. She remained abnormal to the end of her life. The successful analytic treatment took place so long ago that we cannot expect too much from it; it was in the earliest years of my work as an analyst. No doubt the patient's second illness may have sprung from the same source as her first one which had been successfully overcome: it may have been a different manifestation of the same repressed impulses, which the analysis had only incompletely resolved. But I am inclined to think that, were it not for the new trauma, there would have been no fresh outbreak of neurosis.

[1937c, 5020]
At about the time at which the clinic was established and at which he gave up the Chair of Pathological Anatomy, a change occurred in the direction of Charcot's scientific pursuits, and to this we owe the finest of his work. He now pronounced that the theory of organic nervous illnesses was for the time being fairly complete, and he began to turn his attention almost exclusively to hysteria, which thus all at once became the focus of general interest. This, the most enigmatic of all nervous diseases, for the evaluation of which medicine had not yet found a serviceable angle of approach, had just then fallen into thorough discredit; and this discredit extended not only to the patients but to the physicians who concerned themselves with the neurosis. It was held that in hysteria anything was possible, and no credence was given to a hysterical about anything. The first thing that Charcot's work did was to restore its dignity to the topic. Little by little, people gave up the scornful smile with which the patient could at that time feel certain of being met. She was no longer necessarily a malingerer, for Charcot had thrown the whole weight of his authority on the side of the genuineness and objectivity of hysterical phenomena. Charcot had repeated on a small scale the act of liberation in memory of which Pinel's portrait hung in the lecture hall of the Salpêtrière. Once the blind fear of being made a fool of by the unfortunate patient had been given up - a fear which till then had stood in the way of a serious study of the neurosis - the question could arise as to what method of approach would lead most quickly to a solution of the problem. A quite unbiased observer might have arrived at this conclusion: if I find someone in a state which bears all the signs of a painful affect - weeping, screaming and raging - the conclusion seems probable that a mental process is going on in him of which those physical phenomena are the appropriate expression. A healthy person, if he were asked, would be in a position to say what impression it was that was tormenting him; but the hysterical would answer that he did not know. The problem would at once arise of how it is that a hysterical patient is overcome by an affect about whose cause he asserts that he knows nothing. If we keep to our conclusion that a corresponding psychical process must be present, and if nevertheless we believe the patient when he denies it; if we bring together the many indications that the patient is behaving as though he does know about it; and if we enter into the history of the patient's life and find some occasion, some trauma, which would appropriately evoke precisely those expressions of feeling - then everything points to one solution: the patient is in a special state of mind in which all his impressions or his recollections of them are no longer held together by an associative chain, a state of mind in which it is possible for a recollection to express its affect by means of somatic phenomena without the group of the other mental processes, the ego, knowing about it or being able to intervene to prevent it. If we had called to mind the familiar psychological difference between sleep and waking, the strangeness of our hypothesis might have seemed less. No one should object that the theory of a splitting of consciousness as a solution to the riddle of hysteria is much too remote to impress an unbiased and untrained observer. For, by pronouncing possession by a demon to be the cause of hysterical phenomena, the Middle Ages in fact chose this solution; it would only have been a matter of exchanging the religious terminology of that dark and superstitious age for the scientific language of to-day.
[1893f, 281]
Charcot, however, did not follow this path towards an explanation of hysteria, although he drew copiously upon the surviving reports of witch trials and of possession, in order to show that the manifestations of the neurosis were the same in those days as they are now. He treated hysteria as just another topic in neuropathology; he gave a complete description of its phenomena, demonstrated that these had their own laws and uniformities, and showed how to recognize the symptoms which enable a diagnosis of hysteria to be made. The most painstaking investigations, initiated by himself and his pupils, extended over hysterical disturbances of sensibility in the skin and deeper tissues, over the behaviour of the sense organs, and over the peculiarities of hysterical contractures and paralyses, and of trophic disturbances and changes in metabolism. The many different forms of hysterical attack were described, and a schematic plan was drawn up by depicting the typical configuration of the major hysterical attack as occurring in four stages, which made it possible to trace the commonly observed 'minor' attacks back to this same typical configuration. The localization and frequency of occurrence of the so-called 'hysterogenic zones' and their relationship to the attacks were also studied, and so on. Once all this information about the manifestations of hysteria had been arrived at, a number of surprising discoveries were made. Hysteria in males, and especially in men of the working class was found far more often than had been expected; it was convincingly shown that certain conditions which had been put down to alcoholic intoxication or lead-poisoning were of a hysterical nature; it was possible to subsume under hysteria a whole number of affections which had hitherto not been understood and which had remained unclassified; and where the neurosis had become joined with other disorders to form complex pictures, it was possible to separate out the part played by hysteria. Most far-reaching of all were the investigations into nervous illnesses which followed upon severe traumas - the 'traumatic neuroses' - views about which are still under discussion and in connection with which Charcot has successfully put forward the arguments in favour of hysteria.

[1893f, 282]

After the latest extensions of the concept of hysteria had so often led to a rejection of aetiological diagnosis, it became necessary to enter into the aetiology of hysteria itself. Charcot put forward a simple formula for this: heredity was to be regarded as the sole cause. Accordingly, hysteria was a form of degeneracy, a member of the 'famille névropathique'. All other aetiological factors played the part of incidental causes, of 'agents provocateurs'.

[1893f, 282]

Furthermore, the aetiological theories supported by Charcot in his doctrine of the 'famille névropathique', which he made the basis of his whole concept of nervous disorders, will no doubt soon require sifting and emending. So greatly did Charcot over-estimate heredity as a causative agent that he left no room for the acquisition of nervous illness. To syphilis he merely allotted a modest place among the 'agents provocateurs'; nor did he make a sufficiently sharp distinction between organic nervous affections and neuroses, either as regards their aetiology or in other respects. It is inevitable that the advance of our science, as it increases our knowledge, must at the same time lessen the value of a number of things that Charcot taught us; but neither changing times nor changing views can diminish the fame of the man whom - in France and elsewhere - we are mourning to-day.

[1893f, 284]
When you hear such an enumeration of symptoms, you will be inclined to think it safe to assume, even though you are not doctors, that what we have before us is a severe illness, probably affecting the brain, that it offers small prospect of recovery and will probably lead to the patient's early decease. You must be prepared to learn from the doctors, however, that, in a number of cases which display severe symptoms such as these, it is justifiable to take a different and a far more favourable view. If a picture of this kind is presented by a young patient of the female sex, whose vital internal organs (heart, kidneys, etc.) are shown on objective examination to be normal, but who has been subjected to violent emotional shocks - if, moreover, her various symptoms differ in certain matters of detail from what would have been expected - then doctors are not inclined to take the case too seriously. They decide that what they have before them is not an organic disease of the brain, but the enigmatic condition which, from the time of ancient Greek medicine, has been known as 'hysteria' and which has the power of producing illusory pictures of a whole number of serious diseases. They consider that there is then no risk to life but that a return to health - even a complete one - is probable. It is not always quite easy to distinguish a hysteria like this from a severe organic illness. There is no need for us to know, however, how a differential diagnosis of that kind is made; it will suffice to have an assurance that the case of Breuer's patient was precisely of a kind in which no competent physician could fail to make a diagnosis of hysteria. And here we may quote from the report of the patient's illness the further fact that it made its appearance at a time when she was nursing her father, of whom she was devotedly fond, through the grave illness which led to his death, and that, as a result of her own illness, she was obliged to give up nursing him.

[1910a, 2200]

So far it has been an advantage to us to accompany the doctors; but the moment of parting is at hand. For you must not suppose that a patient's prospects of medical assistance are improved in essentials by the fact that a diagnosis of hysteria has been substituted for one of severe organic disease of the brain. Medical skill is in most cases powerless against severe diseases of the brain; but neither can the doctor do anything against hysterical disorders. He must leave it to kindly Nature to decide when and how his optimistic prognosis shall be fulfilled.¹

[1910a, 2201]

Thus the recognition of the illness as hysteria makes little difference to the patient; but to the doctor quite the reverse. It is noticeable that his attitude towards hysterical patients is quite other than towards sufferers from organic diseases. He does not have the same sympathy for the former as for the latter; for the hysteric's ailment is in fact far less serious and yet it seems to claim to be regarded as equally so. And there is a further factor at work. Through his studies, the doctor has learnt many things that remain a sealed book to the layman: he has been able to form ideas on the causes of illness and on the changes it brings about - e.g. in the brain of a person suffering from apoplexy or from a malignant growth - ideas which must to some degree meet the case, since they allow him to understand the details of the illness. But all his knowledge - his training in anatomy, in physiology and in pathology - leaves him in the lurch when he is confronted by the details of hysterical phenomena. He cannot understand hysteria, and in the face of it he is himself a layman. This is not a pleasant situation for anyone who as a rule sets so much store by his knowledge. So it comes about that hysterical patients forfeit his sympathy. He regards them as people who are transgressing the laws of his science - like heretics in the eyes of the orthodox. He attributes every kind of wickedness to them, accuses them of exaggeration, of deliberate deceit, of malingering. And he punishes them by withdrawing his interest from them.

[1910a, 2201]

¹ I am aware that this is no longer the case; but in my lecture I am putting myself and my hearers back into the period before 1880. If things are different now, that is to a great extent the result of the activities whose history I am now sketching.

[1910a, 2201]
GENTLEMEN, - I propose to take the example of psychogenic disturbance of vision, in order to show you the modifications which have taken place in our view of the genesis of disorders of this kind under the influence of psycho-analytic methods of investigation. As you know, hysterical blindness is taken as the type of a psychogenic visual disturbance. It is generally believed, as a result of the researches of the French School (including such men as Charcot, Janet and Binet), that the genesis of these cases is understood. For we are in a position to produce blindness of this kind experimentally if we have at our disposal someone who is susceptible to somnambulism. If we put him into deep hypnosis and suggest the idea to him that he sees nothing with one of his eyes, he will in fact behave as though he had become blind in that eye, like a hysteric who has developed a visual disturbance spontaneously. We may thus construct the mechanism of spontaneous hysterical disturbances of vision on the model of suggested hypnotic ones. In a hysteric the idea of being blind arises, not from the prompting of a hypnotist, but spontaneously - by autosuggestion, as people say; and in both cases this idea is so powerful that it turns into reality, exactly like a suggested hallucination, paralysis, etc. [1910i, 2366]

I will illustrate the first of these theses by a few examples. Hysterical attacks have long been recognized as signs of increased emotional excitement and equated with outbreaks of affect. Charcot attempted to reduce the multiplicity of their modes of manifestation by means of descriptive formulas; Pierre Janet recognized the unconscious ideas operating behind such attacks; while psycho-analysis has shown that they are mimetic representations of scenes (whether actually experienced or only invented) with which the patient's imagination is occupied without his becoming conscious of them. The meaning of these pantomimes is concealed from the spectators by means of condensations and distortions of the acts which they represent. And this applies equally to what are described as the 'chronic' symptoms of hysterical patients. All of them are mimetic or hallucinatory representations of phantasies which unconsciously dominate the subject's emotional life and which have the meaning of fulfilments of secret and repressed wishes. The tormenting character of these symptoms is due to the internal conflict into which these patients' minds are driven by the need to combat such unconscious wishes. [1913j, 2809]

Psycho-analysis grew up in a narrowly-restricted field. At the outset, it had only a single aim - that of understanding something of the nature of what were known as the 'functional' nervous diseases, with a view to overcoming the impotence which had so far characterized their medical treatment. The neurologists of that period had been brought up to have a high respect for chemico-physical and pathologico-anatomical facts; and they were latterly under the influence of the findings of Hitzig and Fritsch, of Ferrier, Goltz and others, who seemed to have established an intimate and possibly exclusive connection between certain functions and particular parts of the brain. They did not know what to make of the psychical factor and could not understand it. They left it to the philosophers, the mystics and - the quacks; and they considered it unscientific to have anything to do with it. Accordingly they could find no approach to the secrets of the neuroses, and in particular of the enigmatic 'hysteria', which was, indeed, the prototype of the whole species. As late as in 1885, when I was studying at the Salpêtrière, I found that people were content to account for hysterical paralyses by a formula which asserted that they were founded on slight functional disturbances of the same parts of the brain which, when they were severely damaged, led to the corresponding organic paralyses. [1924f, 4101]
Hypnosis also proved a valuable aid in the study of the neuroses - once again, first and foremost, of hysteria. Charcot's experiments created a great impression. He suspected that certain paralyses which appeared after a trauma (an accident) were of a hysterical nature, and he showed that, by suggesting a trauma under hypnosis, he was able to provoke paralyses of the same sort artificially. The expectation was thus raised that traumatic influences might in all cases play a part in the production of hysterical symptoms. Charcot himself made no further efforts towards a psychological understanding of hysteria; but his pupil, Pierre Janet, took up the question and was able to show, with the help of hypnosis, that the symptoms of hysteria were firmly dependent on certain unconscious thoughts (idées fixes). Janet attributed to hysteria a supposed constitutional incapacity for holding mental processes together - an incapacity which led to a disintegration (dissociation) of mental life.

Psycho-analysis took hold of this new realization and began to consider the problem of the nature of the psychical processes which led to these unusual consequences. But the direction taken by this enquiry was not to the liking of the contemporary generation of physicians. They had been brought up to respect only anatomical, physical and chemical factors. They were not prepared for taking psychical ones into account and therefore met them with indifference or antipathy. They obviously had doubts whether psychical events allowed of any exact scientific treatment whatever. As an excessive reaction against an earlier phase during which medicine had been dominated by what was known as the 'philosophy of Nature', they regarded such abstractions as those with which psychology is obliged to work as nebulous, fantastic and mystical; while they simply refused to believe in remarkable phenomena which might have been the starting-point of research. The symptoms of hysterical neuroses were looked upon as shamming and the phenomena of hypnotism as a hoax. Even the psychiatrists, upon whose attention the most unusual and astonishing mental phenomena were constantly being forced, showed no inclination to examine their details or enquire into their connections. They were content to classify the variegated array of symptoms and trace them back, so far as they could manage, to somatic, anatomical or chemical aetiological disturbances. During this materialistic or, rather, mechanistic period, medicine made tremendous advances, but it also showed a short-sighted misunderstanding of the most important and most difficult among the problems of life.
For, whether a man is a homosexual or a necrophilic, a hysterical suffering from anxiety, an obsessional neurotic cut off from society, or a raving lunatic, the 'Individual Psychologist' of the Adlerian school will declare that the impelling motive of his condition is that he wishes to assert himself, to overcompensate for his inferiority, to remain 'on top', to pass from the feminine to the masculine line. In my young student days we used to hear something very much the same in the out-patients' department when a case of hysteria was introduced: hysterical patients, we were told, produce their symptoms to make themselves interesting, to draw attention to themselves. It is a remarkable thing how these ancient pieces of wisdom keep on cropping up. But even at that time this fragment of psychology did not seem to cover the riddle of hysteria. It left unexplained, for instance, why the patients used no other methods for attaining their purpose. There must, of course, be something correct in this theory of the 'Individual Psychologists': a small particle is taken for the whole. The self-preservative instinct will try to profit by every situation; the ego will seek to turn even illness to its advantage. In psychoanalysis this is known as the 'secondary gain from illness'. Though, indeed, when we think of the facts of masochism, of the unconscious need for punishment and of neurotic self-injury, which make plausible the hypothesis of there being instinctual impulses that run contrary to self-preservation, we even feel shaken in our belief in the general validity of the commonplace truth on which the theoretical structure of Individual Psychology is erected. But a theory such as this is bound to be very welcome to the great mass of the people, a theory which recognizes no complications, which introduces no new concepts that are hard to grasp, which knows nothing of the unconscious, which gets rid at a single blow of the universally oppressive problem of sexuality and which restricts itself to the discovery of the artifices by which people seek to make life easy. For the mass of the people themselves take things easily: they call for no more than a single reason by way of explanation, they do not thank science for its diffuseness, they want to have simple solutions and to know that problems are solved. When we consider how very far Individual Psychology goes in meeting these demands, we cannot suppress the recollection of a sentence in Wallenstein:
[1933a, 4743]
I must now proceed to touch upon some further relations existing between Dora's genital catarrh and her hysterical symptoms. At a time when any psychological elucidation of hysteria was still very remote, I used to hear experienced fellow-doctors who were my seniors maintain that in the case of hysterical patients suffering from leucorrhoea any increase in the catarrh was regularly followed by an intensification of the hysterical troubles, and especially of loss of appetite and vomiting. No one was very clear about the nature of the connection but I fancy the general inclination was towards the opinion held by gynaecologists. According to their hypothesis, as is well known, disorders of the genitals exercise upon the nervous functions a direct and far-reaching influence in the nature of an organic disturbance - though a therapeutic test of this theory is apt to leave one in the lurch. In the light of our present knowledge we cannot exclude the possibility of the existence of a direct organic influence of this sort; but it is at all events easier to indicate its psychical coating. The pride taken by women in the appearance of their genitals is quite a special feature of their vanity; and disorders of the genitals which they think calculated to inspire feelings of repugnance or even disgust have an incredible power of humiliating them, of lowering their self-esteem, and of making them irritable, sensitive, and distrustful. An abnormal secretion of the mucous membrane of the vagina is looked upon as a source of disgust.
[1905e, 1419]
All these discussions contain much that is typical and valid for hysteria in general. The subject of erection solves some of the most interesting hysterical symptoms. The attention that women pay to the outlines of men's genitals as seen through their clothing becomes, when it has been repressed, a source of the very frequent cases of avoiding company and of dreading society. - It is scarcely possible to exaggerate the pathogenic significance of the comprehensive tie uniting the sexual and the excremental, a tie which is at the basis of a very large number of hysterical phobias.

[1905e, 1370]

Am I now going on to assert that in every instance in which there are periodical attacks of aphonia we are to diagnose the existence of a loved person who is at times away from the patient? Nothing could be further from my intention. The determination of Dora's symptoms is far too specific for it to be possible to expect a frequent recurrence of the same accidental aetiology. But, if so, what is the value of our elucidation of the aphonia in the present case? Have we not merely allowed ourselves to become the victims of a jeu d'esprit? I think not. In this connection we must recall the question which has so often been raised, whether the symptoms of hysteria are of psychical or of somatic origin, or whether, if the former is granted, they are necessarily all of them psychically determined. Like so many other questions to which we find investigators returning again and again without success, this question is not adequately framed. The alternatives stated in it do not cover the real essence of the matter. As far as I can see, every hysterical symptom involves the participation of both sides. It cannot occur without the presence of a certain degree of somatic compliance offered by some normal or pathological process in or connected with one of the bodily organs. And it cannot occur more than once - and the capacity for repeating itself is one of the characteristics of a hysterical symptom - unless it has a psychical significance, a meaning. The hysterical symptom does not carry this meaning with it, but the meaning is lent to it, soldered to it, as it were; and in every instance the meaning can be a different one, according to the nature of the suppressed thoughts which are struggling for expression. However, there are a number of factors at work which tend to make less arbitrary the relations between the unconscious thoughts and the somatic processes that are at their disposal as a means of expression, and which tend to make those relations approximate to a few typical forms. For therapeutic purposes the most important determinants are those given by the fortuitous psychical material; the clearing-up of the symptoms is achieved by looking for their psychical significance. When everything that can be got rid of by psycho-analysis has been cleared away, we are in a position to form all kinds of conjectures, which probably meet the facts, as regards the somatic basis of the symptoms - a basis which is as a rule constitutional and organic. Thus in Dora's case we shall not content ourselves with a psycho-analytic interpretation of her attacks of coughing and aphonia; but we shall also indicate the organic factor which was the source of the 'somatic compliance' that enabled her to express her love for a man who was periodically absent. And if the connection between the symptomatic expression and the unconscious mental content should strike us as being in this case a clever tour de force, we shall be relieved to hear that it succeeds in creating the same impression in every other case and in every other instance.

[1905e, 1378]
Nevertheless, in publishing this paper, incomplete though it is, I had two objects in view. In the first place, I wished to supplement my book on the interpretation of dreams by showing how an art, which would otherwise be useless, can be turned to account for the discovery of the hidden and repressed parts of mental life. (Incidentally, in the process of analysing the two dreams dealt with in the paper, the technique of dream-interpretation, which is similar to that of psychoanalysis, has come under consideration.) In the second place, I wished to stimulate interest in a whole group of phenomena of which science is still in complete ignorance today because they can only be brought to light by the use of this particular method. No one, I believe, can have had any true conception of the complexity of the psychological events in a case of hysteria - the juxtaposition of the most dissimilar tendencies, the mutual dependence of contrary ideas, the repressions and displacements, and so on. The emphasis laid by Janet upon the 'idée fixe' which becomes transformed into a symptom amounts to no more than an extremely meagre attempt at schematization. Moreover, it is impossible to avoid the suspicion that, when the ideas attaching to certain excitations are incapable of becoming conscious, those excitations must act upon one another differently, run a different course, and manifest themselves differently from those other excitations which we describe as 'normal' and which have ideas attaching to them of which we become conscious. When once things have been made clear up to this point, no obstacle can remain in the way of an understanding of a therapeutic method which removes neurotic symptoms by transforming ideas of the former kind into normal ones.

The field I have in mind is indeed very different from yours. I am referring to the therapy employed for certain 'nervous diseases' - what are known as the psychoneuroses - of which hysteria and obsessional ideas may be taken as samples. The method is called 'psychoanalysis'; it was evolved by me from the 'cathartic' method of therapy first practised by Josef Breuer in Vienna.¹ To combat your surprise, I must draw an analogy between the criminal and the hysteric. In both we are concerned with a secret, with something hidden. But in order not to be paradoxical I must at once point out the difference. In the case of the criminal it is a secret which he knows and hides from you, whereas in the case of the hysteric it is a secret which he himself does not know either, which is hidden even from himself. How is this possible? Now we know, through laborious research, that all these illnesses are the result of the patient's having succeeded in repressing certain ideas and memories that are strongly cathected with affect, together with the wishes that arise from them, in such a way that they play no part in his thinking - do not enter into his consciousness - and thus remain unknown to him. But from this repressed psychical material (these 'complexes') are generated the somatic and psychical symptoms which plague the patient in just the same way as a guilty conscience does. In this one respect, therefore, the difference between the criminal and the hysteric is fundamental.

Compulsive acts like this, in two successive stages, of which the second neutralizes the first, are a typical occurrence in obsessional neuroses. The patient's consciousness naturally misunderstands them and puts forward a set of secondary motives to account for them - rationalizes them, in short. (Cf. Jones, 1908.) But their true significance lies in their being a representation of a conflict between two opposing impulses of approximately equal strength: and hitherto I have invariably found that this opposition has been one between love and hate. Compulsive acts of this sort are theoretically of special interest, for they show us a new type of method of constructing symptoms. What regularly occurs in hysteria is that a compromise is arrived at which enables both the opposing tendencies to find expression simultaneously - which kills two birds with one stone;¹ whereas here each of the two opposing tendencies finds satisfaction singly, first one and then the other, though naturally an attempt is made to establish some sort of logical connection (often in defiance of all logic) between the antagonists.²

¹[1905e, 1448]
²[1909d, 2151]
In hysteria it is the rule that the precipitating causes of the illness are overtaken by amnesia no less than the infantile experiences by whose help the precipitating causes are able to transform their affective energy into symptoms. And where the amnesia cannot be complete, it nevertheless subjects the recent traumatic precipitating cause to a process of erosion and robs it at least of its most important components. In this amnesia we see the evidence of the repression which has taken place. The case is different in obsessional neuroses. The infantile preconditions of the neurosis may be overtaken by amnesia, though this is often an incomplete one; but the immediate occasions of the illness are, on the contrary, retained in the memory. Repression makes use of another, and in reality a simpler, mechanism. The trauma, instead of being forgotten, is deprived of its affective cathexis; so that what remains in consciousness is nothing but its ideational content, which is perfectly colourless and is judged to be unimportant. The distinction between what occurs in hysteria and in an obsessional neurosis lies in the psychological processes which we can reconstruct behind the phenomena; the result is almost always the same, for the colourless mnemonic content is rarely reproduced and plays no part in the patient's mental activity. In order to differentiate between the two kinds of repression we have on the surface nothing to rely upon but the patient's assurance that he has a feeling in the one case of having always known the thing and in the other of having long ago forgotten it.¹

[1909d, 2154]

If we consider a number of analyses of obsessional neurotics we shall find it impossible to escape the impression that a relation between love and hatred such as we have found in our present patient is among the most frequent, the most marked, and probably, therefore, the most important characteristics of obsessional neurosis. But however tempting it may be to bring the problem of the 'choice of neurosis' into connection with instinctual life, there are reasons enough for avoiding such a course. For we must remember that in every neurosis we come upon the same suppressed instincts behind the symptoms. After all, hatred, kept suppressed in the unconscious by love, plays a great part in the pathogenesis of hysteria and paranoia. We know too little of the nature of love to be able to arrive at any definite conclusion here; and, in particular, the relation between the negative factor¹ in love and the sadistic components of the libido remains completely obscure. What follows is therefore to be regarded as no more than a provisional explanation. We may suppose, then, that in the cases of unconscious hatred with which we are concerned the sadistic components of love have, from constitutional causes, been exceptionally strongly developed, and have consequently undergone a premature and all too thorough suppression, and that the neurotic phenomena we have observed arise on the one hand from conscious feelings of affection which have become exaggerated as a reaction, and on the other hand from sadism persisting in the unconscious in the form of hatred.

[1909d, 2187]
Turning once more to the case of Schreber, we are bound to admit that any attempt at throwing light upon the transformation in his delusion brings us up against extraordinary difficulties. In what manner and by what means was the ascent from Flechsig to God brought about? From what source did he derive the megalomania which so fortunately enabled him to become reconciled to his persecution, or, in analytical phraseology, to accept the wishful phantasy which had had to be repressed? The Denkwürdigkeiten give us a first clue; for they show us that in the patient's mind 'Flechsig' and 'God' belonged to the same class. In one of his phantasies he overheard a conversation between Flechsig and his wife, in which the former asserted that he was 'God Flechsig', so that his wife thought he had gone mad (82). But there is another feature in the development of Schreber's delusions which claims our attention. If we take a survey of the delusions as a whole we see that the persecutor is divided into Flechsig and God; in just the same way Flechsig himself subsequently splits up into two personalities, the 'upper' and the 'middle' Flechsig, and God into the 'lower' and the 'upper' God. In the later stages of the illness the decomposition of Flechsig goes further still (193). A process of decomposition of this kind is very characteristic of paranoia. Paranoia decomposes just as hysteria condenses. Or rather, paranoia resolves once more into their elements the products of the condensations and identifications which are effected in the unconscious. The frequent repetition of the decomposing process in Schreber's case would, according to Jung, be an expression of the importance which the person in question possessed for him.¹ All of this dividing up of Flechsig and God into a number of persons thus had the same meaning as the splitting of the persecutor into Flechsig and God. They were all duplications of one and the same important relationship.² But, in order to interpret all these details, we must further draw attention to our view of this decomposition of the persecutor into Flechsig and God as a paranoid reaction to a previously established identification of the two figures or their belonging to the same class. If the persecutor Flechsig was originally a person whom Schreber loved, then God must also simply be the reappearance of some one else whom he loved, and probably some one of greater importance.

[1911c, 2421]
(1) Our first reflection will tell us that it cannot be the case that this detachment of the libido occurs exclusively in paranoia; nor can it be that, where it occurs elsewhere, it has such disastrous consequences. It is quite possible that a detachment of the libido is the essential and regular mechanism of every repression. We can have no positive knowledge on that point until the other disorders that are based upon repression have been similarly examined. But it is certain that in normal mental life (and not only in periods of mourning) we are constantly detaching our libido in this way from people or from other objects without falling ill. When Faust freed himself from the world by uttering his curses, the result was not a paranoia or any other neurosis but simply a certain general frame of mind. The detachment of the libido, therefore, cannot in itself be the pathogenic factor in paranoia; there must be some special characteristic which distinguishes a paranoid detachment of the libido from other kinds. It is not difficult to suggest what that characteristic may be. What use is made of the libido after it has been set free by the process of detachment? A normal person will at once begin looking about for a substitute for the lost attachment; and until that substitute has been found the liberated libido will be kept in suspension within his mind, and will there give rise to tensions and colour his mood. In hysteria the liberated libido becomes transformed into somatic innervations or into anxiety. But in paranoia the clinical evidence goes to show that the libido, after it has been withdrawn from the object, is put to a special use. It will be remembered that the majority of cases of paranoia exhibit traces of megalomania, and that megalomania can by itself constitute a paranoia. From this it may be concluded that in paranoia the liberated libido becomes attached to the ego, and is used for the aggrandizement of the ego. A return is thus made to the stage of narcissism (known to us from the development of the libido), in which a person's only sexual object is his own ego. On the basis of this clinical evidence we can suppose that paranoics have brought along with them a fixation at the stage of narcissism, and we can assert that the length of the step back from sublimated homosexuality to narcissism is a measure of the amount of regression characteristic of paranoia.

We are obliged to take quite another view of the process of repression when we consider the picture of a true conversion hysteria. Here the salient point is that it is possible to bring about a total disappearance of the quota of affect. When this is so, the patient displays towards his symptoms what Charcot called 'la belle indifférence hystériques'. In other cases this suppression is not so completely successful: some distressing sensations may attach to the symptoms themselves, or it may prove impossible to prevent some release of anxiety, which in turn sets to work the mechanism of forming a phobia. The ideational content of the instinctual representative is completely withdrawn from consciousness; as a substitute - and at the same time as a symptom - we have an over-strong innervation (in typical cases, a somatic one), sometimes of a sensory, sometimes of a motor character, either as an excitation or an inhibition. The over-innervated area proves on a closer view to be a part of the repressed instinctual representative - a part which, as though by a process of condensation, has drawn the whole cathexis on to itself. These remarks do not of course bring to light the whole mechanism of a conversion hysteria; in especial the factor of regression, which will be considered in another connection, has also to be taken into account. In so far as repression in hysteria is made possible only by the extensive formation of substitutes, it may be judged to be entirely unsuccessful; as regards dealing with the quota of affect, however, which is the true task of repression, it generally signifies a total success. In conversion hysteria the process of repression is completed with the formation of the symptom and does not, as in anxiety hysteria, need to continue to a second phase - or rather, strictly speaking, to continue endlessly.
A great deal of what we have found in anxiety hysteria also holds good for the other two
neuroses, so that we can confine our discussion to their points of difference and to the part
played by anticathexis. In conversion hysteria the instinctual cathexis of the repressed idea is
changed into the innervation of the symptom. How far and in what circumstances the
unconscious idea is drained empty by this discharge into innervation, so that it can relinquish its
pressure upon the system Cs. - these and similar questions had better be reserved for a special
investigation of hysteria. In conversion hysteria the part played by the anticathexis proceeding
from the system Cs. (Pcs.) is clear and becomes manifest in the formation of the symptom. It is
the anticathexis that decides upon what portion of the instinctual representative the whole
cathexis of the latter is able to be concentrated. The portion thus selected to be a symptom
fulfils the condition of expressing the wishful aim of the instinctual impulse no less than the
defensive or punitive efforts of the system Cs.; thus it becomes hypercathected, and it is
maintained from both directions like the substitutive idea in anxiety hysteria. From this
circumstance we may conclude without hesitation that the amount of energy expended by the
system Cs. on repression need not be so great as the cathectic energy of the symptom; for the
strength of the repression is measured by the amount of anticathexis expended, whereas the
symptom is supported not only by this anticathexis but also by the instinctual cathexis from the
system Ucs. which is condensed in the symptom.
[1915e, 3007]

As you probably know, the hysterical neurosis can produce its symptoms in any system of
organs and so disturb any function. Analysis shows that in this way all the so-called perverse
impulses which seek to replace the genital by some other organ manifest themselves: these
organs are then behaving like substitutive genitals. The symptoms of hysteria have actually led
us to the view that the bodily organs, besides the functional part they play, must be recognized
as having a sexual (erotogenic) significance, and that the execution of the first of these tasks is
disturbed if the second of them makes too many claims. Countless sensations and innervations
which we come across as symptoms of hysteria in organs that have no apparent connection
with sexuality are in this way revealed to us as being in the nature of fulfilments of perverse
sexual impulses in relation to which other organs have acquired the significance of the sexual
parts. We learn too to what a large extent the organs for the intake of nourishment and for
excretion can in particular become the vehicles of sexual excitation. Here, then, we have the
same thing that we were shown by the perversions; only in their case it was visible easily and
unmistakably, whereas in hysteria we have to take a circuitous path by way of the interpretation
of symptoms, and do not then ascribe the perverse sexual impulses concerned to the subject's
consciousness but locate them in his unconscious.
[1916-1917, 3380]
A noteworthy relation between the symptoms of the 'actual' neuroses and of the psychoneuroses makes a further important contribution to our knowledge of the formation of symptoms in the latter. For a symptom of an 'actual' neurosis is often the nucleus and first stage of a psychoneurotic symptom. A relation of this kind can be most clearly observed between neurasthenia and the transference neurosis known as 'conversion hysteria', between anxiety neurosis and anxiety hysteria, but also between hypochondria and the forms of disorder which will be mentioned later under the name of paraphrenia (dementia praecox and paranoia). Let us take as an example a case of hysterical headache or lumbar pain. Analysis shows us that, by condensation and displacement, it has become a substitutive satisfaction for a whole number of libidinal phantasies or memories. But this pain was also at one time a real one and it was then a direct sexual-toxic symptom, the somatic expression of a libidinal excitation. We are far from asserting that all hysterical symptoms contain a nucleus of this kind. But it remains a fact that this is especially often the case and that whatever somatic influences (whether normal or pathological) are brought about by libidinal excitation are preferred for the construction of hysterical symptoms. In such cases they play the part of the grain of sand which a mollusc coats with layers of mother-of-pearl. In the same way, the passing indications of sexual excitement which accompany the sexual act are employed by the psychoneurosis as the most convenient and appropriate material for the construction of symptoms.

[1916-1917, 3441]

If we look into the matter more closely we shall see that our patient's first illness (leaving the disturbance of appetite out of account) is not exhausted when we have extracted the phobia from it. It must be regarded as a true hysteria showing not merely anxiety-symptoms but also phenomena of conversion. A portion of the homosexual impulse was retained by the organ concerned in it; from that time forward, and equally during his adult life, his bowel behaved like a hysterically affected organ. The unconscious repressed homosexuality withdrew into his bowel. It was precisely this trait of hysteria which was of such great service in helping to clear up his later illness.

[1918b, 3589]
If the account I have so far given has led the reader to expect that the Studies on Hysteria must, in all essentials of their material content, be the product of Breuer's mind, that is precisely what I myself have always maintained and what it has been my aim to repeat here. As regards the theory put forward in the book, I was partly responsible, but to an extent which it is to-day no longer possible to determine. That theory was in any case unpretentious and hardly went beyond the direct description of the observations. It did not seek to establish the nature of hysteria but merely to throw light upon the origin of its symptoms. Thus it laid stress upon the significance of the life of the emotions and upon the importance of distinguishing between mental acts which are unconscious and those which are conscious (or rather capable of being conscious); it introduced a dynamic factor, by supposing that a symptom arises through the damming-up of an affect, and an economic factor, by regarding that same symptom as the product of the transformation of an amount of energy which would otherwise have been employed in some other way. (This latter process was described as conversion.) Breuer spoke of our method as cathartic; its therapeutic aim was explained as being to provide that the quota of affect used for maintaining the symptom, which had got on to the wrong lines and had, as it were, become strangulated there, should be directed on to the normal path along which it could obtain discharge (or abreaction). The practical results of the cathartic procedure were excellent. Its defects, which became evident later, were those of all forms of hypnotic treatment. There are still a number of psychotherapists who have not gone beyond catharsis as Breuer understood it and who still speak in its favour. Its value as an abridged method of treatment was shown afresh by Simmel in his treatment of war neuroses in the German army during the Great War. The theory of catharsis had not much to say on the subject of sexuality. In the case histories which I contributed to the Studies sexual factors played a certain part, but scarcely more attention was paid to them than to other emotional excitations. Breuer wrote of the girl, who has since become famous as his first patient, that her sexual side was extraordinarily undeveloped. It would have been difficult to guess from the Studies on Hysteria what an importance sexuality has in the aetiology of the neuroses.

[1925d, 4200]

It was now easy to reconstruct the pathogenic process. Let us keep to a simple example, in which a particular impulsion had arisen in the subject's mind but was opposed by other powerful impulsions. We should have expected the mental conflict which now arose to take the following course. The two dynamic quantities - for our present purposes let us call them 'the instinct' and 'the resistance' - would struggle with each other for some time in the fullest light of consciousness, until the instinct was repudiated and the cathexis of energy withdrawn from its impulsion. This would have been the normal solution. In a neurosis, however (for reasons which were still unknown), the conflict found a different outcome. The ego drew back, as it were, on its first collision with the objectionable instinctual impulse; it debarrad the impulse from access to consciousness and to direct motor discharge, but at the same time the impulse retained its full cathexis of energy. I named this process repression; it was a novelty, and nothing like it had ever before been recognized in mental life. It was obviously a primary mechanism of defence, comparable to an attempt at flight, and was only a forerunner of the later-developed normal condemning judgement. The first act of repression involved further consequences. In the first place the ego was obliged to protect itself against the constant threat of a renewed advance on the part of the repressed impulse by making a permanent expenditure of energy, an anticathexis, and it thus impoverished itself. On the other hand, the repressed impulse, which was now unconscious, was able to find means of discharge and of substitutive satisfaction by circuitous routes and thus to bring the whole purpose of the repression to nothing. In the case of conversion hysteria the circuitous route led to the somatic innervation; the repressed impulse broke its way through at some point or other and produced symptoms. The symptoms were thus results of a compromise, for although they were substitutive satisfactions they were nevertheless distorted and deflected from their aim owing to the resistance of the ego.

[1925d, 4206]
The reaction-formations in the ego of the obsessional neurotic, which we recognize as exaggerations of normal character-formation, should be regarded, I think, as yet another mechanism of defence and placed alongside of regression and repression. They seem to be absent or very much weaker in hysteria. Looking back, we can now get an idea of what is peculiar to the defensive process in hysteria. It seems that in it the process is limited to repression alone. The ego turns away from the disagreeable instinctual impulse, leaves it to pursue its course in the unconscious, and takes no further part in its fortunes. This view cannot be absolutely correct, for we are acquainted with the case in which a hysterical symptom is at the same time a fulfilment of a penalty imposed by the super-ego; but it may describe a general characteristic of the behaviour of the ego in hysteria.

[1926d, 4274]

An important element in the theory of repression is the view that repression is not an event that occurs once but that it requires a permanent expenditure. If this expenditure were to cease, the repressed impulse, which is being fed all the time from its sources, would on the next occasion flow along the channels from which it had been forced away, and the repression would either fail in its purpose or would have to be repeated an indefinite number of times. Thus it is because instincts are continuous in their nature that the ego has to make its defensive action secure by a permanent expenditure. This action undertaken to protect repression is observable in analytic treatment as resistance. Resistance presupposes the existence of what I have called anticathexis. An anticathexis of this kind is clearly seen in obsessional neurosis. It appears there in the form of an alteration of the ego, as a reaction-formation in the ego, and is effected by the reinforcement of the attitude which is the opposite of the instinctual trend that has to be repressed - as, for instance, in pity, conscientiousness and cleanliness. These reaction-formations of obsessional neurosis are essentially exaggerations of the normal traits of character which develop during the latency period. The presence of an anticathexis in hysteria is much more difficult to detect, though theoretically it is equally indispensable. In hysteria, too, a certain amount of alteration of the ego through reaction-formation is unmistakable and in some circumstances becomes so marked that it forces itself on our attention as the principal symptom. The conflict due to ambivalence, for instance, is resolved in hysteria by this means. The subject's hatred of a person whom he loves is kept down by an exaggerated amount of tenderness for him and apprehensiveness about him. But the difference between reaction-formations in obsessional neurosis and in hysteria is that in the latter they do not have the universality of a character-trait but are confined to particular relationships. A hysterical woman, for instance, may be specially affectionate with her own children whom at bottom she hates; but she will not on that account be more loving in general than other women or even more affectionate to other children. The reaction-formation of hysteria clings tenaciously to a particular object and never spreads over into a general disposition of the ego, whereas what is characteristic of obsessional neurosis is precisely a spreading-over of this kind - a loosening of relations to the object and a facilitation of displacement in the choice of object.

[1926d, 4310]
There is another kind of anticathexis, however, which seems more suited to the peculiar character of hysteria. A repressed instinctual impulse can be activated (newly cathected) from two directions: from within, through reinforcement from its internal sources of excitation, and from without, through the perception of an object that it desires. The hysterical anticathexis is mainly directed outwards, against dangerous perceptions. It takes the form of a special kind of vigilance which, by means of restrictions of the ego, causes situations to be avoided that would entail such perceptions, or, if they do occur, manages to withdraw the subject's attention from them. Some French analysts, in particular Laforgue, have recently given this action of hysteria the special name of 'scotomization'. This technique of anticathexis is still more noticeable in the phobias, whose interest is concentrated on removing the subject ever further from the possibility of the occurrence of the feared perception. The fact that anticathexis has an opposite direction in hysteria and the phobias from what it has in obsessional neurosis - though the distinction is not an absolute one - seems to be significant. It suggests that there is an intimate connection between repression and external anticathexis on the one hand and between regression and internal anticathexis (i.e. alteration in the ego through reaction-formation) on the other. The task of defence against a dangerous perception is, incidentally, common to all neuroses. Various commands and prohibitions in obsessional neurosis have the same end in view.

[1926d, 4311]

To take the second point first. It is unnecessary here to reproduce the whole pathology of epilepsy, for it would throw no decisive light on the problem. But this may be said. The old morbus sacer is still in evidence as an ostensible clinical entity, the uncanny disease with its incalculable, apparently unprovoked convulsive attacks, its changing of the character into irritability and aggressiveness, and its progressive lowering of all the mental faculties. But the outlines of this picture are quite lacking in precision. The attacks, so savage in their onset, accompanied by biting of the tongue and incontinence of urine and working up to the dangerous status epilepticus with its risk of severe self-injuries, may, nevertheless, be reduced to brief periods of absence, or rapidly passing fits of vertigo or may be replaced by short spaces of time during which the patient does something out of character, as though he were under the control of his unconscious. These attacks, though as a rule determined, in a way we do not understand, by purely physical causes, may nevertheless owe their first appearance to some purely mental cause (a fright, for instance) or may react in other respects to mental excitations. However characteristic intellectual impairment may be in the overwhelming majority of cases, at least one case is known to us (that of Helmholtz) in which the affliction did not interfere with the highest intellectual achievement. (Other cases of which the same assertion has been made are either disputable or open to the same doubts as the case of Dostoevsky himself.) People who are victims of epilepsy may give an impression of dullness and arrested development just as the disease often accompanies the most palpable idiocy and the grossest cerebral defects, even though not as a necessary component of the clinical picture. But these attacks, with all their variations, also occur in other people who display complete mental development and, if anything, an excessive and as a rule insufficiently controlled emotional life. It is no wonder in these circumstances that it has been found impossible to maintain that 'epilepsy' is a single clinical entity. The similarity that we find in the manifest symptoms seems to call for a functional view of them. It is as though a mechanism for abnormal instinctual discharge had been laid down organically, which could be made use of in quite different circumstances - both in the case of disturbances of cerebral activity due to severe histolytic or toxic affections, and also in the case of inadequate control over the mental economy and at times when the activity of the energy operating in the mind reaches crisis-pitch. Behind this dichotomy we have a glimpse of the identity of the underlying mechanism of instinctual discharge. Nor can that mechanism stand remote from the sexual processes, which are fundamentally of toxic origin: the earliest physicians described coition as a minor epilepsy, and thus recognized in the sexual act a mitigation and adaptation of the epileptic method of discharging stimuli.

[1928b, 4556]
The 'epileptic reaction', as this common element may be called, is also undoubtedly at the disposal of the neurosis whose essence it is to get rid by somatic means of amounts of excitation which it cannot deal with psychically. Thus the epileptic attack becomes a symptom of hysteria and is adapted and modified by it just as it is by the normal sexual process of discharge. It is therefore quite right to distinguish between an organic and an 'affective' epilepsy. The practical significance of this is that a person who suffers from the first kind has a disease of the brain, while a person who suffers from the second kind is a neurotic. In the first case his mental life is subjected to an alien disturbance from without, in the second case the disturbance is an expression of his mental life itself.

[1928b, 4557]

We know the meaning and intention of such deathlike attacks. They signify an identification with a dead person, either with someone who is really dead or with someone who is still alive and whom the subject wishes dead. The latter case is the more significant. The attack then has the value of a punishment. One has wished another person dead, and now one is this other person and is dead oneself. At this point psycho-analytical theory brings in the assertion that for a boy this other person is usually his father and that the attack (which is termed hysterical) is thus a self-punishment for a death-wish against a hated father.

[1928b, 4559]

The normal processes in the formation of conscience must be similar to the abnormal ones described here. We have not yet succeeded in fixing the boundary line between them. It will be observed that here the largest share in the outcome is ascribed to the passive component of repressed femininity. In addition, it must be of importance as an accidental factor whether the father, who is feared in any case, is also especially violent in reality. This was true in Dostoevsky's case, and we can trace back the fact of his extraordinary sense of guilt and of his masochistic conduct of life to a specially strong feminine component. Thus the formula for Dostoevsky is as follows: a person with a specially strong innate bisexual disposition, who can defend himself with special intensity against dependence on a specially severe father. This characteristic of bisexuality comes as an addition to the components of his nature that we have already recognized. His early symptoms of death-like attacks can thus be understood as a father-identification on the part of his ego, which is permitted by his super-ego as a punishment. 'You wanted to kill your father in order to be your father yourself. Now you are your father, but a dead father' - the regular mechanism of hysterical symptoms. And further: 'Now your father is killing you.' For the ego the death symptom is a satisfaction in phantasy of the masculine wish and at the same time a masochistic satisfaction; for the super-ego it is a punitive satisfaction - that is, a sadistic satisfaction. Both of them, the ego and the super-ego, carry on the role of father.

[1928b, 4561]
Everything in the sphere of this first attachment to the mother seemed to me so difficult to grasp in analysis - so grey with age and shadowy and almost impossible to revivify - that it was as if it had succumbed to an especially inexorable repression. But perhaps I gained this impression because the women who were in analysis with me were able to cling to the very attachment to the father in which they had taken refuge from the early phase that was in question. It does indeed appear that women analysts - as, for instance, Jeanne Lampl-de Groot and Helene Deutsch - have been able to perceive these facts more easily and clearly because they were helped in dealing with those under their treatment by the transference to a suitable mother-substitute. Nor have I succeeded in seeing my way through any case completely, and I shall therefore confine myself to reporting the most general findings and shall give only a few examples of the new ideas which I have arrived at. Among these is a suspicion that this phase of attachment to the mother is especially intimately related to the aetiology of hysteria, which is not surprising when we reflect that both the phase and the neurosis are characteristically feminine, and further, that in this dependence on the mother we have the germ of later paranoia in women.¹ For this germ appears to be the surprising, yet regular, fear of being killed (?) by the mother. It is plausible to assume that this fear corresponds to a hostility which develops in the child towards her mother in consequence of the manifold restrictions imposed by the latter in the course of training and bodily care and that the mechanism of projection is favoured by the early age of the child's psychical organization.

[1931b, 4591]
It is gratifying that precisely the most valuable and most highly developed persons are best suited for this procedure; and one may also safely claim that in cases where analytic psychotherapy has been able to achieve but little, any other therapy would certainly not have been able to effect anything at all.
[1905a, 1570]
In my *Interpretation of Dreams*, published in 1900, I showed that dreams in general can be interpreted, and that after the work of interpretation has been completed they can be replaced by perfectly correctly constructed thoughts which can be assigned a recognizable position in the chain of mental events. I wish to give an example in the following pages of the only practical application of which the art of interpreting dreams seems to admit. I have already mentioned in my book¹ how it was that I came upon the problem of dreams. The problem crossed my path as I was endeavouring to cure psychoneuroses by means of a particular psychotherapeutic method. For, among their other mental experiences, my patients told me their dreams, and these dreams seemed to call for insertion in the long thread of connections which spun itself out between a symptom of the disease and a pathogenic idea. At that time I learnt how to translate the language of dreams into the forms of expression of our own thought-language, which can be understood without further help. And I may add that this knowledge is essential for the psycho-analyst; for the dream is one of the roads along which consciousness can be reached by the psychical material which, on account of the opposition aroused by its content, has been cut off from consciousness and repressed, and has thus become pathogenic. The dream, in short, is one of the *détours by which repression can be evaded*; it is one of the principal means employed by what is known as the indirect method of representation in the mind. The following fragment from the history of the treatment of a hysterical girl is intended to show the way in which the interpretation of dreams plays a part in the work of analysis. It will at the same time give me a first opportunity of publishing at sufficient length to prevent further misunderstanding some of my views upon the psychical processes of hysteria and upon its organic determinants. I need no longer apologize on the score of length, since it is now agreed that the exacting demands which hysteria makes upon physician and investigator can be met only by the most sympathetic spirit of inquiry and not by an attitude of superiority and contempt. For,

[1905e, 1357]

In 1896, shortly after the appearance of my *Studies on Hysteria* (written in conjunction with Dr. J. Breuer, 1895), I asked an eminent fellow-specialist for his opinion on the psychological theory of hysteria put forward in that work. He bluntly replied that he considered it an unjustifiable generalization of conclusions which might hold good for a few cases. Since then I have seen an abundance of cases of hysteria, and I have been occupied with each case for a number of days, weeks, or years. In not a single one of them have I failed to discover the psychological determinants which were postulated in the *Studies*, namely, a psychical trauma, a conflict of affects, and an additional factor which I brought forward in later publications - a disturbance in the sphere of sexuality. It is of course not to be expected that the patient will come to meet the physician half-way with material which has become pathogenic for the very reason of its efforts to lie concealed; nor must the enquirer rest content with the first 'No' that crosses his path.¹

[1905e, 1364]

Physicians were thus faced by the problem of investigating the nature and origin of the symptoms shown by these nervous or neurotic patients. In the course of this investigation it was found that in some at least of these patients the signs of their illness originate from nothing other than a *change in the action of their minds upon their bodies* and that the immediate cause of their disorder is to be looked for in their minds. What may be the remoter causes of the disturbance which affects their minds is another question, with which we need not now concern ourselves. But medical science was here provided with an opportunity for directing its full attention to what had previously been the neglected side of the mutual relation between body and mind.

[1890a, 1588]
It is not until we have studied pathological phenomena that we can get an insight into normal ones. Many things which had long been known of the influence of the mind on the body were only now brought into their true perspective. The commonest, everyday example of the mind’s action on the body, and one that is to be observed in everyone, is offered by what is known as the ‘expression of the emotions’. A man’s states of mind are manifested, almost without exception, in the tensions and relaxations of his facial muscles, in the adaptations of his eyes, in the amount of blood in the vessels of his skin, in the modifications in his vocal apparatus and in the movements of his limbs and in particular of his hands. These concomitant physical changes are for the most part of no advantage to the person concerned; on the contrary, they often stand in his way if he wishes to conceal his mental processes from other people. But they serve these other people as trustworthy indications from which his mental processes can be inferred and in which more confidence can be placed than in any simultaneous verbal expressions that may be made deliberately. If we are able to submit anyone to a more accurate examination during certain of his mental activities, we come upon further physical consequences, in the shape of changes in his heart-action, alterations in the distribution of blood in his body, and so on.

[1890a, 1588]

In certain mental states described as ‘affects’, the part played by the body is so obvious and on so large a scale that some psychologists have even adopted the view that the essence of these affects consists only in their physical manifestations. It is a matter of common knowledge that extraordinary changes occur in the facial expression, in the circulation, in the excretions and in the state of tension of the voluntary muscles under the influence of fear, of rage, of mental pain and of sexual delight. What is less well known, though equally well established, is the occurrence of other physical results of the affects which cannot be counted as their expression. Persistent affective states of a distressing or ‘depressive’ nature (as they are called), such as sorrow, worry or grief, reduce the state of nourishment of the whole body, cause the hair to turn white, the fat to disappear and the walls of the blood-vessels to undergo morbid changes. On the other hand, under the influence of feelings of joy, of ‘happiness’, we find that the whole body blossoms out and shows signs of a renewal of youth. The major affects evidently have a large bearing on the capacity to resist infectious illness; a good example of this is to be seen in the medical observation that there is a far greater liability to contract such diseases as typhus and dysentery in defeated armies than in victorious ones. The affects, moreover, - this applies almost exclusively to depressive affects - are often sufficient in themselves to bring about both diseases of the nervous system accompanied by manifest anatomical changes and also diseases of other organs. In such cases it must be assumed that the patient already had a predisposition, though hitherto an inoperative one, to the disease in question.

[1890a, 1589]

States of illness that are already present can be very considerably influenced by violent affects. Such changes are usually for the worse; but there is no lack of instances in which a severe shock or a sudden bereavement brings about a peculiar alteration in the tone of the organism which may have a favourable influence on some well-established pathological condition or may even bring it to an end. Finally, there can be no doubt that the duration of life can be appreciably shortened by depressive affects and that a violent shock, or a deep humiliation or disgrace, may put a sudden end to life. Strange to say, this same result may be found to follow too from the unexpected impact of a great joy.

[1890a, 1589]
The affects in the narrower sense are, it is true, characterized by a quite special connection with somatic processes; but, strictly speaking, all mental states, including those that we usually regard as 'processes of thought', are to some degree 'affective', and not one of them is without its physical manifestations or is incapable of modifying somatic processes. Even when a person is engaged in quietly thinking in a string of 'ideas', there are a constant series of excitations, corresponding to the content of these ideas, which are discharged into the smooth or striated muscles. These excitations can be made apparent if they are appropriately reinforced, and certain striking and, indeed, ostensibly 'supernatural' phenomena can be explained by this means. Thus, what is known as 'thought-reading' [Gedanken erraten] may be explained by small, involuntary muscular movements carried out by the 'medium' in the course of an experiment - when, for instance, he has to make someone discover a hidden object. The whole phenomenon might more suitably be described as 'thought-betraying' [Gedanken verraten].

The processes of volition and attention are also capable of exercising a profound effect on somatic processes and of playing a large part in promoting or hindering physical illnesses. A famous English physician has reported that he can succeed in producing a great variety of sensations and pains in any part of his body to which he may choose to direct his attention, and the majority of people appear to behave similarly. It is in general true that in forming a judgement of pains (which are usually regarded as physical phenomena) we must bear in mind their unmistakable dependence upon mental determinants. Laymen, who like to sum up mental influences of this kind under the name of 'imagination', are inclined to have little respect for pains that are due to imagination as contrasted with those caused by injury, illness or inflammation. But this is clearly unjust. However pains may be caused - even by imagination - they themselves are no less real and no less violent on that account.

Just as pains are produced or increased by having attention paid to them, so, too, they disappear if attention is diverted from them. This experience can always be employed as a means of soothing children; adult soldiers do not feel the pain of a wound in the feverish heat of battle; martyrs are probably quite impervious to the pain of their tortures in the over-excitement of their religious feeling and in the concentration of all their thoughts upon the heavenly reward that awaits them. It is not so easy to produce evidence of the influence of volition on pathological somatic processes; but it is quite possible that a determination to recover or a will to die may have an effect on the outcome even of severe and precarious illnesses.

Our interest is most particularly engaged by the mental state of expectation, which puts in motion a number of mental forces that have the greatest influence on the onset and cure of physical diseases. Fearful expectation is certainly not without its effect on the result. It would be of importance to know with certainty whether it has as great a bearing as is supposed on falling ill; for instance, whether it is true that during an epidemic those who are afraid of contracting the illness are in the greatest danger. The contrary state of mind, in which expectation is coloured by hope and faith, is an effective force with which we have to reckon, strictly speaking, in all our attempts at treatment and cure. We could not otherwise account for the peculiar results which we find produced by medicaments and therapeutic procedures.
There is no need, however, to bring forward anything other than mental forces in order to explain miraculous cures. Even under conditions such as these, nothing happens that can be considered as beyond our understanding. Everything proceeds naturally. Indeed, the power of religious faith is reinforced by a number of eminently human motive forces. The individual's pious belief is intensified by the enthusiasm of the crowd of people in whose midst he makes his way as a rule to the sacred locality. All the mental impulses of an individual can be enormously magnified by group influence such as this. In cases in which someone proceeds to the holy place by himself, the reputation of the place and the respect in which it is held act as substitutes for the influence of the group, so that in fact the power of a group is once more in operation. And there is yet another way in which this influence makes itself felt. Since it is well known that divine mercy is always shown only to a few of the many who seek it, each of these is eager to be among the chosen few; the ambition that lies hidden in everyone comes to the help of pious faith. Where so many powerful forces converge, we need feel no surprise if the goal is sometimes really reached.

With your permission, I should like to pause a moment over this event. Never before had anyone removed a hysterical symptom by such a method or had thus gained so deep an insight into its causation. It could not fail to prove a momentous discovery if the expectation were confirmed that others of the patient's symptoms - perhaps the majority of them - had arisen and could be removed in this same manner. Breuer spared no pains in convincing himself that this was so, and he proceeded to a systematic investigation of the pathogenesis of the other and more serious symptoms of the patient's illness. And it really was so. Almost all the symptoms had arisen in this way as residues - 'precipitates' they might be called - of emotional experiences. To these experiences, therefore, we later gave the name of 'psychical traumas', while the particular nature of the symptoms was explained by their relation to the traumatic scenes which were their cause. They were, to use a technical term, 'determined' by the scenes of whose recollection they represented residues, and it was no longer necessary to describe them as capricious or enigmatic products of the neurosis. One unexpected point, however, must be noticed. What left the symptom behind was not always a single experience. On the contrary, the result was usually brought about by the convergence of several traumas, and often by the repetition of a great number of similar ones. Thus it was necessary to reproduce the whole chain of pathogenic memories in chronological order, or rather in reversed order, the latest ones first and the earliest ones last; and it was quite impossible to jump over the later traumas in order to get back more quickly to the first, which was often the most potent one.
In the first place, it must be emphasized that Breuer's patient, in almost all her pathogenic situations, was obliged to suppress a powerful emotion instead of allowing its discharge in the appropriate signs of emotion, words or actions. In the episode of her lady-companion's dog, she suppressed any manifestation of her very intense disgust, out of consideration for the woman's feelings; while she watched at her father's bedside she was constantly on the alert to prevent the sick man from observing her anxiety and her painful depression. When subsequently she reproduced these scenes in her doctor's presence the affect which had been inhibited at the time emerged with peculiar violence, as though it had been saved up for a long time. Indeed, the symptom which was left over from one of these scenes would reach its highest pitch of intensity at the time when its determining cause was being approached, only to vanish when that cause had been fully ventilated. On the other hand, it was found that no result was produced by the recollection of a scene in the doctor's presence if for some reason the recollection took place without any generation of affect. Thus it was what happened to these affects, which might be regarded as displaceable magnitudes, that was the decisive factor both for the onset of illness and for recovery. One was driven to assume that the illness occurred because the affects generated in the pathogenic situations had their normal outlet blocked, and that the essence of the illness lay in the fact that these 'strangulated' affects were then put to an abnormal use. In part they remained as a permanent burden upon the patient's mental life and a source of constant excitation for it; and in part they underwent a transformation into unusual somatic innervations and inhibitions, which manifested themselves as the physical symptoms of the case. For this latter process we coined the term 'hysterical conversion'. Quite apart from this, a certain portion of our mental excitation is normally directed along the paths of somatic innervation and produces what we know as an 'expression of the emotions'. Hysterical conversion exaggerates this portion of the discharge of an emotionally cathected mental process; it represents a far more intense expression of the emotions, which has entered upon a new path. When the bed of a stream is divided into two channels, then, if the current in one of them is brought up against an obstacle, the other will at once be overfilled. As you see, we are on the point of arriving at a purely psychological theory of hysteria, with affective processes in the front rank.

LADIES AND GENTLEMEN, - At about the same time at which Breuer was carrying on the 'talking cure' with his patient, the great Charcot in Paris had begun the researches into hysterical patients at the Salpêtrière which were to lead to a new understanding of the disease. There was no possibility of his findings being known in Vienna at that time. But when, some ten years later, Breuer and I published our 'Preliminary Communication' on the psychical mechanism of hysterical phenomena, we were completely under the spell of Charcot's researches. We regarded the pathogenic experiences of our patients as psychical traumas, and equated them with the somatic traumas whose influence on hysterical paralyses had been established by Charcot; and Breuer's hypothesis of hypnoid states was itself nothing but a reflection of the fact that Charcot had reproduced those traumatic paralyses artificially under hypnosis.
There are a large number of phenomena related to facial and other expressive movements and to speech, as well as many processes of thought (both in normal and sick people), which have hitherto escaped the notice of psychology because they have been regarded as no more than the results of organic disorder or of some abnormal failure in function of the mental apparatus. What I have in mind are 'parapraxes' (slips of the tongue or pen, forgetfulness, etc.), haphazard actions and dreams in normal people, and convulsive attacks, deliria, visions, and obsessive ideas or acts in neurotic subjects. These phenomena (in so far as they were not entirely neglected, as was the case with the parapraxes) were relegated to pathology and an attempt was made to find 'physiological' explanations of them, though these were invariably unsatisfactory. Psycho-analysis, on the contrary, has been able to show that all these things can be explained by means of hypotheses of a purely psychological nature and can be fitted into the chain of psychical events already known to us. Thus on the one hand psycho-analysis has narrowed the region subject to the physiological point of view and on the other hand has brought a large section of pathology into the sphere of psychology. In this instance the normal phenomena provide the more convincing evidence. Psycho-analysis cannot be accused of having applied to normal cases findings arrived at from pathological material. The evidence in the latter and in the former was reached independently and shows that normal processes and what are described as pathological ones follow the same rules.

I will illustrate the first of these theses by a few examples. Hysterical attacks have long been recognized as signs of increased emotional excitement and equated with outbreaks of affect. Charcot attempted to reduce the multiplicity of their modes of manifestation by means of descriptive formulas; Pierre Janet recognized the unconscious ideas operating behind such attacks; while psycho-analysis has shown that they are mimetic representations of scenes (whether actually experienced or only invented) with which the patient's imagination is occupied without his becoming conscious of them. The meaning of these pantomimes is concealed from the spectators by means of condensations and distortions of the acts which they represent. And this applies equally to what are described as the 'chronic' symptoms of hysterical patients. All of them are mimetic or hallucinatory representations of phantasies which unconsciously dominate the subject's emotional life and which have the meaning of fulfilsments of secret and repressed wishes. The tormenting character of these symptoms is due to the internal conflict into which these patients' minds are driven by the need to combat such unconscious wishes.

Psycho-analysis, however, was not in any way based on these researches of Janet's. The decisive factor in its case was the experience of a Viennese physician, Dr. Josef Breuer. In 1881, independently of any outside influence, he was able with the help of hypnosis to study and restore to health a highly-gifted girl who suffered from hysteria. Breuer's findings were not given to the public until fifteen years later, after he had taken the present writer (Freud) into collaboration. This case of Breuer's retains its unique significance for our understanding of the neuroses to this day; so that we cannot avoid dwelling on it a little longer. It is essential to realize clearly in what its peculiarity consisted. The girl had fallen ill while she was nursing her father, to whom she was tenderly attached. Breuer was able to establish that all her symptoms were related to this period of nursing and could be explained by it. Thus it had for the first time become possible to obtain a complete view of a case of this puzzling neurosis, and all its symptoms had turned out to have a meaning. Further, it was a universal feature of the symptoms that they had arisen in situations involving an impulse to an action which, however, had not been carried out but had for other reasons been suppressed. The symptoms had, in fact, appeared in place of the actions that were not performed. Thus, to explain the aetiology of hysterical symptoms, we were led to the subject's emotional life (to affectivity) and to the interplay of mental forces (to dynamics); and since then these two lines of approach have never been dropped.
From a clinical standpoint the neuroses must necessarily be put alongside the intoxications and such disorders as Graves' disease. These are conditions arising from an excess or a relative lack of certain highly active substances, whether produced inside the body or introduced into it from outside - in short, they are disturbances of the chemistry of the body, toxic conditions. If someone succeeded in isolating and demonstrating the hypothetical substance or substances concerned in neuroses, he would have no need to worry about opposition from the medical profession. For the present, however, no such avenue of approach to the problem is open. At the moment we can only start from the symptoms presented by a neurosis - symptoms which in the case of hysteria, for instance, consist of a combination of somatic and mental disturbances. Now Charcot's experiments as well as Breuer's clinical observations taught us that the somatic symptoms of hysteria are psychogenic too - that is, that they are precipitates of mental processes that have run their course. By putting a subject into a state of hypnosis it was possible at will to produce the somatic symptoms of hysteria artificially.

[1925e, 4123]
My observation of Frau Cäcilie M. gave me an opportunity of making a regular collection of symbolizations of this kind. A whole set of physical sensations which would ordinarily be regarded as organically determined were in her case of psychical origin or at least possessed a psychical meaning. A particular series of experiences of hers were accompanied by a stabbing sensation in the region of the heart (meaning 'it stabbed me to the heart'). The pain that occurs in hysteria of nails being driven into the head was without any doubt to be explained in her case as a pain related to thinking. ('Something's come into my head.') Pains of this kind were always cleared up as soon as the problems involved were cleared up. Running parallel to the sensation of a hysterical 'aura' in the throat, when that feeling appeared after an insult, was the thought 'I shall have to swallow this'. She had a whole quantity of sensations and ideas running parallel with each other. Sometimes the sensation would call up the idea to explain it, sometimes the idea would create the sensation by means of symbolization, and not infrequently it had to be left an open question which of the two elements had been the primary one.

Am I now going on to assert that in every instance in which there are periodical attacks of aphonia we are to diagnose the existence of a loved person who is at times away from the patient? Nothing could be further from my intention. The determination of Dora's symptoms is far too specific for it to be possible to expect a frequent recurrence of the same accidental aetiology. But, if so, what is the value of our elucidation of the aphonia in the present case? Have we not merely allowed ourselves to become the victims of a *jeu d'esprit*? I think not. In this connection we must recall the question which has so often been raised, whether the symptoms of hysteria are of psychical or of somatic origin, or whether, if the former is granted, they are necessarily all of them psychically determined. Like so many other questions to which we find investigators returning again and again without success, this question is not adequately framed. The alternatives stated in it do not cover the real essence of the matter. As far as I can see, every hysterical symptom involves the participation of both sides. It cannot occur without the presence of a certain degree of *somatic compliance* offered by some normal or pathological process in or connected with one of the bodily organs. And it cannot occur more than once - and the capacity for repeating itself is one of the characteristics of a hysterical symptom - unless it has a psychical significance, a *meaning*. The hysterical symptom does not carry this meaning with it, but the meaning is lent to it, soldered to it, as it were; and in every instance the meaning can be a different one, according to the nature of the suppressed thoughts which are struggling for expression. However, there are a number of factors at work which tend to make less arbitrary the relations between the unconscious thoughts and the somatic processes that are at their disposal as a means of expression, and which tend to make those relations approximate to a few typical forms. For therapeutic purposes the most important determinants are those given by the fortuitous psychical material; the clearing-up of the symptoms is achieved by looking for their psychical significance. When everything that can be got rid of by psycho-analysis has been cleared away, we are in a position to form all kinds of conjectures, which probably meet the facts, as regards the somatic basis of the symptoms - a basis which is as a rule constitutional and organic. Thus in Dora's case we shall not content ourselves with a psycho-analytic interpretation of her attacks of coughing and aphonia; but we shall also indicate the organic factor which was the source of the 'somatic compliance' that enabled her to express her love for a man who was periodically absent. And if the connection between the symptomatic expression and the unconscious mental content should strike us as being in this case a clever *tour de force*, we shall be relieved to hear that it succeeds in creating the same impression in every other case and in every other instance.

[1895d, 162]

[1905e, 1378]
As she kept on repeating her complaints against her father with a wearisome monotony, and as at the same time her cough continued, I was led to think that this symptom might have some meaning in connection with her father. And apart from this, the explanation of the symptom which I had hitherto obtained was far from fulfilling the requirements which I am accustomed to make of such explanations. According to a rule which I had found confirmed over and over again by experience, though I had not yet ventured to erect it into a general principle, a symptom signifies the representation - the realization - of a phantasy with a sexual content, that is to say, it signifies a sexual situation. It would be better to say that at least one of the meanings of a symptom is the representation of a sexual phantasy, but that no such limitation is imposed upon the content of its other meanings. Any one who takes up psycho-analytic work will quickly discover that a symptom has more than one meaning and serves to represent several unconscious mental processes simultaneously. And I should like to add that in my estimation a single unconscious mental process or phantasy will scarcely ever suffice for the production of a symptom.

[1905e, 1383]

An opportunity very soon occurred for interpreting Dora's nervous cough in this way by means of an imagined sexual situation. She had once again been insisting that Frau K. only loved her father because he was 'ein vermögender Mann' ['a man of means']. Certain details of the way in which she expressed herself (which I pass over here, like most other purely technical parts of the analysis) led me to see that behind this phrase its opposite lay concealed, namely, that her father was 'ein unvermögender Mann' ['a man without means']. This could only be meant in a sexual sense - that her father, as a man, was without means, was impotent.¹ Dora confirmed this interpretation from her conscious knowledge; whereupon I pointed out the contradiction she was involved in if on the one hand she continued to insist that her father's relation with Frau K. was a common love-affair, and on the other hand maintained that her father was impotent, or in other words incapable of carrying on an affair of such a kind. Her answer showed that she had no need to admit the contradiction. She knew very well, she said, that there was more than one way of obtaining sexual gratification. (The source of this piece of knowledge, however, was once more untraceable.) I questioned her further, whether she referred to the use of organs other than the genitals for the purpose of sexual intercourse, and she replied in the affirmative. I could then go on to say that in that case she must be thinking of precisely those parts of the body which in her case were in a state of irritation, - the throat and the oral cavity. To be sure, she would not hear of going so far as this in recognizing her own thoughts; and indeed, if the occurrence of the symptom was to be made possible at all, it was essential that she should not be completely clear on the subject. But the conclusion was inevitable that with her spasmodic cough, which, as is usual, was referred for its exciting stimulus to a tickling in her throat, she pictured to herself a scene of sexual gratification per os between the two people whose love-affair occupied her mind so incessantly. A very short time after she had tacitly accepted this explanation her cough vanished - which fitted in very well with my view; but I do not wish to lay too much stress upon this development, since her cough had so often before disappeared spontaneously.

[1905e, 1384]
What, then, was the meaning of this condition, of this attempted simulation of a perityphlitis? The remainder of the disorder, the dragging of one leg, was entirely out of keeping with perityphlitis. It must, no doubt, fit in better with the secret and possibly sexual meaning of the clinical picture; and if we were elucidated might in its turn throw light on the meaning which we were in search of. I looked about for a method of approaching the puzzle. Periods of time had been mentioned in the dream; and time is assuredly never a matter of indifference in any biological event. I therefore asked Dora when this attack of appendicitis had taken place; whether it had been before or after the scene by the lake. Every difficulty was resolved at a single blow by her prompt reply: 'Nine months later.' The period of time is sufficiently characteristic. Her supposed attack of appendicitis had thus enabled the patient with the modest means at her disposal (the pains and the menstrual flow) to realize a phantasy of childbirth.² Dora was naturally aware of the significance of this period of time, and could not dispute the probability of her having, on the occasion under discussion, read up in the encyclopaedia about pregnancy and childbirth. But what was all this about her dragging her leg? I could now hazard a guess. That is how people walk when they have twisted a foot. So she had made a 'false step': which was true indeed if she could give birth to a child nine months after the scene by the lake. But there was still another requirement upon the fulfilment of which I had to insist. I am convinced that a symptom of this kind can only arise where it has an infantile prototype. All my experience hitherto has led me to hold firmly to the view that recollections derived from the impressions of later years do not possess sufficient force to enable them to establish themselves as symptoms. I scarcely dared hope that Dora would provide me with the material that I wanted from her childhood, for the fact is that I am not yet in a position to assert the general validity of this rule, much as I should like to be able to do so. But in this case there came an immediate confirmation of it. Yes, said Dora, once when she was a child she had twisted the same foot; she had slipped on one of the steps as she was going downstairs. The foot - and it was actually the same one that she afterwards dragged - had swelled up and had to be bandaged and she had had to lie up for some weeks. This had been a short time before the attack of nervous asthma in her eighth year.

² [1905e, 1438]

In this way, unconscious phantasies are the immediate psychical precursors of a whole number of hysterical symptoms. Hysterical symptoms are nothing other than unconscious phantasies brought into view through 'conversion'; and in so far as the symptoms are somatic ones, they are often enough taken from the circle of the same sexual sensations and motor innervations as those which had originally accompanied the phantasy when it was still conscious. In this way the giving up of the habit of masturbation is in fact undone, and the purpose of the whole pathological process, which is a restoration of the original, primary sexual satisfaction, is achieved - though never completely, it is true, but always in a sort of approximation.

² [1908a, 1935]
I will illustrate the first of these theses by a few examples. Hysterical attacks have long been recognized as signs of increased emotional excitement and equated with outbreaks of affect. Charcot attempted to reduce the multiplicity of their modes of manifestation by means of descriptive formulas; Pierre Janet recognized the unconscious ideas operating behind such attacks; while psycho-analysis has shown that they are mimetic representations of scenes (whether actually experienced or only invented) with which the patient's imagination is occupied without his becoming conscious of them. The meaning of these pantomimes is concealed from the spectators by means of condensations and distortions of the acts which they represent. And this applies equally to what are described as the 'chronic' symptoms of hysterical patients. All of them are mimetic or hallucinatory representations of phantasies which unconsciously dominate the subject's emotional life and which have the meaning of fulfilsments of secret and repressed wishes. The tormenting character of these symptoms is due to the internal conflict into which these patients' minds are driven by the need to combat such unconscious wishes.

[1913j, 2809]

When a doctor carries out the psycho-analytic treatment of a neurotic, his interest is by no means directed in the first instance to the patient's character. He would much rather know what the symptoms mean, what instinctual impulses are concealed behind them and are satisfied by them, and what course was followed by the mysterious path that has led from the instinctual wishes to the symptoms. But the technique which he is obliged to follow soon compels him to direct his immediate curiosity towards other objectives. He observes that his investigation is threatened by resistances set up against him by the patient, and these resistances he may justly count as part of the latter's character. This now acquires the first claim on his interest.
[1916d, 3100]

Psycho-analysis, however, was not in any way based on these researches of Janet's. The decisive factor in its case was the experience of a Viennese physician, Dr. Josef Breuer. In 1881, independently of any outside influence, he was able with the help of hypnosis to study and restore to health a highly-gifted girl who suffered from hysteria. Breuer's findings were not given to the public until fifteen years later, after he had taken the present writer (Freud) into collaboration. This case of Breuer's retains its unique significance for our understanding of the neuroses to this day; so that we cannot avoid dwelling on it a little longer. It is essential to realize clearly in what its peculiarity consisted. The girl had fallen ill while she was nursing her father, to whom she was tenderly attached. Breuer was able to establish that all her symptoms were related to this period of nursing and could be explained by it. Thus it had for the first time become possible to obtain a complete view of a case of this puzzling neurosis, and all its symptoms had turned out to have a meaning. Further, it was a universal feature of the symptoms that they had arisen in situations involving an impulse to an action which, however, had not been carried out but had for other reasons been suppressed. The symptoms had, in fact, appeared in place of the actions that were not performed. Thus, to explain the aetiology of hysterical symptoms, we were led to the subject's emotional life (to affectivity) and to the interplay of mental forces (to dynamics); and since then these two lines of approach have never been dropped.
[1924f, 4103]
At about the time at which the clinic was established and at which he gave up the Chair of Pathological Anatomy, a change occurred in the direction of Charcot's scientific pursuits, and to this we owe the finest of his work. He now pronounced that the theory of organic nervous illnesses was for the time being fairly complete, and he began to turn his attention almost exclusively to hysteria, which thus all at once became the focus of general interest. This, the most enigmatic of all nervous diseases, for the evaluation of which medicine had not yet found a serviceable angle of approach, had just then fallen into thorough discredit; and this discredit extended not only to the patients but to the physicians who concerned themselves with the neurosis. It was held that in hysteria anything was possible, and no credence was given to a hysteric about anything. The first thing that Charcot's work did was to restore its dignity to the topic. Little by little, people gave up the scornful smile with which the patient could at that time feel certain of being met. She was no longer necessarily a malingerer, for Charcot had thrown the whole weight of his authority on the side of the genuineness and objectivity of hysterical phenomena. Charcot had repeated on a small scale the act of liberation in memory of which Pinel's portrait hung in the lecture hall of the Salpêtrière. Once the blind fear of being made a fool of by the unfortunate patient had been given up - a fear which till then had stood in the way of a serious study of the neurosis - the question could arise as to what method of approach would lead most quickly to a solution of the problem. A quite unbiased observer might have arrived at this conclusion: if I find someone in a state which bears all the signs of a painful affect - weeping, screaming and raging - the conclusion seems probable that a mental process is going on in him of which those physical phenomena are the appropriate expression. A healthy person, if he were asked, would be in a position to say what impression it was that was tormenting him; but the hysteric would answer that he did not know. The problem would at once arise of how it is that a hysterical patient is overcome by an affect about whose cause he asserts that he knows nothing. If we keep to our conclusion that a corresponding psychical process must be present, and if nevertheless we believe the patient when he denies it; if we bring together the many indications that the patient is behaving as though he does know about it; and if we enter into the history of the patient's life and find some occasion, some trauma, which would appropriately evoke precisely those expressions of feeling - then everything points to one solution: the patient is in a special state of mind in which all his impressions or his recollections of them are no longer held together by an associative chain, a state of mind in which it is possible for a recollection to express its affect by means of somatic phenomena without the group of the other mental processes, the ego, knowing about it or being able to intervene to prevent it. If we had called to mind the familiar psychological difference between sleep and waking, the strangeness of our hypothesis might have seemed less. No one should object that the theory of a splitting of consciousness as a solution to the riddle of hysteria is much too remote to impress an unbiased and untrained observer. For, by pronouncing possession by a demon to be the cause of hysterical phenomena, the Middle Ages in fact chose this solution; it would only have been a matter of exchanging the religious terminology of that dark and superstitious age for the scientific language of to-day.

[1893f, 281]
Charcot, however, did not follow this path towards an explanation of hysteria, although he
drew copiously upon the surviving reports of witch trials and of possession, in order to show that
the manifestations of the neurosis were the same in those days as they are now. He treated
hysteria as just another topic in neuropathology; he gave a complete description of its
phenomena, demonstrated that these had their own laws and uniformities, and showed how to
recognize the symptoms which enable a diagnosis of hysteria to be made. The most
painstaking investigations, initiated by himself and his pupils, extended over hysterical
disturbances of sensibility in the skin and deeper tissues, over the behaviour of the sense
organs, and over the peculiarities of hysterical contractures and paralyses, and of trophic
disturbances and changes in metabolism. The many different forms of hysterical attack were
described, and a schematic plan was drawn up by depicting the typical configuration of the
major hysterical attack as occurring in four stages, which made it possible to trace the
commonly observed 'minor' attacks back to this same typical configuration. The localization and
frequency of occurrence of the so-called 'hysterogenic zones' and their relationship to the
attacks were also studied, and so on. Once all this information about the manifestations of
hysteria had been arrived at, a number of surprising discoveries were made. Hysteria in males,
and especially in men of the working class was found far more often than had been expected; it
was convincingly shown that certain conditions which had been put down to alcoholic
intoxication or lead-poisoning were of a hysterical nature; it was possible to subsume under
hysteria a whole number of affections which had hitherto not been understood and which had
remained unclassified; and where the neurosis had become joined with other disorders to form
complex pictures, it was possible to separate out the part played by hysteria. Most far-reaching
of all were the investigations into nervous illnesses which followed upon severe traumas - the
'traumatic neuroses' - views about which are still under discussion and in connection with which
Charcot has successfully put forward the arguments in favour of hysteria.
[1893f, 282]

Gentlemen, - I am appearing before you to-day with the object of giving you a report on a work
the first part of which has already been published in the Zentralblatt für Neurologie under the
names of Josef Breuer and myself. As you may gather from the title of the work, it deals with the
pathogenesis of hysterical symptoms and suggests that the immediate reasons for the
development of hysterical symptoms are to be looked for in the sphere of psychical life.
[1893a, 287]

In 1896, shortly after the appearance of my Studies on Hysteria (written in conjunction with Dr.
J. Breuer, 1895), I asked an eminent fellow-specialist for his opinion on the psychological theory
of hysteria put forward in that work. He bluntly replied that he considered it an unjustifiable
generalization of conclusions which might hold good for a few cases. Since then I have seen an
abundance of cases of hysteria, and I have been occupied with each case for a number of days,
weeks, or years. In not a single one of them have I failed to discover the psychological
determinants which were postulated in the Studies, namely, a psychical trauma, a conflict of
affects, and an additional factor which I brought forward in later publications - a disturbance in
the sphere of sexuality. It is of course not to be expected that the patient will come to meet the
physician half-way with material which has become pathogenic for the very reason of its efforts
to lie concealed; nor must the enquirer rest content with the first 'No' that crosses his path.¹
[1905e, 1364]
The experience with Herr K. - his making love to her and the insult to her honour which was involved - seems to provide in Dora's case the psychical trauma which Breuer and I declared long ago to be the indispensable prerequisite for the production of a hysterical disorder. But this new case also presents all the difficulties which have since led me to go beyond that theory,¹ besides an additional difficulty of a special kind. For, as so often happens in histories of cases of hysteria, the trauma that we know of as having occurred in the patient's past life is insufficient to explain or to determine the particular character of the symptoms; we should understand just as much or just as little of the whole business if the result of the trauma had been symptoms quite other than tussis nervosa, aphonia, depression, and taedium vitae. But there is the further consideration that some of these symptoms (the cough and the loss of voice) had been produced by the patient years before the time of the trauma, and that their earliest appearances belong to her childhood, since they occurred in her eighth year. If, therefore, the trauma theory is not to be abandoned, we must go back to her childhood and look about there for any influences or impressions which might have had an effect analogous to that of a trauma. Moreover, it deserves to be remarked that in the investigation even of cases in which the first symptoms had not already set in childhood I have been driven to trace back the patients' life history to their earliest years.²

(1) Hysterical symptoms are mnemonic symbols of certain operative (traumatic) impressions and experiences.

With your permission, I should like to pause a moment over this event. Never before had anyone removed a hysterical symptom by such a method or had thus gained so deep an insight into its causation. It could not fail to prove a momentous discovery if the expectation were confirmed that others of the patient's symptoms - perhaps the majority of them - had arisen and could be removed in this same manner. Breuer spared no pains in convincing himself that this was so, and he proceeded to a systematic investigation of the pathogenesis of the other and more serious symptoms of the patient's illness. And it really was so. Almost all the symptoms had arisen in this way as residues - 'precipitates' they might be called - of emotional experiences. To these experiences, therefore, we later gave the name of 'psychical traumas', while the particular nature of the symptoms was explained by their relation to the traumatic scenes which were their cause. They were, to use a technical term, 'determined' by the scenes of whose recollection they represented residues, and it was no longer necessary to describe them as capricious or enigmatic products of the neurosis. One unexpected point, however, must be noticed. What left the symptom behind was not always a single experience. On the contrary, the result was usually brought about by the convergence of several traumas, and often by the repetition of a great number of similar ones. Thus it was necessary to reproduce the whole chain of pathogenic memories in chronological order, or rather in reversed order, the latest ones first and the earliest ones last; and it was quite impossible to jump over the later traumas in order to get back more quickly to the first, which was often the most potent one.

[1905e, 1367]
[1908a, 1936]
[1910a, 2203]
Ladies and Gentlemen, if I may be allowed to generalize - which is unavoidable in so condensed an account as this - I should like to formulate what we have learned so far as follows: our hysterical patients suffer from reminiscences. Their symptoms are residues and mnemic symbols of particular (traumatic) experiences. We may perhaps obtain a deeper understanding of this kind of symbolism if we compare them with other mnemic symbols in other fields. The monuments and memorials with which large cities are adorned are also mnemic symbols. If you take a walk through the streets of London, you will find, in front of one of the great railway termini, a richly carved Gothic column - Charing Cross. One of the old Plantagenet kings of the thirteenth century ordered the body of his beloved Queen Eleanor to be carried to Westminster; and at every stage at which the coffin rested he erected a Gothic cross. Charing Cross is the last of the monuments that commemorate the funeral cortège.¹ At another point in the same town, not far from London Bridge, you will find a towering, and more modern, column, which is simply known as 'The Monument'. It was designed as a memorial of the Great Fire, which broke out in that neighbourhood in 1666 and destroyed a large part of the city. These monuments, then, resemble hysterical symptoms in being mnemic symbols; up to that point the comparison seems justifiable. But what should we think of a Londoner who paused to-day in deep melancholy before the memorial of Queer Eleanor's funeral instead of going about his business in the hurry that modern working conditions demand or instead of feeling joy over the youthful queen of his own heart? Or again what should we think of a Londoner who shed tears before the Monument that commemorates the reduction of his beloved metropolis to ashes although it has long since risen again in far greater brilliance? Yet every single hysteric and neurotic behaves like these two unpractical Londoners. Not only do they remember painful experiences of the remote past, but they still cling to them emotionally; they cannot get free of the past and for its sake they neglect what is real and immediate. This fixation of mental life to pathogenic traumas is one of the most significant and practically important characteristics of neurosis.

[1910a, 2206]

LADIES AND GENTLEMEN, - At about the same time at which Breuer was carrying on the 'talking cure' with his patient, the great Charcot in Paris had begun the researches into hysterical patients at the Salpêtrière which were to lead to a new understanding of the disease. There was no possibility of his findings being known in Vienna at that time. But when, some ten years later, Breuer and I published our 'Preliminary Communication' on the psychical mechanism of hysterical phenomena, we were completely under the spell of Charcot's researches. We regarded the pathogenic experiences of our patients as psychical traumas, and equated them with the somatic traumas whose influence on hysterical paralyses had been established by Charcot; and Breuer's hypothesis of hypnoid states was itself nothing but a reflection of the fact that Charcot had reproduced those traumatic paralyses artificially under hypnosis.

[1910a, 2210]

It was conclusively proved that hysterical symptoms are residues (reminiscences) of profoundly moving experiences, which have been withdrawn from everyday consciousness, and that their form is determined (in a manner that excludes deliberate action) by details of the traumatic effects of the experiences. On this view, the therapeutic prospects lie in the possibility of getting rid of this 'repression', so as to allow part of the unconscious psychical material to become conscious and thus to deprive it of its pathogenic power. This view is a dynamic one, in so far as it regards psychical processes as displacements of psychical energy which can be gauged by the amount of their effect on the affective elements. This is most significant in hysteria, where the process of 'conversion' creates the symptoms by transforming a quantity of mental impulses into somatic innervations.

[1913m, 2545]
The study of dreams may be considered the most trustworthy method of investigating deep mental processes. Now dreams occurring in traumatic neuroses have the characteristic of repeatedly bringing the patient back into the situation of his accident, a situation from which he wakes up in another fright. This astonishes people far too little. They think the fact that the traumatic experience is constantly forcing itself upon the patient even in his sleep is a proof of the strength of that experience: the patient is, as one might say, fixated to his trauma. Fixations to the experience which started the illness have long been familiar to us in hysteria. Breuer and Freud declared in 1893 that 'hysterics suffer mainly from reminiscences'. In the war neuroses, too, observers like Ferenczi and Simmel have been able to explain certain motor symptoms by fixation to the moment at which the trauma occurred.

[1920g, 3719]

Catharsis. - The investigations which lay at the root of Breuer and Freud's studies led to two chief results, and these have not been shaken by subsequent experience: first, that hysterical symptoms have sense and meaning, being substitutes for normal mental acts; and secondly, that the uncovering of this unknown meaning is accompanied by the removal of the symptoms - so that in this case scientific research and therapeutic effort coincide. The observations were carried out upon a series of patients who were treated in the same manner as Breuer's first patient, that is to say, put into a state of deep hypnosis; and the results seemed brilliant, until later their weak side became evident. The theoretical ideas put forward at that time by Breuer and Freud were influenced by Charcot's theories on traumatic hysteria and could find support in the findings of his pupil Pierre Janet, which, though they were published earlier than the Studies, were in fact subsequent to Breuer's first case. From the very beginning the factor of affect was brought into the foreground: hysterical symptoms, the authors maintained, came into existence when a mental process with a heavy charge of affect was in any way prevented from being levelled out along the normal path leading to consciousness and movement (i. e. was prevented from being 'abreacted'); as a result of this the affect, which was in a sense 'strangulated', was diverted along wrong paths and flowed off into the somatic innervation (a process named 'conversion'). The occasions upon which 'pathogenic ideas' of this kind arose were described by Breuer and Freud as 'psychical traumas', and, since these often dated back to the very remote past, it was possible for the authors to say that hysterics suffered mainly from reminiscences (which had not been dealt with). Under the treatment, therefore, 'catharsis' came about when the path to consciousness was opened and there was a normal discharge of affect. It will be seen that an essential part of this theory was the assumption of the existence of unconscious mental processes. Janet too had made use of unconscious acts in mental life; but, as he insisted in his later polemics against psycho-analysis, to him the phrase was no more than a make-shift expression, a 'manière de parler', and he intended to suggest no new point of view by it.

[1923a, 3913]
The Aetiological Significance of Sexual Life. - The second novelty which emerged after the hypnotic technique had been replaced by free associations was of a clinical nature. It was discovered in the course of the prolonged search for the traumatic experiences from which hysterical symptoms appeared to be derived. The more carefully the search was pursued the more extensive seemed to be the network of aetiologically significant impressions involved, but the further back, too, did they reach into the patient's puberty or childhood. At the same time they assumed a uniform character and eventually it became inevitable to bow before the evidence and recognize that at the root of the formation of every symptom there were to be found traumatic experiences from early sexual life. Thus a sexual trauma stepped into the place of an ordinary trauma and the latter was seen to owe its aetiological significance to an associative or symbolic connection with the former, which had preceded it. An investigation of cases of common nervousness (falling into the two classes of neuroasthenia and anxiety neurosis) which was simultaneously undertaken led to the conclusion that these disorders could be traced to contemporary abuses in the patients' sexual life and could be removed if these were brought to an end. It was thus easy to infer that neuroses in general are an expression of disturbances in sexual life, the so-called actual-neuroses being the consequences (by chemical agency) of contemporary injuries and the psycho-neuroses the consequences (by psychical modification) of bygone injuries to a biological function which had hitherto been gravely neglected by science. None of the theses of psycho-analysis has met with such tenacious scepticism or such embittered resistance as this assertion of the preponderating aetiological significance of sexual life in the neuroses. It should, however, be expressly remarked that, in its development up to the present day, psycho-analysis has found no reason to retreat from this opinion.

[1923a, 3920]

The precipitating causes of the symptoms were compared by Breuer to Charcot's traumas. Now it was a remarkable fact that all these traumatic precipitating causes, and all the mental impulses starting from them, were lost to the patient's memory, as though they had never happened; while their products - the symptoms - persisted unaltered, as though, so far as they were concerned, there was no such thing as the effacing effect of time. Here, therefore, we had a fresh proof of the existence of mental processes which were unconscious but for that very reason especially powerful - processes which we had first come to know in post-hypnotic suggestion. The therapeutic procedure adopted by Breuer was to induce the patient, under hypnosis, to remember the forgotten traumas and to react to them with powerful expressions of affect. When this had been done, the symptom, which had till then taken the place of these expressions of emotion, disappeared. Thus one and the same procedure served simultaneously the purposes of investigating and of getting rid of the ailment; and this unusual conjunction was later retained in psycho-analysis.

[1924f, 4104]

After the present writer had, during the early nineties, confirmed Breuer's results in a considerable number of patients, the two, Breuer and Freud, together decided on a publication, Studies on Hysteria (1895d), which contained their findings and an attempt at a theory based on them. This asserted that hysterical symptoms arose when the affect of a mental process cathected with a strong affect was forcibly prevented from being worked over consciously in the normal way and was thus diverted into a wrong path. In cases of hysteria, according to this theory, the affect passed over into an unusual somatic innervation ('conversion'), but could be given another direction and got rid of ('abreacted'), if the experience were revived under hypnosis. The authors gave this procedure the name of 'catharsis' (purging, setting free of a strangulated affect).

[1924f, 4104]
The second of these techniques which we are setting out to describe for the first time, that of isolation, is peculiar to obsessional neurosis. It, too, takes place in the motor sphere. When something unpleasant has happened to the subject or when he himself has done something which has a significance for his neurosis, he interpolates an interval during which nothing further must happen - during which he must perceive nothing and do nothing. This behaviour, which seems strange at first sight, is soon seen to have a relation to repression. We know that in hysteria it is possible to cause a traumatic experience to be overtaken by amnesia. In obsessional neurosis this can often not be achieved: the experience is not forgotten, but, instead, it is deprived of its affect, and its associative connections are suppressed or interrupted so that it remains as though isolated and is not reproduced in the ordinary processes of thought. The effect of this isolation is the same as the effect of repression with amnesia. This technique, then, is reproduced in the isolations of obsessional neurosis; and it is at the same time given motor reinforcement for magical purposes. The elements that are held apart in this way are precisely those which belong together associatively. The motor isolation is meant to ensure an interruption of the connection in thought. The normal phenomenon of concentration provides a pretext for this kind of neurotic procedure: what seems to us important in the way of an impression or a piece of work must not be interfered with by the simultaneous claims of any other mental processes or activities. But even a normal person uses concentration to keep away not only what is irrelevant or unimportant, but, above all, what is unsuitable because it is contradictory. He is most disturbed by those elements which once belonged together but which have been torn apart in the course of his development - as, for instance, by manifestations of the ambivalence of his father-complex in his relation to God, or by impulses attached to his excretory organs in his emotions of love. Thus, in the normal course of things, the ego has a great deal of isolating work to do in its function of directing the current of thought. And, as we know, we are obliged, in carrying out our analytic technique, to train it to relinquish that function for the time being, eminently justified as it usually is.

[1926d, 4279]
Even a purely terminological innovation ought to justify its adoption; it ought to reflect some new point of view or some extension of knowledge. The revival of the concept of defence and the restriction of that of repression takes into account a fact which has long since been known but which has received added importance owing to some new discoveries. Our first observations of repression and of the formation of symptoms were made in connection with hysteria. We found that the perceptual content of exciting experiences and the ideational content of pathogenic structures of thought were forgotten and debarred from being reproduced in memory, and we therefore concluded that the keeping away from consciousness was a main characteristic of hysterical repression. Later on, when we came to study the obsessional neuroses, we found that in that illness pathogenic occurrences are not forgotten. They remain conscious but they are 'isolated' in some way that we cannot as yet grasp, so that much the same result is obtained as in hysterical amnesia. Nevertheless the difference is great enough to justify the belief that the process by which instinctual demands are set aside in obsessional neurosis cannot be the same as in hysteria. Further investigations have shown that in obsessional neurosis a regression of the instinctual impulses to an earlier libidinal stage is brought about through the opposition of the ego, and that this regression, although it does not make repression unnecessary, clearly works in the same sense as repression. We have seen, too, that in obsessional neurosis anticathexis, which is also presumably present in hysteria, plays a specially large part in protecting the ego by effecting a reactive alteration in it. Our attention has, moreover, been drawn to a process of 'isolation' (whose technique cannot as yet be elucidated) which finds direct symptomatic manifestation, and to a procedure, that may be called magical, of 'undoing' what has been done - a procedure about whose defensive purpose there can be no doubt, but which has no longer any resemblance to the process of 'repression'. These observations provide good enough grounds for re-introducing the old concept of defence, which can cover all these processes that have the same purpose - namely, the protection of the ego against instinctual demands - and for subsuming repression under it as a special case. The importance of this nomenclature is heightened if we consider the possibility that further investigations may show that there is an intimate connection between special forms of defence and particular illnesses, as, for instance, between repression and hysteria. In addition we may look forward to the possible discovery of yet another important correlation. It may well be that before its sharp cleavage into an ego and an id, and before the formation of a super-ego, the mental apparatus makes use of different methods of defence from those which it employs after it has reached these stages of organization.

[1926d, 4316]

This was at a date before the investigations of Charcot and Pierre Janet into the origin of hysterical symptoms, and Breuer’s discovery was thus entirely uninfluenced by them. But he did not pursue the matter any further at the time, and it was not until some ten years later that he took it up again in collaboration with Sigmund Freud. In 1895 they published a book, Studies on Hysteria, in which Breuer’s discoveries were described and an attempt was made to explain them by the theory of ‘catharsis’. According to that hypothesis, hysterical symptoms originate through the energy of a mental process being withheld from conscious influence and being diverted into bodily innervation (‘conversion’). A hysterical symptom would thus be a substitute for an omitted mental act and a reminiscence of the occasion which should have given rise to that act. And, on this view, recovery would be a result of the liberation of the affect that had gone astray and of its discharge along a normal path (‘abreaction’). Cathartic treatment gave excellent therapeutic results, but it was found that they were not permanent and that they were not independent of the personal relation between the patient and the physician. Freud, who later proceeded with these investigations by himself, made an alteration in their technique, by replacing hypnosis by the method of free association. He invented the term ‘psycho-analysis’, which in the course of time came to have two meanings: (1) a particular method of treating nervous disorders and (2) the science of unconscious mental processes, which has also been appropriately described as ‘depth-psychology’.

[1926f, 4401]
This analysis, which I have reproduced as accurately as possible, will, I hope, have to some extent clarified the concept of a 'screen memory' as one which owes its value as a memory not to its own content but to the relation existing between that content and some other, that has been suppressed. Different classes of screen memories can be distinguished according to the nature of that relation. We have found examples of two of these classes among what are described as the earliest memories of childhood - that is, if we include under the heading of screen memories the incomplete childhood scenes which are innocent by very reason of their incompleteness. It is to be anticipated that screen memories will also be formed from residues of memories relating to later life as well. Anyone who bears in mind their distinctive feature - namely that they are extremely well remembered but that their content is completely indifferent - will easily recall a number of examples of the sort from his own memory. Some of these screen memories dealing with events later in life owe their importance to a connection with experiences in early youth which have remained suppressed. The connection, that is, is the reverse of the one in the case which I have analysed, where a childhood memory was accounted for by later experiences. A screen memory may be described as 'retrogressive' or as having 'pushed forward' according as the one chronological relation or the other holds between the screen and the thing screened-off. From another point of view, we can distinguish positive screen memories from negative ones (or refractory memories) whose content stands in a contrary relation to the suppressed material. The whole subject deserves a more thorough examination; but I must content myself with pointing out what complicated processes - processes, incidentally, which are altogether analogous to the formation of hysterical symptoms - are involved in the building up of our store of memories.

[1899a, 501]

At this point I will interpolate a remark of a general nature which may perhaps have important implications. It is the Popt. system, which is without the capacity to retain modifications and is thus without memory, that provides our consciousness with the whole multiplicity of sensory qualities. On the other hand, our memories - not excepting those which are most deeply stamped on our minds - are in themselves unconscious. They can be made conscious; but there can be no doubt that they can produce all their effects while in an unconscious condition. What we describe as our 'character' is based on the memory-traces of our impressions; and, moreover, the impressions which have had the greatest effect on us - those of our earliest youth - are precisely the ones which scarcely ever become conscious. But if memories become conscious once more they exhibit no sensory quality or a very slight one in comparison with perceptions. A most promising light would be thrown on the conditions governing the excitation of neurone if it could be confirmed that the \( \Psi \)-systems of memory and the quality that characterizes consciousness are mutually exclusive.¹

[1900a, 972]
In the same connection I will give the explanation of a vision that was described to me by another hysterical patient (a woman of forty) as having happened before she fell ill. One morning she opened her eyes and saw her brother in the room, though, as she knew, he was in fact in an insane asylum. Her small son was sleeping in the bed beside her. To save the child from having a fright and falling into convulsions when he saw his uncle, she pulled the sheet over his face, whereupon the apparition vanished. This vision was a modified version of a memory from the lady's childhood; and, though it was conscious, it was intimately related to all the unconscious material in her mind. Her nurse had told her that her mother (who had died very young, when my patient was only eighteen months old) had suffered from epileptic or hysterical convulsions, which went back to a fright caused by her brother (my patient's uncle) appearing to her disguised as a ghost with a sheet over his head. Thus the vision contained the same elements as the memory: the brother's appearance, the sheet, the fright and its results. But the elements had been arranged in a different context and transferred on to other figures. The obvious motive of the vision, or of the thoughts which it replaced, was her concern lest her little boy might follow in the footsteps of his uncle, whom he greatly resembled physically. [1900a, 978]

It is perfectly true that unconscious wishes always remain active. They represent paths which can always be traversed, whenever a quantity of excitation makes use of them. Indeed it is a prominent feature of unconscious processes that they are indestructible. In the unconscious nothing can be brought to an end, nothing is past or forgotten. This is brought most vividly home to one in studying the neuroses, and especially hysteria. The unconscious path of thoughts, which leads to discharge in a hysterical attack, immediately becomes traversable once more, when sufficient excitation has accumulated. A humiliation that was experienced thirty years ago acts exactly like a fresh one throughout the thirty years, as soon as it has obtained access to the unconscious sources of emotion. As soon as the memory of it is touched, it springs into life again and shows itself cathected with excitation which finds a motor discharge in an attack. This is precisely the point at which psychotherapy has to intervene. Its task is to make it possible for the unconscious processes to be dealt with finally and be forgotten. For the fading of memories and the emotional weakness of impressions which are no longer recent, which we are inclined to regard as self-evident and to explain as a primary effect of time upon mental memory-traces, are in reality secondary modifications which are only brought about by laborious work. What performs this work is the preconscious, and psychotherapy can pursue no other course than to bring the Ucs. under the domination of the Pcs. [1900a, 1007]

(1) Hysterical symptoms are mnemonic symbols of certain operative (traumatic) impressions and experiences. [1908a, 1936]
With your permission, I should like to pause a moment over this event. Never before had anyone removed a hysterical symptom by such a method or had thus gained so deep an insight into its causation. It could not fail to prove a momentous discovery if the expectation were confirmed that others of the patient's symptoms - perhaps the majority of them - had arisen and could be removed in this same manner. Breuer spared no pains in convincing himself that this was so, and he proceeded to a systematic investigation of the pathogenesis of the other and more serious symptoms of the patient's illness. And it really was so. Almost all the symptoms had arisen in this way as residues - 'precipitates' they might be called - of emotional experiences. To these experiences, therefore, we later gave the name of 'psychical traumas', while the particular nature of the symptoms was explained by their relation to the traumatic scenes which were their cause. They were, to use a technical term, 'determined' by the scenes of whose recollection they represented residues, and it was no longer necessary to describe them as capricious or enigmatic products of the neurosis. One unexpected point, however, must be noticed. What left the symptom behind was not always a single experience. On the contrary, the result was usually brought about by the convergence of several traumas, and often by the repetition of a great number of similar ones. Thus it was necessary to reproduce the whole chain of pathogenic memories in chronological order, or rather in reversed order, the latest ones first and the earliest ones last; and it was quite impossible to jump over the later traumas in order to get back more quickly to the first, which was often the most potent one.

Ladies and Gentlemen, if I may be allowed to generalize - which is unavoidable in so condensed an account as this - I should like to formulate what we have learned so far as follows: our hysterical patients suffer from reminiscences. Their symptoms are residues and mnemonic symbols of particular (traumatic) experiences. We may perhaps obtain a deeper understanding of this kind of symbolism if we compare them with other mnemonic symbols in other fields. The monuments and memorials with which large cities are adorned are also mnemonic symbols. If you take a walk through the streets of London, you will find, in front of one of the great railway termini, a richly carved Gothic column - Charing Cross. One of the old Plantagenet kings of the thirteenth century ordered the body of his beloved Queen Eleanor to be carried to Westminster; and at every stage at which the coffin rested he erected a Gothic cross. Charing Cross is the last of the monuments that commemorate the funeral cortège.¹ At another point in the same town, not far from London Bridge, you will find a towering, and more modern, column, which is simply known as 'The Monument'. It was designed as a memorial of the Great Fire, which broke out in that neighbourhood in 1666 and destroyed a large part of the city. These monuments, then, resemble hysterical symptoms in being mnemonic symbols; up to that point the comparison seems justifiable. But what should we think of a Londoner who paused to-day in deep melancholy before the memorial of Queen Eleanor's funeral instead of going about his business in the hurry that modern working conditions demand or instead of feeling joy over the youthful queen of his own heart? Or again what should we think of a Londoner who shed tears before the Monument that commemorates the reduction of his beloved metropolis to ashes although it has long since risen again in far greater brilliance? Yet every single hysterical and neurotic behaves like these two unpractical Londoners. Not only do they remember painful experiences of the remote past, but they still cling to them emotionally; they cannot get free of the past and for its sake they neglect what is real and immediate. This fixation of mental life to pathogenic traumas is one of the most significant and practically important characteristics of neurosis.

[1910a, 2203]

[1910a, 2206]
The mind of the hysterical patient is full of active yet unconscious ideas; all her symptoms proceed from such ideas. It is in fact the most striking character of the hysterical mind to be ruled by them. If the hysterical woman vomits, she may do so from the idea of being pregnant. She has, however, no knowledge of this idea, although it can easily be detected in her mind, and made conscious to her, by one of the technical procedures of psycho-analysis. If she is executing the jerks and movements constituting her 'fit', she does not even consciously represent to herself the intended actions, and she may perceive those actions with the detached feelings of an onlooker. Nevertheless analysis will show that she was acting her part in the dramatic reproduction of some incident in her life, the memory of which was unconsciously active during the attack. The same preponderance of active unconscious ideas is revealed by analysis as the essential fact in the psychology of all other forms of neurosis.

[1912g, 2579]

I will illustrate the first of these theses by a few examples. Hysterical attacks have long been recognized as signs of increased emotional excitement and equated with outbreaks of affect. Charcot attempted to reduce the multiplicity of their modes of manifestation by means of descriptive formulas; Pierre Janet recognized the unconscious ideas operating behind such attacks; while psycho-analysis has shown that they are mimetic representations of scenes (whether actually experienced or only invented ) with which the patient's imagination is occupied without his becoming conscious of them. The meaning of these pantomimes is concealed from the spectators by means of condensations and distortions of the acts which they represent. And this applies equally to what are described as the 'chronic' symptoms of hysterical patients. All of them are mimetic or hallucinatory representations of phantasies which unconsciously dominate the subject's emotional life and which have the meaning of fulfills of secret and repressed wishes. The tormenting character of these symptoms is due to the internal conflict into which these patients' minds are driven by the need to combat such unconscious wishes.

[1913j, 2809]

A noteworthy relation between the symptoms of the 'actual' neuroses and of the psychoneuroses makes a further important contribution to our knowledge of the formation of symptoms in the latter. For a symptom of an 'actual' neurosis is often the nucleus and first stage of a psychoneurotic symptom. A relation of this kind can be most clearly observed between neurasthenia and the transference neurosis known as 'conversion hysteria', between anxiety neurosis and anxiety hysteria, but also between hypochondria and the forms of disorder which will be mentioned later under the name of paraphrenia (dementia praecox and paranoia). Let us take as an example a case of hysterical headache or lumbar pain. Analysis shows us that, by condensation and displacement, it has become a substitutive satisfaction for a whole number of libidinal phantasies or memories. But this pain was also at one time a real one and it was then a direct sexual-toxic symptom, the somatic expression of a libidinal excitation. We are far from asserting that all hysterical symptoms contain a nucleus of this kind. But it remains a fact that this is especially often the case and that whatever somatic influences (whether normal or pathological) are brought about by libidinal excitation are preferred for the construction of hysterical symptoms. In such cases they play the part of the grain of sand which a mollusc coats with layers of mother-of-pearl. In the same way, the passing indications of sexual excitement which accompany the sexual act are employed by the psychoneurosis as the most convenient and appropriate material for the construction of symptoms.

[1916-1917, 3441]
Its further course led it away from the study of the somatic determinants of nervous disease to an extent that was bewildering to physicians. Instead, it was brought into contact with the mental substance of human lives – the lives not only of the sick, but of the healthy, the normal and the supernormal. It had to deal with emotions and passions, and most of all with those which the poets never tire of depicting and celebrating – the emotions of love. It learnt to recognize the power of memories, the unsuspected importance of the years of childhood in shaping the adult, and the strength of wishes, which falsify human judgements and lay down fixed lines for human endeavour.
[1919g, 3703]

The Aetiological Significance of Sexual Life. - The second novelty which emerged after the hypnotic technique had been replaced by free associations was of a clinical nature. It was discovered in the course of the prolonged search for the traumatic experiences from which hysterical symptoms appeared to be derived. The more carefully the search was pursued the more extensive seemed to be the network of aetiologically significant impressions involved, but the further back, too, did they reach into the patient's puberty or childhood. At the same time they assumed a uniform character and eventually it became inevitable to bow before the evidence and recognize that at the root of the formation of every symptom there were to be found traumatic experiences from early sexual life. Thus a sexual trauma stepped into the place of an ordinary trauma and the latter was seen to owe its aetiological significance to an associative or symbolic connection with the former, which had preceded it. An investigation of cases of common nervousness (falling into the two classes of neurasthenia and anxiety neurosis) which was simultaneously undertaken led to the conclusion that these disorders could be traced to contemporary abuses in the patients' sexual life and could be removed if these were brought to an end. It was thus easy to infer that neuroses in general are an expression of disturbances in sexual life, the so-called actual-neuroses being the consequences (by chemical agency) of contemporary injuries and the psycho-neuroses the consequences (by psychical modification) of bygone injuries to a biological function which had hitherto been gravely neglected by science. None of the theses of psycho-analysis has met with such tenacious scepticism or such embittered resistance as this assertion of the preponderating aetiological significance of sexual life in the neuroses. It should, however, be expressly remarked that, in its development up to the present day, psycho-analysis has found no reason to retreat from this opinion.
[1923a, 3920]
When I was back in Vienna I turned once more to Breuer's observation and made him tell me more about it. The patient had been a young girl of unusual education and gifts, who had fallen ill while she was nursing her father, of whom she was devotedly fond. When Breuer took over her case it presented a variegated picture of paralyses with contractures, inhibitions and states of mental confusion. A chance observation showed her physician that she could be relieved of these clouded states of consciousness if she was induced to express in words the affective phantasy by which she was at the moment dominated. From this discovery, Breuer arrived at a new method of treatment. He put her into deep hypnosis and made her tell him each time what it was that was oppressing her mind. After the attacks of depressive confusion had been overcome in this way, he employed the same procedure for removing her inhibitions and physical disorders. In her waking state the girl could no more describe than other patients how her symptoms had arisen, and she could discover no link between them and any experiences of her life. In hypnosis she immediately discovered the missing connection. It turned out that all her symptoms went back to moving events which she had experienced while nursing her father; that is to say, her symptoms had a meaning and were residues or reminiscences of those emotional situations. It was found in most instances that there had been some thought or impulse which she had had to suppress while she was by her father's sick-bed, and that, in place of it, as a substitute for it, the symptom had afterwards appeared. But as a rule the symptom was not the precipitate of a single such 'traumatic' scene, but the result of a summation of a number of similar situations. When the patient recalled a situation of this kind in a hallucinatory way under hypnosis and carried through to its conclusion, with a free expression of emotion, the mental act which she had originally suppressed, the symptom was abolished and did not return. By this procedure Breuer succeeded, after long and painful efforts, in relieving his patient of all her symptoms.

[1925d, 4198]

This does not imply that anxiety occupies an exceptional position among the affective states. In my opinion the other affects are also reproductions of very early, perhaps even pre-individual, experiences of vital importance; and I should be inclined to regard them as universal, typical and innate hysterical attacks, as compared to the recently and individually acquired attacks which occur in hysterical neuroses and whose origin and significance as mnemonic symbols have been revealed by analysis. It would be very desirable, of course, to be able to demonstrate the truth of this view in a number of such affects - a thing which is still very far from being the case. [1926d, 4289]
Even a purely terminological innovation ought to justify its adoption; it ought to reflect some new point of view or some extension of knowledge. The revival of the concept of defence and the restriction of that of repression takes into account a fact which has long since been known but which has received added importance owing to some new discoveries. Our first observations of repression and of the formation of symptoms were made in connection with hysteria. We found that the perceptual content of exciting experiences and the ideational content of pathogenic structures of thought were forgotten and debarred from being reproduced in memory, and we therefore concluded that the keeping away from consciousness was a main characteristic of hysterical repression. Later on, when we came to study the obsessional neuroses, we found that in that illness pathogenic occurrences are not forgotten. They remain conscious and they are 'isolated' in some way that we cannot yet grasp, so that much the same result is obtained as in hysterical amnesia. Nevertheless the difference is great enough to justify the belief that the process by which instinctual demands are set aside in obsessional neurosis cannot be the same as in hysteria. Further investigations have shown that in obsessional neurosis a regression of the instinctual impulses to an earlier libidinal stage is brought about through the opposition of the ego, and that this regression, although it does not make repression unnecessary, clearly works in the same way as repression. We have seen, too, that in obsessional neurosis anticathexis, which is also presumably present in hysteria, plays a specially large part in protecting the ego by effecting a reactive alteration in it. Our attention has, moreover, been drawn to a process of 'isolation' (whose technique cannot as yet be elucidated) which finds direct symptomatic manifestation, and to a procedure, that may be called magical, of 'undoing' what has been done - a procedure about whose defensive purpose there can be no doubt, but which has no longer any resemblance to the process of 'repression'. These observations provide good enough grounds for re-introducing the old concept of defence, which can cover all these processes that have the same purpose - namely, the protection of the ego against instinctual demands - and for subsuming repression under it as a special case. The importance of this nomenclature is heightened if we consider the possibility that further investigations may show that there is an intimate connection between special forms of defence and particular illnesses, as, for instance, between repression and hysteria. In addition we may look forward to the possible discovery of yet another important correlation. It may well be that before its sharp cleavage into an ego and an id, and before the formation of a super-ego, the mental apparatus makes use of different methods of defence from those which it employs after it has reached these stages of organization.

[1926d, 4316]

This was at a date before the investigations of Charcot and Pierre Janet into the origin of hysterical symptoms, and Breuer's discovery was thus entirely uninfluenced by them. But he did not pursue the matter any further at the time, and it was not until some ten years later that he took it up again in collaboration with Sigmund Freud. In 1895 they published a book, Studies on Hysteria, in which Breuer's discoveries were described and an attempt was made to explain them by the theory of 'catharsis'. According to that hypothesis, hysterical symptoms originate through the energy of a mental process being withheld from conscious influence and being diverted into bodily innervation ('conversion'). A hysterical symptom would thus be a substitute for an omitted mental act and a reminiscence of the occasion which should have given rise to that act. And, on this view, recovery would be a result of the liberation of the affect that had gone astray and of its discharge along a normal path ('abreaction'). Cathartic treatment gave excellent therapeutic results, but it was found that they were not permanent and that they were not independent of the personal relation between the patient and the physician. Freud, who later proceeded with these investigations by himself, made an alteration in their technique, by replacing hypnosis by the method of free association. He invented the term 'psycho-analysis', which in the course of time came to have two meanings: (1) a particular method of treating nervous disorders and (2) the science of unconscious mental processes, which has also been appropriately described as 'depth-psychology'.

[1926f, 4401]
I am aware that it is of small service to handle so important a subject in the cursory fashion
that I have here employed. But none the less I have not been able to resist the seduction of an
analogy. The delusions of patients appear to me to be the equivalents of the constructions
which we build up in the course of an analytic treatment - attempts at explanation and cure,
though it is true that these, under the conditions of a psychosis, can do no more than replace
the fragment of reality that is being disavowed in the present by another fragment that had
already been disavowed in the remote past. It will be the task of each individual investigation to
reveal the intimate connections between the material of the present disavowal and that of the
original repression. Just as our construction is only effective because it recovers a fragment of
lost experience, so the delusion owes its convincing power to the element of historical truth
which it inserts in the place of the rejected reality. In this way a proposition which I originally
asserted only of hysteria would apply also to delusions - namely, that those who are subject to
them are suffering from their own reminiscences. I never intended by this short formula to
dispute the complexity of the causation of the illness or to exclude the operation of many other
factors.

[1937d, 5059]
My experiences in analysing dreams have drawn my attention to the fact that trains of thought reaching back to earliest childhood lead off even from dreams which seem at first sight to have been completely interpreted, since their sources and instigating wish have been discovered without difficulty. I have therefore been compelled to ask myself whether this characteristic may not be a further essential precondition of dreaming. Stated in general terms, this would imply that every dream was linked in its manifest content with recent experiences and in its latent content with the most ancient experiences. And I have in fact been able to show in my analysis of hysteria that these ancient experiences have remained recent in the proper sense of the word up to the immediate present. It is still extremely hard to demonstrate the truth of this suspicion; and I shall have to return in another connection (Chapter VII) to a consideration of the probable part played by the earliest experiences of childhood in the formation of dreams.

[1900a, 698]

In the same connection I will give the explanation of a vision that was described to me by another hysterical patient (a woman of forty) as having happened before she fell ill. One morning she opened her eyes and saw her brother in the room, though, as she knew, he was in fact in an insane asylum. Her small son was sleeping in the bed beside her. To save the child from having a fright and falling into convulsions when he saw his uncle, she pulled the sheet over his face, whereupon the apparition vanished. This vision was a modified version of a memory from the lady's childhood; and, though it was conscious, it was intimately related to all the unconscious material in her mind. Her nurse had told her that her mother (who had died very young, when my patient was only eighteen months old) had suffered from epileptic or hysterical convulsions, which went back to a fright caused by her brother (my patient's uncle) appearing to her disguised as a ghost with a sheet over his head. Thus the vision contained the same elements as the memory: the brother's appearance, the sheet, the fright and its results. But the elements had been arranged in a different context and transferred on to other figures. The obvious motive of the vision, or of the thoughts which it replaced, was her concern lest her little boy might follow in the footsteps of his uncle, whom he greatly resembled physically.

[1900a, 978]

¹ [Footnote added 1907:] I may perhaps put forward the following suggestions as regards the mechanism of forgetting in its proper sense. Mnemic material is subject in general to two influences, condensation and distortion. Distortion is the work of the dominant trends in mental life, and is directed above all against the memory traces which have remained affectively operative and which show considerable resistance to condensation. The traces that have grown indifferent succumb unresistingly to the process of condensation; yet it can be observed that in addition to this, the distorting trends feed on the indifferent material if they have remained unsatisfied at the place at which they sought to manifest themselves. As these processes of condensation and distortion continue for long periods, during which every fresh experience acts in the direction of transforming the mnemonic content, it is generally thought that it is time which makes memory uncertain and indistinct. It is highly probable that there is no question at all of there being any direct function of time in forgetting. - In the case of repressed memory-traces it can be demonstrated that they undergo no alteration even in the course of the longest period of time. The unconscious is quite timeless. The most important as well as the strangest characteristic of psychical fixation is that all impressions are preserved, not only in the same form in which they were first received, but also in all the forms which they have adopted in their further developments. This is a state of affairs which cannot be illustrated by comparison with another sphere. Theoretically every earlier state of the mnemonic content could thus be restored to memory again, even if its elements have long ago exchanged all their original connections for more recent ones.

[1901b, 1343]
But in view of the close connections between the psychoneuroses and the simple neuroses, which go so far, indeed, that a differential diagnosis is not always easy for inexperienced observers, it could not be long before the knowledge arrived at in the one field was extended to the other. Moreover, apart from this consideration, a deeper investigation of the psychical mechanism of hysterical symptoms led to the same result. For if the psychical traumas from which the hysterical symptoms were derived were pursued further and further by means of the 'cathartic' procedure initiated by Breuer and me, experiences were eventually reached which belonged to the patient's childhood and related to his sexual life. And this was so, even in cases in which the onset of the illness had been brought about by some commonplace emotion of a non-sexual kind. Unless these sexual traumas of childhood were taken into account it was impossible either to elucidate the symptoms (to understand the way in which they were determined) or to prevent their recurrence. In this way the unique significance of sexual experiences in the aetiology of the psychoneuroses seemed to be established beyond a doubt; and this fact remains to this day one of the corner-stones of my theory. [1906a, 1576]

This theory might be expressed by saying that the cause of life-long hysterical neuroses lies in what are in themselves for the most part the trivial sexual experiences of early childhood; and, put in this way, it might no doubt sound strange. But if we take the historical development of the theory into account, and see as its essence the proposition that hysteria is the expression of a particular behaviour of the individual's sexual function and that this behaviour is decisively determined by the first influences and experiences brought to bear in childhood, we shall be a paradox the poorer but the richer by a motive for turning our attention to something of the highest importance (though it has hitherto been grossly neglected) - the after-effects of the impressions of childhood. [1906a, 1577]

I will postpone until later in this paper a more thorough going discussion of the question whether we are to regard the sexual experiences of childhood as the causes of hysteria (and obsessional neurosis), and I will now return to the form taken by the theory in some of my shorter preliminary publications during the years 1895 and 1896 (Freud, 1896b and 1896c). By laying stress on the supposed aetiological factors it was possible at that time to draw a contrast between the common neuroses as disorders with a contemporary aetiology and psychoneuroses whose aetiology was chiefly to be looked for in the sexual experiences of the remote past. The theory culminated in this thesis: if the vita sexualis is normal, there can be no neurosis. [1906a, 1577]

(1) The attack becomes unintelligible through the fact that it represents several phantasies in the same material simultaneously - that is to say through condensation. The elements common to the two (or more) phantasies constitute the nucleus of the representation, as they do in dreams. The phantasies which are thus made to coincide are often of quite a different nature. They may, for instance, be a recent wish and the re-activation of an infantile impression. The same innervations are in that case made to serve both purposes, often in a most ingenious way. Hysterical patients who make a very extensive use of condensation may find a single form of attack sufficient; others express their numerous pathogenic phantasies by a multiplication of the forms of attack. [1909a, 1982]
Investigation of the childhood history of hysterical patients shows that the hysterical attack is designed to take the place of an auto-erotic satisfaction previously practised and since given up. In a great number of cases this satisfaction (masturbation by contact or by pressure of the thighs, or, again, by movements of the tongue, and so on) recurs during the attack itself, while the subject's consciousness is deflected. Moreover, the onset of an attack that is due to an increase of libido and is in the service of the primary purpose - as a consolation - exactly repeats the conditions under which, at the earlier time, the patient had intentionally sought this auto-erotic satisfaction. The anamnesis of the patient shows the following stages: (a) auto-erotic satisfaction, without ideational content; (b) the same satisfaction, connected with a phantasy which leads to the act of satisfaction; (c) renunciation of the act, with retention of the phantasy; (d) repression of the phantasy, which then comes into effect as a hysterical attack, either in an unchanged form, or in a modified one and adapted to new environmental impressions. Furthermore, (e) the phantasy may even reinstate the act of satisfaction belonging to it which had ostensibly been given up. This is a typical cycle of infantile sexual activity: repression, failure of repression, and return of the repressed.

[1909a, 1983]

Speaking as a whole, hysterical attacks, like hysteria in general, revive a piece of sexual activity in women which existed during their childhood and at that time revealed an essentially masculine character. It can often be observed that girls who have shown a boyish nature and inclinations up to the years before puberty are precisely those who become hysterical from puberty onwards. In a whole number of cases the hysterical neurosis merely represents an excessive accentuation of the typical wave of repression which, by doing away with her masculine sexuality, allows the woman to emerge.²

[1909a, 1984]

In hysteria it is the rule that the precipitating causes of the illness are overtaken by amnesia no less than the infantile experiences by whose help the precipitating causes are able to transform their affective energy into symptoms. And where the amnesia cannot be complete, it nevertheless subjects the recent traumatic precipitating cause to a process of erosion and robs it at least of its most important components. In this amnesia we see the evidence of the repression which has taken place. The case is different in obsessional neuroses. The infantile preconditions of the neurosis may be overtaken by amnesia, though this is often an incomplete one; but the immediate occasions of the illness are, on the contrary, retained in the memory. Repression makes use of another, and in reality a simpler, mechanism. The trauma, instead of being forgotten, is deprived of its affective cathexis; so that what remains in consciousness is nothing but its ideational content, which is perfectly colourless and is judged to be unimportant. The distinction between what occurs in hysteria and in an obsessional neurosis lies in the psychological processes which we can reconstruct behind the phenomena; the result is almost always the same, for the colourless mnemonic content is rarely reproduced and plays no part in the patient's mental activity. In order to differentiate between the two kinds of repression we have on the surface nothing to rely upon but the patient's assurance that he has a feeling in the one case of having always known the thing and in the other of having long ago forgotten it.¹

[1909d, 2154]
I will illustrate the first of these theses by a few examples. Hysterical attacks have long been recognized as signs of increased emotional excitement and equated with outbreaks of affect. Charcot attempted to reduce the multiplicity of their modes of manifestation by means of descriptive formulas; Pierre Janet recognized the unconscious ideas operating behind such attacks; while psycho-analysis has shown that they are mimetic representations of scenes (whether actually experienced or only invented) with which the patient's imagination is occupied without his becoming conscious of them. The meaning of these pantomimes is concealed from the spectators by means of condensations and distortions of the acts which they represent. And this applies equally to what are described as the 'chronic' symptoms of hysterical patients. All of them are mimetic or hallucinatory representations of phantasies which unconsciously dominate the subject's emotional life and which have the meaning of fulfilments of secret and repressed wishes. The tormenting character of these symptoms is due to the internal conflict into which these patients' minds are driven by the need to combat such unconscious wishes.

[1913j, 2809]

**The Aetiological Significance of Sexual Life.** - The second novelty which emerged after the hypnotic technique had been replaced by free associations was of a clinical nature. It was discovered in the course of the prolonged search for the traumatic experiences from which hysterical symptoms appeared to be derived. The more carefully the search was pursued the more extensive seemed to be the network of aetiologically significant impressions involved, but the further back, too, did they reach into the patient's puberty or childhood. At the same time they assumed a uniform character and eventually it became inevitable to bow before the evidence and recognize that at the root of the formation of every symptom there were to be found traumatic experiences from early sexual life. Thus a sexual trauma stepped into the place of an ordinary trauma and the latter was seen to owe its aetiological significance to an associative or symbolic connection with the former, which had preceded it. An investigation of cases of common nervousness (falling into the two classes of neurasthenia and anxiety neurosis) which was simultaneously undertaken led to the conclusion that these disorders could be traced to contemporary abuses in the patients' sexual life and could be removed if these were brought to an end. It was thus easy to infer that neuroses in general are an expression of disturbances in sexual life, the so-called actual-neuroses being the consequences (by chemical agency) of contemporary injuries and the psycho-neuroses the consequences (by psychical modification) of bygone injuries to a biological function which had hitherto been gravely neglected by science. None of the theses of psycho-analysis has met with such tenacious scepticism or such embittered resistance as this assertion of the preponderating aetiological significance of sexual life in the neuroses. It should, however, be expressly remarked that, in its development up to the present day, psycho-analysis has found no reason to retreat from this opinion.

[1923a, 3920]
For a third kind of incompleteness in this report neither the patient nor the author is responsible. It is, on the contrary, obvious that a single case history, even if it were complete and open to no doubt, cannot provide an answer to all the questions arising out of the problem of hysteria. It cannot give an insight into all the types of this disorder, into all the forms of internal structure of the neurosis, into all the possible kinds of relation between the mental and the somatic which are to be found in hysteria. It is not fair to expect from a single case more than it can offer. And any one who has hitherto been unwilling to believe that a psychosexual aetiology holds good generally and without exception for hysteria is scarcely likely to be convinced of the fact by taking stock of a single case history. He would do better to suspend his judgement until his own work has earned him the right to a conviction.¹

[1905e, 1356]

There now arise a whole series of questions of the greatest importance concerning the aetiology of hysteria: is Dora's case to be regarded as aetiologically typical? does it represent the only type of causation? and so on. Nevertheless, I am sure that I am taking the right course in postponing my answer to such questions until a considerable number of other cases have been similarly analysed and published. Moreover, I should have to begin by criticizing the way in which the questions are framed. Instead of answering 'Yes' or 'No' to the question whether the aetiology of this case is to be looked for in masturbation during childhood, I should first have to discuss the concept of aetiology as applied to the psychoneuroses. It would then become evident that the standpoint from which I should be able to answer the question would be very widely removed from the standpoint from which it was put. Let it suffice if we can reach the conviction that in this case the occurrence of masturbation in childhood is established, and that its occurrence cannot be an accidental element nor an immaterial one in the conformation of the clinical picture.¹

[1905e, 1417]

This theory might be expressed by saying that the cause of life-long hysterical neuroses lies in what are in themselves for the most part the trivial sexual experiences of early childhood; and, put in this way, it might no doubt sound strange. But if we take the historical development of the theory into account, and see as its essence the proposition that hysteria is the expression of a particular behaviour of the individual's sexual function and that this behaviour is decisively determined by the first influences and experiences brought to bear in childhood, we shall be a paradox the poorer but the richer by a motive for turning our attention to something of the highest importance (though it has hitherto been grossly neglected) - the after-effects of the impressions of childhood.

[1906a, 1577]

I will postpone until later in this paper a more thorough going discussion of the question whether we are to regard the sexual experiences of childhood as the causes of hysteria (and obsessional neurosis), and I will now return to the form taken by the theory in some of my shorter preliminary publications during the years 1895 and 1896 (Freud, 1896b and 1896c). By laying stress on the supposed aetiological factors it was possible at that time to draw a contrast between the common neuroses as disorders with a contemporary aetiology and psychoneuroses whose aetiology was chiefly to be looked for in the sexual experiences of the remote past. The theory culminated in this thesis: if the vita sexualis is normal, there can be no neurosis.

[1906a, 1577]
The Aetiological Significance of Sexual Life. - The second novelty which emerged after the hypnotic technique had been replaced by free associations was of a clinical nature. It was discovered in the course of the prolonged search for the traumatic experiences from which hysterical symptoms appeared to be derived. The more carefully the search was pursued the more extensive seemed to be the network of aetiologically significant impressions involved, but the further back, too, did they reach into the patient's puberty or childhood. At the same time they assumed a uniform character and eventually it became inevitable to bow before the evidence and recognize that at the root of the formation of every symptom there were to be found traumatic experiences from early sexual life. Thus a sexual trauma stepped into the place of an ordinary trauma and the latter was seen to owe its aetiological significance to an associative or symbolic connection with the former, which had preceded it. An investigation of cases of common nervousness (falling into the two classes of neurasthenia and anxiety neurosis) which was simultaneously undertaken led to the conclusion that these disorders could be traced to contemporary abuses in the patients' sexual life and could be removed if these were brought to an end. It was thus easy to infer that neuroses in general are an expression of disturbances in sexual life, the so-called actual-neuroses being the consequences (by chemical agency) of contemporary injuries and the psycho-neuroses the consequences (by psychical modification) of bygone injuries to a biological function which had hitherto been gravely neglected by science. None of the theses of psycho-analysis has met with such tenacious scepticism or such embittered resistance as this assertion of the preponderating aetiological significance of sexual life in the neuroses. It should, however, be expressly remarked that, in its development up to the present day, psycho-analysis has found no reason to retreat from this opinion.
[1923a, 3920]
Even if I ignore the ill-will of narrow-minded critics such as these, the presentation of my case histories remains a problem which is hard for me to solve. The difficulties are partly of a technical kind, but are partly due to the nature of the circumstances themselves. If it is true that the causes of hysterical disorders are to be found in the intimacies of the patients' psycho-sexual life, and that hysterical symptoms are the expression of their most secret and repressed wishes, then the complete elucidation of a case of hysteria is bound to involve the revelation of those intimacies and the betrayal of those secrets. It is certain that the patients would never have spoken if it had occurred to them that their admissions might possibly be put to scientific uses; and it is equally certain that to ask them themselves for leave to publish their case would be quite unavailing. In such circumstances persons of delicacy, as well as those who were merely timid, would give first place to the duty of medical discretion and would declare with regret that the matter was one upon which they could offer science no enlightenment. But in my opinion the physician has taken upon himself duties not only towards the individual patient but towards science as well; and his duties towards science mean ultimately nothing else than his duties towards the many other patients who are suffering or will some day suffer from the same disorder. Thus it becomes the physician's duty to publish what he believes he knows of the causes and structure of hysteria, and it becomes a disgraceful piece of cowardice on his part to neglect doing so, as long as he can avoid causing direct personal injury to the single patient concerned. I think I have taken every precaution to prevent my patient from suffering any such injury. I have picked out a person the scenes of whose life were laid not in Vienna but in a remote provincial town, and whose personal circumstances must therefore be practically unknown in Vienna. I have from the very beginning kept the fact of her being under my treatment such a careful secret that only one other physician - and one in whose discretion I have complete confidence - can be aware that the girl was a patient of mine. I have waited for four whole years since the end of the treatment and have postponed publication till hearing that a change has taken place in the patient's life of such a character as allows me to suppose that her own interest in the occurrences and psychological events which are to be related here may now have grown faint. Needless to say, I have allowed no name to stand which could put a non-medical reader upon the scent; and the publication of the case in a purely scientific, and technical periodical should, further, afford a guarantee against unauthorized readers of this sort. I naturally cannot prevent the patient herself from being pained if her own case history should accidentally fall into her hands. But she will learn nothing from it that she does not already know; and she may ask herself who besides her could discover from it that she is the subject of this paper.

[1905e, 1351]

In 1896, shortly after the appearance of my Studies on Hysteria (written in conjunction with Dr. J. Breuer, 1895), I asked an eminent fellow-specialist for his opinion on the psychological theory of hysteria put forward in that work. He bluntly replied that he considered it an unjustifiable generalization of conclusions which might hold good for a few cases. Since then I have seen an abundance of cases of hysteria, and I have been occupied with each case for a number of days, weeks, or years. In not a single one of them have I failed to discover the psychological determinants which were postulated in the Studies, namely, a psychical trauma, a conflict of affects, and an additional factor which I brought forward in later publications - a disturbance in the sphere of sexuality. It is of course not to be expected that the patient will come to meet the physician half-way with material which has become pathogenic for the very reason of its efforts to lie concealed; nor must the enquirer rest content with the first 'No' that crosses his path.¹

[1905e, 1364]
¹ Here is an instance of this. Another physician in Vienna, whose conviction of the unimportance of sexual factors in hysteria has probably been very much strengthened by such experiences as this, was consulted in the case of a fourteen-year-old girl who suffered from dangerous hysterical vomiting. He made up his mind to ask her the painful question whether by any chance she had ever had a love-affair with a man. 'No!' answered the child, no doubt with well-affected astonishment; and then repeated to her mother in her irreverent way: 'Only fancy! the old stupid asked me if I was in love!' She afterwards came to me for treatment, and proved - though not during our very first conversation, to be sure - to have been a masturbator for many years, with a considerable leucorrhoeal discharge (which had a close bearing on her vomiting). She had finally broken herself of the habit, but was tormented in her abstinence by the most acute sense of guilt, so that she looked upon every misfortune that befell her family as a divine punishment for her transgression. Besides this, she was under the influence of the romance of an unmarried aunt, whose pregnancy (a second determinant for her vomiting) was supposed to have been happily hidden from her. The girl was looked upon as a 'mere child,' but she turned out to be initiated into all the essentials of sexual relations.

³ All these discussions contain much that is typical and valid for hysteria in general. The subject of erection solves some of the most interesting hysterical symptoms. The attention that women pay to the outlines of men's genitals as seen through their clothing becomes, when it has been repressed, a source of the very frequent cases of avoiding company and of dreading society. - It is scarcely possible to exaggerate the pathogenic significance of the comprehensive tie uniting the sexual and the excremental, a tie which is at the basis of a very large number of hysterical phobias.

No one can undertake the treatment of a case of hysteria until he is convinced of the impossibility of avoiding the mention of sexual subjects, or unless he is prepared to allow himself to be convinced by experience. The right attitude is: 'pour faire une omelette il faut casser des œufs.' The patients themselves are easy to convince; and there are only too many opportunities of doing so in the course of the treatment. There is no necessity for feeling any compunction at discussing the facts of normal or abnormal sexual life with them. With the exercise of a little caution all that is done is to translate into conscious ideas what was already known in the unconscious; and, after all, the whole effectiveness of the treatment is based upon our knowledge that the affect attached to an unconscious idea operates more strongly and, since it cannot be inhibited, more injuriously than the affect attached to a conscious one. There is never any danger of corrupting an inexperienced girl. For where there is no knowledge of sexual processes even in the unconscious, no hysterical symptom will arise; and where hysteria is found there can no longer be any question of 'innocence of mind' in the sense in which parents and educators use the phrase. With children of ten, of twelve, or of fourteen, with boys and girls alike, I have satisfied myself that the truth of this statement can invariably be relied upon.
The interpretation we have just been discussing of Dora’s throat symptoms may also give rise to a further remark. It may be asked how this sexual situation imagined by her can be compatible with our other explanation of the symptoms. That explanation, it will be remembered, was to the effect that the coming and going of the symptoms reflected the presence and absence of the man she was in love with, and, as regards his wife's behaviour, expressed the following thought: 'If I were his wife, I should love him in quite a different way; I should be ill (from longing, let us say) when he was away, and well (from joy) when he was home again.' To this objection I must reply that my experience in the clearing-up of hysterical symptoms has shown that it is not necessary for the various meanings of a symptom to be compatible with one another, that is, to fit together into a connected whole. It is enough that the unity should be constituted by the subject-matter which has given rise to all the various phantasies. In the present case, moreover, compatibility even of the first kind is not out of the question. One of the two meanings is related more to the cough, and the other to the aphonia and the periodicity of the disorder. A closer analysis would probably have disclosed a far greater number of mental elements in relation to the details of the illness.

I was further anxious to show that sexuality does not simply intervene, like a *deus ex machina*, on one single occasion, at some point in the working of the processes which characterize hysteria, but that it provides the motive power for every single symptom, and for every single manifestation of a symptom. The symptoms of the disease are nothing else than the patient’s sexual activity. A single case can never be capable of proving a theorem so general as this one; but I can only repeat over and over again - for I never find it otherwise - that sexuality is the key to the problem of the psychoneuroses and of the neuroses in general. No one who disdains the key will ever be able to unlock the door. I still await news of the investigations which are to make it possible to contradict this theorem or to limit its scope. What I have hitherto heard against it have been expressions of personal dislike or disbelief. To these it is enough to reply in the words of Charcot: ‘Ça n’empêche pas d’exister.’

When erotogenic susceptibility to stimulation has been successfully transferred by a woman from the clitoris to the vaginal orifice, it implies that she has adopted a new leading zone for the purposes of her later sexual activity. A man, on the other hand, retains his leading zone unchanged from childhood. The fact that women change their leading erotogenic zone in this way, together with the wave of repression at puberty, which, as it were, puts aside their childish masculinity, are the chief determinants of the greater proneness of woman to neurosis and especially to hysteria. These determinants, therefore, are intimately related to the essence of femininity.

The hereditary conditions in the case of positive perverts are less well known, for they know how to avoid investigation. Yet there are good reasons to suppose that what is true of the neuroses applies also to the perversions. For it is no rare thing to find perversions and psychoneuroses occurring in the same family, and distributed between the two sexes in such a way that the male members of the family, or one of them, are positive perverts, while the females, true to the tendency of their sex to repression, are negative perverts, that is, hysterics. This is good evidence of the essential connections which we have shown to exist between the two disorders.
This theory might be expressed by saying that the cause of life-long hysterical neuroses lies in what are in themselves for the most part the trivial sexual experiences of early childhood; and, put in this way, it might no doubt sound strange. But if we take the historical development of the theory into account, and see as its essence the proposition that hysteria is the expression of a particular behaviour of the individual's sexual function and that this behaviour is decisively determined by the first influences and experiences brought to bear in childhood, we shall be a paradox the poorer but the richer by a motive for turning our attention to something of the highest importance (though it has hitherto been grossly neglected) - the after-effects of the impressions of childhood.

I will postpone until later in this paper a more thorough going discussion of the question whether we are to regard the sexual experiences of childhood as the causes of hysteria (and obsessional neurosis), and I will now return to the form taken by the theory in some of my shorter preliminary publications during the years 1895 and 1896 (Freud, 1896b and 1896c). By laying stress on the supposed aetiological factors it was possible at that time to draw a contrast between the common neuroses as disorders with a contemporary aetiology and psychoneuroses whose aetiology was chiefly to be looked for in the sexual experiences of the remote past. The theory culminated in this thesis: if the vita sexualis is normal, there can be no neurosis.

I think it is worth emphasizing the fact that, whatever modifications my views on the aetiology of the psychoneuroses have passed through, there are two positions which I have never repudiated or abandoned - the importance of sexuality and of infantilism. Apart from this, accidental influences have been replaced by constitutional factors and 'defence' in the purely psychological sense has been replaced by organic 'sexual repression'. The question may, however, be raised of where convincing evidence is to be found in favour of the alleged aetiological importance of sexual factors in the psychoneuroses, in view of the fact that the onset of these illnesses may be observed in response to the most commonplace emotions or even to somatic precipitating causes, and since I have had to abandon a specific aetiology depending on the particular form of the childhood experiences concerned. To such a question I would reply that the psycho-analytic examination of neurotics is the source from which this disputed conviction of mine is derived. If we make use of that irreplaceable method of research, we discover that the patient's symptoms constitute his sexual activity (whether wholly or in part), which arises from the sources of the normal or perverse component instincts of sexuality. Not only is a large part of the symptomatology of hysteria derived directly from expressions of sexual excitement, not only do a number of erotogenic zones attain the significance of genitals during neuroses owing to an intensification of infantile characteristics, but the most complicated symptoms are themselves revealed as representing, by means of 'conversion', phantasies which have a sexual situation as their subject-matter. Anyone who knows how to interpret the language of hysteria will recognize that the neurosis is concerned only with the patient's repressed sexuality. The sexual function must, however, be understood in its true extent, as it is laid down by disposition in infancy. Wherever some commonplace emotion must be included among the determinants of the onset of the illness, analysis invariably shows that it is the sexual component of the traumatic experience - a component that is never lacking which has produced the pathogenic result.
In this way, unconscious phantasies are the immediate psychical precursors of a whole number of hysterical symptoms. Hysterical symptoms are nothing other than unconscious phantasies brought into view through "conversion"; and in so far as the symptoms are somatic ones, they are often enough taken from the circle of the same sexual sensations and motor innervations as those which had originally accompanied the phantasy when it was still conscious. In this way the giving up of the habit of masturbation is in fact undone, and the purpose of the whole pathological process, which is a restoration of the original, primary sexual satisfaction, is achieved - though never completely, it is true, but always in a sort of approximation.

This method of psycho-analytic investigation, which leads from the conspicuous symptoms to the hidden unconscious phantasies, tells us everything that can be known about the sexuality of psychoneurotics, including the fact which is to be the main subject-matter of this short preliminary publication.

(5) Hysterical symptoms serve the purpose of sexual satisfaction and represent a portion of the subject's sexual life (a portion which corresponds to one of the constituents of his sexual instinct).

(8) Hysterical symptoms may take over the representation of various unconscious impulses which are not sexual, but they can never be without a sexual significance.

Among these various definitions the seventh brings out the nature of hysterical symptoms most completely as the realization of an unconscious phantasy; and the eighth recognizes the proper significance of the sexual factor. Some of the preceding formulas lead up to these two and are contained in them.

(9) Hysterical symptoms are the expression on the one hand of a masculine unconscious sexual phantasy, and on the other hand of a feminine one.

I must expressly state that I cannot claim the same general validity for this formula as I have done for the others. As far as I can see, it applies neither to all the symptoms of a given case nor to all cases. On the contrary, it is not hard to adduce cases in which the impulses belonging to the opposite sexes have found separate symptomatic expression, so that the symptoms of heterosexuality and those of homosexuality can be as clearly distinguished from each other as the phantasies concealed behind them. Nevertheless, the condition of things stated in the ninth formula is common enough, and, when it occurs, important enough to deserve special emphasis. It seems to me to mark the highest degree of complexity to which the determination of a hysterical symptom can attain, and one may therefore only expect to find it in a neurosis which has persisted for a long time and within which a great deal of organization has taken place.
If this idea of a woman with a penis becomes 'fixated' in an individual when he is a child, resisting all the influences of later life and making him as a man unable to do without a penis in his sexual object, then, although in other respects he may lead a normal sexual life, he is bound to become a homosexual, and will seek his sexual object among men who, owing to some other physical and mental characteristics, remind him of women. Real women, when he comes to know them later, remain impossible as sexual objects for him, because they lack the essential sexual attraction; indeed, in connection with another impression of his childhood life, they may even become abhorrent to him. The child, having been mainly dominated by excitations in the penis, will usually have obtained pleasure by stimulating it with his hand; he will have been detected in this by his parents or nurse and terrorized by the threat of having his penis cut off. The effect of this 'threat of castration' is proportionate to the value set upon that organ and is quite extraordinarily deep and persistent. Legends and myths testify to the upheaval in the child's emotional life and to the horror which is linked with the castration complex - a complex which is subsequently remembered by consciousness with corresponding reluctance. The woman's genitalia, when seen later on, are regarded as a mutilated organ and recall this threat, and they therefore arouse horror instead of pleasure in the homosexual. This reaction cannot be altered in any way when the homosexual comes to learn from science that his childish assumption that women had a penis too was not so far wrong after all. Anatomy has recognized the clitoris within the female pudenda as being an organ that is homologous to the penis; and the physiology of the sexual processes has been able to add that this small penis which does not grow any bigger behaves in fact during childhood like a real and genuine penis - that it becomes the seat of excitations which lead to its being touched, that its excitability gives the little girl's sexual activity a masculine character and that a wave of repression in the years of puberty is needed in order for this masculine sexuality to be discarded and the woman to emerge. Since the sexual function of many women is crippled, whether by their obstinate clinging on to this excitability of the clitoris so that they remain anaesthetic in intercourse, or by such excessive repression occurring that its operation is partly replaced by hysterical compensatory formations - all this seems to show that there is some truth in the infantile sexual theory that women, like men, possess a penis.

[1908c, 1971]

The onset of hysterical attacks follows laws that are easily understandable. Since the repressed complex consists of a libidinal cathexis and an ideational content (the phantasy), the attack can be evoked (1) associatively, when the content of the complex (if sufficiently cathected) is touched on by something connected with it in conscious life; (2) organically, when, for internal somatic reasons and as a result of psychical influences from outside, the libidinal cathexis rises above a certain degree; (3) in the service of the primary purpose - as an expression of a 'flight into illness', when reality becomes distressing or frightening - that is, as a consolation; (4) in the service of the secondary purposes, with which the illness allies itself, as soon as, by producing an attack, the patient can achieve an aim that is useful to him. In the last case the attack is directed at particular individuals; it can be put off till they are present, and it gives an impression of being consciously simulated.

[1909a, 1983]
Investigation of the childhood history of hysterical patients shows that the hysterical attack is designed to take the place of an auto-erotic satisfaction previously practised and since given up. In a great number of cases this satisfaction (masturbation by contact or by pressure of the thighs, or, again, by movements of the tongue, and so on) recurs during the attack itself, while the subject's consciousness is deflected. Moreover, the onset of an attack that is due to an increase of libido and is in the service of the primary purpose - as a consolation - exactly repeats the conditions under which, at the earlier time, the patient had intentionally sought this auto-erotic satisfaction. The anamnesis of the patient shows the following stages: (a) auto-erotic satisfaction, without ideational content; (b) the same satisfaction, connected with a phantasy which leads to the act of satisfaction; (c) renunciation of the act, with retention of the phantasy; (d) repression of the phantasy, which then comes into effect as a hysterical attack, either in an unchanged form, or in a modified one and adapted to new environmental impressions. Furthermore, (e) the phantasy may even reinstitute the act of satisfaction belonging to it which had ostensibly been given up. This is a typical cycle of infantile sexual activity: repression, failure of repression, and return of the repressed.

[1909a, 1983]

Speaking as a whole, hysterical attacks, like hysteria in general, revive a piece of sexual activity in women which existed during their childhood and at that time revealed an essentially masculine character. It can often be observed that girls who have shown a boyish nature and inclinations up to the years before puberty are precisely those who become hysterical from puberty onwards. In a whole number of cases the hysterical neurosis merely represents an excessive accentuation of the typical wave of repression which, by doing away with her masculine sexuality, allows the woman to emerge.

[1909a, 1984]

A sexual constitution like that of little Hans does not appear to carry with it a predisposition to the development either of perversions or of their negative (we will limit ourselves to a consideration of hysteria). As far as my experience goes (and there is still a real need for speaking with caution on this point) the innate constitution of hysterics - that this is also true of perverts is almost self-evident - is marked by the genital zone being relatively less prominent than the other erotogenic zones. But we must expressly except from this rule one particular 'aberration' of sexual life. In those who later become homosexuals we meet with the same predominance in infancy of the genital zone (and especially of the penis) as in normal persons. Indeed it is the high esteem felt by the homosexual for the male organ which decides his fate. In his childhood he chooses women as his sexual object, so long as he assumes that they too possess what in his eyes is an indispensable part of the body; when he becomes convinced that women have deceived him in this particular, they cease to be acceptable to him as a sexual object. He cannot forgo a penis in any one who is to attract him to sexual intercourse; and if circumstances are favourable he will fix his libido upon the 'woman with a penis', a youth of feminine appearance. Homosexuals, then, are persons who, owing to the erotogenic importance of their own genitals, cannot do without a similar feature in their sexual object. In the course of their development from auto-erotism to object-love, they have remained at a point of fixation between the two.

[1909b, 2093]
(1) Our first reflection will tell us that it cannot be the case that this detachment of the libido occurs exclusively in paranoia; nor can it be that, where it occurs elsewhere, it has such disastrous consequences. It is quite possible that a detachment of the libido is the essential and regular mechanism of every repression. We can have no positive knowledge on that point until the other disorders that are based upon repression have been similarly examined. But it is certain that in normal mental life (and not only in periods of mourning) we are constantly detaching our libido in this way from people or from other objects without falling ill. When Faust freed himself from the world by uttering his curses, the result was not a paranoia or any other neurosis but simply a certain general frame of mind. The detachment of the libido, therefore, cannot in itself be the pathogenic factor in paranoia; there must be some special characteristic which distinguishes a paranoid detachment of the libido from other kinds. It is not difficult to suggest what that characteristic may be. What use is made of the libido after it has been set free by the process of detachment? A normal person will at once begin looking about for a substitute for the lost attachment; and until that substitute has been found the liberated libido will be kept in suspension within his mind, and will there give rise to tensions and colour his mood. In hysteria the liberated libido becomes transformed into somatic innervations or into anxiety. But in paranoia the clinical evidence goes to show that the libido, after it has been withdrawn from the object, is put to a special use. It will be remembered that the majority of cases of paranoia exhibit traces of megalomania, and that megalomania can by itself constitute a paranoia. From this it may be concluded that in paranoia the liberated libido becomes attached to the ego, and is used for the aggrandizement of the ego. A return is thus made to the stage of narcissism (known to us from the development of the libido), in which a person's only sexual object is his own ego. On the basis of this clinical evidence we can suppose that paranoics have brought along with them a fixation at the stage of narcissism, and we can assert that the length of the step back from sublimated homosexuality to narcissism is a measure of the amount of regression characteristic of paranoia.
[1911c, 2438]

LADIES AND GENTLEMEN, - One would certainly have supposed that there could be no doubt as to what is to be understood by 'sexual'. First and foremost, what is sexual is something improper, something one ought not to talk about. I have been told that the pupils of a celebrated psychiatrist made an attempt once to convince their teacher of how frequently the symptoms of hysterical patients represent sexual things. For this purpose they took him to the bedside of a female hysterical, whose attacks were an unmistakable imitation of the process of childbirth. But with a shake of his head he remarked: 'Well, there's nothing sexual about childbirth.' Quite right. Childbirth need not in every case be something improper.
[1916-1917, 3375]
Thus forearmed we can proceed to the consideration of a suggestion which we shall certainly not be spared. 'Why', we shall be asked, 'are you so obstinate in describing as being already sexuality what on your own evidence are indefinable manifestations in childhood out of which sexual life will later develop? Why should you not be content instead with giving them a physiological description and simply say that in an infant at the breast we already observe activities, such as sensual sucking or holding back the excreta, which show us that he is striving for "organ-pleasure"? In that way you would have avoided the hypothesis, so repugnant to every feeling, of the smallest babies having a sexual life.' - Indeed, Gentlemen, I have no objection at all to organ-pleasure. I know that even the supreme pleasure of sexual union is only an organ-pleasure attached to the activity of the genitals. But can you tell me when this originally indifferent organ-pleasure acquires the sexual character which it undoubtedly possesses in the later phases of development? Do we know any more about 'organ-pleasure' than about sexuality? You will reply that it gains its sexual character precisely when the genitals begin to play their part; 'sexual' coincides with 'genital'. You will even reject the objection raised by the perversions by pointing out to me that in the majority of perversions a genital orgasm is after all aimed at, even if it is arrived at by a method other than the union of the genitals. You are certainly taking up a much stronger position in determining the characteristics of what is sexual if you knock out of it the relation to reproduction which is made untenable by the perversions and put genital activity in its place. But, if so, we are no longer far apart: it is only a question of the genital organs versus the other organs. What are you going to do, however, about the numerous experiences which show you that the genitals can be represented as regards their yield of pleasure by other organs, as in the case of kissing or of the perverse practices of voluptuaries or of the symptoms of hysteria? In that neurosis it is quite usual for signs of stimulation, sensations and innervations, and even the processes of erection, which belong properly to the genitals, to be displaced on to other, remote regions of the body - as, for instance, by transposition upwards, to the head and face. Being thus convinced that you have nothing to catch hold of for your characterization of what is sexual, you will no doubt have to make up your minds to follow my example and extend the description of being 'sexual' to the activities of early childhood, too, which strive for organ-pleasure.

A noteworthy relation between the symptoms of the 'actual' neuroses and of the psychoneuroses makes a further important contribution to our knowledge of the formation of symptoms in the latter. For a symptom of an 'actual' neurosis is often the nucleus and first stage of a psychoneurotic symptom. A relation of this kind can be most clearly observed between neurasthenia and the transference neurosis known as 'conversion hysteria', between anxiety neurosis and anxiety hysteria, but also between hypochondria and the forms of disorder which will be mentioned later under the name of paraphrenia (dementia praecox and paranoia). Let us take as an example a case of hysterical headache or lumbar pain. Analysis shows us that, by condensation and displacement, it has become a substitutive satisfaction for a whole number of libidinal phantasies or memories. But this pain was also at one time a real one and it was then a direct sexual-toxic symptom, the somatic expression of a libidinal excitation. We are far from asserting that all hysterical symptoms contain a nucleus of this kind. But it remains a fact that this is especially often the case and that whatever somatic influences (whether normal or pathological) are brought about by libidinal excitation are preferred for the construction of hysterical symptoms. In such cases they play the part of the grain of sand which a mollusc coats with layers of mother-of-pearl. In the same way, the passing indications of sexual excitement which accompany the sexual act are employed by the psychoneurosis as the most convenient and appropriate material for the construction of symptoms.
The Aetiological Significance of Sexual Life. - The second novelty which emerged after the hypnotic technique had been replaced by free associations was of a clinical nature. It was discovered in the course of the prolonged search for the traumatic experiences from which hysterical symptoms appeared to be derived. The more carefully the search was pursued the more extensive seemed to be the network of aetiologically significant impressions involved, but the further back, too, did they reach into the patient's puberty or childhood. At the same time they assumed a uniform character and eventually it became inevitable to bow before the evidence and recognize that at the root of the formation of every symptom there were to be found traumatic experiences from early sexual life. Thus a sexual trauma stepped into the place of an ordinary trauma and the latter was seen to owe its aetiological significance to an associative or symbolic connection with the former, which had preceded it. An investigation of cases of common nervousness (falling into the two classes of neurasthenia and anxiety neurosis) which was simultaneously undertaken led to the conclusion that these disorders could be traced to contemporary abuses in the patients' sexual life and could be removed if these were brought to an end. It was thus easy to infer that neuroses in general are an expression of disturbances in sexual life, the so-called actual-neuroses being the consequences (by chemical agency) of contemporary injuries and the psycho-neuroses the consequences (by psychical modification) of bygone injuries to a biological function which had hitherto been gravely neglected by science. None of the theses of psycho-analysis has met with such tenacious scepticism or such embittered resistance as this assertion of the preponderating aetiological significance of sexual life in the neuroses. It should, however, be expressly remarked that, in its development up to the present day, psycho-analysis has found no reason to retreat from this opinion.

[1923a, 3920]

In order to reach even half way to an understanding of how, in a hysterical girl, a forbidden sexual wish can change into a painful symptom, it had been necessary to make far-reaching and complicated hypotheses about the structure and functioning of the mental apparatus. There was an evident contradiction here between expenditure of effort and result. If the conditions postulated by psycho-analysis really existed, they were of a fundamental nature and must be able to find expression in other phenomena besides hysterical ones. But if this inference were correct, psycho-analysis would have ceased to be of interest only to neurologists; it could claim the attention of everyone to whom psychological research was of any importance. Its findings would not only have to be taken into account in the field of pathological mental life but could not be overlooked either in coming to an understanding of normal functioning.

[1924f, 4108]
If the account I have so far given has led the reader to expect that the *Studies on Hysteria* must, in all essentials of their material content, be the product of Breuer's mind, that is precisely what I myself have always maintained and what it has been my aim to repeat here. As regards the *theory* put forward in the book, I was partly responsible, but to an extent which it is to-day no longer possible to determine. That theory was in any case unpretentious and hardly went beyond the direct description of the observations. It did not seek to establish the nature of hysteria but merely to throw light upon the origin of its symptoms. Thus it laid stress upon the significance of the life of the emotions and upon the importance of distinguishing between mental acts which are unconscious and those which are conscious (or rather capable of being conscious); it introduced a dynamic factor, by supposing that a symptom arises through the damming-up of an affect, and an economic factor, by regarding that same symptom as the product of the transformation of an amount of energy which would otherwise have been employed in some other way. (This latter process was described as *conversion.*) Breuer spoke of our method as *cathartic*; its therapeutic aim was explained as being to provide that the quota of affect used for maintaining the symptom, which had got on to the wrong lines and had, as it were, become strangulated there, should be directed on to the normal path along which it could obtain discharge (or *abreaction*). The practical results of the cathartic procedure were excellent. Its defects, which became evident later, were those of all forms of hypnotic treatment. There are still a number of psychotherapists who have not gone beyond catharsis as Breuer understood it and who still speak in its favour. Its value as an abridged method of treatment was shown afresh by Simmel in his treatment of war neuroses in the German army during the Great War. The theory of catharsis had not much to say on the subject of sexuality. In the case histories which I contributed to the *Studies* sexual factors played a certain part, but scarcely more attention was paid to them than to other emotional excitations. Breuer wrote of the girl, who has since become famous as his first patient, that her sexual side was extraordinarily undeveloped. It would have been difficult to guess from the *Studies on Hysteria* what an importance sexuality has in the aetiology of the neuroses.

[1925d, 4200]
(e) It follows from what has been said that there remains for hysteria an intimate relation to the
final phase of libidinal development, which is characterized by the primacy of the genitals and
the introduction of the reproductive function. In hysterical neurosis this acquisition is subjected
to repression, which does not involve regression to the pregenital stage. The gap in determining
the disposition owing to our ignorance of ego development is even more obvious here than with
obsessional neurosis.
[1913i, 2631]

On the other hand, it is not hard to show that another regression to an earlier level occurs in
hysteria too. The sexuality of female children, is, as we know, dominated and directed by a
masculine organ (the clitoris) and often behaves like the sexuality of boys. This masculine
sexuality has to be got rid of by a last wave of development at puberty, and the vagina, an
organ derived from the cloaca, has to be raised into the dominant erotogenic zone. Now, it is
very common in hysterical neurosis for this repressed masculine sexuality to be re-activated
and then for the defensive struggle on the part of the ego-syntonic instincts to be directed
against it. But it seems to me too early to enter here into a discussion of the problems of the
disposition to hysteria.
[1913i, 2631]

Discussions like this, Gentlemen, are bound to become some what arid. So let us turn to
clinical material in order to find applications of it that will be a little more impressive. Hysteria
and obsessional neurosis are, as you know, the two chief representatives of the group of
transference neuroses. Now it is true that in hysteria there is a regression of the libido to the
primary incestuous sexual objects and that this occurs quite regularly; but there is as good as
no regression to an earlier stage of the sexual organization. To offset this, the chief part in the
mechanism of hysteria is played by repression. If I might venture to complete what we already
know for certain about this neurosis by making a construction, I might explain the position thus.
The unification of the component instincts under the primacy of the genitals has been
accomplished; but its results come up against the resistance of the preconscious system which
is linked with consciousness. Thus the genital organization holds good for the unconscious, but
not in the same way for the preconscious; and this rejection on the part of the preconscious
brings about a picture which has certain resemblances to the state of things before genital
primacy. But it is nevertheless something quite different.
[1916-1917, 3406]
And now for the true exciting cause of the dream. It had been a hot summer afternoon; and during the evening I had delivered my lecture on the connection between hysteria and the perversions, and everything I had had to say displeased me intensely and seemed to me completely devoid of any value. I was tired and felt no trace of enjoyment in my difficult work; I longed to be away from all this grubbing about in human dirt and to be able to join my children and afterwards visit the beauties of Italy. In this mood I went from the lecture room to a café, where I had a modest snack in the open air, since I had no appetite for food. One of my audience, however, went with me and he begged leave to sit by me while I drank my coffee and choked over my crescent roll. He began to flatter me: telling me how much he had learnt from me, how he looked at everything now with fresh eyes, how I had cleansed the Augean stables of errors and prejudices in my theory of the neuroses. He told me, in short, that I was a very great man. My mood fitted ill with this paean of praise; I fought against my feeling of disgust, went home early to escape from him, and before going to sleep turned over the pages of Rabelais and read one of Conrad Ferdinand Meyer's short stories, 'Die Leiden eines Knaben' ['A Boy's Sorrows'].

It is worth remarking that we have here three symptoms - the disgust, the sensation of pressure on the upper part of the body, and the avoidance of men engaged in affectionate conversation - all of them derived from a single experience, and that it is only by taking into account the interrelation of these three phenomena that we can understand the way in which the formation of the symptoms came about. The disgust is the symptom of repression in the erotogenic oral zone, which, as we shall hear, had been over-indulged in Dora's infancy by the habit of sensual sucking. The pressure of the erect member probably led to an analogous change in the corresponding female organ, the clitoris; and the excitation of this second erotogenic zone was referred by a process of displacement to the simultaneous pressure against the thorax and became fixed there. Her avoidance of men who might possibly be in a state of sexual excitement follows the mechanism of a phobia, its purpose being to safeguard her against any revival of the repressed perception.

[1900a, 913]

[1905e, 1370]
An opportunity very soon occurred for interpreting Dora's nervous cough in this way by means of an imagined sexual situation. She had once again been insisting that Frau K. only loved her father because he was 'ein vermögender Mann' ['a man of means']. Certain details of the way in which she expressed herself (which I pass over here, like most other purely technical parts of the analysis) led me to see that behind this phrase its opposite lay concealed, namely, that her father was 'ein unvermögender Mann' ['a man without means']. This could only be meant in a sexual sense - that her father, as a man, was without means, was impotent.¹ Dora confirmed this interpretation from her conscious knowledge; whereupon I pointed out the contradiction she was involved in if on the one hand she continued to insist that her father's relation with Frau K. was a common love-affair, and on the other hand maintained that her father was impotent, or in other words incapable of carrying on an affair of such a kind. Her answer showed that she had no need to admit the contradiction. She knew very well, she said, that there was more than one way of obtaining sexual gratification. (The source of this piece of knowledge, however, was once more untraceable.) I questioned her further, whether she referred to the use of organs other than the genitals for the purpose of sexual intercourse, and she replied in the affirmative. I could then go on to say that in that case she must be thinking of precisely those parts of the body which in her case were in a state of irritation, - the throat and the oral cavity. To be sure, she would not hear of going so far as this in recognizing her own thoughts; and indeed, if the occurrence of the symptom was to be made possible at all, it was essential that she should not be completely clear on the subject. But the conclusion was inevitable that with her spasmodic cough, which, as is usual, was referred for its exciting stimulus to a tickling in her throat, she pictured to herself a scene of sexual gratification per os between the two people whose love-affair occupied her mind so incessantly. A very short time after she had tacitly accepted this explanation her cough vanished - which fitted in very well with my view; but I do not wish to lay too much stress upon this development, since her cough had so often before disappeared spontaneously.

¹ [1905e, 1384]
As regards the second kind of emotional reaction, which is not directed against me this time, but against my patient - supposing that my view of her is correct - and which regards the perverse nature of her phantasies as horrible, I should like to say emphatically that a medical man has no business to indulge in such passionate condemnation. I may also remark in passing that it seems to me superfluous for a physician who is writing upon the aberrations of the sexual instincts to seize every opportunity of inserting into the text expressions of his personal repugnance at such revolting things. We are faced by a fact; and it is to be hoped that we shall grow accustomed to it, when we have put our own tastes on one side. We must learn to speak without indignation of what we call the sexual perversions - instances in which the sexual function has extended its limits in respect either to the part of the body concerned or to the sexual object chosen. The uncertainty in regard to the boundaries of what is to be called normal sexual life, when we take different races and different epochs into account, should in itself be enough to cool the zealot's ardour. We surely ought not to forget that the perversion which is the most repellent to us, the sensual love of a man for a man, was not only tolerated by a people so far our superiors in cultivation as were the Greeks, but was actually entrusted by them with important social functions. The sexual life of each one of us extends to a slight degree - now in this direction, now in that - beyond the narrow lines imposed as the standard of normality. The perversions are neither bestial nor degenerate in the emotional sense of the word. They are a development of germs all of which are contained in the undifferentiated sexual disposition of the child, and which, by being suppressed or by being diverted to higher, asexual aims - by being 'sublimated' - are destined to provide the energy for a great number of our cultural achievements. When, therefore, any one has become a gross and manifest pervert, it would be more correct to say that he has remained one, for he exhibits a certain stage of inhibited development. All psychoneurotics are persons with strongly marked perverse tendencies, which have been repressed in the course of their development and have become unconscious. Consequently their unconscious phantasies show precisely the same content as the documentarily recorded actions of perverts - even though they have not read Krafft-Ebing's Psychopathia Sexualis, to which simple-minded people attribute such a large share of the responsibility for the production of perverse tendencies. Psychoneuroses are, so to speak, the negative of perversions. In neurotics their sexual constitution, under which the effects of heredity are included, operates in combination with any accidental influences in their life which may disturb the development of normal sexuality. A stream of water which meets with an obstacle in the river-bed is dammed up and flows back into old channels which had formerly seemed fated to run dry. The motive forces leading to the formation of hysterical symptoms draw their strength not only from repressed normal sexuality but also from unconscious perverse activities.¹

[1905e, 1387]
I must now turn to consider a further complication to which I should certainly give no space if I were a man of letters engaged upon the creation of a mental state like this for a short story, instead of being a medical man engaged upon its dissection. The element to which I must now allude can only serve to obscure and efface the outlines of the fine poetic conflict which we have been able to ascribe to Dora. This element would rightly fall a sacrifice to the censorship of a writer, for he, after all, simplifies and abstracts when he appears in the character of a psychologist. But in the world of reality, which I am trying to depict here, a complication of motives, an accumulation and conjunction of mental activities - in a word, overdetermination - is the rule. For behind Dora's supervalent train of thought which was concerned with her father's relations with Frau K. there lay concealed a feeling of jealousy which had that lady as its object - a feeling, that is, which could only be based upon an affection on Dora's part for one of her own sex. It has long been known and often been pointed out that at the age of puberty boys and girls show clear signs, even in normal cases, of the existence of an affection for people of their own sex. A romantic and sentimental friendship with one of her school friends, accompanied by vows, kisses, promises of eternal correspondence, and all the sensibility of jealousy, is the common precursor of a girl's first serious passion for a man. Thenceforward, in favourable circumstances, the homosexual current of feeling often runs completely dry. But if a girl is not happy in her love for a man, the current is often set flowing again by the libido in later years and is increased up to a greater or lesser degree of intensity. If this much can be established without difficulty of healthy persons, and if we take into account what has already been said about the fuller development in neurotics of the normal germs of perversion, we shall expect to find in these latter too a fairly strong homosexual predisposition. It must, indeed, be so; for I have never yet come through a single psycho-analysis of a man or a woman without having to take into account a very considerable current of homosexuality. When, in a hysterical woman or girl, the sexual libido which is directed towards men has been energetically suppressed, it will regularly be found that the libido which is directed towards women has become vicariously reinforced and even to some extent conscious. [1905e, 1397]
I shall not in this place go any further into this important subject, which is especially indispensable to an understanding of hysteria in men, because Dora's analysis came to an end before it could throw any light on this side of her mental life. But I should like to recall the governess, whom I have already mentioned, and with whom Dora had at first enjoyed the closest interchange of thought, until she discovered that she was being admired and fondly treated not for her own sake but for her father's; whereupon she had obliged the governess to leave. She used also to dwell with noticeable frequency and a peculiar emphasis on the story of another estrangement which appeared inexplicable even to herself. She had always been on particularly good terms with the younger of her two cousins the girl who had later on become engaged - and had shared all sorts of secrets with her. When, for the first time after Dora had broken off her stay by the lake, her father was going back to B--, she had naturally refused to go with him. This cousin had then been asked to travel with him instead, and she had accepted the invitation. From that time forward Dora had felt a coldness towards her, and she herself was surprised to find how indifferent she had become, although, as she admitted, she had very little ground for complaint against her. These instances of sensitiveness led me to inquire what her relations with Frau K. had been up till the time of the breach. I then found that the young woman and the scarcely grown girl had lived for years on a footing of the closest intimacy. When Dora stayed with the K.’s she used to share a bedroom with Frau K., and the husband used to be quartered elsewhere. She had been the wife's confidante and adviser in all the difficulties of her married life. There was nothing they had not talked about. Medea had been quite content that Creusa should make friends with her two children; and she certainly did nothing to interfere with the relations between the girl and the children's father. How Dora managed to fall in love with the man about whom her beloved friend had so many bad things to say is an interesting psychological problem. We shall not be far from solving it when we realize that thoughts in the unconscious live very comfortably side by side, and even contraries get on together without disputes - a state of things which persists often enough even in the conscious.

[1905e, 1398]
When Dora talked about Frau K., she used to praise her 'adorable white body' in accents more appropriate to a lover than to a defeated rival. Another time she told me, more in sorrow than in anger, that she was convinced the presents her father had brought her had been chosen by Frau K., for she recognized her taste. Another time, again, she pointed out that, evidently through the agency of Frau K., she had been given a present of some jewellery which was exactly like some that she had seen in Frau K.'s possession and had wished for aloud at the time. Indeed, I can say in general that I never heard her speak a harsh or angry word against the lady, although from the point of view of her supervalent thought she should have regarded her as the prime author of her misfortunes. She seemed to behave inconsequently; but her apparent inconsequence was precisely the manifestation of a complicating current of feeling. For how had this woman to whom Dora was so enthusiastically devoted behaved to her? After Dora had brought forward her accusation against Herr K., and her father had written to him and had asked for an explanation, Herr K. had replied in the first instance by protesting sentiments of the highest esteem for her and by proposing that he should come to the manufacturing town to clear up every misunderstanding. A few weeks later, when her father spoke to him at B--, there was no longer any question of esteem. On the contrary, Herr K. spoke of her with disparagement, and produced as his trump card the reflection that no girl who read such books and was interested in such things could have any title to a man's respect. Frau K., therefore, had betrayed her and had calumniated her; for it had only been with her that she had read Mantegazza and discussed forbidden topics. It was a repetition of what had happened with the governess: Frau K. had not loved her for her own sake but on account of her father. Frau K. had sacrificed her without a moment's hesitation so that her relations with her father might not be disturbed. This mortification touched her, perhaps, more nearly and had a greater pathogenic effect than the other one, which she tried to use as a screen for it, - the fact that she had been sacrificed by her father. Did not the obstinacy with which she retained the particular amnesia concerning the sources of her forbidden knowledge point directly to the great emotional importance for her of the accusation against her upon that score, and consequently to her betrayal by her friend?

I believe, therefore, that I am not mistaken in supposing that Dora's supervalent train of thought, which was concerned with her father's relations with Frau K., was designed not only for the purpose of suppressing her love for Herr K., which had once been conscious, but also to conceal her love for Frau K., which was in a deeper sense unconscious. The supervalent train of thought was directly contrary to the latter current of feeling. She told herself incessantly that her father had sacrificed her to this woman, and made noisy demonstrations to show that she grudged her the possession of her father; and in this was she concealed from herself the contrary fact, which was that she grudged her father Frau K.'s love, and had not forgiven the woman she loved for the disillusionment she had been caused by her betrayal. The jealous emotions of a woman were linked in the unconscious with a jealousy such as might have been felt by a man. These masculine or, more properly speaking, gynaecophilic currents of feeling are to be regarded as typical of the unconscious erotic life of hysterical girls.

[1905e, 1399]

[1905e, 1400]
I may here add a few supplementary interpretations to those that have already been given: The 'Madonna' was obviously Dora herself; in the first place because of the 'adorer' who had sent her the pictures, in the second place because she had won Herr K.'s love chiefly by the motherliness she had shown towards his children, and lastly because she had had a child though she was still a girl (this being a direct allusion to the phantasy of childbirth). Moreover, the notion of the 'Madonna' is a favourite counter-idea in the mind of girls who feel themselves oppressed by imputations of sexual guilt, - which was the case with Dora. A first suspicion of this connection came to me while I was working as a physician at the Psychiatric Clinic of the University. I there came across a case of confusional insanity with hallucinations, in which the attack, which ran a rapid course, turned out to be a reaction to a reproach made against the patient by her fiancé. - If the analysis had been continued, Dora's maternal longing for a child would probably have been revealed as an obscure though powerful motive in her behaviour. The numerous questions which she had been raising lately seem to have been belated derivatives of questions inspired by the sexual curiosity which she had tried to gratify with the encyclopaedia. The subjects which she read up in it were presumably pregnancy, childbirth, virginity, and so on. - In reproducing the dream Dora had forgotten one of the questions which need to be inserted into the course of the second situation in the dream. This question could only be: 'Does Herr -- live here?' or "Where does Herr -- live?" There must have been some reason for her having forgotten this apparently innocent question, especially as she need not have brought it into the dream at all. This reason, it seems to me, lay in her surname itself, which also denoted an object and in fact more than one kind of object, and which could therefore be regarded as an 'ambiguous' word. Unluckily I cannot give the name and show how well designed it was to indicate something 'ambiguous' and 'improper'. This interpretation was supported by the discovery of a similar play upon words in another part of the dream, where the material was derived from Dora's recollections of her aunt's death ('they have already gone to the cemetery') and where there was similarly a play upon her aunt's name. These improper words seemed to point to a second and oral source of information, since the encyclopaedia would not cover them. I should not have been surprised to hear that this source had been Frau K. herself, Dora's calumniator. In that case she would have been the one person whom Dora generously spared, while she pursued the others with an almost malignant vindictiveness. Behind the almost limitless series of displacements which were thus brought to light, it was possible to divine the operation of a single simple factor - Dora's deep-rooted homosexual love for Frau K.

I will add a few remarks on the structure of this dream, though it is not possible to understand it thoroughly enough to allow of a synthesis being attempted. A prominent piece of the dream is to be seen in the phantasy of revenge against her father, which stands out like a façade in front of the rest. (She had gone away from home by her own choice; her father was ill, and then dead. . . Then she went home; all the others were already at the cemetery. She went to her room, not the least sadly, and calmly began reading the encyclopaedia.) This part of the material also contained two allusions to her other act of revenge, which she had actually carried out, when she let her parents discover a farewell letter from her. (The letter - from her mother, in the dream and the mention of the funeral of the aunt who had always been her model.) Behind this phantasy lie concealed her thoughts of revenge against Herr K., for which she found an outlet in her behaviour to me. (The maidservant, the invitation, the wood, the two and a half hours - all these came from material connected with the events at L--.) Her recollection of the governess, and of the latter's exchange of letters with her parents, is related, no less than her farewell letter, to the letter in the dream allowing her to come home. Her refusal to let herself be accompanied and her decision to go alone may perhaps be translated into these words: 'Since you have treated me like a servant, I shall take no more notice of you, I shall go my own way by myself, and not marry.' - Screened by these thoughts of revenge, glimpses can be caught in other places of material derived from tender phantasies based upon the love for Herr K. which still persisted unconsciously in Dora, ('I would have waited for you till I could be your wife' - defloration - childbirth.) - Finally, we can see the action of the fourth and most deeply buried group of thoughts - those relating to her love for Frau K. - in the fact that the phantasy of defloration is represented from the man's point of view (her identification of herself with her admirer who lived abroad) and in the fact that in two places there are the clearest allusions to ambiguous speeches ('Does Herr -- live here?') and to that source of her sexual knowledge which had not been oral (the encyclopaedia). - Cruel and sadistic tendencies find satisfaction in this dream.

[1905e, 1439, 1445]
¹ The longer the interval of time that separates me from the end of this analysis, the more probable it seems to me that the fault in my technique lay in this omission: I failed to discover in time and to inform the patient that her homosexual (gynaecophilic) love for Frau K. was the strongest unconscious current in her mental life. I ought to have guessed that the main source of her knowledge of sexual matters could have been no one but Frau K. - the very person who later on charged her with being interested in those same subjects. Her knowing all about such things and, at the same time, her always pretending not to know where her knowledge came from was really too remarkable. I ought to have attacked this riddle and looked for the motive of such an extraordinary piece of repression. If I had done this, the second dream would have given me my answer. The remorseless craving for revenge expressed in that dream was suited as nothing else was to conceal the current of feeling that ran contrary to it - the magnanimity with which she forgave the treachery of the friend she loved and concealed from every one the fact that it was this friend who had herself revealed to her the knowledge which had later been the ground of the accusations against her. Before I had learnt the importance of the homosexual current of feeling in psychoneurotics, I was often brought to a standstill in the treatment of my cases or found myself in complete perplexity.

[1905e, 1453]

The hereditary conditions in the case of positive perverts are less well known, for they know how to avoid investigation. Yet there are good reasons to suppose that what is true of the neuroses applies also to the perversions. For it is no rare thing to find perversions and psychoneuroses occurring in the same family, and distributed between the two sexes in such a way that the male members of the family, or one of them, are positive perverts, while the females, true to the tendency of their sex to repression, are negative perverts, that is, hysterics. This is good evidence of the essential connections which we have shown to exist between the two disorders.

[1905d, 1546]

I think it is worth emphasizing the fact that, whatever modifications my views on the aetiology of the psychoneuroses have passed through, there are two positions which I have never repudiated or abandoned - the importance of sexuality and of infantilism. Apart from this, accidental influences have been replaced by constitutional factors and 'defence' in the purely psychological sense has been replaced by organic 'sexual repression'. The question may, however, be raised of where convincing evidence is to be found in favour of the alleged aetiological importance of sexual factors in the psychoneuroses, in view of the fact that the onset of these illnesses may be observed in response to the most commonplace emotions or even to somatic precipitating causes, and since I have had to abandon a specific aetiology depending on the particular form of the childhood experiences concerned. To such a question I would reply that the psycho-analytic examination of neurotics is the source from which this disputed conviction of mine is derived. If we make use of that irreplaceable method of research, we discover that the patient's symptoms constitute his sexual activity (whether wholly or in part), which arises from the sources of the normal or perverse component instincts of sexuality. Not only is a large part of the symptomatology of hysteria derived directly from expressions of sexual excitement, not only do a number of erotogenic zones attain the significance of genitals during neuroses owing to an intensification of infantile characteristics, but the most complicated symptoms are themselves revealed as representing, by means of 'conversion', phantasies which have a sexual situation as their subject-matter. Anyone who knows how to interpret the language of hysteria will recognize that the neurosis is concerned only with the patient's repressed sexuality. The sexual function must, however, be understood in its true extent, as it is laid down by disposition in infancy. Wherever some commonplace emotion must be included among the determinants of the onset of the illness, analysis invariably shows that it is the sexual component of the traumatic experience - a component that is never lacking which has produced the pathogenic result.

[1906a, 1582]
In this way, unconscious phantasies are the immediate psychical precursors of a whole number of hysterical symptoms. Hysterical symptoms are nothing other than unconscious phantasies brought into view through “conversion”; and in so far as the symptoms are somatic ones, they are often enough taken from the circle of the same sexual sensations and motor innervations as those which had originally accompanied the phantasy when it was still conscious. In this way the giving up of the habit of masturbation is in fact undone, and the purpose of the whole pathological process, which is a restoration of the original, primary sexual satisfaction, is achieved - though never completely, it is true, but always in a sort of approximation. [1908a, 1935]

This method of psycho-analytic investigation, which leads from the conspicuous symptoms to the hidden unconscious phantasies, tells us everything that can be known about the sexuality of psychoneurotics, including the fact which is to be the main subject-matter of this short preliminary publication. [1908a, 1935]

(6) Hysterical symptoms correspond to a return of a mode of sexual satisfaction which was a real one in infantile life and has since been repressed. [1908a, 1936]

This connection between symptoms and phantasies makes it easy to arrive from a psycho-analysis of the former at a knowledge of the components of the sexual instincts which dominate the individual, as I have demonstrated in my Three Essays on the Theory of Sexuality. In some cases, however, investigation by this means yields an unexpected result. It shows that there are many symptoms where the uncovering of a sexual phantasy (or of a number of phantasies, one of which, the most significant and the earliest, is of a sexual nature) is not enough to bring about a resolution of the symptoms. To resolve it one has to have two sexual phantasies, of which one has a masculine and the other a feminine character. Thus one of these phantasies springs from a homosexual impulse. This new finding does not alter our seventh formula. It remains true that a hysterical symptom must necessarily represent a compromise between a libidinal and a repressing impulse; but it may also represent a union of two libidinal phantasies of an opposite sexual character. [1908a, 1937]

I must expressly state that I cannot claim the same general validity for this formula as I have done for the others. As far as I can see, it applies neither to all the symptoms of a given case nor to all cases. On the contrary, it is not hard to adduce cases in which the impulses belonging to the opposite sexes have found separate symptomatic expression, so that the symptoms of heterosexuality and those of homosexuality can be as clearly distinguished from each other as the phantasies concealed behind them. Nevertheless, the condition of things stated in the ninth formula is common enough, and, when it occurs, important enough to deserve special emphasis. It seems to me to mark the highest degree of complexity to which the determination of a hysterical symptom can attain, and one may therefore only expect to find it in a neurosis which has persisted for a long time and within which a great deal of organization has taken place.¹ [1908a, 1938]
If this idea of a woman with a penis becomes "fixated" in an individual when he is a child, resisting all the influences of later life and making him as a man unable to do without a penis in his sexual object, then, although in other respects he may lead a normal sexual life, he is bound to become a homosexual, and will seek his sexual object among men who, owing to some other physical and mental characteristics, remind him of women. Real women, when he comes to know them later, remain impossible as sexual objects for him, because they lack the essential sexual attraction; indeed, in connection with another impression of his childhood life, they may even become abhorrent to him. The child, having been mainly dominated by excitations in the penis, will usually have obtained pleasure by stimulating it with his hand; he will have been detected in this by his parents or nurse and terrorized by the threat of having his penis cut off. The effect of this 'threat of castration' is proportionate to the value set upon that organ and is quite extraordinarily deep and persistent. Legends and myths testify to the upheaval in the child's emotional life and to the horror which is linked with the castration complex - a complex which is subsequently remembered by consciousness with corresponding reluctance. The woman's genitalia, when seen later on, are regarded as a mutilated organ and recall this threat, and they therefore arouse horror instead of pleasure in the homosexual. This reaction cannot be altered in any way when the homosexual comes to learn from science that his childish assumption that women had a penis too was not so far wrong after all. Anatomy has recognized the clitoris within the female pudenda as being an organ that is homologous to the penis; and the physiology of the sexual processes has been able to add that this small penis which does not grow any bigger behaves in fact during childhood like a real and genuine penis - that it becomes the seat of excitations which lead to its being touched, that its excitability gives the little girl's sexual activity a masculine character and that a wave of repression in the years of puberty is needed in order for this masculine sexuality to be discarded and the woman to emerge. Since the sexual function of many women is crippled, whether by their obstinate clinging on to this excitability of the clitoris so that they remain anaesthetic in intercourse, or by such excessive repression occurring that its operation is partly replaced by hysterical compensatory formations - all this seems to show that there is some truth in the infantile sexual theory that women, like men, possess a penis.

Investigation of the childhood history of hysterical patients shows that the hysterical attack is designed to take the place of an auto-erotic satisfaction previously practised and since given up. In a great number of cases this satisfaction (masturbation by contact or by pressure of the thighs, or, again, by movements of the tongue, and so on) recurs during the attack itself, while the subject's consciousness is deflected. Moreover, the onset of an attack that is due to an increase of libido and is in the service of the primary purpose - as a consolation - exactly repeats the conditions under which, at the earlier time, the patient had intentionally sought this auto-erotic satisfaction. The anamnesis of the patient shows the following stages: (a) auto-erotic satisfaction, without ideational content; (b) the same satisfaction, connected with a phantasy which leads to the act of satisfaction; (c) renunciation of the act, with retention of the phantasy; (d) repression of the phantasy, which then comes into effect as a hysterical attack, either in an unchanged form, or in a modified one and adapted to new environmental impressions. Furthermore, (e) the phantasy may even reinstate the act of satisfaction belonging to it which had ostensibly been given up. This is a typical cycle of infantile sexual activity: repression, failure of repression, and return of the repressed.
Speaking as a whole, hysterical attacks, like hysteria in general, revive a piece of sexual activity in women which existed during their childhood and at that time revealed an essentially masculine character. It can often be observed that girls who have shown a boyish nature and inclinations up to the years before puberty are precisely those who become hysterical from puberty onwards. In a whole number of cases the hysterical neurosis merely represents an excessive accentuation of the typical wave of repression which, by doing away with her masculine sexuality, allows the woman to emerge.²

[1909a, 1984]

There is another question that I might draw your attention to, which has been dealt with too little in our discussions: that of 'unconscious' masturbation. I mean masturbation during sleep, during abnormal states, or fits. You will recall the many hysterical fits in which masturbatory acts recur in a disguised or unrecognizable way, after the subject has renounced that form of satisfaction, and the many symptoms in obsessional neurosis which seek to replace and repeat this kind of sexual activity, which has formerly been forbidden. We may also speak of a therapeutic return of masturbation. A number of you will have found on occasion, as I have, that it represents a great advance if during the treatment the patient ventures to take up masturbation once more, though he may have no intention of making a permanent stop at that infantile halting-place. In this connection I may remind you that a considerable number of precisely the most severe sufferers from neurosis have avoided all recollection of masturbation during historic times, while psycho-analysis is able to prove that that species of sexual activity had by no means been strange to them during the forgotten earliest period of their lives.

[1912f, 2574]

We shall not be able to dismiss a second objection so easily. If you survey a fairly long series of interpretations of symptoms, you will probably start by judging that the concept of a substitutive sexual satisfaction has been stretched to its extreme limits in them. You will not fail to emphasize the fact that these symptoms offer nothing real in the way of satisfaction, that often enough they are restricted to the revival of a sensation or the representation of a phantasy derived from a sexual complex. And you will further point out that these supposed sexual satisfactions often take on a childish and discreditable form, approximate to an act of masturbation perhaps, or recall dirty kinds of naughtiness which are forbidden even to children - habits of which they have been broken. And, going on from this, you will also express surprise that we are representing as a sexual satisfaction what would rather have to be described as the satisfaction of lusts that are cruel or horrible or would even have to be called unnatural. We shall come to no agreement, Gentlemen, on this latter point till we have made a thorough investigation of the sexual life of human beings and till, in doing so, we have decided what it is that we are justified in calling 'sexual'.

[1916-1917, 3374]
As you probably know, the hysterical neurosis can produce its symptoms in any system of organs and so disturb any function. Analysis shows that in this way all the so-called perverse impulses which seek to replace the genital by some other organ manifest themselves: these organs are then behaving like substitutive genitals. The symptoms of hysteria have actually led us to the view that the bodily organs, besides the functional part they play, must be recognized as having a sexual (erotogenic) significance, and that the execution of the first of these tasks is disturbed if the second of them makes too many claims. Countless sensations and innervations which we come across as symptoms of hysteria in organs that have no apparent connection with sexuality are in this way revealed to us as being in the nature of fulfilments of perverse sexual impulses in relation to which other organs have acquired the significance of the sexual parts. We learn too to what a large extent the organs for the intake of nourishment and for excretion can in particular become the vehicles of sexual excitation. Here, then, we have the same thing that we were shown by the perversions; only in their case it was visible easily and unmistakably, whereas in hysteria we have to take a circuitous path by way of the interpretation of symptoms, and do not then ascribe the perverse sexual impulses concerned to the subject's consciousness but locate them in his unconscious.

[1916-1917, 3380]
This connection between symptoms and phantasies makes it easy to arrive from a psychoanalysis of the former at a knowledge of the components of the sexual instincts which dominate the individual, as I have demonstrated in my *Three Essays on the Theory of Sexuality*. In some cases, however, investigation by this means yields an unexpected result. It shows that there are many symptoms where the uncovering of a sexual phantasy (or of a number of phantasies, one of which, the most significant and the earliest, is of a sexual nature) is not enough to bring about a resolution of the symptoms. To resolve it one has to have two sexual phantasies, of which one has a masculine and the other a feminine character. Thus one of these phantasies springs from a homosexual impulse. This new finding does not alter our seventh formula. It remains true that a hysterical symptom must necessarily represent a compromise between a libidinal and a repressing impulse; but it may also represent a union of two libidinal phantasies of an opposite sexual character.

[1908a, 1937]
The part played by the erotogenic zones is immediately obvious in the case of those perversions which assign a sexual significance to the oral and anal orifices. These behave in every respect like a portion of the sexual apparatus. In hysteria these parts of the body and the neighbouring tracts of mucous membrane become the seat of new sensations and of changes in innervation - indeed, of processes that can be compared to erection - in just the same way as do the actual genitalia under the excitations of the normal sexual processes. [1905d, 1493]

The significance of the erotogenic zones as apparatuses subordinate to the genitals and as substitutes for them is, among all the psychoneuroses, most clearly to be seen in hysteria; but this does not imply that that significance is any the less in the other forms of illness. It is only that in them it is less recognizable, because in their case (obsessional neurosis and paranoia) the formation of the symptoms takes place in regions of the mental apparatus which are more remote from the particular centres concerned with somatic control. In obsessional neurosis what is more striking is the significance of those impulses which create new sexual aims and seem independent of erotogenic zones. Nevertheless, in scopophilia and exhibitionism the eye corresponds to an erotogenic zone; while in the case of those components of the sexual instinct which involve pain and cruelty the same role is assumed by the skin - the skin, which in particular parts of the body has become differentiated into sense organs or modified into mucous membrane, and is thus the erotogenic zone _par excellence_.¹ [1905d, 1493]

The character of erotogenicity can be attached to some parts of the body in a particularly marked way. There are predestined erotogenic zones, as is shown by the example of sucking. The same example, however, also shows us that any other part of the skin or mucous membrane can take over the functions of an erotogenic zone, and must therefore have some aptitude in that direction. Thus the quality of the stimulus has more to do with producing the pleasurable feeling than has the nature of the part of the body concerned. A child who is indulging in sensual sucking searches about his body and chooses some part of it to suck - a part which is afterwards preferred by him from force of habit; if he happens to hit upon one of the predestined regions (such as the nipples or genitals) no doubt it retains the preference. A precisely analogous tendency to displacement is also found in the symptomatology of hysteria. In that neurosis repression affects most of all the actual genital zones and these transmit their susceptibility to stimulation to other erotogenic zones (normally neglected in adult life), which then behave exactly like genitals. But besides this, precisely as in the case of sucking, any other part of the body can acquire the same susceptibility to stimulation as is possessed by the genitals and can become an erotogenic zone. Erotogenic and hysterogenic zones show the same characteristics.¹ [1905d, 1504]

When erotogenic susceptibility to stimulation has been successfully transferred by a woman from the clitoris to the vaginal orifice, it implies that she has adopted a new leading zone for the purposes of her later sexual activity. A man, on the other hand, retains his leading zone unchanged from childhood. The fact that women change their leading erotogenic zone in this way, together with the wave of repression at puberty, which, as it were, puts aside their childish masculinity, are the chief determinants of the greater proneness of woman to neurosis and especially to hysteria. These determinants, therefore, are intimately related to the essence of femininity. [1905d, 1534]
I think it is worth emphasizing the fact that, whatever modifications my views on the aetiology of the psychoneuroses have passed through, there are two positions which I have never repudiated or abandoned - the importance of sexuality and of infantilism. Apart from this, accidental influences have been replaced by constitutional factors and 'defence' in the purely psychological sense has been replaced by organic 'sexual repression'. The question may, however, be raised of where convincing evidence is to be found in favour of the alleged aetiological importance of sexual factors in the psychoneuroses, in view of the fact that the onset of these illnesses may be observed in response to the most commonplace emotions or even to somatic precipitating causes, and since I have had to abandon a specific aetiology depending on the particular form of the childhood experiences concerned. To such a question I would reply that the psycho-analytic examination of neurotics is the source from which this disputed conviction of mine is derived. If we make use of that irreplaceable method of research, we discover that the patient's symptoms constitute his sexual activity (whether wholly or in part), which arises from the sources of the normal or perverse component instincts of sexuality. Not only is a large part of the symptomatology of hysteria derived directly from expressions of sexual excitement, not only do a number of erotogenic zones attain the significance of genitals during neuroses owing to an intensification of infantile characteristics, but the most complicated symptoms are themselves revealed as representing, by means of 'conversion', phantasies which have a sexual situation as their subject-matter. Anyone who knows how to interpret the language of hysteria will recognize that the neurosis is concerned only with the patient's repressed sexuality. The sexual function must, however, be understood in its true extent, as it is laid down by disposition in infancy. Wherever some commonplace emotion must be included among the determinants of the onset of the illness, analysis invariably shows that it is the sexual component of the traumatic experience - a component that is never lacking which has produced the pathogenic result. [1906a, 1582]
If this idea of a woman with a penis becomes 'fixated' in an individual when he is a child, resisting all the influences of later life and making him as a man unable to do without a penis in his sexual object, then, although in other respects he may lead a normal sexual life, he is bound to become a homosexual, and will seek his sexual object among men who, owing to some other physical and mental characteristics, remind him of women. Real women, when he comes to know them later, remain impossible as sexual objects for him, because they lack the essential sexual attraction; indeed, in connection with another impression of his childhood life, they may even become abhorrent to him. The child, having been mainly dominated by excitations in the penis, will usually have obtained pleasure by stimulating it with his hand; he will have been detected in this by his parents or nurse and terrorized by the threat of having his penis cut off. The effect of this 'threat of castration' is proportionate to the value set upon that organ and is quite extraordinarily deep and persistent. Legends and myths testify to the upheaval in the child's emotional life and to the horror which is linked with the castration complex - a complex which is subsequently remembered by consciousness with corresponding reluctance. The woman's genitalia, when seen later on, are regarded as a mutilated organ and recall this threat, and they therefore arouse horror instead of pleasure in the homosexual. This reaction cannot be altered in any way when the homosexual comes to learn from science that his childish assumption that women had a penis too was not so far wrong after all. Anatomy has recognized the clitoris within the female pudenda as being an organ that is homologous to the penis; and the physiology of the sexual processes has been able to add that this small penis which does not grow any bigger behaves in fact during childhood like a real and genuine penis - that it becomes the seat of excitations which lead to its being touched, that its excitability gives the little girl's sexual activity a masculine character and that a wave of repression in the years of puberty is needed in order for this masculine sexuality to be discarded and the woman to emerge. Since the sexual function of many women is crippled, whether by their obstinate clinging on to this excitability of the clitoris so that they remain anaesthetic in intercourse, or by such excessive repression occurring that its operation is partly replaced by hysterical compensatory formations - all this seems to show that there is some truth in the infantile sexual theory that women, like men, possess a penis.

Psycho-analysis is unjustly reproached, Gentlemen, for leading to purely psychological theories of pathological problems. The emphasis which it lays on the pathogenic role of sexuality, which, after all, is certainly not an exclusively psychical factor should alone protect it from this reproach. Psycho-analysts never forget that the mental is based on the organic, although their work can only carry them as far as this basis and no beyond it. Thus psycho-analysis is ready to admit, and indeed to postulate, that not all disturbances of vision need be psychogenic, like those that are evoked by the repression of erotic scopophilia. If an organ which serves the two sorts of instinct increases its erotogenic role, it is in general to be expected that this will not occur without the excitability and innervation of the organ undergoing changes which will manifest themselves as disturbances of its function in the service of the ego. Indeed, if we find that an organ normally serving the purpose of sense-perception begins to behave like an actual genital when its erotogenic role is increased, we shall not regard it as improbable that toxic changes are also occurring in it. For lack of a better name we must retain the old unsuitable term of 'neurotic' disturbances for both classes of functional disturbances - those of physiological as well as those of toxic origin - which follow from an increase in the erotogenic factor. Generally speaking, the neurotic disturbances of vision stand in the same relation to the psychogenic ones as the 'actual neuroses' do to the psychoneuroses: psychogenic visual disturbances can no doubt hardly ever appear without neurotic ones, but the latter can appear without the former. These neurotic symptoms are unfortunately little appreciated and understood even today; for they are not directly accessible to psycho-analysis, and other methods of research have left the standpoint of sexuality out of account.
As you probably know, the hysterical neurosis can produce its symptoms in any system of organs and so disturb any function. Analysis shows that in this way all the so-called perverse impulses which seek to replace the genital by some other organ manifest themselves: these organs are then behaving like substitutive genitals. The symptoms of hysteria have actually led us to the view that the bodily organs, besides the functional part they play, must be recognized as having a sexual (erotogenic) significance, and that the execution of the first of these tasks is disturbed if the second of them makes too many claims. Countless sensations and innervations which we come across as symptoms of hysteria in organs that have no apparent connection with sexuality are in this way revealed to us as being in the nature of fulfilments of perverse sexual impulses in relation to which other organs have acquired the significance of the sexual parts. We learn too to what a large extent the organs for the intake of nourishment and for excretion can in particular become the vehicles of sexual excitation. Here, then, we have the same thing that we were shown by the perversions; only in their case it was visible easily and unmistakably, whereas in hysteria we have to take a circuitous path by way of the interpretation of symptoms, and do not then ascribe the perverse sexual impulses concerned to the subject's consciousness but locate them in his unconscious.
[1916-1917, 3380]
This connection between symptoms and phantasies makes it easy to arrive from a psycho-
analysis of the former at a knowledge of the components of the sexual instincts which dominate
the individual, as I have demonstrated in my *Three Essays on the Theory of Sexuality*. In some
cases, however, investigation by this means yields an unexpected result. It shows that there are
many symptoms where the uncovering of a sexual phantasy (or of a number of phantasies, one
of which, the most significant and the earliest, is of a sexual nature) is not enough to bring about
a resolution of the symptoms. To resolve it one has to have *two* sexual phantasies, of which one
has a masculine and the other a feminine character. Thus one of these phantasies springs from
a homosexual impulse. This new finding does not alter our seventh formula. It remains true that
a hysterical symptom must necessarily represent a compromise between a libidinal and a
repressing impulse; but it may also represent a union of two libidinal phantasies of an opposite
sexual character.

[1908a, 1937]

I shall refrain from giving examples in support of this thesis. I have found from experience that
short analyses, condensed into extracts, can never have the convincing effect which they are
designed to produce. And on the other hand, accounts of fully analysed cases must be left for
another occasion.

[1908a, 1938]

(9) Hysterical symptoms are the expression on the one hand of a masculine unconscious
sexual phantasy, and on the other hand of a feminine one.

[1908a, 1938]

I must expressly state that I cannot claim the same general validity for this formula as I have
done for the others. As far as I can see, it applies neither to all the symptoms of a given case
nor to all cases. On the contrary, it is not hard to adduce cases in which the impulses belonging
to the opposite sexes have found separate symptomatic expression, so that the symptoms of
heterosexuality and those of homosexuality can be as clearly distinguished from each other as
the phantasies concealed behind them. Nevertheless, the condition of things stated in the ninth
formula is common enough, and, when it occurs, important enough to deserve special
emphasis. It seems to me to mark the highest degree of complexity to which the determination
of a hysterical symptom can attain, and one may therefore only expect to find it in a neurosis
which has persisted for a long time and within which a great deal of organization has taken
place.¹

[1908a, 1938]

The bisexual nature of hysterical symptoms, which can in any event be demonstrated in
numerous cases, is an interesting confirmation of my view that the postulated existence of an
innate bisexual disposition in man is especially clearly visible in the analysis of
psychoneurotics.² An exactly analogous state of affairs occurs in the same field when a person
who is masturbating tries in his conscious phantasies to have the feelings both of the man and
of the woman in the situation which he is picturing. Further counterparts are to be found in
certain hysterical attacks in which the patient simultaneously plays both parts in the underlying
sexual phantasy. In one case which I observed, for instance, the patient pressed her dress up
against her body with one hand (as the woman), while she tried to tear it off with the other (as
the man). This simultaneity of contradictory actions serves to a large extent to obscure the
situation, which is otherwise so plastically portrayed in the attack, and it is thus well suited to
conceal the unconscious phantasy that is at work.

[1908a, 1938]
In psycho-analytic treatment it is very important to be prepared for a symptom's having a bisexual meaning. We need not then be surprised or misled if a symptom seems to persist undiminished although we have already resolved one of its sexual meanings; for it is still being maintained by the - perhaps unsuspected - one belonging to the opposite sex. In the treatment of such cases, moreover, one may observe how the patient avails himself, during the analysis of the one sexual meaning, of the convenient possibility of constantly switching his associations, as though on to an adjoining track, into the field of the contrary meaning. 
[1908a, 1939]

The normal processes in the formation of conscience must be similar to the abnormal ones described here. We have not yet succeeded in fixing the boundary line between them. It will be observed that here the largest share in the outcome is ascribed to the passive component of repressed femininity. In addition, it must be of importance as an accidental factor whether the father, who is feared in any case, is also especially violent in reality. This was true in Dostoevsky's case, and we can trace back the fact of his extraordinary sense of guilt and of his masochistic conduct of life to a specially strong feminine component. Thus the formula for Dostoevsky is as follows: a person with a specially strong innate bisexual disposition, who can defend himself with special intensity against dependence on a specially severe father. This characteristic of bisexuality comes as an addition to the components of his nature that we have already recognized. His early symptoms of death-like attacks can thus be understood as a father-identification on the part of his ego, which is permitted by his super-ego as a punishment. ‘You wanted to kill your father in order to be your father yourself. Now you are your father, but a dead father’ - the regular mechanism of hysterical symptoms. And further: ‘Now your father is killing you.’ For the ego the death symptom is a satisfaction in phantasy of the masculine wish and at the same time a masochistic satisfaction; for the super-ego it is a punitive satisfaction - that is, a sadistic satisfaction. Both of them, the ego and the super-ego, carry on the role of father.
[1928b, 4561]
The many modifications of the typical dream with a dental stimulus (dreams, for instance, of a tooth being pulled out by someone else, etc.) are, I think, to be explained in the same way.¹ It may, however, puzzle us to discover how 'dental stimuli' have come to have this meaning. But I should like to draw attention to the frequency with which sexual repression makes use of transpositions from a lower to an upper part of the body. Thanks to them it becomes possible in hysteria for all kinds of sensations and intentions to be put into effect, if not where they properly belong - in relation to the genitals, at least in relation to other, unobjectionable parts of the body. One instance of a transposition of this kind is the replacement of the genitals by the face in the symbolism of unconscious thinking. Linguistic usage follows the same line in recognizing the buttocks as homologous to the cheeks, and by drawing a parallel between the 'labia' and the lips which frame the aperture of the mouth. Comparisons between nose and penis are common, and the similarity is made more complete by the presence of hair in both places. The one structure which affords no possibility of an analogy is the teeth; and it is precisely this combination of similarity and dissimilarity which makes the teeth so appropriate for representational purposes when pressure is being exercised by sexual repression.

In order to particularize Dora's case it is not enough merely to draw attention to the reversal of affect; there has also been a displacement of sensation. Instead of the genital sensation which would certainly have been felt by a healthy girl in such circumstances,¹ Dora was overcome by the unpleasurable feeling which is proper to the tract of mucous membrane at the entrance to the alimentary canal - that is by disgust. The stimulation of her lips by the kiss was no doubt of importance in localizing the feeling at that particular place; but I think I can also recognize another factor in operation.²

The disgust which Dora felt on that occasion did not become a permanent symptom, and even at the time of the treatment it was only, as it were, potentially present. She was a poor eater and confessed to some disinclination for food. On the other hand, the scene had left another consequence behind it in the shape of a sensory hallucination which occurred from time to time and even made its appearance while she was telling me her story. She declared that she could still feel upon the upper part of her body the pressure of Herr K.'s embrace. In accordance with certain rules of symptom-formation which I have come to know, and at the same time taking into account certain other of the patient's peculiarities, which were otherwise inexplicable, - such as her unwillingness to walk past any man whom she saw engaged in eager or affectionate conversation with a lady, - I have formed in my own mind the following reconstruction of the scene. I believe that during the man's passionate embrace she felt not merely his kiss upon her lips but also the pressure of his erect member against her body. This perception was revolting to her; it was dismissed from her memory, repressed, and replaced by the innocent sensation of pressure upon her thorax, which in turn derived an excessive intensity from its repressed source. Once more, therefore, we find a displacement from the lower part of the body to the upper.³ On the other hand, the compulsive piece of behaviour which I have mentioned was formed as though it were derived from the undistorted recollection of the scene: she did not like walking past any man who she thought was in a state of sexual excitement, because she wanted to avoid seeing for a second time the somatic sign which accompanies it.

³ The occurrence of displacements of this kind has not been assumed for the purpose of this single explanation; the assumption has proved indispensable for the explanation of a large class of symptoms. Since treating Dora I have come across another instance of an embrace (this time without a kiss) causing a fright. It was a case of a young woman who had previously been devotedly fond of the man she was engaged to, but had suddenly begun to feel a coldness towards him, accompanied by severe depression, and on that account came to me for treatment. There was no difficulty in tracing the fright back to an erection on the man's part, which she had perceived but had dismissed from her consciousness.

[1905e, 1369]
¹ This word played the same part with the fourteen-year old girl whose case history I have compressed into a few lines on p. 1365. I had established the child in a pension with an intelligent lady, who took charge of her for me. The lady reported that the little girl could not bear her to be in the room while she was going to bed, and that when she was in bed she had a marked cough, of which there was no trace in the daytime. When the girl was questioned about these symptoms, the only thing that occurred to her was that her grandmother coughed in the same way, and that she was said to have a catarrh. It was clear from this that the child herself had a catarrh, and that she did not want to be observed while she performed her evening ablutions. This catarrh which, thanks to its name, had been displaced from the lower to the upper part of her body, exhibited a quite unusual degree of intensity.
[1905e, 1418]

The character of erotogenicity can be attached to some parts of the body in a particularly marked way. There are predestined erotogenic zones, as is shown by the example of sucking. The same example, however, also shows us that any other part of the skin or mucous membrane can take over the functions of an erotogenic zone, and must therefore have some aptitude in that direction. Thus the quality of the stimulus has more to do with producing the pleasurable feeling than has the nature of the part of the body concerned. A child who is indulging in sensual sucking searches about his body and chooses some part of it to suck - a part which is afterwards preferred by him from force of habit; if he happens to hit upon one of the predestined regions (such as the nipples or genitals) no doubt it retains the preference. A precisely analogous tendency to displacement is also found in the symptomatology of hysteria. In that neurosis repression affects most of all the actual genital zones and these transmit their susceptibility to stimulation to other erotogenic zones (normally neglected in adult life), which then behave exactly like genitals. But besides this, precisely as in the case of sucking, any other part of the body can acquire the same susceptibility to stimulation as is possessed by the genitals and can become an erotogenic zone. Erotogenic and hysterogenic zones show the same characteristics.¹
[1905d, 1504]
Thus forarmed we can proceed to the consideration of a suggestion which we shall certainly not be spared. 'Why', we shall be asked, 'are you so obstinate in describing as being already sexuality what on your own evidence are indefinable manifestations in childhood out of which sexual life will later develop? Why should you not be content instead with giving them a physiological description and simply say that in an infant at the breast we already observe activities, such as sensual sucking or holding back the excreta, which show us that he is striving for "organ-pleasure"? In that way you would have avoided the hypothesis, so repugnant to every feeling, of the smallest babies having a sexual life.' - Indeed, Gentlemen, I have no objection at all to organ-pleasure. I know that even the supreme pleasure of sexual union is only an organ-pleasure attached to the activity of the genitals. But can you tell me when this originally indifferent organ-pleasure acquires the sexual character which it undoubtedly possesses in the later phases of development? Do we know any more about 'organ-pleasure' than about sexuality? You will reply that it gains its sexual character precisely when the genitals begin to play their part; 'sexual' coincides with 'genital'. You will even reject the objection raised by the perversions by pointing out to me that in the majority of perversions a genital orgasm is after all aimed at, even if it is arrived at by a method other than the union of the genitals. You are certainly taking up a much stronger position in determining the characteristics of what is sexual if you knock out of it the relation to reproduction which is made untenable by the perversions and put genital activity in its place. But, if so, we are no longer far apart: it is only a question of the genital organs versus the other organs. What are you going to do, however, about the numerous experiences which show you that the genitals can be represented as regards their yield of pleasure by other organs, as in the case of kissing or of the perverse practices of voluptuaries or of the symptoms of hysteria? In that neurosis it is quite usual for signs of stimulation, sensations and innervations, and even the processes of erection, which belong properly to the genitals, to be displaced on to other, remote regions of the body - as, for instance, by transposition upwards, to the head and face. Being thus convinced that you have nothing to catch hold of for your characterization of what is sexual, you will no doubt have to make up your minds to follow my example and extend the description of being 'sexual' to the activities of early childhood, too, which strive for organ-pleasure.
[1916-1917, 3392]
The character of erotogenicity can be attached to some parts of the body in a particularly marked way. There are predestined erotogenic zones, as is shown by the example of sucking. The same example, however, also shows us that any other part of the skin or mucous membrane can take over the functions of an erotogenic zone, and must therefore have some aptitude in that direction. Thus the quality of the stimulus has more to do with producing the pleasurable feeling than has the nature of the part of the body concerned. A child who is indulging in sensual sucking searches about his body and chooses some part of it to suck - a part which is afterwards preferred by him from force of habit; if he happens to hit upon one of the predestined regions (such as the nipples or genitals) no doubt it retains the preference. But besides this, precisely as in the case of sucking, any other part of the body can acquire the same susceptibility to stimulation as is possessed by the genitals and can become an erotogenic zone. Erotogenic and hysterogenic zones show the same characteristics.¹

[1905d, 1504]
Am I now going on to assert that in every instance in which there are periodical attacks of aphonia we are to diagnose the existence of a loved person who is at times away from the patient? Nothing could be further from my intention. The determination of Dora's symptoms is far too specific for it to be possible to expect a frequent recurrence of the same accidental aetiology. But, if so, what is the value of our elucidation of the aphonia in the present case? Have we not merely allowed ourselves to become the victims of a *jeu d'esprit*? I think not. In this connection we must recall the question which has so often been raised, whether the symptoms of hysteria are of psychical or of somatic origin, or whether, if the former is granted, they are necessarily *all* of them psychically determined. Like so many other questions to which we find investigators returning again and again without success, this question is not adequately framed. The alternatives stated in it do not cover the real essence of the matter. As far as I can see, every hysterical symptom involves the participation of both sides. It cannot occur without the presence of a certain degree of *somatic compliance* offered by some normal or pathological process in or connected with one of the bodily organs. And it cannot occur more than once - and the capacity for repeating itself is one of the characteristics of a hysterical symptom - unless it has a psychical significance, a *meaning*. The hysterical symptom does not carry this meaning with it, but the meaning is lent to it, soldered to it, as it were; and in every instance the meaning can be a different one, according to the nature of the suppressed thoughts which are struggling for expression. However, there are a number of factors at work which tend to make less arbitrary the relations between the unconscious thoughts and the somatic processes that are at their disposal as a means of expression, and which tend to make those relations approximate to a few typical forms. For therapeutic purposes the most important determinants are those given by the fortuitous psychical material; the clearing-up of the symptoms is achieved by looking for their psychical significance. When everything that can be got rid of by psycho-analysis has been cleared away, we are in a position to form all kinds of conjectures, which probably meet the facts, as regards the somatic basis of the symptoms - a basis which is as a rule constitutional and organic. Thus in Dora's case we shall not content ourselves with a psycho-analytic interpretation of her attacks of coughing and aphonia; but we shall also indicate the organic factor which was the source of the 'somatic compliance' that enabled her to express her love for a man who was periodically absent. And if the connection between the symptomatic expression and the unconscious mental content should strike us as being in this case a clever *tour de force*, we shall be relieved to hear that it succeeds in creating the same impression in every other case and in every other instance.

[1905e, 1378]
Nevertheless, in publishing this paper, incomplete though it is, I had two objects in view. In the first place, I wished to supplement my book on the interpretation of dreams by showing how an art, which would otherwise be useless, can be turned to account for the discovery of the hidden and repressed parts of mental life. (Incidentally, in the process of analysing the two dreams dealt with in the paper, the technique of dream-interpretation, which is similar to that of psycho-analysis, has come under consideration.) In the second place, I wished to stimulate interest in a whole group of phenomena of which science is still in complete ignorance to-day because they can only be brought to light by the use of this particular method. No one, I believe, can have had any true conception of the complexity of the psychological events in a case of hysteria - the juxtaposition of the most dissimilar tendencies, the mutual dependence of contrary ideas, the repressions and displacements, and so on. The emphasis laid by Janet upon the 'idée fixe' which becomes transformed into a symptom amounts to no more than an extremely meagre attempt at schematization. Moreover, it is impossible to avoid the suspicion that, when the ideas attaching to certain excitations are incapable of becoming conscious, those excitations must act upon one another differently, run a different course, and manifest themselves differently from those other excitations which we describe as 'normal' and which have ideas attaching to them of which we become conscious. When once things have been made clear up to this point, no obstacle can remain in the way of an understanding of a therapeutic method which removes neurotic symptoms by transforming ideas of the former kind into normal ones.

[1905e, 1448]

The removal of the symptoms of hysterical patients by psycho-analysis proceeds on the supposition that those symptoms are substitutes - transcriptions as it were - for a number of emotionally cathected mental processes, wishes and desires, which, by the operation of a special psychical procedure (repression), have been prevented from obtaining discharge in psychical activity that is admissible to consciousness. These mental processes, therefore, being held back in a state of unconsciousness, strive to obtain an expression that shall be appropriate to their emotional importance - to obtain discharge; and in the case of hysteria they find such an expression (by means of the process of 'conversion') in somatic phenomena, that is, in hysterical symptoms. By systematically turning these symptoms back (with the help of a special technique) into emotionally cathected ideas - ideas that will now have become conscious - it is possible to obtain the most accurate knowledge of the nature and origin of these formerly unconscious psychical structures.

[1905d, 1489]

The hereditary conditions in the case of positive perverts are less well known, for they know how to avoid investigation. Yet there are good reasons to suppose that what is true of the neuroses applies also to the perversions. For it is no rare thing to find perversions and psychoneuroses occurring in the same family, and distributed between the two sexes in such a way that the male members of the family, or one of them, are positive perverts, while the females, true to the tendency of their sex to repression, are negative perverts, that is, hysterics. This is good evidence of the essential connections which we have shown to exist between the two disorders.

[1905d, 1546]
The field I have in mind is indeed very different from yours. I am referring to the therapy employed for certain 'nervous diseases' - what are known as the psychoneuroses - of which hysteria and obsessional ideas may be taken as samples. The method is called 'psycho-analysis'; it was evolved by me from the 'cathartic' method of therapy first practised by Josef Breuer in Vienna.¹ To combat your surprise, I must draw an analogy between the criminal and the hysteric. In both we are concerned with a secret, with something hidden. But in order not to be paradoxical I must at once point out the difference. In the case of the criminal it is a secret which he knows and hides from you, whereas in the case of the hysteric it is a secret which he himself does not know either, which is hidden even from himself. How is this possible? Now we know, through laborious research, that all these illnesses are the result of the patient's having succeeded in repressing certain ideas and memories that are strongly cathexed with affect, together with the wishes that arise from them, in such a way that they play no part in his thinking - do not enter into his consciousness - and thus remain unknown to him. But from this repressed psychical material (these 'complexes') are generated the somatic and psychical symptoms which plague the patient in just the same way as a guilty conscience does. In this one respect, therefore, the difference between the criminal and the hysteric is fundamental.

[1906c, 1892]

If this idea of a woman with a penis becomes 'fixated' in an individual when he is a child, resisting all the influences of later life and making him as a man unable to do without a penis in his sexual object, then, although in other respects he may lead a normal sexual life, he is bound to become a homosexual, and will seek his sexual object among men who, owing to some other physical and mental characteristics, remind him of women. Real women, when he comes to know them later, remain impossible as sexual objects for him, because they lack the essential sexual attraction; indeed, in connection with another impression of his childhood life, they may even become abhorrent to him. The child, having been mainly dominated by excitations in the penis, will usually have obtained pleasure by stimulating it with his hand; he will have been detected in this by his parents or nurse and terrorized by the threat of having his penis cut off. The effect of this 'threat of castration' is proportionate to the value set upon that organ and is quite extraordinarily deep and persistent. Legends and myths testify to the upheaval in the child's emotional life and to the horror which is linked with the castration complex - a complex which is subsequently remembered by consciousness with corresponding reluctance. The woman's genitalia, when seen later on, are regarded as a mutilated organ and recall this threat, and they therefore arouse horror instead of pleasure in the homosexual. This reaction cannot be altered in any way when the homosexual comes to learn from science that his childish assumption that women had a penis too was not so far wrong after all. Anatomy has recognized the clitoris within the female pudenda as being an organ that is homologous to the penis; and the physiology of the sexual processes has been able to add that this small penis which does not grow any bigger behaves in fact during childhood like a real and genuine penis - that it becomes the seat of excitations which lead to its being touched, that its excitability gives the little girl's sexual activity a masculine character and that a wave of repression in the years of puberty is needed in order for this masculine sexuality to be discarded and the woman to emerge. Since the sexual function of many women is crippled, whether by their obstinate clinging on to this excitability of the clitoris so that they remain anaesthetic in intercourse, or by such excessive repression occurring that its operation is partly replaced by hysterical compensatory formations - all this seems to show that there is some truth in the infantile sexual theory that women, like men, possess a penis.

[1908c, 1971]

The two last-mentioned forms of distortion give us some idea of the intensity of the resistances which the repressed material must take into account even when it breaks through in a hysterical attack.

[1909a, 1982]
Investigation of the childhood history of hysterical patients shows that the hysterical attack is designed to take the place of an auto-erotic satisfaction previously practised and since given up. In a great number of cases this satisfaction (masturbation by contact or by pressure of the thighs, or, again, by movements of the tongue, and so on) recurs during the attack itself, while the subject's consciousness is deflected. Moreover, the onset of an attack that is due to an increase of libido and is in the service of the primary purpose - as a consolation - exactly repeats the conditions under which, at the earlier time, the patient had intentionally sought this auto-erotic satisfaction. The anamnesis of the patient shows the following stages: (a) auto-erotic satisfaction, without ideational content; (b) the same satisfaction, connected with a phantasy which leads to the act of satisfaction; (c) renunciation of the act, with retention of the phantasy; (d) repression of the phantasy, which then comes into effect as a hysterical attack, either in an unchanged form, or in a modified one and adapted to new environmental impressions. Furthermore, (e) the phantasy may even reinstate the act of satisfaction belonging to it which had ostensibly been given up. This is a typical cycle of infantile sexual activity: repression, failure of repression, and return of the repressed.

[1909a, 1983]

Speaking as a whole, hysterical attacks, like hysteria in general, revive a piece of sexual activity in women which existed during their childhood and at that time revealed an essentially masculine character. It can often be observed that girls who have shown a boyish nature and inclinations up to the years before puberty are precisely those who become hysterical from puberty onwards. In a whole number of cases the hysterical neurosis merely represents an excessive accentuation of the typical wave of repression which, by doing away with her masculine sexuality, allows the woman to emerge.²

[1909a, 1984]

In hysteria it is the rule that the precipitating causes of the illness are overtaken by amnesia no less than the infantile experiences by whose help the precipitating causes are able to transform their affective energy into symptoms. And where the amnesia cannot be complete, it nevertheless subjects the recent traumatic precipitating cause to a process of erosion and robs it at least of its most important components. In this amnesia we see the evidence of the repression which has taken place. The case is different in obsessional neuroses. The infantile preconditions of the neurosis may be overtaken by amnesia, though this is often an incomplete one; but the immediate occasions of the illness are, on the contrary, retained in the memory. Repression makes use of another, and in reality a simpler, mechanism. The trauma, instead of being forgotten, is deprived of its affective cathexis; so that what remains in consciousness is nothing but its ideational content, which is perfectly colourless and is judged to be unimportant. The distinction between what occurs in hysteria and in an obsessional neurosis lies in the psychological processes which we can reconstruct behind the phenomena; the result is almost always the same, for the colourless mnemonic content is rarely reproduced and plays no part in the patient's mental activity. In order to differentiate between the two kinds of repression we have on the surface nothing to rely upon but the patient's assurance that he has a feeling in the one case of having always known the thing and in the other of having long ago forgotten it.¹

[1909d, 2154]
There can be no doubt that the patient felt a need for finding experiences of this kind to act as props for his superstition, and that it was for that reason that he occupied himself so much with the inexplicable coincidences of everyday life with which we are all familiar, and helped out their shortcomings with unconscious activity of his own. I have come across a similar need in many other obsessional patients and have suspected its presence in many more besides. It seems to me easily explicable in view of the psychological characteristics of the obsessional neurosis. In this disorder, as I have already explained (p. 2155), repression is effected not by means of amnesia but by a severance of causal connections brought about by a withdrawal of affect. These repressed connections appear to persist in some kind of shadowy form (which I have elsewhere compared to an endopsychic perception), and they are thus transferred, by a process of projection, into the external world, where they bear witness to what has been effaced from consciousness.

[1909d, 2181]

The further question could then be raised as to what these forces were and what the determinants were of the repression in which we now recognized the pathogenic mechanism of hysteria. A comparative study of the pathogenic situations which we had come to know through the cathartic procedure made it possible to answer this question. All these experiences had involved the emergence of a wishful impulse which was in sharp contrast to the subject’s other wishes and which proved incompatible with the ethical and aesthetic standards of his personality. There had been a short conflict, and the end of this internal struggle was that the idea which had appeared before consciousness as the vehicle of this irreconcilable wish fell a victim to repression, was pushed out of consciousness with all its attached memories, and was forgotten. Thus the incompatibility of the wish in question with the patient’s ego was the motive for the repression; the subject’s ethical and other standards were the repressing forces. An acceptance of the incompatible wishful impulse or a prolongation of the conflict would have produced a high degree of unpleasure; this unpleasure was avoided by means of repression, which was thus revealed as one of the devices serving to protect the mental personality.

[1910a, 2212]

Nor is it advisable to attempt to explain the case of Breuer’s patient from the point of view of repression. That case history is not suited to this purpose, because its findings were reached with the help of hypnotic influence. It is only if you exclude hypnosis that you can observe resistances and repressions and form an adequate idea of the truly pathogenic course of events. Hypnosis conceals the resistance and renders a certain area of the mind accessible; but, as against this, it builds up the resistance at the frontiers of this area into a wall that makes everything beyond it inaccessible.

[1910a, 2214]

Psycho-analysis started with researches into hysteria, but in the course of years it has extended far beyond that field of work. The Studies on Hysteria by Breuer and myself, published in 1895, were the beginnings of psycho-analysis. They followed in the track of Charcot’s work on ‘traumatic’ hysteria, Liébeault’s and Bernheim’s investigations of the phenomena of hypnosis, and Janet’s studies of unconscious mental processes. Psycho-analysis soon found itself in sharp opposition to Janet’s views, because (a) it declined to trace back hysteria directly to congenital hereditary degeneracy, (b) it offered, instead of a mere description, a dynamic explanation based on the interplay of psychical forces and (c) it ascribed the origin of psychical dissociation (whose importance had been recognized by Janet as well) not to a failure of mental synthesis resulting from a congenital disability, but to a special psychical process known as ‘repression’ (‘Verdrängung’).

[1913m, 2545]
We are obliged to take quite another view of the process of repression when we consider the picture of a true conversion hysteria. Here the salient point is that it is possible to bring about a total disappearance of the quota of affect. When this is so, the patient displays towards his symptoms what Charcot called 'la belle indifférence hystériques'. In other cases this suppression is not so completely successful: some distressing sensations may attach to the symptoms themselves, or it may prove impossible to prevent some release of anxiety, which in turn sets to work the mechanism of forming a phobia. The ideational content of the instinctual representative is completely withdrawn from consciousness; as a substitute - and at the same time as a symptom - we have an over-strong innervation (in typical cases, a somatic one), sometimes of a sensory, sometimes of a motor character, either as an excitation or an inhibition. The over-innervated area proves on a closer view to be a part of the repressed instinctual representative itself - a part which, as though by a process of condensation, has drawn the whole cathexis on to itself. These remarks do not of course bring to light the whole mechanism of a conversion hysteria; in especial the factor of regression, which will be considered in another connection, has also to be taken into account. In so far as repression in hysteria is made possible only by the extensive formation of substitutes, it may be judged to be entirely unsuccessful; as regards dealing with the quota of affect, however, which is the true task of repression, it generally signifies a total success. In conversion hysteria the process of repression is completed with the formation of the symptom and does not, as in anxiety hysteria, need to continue to a second phase - or rather, strictly speaking, to continue endlessly.

Discussions like this, Gentlemen, are bound to become somewhat arid. So let us turn to clinical material in order to find applications of it that will be a little more impressive. Hysteria and obsessional neurosis are, as you know, the two chief representatives of the group of transference neuroses. Now it is true that in hysteria there is a regression of the libido to the primary incestuous sexual objects and that this occurs quite regularly; but there is as good as no regression to an earlier stage of the sexual organization. To offset this, the chief part in the mechanism of hysteria is played by repression. If I might venture to complete what we already know for certain about this neurosis by making a construction, I might explain the position thus. The unification of the component instincts under the primacy of the genitals has been accomplished; but its results come up against the resistance of the preconscious system which is linked with consciousness. Thus the genital organization holds good for the unconscious, but not in the same way for the preconscious; and this rejection on the part of the preconscious brings about a picture which has certain resemblances to the state of things before genital primacy. But it is nevertheless something quite different.

It is essentially in hysteria and in states of a hysterical type that this is found. Here the mechanism by which the sense of guilt remains unconscious is easy to discover. The hysterical ego fends off a distressing perception with which the criticisms of its super-ego threaten it, in the same way in which it is in the habit of fending off an unendurable object-cathexis - by an act of repression. It is the ego, therefore, that is responsible for the sense of guilt remaining unconscious. We know that as a rule the ego carries out repressions in the service and at the behest of its super-ego; but this is a case in which it has turned the same weapon against its harsh taskmaster. In obsessional neurosis, as we know, the phenomena of reaction-formation predominate; but here the ego succeeds only in keeping at a distance the material to which the sense of guilt refers.
It was now easy to reconstruct the pathogenic process. Let us keep to a simple example, in which a particular impulsion had arisen in the subject's mind but was opposed by other powerful impulsions. We should have expected the mental conflict which now arose to take the following course. The two dynamic quantities - for our present purposes let us call them 'the instinct' and 'the resistance' - would struggle with each other for some time in the fullest light of consciousness, until the instinct was repudiated and the cathexis of energy withdrawn from its impulsion. This would have been the normal solution. In a neurosis, however (for reasons which were still unknown), the conflict found a different outcome. The ego drew back, as it were, on its first collision with the objectionable instinctual impulse; it debarred the impulse from access to consciousness and to direct motor discharge, but at the same time the impulse retained its full cathexis of energy. I named this process repression; it was a novelty, and nothing like it had ever before been recognized in mental life. It was obviously a primary mechanism of defence, comparable to an attempt at flight, and was only a forerunner of the later-developed normal condemning judgement. The first act of repression involved further consequences. In the first place the ego was obliged to protect itself against the constant threat of a renewed advance on the part of the repressed impulse by making a permanent expenditure of energy, an anticathexis, and it thus impoverished itself. On the other hand, the repressed impulse, which was now unconscious, was able to find means of discharge and of substitutive satisfaction by circuitous routes and thus to bring the whole purpose of the repression to nothing. In the case of conversion hysteria the circuitous route led to the somatic innervation; the repressed impulse broke its way through at some point or other and produced symptoms. The symptoms were thus results of a compromise, for although they were substitutive satisfactions they were nevertheless distorted and deflected from their aim owing to the resistance of the ego.
[1925d, 4206]

The reaction-formations in the ego of the obsessional neurotic, which we recognize as exaggerations of normal character-formation, should be regarded, I think, as yet another mechanism of defence and placed alongside of regression and repression. They seem to be absent or very much weaker in hysteria. Looking back, we can now get an idea of what is peculiar to the defensive process in hysteria. It seems that in it the process is limited to repression alone. The ego turns away from the disagreeable instinctual impulse, leaves it to pursue its course in the unconscious, and takes no further part in its fortunes. This view cannot be absolutely correct, for we are acquainted with the case in which a hysterical symptom is at the same time a fulfilment of a penalty imposed by the super-ego; but it may describe a general characteristic of the behaviour of the ego in hysteria.
[1926d, 4274]
